The child node passed to the `insertChild()` method must have been created from the same DOM document object, for example with the `om.DomDocument.createElement()` method.

Example

```om
DEFINE parent, other, child om.DomNode
...
LET child = mydoc.createElement("Item")
CALL parent.insertBefore(child, other)
```

om.DomNode.loadXml
Load an XML file into the current node.

Syntax

```om
loadXml(
    filename STRING )
RETURNING result om.DomNode
```

1. `filename` is the path to the XML file.

Usage

The `loadXml()` method takes a file path as parameter and loads the XML content into the current node, by creating a new DOM structure in memory. The method then returns the new created child DOM node.

To hold the reference to the new node, define a variable with the type `om.DomNode` type.

Example

```om
DEFINE parent, new om.DomNode
...
LET new = parent.loadXml("myfile.xml")
```
om.Donode.parse
Parses an XML formatted string and creates the DOM structure in the current node.

Syntax

\[
\text{parse (}
    \text{string STRING)
\text{RETURNING result om.Donode}
\]

1. \textit{string} is an XML formatted string.

Usage

The \texttt{parse()} method scans the XML formatted string passed as parameter and creates the corresponding DOM nodes into the current node. The method then returns the new created child DOM node.

The node must be created before it is passed as parameter to this method, typically, with \texttt{om.Donode.createElement()}. 

Example

\[
\text{DEFINE parent, child om.Donode}
\ldots
\text{LET child = parent.parse("<Item/>")}
\]

om.Donode.getAttribute
Returns the value of a DOM node attribute.

Syntax

\[
\text{getAttribute (}
    \text{name STRING)
\text{RETURNING result STRING}
\]

1. \textit{name} is the name of the attribute.

Usage

The \texttt{getAttribute()} method returns the value of the attribute passed as parameter, as defined in the current node.

DOM node attribute names are case-sensitive.

If the attribute does not exist for this node type, or if the attribute is not set, the method returns \texttt{NULL}.

For character nodes (created for example with the \texttt{createChars()} of a \texttt{DomDocument} object), you can get the text value by passing the @chars attribute name to the method.

Example

\[
\text{DEFINE node om.Donode}
\ldots
\text{DISPLAY node.getAttribute("color")}
\]

**getAttributeInteger**

Returns the value of a DOM node attribute, with default integer value.

**Syntax**

```
getAttributeInteger(
    name STRING,
    def STRING
) RETURNING result INTEGER
```

1. `name` is the name of the attribute.
2. `def` is the default value.

**Usage**

The `getAttributeInteger()` method returns the value of the attribute passed as parameter, as defined in the current node.

DOM node attribute names are case-sensitive.

If the attribute is not defined, the method returns the default value passed as second parameter.

**getAttributesCount**

Returns the number of attributes in the DOM node.

**Syntax**

```
getAttributesCount()
```

**Usage**

The `getAttributesCount()` method returns the number of attributes defined in the current node.

This method is typically used to scan all the attributes of a node by position, with the `getAttributeName()` and `getAttributeValue()` methods.

**Example**

```
DEFINE node om.DomNode,
    index INTEGER
...
FOR index = 1 TO node.getAttributesCount()
    DISPLAY node.getAttributeName(index)
    node.getAttributeValue(index)
END FOR
```

**getAttributeString**

Returns the value of a DOM node attribute, with default string value.

**Syntax**

```
getAttributeString(
    name STRING,
    def STRING
) RETURNING result STRING
```

1. `name` is the name of the attribute.
2. `def` is the default value.
**Usage**

The `getAttributeString()` method returns the value of the attribute passed as parameter, as defined in the current node.

DOM node attribute names are case-sensitive.

If the attribute is not defined, the method returns the default value passed as second parameter.

`om.DomNode.getAttributeName`

Returns the name of a DOM node attribute by position.

**Syntax**

```
缢 line (        
    index INTEGER ) 
RETURNING result STRING
```

1. `index` is the index of the attribute, starts at 1.

**Usage**

The `getAttributeName()` method returns the name of an attribute by position in the current node.

DOM node attribute names are case-sensitive.

If the attribute does not exist at the given position, the method returns `NULL`.

**Example**

```
DEFINE node om.DomNode
...
DISPLAY node.getAttributeName(12)
```

**Usage**

The `getAttributeValue()` method returns the value of an attribute by position in the current node.

DOM node attribute names are case-sensitive.

If the attribute does not exist at the given position, the method returns `NULL`.

**Example**

```
DEFINE node om.DomNode
...
DISPLAY node.getAttributeValue(12)
```
om.DomNode.getChildByIndex
Returns a child DOM node by position.

Syntax

```
getChildByIndex(
    index INTEGER )
RETURNING result om.DomNode
```

1. `index` is the index of the child node, starts at 1.

Usage

The `getChildByIndex()` method returns the child DOM node by position in the current node.

If there is no child node at the give position, the method returns `NULL`.

om.DomNode.getChildCount
Returns the number of children nodes.

Syntax

```
getChildCount()
RETURNING result INTEGER
```

Usage

The `getChildCount()` method returns the number of children nodes in the current node.

This method is typically used to scan the children nodes of a DOM node, with the `getChildByIndex()` method.

Example

```
DEFINE parent, child om.DomNode,
    index INTEGER
...
FOR index=1 TO node.getChildCount()
    LET child = parent.getChildByIndex(index)
    ...
END FOR
```

om.DomNode.getFirstChild
Returns the first child DOM node.

Syntax

```
getFirstChild()
RETURNING result om.DomNode
```

Usage

The `getFirstChild()` method returns the first child DOM node in the current node.

This method is typically used to scan children nodes with the `getNext()` method, until `getNext()` returns `NULL`. 
om.DomNode.getId
Returns the internal AUI tree id of a DOM node.

Syntax

getId()
RETURNING result INTEGER

Usage
The getId() method returns to internal integer identifier generated automatically for any om.DomNode object created in the abstract user interface tree.
The internal id is typically used to reference a DOM node in an attribute of another node, to link logically nodes together.
If the DOM node does not belong to the AUI tree, the method returns zero.

om.DomNode.getLastChild
Returns the last child DOM node.

Syntax

getLastChild()
RETURNING result om.DomNode

Usage
The getLastChild() method returns the last child DOM node in the current node.
This method is typically used to scan children nodes with the getPrevious() method, until getPrevious() returns NULL.

Example

DEFINE parent, child om.DomNode
...
LET child = parent.getFirstChild()
WHILE child IS NOT NULL
...
LET child = child.getNext()
END WHILE

DEFINE parent, child om.DomNode
...
LET child = parent.getLastChild()
WHILE child IS NOT NULL
...
LET child = child.getPrevious()
END WHILE
om.DomNode.getNext
Returns the next sibling DOM node of this node.

Syntax

```
getNext()
  RETURNING result om.DomNode
```

Usage

The `getNext()` method returns the next sibling DOM node following the current node, within the children list of the parent node.

om.DomNode.getParent
Returns the parent DOM node.

Syntax

```
getParent()
  RETURNING result om.DomNode
```

Usage

The `getParent()` method returns the parent DOM node of the current node.
If the current node is the root node, the method returns `NULL`.

Example

```
DEFINE parent, current om.DomNode
...
LET parent = current.getParent()
```

om.DomNode.getPrevious
Returns previous sibling DOM node of this node.

Syntax

```
getPrevious()
  RETURNING result om.DomNode
```

Usage

The `getPrevious()` method returns the previous sibling DOM node preceding the current node, within the children list of the parent node.

om.DomNode.getTagname
Returns the XML tag name of a DOM node.

Syntax

```
getTagname()
  RETURNING result STRING
```
Usage

The `getTagName()` method returns the XML tag name of the node.

Use this method to identify the type of the node.

om.DomNode.removeAttribute
Delete the specified attribute from the DOM node.

Syntax

```
removeAttribute(
    name STRING )
RETURNING result STRING
```

1. `name` is the name of the attribute.

Usage

The `removeAttribute()` method deletes the attribute identified by the name passed as parameter.

DOM node attribute names are case-sensitive.

If the attribute does not exist for this node the method returns silently.

Example

```
DEFINE node om.DomNode
...
CALL node.removeAttribute("comments")
```

om.DomNode.removeChild
Deletes the specified child node from the current node.

Syntax

```
removeChild(
    node om.DomNode )
```

1. `node` is a reference to a node.

Usage

The `removeChild()` method detaches a `om.DomNode` element node from the current node.

The removed node is not destroyed, if it is still referenced by a variable: The `removeChild()` method will only break the link between the parent node and the child node. The child node still exists in the DOM document, but it is an orphan node, that can be attached to another parent node in the document.

Example

```
MAIN
    DEFINE doc om.DomDocument,
        r om.DomNode,
        p om.DomNode,
        c om.DomNode
    LET doc = om.DomDocument.create("Items")
    LET r = doc.createElement("Zoo")
```
LET p = doc.createElement("DodoList")
CALL r.appendChild(p)

LET c = doc.createElement("Dodo")
CALL c.setAttribute("name", "momo")
CALL c.setAttribute("gender", "male")
CALL p.appendChild(c)

CALL r.writeXml("file1.xml")
CALL p.removeChild(c)

-- c is orphan but still exists
CALL c.writeXml("file2.xml")
LET c = NULL -- unref/destroy the node

CALL r.writeXml("file3.xml")
END MAIN

The above program will produce the following files:

file1.xml

<?xml version='1.0' encoding='ASCII'?><Zoo><DodoList><Dodo name="momo" gender="male"/></DodoList></Zoo>

file2.xml

<?xml version='1.0' encoding='ASCII'?><Dodo name="momo" gender="male"/>

file3.xml

<?xml version='1.0' encoding='ASCII'?><Zoo><DodoList/></Zoo>

om.DomNode.replaceChild
Replaces a node by another in the children nodes of the current node.

Syntax

replaceChild(
    new om.DomNode,
    old om.DomNode)

1. new is a reference to the new node.
2. old is the node to be replaced.

Usage

The replaceChild() method puts the om.DomNode element passed as first parameter at the place of the node referenced by the second parameter, in the children list of the object node calling the method.
The new child node passed to the `replaceChild()` method must have been created from the same DOM document object, for example with the `om.DomDocument.createElement()` method.

The old node is not destroyed, if it is still referenced by a variable. The old node still exists in the DOM document, but it is an orphan node, that can be attached to another parent node in the document.

---

**Example**

```plaintext
MAIN
  DEFINE doc om.DomDocument,
     r om.DomNode,
     p om.DomNode,
     o om.DomNode,
     n om.DomNode
  LET doc = om.DomDocument.create("Items")
  LET r = doc.createElement("Zoo")
  LET p = doc.createElement("DodoList")
  CALL r.appendChild(p)
  LET o = doc.createElement("Dodo")
  CALL o.setAttribute("name", "momo")
  CALL o.setAttribute("gender", "male")
  CALL p.appendChild(o)
  CALL r.writeXml("file1.xml")
  LET n = doc.createElement("Dodo")
  CALL n.setAttribute("name", "kiki")
  CALL n.setAttribute("gender", "female")
  CALL p.replaceChild(n, o)
  -- o is orphan but still exists
  CALL o.writeXml("file2.xml")
  LET o = NULL -- unref/destroy the node
  CALL r.writeXml("file3.xml")
END MAIN
```

The above program will produce following files:

file1.xml

```xml
<?xml version='1.0' encoding='ASCII'?>
<Zoo>
   <DodoList>
      <Dodo name="momo" gender="male"/>
   </DodoList>
</Zoo>
```

file2.xml

```xml
<?xml version='1.0' encoding='ASCII'?>
<Dodo name="momo" gender="male"/>
```

file3.xml

```xml
<?xml version='1.0' encoding='ASCII'?>
<Zoo>
```
om.DomNode.setAttribute
Sets the value of a DOM node attribute.

Syntax

```javascript
setAttribute(
    name STRING,
    value STRING
)
```

1. `name` is the name of the attribute.
2. `value` is the attribute value.

Usage

The `setAttribute()` method sets the value of an attribute in the current node.

DOM node attribute names are case-sensitive.

**Note:** Make sure that the strings passed to the method do not contain illegal XML characters: Illegal XML characters will be silently ignored. Illegal XML characters are any character below space (ASCII 32), except \r (ASCII 13), \n (ASCII 10) and \t (ASCII 9).

Example

```javascript
DEFINE node om.DomNode
...
CALL node.setAttribute("name", "tiger")
```

om.DomNode.toString
Serializes the current node into an XML formatted string.

Syntax

```javascript
toString()
RETURNING result STRING
```

Usage

The `toString()` method builds an XML formatted string with the DOM structure of the current node and returns the string.

Example

```javascript
DEFINE node om.DomNode, s STRING
...
LET s = node.toString()
```
**om.DomNode.write**  
Processes a DOM document with a SAX document handler.

**Syntax**

```plaintext
write(
    sdh om.SaxDocumentHandler
)
```

1. `sdh` references a SAX document handler.

**Usage**

The `write()` method processes the current DOM node content with the SAX document handler passed as parameter.

See the SAX document handler class for more details.

**om.DomNode.writeXml**  
Creates an XML file from the current DOM node.

**Syntax**

```plaintext
writeXml(
    filename STRING
)
```

1. `filename` is the path to the XML file.

**Usage**

The `writeXml()` method writes the content of the current DOM node to the file passed as parameter.

**Example**

```plaintext
DEFINE node om.DomNode
...
CALL noe.writeXml("output.xml")
```

**om.DomNode.selectByPath**  
Finds descendant DOM nodes according to an XPath-like pattern.

**Syntax**

```plaintext
selectByPath(
    xpath STRING
) RETURNING result om.NodeList
```

1. `xpath` is an XPath-like pattern, using `. .

**Usage**

The `selectByPath()` method scans the DOM tree for descendant nodes according to the specified XPath-like pattern.

The pattern supported is limited to the following syntax:

```
/ | // | TagName | [@AttributeName="Value"] | [...]
```

DOM node tag names and attributes names are case-sensitive.
The method creates a list of nodes as a `om.NodeList` object. This list object is then used to process the nodes found.

**Example**

```
DEFINE node om.DomNode,
    nodelist om.NodeList
...
LET nodelist = node.selectByPath("//Grid/Table[@tabName="t1"]")
```

`om.DomNode.selectByTagName`

Finds descendant DOM nodes according to a tag name.

**Syntax**

```
selectByTagName(
tagname STRING)
RETURNING result om.NodeList
```

1. `tagname` is a tag name for the search.

**Usage**

The `selectByTagName()` method scans the DOM tree for descendant nodes defined with the tag name specified as parameter.

DOM node tag names are case-sensitive.

The method creates a list of nodes as a `om.NodeList` object. This list object is then used to process the nodes found.

**Example**

```
DEFINE node om.DomNode,
    nodelist om.NodeList
...
LET nodelist = node.selectByTagName("Car")
```

**Examples**

Example 1: Creating a DOM tree

To create a DOM tree with the following structure (represented in XML format):

```xml
<Vehicles>
    <Car name="Corolla" color="Blue" weight="1546">Nice car!</Car>
    <Bus name="Maxibus" color="Yellow" weight="5278">
        <Wheel width="315" diameter="925" />
        <Wheel width="315" diameter="925" />
        <Wheel width="315" diameter="925" />
    </Bus>
</Vehicles>
```

You write the following:

```
MAIN
    DEFINE d om.DomDocument
    DEFINE r, n, t, w om.DomNode
```
DEFINE i INTEGER

LET d = om.DomDocument.create("Vehicles")
LET r = d.getDocumentElement()

LET n = r.createChild("Car")
CALL n.setAttribute("name","Corolla")
CALL n.setAttribute("color","Blue")
CALL n.setAttribute("weight","1546")

LET t = d.createChars("Nice car!")
CALL n.appendChild(t)
LET t = d.createEntity("nbsp")
CALL n.appendChild(t)
LET t = d.createChars("Yes, very nice!")
CALL n.appendChild(t)

LET n = r.createChild("Bus")
CALL n.setAttribute("name","Maxibus")
CALL n.setAttribute("color","yellow")
CALL n.setAttribute("weight","5278")
FOR i=1 TO 4
  LET w = n.createChild("Wheel")
  CALL w.setAttribute("width","315")
  CALL w.setAttribute("diameter","925")
END FOR

CALL r.writeXml("Vehicles.xml")
END MAIN

Example 2: Displaying a DOM tree recursively

The following example displays a DOM tree content recursively:

FUNCTION displayDomNode(n,e)
  DEFINE n om.DomNode
  DEFINE e, i, s INTEGER

  LET s = e*2
  DISPLAY s SPACES || "Tag: " || n.getTagName()

  DISPLAY s SPACES || "Attributes:"
  FOR i=1 TO n.getAttributesCount()
    DISPLAY s SPACES || "  " || n.getAttributeName(i) || "=" || n.getAttributeValue(i) || ""
  END FOR

  LET n = n.getFirstChild()

  DISPLAY s SPACES || "Child Nodes:"
  WHILE n IS NOT NULL
    CALL displayDomNode(n,e+1)
    LET n = n.getNext()
  END WHILE

END FUNCTION

Example 3: Writing a DOM tree to a SAX handler

The following example outputs a Dom tree without indentation.
DEFINE r, n, t, w om.DomNode
DEFINE dh om.SaxDocumentHandler
DEFINE i INTEGER

LET dh = om.XmlWriter.createPipeWriter("cat")
CALL dh.setIndent(FALSE)

LET d = om.DomDocument.create("Vehicles")
LET r = d.getDocumentElement()

LET n = r.createChild("Car")
CALL n.setAttribute("name","Corolla")
CALL n.setAttribute("color","Blue")
CALL n.setAttribute("weight","1546")

LET t = d.createChars("Nice car!")
CALL n.appendChild(t)

LET n = r.createChild("Bus")
CALL n.setAttribute("name","Maxibus")
CALL n.setAttribute("color","yellow")
CALL n.setAttribute("weight","5278")
FOR i=1 TO 4
  LET w = n.createChild("Wheel")
  CALL w.setAttribute("width","315")
  CALL w.setAttribute("diameter","925")
END FOR

CALL r.write(dh)

END MAIN

The NodeList class
A om.NodeList object hold a list of DOM nodes.

The list is created from a om.DomNode.selectByTagName() or om.DomNode.selectByPath() method.

After creating the node list, you can process the nodes with the getLength() and item() methods of the om.NodeList object.

om.NodeList methods
Methods of the om.NodeList class.

Table 412: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getLength()</td>
<td>RETURNS result INTEGER&lt;br&gt;Returns the number of elements in the node list.</td>
</tr>
<tr>
<td>item(index INTEGER )</td>
<td>RETURNS result om.DomNode&lt;br&gt;Returns a DOM node element by position in the node list.</td>
</tr>
</tbody>
</table>
om.NodeList.getLength
Returns the number of elements in the node list.

Syntax

```
getLength()
   RETURNING result INTEGER
```

1. *node* is a reference to a node.

Usage

The `getLength()` method returns the size of the node list.

Query for node list for elements with the `item()` method, in the range 1 to `getLength()`.

```
DEFINE list om.NodeList
...
DISPLAY list.getLength()
```

om.NodeList.item
Returns a DOM node element by position in the node list.

Syntax

```
item( index INTEGER )
   RETURNING result om.DomNode
```

1. *index* is the ordinal position of the node in the list.

Usage

The `item()` method returns the `om.DomNode` object at the position specified.

First element is at position 1.

If there is no element at the specified index, the method returns `NULL`.

```
DEFINE list om.NodeList,
    node om.DomNode
...
LET node = list.item(12)
```

Examples

Example 1: Search for child nodes by tag name

```
MAIN
   DEFINE nl om.NodeList
   DEFINE r, n om.DomNode
   DEFINE i INTEGER

   LET r = ui.Interface.getRootNode()
   LET nl = r.selectByTagName("Form")
   FOR i=1 to nl.getLength()
```
LET n = nl.item(i)
DISPLAY n.getAttribute("name")
END FOR

END MAIN

Example 2: Search for child nodes by XPath

MAIN
DEFINE nl om.NodeList
DEFINE r, n om.DomNode
DEFINE i INTEGER

LET r = ui.Interface.getRootNode()
LET nl = r.selectByPath("//Window[@name="screen"]")

FOR i=1 to nl.getLength()
  LET n = nl.item(i)
  DISPLAY n.getAttribute("name")
END FOR

END MAIN

The SaxAttributes class
The om.SaxAttributes class holds a set of attributes to process with a SAX reader or writer.

To process SAX attributes, create a om.SaxAttributes object with a SAX reader or SAX writer object.

Get an instance of SaxAttributes with the om.XmlReader.getAttributes() method.

om.SaxAttributes methods
Methods of the om.SaxAttributes class.

Table 413: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy(attrs om.SaxAttributes)</td>
<td>Clones an existing SAX attributes object.</td>
</tr>
<tr>
<td>create()</td>
<td>Create a new SAX attributes object.</td>
</tr>
</tbody>
</table>

Table 414: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>addAttribute(name STRING, value STRING)</td>
<td>Appends a new attribute to the end of the list.</td>
</tr>
<tr>
<td>clear()</td>
<td>Clears the SAX attribute list.</td>
</tr>
<tr>
<td>getLength()</td>
<td>Returns the number of attributes in the list.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| getName(  
   index INTEGER )  
RETURNING result STRING | Returns the name of an attribute by position. |
| getValue(  
   name STRING )  
RETURNING result STRING | Returns the value of an attribute by name. |
| getValueByIndex(  
   index INTEGER )  
RETURNING result STRING | Returns an attribute value by position. |
| removeAttribute(  
   index INTEGER ) | Delete an attribute by position. |
| setAttributes(  
   attrs om.SaxAttributes ) | Clears the list and copies the attributes passed. |

om.SaxAttributes.addAttribute
Appends a new attribute to the end of the list.

**Syntax**

```
addAttribute(  
   name STRING,  
   value STRING )
```

1. *name* is the name of the attribute.
2. *value* is the value of the attribute.

**Usage**
The `addAttribute()` method appends a new attribute with name and value at the end of the list.

Attribute names are case-sensitive.

**Note:** Make sure that the strings passed to the method do not contain illegal XML characters: Illegal XML characters will be silently ignored. Illegal XML characters are any character below space (ASCII 32), except \r (ASCII 13), \n (ASCII 10) and \t (ASCII 9).

**Example**

```
DEFINE attrs om.SaxAttributes
...
CALL attrs.addAttribute("name","jo")
```
om.SaxAttributes.copy
Clones an existing SAX attributes object.

Syntax

copy(
    attrs om.SaxAttributes )
RETURNING result om.SaxAttributes

1. attrs is a set of SAX attributes to clone.

Usage

The om.SaxAttributes.copy() class method makes a clone of the om.SaxAttributes object passed as reference and returns the new created object.

Example

DEFINE copy, orig om.SaxAttributes
...
LET copy = om.SaxAttributes.copy(orig)

om.SaxAttributes.create
Create a new SAX attributes object.

Syntax

create()
RETURNING result om.SaxAttributes

Usage

The om.SaxAttributes.create() class method create a new om.SaxAttributes object returns it.

To hold the reference to a SAX attributes object, define a variable with the type om.SaxAttributes type.

Example

DEFINE attrs om.SaxAttributes
...
LET attrs = om.SaxAttributes.create()

om.SaxAttributes.clear
Clears the SAX attribute list.

Syntax

clear()

Usage

Use the clear() method the clean the SAX attribute list.
om.SaxAttributes.getLength

Returns the number of attributes in the list.

**Syntax**

```plaintext
getLength()
  RETURNING result INTEGER
```

**Usage**

The `getLength()` method returns the number of attributes in the current SAX attribute list.

Use this method with `getName()` and `getValueByIndex()` to retrieve attributes by position.

```
DEFINE attrs om.SaxAttributes,
  index INTEGER
...
FOR index = 1 TO attrs.getLength()
  DISPLAY attrs.getName(index), " = ",
  attrs.getValueByIndex(index)
END FOR
```

om.SaxAttributes.getName

Returns the name of an attribute by position.

**Syntax**

```plaintext
getName(
  index INTEGER )
  RETURNING result STRING
```

1. `index` is the position of the attribute in the list.

**Usage**

The `getName()` method returns the name of the attribute at the specified ordinal position in the list.

If the attribute does not exist at the given position, the method returns `NULL`.

om.SaxAttributes.getValue

Returns the value of an attribute by name.

**Syntax**

```plaintext
getValue(
  name STRING )
  RETURNING result STRING
```

1. `name` is the name of an attribute.

**Usage**

The `getValue()` method returns the value of the attribute identified by the name passed as parameter.

If the attribute does not exist, the method returns `NULL`. 
Example

```plaintext
DEFINE attrs om.SaxAttributes
...
DISPLAY attrs.getValue("name")
```

om.SaxAttributes.getValueByIndex

Returns an attribute value by position.

Syntax

```plaintext
getValueByIndex(
    index INTEGER )
RETURNING result STRING
```

1. `index` is the position of the attribute in the list.

Usage

The `getValueByIndex()` method returns the value of the attribute at the specified ordinal position in the list. If the attribute does not exist at the given position, the method returns `NULL`.

om.SaxAttributes.removeAttribute

Delete an attribute by position.

Syntax

```plaintext
removeAttribute(
    index INTEGER )
```

1. `index` is the position of the attribute in the list.

Usage

The `removeAttribute()` method removes the attribute at the given ordinal position. If the attribute does not exist at the given position, the method returns silently.

Example

```plaintext
DEFINE attrs om.SaxAttributes
...
CALL attrs.removeAttribute( attrs.getLength() )
```

om.SaxAttributes.setAttributes

Clears the list and copies the attributes passed.

Syntax

```plaintext
setAttributes(
    attrs om.SaxAttributes )
```

1. `attrs` is a reference to list of attributes.
Usage

The `setAttributes()` method takes an existing `om.SaxAttributes` object reference and makes a copy of all attributes into the current attribute list.

Example

```plaintext
DEFINE curr, orig om.SaxAttributes
...
CALL curr.setAttributes(orig)
```

Examples

Example 1: Displaying SAX attributes of an XML node

```plaintext
FUNCTION displayAttributes( a )
  DEFINE a om.SaxAttributes
  DEFINE i INTEGER
  FOR i=1 to a.getLength()
    DISPLAY a.getName(i) || "=" || a.getValueByIndex(i) || ""
  END FOR
END FUNCTION
```

The SaxDocumentHandler class

The `om.SaxDocumentHandler` class provides an interface to write an XML filter with events.

This class follows the SAX standards.

A `om.SaxDocumentHandler` object can be used in two different ways:

1. To implement an XML SAX filter, based of functions defined in a .4gl module, by using the `createForName()` class method.
2. To write an XML document to a file, process or socket output, by using `om.XmlWriter` creation methods, and the `om.SaxDocumentHandler` processing methods.

The `om.SaxDocumentHandler` class also provides methods to process all SAX events by hand. This is useful if you want to chain SAX filters.

**om.SaxDocumentHandler methods**

Methods of the `om.SaxDocumentHandler` class.

**Table 415: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>om.SaxDocumentHandler.createForName( module STRING )</code> RETURNING result <code>om.SaxDocumentHandler</code></td>
<td>Creates a new SAX document handler object for the given .4gl module.</td>
</tr>
</tbody>
</table>

**Table 416: Object methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>characters()</code></td>
<td>Processes a text node.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>data STRING ()</code></td>
<td>Processes the end of the document.</td>
</tr>
<tr>
<td><code>endDocument()</code></td>
<td>Processes the end of an element.</td>
</tr>
<tr>
<td><code>endElement (tagname STRING )</code></td>
<td>Processes a processing instruction.</td>
</tr>
<tr>
<td><code>processingInstruction (name STRING, data STRING )</code></td>
<td>Processes a processing instruction.</td>
</tr>
<tr>
<td><code>readXmlFile (filename STRING )</code></td>
<td>Reads and processes an XML file with the SAX document handler.</td>
</tr>
<tr>
<td><code>setIndent (on BOOLEAN )</code></td>
<td>Controls indentation in XML output.</td>
</tr>
<tr>
<td><code>startDocument ()</code></td>
<td>Processes the beginning of the document.</td>
</tr>
<tr>
<td><code>startElement (tagname STRING, attrs om.SaxAttributes )</code></td>
<td>Processes the beginning of an element.</td>
</tr>
<tr>
<td><code>skippedEntity (name STRING )</code></td>
<td>Processes an unresolved entity.</td>
</tr>
</tbody>
</table>

om.SaxDocumentHandler.createForName
Creates a new SAX document handler object for the given .4gl module.

**Syntax**

```java
om.SaxDocumentHandler.createForName(
    module STRING )
RETURNING result om.SaxDocumentHandler
```

1. `module` is the name of the .4gl module defining the document handler events.

**Usage**

The `om.SaxDocumentHandler.createForName()` method creates a `om.SaxDocumentHandler` instance and binds the .4gl module passed as argument to the object.

To hold the reference to a SAX document handler object, define a variable with the type `om.SaxDocumentHandler type`.

The .4gl module must be available as a compiled 42m file, loadable according to environment settings (FGLLDPATH).

The .4gl module must implement the following functions to process the SAX filter events:
### Table 417: Functions of the SAX document handler module

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startDocument()</td>
<td>Called once at the beginning of the document processing.</td>
</tr>
<tr>
<td>endDocument()</td>
<td>Called once at the end of the document processing.</td>
</tr>
<tr>
<td>startElement( tagname STRING, attrs om.SaxAttributes )</td>
<td>Called when an XML element is reached. Use the om.SaxAttributes methods to handle the attributes of the processed element.</td>
</tr>
<tr>
<td>endElement( tagname STRING )</td>
<td>Called when the end of an XML element is reached.</td>
</tr>
<tr>
<td>processingInstruction( piname STRING, data STRING )</td>
<td>Called when a processing instruction is reached.</td>
</tr>
<tr>
<td>characters( data STRING )</td>
<td>Called when a text node is reached.</td>
</tr>
<tr>
<td>skippedEntity( name STRING )</td>
<td>Called when an unknown entity node is reached (like &amp;xxx; for example).</td>
</tr>
</tbody>
</table>

### Example

```java
DEFINE f om.SaxDocumentHandler
LET f = om.SaxDocumentHandler.createForName("mysaxmod")
```

**om.SaxDocumentHandler.characters**

Processes a text node.

### Syntax

```java
characters( data STRING )
```

1. `data` is the content of the text node.
Usage

The `characters()` method processes a text node with the SAX interface.

**Note:** Make sure that the strings passed to the method do not contain illegal XML characters: Illegal XML characters will be silently ignored. Illegal XML characters are any character below space (ASCII 32), except \r (ASCII 13), \n (ASCII 10) and \t (ASCII 9).

```java
om.SaxDocumentHandler.endDocument
Processes the end of the document.
```

Syntax

```java
endDocument()
```

Usage

The `endDocument()` method ends the document processing with the SAX interface.

```java
om.SaxDocumentHandler.endElement
Processes the end of an element.
```

Syntax

```java
endElement(
    tagname STRING
)
```

1. `tagname` is the tag name of element.

Usage

The `endElement()` method processes the end of an element with the SAX interface.

```java
om.SaxDocumentHandler.processingInstruction
Processes a processing instruction.
```

Syntax

```java
processingInstruction(
    name STRING,
    data STRING
)
```

1. `name` is the name of the processing instruction (token after `<?`).
2. `data` is the string in the processing instruction tag.

Usage

The `processingInstruction()` method processes a processing instruction with the SAX interface.

A processing instruction appears in an XML formatted text as:

```xml
<?name data ?>
```

```java
om.SaxDocumentHandler.readXmlFile
Reads and processes an XML file with the SAX document handler.
```

Syntax

```java
readXmlFile(
```
1. *filename* is the path to an XML formatted file.

**Usage**

Use the `readXmlFile()` method after creating the `om.SaxDocumentHandler` object, to process the XML data from a file input stream.

**Example**

```om
DEFINE f om.SaxDocumentHandler
LET f = om.SaxDocumentHandler.createForName("mysaxmod")
CALL f.readXmlFile("cars.xml")
```

`om.SaxDocumentHandler.setIndent`

Controls indentation in XML output.

**Syntax**

```om
setIndent (  
on BOOLEAN  )
```

1. *on* is a boolean: `TRUE` enables indentation; `FALSE` disables indentation.

**Usage**

By default, the `om.SaxDocumentHandler` object outputs XML with indentation.

In order to disable indentation, use the `setIndent(FALSE)` method.

`om.SaxDocumentHandler.startDocument`

Processes the beginning of the document.

**Syntax**

```om
startDocument ()
```

**Usage**

The `startDocument()` method begins the document processing with the SAX interface.

`om.SaxDocumentHandler.startElement`

Processes the beginning of an element.

**Syntax**

```om
startElement (  
tagname STRING,  
attrs om.SaxAttributes  )
```

1. *tagname* is the tag name of element.
2. *attrs* is the list of attributes of the element.

**Usage**

The `startElement()` method processes the beginning of an element with the SAX interface.
Use the `om.SaxAttributes` methods to handle the attributes of an element.

### Example

```om
DEFINE out om.SaxDocumentHandler
  attrs om.SaxAttributes,
  node om.DomNode,
  x INTEGER
...
CALL attrs.clear()
FOR x=1 TO r.getAttributesCount()
  CALL attrs.getAttributeValue(x)
  CALL out.startElement( node.getTagName(), attrs )
END FOR
```

`om.SaxDocumentHandler.skippedEntity` processes an unresolved entity.

**Syntax**

```om
skippedEntity(
  name STRING )
```

1. `name` is the name of the unknown entity.

**Usage**

The `skippedEntity()` method processes an entity that is not known by the XML parser.

**Examples**

**Example 1:** Extracting phone numbers from a directory.

This example shows how to write a SAX filter to extract phone numbers from a directory file written in XML.

```om
MAIN
  DEFINE f om.SaxDocumentHandler
  LET f = om.SaxDocumentHandler.createForName("module1")
  CALL f.readXmlFile("customers")
END MAIN
```

**Note:**

1. The parameter of the `createForName()` method specifies the name of a source file that has been compiled into a .42m file ("module1.42m" in our example).

The module "module1.4gl":

```om
FUNCTION startDocument ()
END FUNCTION

FUNCTION processingInstruction(name, data)
  DEFINE name, data STRING
END FUNCTION

FUNCTION startElement(name, attr)
  DEFINE name STRING
  DEFINE attr om.SaxAttributes
  DEFINE i INTEGER
  IF name="Customer" THEN
    DISPLAY attr.getValue("lname"); " ",
```
The XML file "customers":

```xml
<Customers>
  <Customer customer_num="101" fname="Ludwig" lname="Pauli"
   company="All Sports Supplies" address1="213 Erstwild Court"
   address2="" city="Sunnyvale" state="CA" zip-code="94086"
   phone="408-789-8075" />
  <Customer customer_num="102" fname="Carole" lname="Sadler"
   company="Sports Spot" address1="785 Geary St"
   address2="" city="San Francisco" state="CA" zip-code="94117"
   phone="415-822-1289" />
  <Customer customer_num="103" fname="Philip" lname="Currie"
   company="Phil's Sports" address1="654 Poplar"
   address2="P. O. Box 3498" city="Palo Alto" state="CA"
   zip-code="94303" phone="415-328-4543" />
</Customers>
```

**The XmlReader class**

The `om.XmlReader` class provides methods to read and process a file written in XML format.

The processing of the XML file is streamed-data based; the file is loaded and processed sequentially with events. To process XML element attributes, an `om.XmlReader` object must cooperate with a `om.SaxAttributes` object. The XmlReader class can only read from a file. To write to a file, use the `om.XmlWriter` class.

Steps to use a XML reader:

1. Declare a variable with the `om.XmlReader` type.
2. Create the reader object with the `createFileReader()` method and assign the reference to the variable.
3. Process SAX events in a WHILE loop, by reading document fragments with the `read()` method.
4. Inside the loop, according to the SAX event, process element attributes with `getAttributes()` or get the element data with the `getCharacters()` methods.
om.XmlReader methods
Methods of the `om.XmlReader` class.

### Table 418: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>createFileReader( filename STRING )</code> RETURNING result <code>om.XmlReader</code></td>
<td>Creates an XML reader object from a file.</td>
</tr>
</tbody>
</table>

### Table 419: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getCharacters()</code></td>
<td>Returns the character data of the current processed element.</td>
</tr>
<tr>
<td>RETURNING result STRING</td>
<td></td>
</tr>
<tr>
<td><code>getAttributes()</code></td>
<td>Builds an attribute list for the current processed element.</td>
</tr>
<tr>
<td>RETURNING result <code>om.SaxAttributes</code></td>
<td></td>
</tr>
<tr>
<td><code>getTagName()</code></td>
<td>Returns the tag name of the current processed element.</td>
</tr>
<tr>
<td>RETURNING result STRING</td>
<td></td>
</tr>
<tr>
<td><code>read()</code></td>
<td>Reads the next SAX event to process.</td>
</tr>
<tr>
<td>RETURNING result STRING</td>
<td></td>
</tr>
<tr>
<td><code>skippedEntity()</code></td>
<td>Returns the name of an unresolved entity.</td>
</tr>
<tr>
<td>RETURNING result STRING</td>
<td></td>
</tr>
</tbody>
</table>

`om.XmlReader.createFileReader
Creates an XML reader object from a file.

**Syntax**

```plaintext
createFileReader( 
    filename STRING ) 
RETURNING result om.XmlReader
```

1. `filename` is the path to an XML formatted file.

**Usage**

Use the `om.XmlReader.createFileReader()` method to create a new `om.XmlReader` object, to process the XML data from a file input stream.

To hold the reference to an XmlReader object, define a variable with the type `om.XmlReader` type.

**Example**

```plaintext
DEFINE r om.XmlReader
```
om.XmlReader.createFileReader("cars.xml")

Builds an attribute list for the current processed element.

Syntax

```om
getAttributes()
RETURNING result om.SaxAttributes
```

Usage

Use the `getAttributes()` method to create a list of attributes as an `om.SaxAttributes` object, from the current processed element, in the `StartElement` or `EndElement` event context.

Declare a variable with the `om.SaxAttributes` type to reference the attribute list.

Note that once created with the `getAttributes()` method, the `om.SaxAttributes` object is automatically updated based on the element currently processed by the `om.XmlReader`.

Example

```om
DEFINE r om.XmlReader,
e STRING, i INT
a om.SaxAttributes
...
LET e = r.read()
WHILE e IS NOT NULL
  CASE e
    ...
    WHEN "StartElement"
      LET a = r.getAttributes()
      FOR i=1 to a.getLength()
        ...
```

om.XmlReader.getCharacters

Returns the character data of the current processed element.

Syntax

```om
getCharacters()
RETURNING result STRING
```

Usage

Use the `getCharacters()` method to get the character data of the current processed element, in the `Characters` event context.

Example

```om
DEFINE r om.XmlReader,
e STRING
...
LET e = r.read()
WHILE e IS NOT NULL
  CASE e
    ...
    WHEN "Characters"
```
om.XmlReader.getTagTagName
Returns the tag name of the current processed element.

Syntax

```sql
getTagName()
RETURNING result STRING
```

Usage

Use the `readXmlFile()` method to get the tag name of the current processed element, in the `StartElement` or `EndElement` event context.

Example

```sql
DEFINE r om.XmlReader,
    e STRING
...
LET e = r.read()
WHILE e IS NOT NULL
    CASE e
        ...
        WHEN "StartElement"
            DISPLAY "TagName = ", r.getTagTagName()
            ...
```

om.XmlReader.read
Reads the next SAX event to process.

Syntax

```sql
read()
RETURNING result STRING
```

Usage

The `read()` method reads the next XML fragment and returns the name of the SAX event to process.
Table 420: Events that can be returned by the `read()` method

<table>
<thead>
<tr>
<th>Event name</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>StartDocument</td>
<td>Beginning of the document</td>
<td>Prepare processing (allocate resources)</td>
</tr>
<tr>
<td>StartElement</td>
<td>Beginning of a node</td>
<td>Get current element's tag name or attributes with <code>getTagName()</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>getAttributes()</code></td>
</tr>
<tr>
<td>Characters</td>
<td>Value of the current element</td>
<td>Get current text element's value with <code>getCharacters()</code></td>
</tr>
<tr>
<td>SkippedEntity</td>
<td>Reached skipped entity</td>
<td>Get current skipped entity element's value with <code>skippedEntity()</code></td>
</tr>
<tr>
<td>EndElement</td>
<td>Ending of a node</td>
<td>Get current element's tagname with <code>getTagName()</code></td>
</tr>
<tr>
<td>EndDocument</td>
<td>Ending of the document</td>
<td>Finish processing (release resources)</td>
</tr>
</tbody>
</table>

**Example**

```plaintext
DEFINE r om.XmlReader,
  e STRING
...
  LET e = r.read()
WHILE e IS NOT NULL
  CASE e
    ...
  END CASE
  LET e = r.read()
END WHILE
```

`om.XmlReader.skippedEntity`
Returns the name of an unresolved entity.

**Syntax**

```plaintext
skippedEntity()
  RETURNING result STRING
```

**Usage**
The `skippedEntity()` method returns the name of the unresolved entity, in the SkippedEntity event context.

The parser identifies well know character entities such as `&amp;`/`&apos;`/`&lt;`/`&gt;`/`&quot;`, other character entities are treated as skipped entities and can be processed in the SkippedEntity event.

**Example**

```plaintext
DEFINE r om.XmlReader,
  e STRING
...
```
Examples

Example 1: Parsing an XML file

```plaintext
MAIN
DEFINE i, l INTEGER
DEFINE r om.XmlReader
DEFINE e String
DEFINE a om.SaxAttributes
LET r = om.XmlReader.createFileReader("myfile.xml")
LET l = 0
LET e = r.read()
WHILE e IS NOT NULL
CASE e
WHEN "StartDocument"
   DISPLAY "StartDocument:"
WHEN "StartElement"
   LET l=l+1
   DISPLAY l SPACES, "StartElement:", r.getTagName()
   LET a = r.getAttributes()
   FOR i=1 to a.getLength()
      DISPLAY l SPACES,"  ",
      a.getName(i)," = ",
      a.getValueByIndex(i)
   END FOR
WHEN "Characters"
   DISPLAY l SPACES, "  Characters:'",r.getCharacters(),"'"
WHEN "EndElement"
   DISPLAY l SPACES, "EndElement:", r.getTagName()
   LET l=l-1
WHEN "EndDocument"
   DISPLAY "EndDocument:"
OTHERWISE
   DISPLAY "Invalid event: ",e
END CASE
LET e=r.read()
END WHILE
END MAIN
```

The XmlWriter class

The om.XmlWriter class implements methods to write XML to a stream.

Steps to use a XML writer:

1. Declare a variable with the om.SaxDocumentHandler type.
2. Create the writer object with one of the class methods of om.XmlWriter and assign the reference to the variable.
   - `om.XmlWriter.createFileWriter(filename)` creates an object writing to a file.
   - `om.XmlWriter.createPipeWriter(command)` creates an object writing to a pipe opened by a sub-process.
   - `om.XmlWriter.createSocketWriter(hostname, portnum)` creates an object writing to the TCP socket.
3. Output XML data with the methods of the om.SaxDocumentHandler object:
   a. Use the method startDocument() to start writing to the output.
   b. From this point, the order of method calls defines the structure of the XML document. To write an element, fill an om.SaxAttributes object with attributes.
   c. Then, initiate the element output with the method startElement().
   d. Write element data with the characters() method.
   e. Entity nodes are created with the skippedEntity() method.
   f. Finish element output with a call to the endElement() method.
   g. Repeat these steps as many times as you have elements to write.
   h. Instead of using the startElement() method, you can generate processing instruction elements with processingInstruction().
   i. Finally, you must finish the document output with a endDocument() call.

om.XmlWriter methods
Methods of the om.XmlWriter class.

Table 421: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>om.XmlWriter.createPipeWriter( command STRING ) RETURNING result om.SaxDocumentHandler</td>
<td>Creates an om.SaxDocumentHandler object writing to a pipe created for a process.</td>
</tr>
<tr>
<td>om.XmlWriter.createSocketWriter( host STRING, port INTEGER ) RETURNING result om.SaxDocumentHandler</td>
<td>Creates an om.SaxDocumentHandler object writing to a socket.</td>
</tr>
</tbody>
</table>

om.XmlWriter.createChannelWriter
Creates an om.SaxDocumentHandler object writing to a channel object.

Syntax

```java
om.XmlWriter.createChannelWriter( channel base.Channel ) RETURNING result om.SaxDocumentHandler
```

1. `channel` is a base.Channel object reference.
Usage

The om.XmlWriter.createChannelWriter() class method creates an om.SaxDocumentHandler object that will write to the specified channel object, when using the om.SaxDocumentHandler methods. The base.Channel object must exist and be open to receive data from the SAX document handler.

Example

The next example uses the channel to write to stdout, passing NULL as file name to the base.Channel.openFile() method:

```
DEFINE w om.SaxDocumentHandler
DEFINE ch base.Channel
...
LET ch = base.Channel.create()
CALL ch.openFile(NULL,"w")
LET w = om.XmlWriter.createChannelWriter(ch)
...
```

om.XmlWriter.createFileWriter

Creates an om.SaxDocumentHandler object writing to a file.

Syntax

```
om.XmlWriter.createFileWriter(
    filename STRING 
) RETURNING result om.SaxDocumentHandler
```

1. `filename` is the path to the file.

Usage

The om.XmlWriter.createFileWriter() class method creates an om.SaxDocumentHandler object that will write to the specified file when using the om.SaxDocumentHandler methods.

The file is created if it does not exist. If the file cannot be created, the method returns NULL.

When passing NULL as file name, the XmlWriter can be used to write to stdout.

Example

```
DEFINE w om.SaxDocumentHandler
...
LET w = om.XmlWriter.createFileWriter("mydata.xml")
IF w IS NULL THEN
    ERROR "Could not create file."
    EXIT PROGRAM 1
END IF
...

-- Create an XmlWriter object to write to stdout:
LET w = om.XmlWriter.createFileWriter(NULL)
...
om.XmlWriter.createPipeWriter
Creates an om.SaxDocumentHandler object writing to a pipe created for a process.

Syntax

```java
om.XmlWriter.createPipeWriter(
    command STRING )
RETURNING result om.SaxDocumentHandler
```

1. `command` is the command to be executed.

Usage

The `om.XmlWriter.createPipeWriter()` class method creates an `om.SaxDocumentHandler` object that will write to a pipe created for the specified command. XML data will be send through the pipe when using the `om.SaxDocumentHandler` methods.

If the process or pipe cannot be created, the method returns NULL.

Example

```java
DEFINE w om.SaxDocumentHandler
...
LET w = om.XmlWriter.createPipeWriter("sort -u")
IF w IS NULL THEN
    ERROR "Could not create process."
    EXIT PROGRAM 1
END IF
```

om.XmlWriter.createSocketWriter
Creates an om.SaxDocumentHandler object writing to a socket.

Syntax

```java
om.XmlWriter.createSocketWriter(
    host STRING,
    port INTEGER )
RETURNING result om.SaxDocumentHandler
```

1. `host` is the name of the host computer listening to the TCP port.
2. `port` is the port number to connect to.

Usage

The `om.XmlWriter.createSocketWriter()` class method creates an `om.SaxDocumentHandler` object that will write to a socket identified by the host and port number passed as parameters. XML data will be send through the socket when using the `om.SaxDocumentHandler` methods.

If the socket cannot be opened, the method returns NULL. No timeout is used.

Example

```java
DEFINE w om.SaxDocumentHandler
...
LET w = om.XmlWriter.createSocketWriter("myhost",8012)
IF w IS NULL THEN
    ERROR "Could not open socket."
    EXIT PROGRAM 1
```
Examples
Example 1: Writing XML to a file

```
MAIN
    DEFINE w om.SaxDocumentHandler
    DEFINE a, n om.SaxAttributes

    LET w = om.XmlWriter.createFileWriter("sample.html")
    LET a = om.SaxAttributes.create()
    LET n = om.SaxAttributes.create()

    CALL n.clear()
    CALL w.startDocument()

    CALL w.startElement("HTML", n)
    CALL w.startElement("HEAD", n)
    CALL w.startElement("TITLE", n)
    CALL w.characters("HTML page generated with XmlWriter")
    CALL w.endElement("TITLE")
    CALL a.clear()
    CALL a.addAttribute("type", "text/css")
    CALL w.startElement("STYLE", a)
    CALL w.characters("\nBODY { background-color:#c0c0c0; }\n")
    CALL w.endElement("STYLE")
    CALL w.endElement("HEAD")
    CALL w.startElement("BODY", n)
    CALL addHLine(w)
    CALL addTitle(w, "What is XML?", 1, "55ff55")
    CALL addParagraph(w, "XML = eXtensible Markup Language ...")
    CALL addHLine(w)
    CALL addTitle(w, "What is SAX?", 1, "55ff55")
    CALL addParagraph(w, "SAX = Simple Api for XML ...")
    CALL w.endElement("BODY")
    CALL w.endElement("HTML")
    CALL w.endDocument()
END MAIN
```

FUNCTION addHLine(w)
```
    DEFINE w om.SaxDocumentHandler
    DEFINE a om.SaxAttributes
    LET a = om.SaxAttributes.create()
    CALL a.clear()
    CALL a.addAttribute("width", "100%")
    CALL w.startElement("HR", a)
    CALL w.endElement("HR")
END FUNCTION
```

FUNCTION addTitle(w, t, x, c)
```
DEFINE w om.SaxDocumentHandler
DEFINE t VARCHAR(100)
DEFINE x INTEGER DEFINE c VARCHAR(20)
DEFINE a om.SaxAttributes
DEFINE n varchar(10)
LET a = om.SaxAttributes.create()
LET n = "h" || x
CALL a.clear()
CALL w.startElement(n,a)
IF c IS NOT NULL THEN CALL a.addAttribute("color",c)
END IF CALL w.startElement("FONT",a)
CALL w.characters(t)
CALL w.endElement("FONT")
CALL w.endElement(n)
END FUNCTION

FUNCTION addParagraph(w,t)
DEFINE w om.SaxDocumentHandler
DEFINE t VARCHAR(2000)
DEFINE a om.SaxAttributes
LET a = om.SaxAttributes.create()
CALL a.clear()
CALL w.startElement("P",a)
CALL w.characters("Text is:")
CALL w.characters("is")
CALL w.characters(t)
CALL w.endElement("P")
END FUNCTION

Built-in front calls

This section contains the description of all built-in front calls.

- Built-in front calls on page 1887
- Standard front calls on page 1895
- Webcomponent front calls on page 1908
- Genero Desktop Client front calls on page 1910
- Genero Application Server front calls on page 1930
- Genero Mobile common front calls on page 1931
- Genero Mobile Android front calls on page 1946
- Genero Mobile iOS front calls on page 1950

Built-in front calls

Various front-end functions are implemented within Genero front-ends.

This section describes the front-end functions available for all type of front-ends. Note that several front-end functions are specific to the type of front-end.

Table 422: Standard front-end functions

Standard front calls

Standard front call functions provide common utility APIs to control the front-end.

This table shows the functions implemented by the front-ends in the "standard" module, available on all front-ends.

Table 432: Standard front-end functions

<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
### Function Name | Description | GDC | GWC-JS | GMA | GMI
--- | --- | --- | --- | --- | ---

| [path, name, filetype, caption], [result] | Override the font used for report generation for the current application. | Yes | No | No | No |

ui.Interface.frontCall("standard", "setReportFont", [font], [result])

| [printer], [result] | Override the printer configuration used for report generation for the current application. | Yes | No | No | No |

ui.Interface.frontCall("standard", "setReportPrinter", [printer], [result])

| [path], [] | Defines the base path where web components are located. | Yes | N/A | Yes | Yes |

ui.Interface.frontCall("standard", "setWebComponentPath", [path], [])

| [document, action], [result] | Opens a file on the front-end platform with the program associated to the file extension. | Yes | No | No | No |

ui.Interface.frontCall("standard", "shellExec", [document, action], [result])

---

**cbAdd**

Adds to the content of the clipboard.

**Syntax**

```javascript
ui.Interface.frontCall("standard", "cbAdd", [text], [result])
```

1. `text` - The text to be added.
2. `result` - Holds the execution result (TRUE=success, FALSE=error).

**Usage**

The "cbAdd" front call adds the text passed as parameter to the content of the clipboard of the front-end platform.

**cbClear**

Clears the content of the clipboard.

**Syntax**

```javascript
ui.Interface.frontCall("standard", "cbClear", [], [result])
```

1. `result` - Holds the execution result (TRUE=success, FALSE=error).

**Usage**

The "cbClear" front call clears the content of the clipboard. This front call takes no input parameters.
**cbGet**
Gets the content of the clipboard.

**Syntax**
```
ui.Interface.frontCall("standard", "cbGet", [], [text])
```

1. `text` - Holds the text found in the clipboard.

**Usage**
The "cbGet" front call returns the current content of the clipboard. This front call takes no input parameters.

**cbPaste**
Pastes the content of the clipboard to the current field.

**Syntax**
```
ui.Interface.frontCall("standard", "cbPaste", [], [result])
```

1. `result` - Holds the execution result (TRUE=succes, FALSE=error).

**Usage**
The "cbPaste" front call pastes the content of the clipboard to the current field. This front call takes no input parameters.

**cbSet**
Set the content of the clipboard.

**Syntax**
```
ui.Interface.frontCall("standard", "cbSet", [text], [result])
```

1. `text` - The text to be set.
2. `result` - Holds the execution result (TRUE=succes, FALSE=error).

**Usage**
The "cbSet" front call sets the content of the clipboard with the text passed as parameter.

**execute**
Executes a command on the front-end platform, with or without waiting.

**Syntax**
```
ui.Interface.frontCall("standard", "execute", [cmd, wait], [result])
```

1. `cmd` - The command to be executed.
2. `wait` - The wait option (TRUE=wait, FALSE=do not wait).
3. `result` - Holds the execution result (TRUE=succes, FALSE=error).
### Usage

The "execute" front call runs a command on the front-end platform, with or without waiting option. If the second parameter is set to 1 (TRUE), the runtime system will wait until the front-end gives the control back after the local command was executed.

#### feInfo

Queries general front-end properties.

### Syntax

```javascript
ui.Interface.frontCall("standard", "feInfo", [name], [result])
```

1. **name** - The name of the property.
2. **result** - Holds the value of the property.

### Usage

The `feInfo` front call returns a front-end property value according to the property name passed in as the parameter.

Some `feInfo` options take an optional parameter, such as `screenResolution`:

```javascript
CALL ui.Interface.frontCall("standard", "feInfo", ["screenResolution", 2], [resolution])
```

| deviceId      | • With Genero Mobile for iOS, returns the identifierForVendor.  
• With Genero Mobile for Android, returns this IMEI, otherwise the Android id (but may change after device reinstallation) | Yes | No | Yes | Yes |
| feName        | The code identifying the type of front-end component.  
The possible values returned are:  
• "Genero Desktop Client" for Genero Desktop Client.  
• "GBC" for Genero Web Client - JavaScript (GWC-JS).  
• "GWC" for Genero Web Client - HTML5 theme.  
• "GMA" for Genero Mobile for Android.  
• "GMI" for Genero Mobile for iOS. | Yes | Yes | Yes | Yes |
| fePath        | The installation directory of the front-end executable.  
• With Genero Desktop Client, it returns the path to the installation directory of the GDC.  
• When Genero Web Client, it returns the path to the installation directory of the GAS.  
• With Genero Mobile for Android, it returns the installation directory. For example, "/data/data/com.fourjs.gma/fgl".  
• With Genero Mobile for iOS, it returns the installation directory. For example: "/private/var/mobile/Applications/B3E6-C48A-ED4EFA". Below the installation directory are the "Documents" (which is by default pwd), "GMI.app" (deployed p-code resides in GMI.app/app/) and "tmp" directories.  
**Important:** The installation path returned by this front call may change in future versions, do not based application code on this. On mobile devices, consider using the os.Path.pwd on page 2012 utility function to get the application working directory when executing programs. | Yes | No | Yes | Yes |
<p>| freeStorageSpace | Returns the number of bytes available on the device. | Yes | No | Yes | Yes |</p>
<table>
<thead>
<tr>
<th>Property name</th>
<th>Description</th>
<th>GDC</th>
<th>GWC-JS</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
</table>
| iccid         | • With Genero Mobile for iOS, returns an error (not allowed).  
               • With Genero Mobile for Android, returns the ICCID if available, otherwise raise an error. | N/A | N/A | Yes | Yes |
| imei          | • With Genero Mobile for iOS, returns an error (not allowed).  
               • With Genero Mobile for Android, returns the IMEI if available, otherwise raises an error. | N/A | N/A | Yes | Yes |
| ip            | Returns the IP address of the network interface used for the GUI connection.  
               For mobile platforms, this is the preferred IP address of the device: if there is WIFI, either the IPv4 address is given back (for example: 192.168.0.12) or if there is no IPv4 address, the IPv6 address is given back (for example: 2a02:810a:82c0:478:d462:e334:6a1d:fb78).  
               If there is no WIFI, either the cellular IPv4 or IPv6 address is given back. If there is no network, NULL is returned. | Yes | No | Yes | Yes |
| isActiveX     | Returns "1" if the front-end runs in Active X mode (GDC specific).  
               For Genero Mobile clients, the return value will always be "0" | Yes | No | Yes | Yes |
| numScreens    | Number of screens available on the front-end platform.  
               On typical front-end platforms and devices, the number of screens is 1. In some rare cases, a desktop computer can be configured with more than one screen. | Yes | No | No | No |
| osType        | The operating system type where the front-end is running.  
               Possible return values include "WINDOWS", "LINUX", "OSX", "ANDROID", "IOS". | Yes | Yes | Yes | Yes |
| osVersion     | The version of the operating system.  
               Example of returned values: "4.3", "5.10.15". | Yes | No | Yes | Yes |
| outputMap     | Returns the GWC application output map of the current application. This option is only supported with a GAS >= 2.22.00.  
               Example of returned value: "DUA_HTML5", ... | No | No | No | No |
<p>| ppi           | Returns the screen pixel density of the front-end platform (Pixels Per Inch). This front call takes an | Yes | No | Yes | Yes |</p>
<table>
<thead>
<tr>
<th>Property name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>optional screen number as parameter (1 is the default).</td>
<td>Returns the screen resolution of the front-end platform. This front call takes an optional screen number as parameter (1 is the default). Example of returned values: &quot;1200x1824&quot;, &quot;1920x1104&quot;. Note: For mobile devices, the value can change depending on the device orientation.</td>
</tr>
<tr>
<td>Returns the build platform target code name, identifying the operating system the front-end binary was compiled. This front call is provided for debugging purpose, do not base code on the returned value, it can change if the target OS version is upgraded for example. Use the osType property instead. Example of returned values:</td>
<td>Yes</td>
</tr>
<tr>
<td>Returns the current size of the front-end view-port.</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Example of returned values: "1200x1824", "1920x1104".
**getEnv**
Returns an environment variable set in the user session on the front end platform.

**Syntax**
```
ui.Interface.frontCall("standard", "getEnv", [name], [value])
```

1. *name* - The name of the environment variable.
2. *value* - Holds the value of the environment variable.

**Usage**
The "getEnv" front call returns an environment variable set in the user session on the front-end platform.

**getWindowId**
Returns the local window manager identifier of the window corresponding to the AUI window id passed as parameter.

**Syntax**
```
ui.Interface.frontCall("standard", "getWindowId", [aui-win-id], [loc-win-id])
```

1. *aui-win-id* - The id of the window node in the AUI tree.
2. *loc-win-id* - The id of the window in the window manager where the front-end is running.

**Usage**
Returns the local identifier that corresponds to the AUI window id passed as parameter, in the window manager where the front-end is displaying the application forms.

The node id must reference a Window node, otherwise "0" is returned; in traditional mode, window widgets are simple frames; Use "0" as aui-win-id parameter to get the top level window id in the local windowing system.

**hardCopy**
Prints a screen shot of the current window.

**Syntax**
```
ui.Interface.frontCall("standard", "hardCopy", [pgsize], [result])
```

1. *pgsize* - Pass "1" to adapt the screen shot to the page size.
2. *result* - Holds the execution result (TRUE=success, FALSE=error).

**Usage**
The "hardCopy" front call allows you to print a screen shot of the current window.

The *pgsize* parameter is optional; Either leave out, or enter "1" to indicate that the screen shot must be adapted to the page size.
launchURL
Opens an URL with the default URL handler of the front-end.

Syntax

```
ui.Interface.frontCall("standard", "launchURL",
   [ url 1, mode 1 ], [] )
```

1. `url` - The URL to invoke.
2. `mode` (optional) - front-end specific meaning (see below).

Usage (General)

The "launchURL" front call opens an URL with the default URL handler available on the front-end platform; This is typically the web browser for "HTTP:" URLs, or the mailer for "mailto:" URLs, but the corresponding application may also be dedicated to the type of object specified by the URL (for example, a mapping service or to initiate a phone call).

This front call is a powerful feature: Front-end applications can register themselves as URL handlers, so you can start applications on the front-end through the launchURL front call.

Supported schemes depend on your system configuration.

**Important:** Some type of URLs are not supported by all front-end platforms. Make sure that you test all target front-ends when using a launchURL front call.

The `mode` parameter is optional and is interpreted differently according to the front-end type:

- With Genero Web Client (GWC), use "replace" for the `mode` parameter, if you want the current application in the browser window or tab to be replaced with the new URL, instead of launching a new browser window or tab. If it is not present, or if a value other than "replace" is specified, the Genero Web Client behaves like the Genero Desktop Client, opening the URL in a new browser window.
- With Genero Mobile and Genero Desktop Client (GDC) front-ends, the `mode` parameter is ignored if specified.

**Example**

To invoke Google Play Store:

```
CALL ui.Interface.frontCall("standard", "launchURL",
   ["market://details?id=com.google.android.apps.currents"], [] )
```

To open Google Maps:

```
CALL ui.Interface.frontCall("standard", "launchURL",
   ["geo:48.613363,7.711083?z=17"], [] )
```

To open Google Street View:

```
CALL ui.Interface.frontCall("standard", "launchURL",
   ["google.streetview:cbll=48.613363,7.711083&cbp=1,0,,0,1.0&mz=17"], [] )
```
To initiate a phone call:

```javascript
CALL ui.Interface.frontCall("standard", "launchURL", ["tel:+336717623"], [])
```

**mdClose**

Unloads a DLL or shared library front call module.

**Syntax**

```javascript
ui.Interface.frontCall("standard", "mdClose", [name], [result])
```

1. **name** - The name of the module to be closed.
2. **result** - Holds the result (0 = success, -1 = module not found, -2 = cannot unload (busy)).

**Usage**

Front call modules are loaded on demand. After calling a function of a specific module, you can use the "mdClose" front call to unload the shared library and save resources.

**openDir**

Displays a file dialog window to get a directory path on the local file system.

**Syntax**

```javascript
ui.Interface.frontCall("standard", "openDir", [path, caption], [result])
```

1. **path** - The default path.
2. **caption** - The caption to be displayed.
3. **result** - Holds the name of the selected directory (or NULL if canceled).

**Usage**

When invoking the "openDir" front call, the front-end displays the typical file dialog window on the local file system, to let the end user enter a directory path.

If the user cancels the dialog, the front call returns NULL in the result variable.

**openFile**

Displays a file dialog window to get a path to open a file on the local file system.

**Syntax**

```javascript
ui.Interface.frontCall("standard", "openFile", [path, name, wildcards, caption], [result])
```

1. **path** - The default path.
2. **name** - The name to be displayed for the file type.
3. **wildcards** - A blank separated list of wildcards (for ex: ".pdf" or "README* test*.txt")
4. **caption** - The caption to be displayed.
5. **result** - Holds the name of the selected file (or NULL if canceled).

**Usage**

When invoking the "openFile" front call, the front-end displays a file dialog window using the local file system, to let the end user enter a file path, to select an existing file.
If the user cancels the dialog, the front call returns NULL in the result variable.

**Note:** With the GWS-JS front-end, the *path* parameter is ignored, and *wildcards* can only be hold one type of file extension.

**playSound**
Plays the sound file passed as parameter on the front-end platform.

**Syntax**

```javascript
ui.Interface.frontCall("standard", "playSound",
    [filename], [])
```

1. *filename* - The sound file to play.

**Usage**
The "playSound" front call opens the sound file passed as parameter and plays the sound on the front-end.

If the file is not located on the front-end, it will automatically be transferred to the front-end through the file-transfer facility.

Supported sound file format depends on the front-end infrastructure (platform, technology, web browser, ...)

**Example**

```javascript
CALL ui.Interface.frontCall("standard", "playSound",
    ["/opt/var/sounds/beep.mp3"], []);
```

**saveFile**
Displays a file dialog window to get a path to save a file on the local file system.

**Syntax**

```javascript
ui.Interface.frontCall("standard", "saveFile",
    [path, name, filetype, caption],
    [result])
```

1. *path* - The default path.
2. *name* - The name to be displayed for the file type.
3. *filetype* - The file types (as a blank separated list of extensions).
4. *caption* - The caption to be displayed.
5. *result* - Holds the name of the selected file (or NULL if canceled).

**Usage**
When invoking the "saveFile" front call, the front-end displays the typical file dialog window on the local file system, to let the end user enter a file path, to save data to a new file.

If the user cancels the dialog, the front call returns NULL in the result variable.

**setReportFont**
Override the font used for report generation for the current application.

**Syntax**

```javascript
ui.Interface.frontCall("standard", "setReportFont",
    [font], [result])
```
1. **font** - A string describing the font to use for report generation (see Usage for details).

2. **result** - Holds the execution result (TRUE = success, FALSE = error).

**Usage**
The "setReportFont" front call allows you to override the font used for report generation for the current application. You can simply copy/paste the font string from the "Report To Printer" font panel from GDC Monitor. An empty or null string reset to the default behavior.

The **font** parameter is a string that describe the font to use for report generation. For example: "Helvetica, Bold, Italic, 13". Alternatively, you can specify "<ASK_ONCE>" , "<ASK_ALWAYS>" , "<USER_DEFINED>" or "<USE_DEFAULT>" which will perform the corresponding actions.

**setReportPrinter**
Override the printer configuration used for report generation for the current application.

**Syntax**

```
ui.Interface.frontCall("standard", "setReportPrinter", [printer], [result])
```

1. **printer** - A string describing the printer to use for report generation (see Usage for details).

2. **result** - Holds the execution result (TRUE = success, FALSE = error).

**Usage**
The "setReportPrinter" front call allows you to override the printer configuration used for report generation for the current application. You can simply copy/paste the printer string from the "Report To Printer" printer panel from GDC Monitor. An empty or null string reset to the default behavior.

The **printer** parameter is a string that describe the printer to use for report generation. For example: "moliere, Portrait, A4, 96 dpi, 1 copy, Ascendent, Color, Auto". Alternatively, you can specify "<ASK_ONCE>" , "<ASK_ALWAYS>" , "<USER_DEFINED>" or "<USE_DEFAULT>" which will perform the corresponding actions.

**setWebComponentPath**
Defines the base path where web components are located.

**Syntax**

```
ui.Interface.frontCall("standard", "setWebComponentPath", [path], [])
```

1. **path** - The base url. For example, "http://myserver/components" or "file:///c:/components".

**Usage**
This front call defines the base path to find gICAPI web components files.

For the Genero Desktop Client, it defines the base path where web components are located, when GDC is directly connected to the runtime system. This is ignored when GDC is connected to the GAS.

For Genero Mobile, it sets the main web component lookup path. An URI is expected. For example, "file:///data/data/com.fourjs.gma/cache/appdata/mywebcomponents" or "http://mygas/mywebcomponents/".
shellExec
Opens a file on the front-end platform with the program associated to the file extension.

Syntax

```javascript
ui.Interface.frontCall("standard", "shellExec",
    [document, action], [result])
```

1. **document** - The document file to be opened.
2. **action** - (optional, Windows™ Only!) The action to perform, related to the way the file type is registered in Windows™ Registry.
3. **result** - Holds the execution result (TRUE=success, FALSE=error).

Usage
The "shellExec" front call opens a file on the front-end platform with the program associated to the file extension.

This front call is mainly designed for the Genero Desktop Client on Windows™ platforms.

**Important:** Under X11 Systems, this uses xdg-open, which needs to be installed and configured on your system. Kfmclient will be used as a workaround when xdg-open is not available.

**Tip:** In order to view a document (like a PDF for example), if that document can be displayed by web browsers, use the launchURL on page 1904 front call instead, especially if you want to use both the Genero Desktop Client (GDC) and the Genero Web Client (GWC) front-ends.

Webcomponent front calls
This section describes Webcomponent specific front calls.

This table shows the functions provided by the "webcomponent" module on the front-ends supporting web components.

**Table 434: Webcomponent module front-end functions**

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ui.Interface.frontCall(&quot;webcomponent&quot;, &quot;call&quot;, [aui-name, function-name, _param1, param2, ...], [result])</code></td>
<td>Calls a JavaScript function through the web component.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;webcomponent&quot;, &quot;frontCallAPIVersion&quot;, []),[result])</code></td>
<td>Returns the API version of web component front-end calls.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;webcomponent&quot;, &quot;getTitle&quot;, [aui-name], [result])</code></td>
<td>Returns the title of the HTML doc rendered by a web component.</td>
</tr>
</tbody>
</table>

**call**
Calls a JavaScript function through the web component.

Syntax

```javascript
ui.Interface.frontCall("webcomponent", "call",
```
1. **aui-name** - This is the name of the web component name in the AUI tree.
2. **function-name** - This is the name of the web component JavaScript function to be called.
3. **param1, param2, ...** - Optional parameters to be passed to the web component JavaScript function.
4. **result** - Holds the JavaScript function return value.

**Usage**

Calls a JavaScript function through the web component. The JavaScript function must be implemented in the HTML content pointed by the URL-based web component, or in the user-defined JavaScript of a gICAPI-based web component.

The **aui-name** and **function-name** arguments are mandatory.

The arguments following the **function-name** argument will be passed to the JavaScript function.

That the **result** variable will contain the value returned by the JavaScript function.

**Example**

```
DEFINE result STRING
CALL ui.Interface.frontCall("webcomponent","call",
["formonly.data","echoString","abcdef"],[result])
```

For a complete example, see Example 2: Calling a JavaScript function of a gICAPI web component on page 1435.

**frontCallAPIVersion**

Returns the API version of web component front-end calls.

**Syntax**

```
ui.Interface.frontCall("webcomponent","frontCallAPIVersion",
[],[result])
```

1. **result** - Holds the API version for web component front calls.

**Usage**

This front call can be used to check the API version for the web component front calls.

If the API version changes, you must adapt the code to the expected front call API implemented for the web components.

The value returned by this front call is a typically version number such as 1.0, 1.1, etc.

**Example**

```
FUNCTION wc_api_version()
    DEFINE vers STRING
    TRY
        CALL
        ui.Interface.frontCall("webcomponent","frontCallAPIVersion",[],
        [vers])
        -- we can safely call "webcomponent" "call" in the code
        RETURN vers
    CATCH
        -- we can't call the "webcomponent" functions...
```
getTitle
Returns the title of the HTML doc rendered by a web component.

Syntax

```javascript
ui.Interface.frontCall("webcomponent", "getTitle", [aui-name], [result])
```

1. `aui-name` - This is the name of the web component name in the AUI tree.
2. `result` - Holds the title of the HTML document.

Usage

This front call can be used to get the title of the HTML document that is rendered by the web component identified by the `aui-name`. For more details refer to http://www.w3schools.com/tags/tag_title.asp.

A typical usage of this front call is when implementing a web component based on the O-Auth mechanism to identify the current user: For example, with the Google accounts authentication service, after the login and password were validated by Google, the authentication token will be returned in the title of the HTML document. This token is typically used by the application to identify the user in distant API calls.

Genero Desktop Client front calls

This section describes GDC specific front calls.

The GDC front-end implements the following front call modules:

- Windows DDE Support on page 1910
- Windows COM Support on page 1916
- Windows Mail extension on page 1923

  **Important**: These front call modules are only available on Windows™ platforms.

Windows™ DDE Support

Description of Windows™ DDE support.

  **Important**: The Win DDE front call library is deprecated.

Dynamic Data Exchange (DDE) is a form of inter-process communication implemented by Microsoft™ for Windows™ platforms. DDE uses shared memory to exchange data between applications. Applications can use DDE for one-time data transfers and for ongoing exchanges in applications that send updates to one another as new data becomes available.

Please refer to your Microsoft™ documentation for DDE compatibility between existing versions. As an example, DDE commands were changed between Office 97 and Office 98.

We provide a DDE interface as a Front-End Extension: WinDDE.DLL

- Using the WinDDE API on page 1911
- The DDE API function list on page 1911
- WinDDE example on page 1915
Using the WinDDE API
With WinDDE Support, you can invoke a Windows™ application and send or receive data to or from it. To use this functionality, the program must use the Windows™ Front End.

Before using the DDE functions, the TCP communication channel between the application and the front end must be established with a display (OPEN WINDOW, MENU, DISPLAY TO).

Figure 104: The four-part procedure of the DDE API

The DDE API is used in a four-part procedure, as described in the following steps:

1. The application sends to the Front End the DDE order using the TCP/IP channel.
2. The Front End executes the DDE order and sends the data to the Windows™ application through the DDE API.
3. The Windows™ application executes the command and sends the result, which can be data or an error code, to the Front End.
4. The Windows™ Front End sends back the result to the application using the TCP/IP channel.

A DDE connection is uniquely identified by two values: The name of the DDE Application and the document. Most DDE functions require these two values to identify the DDE source or target.

The DDE API function list
The DDE API is based on the front call technique.

The DDE API is based on the front call technology. All DDE functions are grouped in the WINDDE front end function module.

Table 435: Windows DDE front-end functions

<table>
<thead>
<tr>
<th>Function name</th>

<tr>
<td>CALL</td>
<td>DDEPoke sends data to the specified program and document using the DDE channel.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;WINDE&quot;, &quot;DDEPoke&quot;, [ program, container, cells, values, encoding ], [result])</td>
<td></td>
</tr>
</tbody>
</table>

**DDEConnect**
DDEConnect opens a DDE connection.

**Syntax**

```
CALL ui.Interface.frontCall("WINDE", "DDEConnect", [ program, document, encoding ], [result])
```

- **program** is the name of the DDE application.
- **document** is the document that is to be opened.
- **encoding** is an optional parameter. It allows to force the encoding to use between ASCII and wide char/unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are:
  - UNICODE
  - ASCII
- **result** is an integer variable receiving the status.
- **result** is TRUE if the function succeeded, FALSE otherwise.
- If the function failed, use **DDEError** to get the description of the error.
**Warnings**

- If the function failed with DMLERR_NO_CONV_ESTABLISHED, then the DDE application was probably not running. Use the execute or shellexec front call to start the DDE application.
- In Microsoft™ Office 2010, the use of DDE is disabled by default. You need to uncheck **Ignore other applications that use Dynamic Data Exchange(DDE)** in advanced options, otherwise DDEConnect will fail.

**DDEExecute**

**DDEExecute** executes a DDE command.

**Syntax**

```
CALL ui.Interface.frontCall("WINDDE","DDEExecute",
[ program, document, command, encoding ], [result] )
```

- `program` is the name of the DDE application.
- `document` is the document that is to be used.
- `command` is the command that needs to be executed.
- `encoding` is an optional parameter. It allows to force the encoding to use between ASCII and wide char/unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are: "UNICODE", "ASCII"
- Refer to the `program` documentation to know the syntax of `command`.
- `result` is an integer variable receiving the status.
- `result` is TRUE if the function succeeded, FALSE otherwise.
- If the function failed, use **DDEError** to get the description of the error.

**Warnings**

- The DDE connection must be opened see **DDEConnect**.

**DDEFinish**

**DDEFinish** closes a DDE connection.

**Syntax**

```
CALL ui.Interface.frontCall("WINDDE","DDEFinish",
[ program, document ], [result] )
```

- `program` is the name of the DDE application.
- `document` is the document that is to be closed.
- `result` is an integer variable receiving the status.
- `result` is TRUE if the function succeeded, FALSE otherwise.
- If the function failed, use **DDEError** to get the description of the error.

**Warnings**

- The DDE connection must be opened, see **DDEConnect**.

**DDEFinishAll**

**DDEFinishAll** closes all DDE connections.

**Syntax**

```
CALL ui.Interface.frontCall("WINDDE","DDEFinishAll",
[ ], [result] )
```
• result is TRUE if the function succeeded, FALSE otherwise.

Usage
This function closes all DDE connections, as well as the DDE server program.

DDEError
DDEError returns error information about the last DDE operation.

Syntax
CALL ui.Interface.frontCall("WINDDE","DDEError", [], [errmsg ] )

• errmsg is the error message. It is set to NULL if no error occurred.

DDEPeek
DDEPeek retrieves data from the specified program and document using the DDE channel.

Syntax
CALL ui.Interface.frontCall("WINDDE","DDEPeek", [ program, container, cells, encoding ], [ result, value ] )

• program is the name of the DDE application.
• container is the document or sub-document that is to be used. A sub-document can, for example, be a sheet in Microsoft™ Excel.
• cells represents the working items; see the program documentation to know the format of cells.
• encoding is an optional parameter. It allows to force the encoding to use between ASCII and wide char/unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are: "UNICODE", "ASCII"
• value represents the data to be retrieved; see the program documentation to know the format of values.
• result is an integer variable receiving the status.
• result is TRUE if the function succeeded, FALSE otherwise.
• If the function failed, use DDEError to get the description of the error.
• value is a variable receiving the cells values.

Warnings
• The DDE connection must be opened; see DDEConnect.
• DDEError can only be called once to check if an error occurred.

DDEPoke
DDEPoke sends data to the specified program and document using the DDE channel.

Syntax
CALL ui.Interface.frontCall("WINDDE","DDEPoke", [ program, container, cells, values, encoding ], [ result ] )

• program is the name of the DDE application.
• container is the document or sub-document that is to be used. A sub-document can, for example, be a sheet in Microsoft™ Excel.
• cells represents the working items; see the program documentation to know the format of cells.
• values represents the data to be sent; see the program documentation to know the format of values.
• *encoding* is an optional parameter. It allows to force the encoding to use between ASCII and wide char/unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are: "UNICODE", "ASCII"

• *result* is an integer variable receiving the status.

• *result* is TRUE if the function succeeded, FALSE otherwise.

• If the function failed, use **DDEError** to get the description of the error.

**Warnings**

• The DDE connection must be opened; see **DDEConnect**.

• An error may occur if you try to set many (thousands of) cells in a single operation.

**WinDDE example**

This section provides a WinDDE example.

Windows™ COM Support

"COM" stands for Component Object Model. It allows anyone to directly access Windows™ Applications Objects. You can create instances of those objects, call methods on them, and get or set their properties.

**Important**: The WinCOM front call library is deprecated.

- Using the WinCOM API on page 1916
- The WinCOM API function list on page 1916
- WinCOM examples on page 1919

Using the WinCOM API

With WinCOM Support, you can invoke a Windows™ application and send or receive data to or from it.

To use this functionality, the program must use the Windows™ Front End.

The WinCOM API function list

The WinCOM API is based on the front call technique as described in Front End Functions. All WinCOM functions are grouped in the WinCOM front end function module.

Table 436: Windows COM front-end functions

<table>
<thead>
<tr>
<th>Function name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL <code>ui.Interface.frontCall(&quot;WinCOM&quot;,&quot;CreateInstance&quot;, [ program ], [ handle] )</code></td>
<td>The <code>CreateInstance</code> function creates an instance of a registered COM object.</td>
</tr>
<tr>
<td>CALL <code>ui.Interface.frontCall(&quot;WINCOM&quot;,&quot;CallMethod&quot;, [ handle, method, arg1, ... ], [result] )</code></td>
<td>The <code>CallMethod</code> function calls a method on a specified object.</td>
</tr>
<tr>
<td>CALL <code>ui.Interface.frontCall(&quot;WINCOM&quot;,&quot;CallMethod&quot;, [ handle, method(arg1, ...) ], [result] )</code></td>
<td></td>
</tr>
<tr>
<td>CALL <code>ui.Interface.frontCall(&quot;WINCOM&quot;,&quot;GetProperty&quot;, [ handle, member ], [result] )</code></td>
<td>The <code>GetProperty</code> function gets a property of an object.</td>
</tr>
<tr>
<td>CALL <code>ui.Interface.frontCall(&quot;WINCOM&quot;,&quot;SetProperty&quot;, [ handle, member ], [result] )</code></td>
<td>The <code>SetProperty</code> function sets a property of an object.</td>
</tr>
</tbody>
</table>
### Function name

<table>
<thead>
<tr>
<th>Function name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[handle, member, value], [result]</td>
<td>Returns a description of the last error which occurred.</td>
</tr>
</tbody>
</table>

**CALL**

```
ui.Interface.frontCall("WINCOM","GetError", [], [result])
```

The GetError function gets a description of the last error which occurred.

**CALL**

```
ui.Interface.frontCall("WINCOM","ReleaseInstance", [handle], [result])
```

The ReleaseInstance function releases an Instance of a COM object.

---

**Supported syntax**

COM language syntax is very flexible and allows lots of notation. Genero WinCOM API is slightly more strict:

- **:= notation is allowed** in version 2.00.1e (or later) only; for instance: `myFunction(SourceType:=3)`
- **"no parenthesis" notation is not allowed**; for instance: `myFunction 3` must be `myFunction(3)`
- Numeric constants **are allowed** in version 2.00.1e (or later) only. The constant list depends on the application used via WinCOM, therefore the list is configurable: a file named etc/WinCOM.cst gathers all the constants provided today by Microsoft™ for Office XP. It can be modified to add user-defined constants. Example with Word:

```
```

Here, "9999998" stands for the constant `wdToggle` (see etc/WinCOM.cst).

- There is no way to handle an array as a method argument. This is also due to BDL limitation: you can't pass BDL Arrays to frontcalls.

---

**CreateInstance**

The CreateInstance function creates an instance of a registered COM object.

**Syntax**

```
CALL ui.Interface.frontCall("WinCOM","CreateInstance", [ program ], [handle])
```

- **program** is the classname of the registered COM object.
- **handle** is an integer variable receiving the status.
- **handle** is -1 if there as an error, otherwise an integer value that can be used for a later call to the API.
- If the function failed, use GetError to get the description of the error.

**CallMethod**

The CallMethod function calls a method on a specified object.

**Syntax**

```
CALL ui.Interface.frontCall("WINCOM","CallMethod", [ handle, method, arg1, ... ], [result])
```

OR

```
CALL ui.Interface.frontCall("WINCOM","CallMethod", [ handle, method(arg1, ...) ], [result])
```
• **handle** is the handle returned by another front call (CreateInstance, CallMethod, GetProperty).
• **method** is the member name to call.
• **arg1 (and ...)** are the arguments to pass to the method call. Depending on the syntax allowed by the version of the program you're interacting with, arguments might be used inside brackets or outside. The best way for Microsoft™ applications (such as Excel or Word) is to initially test your code with a macro of the manipulation you're expecting to do. According to the method which is used, arguments may or may not be optional.
• **result** is either a handle or a value of a predefined type.
• **result** is -1 in case of error (use GetLastError to get the description of the error).

GetProperty
The GetProperty function gets a property of an object.

**Syntax**

```plaintext
CALL ui.Interface.frontCall("WINCOM","GetProperty",
[ handle, member ], [result])
```

• **handle** is the handle returned by another front call (CreateInstance, CallMethod, GetProperty).
• **member** is the member property name to get.
• **result** is either a handle or a value of a predefined type.
• **result** is -1 in case of error (use GetLastError to get the description of the error).

SetProperty
The SetProperty function sets a property of an object.

**Syntax**

```plaintext
CALL ui.Interface.frontCall("WINCOM","SetProperty",
[handle, member, value], [result])
```

• **handle** is the handle returned by another front call (CreateInstance, CallMethod, GetProperty).
• **member** is the member property name to set.
• **value** is the value to which the property will be set.
• **result** is -1 in case of error (use GetLastError to get the description of the error), otherwise it is 0.

GetError
The GetError function gets a description of the last error which occurred.

**Syntax**

```plaintext
CALL ui.Interface.frontCall("WINCOM","GetError",
[], [result])
```

• **result** is the description of the last error.
• the returned value is NULL if there was no error.

ReleaseInstance
The ReleaseInstance function releases an Instance of a COM object.

**Syntax**

```plaintext
CALL ui.Interface.frontCall("WINCOM","ReleaseInstance",
[handle], [result])
```

• **handle** is the handle returned by another front call (CreateInstance, CallMethod, GetProperty).
• *result* is -1 in case of error (use *GetError* to get the description of the error), otherwise it is 0.

**WinCOM examples**

Various WinCOM examples.

• *Wincom and Excel example* on page 1919
• *Wincom and Word example* on page 1920
• *Wincom and Outlook example* on page 1921
• *Wincom and Internet Explorer example* on page 1922

**Wincom and Excel example**

This section provides a Wincom and Excel example.

This example puts “foo” in the first row of the 1st column of an Excel Sheet.

Windows™ Mail extension
Description of the Windows™ Mail extension.

Important: The WinMAIL front call library is deprecated. If used, the GDC executable format must match the WinAPI executable format: The 32-bit WinAPI can only be used with a 32-bit GDC.

Send mail using MAPI

MAPI is an acronym for Messaging Application Programming Interface. The MAPI extension will create a new mail in the default mailer software, which needs to be "MAPI" compatible, and ask the user to send the mail. The mail sent using MAPI will be stored by the default mailer software in the same way as any other mail created by the user.

Send mail using an SMTP server

Another method of sending mail is to connect directly to an SMTP server (Simple Mail Transfer Protocol is the de facto standard for email transmission across the Internet). The extension will connect to a given SMTP server and send the mail through this server. The mail is not kept on the client side.

• The WinMail API on page 1924
The WinMail API

The WinMail API is based on the front call technique as described in Front End Functions. All WinMail functions are grouped in the WinMail front end function module.

**Table 437: WinMail front-end functions: General**

<table>

</tr>
<tr>
<td></td>
<td><code>ui.Interface.frontCall(&quot;WinMail&quot;,&quot;AddAttachment&quot;, [id,fileName],[result])</code></td>
</tr>
<tr>
<td>CALL</td>
<td>The <code>SendMailSMTP</code> function sends the mail with the SMTP protocol.</td>
</tr>
<tr>
<td></td>
<td><code>ui.Interface.frontCall(&quot;WinMail&quot;,&quot;SendMailSMTP&quot;)</code></td>
</tr>
</tbody>
</table>
The following functions are needed when you use SMTP server connections:

Table 438: WinMail front-end functions: SMTP-specific

<table>
<thead>
<tr>
<th>Function name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL ui.Interface.frontCall(&quot;WinMail&quot;,&quot;SendMailMAPI&quot;, [ id ], [ result ] )</td>
<td>The <code>SendMailMAPI</code> function sends the mail with the MAPI protocol.</td>
</tr>
<tr>
<td>CALL ui.Interface.frontCall(&quot;WinMail&quot;,&quot;GetError&quot;, [ id ], [ result ] )</td>
<td>The <code>GetError</code> function gets a description of the last error that occurred.</td>
</tr>
</tbody>
</table>

The Init function initializes the module.

Syntax

```
CALL ui.Interface.frontCall("WinMail","Init", [], [id ] )
```

- `ret` is the identifier of the message initialized.
- For each Init function, a Close must be called.

Usage

This function initializes the module. It returns the identifier for the message, which will be used in other functions.

Close

The Close function clears all information corresponding to a message, and frees the memory occupied by the message.

Syntax

```
CALL ui.Interface.frontCall("WinMail","Close", [id], [ result ] )
```

- `id` is the message identifier.
SetBody
The SetBody function sets the body of the mail.

Syntax
CALL ui.Interface.frontCall("WinMail", "SetBody", [id, body], [result])

- id is the message identifier.
- body is the string text containing the body of the mail.
- result is the status of the function.

SetSubject
The SetSubject function sets the subject of the mail.

Syntax
CALL ui.Interface.frontCall("WinMail", "SetSubject", [id, subject], [result])

- id is the message identifier.
- subject is the string text containing the subject of the mail.
- result is the status of the function.

AddTo
The AddTo function adds a "To" addressee to the mail.

Syntax
CALL ui.Interface.frontCall("WinMail", "AddTo", [id, name, address], [result])

- id is the message identifier.
- name is the name to be displayed in the mail.
- address is the mail address to be used for this addressee.
- result is the status of the function.

Usage
This function adds a "To" Addressee to the mail. The Addressee has a name and a mail address.

AddCC
The AddCC function adds a "CC" addressee to the mail.

Syntax
CALL ui.Interface.frontCall("WinMail", "AddCC", [id, name, address], [result])

- id is the message identifier.
- name is the name to be displayed in the mail.
- address is the mail address to be used for this addressee.
- result is the status of the function.
Usage
This function adds a “CC” Addressee to the mail. The Addressee has a name and a mail address.

AddBCC
The AddBCC function adds a “BCC” addressee to the mail.

Syntax
CALL ui.Interface.frontCall("WinMail", "AddBCC", [ id, name, address ], [ result ] )

- \texttt{id} is the message identifier.
- \texttt{name} is the name to be displayed in the mail.
- \texttt{address} is the mail address to be used for this addressee.
- \texttt{result} is the status of the function.

Usage
This function adds a “BCC” Addressee to the mail. The Addressee has a name and a mail address.

AddAttachment
The AddAttachment function adds a file as an attachment to the mail.

Syntax
CALL ui.Interface.frontCall("WinMail", "AddAttachment", [ id, fileName ], [ result ] )

- \texttt{id} is the message identifier.
- \texttt{fileName} is the path of the attachment; the path can be relative to the directory from which GDC is run, or absolute.
- \texttt{result} is the status of the function.

Usage
This function adds a file as an attachment to the mail. The file must be located on the front-end.

SendMailSMTP
The SendMailSMTP function sends the mail with the SMTP protocol.

Syntax
CALL ui.Interface.frontCall("WinMail", "SendMailSMTP", [ id ], [ result ] )

- \texttt{id} is the message identifier.
- \texttt{result} is TRUE in case of success; use \texttt{GetError} to get the description of the error when needed.

Usage
This function sends the mail by using the SMTP protocol. default mailer software is called to create the mail. The user must press the "send" button to send the mail.

SendMailMAPI
The `SendMailMAPI` function sends the mail with the MAPI protocol.

**Syntax**

```
CALL ui.Interface.frontCall("WinMail","SendMailMAPI",
    [ id ], [ result ] )
```

- `id` is the message identifier.
- `result` is TRUE in case of success; use `GetError` to get the description of the error when needed.

**Important:**
- MAPI needs to log in to the mailer software. The first login could take time, depending on the mailer software. Your Genero application will be blocked until MAPI returns.
- MAPI depends on the mailer software for error management. For instance, Mozilla Thunderbird returns "success" when the mail is created, but Outlook 2002 only returns "success" when the mail is sent.

**Usage**

This function sends the mail by using the MAPI protocol. With MAPI, the default mailer software is called to create the mail. The user must press the "send" button to send the mail.

**GetError**

The `GetError` function gets a description of the last error that occurred.

**Syntax**

```
CALL ui.Interface.frontCall("WinMail","GetError",
    [ id ], [ result ] )
```

- `id` is the message identifier.
- `result` is the description of the last error.
- the returned value is NULL if there was no error.

**SetSmtp**

The `SetSmtp` function sets the SMTP server to be used.

**Syntax**

```
CALL ui.Interface.frontCall("WinMail","SetSmtp",
    [ id, smtp:port ], [ result ] )
```

- `id` is the message identifier.
- `smtp` is the string text containing the SMTP server to be used.
- `port` is optional. It allows to specify a port for your SMTP server. When not specified, the default port remains 25.
- `result` is the status of the function.

**SetFrom**

The `SetFrom` function sets sender information.

**Syntax**

```
CALL ui.Interface.frontCall("WinMail","SetFrom",
    [ id, name, address ], [ result ] )
```

- `id` is the message identifier.
• *name* is the name to be displayed in the mail.
• *address* is the mail address to be used for this addressee.
• *result* is the status of the function.

WinMail examples
Various WinMail examples.

- Mail using MAPI on page 1929
- Mail using SMTP server on page 1929

Mail using MAPI
This topic provides an example of sending mail using MAPI.

```
MAIN
  DEFINE result, id INTEGER
  DEFINE str STRING
  -- first, we initialize the module
  CALL ui.Interface.frontCall("WinMail", "Init", [], [id])

  -- Set the body of the mail
  CALL ui.Interface.frontCall("WinMail", "SetBody", [id, "This is a text mail using WinMail API - MAPI"], [result])

  -- Set the subject of the mail
  CALL ui.Interface.frontCall("WinMail", "SetSubject", [id, "test mail - ignore it"], [result])

  -- Add an Addressee as "TO"
  CALL ui.Interface.frontCall("WinMail", "AddTo", [id, "myBoss", "boss@mycompany.com"], [result])

  -- Add another Addressee as "BCC"
  CALL ui.Interface.frontCall("WinMail", "AddBCC", [id, "my friend", "friend@mycompany.com"], [result])

  -- Add Two attachments
  CALL ui.Interface.frontCall("WinMail", "AddAttachment", [id, "c:\mydocs\report.doc"], [result])
  CALL ui.Interface.frontCall("WinMail", "AddAttachment", [id, "c:\mydocs\demo.png"], [result])

  -- Send the mail via the default mailer
  CALL ui.Interface.frontCall("WinMail", "SendMailMAPI", [id], [result])
  IF result == TRUE THEN
    DISPLAY "Message sent successfully"
  ELSE
    CALL ui.Interface.frontCall("WinMail", "GetError", [id], [str])
    DISPLAY str
  END IF

  CALL ui.Interface.frontCall("WinMail", "Close", [id], [result])
END MAIN
```

Mail using SMTP server
This topic provides an example of sending mail using an SMTP server.

```
MAIN
  DEFINE result, id INTEGER
  DEFINE str STRING
  -- first, we initialize the module
  CALL ui.Interface.frontCall("WinMail", "Init", [], [id])
```
-- Set the body of the mail
CALL ui.interface.frontCall("WinMail", "SetBody", [id, "This is a text mail using WinMail API - MAPI"], [result])

-- Set the subject of the mail
CALL ui.interface.frontCall("WinMail", "SetSubject", [id, "test mail - ignore it"], [result])

-- Set the mail sender
CALL ui.Interface.frontCall("WinMail", "SetFrom", [id, "mySelf", "me@mycompany.com"], [result])

-- Set the SMTP server
CALL ui.Interface.frontCall("WinMail", "SetSmtp", [id, "smtp.mycompany.com"], [result])

-- Add an Addressee as "TO"
CALL ui.Interface.frontCall("WinMail", "AddTo", [id, "myBoss", "boss@mycompany.com"], [result])

-- Add another Addressee as "BCC"
CALL ui.Interface.frontCall("WinMail", "AddBCC", [id, "my friend", "friend@mycompany.com"], [result])

-- Add Two attachments
CALL ui.Interface.frontCall("WinMail", "AddAttachment", [id, "c:\mydocs\report.doc"], [result])
CALL ui.Interface.frontCall("WinMail", "AddAttachment", [id, "c:\mydocs\demo.png"], [result])

-- Send the mail via smtp
CALL ui.Interface.frontCall("WinMail", "SendMailSMTP", [id], [result])
IF result == TRUE THEN
  DISPLAY "Message sent successfully"
ELSE
  CALL ui.Interface.frontCall("WinMail", "GetError", [id], [str])
  DISPLAY str
END IF
CALL ui.Interface.frontCall("WinMail", "Close", [id], [result])
END MAIN

Genero Application Server front calls
Front-end functions of the session module allow you to dynamically set and get session variables from within your Genero application.

Table 439: Session module front-end functions

<table>
<thead>
<tr>
<th>Function name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ui.Interface.frontCall(&quot;session&quot;, &quot;getVar&quot;, [name], [result])</td>
<td>Returns the value of a session variable.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;session&quot;, &quot;setVar&quot;, [name, value], [result])</td>
<td>Sets a value of a session variable.</td>
</tr>
</tbody>
</table>
**setVar**
Sets a value of a session variable.

**Syntax**
```
ui.Interface.frontCall("session", "setVar",
   [name, value], [result])
```
- *name* is the name of the session variable.
- *value* is the value to set to the named session variable.
- *result* returns 1 if successful; 0 otherwise.

**Usage**
The `setVar` function sets a session variable to the value specified.
Setting a variable to an empty string is equivalent to deleting the variable.

**getVar**
Returns the value of a session variable.

**Syntax**
```
ui.Interface.frontCall("session", "getVar",
   [name], [result])
```
- *name* is the name of the session variable.
- *result* is the value of the session variable, or an empty string if the variable does not exist.

**Usage**
The `getVar` function retrieves the value for a session variable.

**Genero Mobile common front calls**
This section describes common front calls provided by all mobile front-ends.

This table shows the functions implemented by all mobile front-ends in the "mobile" module.

**Table 440: Common mobile module front-end functions**

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ui.Interface.frontCall(&quot;mobile&quot;, &quot;chooseContact&quot;, [])</code>, [result])`</td>
<td>Lets the user choose a contact from the mobile device contact list and returns the vCard.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;mobile&quot;, &quot;choosePhoto&quot;, [])</code>, [path])</td>
<td>Lets the user select a picture from the mobile device's photo gallery and returns a picture identifier.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;mobile&quot;, &quot;chooseVideo&quot;, [])</code>, [path])</td>
<td>Lets the user select a video from the mobile device's video gallery and returns a video identifier.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;mobile&quot;, &quot;composeMail&quot;, [to, subject, content, cc, bcc, attachments ...])</code>,</td>
<td>Invokes the user's default mail application for a new mail to send.</td>
</tr>
<tr>
<td>Function Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;composeSMS&quot;, [recipients, content], [result])</td>
<td>Sends an SMS text to one or more phone numbers.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;connectivity&quot;, [])</td>
<td>Returns the type of network available for the mobile device.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;getGeolocation&quot;, [status, latitude, longitude])</td>
<td>Returns the Global Positioning System (GPS) location of a mobile device.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;getRemoteNotifications&quot;, [sender_id], [data])</td>
<td>This front call retrieves push notification messages.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;importContact&quot;, [vcard], [result])</td>
<td>Creates a new, or merges to an existing entry, the contact details passed in vCard string.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;registerForRemoteNotifications&quot;, [sender_id], [registration_token])</td>
<td>This front call registers a mobile device for push notifications.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;runOnServer&quot;, [appurl, timeout], [])</td>
<td>Run an application from the Genero Application Server according to the specified URL.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;scanBarCode&quot;, [])</td>
<td>Allow the user to scan a barcode with a mobile device</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;takePhoto&quot;, [])</td>
<td>Lets the user take a picture with the mobile device and returns the corresponding picture identifier.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;takeVideo&quot;, [])</td>
<td>Lets the user take a video with the mobile device and returns the corresponding video identifier.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;unregisterFromRemoteNotifications&quot;, [sender_id], [])</td>
<td>This front call unregisters the mobile device from push notifications.</td>
</tr>
</tbody>
</table>
**chooseContact**
Lets the user choose a contact from the mobile device contact list and returns the vCard.

**Syntax**

\[
\text{ui.Interface.frontCall("mobile", "chooseContact", [], [result])}
\]

- **result** - The vCard string from the device's contacts database.

**Usage**
The "chooseContact" front call opens the mobile device contact chooser, lets the user select a contact and returns the contact as a vCard string.

If the user cancels the contact chooser, **NULL** is returned.

**Example**

```sql
DEFINE vcard STRING
CALL ui.Interface.frontCall("mobile", "chooseContact", [], [vcard])
```

**choosePhoto**
Lets the user select a picture from the mobile device's photo gallery and returns a picture identifier.

**Syntax**

\[
\text{ui.Interface.frontCall("mobile", "choosePhoto", [], [path])}
\]

1. **path** - Holds the device opaque path to the chosen photo.

**Usage**
The "choosePhoto" front call starts the system's photo chooser (the device's photo gallery), allows the user to choose a photo, and returns the path/URL on the mobile device of the chosen photo.

If the user cancels the photo chooser, **NULL** is returned.

The value returned in the **path** variable contains a reference to the system location of the picture on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the picture.

For more details about mobile image handling, see images handling on mobile devices.

**chooseVideo**
Lets the user select a video from the mobile device's video gallery and returns a video identifier.

**Syntax**

\[
\text{ui.Interface.frontCall("mobile", "chooseVideo", [], [path])}
\]

1. **path** - Holds the device opaque path to the selected video.
Usage

The "chooseVideo" front call starts the system's video chooser (the device's video gallery), allows the user to choose a video, and returns the path/URL on the mobile device of the selected video.

If the user cancels the video chooser, NULL is returned.

The value returned in the path variable contains a reference to the system location of the video on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the video.

Once the video identifier/path is known, it is possible to fetch the video file from the device to the program context with the fgl_getfile() API. The procedure is similar to fetching photos from the device. For more details, see the section about video handling on mobile devices.

To play the video, you can perform a "launchURL" front call, with the opaque path returned by this front call.

composeMail
Invoices the user's default mail application for a new mail to send.

Syntax

```plaintext
ui.Interface.frontCall("mobile", "composeMail",
    [to, subject, content, cc, bcc, attachments ...],
    [result])
```

- **to** - A list of recipients, separated by commas. While the list uses commas to separate the recipients in the list, the list itself is enclosed in a single set of quotes.
- **subject** - The subject of the email.
- **content** - The body of the email.
- **cc** - (optional) A list of recipients for the carbon-copy email field, separated by commas. While the list uses commas to separate the recipients in the list, the list itself is enclosed in a single set of quotes.
- **bcc** - (optional) A list of recipients for the blind carbon-copy email field, separated by commas. While the list uses commas to separate the recipients in the list, the list itself is enclosed in a single set of quotes.
- **attachments** ... - (optional) All remaining arguments are treated as paths to attachment files. Each attachment file name is enclosed in its own set of quotes. The comma is used to separate the attachments in the list.
- **result** - Holds a status message.

Usage

The "composeMail" front call invokes the user's default mail application and sets up a new mail to send.

The returned result string can take one of the following values:

- "ok": The email was sent.
- "cancel": The email was canceled.
- "saved": The email was saved.
- "failed: reason": The email could not be sent.

This example opens an email and populates the To, CC, and BCC fields, the Subject line, the message body, and it specifies two attachments.

```plaintext
DEFINE result STRING
CALL ui.Interface.frontCall("mobile", "composeMail",
    ["john.doe@4js.com,jane.doe@4js.com", "Hello world",
     "This is the hello world text", "john.doe@4js.com,jane.doe@4js.com",
     "hidden@4js.com",]}
```
The next example opens an email and populates the To field, the Subject line, and the message body. No CC or BCC recipients and no attachments are specified.

```
DEFINE result STRING
CALL ui.Interface.frontCall("mobile","composeMail",
["huhu@haha.com","test mail","sent from my device"],[result])
```

define

Sends an SMS text to one or more phone numbers.

Syntax

```
ui.Interface.frontCall("mobile", "composeSMS",
[ recipients, content ],
[ result ] )
```

- **recipients** - A list of phone numbers, separated by commas. While the list uses commas to separate the phone numbers in the list, the list itself is enclosed in a single set of quotes.
- **content** - The SMS message.
- **result** - Holds a status message.

Usage

The "composeSMS" front call sends an SMS text to one or more phone numbers. Consider using global phone numbers with a + plus sign, as described in [RFC3966].

The returned result string can take one of the following values:

- "ok": The SMS was send.
- "cancel": The SMS was canceled.
- "failed": The SMS could not be sent.

Error -6333 is raised, if there is no permission to compose an SMS on the mobile phone.

```
DEFINE result STRING
CALL ui.Interface.frontCall("mobile", "composeSMS",
["+332781211,+339956789", "This is the SMS text"],
[result])
```

connectivity

Returns the type of network available for the mobile device.

Syntax

```
ui.Interface.frontCall("mobile", "connectivity",
[ ], [ result ] )
```

- **result** - Holds the type of network available.

Usage

The "connectivity" front call checks for the best available mobile network connectivity to the internet. The returned result string can take one of the following values:
- "NONE": No connectivity is available to the internet or the specified host.
- "MobileNetwork": Connectivity is available via the mobile network (Edge, 3G, 4G).
- "WIFI": Connectivity is available via a WIFI connection.

**Example**

```plaintext
DEFINE network STRING
CALL ui.Interface.frontCall("mobile", "connectivity", [], [network] )
IF network == "WIFI" THEN
    ...
END IF
```

**getGeolocation**

Returns the Global Positioning System (GPS) location of a mobile device.

**Syntax**

```plaintext
ui.Interface.frontCall("mobile", "getGeolocation", [], [status, latitude, longitude] )
```

1. **status** - Holds the status of the front call execution.
2. **latitude** - Holds the current latitude.
3. **longitude** - Holds the current longitude.

**Usage**

The "getGeolocation" front call returns the current location of the mobile device, based on the current GPS information.

The possible values returned in the status parameter are:

- "ok": The mobile device location could be found.
- In case of failure, the status variable contains the error description, for example, "location services not enabled".

The returned coordinates should be stored in FLOAT variables.

If the device location cannot be found within a given period, the front call returns an error status.

**Example**

```plaintext
DEFINE status STRING, latitude, longitude FLOAT
CALL ui.Interface.frontCall("mobile", "getGeolocation", [], [status, latitude, longitude] )
MESSAGE SFMT("Geo location: (status=%1) Latitude=%2 Longitude=%3", status, latitude, longitude )
```

**getRemoteNotifications**

This front call retrieves push notification messages.

**Syntax**

```plaintext
ui.Interface.frontCall("mobile", "getRemoteNotifications", [sender_id], [data] )
```
1. **sender_id** - For GMA, the `sender_id` identifies the mobile device. It's obtained when you create a GCM project. This parameter is ignored by GMI.

2. **data** - STRING containing a JSON array of notifications.

**Usage**

After registering for push notifications with the `registerForRemoteNotifications` on page 1940 front call, the `getRemoteNotifications` front call can be called in the context of an ON ACTION `notificationpushed` action handler.

The GMI or GMA front-end will send the `notificationpushed` special action, when it receives notifications from the push notification server. When this action is fired, use the `getRemoteNotifications` front call to get notification data. On GMA, identify the GCM client by passing the `sender_id` obtained from the GCM project as a parameter. On GMI, the `sender_id` can be NULL, as it is ignored.

**Important:**

When an app restarts, if notifications are pending and the app has already registered for push notification in a previous execution, the `notificationpushed` action will be raised as soon as a dialog with the corresponding ON ACTION handler activates. The app should then perform a `getRemoteNotifications` on page 1936 front call as in the regular case, to get the pending notifications pushed to the device while the app was off.

However, special consideration needs to be given to iOS devices. When push notification arrives for an iOS app that has not started, there is no mechanism to wake up the app and get the push data. Therefore, when the user starts the app from the springboard, there will never have any push data available. Depending on the context, implement the following programming patterns to solve this problem:

1. If the push notification contains a badge number, the app can verify if the badge is greater than 0 (with the `getBadgeNumber` front call) in order to perform a `getRemoteNotifications` front call. Even if there is no data available with the front call, the app should directly ask the server push provider to get last push data.

2. If the push notification does not contain badge numbers, the app should always perform a `getRemoteNotification` front call when it starts. If there is no push data available from the front call, the app should ask the server push provider if there is push data available. This is by the way also recommended when receiving a `notificationpushed` action during application life time.

3. If the user starts the app from the Notification Center, the app is launched with push data transmitted from the system, and the `notificationpushed` action is sent. The app should perform, the `getRemoteNotifications` front call and get the push data.

The "getRemoteNotifications" front call returns a list of notification records as a JSON array string. Use the `util.JSONArray` or `util.JSON` class to extract notification data from the returned string. The structure of a push notification is platform specific. See below for details.

**Important:** When an iOS app is in background, silent push notifications can occur, but notification message data (i.e. the payload) may not be available. In such case, GMI is able to detect that a notification arrived (i.e. when the app badge number is greater than zero) and raise the `notificationpushed` action, but the `getRemoteNotifications` front call will return no message data (`data` return param is NULL). If such case, implement a fallback mechanism (based on RESTful web services for example), to contact the push notification provider and retrieve the message information.

**Push notification records with GMA / Android™**

The returned JSON string from a GCM notification server contains an array of notification records. A notification record contains the following JSON keys:
• "type" - can be "message" or "token".
• "data" - Contains notification data.

  • When "type": "message", the notification record is a GCM application message, and the data attribute contains custom notification information.

    An element of "data" can be a "genero_notification" record, that will produce an Android graphical notification. This record must define the following attributes:
    • "title" - title of the graphical notification
    • "content" - text content of the graphical notification
    • "icon" - icon of the graphical notification

    The "genero_notification" record can be followed by custom notification data.

  • When "type": "token", the notification record is a registration token update, and the "data" attribute contains the new registration token, which should be re-sent to the push notification server.

• "from" - Contains the GCM project id.

JSON push notification data example for GMA:

```
[
  {
    "type": "message",
    "data": { custom-attributes ... },
    "from": "project-id"
  },
  {
    "type": "token",
    "data": "new-registration-token",
    "from": "project-id"
  },
  ... ]
```

Note that the JSON push notification data can contain a "data" attribute with a "genero_notification" record, that will produce an Android graphical notification:

```
[
  {
    "type": "message",
    "data": {
      "genero_notification": {
        "title": "Game Request!",
        "content": "Bob wants to play poker...",
        "icon": "smiley"
      },
      custom-attributes
      ...
    },
    "from": "project-id"
  },
  ...
]
```

Push notification records with GMI / iOS

The returned JSON string from an Apple Push Notification contains an array of notification records. A push notification record contains the following JSON attributes:

• "aps" (required) - key to be recognized by devices as an Apple Push Notification
• "alert" (required) - key of the push notification content. If not specified as a single value, the alert key can hold:
  • "title" - title of the alert.
  • "body" - the message to be displayed.
• "badge" (optional) - the number to display as the badge of the app icon. If this property is absent, the badge is not changed. You need to manage it through your push notification provider.
• "sound" (optional) - the sound played by the alert (aiff, wav, or caf format). default value: "default". To use a custom file you will need to use the gmi extension project and be familiar with Objective-C. The file must bundled with the app.
• "content-available" (required) - The content-available property with a value of 1 lets the remote notification act as a "silent" notification. Notifications received in background mode should be stored for delivery when the app enters foreground mode.

JSON push notification data example for GMI:

```
[   
  {     
    "aps" : {       
      "alert" : "My first push",       
      "badge" : 1,       
      "sound" : "default",       
      "content-available" : 1     
    },  
  },   
  {     
    "aps" : {       
      "alert" : {       
        "title" : "Push",       
        "body" : "My second push"       
      },       
      "badge" : 2,       
      "sound" : "default",       
      "content-available" : 1     
    },     
    "new_ids" : [ "XV234", "ZF452", "RT563" ],     
    "updated_ids" : [ "AC634", "HJ153" ]     
  }
]
```

In the last record, custom information is provided in the "new_ids" and "updated_ids" attributes, as a JSON array of identifiers.

For more details, see Apple Push Notification Service.

Example

```python
IMPORT util -- JSON API
CONSTANT GCM_SENDER_ID = "<enter your GCM Sender ID (NULL for APNs)>
...
DEFINE notif_list STRING,
  sender_id STRING

LET sender_id = GCM_SENDER_ID
DIALOG ...
```
ON ACTION notificationpushed

CALL ui.Interface.frontCall(
    "mobile", "getRemoteNotifications",
    [ sender_id ], [ notif_list ] )

-- Analyse content of notiflist
DISPLAY util.JSON.format(notif_list)
...

importContact
Creates a new, or merges to an existing entry, the contact details passed in vCard string.

Syntax

ui.Interface.frontCall("mobile", "importContact",
    [vcard], [result] )

1. vcard - Holds a vCard string to be imported into the device's contacts database.
2. result - Holds the completed vCard string.

Usage
The "importContact" front call sends the vCard definition passed as parameter to the mobile device.

If the contact import is canceled, the front-end returns NULL. Otherwise, it returns the vCard data.

On iOS devices, the user has the choice to create a new contact, or complete an existing contact entry.
When creating a new entry, the contact input form is opened on the mobile device, to let the user complete
the default values passed as parameter. When merging contact information to an existing entry, the user
selects an entry from the contact list. If the contact import is validated, the front call returns the completed
vCard string.

On Android™ devices, this front call creates a new contact entry directly in the mobile contact list,
according to the VCard definition passed as parameter, no intermediate input form is proposed to the end
user. If the contact import is validated, the front call returns the original vCard string passed as parameter.

Example

DEFINE vcard, result STRING
LET vcard="BEGIN:VCARD
    "VERSION:3.0"
    "N:Willi;;;;"
    "TEL;type=HOME;type=VOICE;type=pref:03812225610"
    "END:VCARD"
CALL ui.interface.frontcall("mobile","importContact",[vcard],
    [result])

registerForRemoteNotifications
This front call registers a mobile device for push notifications.

Syntax

ui.Interface.frontCall("mobile","registerForRemoteNotifications",
    [sender_id], [registration_token] )

1. sender_id - For GMA, the sender_id identifies the mobile device. It's obtained when you create a GCM
project. This parameter is ignored by GMI.
2. **registration_token** - Registration token to be sent to the push notification provider. For GMA/Android, this is the “registration token” obtained from GCM, for GMI/iOS, this is the “device token” obtained from APNs.

**Usage**

The “registerForRemoteNotifications” front call registers the mobile device for push notifications. Once the registration procedure is done (see below for platform specifics), it is possible to get notification events through the notificationpushed predefined action, and retrieve notification data with the getRemoteNotifications on page 1936 front call.

**Note:** The app does not need to register for notification each time it is restarted: Even if the app is closed, the registration is still active until the unregisterFromRemoteNotifications front call is performed. At first execution, an app will typically ask if the user wants to get push notifications and register to the push service if needed. To disable push notification, apps usually implement an option that can be disabled (to unregister) and re-enabled (to register again) by the user. On Android, that the app must register for notification each time it is upgraded.

On Android when using GCM, you get the `sender_id` and an API key when you create a GCM project (see https://developers.google.com/cloud-messaging/android/client#get-config). The `registration_token` is the registration token returned by GCM. Once registered with the GCM service, the app must also send this registration token to the GCM application server. Registration tokens are typically sent to the GCM application server using a RESTful HTTP POST. For more details, see GCM documentation on the Google developer web site. For more details about GCM registration, see About GCM Connection Server.

**Note:** Android apps using push notification services need specific permissions to be defined in the manifest, such as `android.permission.GET_ACCOUNTS`, `com.google.android.c2dm.permission.RECEIVE`, and especially `application-package-name.permission.C2D_MESSAGE`. These Android permissions will be automatically set by the gmabuildtool, according to the package name specified with the `--build-app-package-name` option. For more details, see GCM documentation.

On iOS when using APNs, the `sender_id` is ignored. The `registration_token` is the device token returned by the Apple Push Notification service. Once registered with the Apple Push Notification service, the app must also send this device token to the push notification provider, typically using a RESTful HTTP POST.

For more details about Apple Push Notification Provider, see Apple Push Notification Service web site.

**Example**

The following code example registers with Google Cloud Messaging or Apple Push Notification service. It then sends the registration token to the push notification provider:

```
IMPORT com -- For RESTful post
IMPORT util -- JSON API

CONSTANT GCM_SENDER_ID = "<enter your GCM Sender ID (NULL for APNs)>"
...

DEFINE sender_id STRING,
registration_token STRING
DEFINE req com.HTTPRequest,
obj util.JSONObject,
resp com.HTTPResponse

-- First get the registration token
LET sender_id = GCM_SENDER_ID
CALL ui.Interface.frontCall(  
    "mobile", "registerForRemoteNotifications",
    [ sender_id ], [ registration_token ] )
```

-- Then send registration token to push notification provider
TRY
LET req = com.HTTPRequest.create("http://SERVER_IP:4930")
CALL req.setHeader("Content-Type", "application/json")
CALL req.setMethod("POST")
CALL req.setTimeOut(5)
LET obj = util.JSONObject.create()
CALL obj.put("registration_token", registration_token)
CALL req.doTextRequest(obj.toString())
LET resp = req.getResponse()
IF resp.getStatusCode() != 200 THEN
    MESSAGE SFMT("HTTP Error (%1) %2",
        resp.getStatusCode(),
        resp.getStatusDescription())
ELSE
    MESSAGE "Registration token sent."
END IF
CATCH
    MESSAGE SFMT("Could not post registration token to server: %1", STATUS)
END TRY
...

runOnServer
Run an application from the Genero Application Server according to the specified URL.

Syntax
ui.Interface.frontCall("mobile", "runOnServer",
    [ appurl, timeout ], [] )

•  appurl - The GAS URL to the Genero application (this must be a ua/r URL).
•  timeout - The timeout (in seconds) to wait for the remote application.

Usage
The runOnServer front call allows you to start an application in the Genero Application Server (GAS), from an embedded/local application running on the mobile device. The remote application's graphical user interface displays on the mobile device.

The front call returns when the called application ends, and the control goes back to the initial application executing on the mobile device.

The applications executed on the GAS server must use the UTF-8 encoding. Mobile front-ends will reject any attempt to display forms of an application using an encoding other than UTF-8.

The remote application cannot use RUN WITHOUT WAITING to start child programs. Only RUN is supported.

The first parameter (appurl) identifies the remote application to be started and must contain an "ua/r" URL syntax (the UA protocol introduced with the GAS 3.00).

For example: http://myappserver:6394/ua/r/myapp.

This URL may contain a query string, with parameters for the application to be executed by the GAS.

The timeout parameter is optional. It can be used to give the control back to the local app, if the remote app takes too long to respond. If not specified, or when zero is passed, the timeout is infinite.

In case of failure (such as application not found, or timeout expired), the front call raises the runtime error -6333 and the HTTP status code of the request can be found in the error message details.
The application running on the GAS can only access the `data-directory` directory, in the sandbox of the embedded application that executes the `runOnServer` front call. File handling APIs like `fgl_getfile()` and `fgl_putfile()` can only access this directory on the mobile device. If no absolute path is specified in the file path for the mobile device, the `data-directory` is used.

### Example

```plaintext
TRY
    CALL ui.interface.frontcall("mobile","runOnServer","http://santana:6394/ua/r/orders"),[]
CATCH
    ERROR err_get(STATUS)
END TRY
```

### scanBarCode

Allow the user to scan a barcode with a mobile device

**Syntax**

```plaintext
ui.Interface.frontCall("mobile", "scanBarCode", [], [code, type] )
```

1. `code` - Holds a string representation of the barcode.
2. `type` - Holds the name of the barcode type.

### Usage

The "scanBarCode" front call starts the barcode scanner to let the user scan a barcode with the device. After reading the barcode, the front call returns the string representation of the barcode and the barcode type (i.e. symbology).

The `code` return parameter contains the barcode string.

The `type` return parameter indicates the type of barcode that was scanned.

If the barcode scan was canceled, the `code` return parameter is set to `NULL` and `type` is set to "canceled".

- On iOS devices, the barcode reader used by GMI is "ZBar". For more details, see [http://zbar.sourceforge.net](http://zbar.sourceforge.net)

### Table 441: Barcode type codes returned by GMI and GMA

</table>

**takePhoto**

Lets the user take a picture with the mobile device and returns the corresponding picture identifier.

**Syntax**

```javascript
ui.Interface.frontCall("mobile", "takePhoto", [], [path] )
```

1. *path* - Holds the device opaque path to the picture that has been taken.

**Usage**

The "takePhoto" front call invokes the mobile device's camera to let the user take a picture and returns the local path/URL on the mobile device to the picture.

If the photo is canceled by the user, the front call returns `NULL`.

The value returned in the *path* variable contains a reference to the system location of the picture on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the picture.

For more details about mobile image handling, see images handling on mobile devices.

**takeVideo**

Lets the user take a video with the mobile device and returns the corresponding video identifier.

**Syntax**

```javascript
ui.Interface.frontCall("mobile", "takeVideo", [], [path] )
```
1. path - Holds the device opaque path to the video.

Usage
The "takeVideo" front call invokes the mobile device's camera to let the user take a video and returns the local path/URL to the video on the mobile device.

If the photo is canceled by the user, the front call returns NULL.

The value returned in the path variable contains a reference to the system location of the video on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the video.

Once the video identifier/path is known, it is possible to fetch the video file from the device to the program context with the fgl_getfile() API. The procedure is similar to fetching photos from the device. For more details, see the section about video handling on mobile devices.

To play the video, you can perform a "launchURL" front call, with the opaque path returned by this front call.

unregisterFromRemoteNotifications
This front call unregisters the mobile device from push notifications.

Syntax
ui.Interface.frontCall("mobile","unregisterFromRemoteNotifications", [ sender_id ], [ ] )

1. sender_id - For GMA, the sender_id identifies the mobile device. It's obtained when you create a GCM project. This parameter is ignored by GMI.

Usage
The "unregisterFromRemoteNotifications" front call unregisters the device from push notifications after it has been registered with the registerForRemoteNotifications on page 1940 front call.

On Android with GCM, to unregister the mobile device from GCM push notifications, pass the sender_id used to identify the GCM client. You obtain the sender_id when you create the GCM project.

On iOS with APNs, provide a NULL as sender_id, to unregister the iOS mobile device from push notifications.

Example
DEFINE sender_id STRING
...
IF get_device_type() == "GMA" THEN
  LET sender_id = "94019931415" -- Got from GCM project creation
ELSE
  LET sender_id = NULL -- Ignored by GMI
END IF
CALL ui.Interface.frontCall( "mobile", "unregisterFromRemoteNotifications", [ sender_id ], [ ] )
...
Genero Mobile Android™ front calls
This section describes front calls specific to the Android platform.

This table shows the functions implemented by the Android front-end in the "android" module.

Table 442: Android module front-end functions

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ui.Interface.frontCall(&quot;android&quot;, &quot;askForPermission&quot;, [permission], [result])</td>
<td>Ask the user to enable a dangerous feature on the Android device.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;android&quot;, &quot;showAbout&quot;, [])</td>
<td>Shows the GMA about box displaying version information.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;android&quot;, &quot;showSettings&quot;, [])</td>
<td>Shows the GMA settings box controlling debug options.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;android&quot;, &quot;startActivity&quot;, [action, data, category, type, component, extras], [])</td>
<td>Starts an external Android application (activity), and returns to the GMA application immediately.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;android&quot;, &quot;startActivityForResult&quot;, [action, data, category, type, component, extras], [outdata, outextras])</td>
<td>Starts an external application (Android activity) and waits until the activity is closed.</td>
</tr>
</tbody>
</table>

askForPermission (Android™)
Ask the user to enable a dangerous feature on the Android device.

Syntax

ui.Interface.frontCall("android", "askForPermission", [permission], [result])

1. permission - Identifies the Android permission to enable.
2. result - Holds the execution status of the front call:
   - "ok": the user accepted the permission.
   - "rejected": the user refused the permission.

Usage

The "askForPermission" front call opens a message box to let the end user confirm the access to a "dangerous" Android permission, in order to enable a risky feature of the mobile device for the current app.

**Important:** Starting with Android 6, permissions to access dangerous mobile functions are no longer asked during app installation: The app must ask the user for dangerous permissions when needed, by using the askForPermission front call.

The permissions parameter defines the Android permission to be asked. It must be a string representing one of the Android permission constants, as defined in Android's Manifest permissions, prefixed by the "android.permission." string. For example, the
"android.permission.WRITE_EXTERNAL_STORAGE" string can be used to identify the permission to access the SDCARD storage unit.

**Important:** Specific Android permissions required by the app still need to be specified when building the app. However, it is not needed to specify Android permissions required for built-in front calls: For example, if the app code makes a `choosePhoto` front call, the GMA will implicitly ask the user and set the Android permission to access the photo gallery. For more details, see Android permissions on page 2589.

The front call will raise a runtime exception if the permission identifier is not valid.

### Example

The following code example asks the user to access the SDCARD, and handles the user choice:

```java
DEFINE result STRING
CALL ui.Interface.frontCall(
    "android", "askForPermission",
    ["android.permission.WRITE_EXTERNAL_STORAGE"],
    [result] )
CASE result
    WHEN "ok"
        CALL os.Path.mkDir("/sdcard/myfiles")
    WHEN "rejected"
        ERROR "SDCARD access was denied by user"
END CASE
```

### showAbout (Android™)

Shows the GMA about box displaying version information.

**Syntax**

```java
ui.Interface.frontCall("android", "showAbout", [], [])
```

**Usage**

This front call simply shows a typical about box, indicating GMA version information.

**Important:** This front call is only available for an application running on an Android device.

No input parameters are required, and no parameters are returned.

### showSettings (Android™)

Shows the GMA settings box controlling debug options.

**Syntax**

```java
ui.Interface.frontCall("android", "showSettings", [], [])
```

**Usage**

This front call opens the settings box to enable or disable GMA programming options.

**Important:** This front call is only available for an application running on an Android device.

No input parameters are required, and no parameters are returned.
The following features can be controlled with the GMA settings box:

- HTTP debug server on port 6480 (to inspect the AUI tree and show app logs)
- GUI display (FGLSERVER on page 188) and remote debug with fgldb on port 6400
- Android logcat recording
- Managing allowed certificates (SSH connections)
- Cookies cleanup (for SSO authentication tokens)

**startActivity (Android™)**

Starts an external Android application (activity), and returns to the GMA application immediately.

**Syntax**

```java
ui.Interface.frontCall("android","startActivity",
    [action, data, category, type, component, extras],
    [])
```

1. **action** - Identifies the activity to be started on the Android device.
2. **data** - (optional) The data to operate on in the activity (URL, etc).
3. **category** - (optional) A comma separated list of categories.
4. **type** - (optional) Specifies the type of the data passed to the activity.
5. **component** - (optional) Specifies a component class to use for the intent.
6. **extras** - (optional) This is a JSON string containing parameters to pass to the activity.

**Usage**

The "startActivity" front call starts an external application (Android activity), and returns to the GMA application immediately after invoking the activity.

**Important:** This front call is only available for an application running on an Android device.

This front call is similar to the **RUN WITHOUT WAITING** statement: It allows the user to switch between the GMA and the launched application.

The parameters passed to this front call are used to build an Android "intent" object to start an "activity". For more details about Android intent object, refer to the Android "Intent" definition.

The **action** parameter defines the Android activity to perform, such as "android.intent.action.MAIN", "android.intent.action.VIEW", and so on.

The **data** (optional) parameter contains the data to operate on. This is the main parameter to transmit data to the activity. It can for example be an URL.

The **category** (optional) parameter contains a comma separated list of categories, where a category gives additional information about the action to execute. For example, "android.intent.category.LAUNCHER" means it should appear in the Launcher as a top-level application. See the Android documentation for details about possible categories for a given activity.

The **type** (optional) parameter defines the type (in fact, a MIME type) of the activity data. Normally the type is inferred from the data itself. By setting this attribute, you disable that evaluation and force an explicit type.

The **component** (optional) parameter defines the name of a component class to use for the intent. Normally this is determined by looking at the other information in the intent. The component name typically specified as "apk-package-name/java-class-name" or "java-class-name" (the APK package name is optional). If the APK package is not specified, GMA considers that the Java class is included in the current APK.
The \textit{extras} (optional) parameter specifies a JSON string containing parameters to pass to the activity. This can be used to provide extended information to the component. For example, with an action sending an e-mail message, the extra data can include data to supply a subject, body, for the e-mail.

\begin{verbatim}
Example

The following code example starts the VIEW Android activity to show an image. The Genero program flow will continue after this call, but the started activity will be shown. Note that such action is rather performed with a \texttt{launchurl} front call.

CALL ui.Interface.frontCall(
  "android", "startActivity",
  [ "android.intent.action.VIEW",
    "file:///storage/path_to_image_file",
    NULL, "image/*" ],
  [ ] )
\end{verbatim}

\textbf{startActivityForResult (Android”)}

Starts an external application (Android activity) and waits until the activity is closed.

\textbf{Syntax}

\begin{verbatim}
ui.Interface.frontCall("android", "startActivityForResult",
  [action, data, category, type, component, extras],
  [outdata, outextras])
\end{verbatim}

1. \textit{action} - Identifies the activity to be started on the Android device.
2. \textit{data} - (optional) The data to operate on in the activity (URL, etc).
3. \textit{category} - (optional) A comma separated list of categories.
4. \textit{type} - (optional) Specifies the type of the data passed to the activity.
5. \textit{component} - (optional) Specifies a component class to use for the intent.
6. \textit{extras} - (optional) This is a JSON string containing parameters to pass to the activity.

Return values include:

1. \textit{outdata} - holds the flat value returned by the invoked activity.
2. \textit{outextras} - holds the JSON data of structured value returned by the invoked activity.

The return values depend entirely on the invoked activity.

\textbf{Usage}

The \texttt{"startActivityForResult"} front call starts an external application (Android activity), then waits for the user to exit the external application prior to returning the GMA application.

\textbf{Important}: This front call is only available for an application running on an Android device.

This front call is similar to the \texttt{RUN} statement: The user cannot return to the GMA application while the activity is executing.

The parameters passed to this front call are used to build an Android "intent" object to start an "activity". For more details about Android intent object, refer to the Android "Intent" definition.

The \textit{action} parameter defines the Android activity to perform, such as \texttt{"android.intent.action.MAIN"}, \texttt{"android.intent.action.VIEW"}, and so on.

The \textit{data} (optional) parameter contains the data to operate on. This is the main parameter to transmit data to the activity. It can for example be an URL.
The category (optional) parameter contains a comma separated list of categories, where a category gives additional information about the action to execute. For example, "android.intent.category.LAUNCHER" means it should appear in the Launcher as a top-level application. See the Android documentation for details about possible categories for a given activity.

The type (optional) parameter defines the type (in fact, a MIME type) of the activity data. Normally the type is inferred from the data itself. By setting this attribute, you disable that evaluation and force an explicit type.

The component (optional) parameter defines the name of a component class to use for the intent. Normally this is determined by looking at the other information in the intent. The component name typically specified as "apk-package-name/java-class-name" or "java-class-name" (the APK package name is optional). If the APK package is not specified, GMA considers that the Java class is included in the current APK.

The extras (optional) parameter specifies a JSON string containing parameters to pass to the activity. This can be used to provide extended information to the component. For example, with an action sending an e-mail message, the extra data can include data to supply a subject, body, for the e-mail.

The outdata returning argument will contain the flag value returned from the activity, typically when the data is simple and not structured.

The outextras returning argument can hold JSON data of any structured value returned by the invoked activity, or NULL in case of error (for example, when the application corresponding to the activity is not installed)

Example
This example invokes the barcode scanner application, and returns the scanned barcode.

```plaintext
IMPORT util ...
DEFINE data, extras STRING,
    json_object util.JSONObject,
    scanned_value STRING ...
CALL ui.Interface.frontCall("android", "startActivityForResult",
    [ "com.google.zxing.client.android.SCAN",
      NULL, "android.intent.category.DEFAULT" ],
    [ data, extras ])
IF extras IS NULL THEN
    -- If the application isn't installed invoke
    -- the Play Store to give the user a chance to install it
    CALL ui.Interface.frontCall("standard", "launchurl",
        ["market://details?id=com.google.zxing.client.android"], [])
ELSE
    LET json_object = util.JSONObject.parse(extras)
    -- Fetch the scanned value
    LET scanned_value = json_object.get("SCAN_RESULT")
END IF
```

Genero Mobile iOS front calls
This section describes front calls specific to the iOS platform.

This table shows the functions implemented by the iOS front-end in the "ios" module.
Table 443: iOS module front-end functions

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ui.Interface.frontCall(&quot;ios&quot;, [&quot;getBadgeNumber&quot;], [value])</code></td>
<td>Returns the current badge number associated to the app.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;ios&quot;, [&quot;newContact&quot;], [defaults], [vcard])</code></td>
<td>Lets the user input contact information to create a new entry in the contact database of the mobile device.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;ios&quot;, [&quot;setBadgeNumber&quot;], [value], [])</code></td>
<td>Sets the current badge number associated to the app.</td>
</tr>
</tbody>
</table>

**getBadgeNumber (iOS)**

Returns the current badge number associated to the app.

**Syntax**

```plaintext
define value integer
call ui.interface.frontcall("ios", "getBadgeNumber", [], [value])
```

- **value** - Holds the current badge number.

**Usage**

The iOS "getBadgeNumber" front call returns the current badge number associated to the app.

**Important:** This front call is only available for an application running on an iOS device.

The badge number appears on the app icon and is typically used for Push notifications on page 2611.

**Important:** In order to query or set the badge number, the app program must have executed a `registerForRemoteNotifications` front call before (in the current or prior execution instance). This registration is required in order to set the appropriate app permissions to access badge number data.

**Example**

```plaintext
define value integer
call ui.interface.frontcall("ios", "getBadgeNumber", [], [value])
```

**newContact (iOS)**

Lets the user input contact information to create a new entry in the contact database of the mobile device.

**Syntax**

```plaintext
define defaults string
define vcard string
ui.Interface.frontCall("ios", "newContact", [defaults], [vcard])
```

- **defaults** - A vCard string with default values for the new contact input.
- **vcard** - Holds the vCard string of the new created contact.
Usage
The iOS "newContact" front call opens the contact input form on the mobile device, with default values passed in the vCard structure of the first parameter, lets the user enter contact information.

Important: This front call is only available for an application running on an iOS device.

If the contact creation is validated, the front call returns the completed vCard string. If the contact import is canceled, the front-end returns NULL.

Example

DEFINE defaults, vcard STRING
LET defaults="BEGIN:VCARD
"||"VERSION:3.0\n"
"N:Willi;;;;\n"
"TEL;type=HOME;type=VOICE;type=pref:03812225610\n"
"END:VCARD\n"
CALL ui.interface.frontcall("ios","newContact",[defaults],[vcard])

setBadgeNumber (iOS)
Sets the current badge number associated to the app.

Syntax

ui.Interface.frontCall("ios", "setBadgeNumber", [value], [])

• value - Holds the badge number to be set.

Usage
The iOS "setBadgeNumber" front call sets the badge number associated to the app.

Important: This front call is only available for an application running on an iOS device.

The badge number appears on the app icon and is typically used for Push notifications on page 2611.

Important: In order to query or set the badge number, the app program must have executed a registerForRemoteNotifications front call before (in the current or prior execution instance). This registration is required in order to set the appropriate app permissions to access badge number data.

Example

DEFINE value INTEGER
LET value = 2
CALL ui.interface.frontcall("ios","setBadgeNumber",[value],[])

Extension packages

Several utility classes and functions are provided in additional packages to be included with the IMPORT instruction.

• The util package on page 1953
• The os package on page 1998
The util package
These topics cover the classes for the util package.

The util.Date class
The util.Date class provides DATE data-type related utility methods.
This class is provided in the util C-Extension library; To use the util.Date class, you must import the util package in your program:

```plaintext
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

util.Date methods
Methods for the util.Date class.

Table 444: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>util.Date.isLeapYear( year )</code></td>
<td>Checks is the year passed as parameter is a leap year.</td>
</tr>
<tr>
<td><code>util.Date.parse( src STRING, fmt STRING )</code></td>
<td>Converts a string to a DATE value according to a format specification.</td>
</tr>
</tbody>
</table>

util.Date.parse
Converts a string to a DATE value according to a format specification.

**Syntax**

```plaintext
util.Date.parse( src STRING, fmt STRING )
```

1. `src` is the source string to be parsed.
2. `fmt` is the format specification (see Formatting DATE values on page 223).

**Usage**

The util.Date.parse() method parses a string according to a format specification, to produce a DATE value.

The format specification must be a combination of dd, mm, yyyy place holders as with the USING operator.

The method returns NULL, if the source string cannot be converted to a DATE value according to the format specification.
For more details about the supported formats, see Formatting DATE values on page 223.

**Example**

```c
IMPORT util
MAIN
    DISPLAY util.Date.parse( "2014-03-15", "yyyy-mm-dd" )
END MAIN
```

util.Date.isLeapYear

Checks is the year passed as parameter is a leap year.

**Syntax**

```c
util.Date.isLeapYear( year )
    RETURNING res BOOLEAN
```

1. `year` is an `INTEGER` representing a year.
2. `res` is `TRUE` if `year` is a leap year, otherwise `res` is `FALSE`.

**Usage**

The `util.Date.isLeapYear()` method returns `TRUE` if the year passed in parameter is a leap year.

```c
IMPORT util
MAIN
    DISPLAY util.Date.isLeapYear( 2003 )
    DISPLAY util.Date.isLeapYear( 2004 )
END MAIN
```

**The util.Datetime class**

The `util.Datetime` class provides DATETIME data-type related utility methods.

This class is provided in the `util C-Extension` library; To use the `util.Datetime` class, you must import the `util` package in your program:

```c
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

**util.Datetime methods**

Methods for the `util.Datetime` class.

**Table 445: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>util.Datetime.format( value DATETIME q1 TO q2, fmt STRING )</code></td>
<td>Formats a datetime value according to format specification.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>RETURNING res STRING</td>
<td></td>
</tr>
<tr>
<td><code>util.Datetime.fromSecondsSinceEpoch</code> (seconds FLOAT)</td>
<td>Converts a number of seconds since Epoch to a datetime.</td>
</tr>
<tr>
<td>RETURNING local DATETIME q1 TO q2</td>
<td></td>
</tr>
<tr>
<td><code>util.Datetime.getCurrentAsUTC</code> ( )</td>
<td>Returns the current date/time in UTC.</td>
</tr>
<tr>
<td>RETURNING utc DATETIME YEAR TO FRACTION(5)</td>
<td></td>
</tr>
<tr>
<td><code>util.Datetime.parse</code> (src STRING, fmt STRING)</td>
<td>Converts a string to a DATETIME value according to a format specification.</td>
</tr>
<tr>
<td>RETURNING res DATETIME q1 TO q2</td>
<td></td>
</tr>
<tr>
<td><code>util.Datetime.toLocalTime</code> (utc DATETIME q1 TO q2)</td>
<td>Converts a UTC datetime to the local time.</td>
</tr>
<tr>
<td>RETURNING local DATETIME q1 TO q2</td>
<td></td>
</tr>
<tr>
<td><code>util.Datetime.toSecondsSinceEpoch</code> (local DATETIME q1 TO q2)</td>
<td>Converts a datetime to a number of seconds since Epoch.</td>
</tr>
<tr>
<td>RETURNING seconds FLOAT</td>
<td></td>
</tr>
<tr>
<td><code>util.Datetime.toUTC</code> (local DATETIME q1 TO q2)</td>
<td>Converts a datetime value to the UTC datetime.</td>
</tr>
<tr>
<td>RETURNING utc DATETIME q1 TO q2</td>
<td></td>
</tr>
</tbody>
</table>

`util.Datetime.format`  
Formats a datetime value according to format specification.

**Syntax**

```sql
util.Datetime.format(
    value DATETIME q1 TO q2,
    fmt STRING
) RETURNING res STRING
```

1. `value` is the datetime value to be formatted.
2. `fmt` is the format string, as described in Formatting DATETIME values on page 224.

**Usage**

The `util.Datetime.format()` method formats a DATETIME value according to the format specification.
The format string must be a combination of place holders such as \%Y, \%m, \%d, as described in Formatting DATETIME values on page 224.

If the source value is NULL the result will be NULL.

Example

```plaintext
IMPORT util
MAIN
  DISPLAY util.Datetime.format( CURRENT, \"%Y-%m-%d %H:%M\" )
END MAIN
```

util.Datetime.fromSecondsSinceEpoch
Converts a number of seconds since Epoch to a datetime.

Syntax

```plaintext
util.Datetime.fromSecondsSinceEpoch(
  seconds FLOAT
)
  RETURNING local DATETIME q1 TO q2
```

1. `seconds` is the number of seconds since Epoch. This can be a whole integer or a decimal, if the target datetime
2. `local` is the local datetime value.

Usage

The `util.Datetime.fromSecondsSinceEpoch()` method converts the number of seconds since the Unix Epoch (1970-01-01 00:00:00 GMT) passed as parameter, to a DATETIME value, in the local time.

**Important:** If the number of seconds passed as parameter is a floating point number including a fraction of seconds, the result will be a DATETIME YEAR TO FRACTION(N), otherwise it is DATETIME YEAR TO SECOND.

Example

```plaintext
IMPORT util
MAIN
  DEFINE dt DATETIME YEAR TO SECOND
  LET dt = util.Datetime.fromSecondsSinceEpoch( 9876234 )
  DISPLAY dt
END MAIN
```

util.Datetime.getCurrentAsUTC
Returns the current date/time in UTC.

Syntax

```plaintext
util.Datetime.getCurrentAsUTC( )
  RETURNING utc DATETIME YEAR TO FRACTION(5)
```

1. `utc` is the datetime value in UTC, with the precision DATETIME YEAR TO FRACTION(5).

Usage

The `util.Datetime.getCurrentAsUTC()` method returns the current system date/time in UTC (Universal Time).
This method is provided to solve the daylight saving time transition issue of the
util.Datetime.toUTC() method.

**Note:** The precision of the value returned by this method is a **DATETIME YEAR TO FRACTION(5)**. Note that this precision is different from the default **CURRENT** precision when no qualifiers are specified.

### Example

```
IMPORT util
MAIN
    DEFINE utc DATETIME YEAR TO FRACTION(5)
    LET utc = util.Datetime.getCurrentAsUTC()
    DISPLAY "Current UTC: ", utc
END MAIN
```

### util.Datetime.parse

Converts a string to a **DATETIME** value according to a format specification.

**Syntax**

```
util.Datetime.parse(
    src STRING,
    fmt STRING
)
RETURNING res DATETIME q1 TO q2
```

1. **src** is the source string to be parsed.
2. **fmt** is the format specification (see Formatting **DATETIME** values on page 224).

**Usage**

The `util.Datetime.parse()` method parses a string according to a format specification, to produce a **DATETIME** value.

The format specification must be a combination of place holders such as `%Y`, `%m`, `%d`, etc.

The precision of the resulting **DATETIME** value depends on the format specification. For example, when using "%Y-%m-%d %H:%M", the resulting value will be a **DATETIME YEAR TO MINUTE**.

The method returns **NULL**, if the source string cannot be converted to a **DATETIME** value according to the format specification.

For more details about the supported formats, see Formatting **DATETIME** values on page 224.

### Example

```
IMPORT util
MAIN
    DEFINE dt DATETIME YEAR TO MINUTE
    LET dt = util.Datetime.parse( "2014-12-24 23:45", "%Y-%m-%d %H:%M" )
    DISPLAY dt
END MAIN
```
**util.Datetime.toLocalTime**
Converts a UTC datetime to the local time.

**Syntax**

```plaintext
util.Datetime.toLocalTime (  
    utc DATETIME q1 TO q2  
)  
RETURNING local DATETIME q1 TO q2
```

1. `utc` is the datetime value in UTC.
2. `local` is the local timezone datetime value.

**Usage**
The `util.Datetime.toLocalTime()` method converts a `DATETIME` value from "Coordinated Universal Time" (UTC), also known as "Greenwich Mean Time" (GMT), to the local timezone datetime.

```
IMPORT util
MAIN
  DEFINE loc DATETIME YEAR TO SECOND
  LET loc = util.Datetime.toLocalTime( DATETIME(2015-08-22 15:34:56) YEAR TO SECOND )
  DISPLAY "LOC: ", loc
END MAIN
```

**util.Datetime.toSecondsSinceEpoch**
Converts a datetime to a number of seconds since Epoch.

**Syntax**

```plaintext
util.Datetime.toSecondsSinceEpoch (  
    local DATETIME q1 TO q2  
)  
RETURNING seconds FLOAT
```

1. `local` is the local datetime value.
2. `seconds` is the number of seconds since Epoch. Note that this is a `FLOAT` value as the source can be a `DATETIME YEAR TO FRACTION(N)`.

**Usage**
The `util.Datetime.toSecondsSinceEpoch()` method converts the `DATETIME` value passed as parameter to a number of seconds since the Unix Epoch (1970-01-01 00:00:00 GMT)

**Important:** The result is a whole number when the source is a `DATETIME YEAR TO SECOND`, but will be a floating point number when the source is a `DATETIME YEAR TO FRACTION(N)`, to include the fractional part.

```
IMPORT util
MAIN
  DEFINE sec INTEGER, loc DATETIME YEAR TO SECOND
  LET loc = CURRENT YEAR TO SECOND
  LET sec = util.Datetime.toSecondsSinceEpoch( loc )
```
util.Datetime.toUTC
Converts a datetime value to the UTC datetime.

Syntax

```plaintext
util.Datetime.toUTC(
    local DATETIME q1 TO q2
) RETURNING utc DATETIME q1 TO q2
```

1. `local` is the local timezone datetime value.
2. `utc` is the datetime value in UTC.

Usage

The `util.Datetime.toUTC()` method converts the local timezone `DATETIME` value passed as parameter to the "Coordinated Universal Time" (UTC), also known as "Greenwich Mean Time" (GMT).

The `toUTC()` method on local timezone information settings.

Fall/Autumn daylight saving time transition period

Important: The `toUTC()` function cannot determine if the local datetime value represents a time before or after the daylight saving time change, when the value is in the hour of the daylight saving time transition period in the fall (this is for example, the hour 02:00 PM to 03:00 PM on the last Sunday of October in Europe and first Sunday of November in the USA).

Depending on the operating system, the `toUTC()` method can interpret the local time as a Summer time or as a Winter time. In order to get the current system time in UTC, use the `util.Datetime.getCurrentAsUTC()` method.

The `DATETIME` value passed as parameter to the `toUTC()` method is the datetime in the local timezone. However, this value does not contain the GMT offset indicator or daylight saving time information.

When passing local datetime values in the hour of the daylight saving time transition period in the fall (when clocks roll back one hour), the `toUTC()` function cannot determine if the local datetime value represents a point in time before or after the daylight saving time transition occurred. Depending on the operating system, the `toUTC()` method can interpret the local time as a Summer time or as a Winter time.

As a result, the conversion to the UTC time can be mis-interpreted.

For example, in Europe, the fall daylight saving time changes on the 25 of October, at 3:00 PM. The ambiguous period is between 2:00 PM and 3:00 PM (local time). If you pass for example, the datetime value 2015-10-25 02:34:11 to the `toUTC()` method, there is no way for the method to know if this local time is the time before (CEST / UTC+2h) or after (CET / UTC+1h) the daylight saving time change.

This behavior can be illustrated with the following code example:

```plaintext
IMPORT util

MAIN
    DISPLAY "Original UTC Local time (Paris) toUTC(local-time)
             ( toUTC() - Orig UCT )"
    CALL test( "2015-10-24 23:59:59" )
    CALL test( "2015-10-25 00:59:59" )
    CALL test( "2015-10-25 01:59:59" )
    CALL test( "2015-10-25 02:59:59" )
END MAIN
```
FUNCTION test(utc)
  DEFINE utc, loc, utc2 DATETIME YEAR TO SECOND
  LET loc = util.Datetime.toLocalTime(utc)
  LET utc2 = util.Datetime.toUTC(loc)
  DISPLAY SFMT("%1 %2 %3 %4", utc,loc,utc2,utc2-utc)
END FUNCTION

The above code will produce the following output on Linux, with with TZ='Europe/Paris':

<table>
<thead>
<tr>
<th>Original UTC</th>
<th>Local time (Paris)</th>
<th>toUTC(local-time)</th>
<th>( toUTC() - Orig UCT )</th>
</tr>
</thead>
<tbody>
<tr>
<td>00:00:00</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>00:00:00</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>01:00:00</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>00:00:00</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

As you can see, the local time 2015-10-25 02:59:59 is always converted to UTC 2015-10-25 00:59:59.

Example

IMPORT util
MAIN
  DEFINE utc DATETIME YEAR TO SECOND
  LET utc = util.Datetime.toUTC( DATETIME(2015-08-22 15:34:56)
     YEAR TO SECOND)
  DISPLAY "UTC: ", utc
END MAIN

The util.Interval class
The util.Interval class provides INTERVAL data-type related utility methods.

This class is provided in the util C-Extension library; To use the util.Interval class, you must import the util package in your program:

IMPORT util

This class does not have to be instantiated; it provides class methods for the current program.

util.Interval methods
Methods for the util.Interval class.

Table 446: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>util.Interval.format(</td>
<td>Formats an interval value according to format specification.</td>
</tr>
</tbody>
</table>
  value INTERVAL q1 TO q2, |
  fmt STRING |
  ) |
| RETURNING res STRING |
| util.Interval.parse( | Converts a string to a DATETIME value according to a format specification. |
  src STRING, |
  fmt STRING |
Name | Description
--- | ---
| RETURNING res DATETIME q1 TO q2

util.Interval.format
Formats an interval value according to format specification.

**Syntax**

```java
util.Interval.format(
    value INTERVAL q1 TO q2,
    fmt STRING
)
RETURNING res STRING
```

1. `value` is the interval value to be formatted.
2. `fmt` is the format string, as described in Formatting INTERVAL values on page 226.

**Usage**
The `util.Interval.format()` method formats an INTERVAL value according to the format specification.

The format string must be a combination of place holders such as `%Y`, `%m`, `%d`, as described in Formatting INTERVAL values on page 226.

If the source value is NULL the result will be NULL.

**Example**

```java
IMPORT util
MAIN
    DEFINE iv INTERVAL DAY(6) TO MINUTE
    LET iv = "-157 11:23"
    DISPLAY util.Interval.format(iv, "%d %H:%M")
END MAIN
```

util.Interval.parse
Converts a string to a DATETIME value according to a format specification.

**Syntax**

```java
util.Interval.parse(
    src STRING,
    fmt STRING
)
RETURNING res DATETIME q1 TO q2
```

1. `src` is the source string to be parsed.
2. `fmt` is the format specification (see Formatting INTERVAL values on page 226).

**Usage**

The `util.Interval.parse()` method parses a string according to a format specification, to produce an INTERVAL value.

The format specification must be a combination of place holders such as `%Y`, `%m`, `%d`, etc.
The precision of the resulting \texttt{INTERVAL} value depends on the format specification. For example, when using \texttt{"\%Y-\%m"}, the resulting value will be an \texttt{INTERVAL YEAR TO MONTH}.

The method returns \texttt{NULL}, if the source string cannot be converted to an \texttt{INTERVAL} value according to the format specification.

For more details about the supported formats, see Formatting \texttt{INTERVAL} values on page 226.

\begin{center}
\begin{verbatim}
Example

IMPORT util

MAIN
  DEFINE iv INTERVAL DAY(6) TO FRACTION(5)
  LET iv = util.Interval.parse( "-37467 + 23:45:34.12345", "\%d + \%H:\%M:\%S\%F5" )
END MAIN
\end{verbatim}
\end{center}

\textbf{The util.Strings class}

The \texttt{util.Strings} class provides \texttt{STRING} data-type related utility methods.

This class is provided in the \texttt{util C-Extension} library; To use the \texttt{util.Strings} class, you must import the \texttt{util} package in your program:

\begin{center}
\begin{verbatim}
IMPORT util
\end{verbatim}
\end{center}

This class does not have to be instantiated; it provides class methods for the current program.

\textbf{util.Strings methods}

Methods for the \texttt{util.Strings} class.

\begin{center}
\begin{table}
\caption{Class methods}
\begin{tabular}{|l|l|}
\hline
Name & Description \\
\hline
util.Strings.base64Decode( source STRING, filename STRING ) & Decodes a Base64 encoded string and writes the bytes to a file. \\
\hline
util.Strings.base64Encode( filename STRING ) & Converts the content of a file to a Base64 encoded string. \\
& RETURNING result STRING \\
\hline
util.Strings.base64DecodeToString( source STRING ) & Converts the string passed as parameter to a Base64 encoded string. \\
& RETURNING result STRING \\
\hline
util.Strings.base64EncodeFromString( source STRING ) & Decodes a base64 encoded string and returns the corresponding string. \\
\hline
\end{tabular}
\end{table}
\end{center}
util.Strings.urlDecode
Converts the URL-encoded string to a string in the current application locale.

util.Strings.urlEncode
Converts a string from the current codeset to a URL-encoded string.

util.Strings.base64Decode
Decodes a Base64 encoded string and writes the bytes to a file.

**Syntax**

```plaintext
util.Strings.base64Decode(
    source STRING,
    filename STRING
)
```

1. `source` is the Base64 encoded string.
2. `filename` is the name of the file to write to.

**Usage**

The `util.Strings.base64Decode()` method converts the Base64 encoded string passed as first parameter, and writes the bytes to file specified as second parameter.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE base64 STRING
    LET base64 = util.Strings.base64Encode( "picture1.png" )
    DISPLAY base64
    CALL util.Strings.base64Decode( base64, "picture2.png" )
END MAIN
```

util.Strings.base64Encode
Converts the content of a file to a Base64 encoded string.

**Syntax**

```plaintext
util.Strings.base64Encode(
    filename STRING
)
```

1. `filename` is the name of the file to read from.
2. `result` is the resulting Base64 encoded string.
Usage

The `util.Strings.base64Encode()` method reads the content of the file passed as parameter, and converts the bytes to a Base64 encoded string.

**Example**

```java
IMPORT util
MAIN
    DISPLAY util.Strings.base64Encode( "picture.png" )
END MAIN
```

`util.Strings.base64DecodeToString`

Decodes a base64 encoded string and returns the corresponding string.

**Syntax**

```java
util.Strings.base64DecodeToString(
    source STRING
) RETURNING result STRING
```

1. `source` is the Base64 encoded string.
2. `result` is the decoded string.

**Usage**

The `util.Strings.base64DecodeToString()` method converts the Base64 encoded string passed as parameter to an array of bytes, then it converts the byte array to a string representation in the current locale, and returns that string.

If the Base64 source string contains a sequence of bytes that does not represent a valid character in the current application locale, the function returns `NULL`.

**Note:** In contrast to `util.Strings.urlDecode` on page 1965, the original string is not converted from UTF-8 to the application character encoding: The Base64 source string must represent valid characters in the current application locale.

**Example**

```java
IMPORT util
MAIN
    DEFINE base64 STRING
    LET base64 = util.Strings.base64EncodeFromString( "Forêt" )
    DISPLAY base64
    DISPLAY util.Strings.base64DecodeToString( base64 )
END MAIN
```

`util.Strings.base64EncodeFromString`

Converts the string passed as parameter to a Base64 encoded string.

**Syntax**

```java
util.Strings.base64EncodeFromString(
    source STRING
) RETURNING result STRING
```
1. *source* is the source string to convert in Base64.
2. *result* is the resulting Base64 encoded string.

**Usage**

The `util.Strings.base64EncodeFromString()` method first converts the string passed as parameter to an array of bytes, then it converts the array of bytes the a Base64 representation, and returns the resulting Base64 encoded string.

**Note:** In contrast to `util.Strings.urlEncode` on page 1966, the original string is not converted from the application locale to UTF-8, before performing the encoding to Base64: The resulting Base64 encoded string will contain byte sequences representing characters in the current application locale.

**Example**

```java
IMPORT util
MAIN
  DISPLAY util.Strings.base64EncodeFromString( "Forêt" )
END MAIN
```

**util.Strings.urlDecode**

Converts the URL-encoded string to a string in the current application locale.

**Syntax**

```java
util.Strings.urlDecode(  
  source STRING
)  
RETURNING result STRING
```

1. *source* is the URL-encoded source string (UTF-8 bytes).
2. *result* is the resulting Base64 encoded string.

**Usage**

The `util.Strings.urlDecode()` method converts the URL-encoded string passed as parameter to a character string.

The source string must contain ASCII characters and/or `%xx` hexadecimal representation of UTF-8 encoding bytes.

The decoder is error tolerant:

- Alphabetic characters of a `%xx` element can be uppercase or lowercase (%b2 = %B2).
- If the source string contains a set of `%xx` elements that represent a UTF-8 encoded character which is not existing in the current application locale, it will be converted to a `?` question mark.
- If the percent character is not followed by two hexadecimal digits, then a `%` is copied to the result string and the decoder continues at the next character.

**Example**

```java
IMPORT util
MAIN
  DISPLAY util.Strings.urlDecode("abc%C3%A4%E2%82%AC")
END MAIN

Output:
abcÅ
```
util.Strings.urlEncode
Converts a string from the current codeset to a URL-encoded string.

Syntax

```plaintext
util.Strings.urlEncode(
    source STRING
)
RETURNING result STRING
```

1. `source` is the source string to url-encode.
2. `result` is the resulting url encoded string.

Usage

The `util.Strings.urlEncode()` method converts the character string passed as parameter to a URL-encoded string.

All characters not matching `[-_.~a-zA-Z0-9]` are "percent encoded": Percent-encoding involves converting those characters to UTF-8 and representing its corresponding byte values by a percent sign ("%") and a pair of hexadecimal digits.

Example

```plaintext
IMPORT util
MAIN
    DISPLAY util.Strings.urlEncode("abcĀ")
END MAIN

Output:
abc%C3%84%E2%82%AC
```

The `util.Math` class

The `util.Math` class provides basic mathematical functions based on floating point numbers (`FLOAT`).

This class does not have to be instantiated; it provides class methods for the current program.

This class is provided in the `util C-Extension` library; To use the `util.Math` class, you must import the `util` package in your program:

```plaintext
IMPORT util
```

`util.Math` methods

Methods for the `util.Math` class.

Table 448: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<td>Converts an angle measured in radians to an approximately equivalent angle measured in degrees.</td>
</tr>
<tr>
<td><code>util.Math.toRadians( val FLOAT ) RETURNING result FLOAT</code></td>
<td>Converts an angle measured in degrees to an approximately equivalent angle measured in radians.</td>
</tr>
</tbody>
</table>

**util.Math.acos**
Computes the arc cosine of the passed value, measured in radians.

**Syntax**

```
util.Math.acos(
    val FLOAT
) RETURNING result FLOAT
```

1. `val` is a floating point value.

**Usage**

Returns `NULL` if the argument provided is invalid.

**util.Math.asin**
Computes the arc sine of the passed value, measured in radians.

**Syntax**

```
util.Math.asin(
    val FLOAT
) RETURNING result FLOAT
```

1. `val` is a floating point value.

**Usage**

Returns `NULL` if the argument provided is invalid.

**util.Math.atan**
Computes the arc tangent of the passed value, measured in radians.

**Syntax**

```
util.Math.atan(
    val FLOAT
) RETURNING result FLOAT
```

1. `val` is a floating point value.

**Usage**

Returns `NULL` if the argument provided is invalid.
util.Math.cos
Computes the cosine of the passed value, measured in radians.

Syntax

```java
util.Math.cos(
    val FLOAT )
RETURNING result FLOAT
```

1. `val` is a floating point value.

Usage:
Returns `NULL` if the argument provided is invalid.

util.Math.exp
Computes the base-e exponential of the value passed as parameter.

Syntax

```java
util.Math.exp(
    val FLOAT )
RETURNING result FLOAT
```

1. `val` is a floating point value.

Usage
Returns `NULL` if the argument provided on error.

util.Math.pi
Returns the FLOAT value of PI.

Syntax

```java
util.Math.pi()
RETURNING result FLOAT
```

util.Math.pow
Computes the value of `x` raised to the power `y`.

Syntax

```java
util.Math.pow(
    x FLOAT,
    y FLOAT )
RETURNING result FLOAT
```

1. `x` is the value to be raised.
2. `y` is the power operand.

Usage
The function returns `NULL` if one of the argument provided is invalid.
If `x` is negative, the caller should ensure that `y` is an integer value.
util.Math.rand
Returns a positive pseudo-random number.

Syntax

```
util.Math.rand(
    max INTEGER )
RETURNING result INTEGER
```

1.  *max* is the maximum random number that can be generated.

Usage

The **rand()** function returns a pseudo-random integer number between zero and *max*.

**Important:**

The **srand()** function initializes the pseudo-random numbers generator. It must be called before subsequent calls to the **rand()** function. If you do not call the **srand()** function, the **rand()** function will generate the same sequence of numbers for every program execution. The numbers generated by **rand()** can vary according to the operating system.

The maximum random number returned by the **rand()** function is 2,147,483,646.

The **rand()** function returns zero if the argument is lower or equal to 0.

**Example**

```
IMPORT util
MAIN
    DEFINE i SMALLINT
    DISPLAY "Before srand() call:"
    FOR i=1 TO 3
        DISPLAY util.Math.rand(100)
    END FOR
    CALL util.Math.srand()
    DISPLAY "After srand() call:"
    FOR i=1 TO 3
        DISPLAY util.Math.rand(100)
    END FOR
END MAIN
```

(run this example several times)

util.Math.sin
Computes the sine of the passed value, measured in radians.

Syntax

```
util.Math.sin(
    val FLOAT )
RETURNING result FLOAT
```

1.  *val* is a floating point value.

Usage

Returns **NULL** if the argument provided is invalid.
util.Math.sqrt
Returns the square root of the argument provided.

Syntax
```
util.Math.sqrt(
    val FLOAT )
RETURNING result FLOAT
```

1. `val` is a floating point value.

Usage
The function returns `NULL` if the argument provided is invalid.

util.Math.srand
Initializes the pseudo-random numbers generator.

Syntax
```
util.Math.srand()
```

Usage
The `srand()` function initializes the pseudo-random numbers generator. It must be called before subsequent calls to the `rand()` function. If you do not call the `srand()` function, the `rand()` function will generate the same sequence of numbers for every program execution. The numbers generated by `rand()` can vary according to the operating system.

util.Math.tan
Computes the tangent of the passed value, measured in radians.

Syntax
```
util.Math.tan(
    val FLOAT )
RETURNING result FLOAT
```

1. `val` is a floating point value.

Usage
Returns `NULL` if the argument provided is invalid.

util.Math.log
Computes the natural logarithm of the passed value.

Syntax
```
util.Math.log(
    val FLOAT )
RETURNING result FLOAT
```

1. `val` is a floating point value.

Usage
Returns `NULL` if the argument provided is invalid.
util.Math.toDegrees
Converts an angle measured in radians to an approximately equivalent angle measured in degrees.

**Syntax**

```
util.Math.toDegrees(
  val FLOAT )
RETURNING result FLOAT
```

1. `val` is a floating point value to be converted to degrees.

util.Math.toRadians
Converts an angle measured in degrees to an approximately equivalent angle measured in radians.

**Syntax**

```
util.Math.toRadians(
  val FLOAT )
RETURNING result FLOAT
```

1. `val` is a floating point value to be converted to radians.

**The util.JSON class**
The `util.JSON` class provides a basic interface to convert program variable values to/from JSON data.

The `util.JSON` class is provided in the `util` C-Extension library; To use the `util.JSON` class, you must import the `util` package in your program:

```
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

The purpose of the `util.JSON` class is to convert a JSON string from/to a BDL variable, to interface with other software based on the JSON format.

The BDL variable can be a simple variable (defined with a primitive type), a structured variable (`RECORD`), or dynamic array.

It is not possible to modify JSON elements with this class. In order to manipulate JSON objects, use the `util.JSONObject` and `util.JSONArray` classes.

**util.JSON methods**
Methods for the `util.JSON` class.

**Table 449: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

</tr>
</tbody>
</table>

**util.JSON.format**

Formats JSON string with indentation.

**Syntax**

```javascript
util.JSON.format(
    source STRING
)
RETURNING result STRING
```

1. `source` is a string value that contains JSON formatted data.
2. `result` is a string that is well formatted and indented.

**Usage**

The `util.JSON.format()` class method takes a JSON formatted string as parameter and indents the JSON string.

The main purpose of this method is to beautify a JSON data string that is on a single line, by adding line breaks and indentation.

**util.JSON.parse**

Parses a JSON string and fills program variables with the values.

**Syntax**

```javascript
util.JSON.parse(
    source STRING,
    destination ↓ RECORD ↓ DYNAMIC ARRAY ↓)
```

1. `source` is a string value that contains JSON formatted data.
2. `destination` is the variable to be initialized with values of the JSON string.

**Important:** The `dest` record is passed by reference to the method.
**Usage**

The `util.JSON.parse()` class method scans the JSON source string passed as parameter and fills the destination variable members by name.

The destination variable should have the same structure as the JSON source data, it can be a `RECORD` or a `DYNAMIC ARRAY`.

See [JSON to Genero BDL conversion rules](#) on page 1995 for details on how the destination variable is populated when the structures are not identical.

**Example**

```plaintext
IMPORT util

MAIN

DEFINE cust_rec RECORD
    cust_num INTEGER,
    cust_name VARCHAR(30),
    order_ids DYNAMIC ARRAY OF INTEGER
END RECORD

DEFINE js STRING
LET js='{ "cust_num":2735, "cust_name":"McCarlson",
    "order_ids":[234,3456,24656,34561] }'
CALL util.JSON.parse( js, cust_rec )
DISPLAY cust_rec.cust_name
DISPLAY cust_rec.order_ids[4]
END MAIN
```

**util.JSON.proposeType**

Describes the record structure that can hold a given JSON data string.

**Syntax**

```plaintext
util.JSON.proposeType( 
    source STRING )
RETURNING result STRING
```

1. `source` is a string value that contains JSON formatted data.
2. `result` is a string that represents the definition of a `RECORD`.

**Usage**

The `util.JSON.proposeType()` class method takes a JSON formatted string as parameter and generates the `RECORD` definition that corresponds to the source JSON string.

This method is useful to define a record variable that must hold the given JSON string.

**Example**

```plaintext
IMPORT util

MAIN

DEFINE js STRING
LET js='{ "cust_num":2735, "cust_name":"McCarlson",
    "orderids":[234,3456,24656,34561] }'
DISPLAY util.JSON.proposeType( js )
END MAIN

Displays:

```
```
Library reference | 1975

cust_num FLOAT,
cust_name STRING,
orderids DYNAMIC ARRAY OF FLOAT
END RECORD

util.JSON.stringify
Transforms a record variable to a flat JSON formatted string, by including empty records and empty arrays.

Syntax

util.JSON.stringify(
  source ↓ RECORD ↓ DYNAMIC ARRAY ↓ )
RETURNING result STRING

1. source is the program variable to be converted to a JSON string.
2. result is a JSON formatted string created from the source record.

Usage

The util.JSON.stringify() class method takes a RECORD or DYNAMIC ARRAY variable as parameter, and generates the corresponding data string in JSON format, as defined in the [RFC4627] specification.

Important: Unlike util.JSON.stringifyOmitNulls(), empty records (where all members are NULL), and empty arrays will be written in the JSON string.

For more details about FGL to JSON conversion, see Genero BDL to JSON conversion rules on page 1996.

The method raises error -8110 if the JSON string cannot be generated.

Example

IMPORT util
MAIN
  DEFINE cust_rec RECORD
  cust_data RECORD
    cust_num INTEGER,
    cust_name VARCHAR(30),
    cust_phone VARCHAR(20)
  END RECORD,
  order_ids DYNAMIC ARRAY OF INTEGER
  END RECORD
  DEFINE js STRING
  LET cust_rec.cust_data.cust_num = 345
  LET cust_rec.cust_data.cust_name = "McMaclum"
  LET cust_rec.cust_data.cust_name = NULL
  LET cust_rec.order_ids[1] = 4732
  LET cust_rec.order_ids[2] = NULL
  LET cust_rec.order_ids[3] = 2194
  DISPLAY "=== With values:"
  LET js = util.JSON.stringify( cust_rec )
  DISPLAY "1: stringify():\n", util.JSON.format( js )
  LET js = util.JSON.stringifyOmitNulls( cust_rec )
  DISPLAY "2: stringifyOmitNulls():\n", util.JSON.format( js )
  DISPLAY "=== NULLs:"
  INITIALIZE cust_rec TO NULL
  LET js = util.JSON.stringify( cust_rec )
  DISPLAY "3: stringify()\n", util.JSON.format( js )
  LET js = util.JSON.stringifyOmitNulls( cust_rec )
  DISPLAY "4: stringifyOmitNulls()\n", util.JSON.format( js )
Displays following output:

```plaintext
=== With values:
1: stringify():
   
   "cust_data": {
     "cust_num": 345,
   },
   "order_ids": [4732,null,2194
  ]
}
2: stringifyOmitNulls():
   
   "cust_data": {
     "cust_num": 345,
   },
   "order_ids": [4732,null,2194
  ]
}
=== NULLs:
3: stringify():
   
   "cust_data": {
   },
   "order_ids": [     ]
}
4: stringifyOmitNulls():
   
   
```

util.JSON.stringifyOmitNulls
Transforms a record variable to a flat JSON formatted string, by excluding empty records and empty arrays.

**Syntax**

```plaintext
util.JSON.stringifyOmitNulls(
    source ↓ RECORD ↓ DYNAMIC ARRAY ↓ )
RETURNING result STRING
```

1. `source` is the program variable to be converted to a JSON string.
2. `result` is a JSON formatted string created from the source record.

**Usage**

The `util.JSON.stringifyOmitNulls()` class method takes a `RECORD` or `DYNAMIC ARRAY` variable as parameter, and generates the corresponding data string in JSON format, as defined in the [RFC4627] specification.

**Important:** Unlike `util.JSON.stringify()`, empty records (where all members are `NULL`), and empty arrays will **NOT** be written in the JSON string.

For more details about FGL to JSON conversion, see [Genero BDL to JSON conversion rules](link) on page 1996.

The method raises error `-8110` if the JSON string cannot be generated.
Example

IMPORT util
MAIN
  DEFINE cust_rec RECORD
    cust_data RECORD
      cust_num INTEGER,
      cust_name VARCHAR(30),
      cust_phone VARCHAR(20)
    END RECORD,
    order_ids DYNAMIC ARRAY OF INTEGER
  END RECORD
  DEFINE js STRING
  LET cust_rec.cust_data.cust_num = 345
  LET cust_rec.cust_data.cust_name = "McMaclum"
  LET cust_rec.cust_data.cust_name = NULL
  LET cust_rec.order_ids[1] = 4732
  LET cust_rec.order_ids[2] = NULL
  LET cust_rec.order_ids[3] = 2194
  DISPLAY "=== With values:"
  LET js = util.JSON.stringify( cust_rec )
  DISPLAY "1: stringify():\n", util.JSON.format( js )
  LET js = util.JSON.stringifyOmitNulls( cust_rec )
  DISPLAY "2: stringifyOmitNulls():\n", util.JSON.format( js )
  DISPLAY "=== NULLs:"
  INITIALIZE cust_rec TO NULL
  LET js = util.JSON.stringify( cust_rec )
  DISPLAY "3: stringify():\n", util.JSON.format( js )
  LET js = util.JSON.stringifyOmitNulls( cust_rec )
  DISPLAY "4: stringifyOmitNulls():\n", util.JSON.format( js )
END MAIN

Displays following output:

  === With values:
  1: stringify():
  {  
    "cust_data": {  
      "cust_num": 345  
    },  
    "order_ids": [4732,null,2194]  
  }  

  2: stringifyOmitNulls():
  {  
    "cust_data": {  
      "cust_num": 345  
    },  
    "order_ids": [4732,null,2194]  
  }  

  === NULLs:
  3: stringify():
  {  
    "cust_data": {  
    },  
    "order_ids": [ ]  
  }  

  4: stringifyOmitNulls():
  {  

Examples
Example 1: Reading a JSON file

This program reads JSON data from customers.json, parses the line to fill the program variables, converses the program variable back to JSON and writes a formatted JSON string to the standard output.

We assume that the source file contains the list of customers in a single line that can be read with base.Channel.readLine():

```
IMPORT util
MAIN
  DEFINE custlist DYNAMIC ARRAY OF RECORD
    num INTEGER,
    name VARCHAR(40)
  END RECORD
  DEFINE ch base.Channel
  LET ch = base.Channel.create()
  CALL ch.openFile("customers.json","r")
  CALL util.JSON.parse( ch.readLine(), custlist )
  DISPLAY custlist.getLength()
  DISPLAY util.JSON.format( util.JSON.stringify(custlist) )
  CALL ch.close()
END MAIN
```

-- customers.json file:
```
[  { "num":823, "name":"Mark Renbing" }, { "num":234, "name":"Clark Gambler" } ]
```

Note that the JSON file does not contain the name of the dynamic array (custlist), but starts directly with the JSON array in [ ] square braces.

The util.JSONObject class

The util.JSONObject class provides methods to handle an structured data object following the JSON string syntax.

The util.JSONObject class is provided in the util C-Extension library; To use the util.JSONObject class, you must import the util package in your program:

```
IMPORT util
```

A JSONObject is an unordered collection of name/value pairs. The format of a JSON object string is a comma-separated "name":value pairs, wrapped in curly braces. The value can be simple numeric or string value, but it can also be an array of values enclosed in square braces, or a sub-element enclosed in curly braces:

```
{
  "cust_num":2735,
  "cust_name":"McCarlson",
  "order_ids":[234,3456,24656,34561],
  "address": { 
    "street":"34, Sunset Bld",
    "city":"Los Angeles",
    "state":"CA"
  }
}
```

A JSONObject object must be created before usage with one of the class methods like util.JSONObject.create().
The JSONObject class provides methods for accessing, adding/replacing or deleting the values by name with the get(), put() and remove() methods.

The get() method can return a simple value, a util.JSONObject or a util.JSONArray object reference.

The put() method can take a simple value, a RECORD, or an ARRAY as parameter.

If the structure of the JSON object is not known at compile time, you can introspect the elements of the object with the getLength(), getType() and name() methods.

**util.JSONObject methods**
Methods for the util.JSONObject class.

**Table 450: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>

### util.JSONObject.create

Creates a new JSON object.

**Syntax**

```plaintext
util.JSONObject.create()
RETURNING object util.JSONObject
```

**Usage**

The `util.JSONObject.create()` method create a new JSON object.

The new created object must be assigned to a program variable defined with the `util.JSONObject` type.

**Example**

```plaintext
IMPORT util
MAIN
  DEFINE obj util.JSONObject
  LET obj = util.JSONObject.create()
  ...  
END MAIN
```

### util.JSONObject.fromFGL

Creates a new JSON object from a RECORD.

**Syntax**

```plaintext
util.JSONObject.fromFGL(
  source RECORD )
RETURNING object util.JSONObject
```

1. `source` is the RECORD variable used to create the JSON object.
Usage

The `util.JSONObject.fromFGL()` method creates a new JSON object from the `RECORD` variable passed as parameter.

The new created object must be assigned to a program variable defined with the `util.JSONObject` type.

The members of the `RECORD` are converted to name/value pairs in the JSON object.

For more details about FGL to JSON conversion, see Genero BDL to JSON conversion rules on page 1996.

Example

```genero
IMPORT util
MAIN
  DEFINE cust_rec RECORD
    cust_num INTEGER,
    cust_name VARCHAR(30),
    order_ids DYNAMIC ARRAY OF INTEGER
  END RECORD
  DEFINE obj util.JSONObject
  LET cust_rec.cust_num = 345
  LET cust_rec.cust_name = "McMaclum"
  LET cust_rec.order_ids[1] = 4732
  LET cust_rec.order_ids[2] = 9834
  LET cust_rec.order_ids[3] = 2194
  LET obj = util.JSONObject.fromFGL(cust_rec)
  DISPLAY obj.toString()
END MAIN
```

`util.JSONObject.parse`

Parses a JSON string and creates a JSON object from it.

Syntax

```genero
def util.JSONObject.parse(  
  source STRING  
)  
RETURNING result util.JSONObject
```

1. `source` is a string value that contains JSON formatted data.

Usage

The `util.JSONObject.parse()` method scans the JSON source string passed as parameter and creates a JSON object from it.

The new created object must be assigned to a program variable defined with the `util.JSONObject` type.

The source string must follow the JSON format specification. It can contain multi-level structured data, but it must start with a curly brace.

The method raises error `-8109` if the JSON source string is not properly formatted.

Example

```genero
IMPORT util
MAIN
  DEFINE js STRING
  DEFINE obj util.JSONObject
  LET js='{"cust_num":2735, "cust_name":"McCarlson",
    "orderids":[234,3456,24656,34561]}'
  LET obj = util.JSONObject.parse(js)
  DISPLAY obj.toString()
END MAIN
```
util.JSONObject.get
Returns the value corresponding to the specified entry name.

Syntax

```plaintext
util.JSONObject.get(
    name STRING
) RETURNING result result-type
```

1. `name` is the string identifying the JSON object property.
2. `result-type` can be a simple type, a `util.JSONObject` or a `util.JSONArray` object reference.

Usage
The `get()` method returns the value or JSON object corresponding to the element name passed as parameter.

If the element identified by the name is a simple value, the method returns a string. If the element is structured, the method returns a `util.JSONObject` instance and the returned object must be assigned to a program variable defined with the `util.JSONObject` type. If the element is a list of values, the method a `util.JSONArray` instance and the returned object must be assigned to a program variable defined with the `util.JSONArray` type.

A name/value pair can be set with the `put()` method.

Example

```plaintext
IMPORT util
MAIN
    DEFINE obj, sub util.JSONObject
    DEFINE jarr util.JSONArray
    DEFINE rec RECORD
        id INTEGER,
        name STRING
    END RECORD
    DEFINE arr DYNAMIC ARRAY OF INTEGER
    DEFINE x INT
    LET obj = util.JSONObject.create()
        -- Simple value
        CALL obj.put("simple", 234)
        LET x = obj.get("simple")
        -- Sub-element
        LET rec.id = 234
        LET rec.name = "Barton"
        CALL obj.put("record", rec)
        LET sub = obj.get("record")
        -- Array
        LET arr[1] = 234
        LET arr[2] = 2837
        CALL obj.put("array", arr)
        LET jarr = obj.get("array")
    END MAIN
```
util.JSONObject.getLength
Returns the number of name-value pairs in the JSON object.

Syntax

```plaintext
util.JSONObject.getLength()
    RETURNING len INTEGER
```

Usage

The `getLength()` method returns the number of name-value pairs in the JSON object.

This method can be used in conjunction with the `name()` and `getType()` methods to read the entries of a JSON object.

Example

```plaintext
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    DEFINE i INTEGER
    LET obj = util.JSONObject.parse('{"id":123,"name":"Scott"}')
    FOR i=1 TO obj.getLength()
        DISPLAY i, " : ", obj.name(i), " = ", obj.get(obj.name(i))
    END FOR
END MAIN
```

util.JSONObject.getType
Returns the type of a JSON object element.

Syntax

```plaintext
util.JSONObject.getType(
    name STRING )
    RETURNING type STRING
```

1. `name` is the name of the element.

Usage

The `getType()` method returns the JSON data type name corresponding to the entry identified by the name passed as parameter.

This method can be used in conjunction with the `name()` and `getLength()` methods to read the entries of a JSON object.

Possible values returned by this method are:

- **NUMBER**: A numeric value.
- **STRING**: A string value delimited by double quotes.
- **BOOLEAN**: A boolean value (true/false)
- **NULL**: A non-existing element.
- **OBJECT**: A structured object.
- **ARRAY**: An ordered list of elements.

Example

```plaintext
IMPORT util
```
Library reference | 1984

MAIN
DEFINE obj util.JSONObject
LET obj = util.JSONObject.create()
CALL obj.put("id", 8723)
DISPLAY obj.getType("id") -- NUMBER
CALL obj.put("name", "Brando")
DISPLAY obj.getType("name") -- STRING
DISPLAY obj.getType("undef") -- NULL
END MAIN
util.JSONObject.has
Checks if the JSON object contains a specific entry name.
Syntax
util.JSONObject.has(
name STRING )
RETURNING result BOOLEAN
1. name is a string identifying a JSON object property.
Usage
The has() method determines if the JSON object holds a property identified by the name passed as
parameter.
The method returns TRUE if the name/value pair exists in the JSON object.
A name/value pair can be set with the put() method.
util.JSONObject.name
Returns the name of a JSON object entry by position.
Syntax
util.JSONObject.name(
index INTEGER )
RETURNING result STRING
1. index is the index of the name-value pair in the JSON object.
Usage
The name() method returns the entry name in the JSON object at the given position.
The index corresponding to the first name-value pair is 1.
If no entry exists at the given index, the method returns NULL.
This method can be used in conjunction with the getLength() and getType() methods to read the
entries of a JSON object.
Example
IMPORT util
MAIN
DEFINE obj util.JSONObject
DEFINE i INTEGER
LET obj = util.JSONObject.parse('{"id":123,"name":"Scott"}')
FOR i=1 TO obj.getLength()
DISPLAY i, ": ", obj.name(i)


util.JSONObject.put
Sets a name-value pair in the JSON object.

Syntax

```
util.JSONObject.put(
    name STRING,
    value value-type )
```

1. **name** is a string defining the entry name.
2. **value** is the value to be associated to the name.
3. **value-type** can be a simple string or numeric type, a **RECORD** or a **DYNAMIC ARRAY**.

Usage

The `put()` method adds a name-value pair to the JSON object. The first parameter is the name of the element. The second parameter can be a simple string or numeric value, or a complex variable defined as **RECORD** or **DYNAMIC ARRAY**.

If the element exists, the existing value is replaced.

**Example**

```
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    DEFINE rec RECORD
        id INTEGER,
        name STRING
    END RECORD
    DEFINE arr DYNAMIC ARRAY OF INTEGER
    LET obj = util.JSONObject.create()
    CALL obj.put("simple", 234)
    LET rec.id = 234
    LET rec.name = "Barton"
    CALL obj.put("record", rec)
    LET arr[1] = 234
    LET arr[2] = 2837
    CALL obj.put("array", arr)
    DISPLAY obj.toString()
END MAIN
```

util.JSONObject.remove
Removes the specified element in the JSON object.

Syntax

```
util.JSONObject.remove(
    name STRING )
```

1. **name** is the string identifying the JSON object property.

Usage

The `remove()` method deletes a name-value pair identified by the name passed as parameter.
**Example**

```
IMPORT util
MAIN
  DEFINE obj util.JSONObject
  LET obj = util.JSONObject.create()
  CALL obj.put("address", "5 Brando Street")
  CALL obj.remove("address")
  DISPLAY obj.get("address")
END MAIN
```

**util.JSONObject.toFGL**
Fills a record variable with the entries contained in the JSON object.

**Syntax**

```
util.JSONObject.toFGL(
  dest RECORD )
```

1. `dest` is the variable to be set with values of the JSON string.

   **Important:** The `dest` is a RECORD variable is passed by reference to the method.

**Usage**
The `toFGL()` method fills the RECORD variable passed as parameter with the corresponding values defined in the JSON object.

The destination record must have the same structure as the JSON source data. For more details see **JSON to Genero BDL conversion rules** on page 1995.

**Example**

```
IMPORT util
MAIN
  DEFINE cust_rec RECORD
    cust_num INTEGER,
    cust_name VARCHAR(30),
    order_ids DYNAMIC ARRAY OF INTEGER
  END RECORD
  DEFINE js STRING
  DEFINE obj util.JSONObject
  LET js='{"cust_num":2735, "cust_name":"McCarlson",
    "order_ids":[234,3456,24656,34561] }'
  LET obj = util.JSONObject.parse( js )
  CALL obj.toFGL( cust_rec )
  DISPLAY cust_rec.cust_name
  DISPLAY cust_rec.order_ids[4]
END MAIN
```

**util.JSONObject.toString**
Builds a JSON string from the values contained in the JSON object.

**Syntax**

```
util.JSONObject.toString()
RETURNING result STRING
```
Usage

The `toString()` method produces a JSON formatted string from the name-value pairs contained in the JSON object.

Example

```
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    LET obj = util.JSONObject.create()
    CALL obj.put("num", "75263")
    CALL obj.put("name", "Ferguson")
    CALL obj.put("address", "12 Marylon Street")
    DISPLAY obj.toString()
END MAIN
```

The `util.JSONArray` class

The `util.JSONArray` class provides methods to handle an array of values, following the JSON string syntax.

The `util.JSONArray` class is provided in the `util C-Extension` library; To use the `util.JSONArray` class, you must import the `util` package in your program:

```
IMPORT util
```

A `JSONArray` is an sequence of unnamed values. The format of a JSON array string is a list of values wrapped in square braces with commas between the values:

```
[123,546,"abc","def","xyz"]
```

A `JSONArray` object must be created before usage with one of the class methods like `util.JSONArray.create()`.

The `JSONArray` class provides methods for accessing, adding/replacing or deleting the array values by index with the `get()`, `put()` and `remove()` methods.

If the structure of the JSON array is not known at compile time, you can introspect the elements of the array with the `getLength()` and `getType()` methods.

**util.JSONArray methods**

Methods for the `util.JSONArray` class.

**Table 452: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>util.JSONArray.create()</code></td>
<td>Creates a new JSON array object.</td>

</tr>
<tr>
<td><code>util.JSONArray.toString()</code></td>
<td>Builds a JSON string from the elements contained in the JSON array object.</td>
</tr>
</tbody>
</table>

`util.JSONArray.create`
Creates a new JSON array object.

**Syntax**

```java
util.JSONArray.create()
RETURNING array util.JSONArray
```

**Usage**
The `util.JSONArray.create()` method creates a new JSON array object.
The new created object must be assigned to a program variable defined with the `util.JSONArray` type.

**Example**

```java
IMPORT util
MAIN
```
DEFINE arr util.JSONArray
LET arr = util.JSONArray.create()
...
END MAIN

util.JSONArray/fromFGL
Creates a new JSON array object from a DYNAMIC ARRAY.

Syntax

util.JSONArray/fromFGL(
   source DYNAMIC ARRAY
)
RETURNING array util.JSONArray

1. source is the DYNAMIC ARRAY variable used to create the JSON array object.

Usage
The util.JSONArray/fromFGL() method creates a new JSON array from the DYNAMIC ARRAY variable passed as parameter.

The new created object must be assigned to a program variable defined with the util.JSONArray type.

The members of the DYNAMIC ARRAY are converted to a list of name/value pairs in the JSON array object.

The dynamic array can be structured with a RECORD definition: the elements of the array will be converted individually.

For more details about FGL to JSON conversion, see Genero BDL to JSON conversion rules on page 1996.

Example

IMPORT util
MAIN
   DEFINE da DYNAMIC ARRAY OF INTEGER
   DEFINE arr util.JSONArray
   LET da[1] = 123
   LET da[2] = 972
   LET arr = util.JSONArray/fromFGL(da)
   DISPLAY arr.toString()
END MAIN

util.JSONArray.parse
Parses a JSON string and creates a JSON array object from it.

Syntax

util.JSONArray.parse(
   source STRING
)
RETURNING result util.JSONArray

1. source is a string value that contains JSON formatted data as a list of elements delimited by square braces.

Usage
The util.JSONArray.parse() method scans the JSON source string passed as parameter and creates a new JSON array object from it.
The new created object must be assigned to a program variable defined with the `util.JSONArray` type. The source string must follow the JSON format specification. Elements of the list can contain multi-level structured data, but the string must follow the JSON array string syntax `'[ element, ... ]'` with square braces.

The method raises error -8109 if the JSON source string is not properly formatted.

```
Example

IMPORT util
MAIN
    DEFINE da DYNAMIC ARRAY OF INTEGER
    DEFINE arr util.JSONArray
    LET arr = util.JSONArray.parse("[1,2,3,4,5]")
    DISPLAY arr.toString()
END MAIN
```

**util.JSONArray.get**

Returns the value of a JSON array element.

**Syntax**

```
util.JSONArray.get(
    index INTEGER )
RETURNING result result-type
```

1. `index` is the index of the element in the JSON array object.
2. `result-type` can be a simple type, a `util.JSONObject` or a `util.JSONArray` object reference.

**Usage**

The `get()` method returns the value or JSON object corresponding to the element at the given position.

The index corresponding to the first element is 1.

If no element exists at the given index, the method returns NULL.

If the element identified by the name is a simple value, the method returns a string. If the element is structured, the method returns a `util.JSONObject` instance and the returned object must be assigned to a program variable defined with the `util.JSONObject` type. If the element is a list of values, the method a `util.JSONArray` instance and the returned object must be assigned to a program variable defined with the `util.JSONArray` type.

A name/value pair can be set with the `put()` method.

```
Example

IMPORT util
MAIN
    DEFINE arr util.JSONArray
    LET arr = util.JSONArray.parse('[123,"abc",null]')
    DISPLAY arr.get(2) -- abc
END MAIN
```
util.JSONArray.getLength
Returns the number of elements in the JSON array object.

Syntax

util.JSONArray.getLength()
RETURNING length INTEGER

Usage
The getLength() method returns the number of elements in the JSON array object.
This method can be used in conjunction with the get() and getType() method to read elements of a JSON array object.

Example

IMPORT util
MAIN
DEFINE arr util.JSONArray
DEFINE i INTEGER
LET arr = util.JSONArray.parse('[123,8723,9232]')
FOR i=1 TO arr.getLength()
    DISPLAY i, " : ", arr.get(i)
END FOR
END MAIN

util.JSONArray.getType
Returns the type of a JSON array element.

Syntax

util.JSONArray.getType(
    index INTEGER )
RETURNING type STRING

1. index is the ordinal position of the element.

Usage
The getType() method returns the data type name corresponding to the JSON array element at the given position.
The index corresponding to the first element is 1.
This method can be used in conjunction with the getLength() method to read the entries of a JSON array object.
Possible values returned by this method are:
• NUMBER: A numeric value.
• STRING: A string value delimited by double quotes.
• BOOLEAN: A boolean value (true/false)
• NULL: A non-existing element.
• OBJECT: A structured object.
• ARRAY: An ordered list of elements.
Example

IMPORT util
MAIN
  DEFINE arr util.JSONArray
  LET arr = util.JSONArray.parse('[123,"abc",null]')
  DISPLAY arr.getType(1) -- NUMBER
  DISPLAY arr.getType(2) -- STRING
  DISPLAY arr.getType(3) -- NULL
END MAIN

util.JSONArray.put
Sets an element by position in the JSON array object.

Syntax

util.JSONArray.put(
    index INTEGER,
    value value-type )

1. index is the index of the element in the JSON array object.
2. value is the value to be associated to the index.
3. value-type can be a simple string or numeric type, a RECORD or a DYNAMIC ARRAY.

Usage

The put() method sets an element value by position in the JSON array object.

The first parameter is the index of the element. The second parameter can be a simple string or numeric value, or a complex variable defined as RECORD or DYNAMIC ARRAY.

The index corresponding to the first element is 1.

If the element exists, the existing value is replaced.

Example

IMPORT util
MAIN
  DEFINE ja util.JSONArray
  DEFINE rec RECORD
      id INTEGER,
      name STRING
  END RECORD
  DEFINE arr DYNAMIC ARRAY OF INTEGER
  LET ja = util.JSONArray.create()
  CALL ja.put(1, 234)
  LET rec.id = 234
  LET rec.name = "Barton"
  CALL ja.put(2, rec)
  LET arr[1] = 234
  LET arr[2] = 2837
  CALL ja.put(3, arr)
  DISPLAY ja.toString()
util.JSONArray.remove
Removes the specified entry in the JSON array object.

Syntax

util.JSONArray.remove(
    index INTEGER )

1. `index` is the index of the element in the JSON array object.

Usage

The `remove()` method deletes an element in the JSON array object at the given position.

The index corresponding to the first element is 1.

If no element exists at the specified index, the method returns silently.

Example

```
IMPORT util
MAIN
    DEFINE arr util.JSONArray
    LET arr = util.JSONArray.parse('["aa","bb","cc"]')
    CALL arr.remove(2)
    DISPLAY arr.get(2) -- cc
END MAIN
```

util.JSONArray.toFGL
Fills a dynamic array variable with the elements contained in the JSON array object.

Syntax

util.JSONArray.toFGL(
    dest DYNAMIC ARRAY )

1. `dest` is the array variable to be set with values of the JSON string.

   **Important:** The `dest` is a dynamic array passed by reference to the method.

Usage

The `toFGL()` method fills the `DYNAMIC ARRAY` passed as parameter with the corresponding values defined in the JSON array object.

The destination array must have the same structure as the JSON source data. For more details see [JSON to Genero BDL conversion rules](#) on page 1995.

Example

```
IMPORT util
MAIN
    DEFINE ja util.JSONArray
    DEFINE arr DYNAMIC ARRAY OF STRING
    LET ja = util.JSONArray.parse('["aa","bb","cc"]')
    CALL ja.toFGL(arr)
    DISPLAY arr[2] -- bb
END MAIN
```
util.JSONArray.toString
Builds a JSON string from the elements contained in the JSON array object.

Syntax

```javascript
util.JSONArray.toString()
RETURNING result STRING
```

Usage

The `toString()` method produces a JSON formatted string from the elements contained in the JSON array object.

Example

```plaintext
IMPORT util
MAIN
   DEFINE ja util.JSONArray
   LET ja = util.JSONArray.create()
   CALL ja.put(1,"aa")
   CALL ja.put(2,"bb")
   CALL ja.put(3,"cc")
   DISPLAY ja.toString() -- ["aa","bb","cc"]
END MAIN
```

JSON classes

Gives a basic introduction to JSON.

What is JSON?

JSON (JavaScript™ Object Notation) is a well known lightweight data-interchange format for JavaScript™.

A JSON string (or object) is a comma-separated list of name/value pairs, with a : colon separating the key and the value. The list of name/value pairs is enclosed in {} curly braces. The names are delimited by double-quotes. The value can be a single numeric value, a double-quotes string, an array, or a sub-element. Arrays are defined by a comma-separated list of values enclosed in [] square brackets. Sub-elements are defined inside {} curly braces and defineds name/value pairs.

For example:

```json
{
   "cust_num":865234,
   "cust_name":"McCarlson",
   "order_ids":[234,3456,24656,34561],
   "address": {
      "street":"34, Sunset Bld",
      "city":"Los Angeles",
      "state":"CA"
   }
}
```

For more details, see [http://www.json.org](http://www.json.org).

JSON utility classes

The `util` library provides a set of JSON classes to convert JSON documents to/from RECORD and ARRAY variables, and to manipulate JSON objects, if you need to handle JSON objects that do not map to a RECORD or ARRAY:
The util.JSON class on page 1972
The util.JSONObject class on page 1978
The util.JSONArray class on page 1987

JSON to Genero BDL conversion rules
The JSON utility classes implement methods that can fill a Genero BDL RECORD or DYNAMIC ARRAY. This topic describes how JSON data is converted to Genero BDL data.

The destination record or array must have the same structure as the JSON source data.

Each JSON element is assigned to a record member by name, not by position. Elements in the JSON string can be at a different ordinal position as the corresponding members in the destination record.

Element name matching is case-insensitive. For example, if the Genero BDL record member is defined as CustNo, and the JSON data string contains the "custno":999 name/value pair, the value will be assigned. However, since Genero BDL record member names are used as-is to write JSON data, is it strongly recommended to define the Genero BDL records with the exact names used in JSON data string.

Elements in the JSON string that do not match an Genero BDL record member are ignored; no error is thrown if there is no corresponding Genero BDL member.

Genero BDL record members that have no matching JSON element are initialized to NULL.

Important: JSON specifications allow you to define element names with characters that cannot be used in Genero BDL identifiers. For example, a JSON element name can be "customer.name" or "customer:name", however it is not possible to define a program variable with these same names. To work around this issue, define the record elements with underscores in place of unsupported characters, and before assigning the JSON string to the Genero BDL record, replace all element names by the corresponding record member names (using base.StringBuffer.replace to do the replacements).

The JSON value must match the data format of the destination member. If the value does not correspond to the type (for example, if the JSON value is a character string while the target record member is defined with a numeric type), the target member will be set to NULL.

JSON arrays delimited by square brackets are used to fill a program array of the destination record. The destination array should be a dynamic array. If the array is defined as static, the additional elements of the source JSON array will be discarded, while missing elements will be initialized to NULL.

The JSON source string must follow the JSON format specification. It can contain multilevel structured data. If the source string is not well formatted, the runtime system will throw error -8109.

Table 454: JSON to Genero BDL type conversion rules

<table>
<thead>
<tr>
<th>Target Genero BDL type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN</td>
<td>The JSON value should be null, true or false. If the JSON value is a number or a string, the language conversion rules from number/string to BOOLEAN apply.</td>
</tr>
<tr>
<td>TINYINT, SMALLINT, INTEGER, BIGINT, SMALLFLOAT, FLOAT, DECIMAL, MONEY</td>
<td>A JSON number can be assigned to any language numeric type. The limits of the target type cause potential overflows errors. On error the target variable will be initialized to NULL, the parser continues without an error.</td>
</tr>
<tr>
<td>DATE</td>
<td>The JSON value must be a string formatted as &quot;YYYY-MM-DD&quot;.</td>
</tr>
<tr>
<td>DATETIME</td>
<td>If the value is a JSON string, it must be formatted as &quot;YYYY-MM-DD hh:mm:ss.ffffff&quot;,</td>
</tr>
<tr>
<td>Target Genero BDL type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>or represent as an ISO 8601 formatted date-time, in UTC (with Z indicator) or with a timezone offset (+/-hh:mm)). For example: &quot;2013-02-21T15:18:44.456Z&quot;, &quot;2013-02-21T20:18:44.456+02:00&quot;. If the value is a JSON number, it is interpreted as UNIX™ time (seconds since the Epoch 00:00:00 UTC, January 1, 1970). Note that the YYYY-MM-DD hh:mm:ss.fffff format is used to represent the local time. When exchanging date-time values in communications across different time zones, consider to convert date-time values to Coordinated Universal Time (UTC), by using the util.Datetime methods.</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>The JSON valid must be a string formatted as &quot;YYYY-MM&quot; or &quot;DD hh:mm:ss.ffff&quot;, according to interval class of the target variable.</td>
</tr>
<tr>
<td>BYTE</td>
<td>The JSON string value must be encoded in Base64. The Base64 encoding is described in [RFC4648].</td>
</tr>
<tr>
<td>TEXT, CHAR, VARCHAR, STRING</td>
<td>If the value is a number, the result string uses the locale specific decimal point. Any character in the Basic Multilingual Plane (U+0000 through U+FFFF) may be escaped: \u followed by exactly 4 hexadecimal digits ([0-9a-fA-F]). The hexadecimal digits encode the code point. Escaping of characters outside the Basic Multilingual Plane my be escaped by there UTF-16 surrogate pairs. Example: This is the representation of the G clef character (U+1D11E) &quot;\uD834\uDD1E&quot;.</td>
</tr>
</tbody>
</table>

**Genero BDL to JSON conversion rules**

The JSON utility classes implement methods that can convert a Genero BDL RECORD or DYNAMIC ARRAY to a JSON data string. This topic describes how Genero BDL data is converted to JSON data.

To name the JSON elements, the names of the record members are used as defined in the program source. Since JSON is case-sensitive, make sure the names of the Genero BDL record members match exactly the names expected in the resulting JSON data string: CustNo will be different from custNo.

**Important:** JSON specifications allow you to define element names with characters that cannot be used in Genero BDL identifiers. For example, a JSON element name can be "customer.name" or "customer:name", however it is not possible to define a program variable with these same names. To work around this issue, define the record elements with underscores in place of unsupported characters, and before assigning the JSON string to the Genero BDL record, replace all element names by the corresponding record member names (using base.StringBuffer.replace to do the replacements).

When serializing a program variable with the util.JSON.stringify on page 1975 method, empty arrays and empty records (that is where all members are NULL) are written to the resulting string. To avoid empty elements in the JSON string, use the util.JSON.stringifyOmitNulls on page 1976 method instead.

Program array members in the record are converted to JSON arrays delimited by square brackets ([]).
<table>
<thead>
<tr>
<th>Target Genero BDL type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN</td>
<td>Will be serialized with the JSON values <code>true</code> or <code>false</code>.</td>
</tr>
<tr>
<td>TINYINT, SMALLINT, INTEGER, BIGINT, SMALLFLOAT, FLOAT, DECIMAL, MONEY</td>
<td>Any numeric type will be serialized to this form: an optional minus sign (-), a sequence of digits (0-9), containing an optional decimal separator (.), followed by an optional exponent. The exponent has the form (e) followed by an optional minus sign and an sequence of digits. The representation of numeric values does not depend from the current locale. The decimal separator is always a dot (.). <code>&lt;MONEY&gt;</code> values will be represented like <code>&lt;DECIMAL&gt;</code> values: the currency symbol will be omitted.</td>
</tr>
<tr>
<td>DATE</td>
<td>The date value will be formatted as &quot;YYYY-MM-DD&quot; (with double quotes)</td>
</tr>
</tbody>
</table>
| DATETIME               | The date-time value will be formatted as "YYYY-MM-DD hh:mm:ss.fffff" (with double quotes), based on the date-time type definition. For example, a `DATETIME HOUR TO MINUTE` will produce "hh:mm" formatted values.  
Note that the `YYYY-MM-DD hh:mm:ss.fffff` format is used to represent the local time. When exchanging date-time values in communications across different time zones, consider to convert date-time values to Coordinated Universal Time (UTC), by using the `util.Datetime` methods. |
| INTERVAL               | The interval value will be formatted as "YYYY-MM" or "DD hh:mm:ss.fffff" (with double quotes), depending on the interval type definition. |
| BYTE                   | Will be serialized to a Base64 encoded double quoted string. The Base64 encoding is described in [RFC4648]. |
| TEXT, CHAR, VARCHAR, STRING | Character string data will be serialized as a double quoted string with backslash escaping.  
List of characters requiring escaping:  
```
\ \ backslash U+005C
\" quotation mark U+0022
\b backspace U+0008
\f form feed U+000C
\n line feed U+000A
\r carriage return U+000D
\t tab U+0009
```
| Other                  | Any other type will be serialized as a double quoted (*) string. |
**The os package**

These topics cover the classes for the os package.

**The os.Path class**

The os.Path class provides functions to manipulate files and directories on the machine where the program executes.

This class is provided in the util C-Extension library; To use the os.Path extension, you must import the os package in your program:

```python
import os
```

In order to manipulate files, this API gives you access to low-level system functions. Pay attention to operating system specific conventions like path separators. Some functions are OS specific, like `rwx()` which works only on UNIX™ systems.

**os.Path methods**

**Table 456: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>os.Path.atime (fname STRING)</code></td>
<td>Returns the time of the last file access.</td>
</tr>
<tr>
<td><code>os.Path.baseName (filename STRING)</code></td>
<td>Returns the last element of a path.</td>
</tr>
<tr>
<td><code>os.Path.chDir (newdir STRING)</code></td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td><code>os.Path.chOwn (fname STRING, uid INTEGER, gui INTEGER)</code></td>
<td>Changes the UNIX™ owner and group of a file.</td>
</tr>
<tr>
<td><code>os.Path.chRwx (fname STRING, mode INTEGER)</code></td>
<td>Changes the UNIX™ permissions of a file.</td>
</tr>
<tr>
<td><code>os.Path.chVolume (new STRING)</code></td>
<td>Changes the current working volume.</td>
</tr>
<tr>
<td><code>os.Path.copy (source STRING, dest STRING)</code></td>
<td>Creates a new file by copying an existing file.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------------------------------</td>

<td></td>
</tr>
<tr>
<td><strong>os.Path.dirClose</strong></td>
<td>Closes the directory referenced by the directory opened by <code>os.Path.diropen()</code>.</td>
</tr>
<tr>
<td><code>os.Path.dirClose(dirhandle INTEGER)</code></td>
<td></td>
</tr>
<tr>
<td><strong>os.Path.dirFMask</strong></td>
<td>Defines a filter mask for <code>os.Path.dirOpen()</code>.</td>
</tr>
<tr>
<td><code>os.Path.dirFMask(mask INTEGER)</code></td>
<td></td>
</tr>
<tr>
<td><strong>os.Path.dirName</strong></td>
<td>Returns all components of a path excluding the last one.</td>
</tr>
<tr>
<td><code>os.Path.dirName(filename STRING)</code></td>
<td></td>
</tr>
<tr>
<td><code>RETURNING result STRING</code></td>
<td></td>
</tr>
<tr>
<td><strong>os.Path.dirNext</strong></td>
<td>Reads the next entry in the directory opened with <code>os.Path.dirOpen()</code>.</td>
</tr>
<tr>
<td><code>os.Path.dirNext(dirhandle INTEGER)</code></td>
<td></td>
</tr>
<tr>
<td><code>RETURNING direntry STRING</code></td>
<td></td>
</tr>
<tr>
<td><strong>os.Path.dirOpen</strong></td>
<td>Opens a directory and returns an integer handle to this directory.</td>
</tr>
<tr>
<td><code>os.Path.dirOpen(dname STRING)</code></td>
<td></td>
</tr>
<tr>
<td><code>RETURNING dirhandle INTEGER</code></td>
<td></td>
</tr>
<tr>
<td><strong>os.Path.dirSort</strong></td>
<td>Defines the sort criteria and sort order for <code>os.Path.dirOpen()</code>.</td>
</tr>
<tr>
<td><code>os.Path.dirSort(criteria STRING, order INTEGER)</code></td>
<td></td>
</tr>
<tr>
<td><strong>os.Path.executable</strong></td>
<td>Checks if a file is executable.</td>
</tr>
<tr>
<td><code>os.Path.executable(fname STRING)</code></td>
<td></td>
</tr>
<tr>
<td><code>RETURNING result INTEGER</code></td>
<td></td>
</tr>
<tr>
<td><strong>os.Path.exists</strong></td>
<td>Checks if a file exists.</td>
</tr>
<tr>
<td><code>os.Path.exists(fname STRING)</code></td>
<td></td>
</tr>
<tr>
<td><code>RETURNING result INTEGER</code></td>
<td></td>
</tr>
<tr>
<td><strong>os.Path.extension</strong></td>

</tbody>
</table>

### os.Path.atime

Returns the time of the last file access.

#### Syntax

```python
os.Path.atime(
    fname STRING
) RETURNING result STRING
```

1. `fname` is the name of the file.

#### Usage

The function returns a string containing the last access time for the specified file, in the standard format 'YYYY-MM-DD HH:MM:SS'.

If the function fails, it returns `NULL`.

### os.Path.baseName

Returns the last element of a path.

#### Syntax

```python
os.Path.baseName(
    filename STRING
) RETURNING result STRING
```

1. `filename` is the name of the file.

#### Usage

This method extracts the last component of a path provided as argument.

For example, if you pass "/root/dir1/file.ext" as the parameter, it will return "file.ext".

See Example 1: Extracting the parts of a file name on page 2015 for more examples.

### os.Path.copy

Creates a new file by copying an existing file.

#### Syntax

```python
os.Path.copy(
    source STRING,
    dest STRING
) RETURNING result INTEGER
```

1. `source` is the name of the file to copy.
2. `dest` is the destination name of the copied file.
Usage
The function returns TRUE if the file has been successfully copied, FALSE otherwise.

os.Path.chDir
Changes the current working directory.

Syntax

```plaintext
os.Path.chDir(
    newdir STRING
) RETURNING result INTEGER
```

1. `newdir` is the directory to select.

Usage
Use this function to change the current working directory.

The function returns TRUE if the current directory could be successfully selected, FALSE otherwise.

os.Path.chRwx
Changes the UNIX™ permissions of a file.

Syntax

```plaintext
os.Path.chRwx(
    fname STRING,
    mode INTEGER )
RETURNING result INTEGER
```

1. `fname` is the name of the file.
2. `mode` is the UNIX™ permission combination in decimal (not octal!).

Usage
This method can only be used on UNIX™!

Function returns TRUE on success, FALSE otherwise.

The `mode` must be a decimal value which is the combination of read, write and execution bits for the user, group and other part of the UNIX™ file permission. Make sure to pass the `mode` as the decimal version of permissions, not as octal (the chrwx UNIX™ command takes an octal value as parameter). For example, to set `-rw-r--r--` permissions, you must pass `((4+2) *64) + (4 * 8) + 4 ) = 420` to this method.

os.Path.chOwn
Changes the UNIX™ owner and group of a file.

Syntax

```plaintext
os.Path.chOwn(
    fname STRING,
    uid INTEGER,
    gui INTEGER )
RETURNING result INTEGER
```

1. `fname` is the name of the file.
2. `uid` is the user id.
3. `gui` is the group id.
Usage
This method can only be used on UNIX™!
Function returns TRUE on success, FALSE otherwise.

**os.Path.chVolume**
Changes the current working volume.

Syntax

```java
os.Path.chVolume(
    new STRING)
RETURNING result INTEGER
```

1. `new` is the volume to select as the new current working volume.

Usage
To change the current volume to C:

```java
LET result = os.Path.chVolume("C:\")
```

The function returns TRUE if the current working volume could be successfully changed, FALSE otherwise.

**os.Path.delete**
Deletes a file or a directory.

Syntax

```java
os.Path.delete(
    dname STRING)
RETURNING result INTEGER
```

1. `dname` is the name of the file or directory to delete.

Usage
A directory can only be deleted if it is empty.
The function TRUE if the file has been successfully deleted, FALSE otherwise.

**os.Path.dirClose**
Closes the directory referenced by the directory opened by `os.Path.diropen()`.

Syntax

```java
os.Path.dirClose(
    dirhandle INTEGER)
```

1. `dirhandle` is the directory handle of the directory to close.

Usage
This function closes the directory search handle opened with `os.Path.dirOpen()`.
os.Path.dirFMask
Defines a filter mask for os.Path.dirOpen().

Syntax

```plaintext
os.Path.dirFMask(
    mask INTEGER)
```

1. `mask` defines the filter mask.

Usage

When you call this function, you define the filter mask for any subsequent os.Path.dirOpen() call.

By default, all kinds of directory entries are selected by the dirOpen() function. You can restrict the number of entries by using a filter mask.

The parameter of the os.Path.dirFMask() function must be a combination of the following bits:

• 0x01 = Exclude hidden files (.*)
• 0x02 = Exclude directories
• 0x04 = Exclude symbolic links
• 0x08 = Exclude regular files

For example, to retrieve only regular files, you must call:

```plaintext
CALL os.Path.dirFMask( 1 + 2 + 4 )
```

os.Path.dirName
Returns all components of a path excluding the last one.

Syntax

```plaintext
os.Path.dirName(
    filename STRING)
RETURNING result STRING
```

1. `filename` is the name of the file.
2. `result` contains all the elements of the path excluding the last one.

Usage

This method removes the last component of a path provided as argument.

For example, if you pass "/root/dir1/file.ext" as the parameter, it will return "/root/dir1".

See Example 1: Extracting the parts of a file name on page 2015 for more examples.

os.Path.dirNext
Reads the next entry in the directory opened with os.Path.dirOpen().

Syntax

```plaintext
os.Path.dirNext(
    dirhandle INTEGER)
RETURNING dirent STRING
```

1. `dirhandle` is the directory handle of the directory to read.
2. `dirent` is the name of the entry read or NULL if all entries have been read.
Usage
This function returns the next entry of the directory opened with \texttt{os.Path.dirOpen()}.\par

\texttt{os.Path.dirOpen} \par
Opens a directory and returns an integer handle to this directory.\par

Syntax
\begin{verbatim}
\texttt{os.Path.dirOpen}(
    \texttt{dname} \texttt{STRING})
RETURNING \texttt{dirhandle} \texttt{INTEGER}
\end{verbatim}\par

1. \texttt{dname} is the name of the directory.\par
2. \texttt{dirhandle} is the directory handle.\par

Usage
This function creates a handle to scan the elements of a directory.\par
The function returns a value of 0 if it fails to open the directory.\par
Before calling the \texttt{dirOpen()} method, you can define a filter with \texttt{os.Path.dirFMask()}, and a sort order with \texttt{os.Path.dirSort()}.\par

\texttt{os.Path.dirSort} \par
Defines the sort criteria and sort order for \texttt{os.Path.dirOpen()}.\par

Syntax
\begin{verbatim}
\texttt{os.Path.dirSort}(
    \texttt{criteria} \texttt{STRING},
    \texttt{order} \texttt{INTEGER})
\end{verbatim}\par

1. \texttt{criteria} is the sort criteria.\par
2. \texttt{order} defines ascending (1) or descending (-1) order.\par

Usage
When you call this function, you define the sort criteria and sort order for any subsequent \texttt{os.Path.dirOpen()} call.\par
The \texttt{criteria} parameter must be one of the following strings: \par
- "undefined" = No sort. This is the default. Entries are read as returned by the OS functions.\par
- "name" = Sort by file name.\par
- "size" = Sort by file size.\par
- "type" = Sort by file type (directory, link, regular file).\par
- "atime" = Sort by access time.\par
- "mtime" = Sort by modification time.\par
- "extension" = Sort by file extension.\par
When sorting by name, directory entries will be ordered according to the current locale.\par
When sorting by any criteria other than the file name, entries having the same value for the given criteria are ordered by name following the value of the \texttt{order} parameter.
os.Path.executable
Checks if a file is executable.

Syntax

```java
os.Path.executable(
    fname STRING)
RETURNING result INTEGER
```

1. `fname` is the file name.

Usage
The function returns `TRUE` if the file is executable, `FALSE` otherwise.

os.Path.exists
Checks if a file exists.

Syntax

```java
os.Path.exists(
    fname STRING)
RETURNING result INTEGER
```

1. `fname` is the file name.

Usage
The function returns `TRUE` if the file exists, `FALSE` otherwise.

os.Path.extension
Returns the file extension.

Syntax

```java
os.Path.extension(
    fname STRING)
RETURNING result STRING
```

1. `fname` is the file name.

Usage
The function returns the string following the last dot found in `fname`. If `fname` does not have an extension, the function returns `NULL`.

os.Path.fullPath
Returns the canonical equivalent of a path.

Syntax

```java
os.Path.fullPath(
    path STRING)
RETURNING result STRING
```

1. `path` is the path to complete.
Usage

The `os.path.fullPath()` class method takes a path as parameter and resolves extra path separator characters (/ on UNIX™, \ on Windows™), as well as references to current (.) and parent directory (..). The result is called a canonical path.

On UNIX™, symbolic links are not followed. Use the `os.Path.isLink()` method to identify symbolic links.

```
Example

DISPLAY os.Path.fullPath("/home/usr//scott/tmp/..//images")

Resolves to:

/home/usr/scott/images
```

`os.Path.gid`

Returns the UNIX™ group id of a file.

Syntax

```
os.Path.gid(
    fname STRING)
RETURNING id INTEGER
```

1. `fname` is the name of the file.
2. `id` is the group id.

Usage

This method can only be used on UNIX™!

Function returns -1 if it fails to get the user id.

`os.Path.homeDir`

Returns the path to the HOME directory of the current user.

Syntax

```
os.Path.homeDir()
RETURNING homedir STRING
```

1. `homedir` Path to the HOME directory of the user.

`os.Path.isDirectory`

Checks if a file is a directory.

Syntax

```
os.Path.isDirectory (    fname STRING)
RETURNING result BOOLEAN
```

1. `fname` is the file name.

Usage

The function returns TRUE if the file is a directory, FALSE otherwise.
os.Path.isFile
Checks if a file is a regular file.

Syntax

```
os.Path.isFile(
  fname STRING)
RETURNING result BOOLEAN
```

1. `fname` is the file name.

Usage
The function returns `TRUE` if the file is a regular file, `FALSE` otherwise.

os.Path.isHidden
Checks if a file is hidden.

Syntax

```
os.Path.isHidden(
  fname STRING)
RETURNING result BOOLEAN
```

1. `fname` is the file name.

Usage
The function returns `TRUE` if the file is hidden, `FALSE` otherwise.

For example, on UNIX™, files starting with a dot in the file name are considered as hidden when using the `ls` command.

os.Path.isLink
Checks if a file is UNIX™ symbolic link.

Syntax

```
os.Path.isLink(
  fname STRING)
RETURNING result BOOLEAN
```

1. `fname` is the file name.

Usage
The function returns `TRUE` if the files is a symbolic link, `FALSE` otherwise.

This method can only be used on UNIX™!

os.Path.isRoot
Checks if a file path is a root path.

Syntax

```
os.Path.isRoot(
  path STRING)
RETURNING result BOOLEAN
```
1. path is the path to check.

Usage
The function returns TRUE if the path is a root path, FALSE otherwise.
On UNIX™ the root path is '/'.
On Windows™ the root path matches "[a-zA-Z]:\".
os.Path.join
Joins two path segments adding the platform-dependent separator.

Syntax

```java
os.Path.join( begin STRING, end STRING ) RETURNING result STRING
```

1. begin is the beginning path segment.
2. end is the ending path segment.

Usage
Use this method to construct a path with no system-specific code to use the correct path separator:

```java
LET path = os.Path.join(os.Path.homedir(), name)
```
This method returns the ending path segment if it is an absolute path.
If one of the arguments is NULL, the function returns NULL.
os.Path.makeTempName
Generates a temporary file name.

Syntax

```java
os.Path.makeTempName() RETURNING result STRING
```

Usage
This method creates a new temporary file path, with the unique file name, in the temporary directory of the process.
The temporary directory is found according to the type of platform, see DBTEMP environment variable for more details.

Note: If a file is created with the given path, it must be deleted explicitly.
os.Path.mtime
Returns the time of the last file modification.

Syntax

```java
os.Path.mtime( fname STRING) RETURNING result STRING
```
1. `fname` is the name of the file.
2. `result` is the last modification time.

**Usage**

The function returns a string containing the last modification time for the specified file, in the standard format 'YYYY-MM-DD HH:MM:SS'.

If the function fails, it returns `NULL`.

`os.Path.mkDir`

Creates a new directory.

**Syntax**

```java
os.Path.mkDir(
    dname STRING
)
RETURNING result INTEGER
```

1. `dname` is the name of the directory to create.

**Usage**

The function returns `TRUE` if the directory has been successfully created, `FALSE` otherwise.

`os.Path.pathSeparator`

Returns the character used in environment variables to separate path elements.

**Syntax**

```java
os.Path.pathSeparator()
RETURNING result STRING
```

**Usage**

You typically use this method to build a path from two components.

On UNIX™, the path separator is `':'`.

On Windows™, the path separator is `';'`.

`os.Path.pathType`

Checks if a path is a relative path or an absolute path.

**Syntax**

```java
os.Path.pathType(
    path STRING
)
RETURNING result STRING
```

1. `path` is the path to check.

**Usage**

The function returns "absolute" if the path is an absolute path, or "relative" if the path is a relative path.

If the path is `NULL`, the function returns `NULL`. 
os.Path.pwd
Returns the current working directory.

Syntax

```python
os.Path.pwd()
    RETURNING result STRING
```

Usage

This function returns the path of the current working directory.
On a mobile device, this front call returns the current application working directory:

- On Android™, it returns the directory where the program executes.
- On iOS, it returns the "Documents" directory under the application directory.

os.Path.readable
Checks if a file is readable.

Syntax

```python
os.Path.readable(  
    fname STRING)
    RETURNING result INTEGER
```

1. `fname` is the file name.

Usage

The function returns `TRUE` if the file is readable, `FALSE` otherwise.

os.Path.rename
Renames a file or a directory.

Syntax

```python
os.Path.rename(  
    oldname STRING,  
    newname STRING )
    RETURNING result INTEGER
```

1. `oldname` is the current name of the file or directory to be renamed.
2. `newname` is the new name to assign to the file or directory.

Usage

The function returns `TRUE` if the file or directory has been successfully renamed, `FALSE` otherwise.
On UNIX™ platforms, you can rename/move files and directories.
On Microsoft™ Windows™ platforms only files can be renamed/moved. However, on Windows™ you can move files across disks and directories.

os.Path.separator
Returns the character used to separate path segments.

Syntax

```python
os.Path.separator()
```
**Usage**

Use this method to build a path from two components.

On UNIX™, the directory separator is '/'.

On Windows™, the directory separator is '\'.

**os.Path.size**

Returns the size of a file.

**Syntax**

```cpp
os.Path.size(
    fname STRING)
RETURNING result INTEGER
```

1. `fname` is the file name.

**Usage**

The function returns the size in bytes for the specified file.

**os.Path.rootDir**

Returns the root directory of the current working path.

**Syntax**

```cpp
os.Path.rootDir()
RETURNING rootdir STRING
```

1. `rootdir` is the root directory of the current working path.

**Usage**

On UNIX™, it always returns "/".

On Windows™ it returns the current working drive as "[a-zA-Z]:\"

**os.Path.rootName**

Returns the file path without the file extension of the last element of the file path.

**Syntax**

```cpp
os.Path.rootName(
    filename STRING)
RETURNING result STRING
```

1. `filename` is the file path.

**Usage**

This method removes the file extension from the path provided as parameter.

For example, if you pass "/root/dir1/file.ext" as the parameter it will return "/root/dir1/file".

See Example 1: Extracting the parts of a file name on page 2015 for more examples.
os.Path.rwx
Returns the UNIX™ file permissions of a file.

**Syntax**

```plaintext
os.Path.rwx(
    fname STRING)
RETURNING mode INTEGER
```

1. *fname* is the name of the file.
2. *mode* is the combination of permissions for user, group and other.

**Usage**

This method can only be used on UNIX™!

Function returns -1 if it fails to get the permissions.

The *mode* is returned as a decimal value which is the combination of read, write and execution bits for the user, group and other part of the UNIX™ file permission. For example, if a file has the `-rwxr-xr-x` permissions, the method returns `((4+2+1) * 64 + (4+1) * 8) + (4+1) ) = 493`.

os.Path.type
Returns the file type as a string.

**Syntax**

```plaintext
os.Path.type(
    fname STRING)
RETURNING result STRING
```

1. *fname* is the file name.

**Usage**

On UNIX™, this method follows symbolic links. Use the `os.Path.islink()` method to identify symbolic links.

The possible values returned by this method are:

1. *file*: the file is a regular file
2. *directory*: the file is a directory
3. *socket*: the file is a socket
4. *fifo*: the file is a fifo
5. *block*: the file is a block device
6. *char*: the file is a character device

os.Path.uid
Returns the UNIX™ user id of a file.

**Syntax**

```plaintext
os.Path.uid(
    fname STRING)
RETURNING id INTEGER
```

1. *fname* is the name of the file.
2. *id* is the user id.
Usage
This method can only be used on UNIX™!
Function returns -1 if it fails to get the user id.

Function returns -1 if it fails to get the user id.

os.Path.volumes
Returns the available volumes.

Syntax

```python
os.Path.volumes()
RETURNING volumes STRING
```

1. `volumes` contains the list of all available volumes separated by "|".

Usage
To display the list of available volumes, a volume is identified by its letter, followed by a colon and a backslash (:\).

```python
DISPLAY os.Path.volumes()
```

Output example:

```
C:|E:|F:
```

os.Path.writable
Checks if a file is writable.

Syntax

```python
os.Path.writable(
  fname STRING)
RETURNING result INTEGER
```

1. `fname` is the file name.

Usage
The function returns `TRUE` if the file is writable, `FALSE` otherwise.

Examples
Example 1: Extracting the parts of a file name
This program uses the file functions to extract the directory name, the base name, the root name, and the file extension:

```python
IMPORT os
MAIN
  DISPLAY "Dir name   = ", os.Path.dirName(arg_val(1))
  DISPLAY "Base name  = ", os.Path.baseName(arg_val(1))
  DISPLAY "Root name  = ", os.Path.rootName(arg_val(1))
  DISPLAY "Extension = ", os.Path.extension(arg_val(1))
END MAIN
```

Example results:
Table 457: Example results

<table>

</table>

These examples use UNIX™ file names. On Windows™ the result would be different, as the file name separator is a backslash (\).

Example 2: Browsing directories

This program takes a directory path as an argument and scans the content recursively:

```python
IMPORT os

MAIN
  CALL showDir(arg_val(1))
END MAIN

FUNCTION showDir(path)
  DEFINE path STRING
  DEFINE child STRING
  DEFINE h INTEGER
  IF NOT os.Path.exists(path) THEN
    RETURN
```
The com package

The Genero Web Services com package provides classes and methods that allow you to perform tasks associated with creating Services and Clients, and managing the services.

Use the IMPORT statement at the top of the module using this library:

```java
IMPORT com
```

Web services classes
The Web services classes manage Web Services servers.

- The WebService class on page 2017
- The WebOperation class on page 2026
- The WebServiceEngine class on page 2033
- The HTTPServiceRequest class on page 2044

The WebService class
The com.WebService class provides an interface to create and manage Genero Web Services.

The com.WebServices class is used to implement a Web Service on the server.

**Important:** This Web Services class is not supported on GMI mobile devices.

com.WebServices methods
Methods for the com.WebService class.

<td><code>java com.WebService.CreateStatefulWebService ( name STRING, namespace STRING, state state-type ) RETURNING result com.WebService </code></td>
<td>Creates a new object to implement a stateful Web Service.</td>
</tr>
</tbody>
</table>
### Table 459: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>namespace STRING ()</code></td>
<td>RETRUNING result com.WebService</td>
</tr>
</tbody>
</table>

- **createFault**(`fault fault-type, encoded BOOLEAN`) - Creates a new object to implement a Web Service.
- **createHeader**(`header header-type, encoded BOOLEAN`) - Defines the header for the Web Service object.
- **generateWSDL**(`location STRING`) - RETRUNING result xml.DomDocument - Creates a `xml.domDocument` object with the WSDL corresponding to the Web Service object.
- **publishOperation**(`operation com.WebOperation, role STRING`) - Publishes a Web Operation.
- **registerInputHTTPVariable**(`http-in http-in-type`) - Registers the record variable for HTTP input.
- **registerInputRequestHandler**(`funcname STRING`) - Registers the function to be executed on incoming SOAP requests.
- **registerOutputHTTPVariable**(`http-out http-out-type`) - Registers the record variable for HTTP output.
- **registerOutputRequestHandler**(`funcname STRING`) - Registers the function to be executed just before the SOAP response is forwarded to the client.
- **registerWSDLHandler**(`funcname STRING`) - Registers the function to be executed when a WSDL is generated.
- **saveWSDL**(`location STRING`) - RETRUNING result INTEGER - Writes to a file the WSDL corresponding to the Web Service object.
- **setComment** - Defines the comment for the Web Service object.
com.WebService.createFault

Creates a new object to implement a Web Service.

Syntax

```java
createFault(
  fault fault-type,
  encoded BOOLEAN )
```

1. `fault` defines the header for the Web Service object.
2. `fault-type` is a simple data type, a RECORD or an ARRAY.
3. `encoded` specifies the encoding mechanism.

Usage

The `createFault()` method creates a global fault for this Web Service object.

The `fault` parameter can be of any type and defines the SOAP fault in a SOAP response. In case of SOAP fault, the client for this Web Service will receive a variable with the same structure.

When `encoded` is TRUE, the SOAP Section 5 encoding mechanism is used, when FALSE, the XML Schema mechanism is used.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.WebService.createHeader

Defines the header for the Web Service object.

Syntax

```java
createHeader(
  header header-type,
  encoded BOOLEAN )
```

1. `header` defines the header for the Web Service object.
2. `header-type` is a simple data type or a RECORD structure, or an ARRAY.
3. `encoded` specifies the encoding mechanism.

Usage

The `createHeader()` method creates a global header for the current Web Service object.

The Web Service header is defined by the first parameter. This will define SOAP headers exchanged by the client and server.

When `encoded` is TRUE, the SOAP Section 5 encoding mechanism will be used. If FALSE, the XML Schema mechanism will be used.
Important: Since Web Services headers are generally in Document Style, we recommend to set the `encoded` parameter to `FALSE`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```
com.WebService.CreateWebService
Creates a new object to implement a Web Service.
```

**Syntax**

```java
com.WebService.CreateWebService(
    name STRING,
    namespace STRING )
RETURNING result com.WebService
```

1. `name` is the Web Service identifier.
2. `namespace` is the name space for the Web Service name.

**Usage**

The `name` and `namespace` must uniquely identify the Web Service across the entire application, when multiple Web Service programs run on the same server. In theory, `namespace+name` must be unique on the internet.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```
com.WebService.CreateStatefulWebService
Creates a new object to implement a stateful Web Service.
```

**Syntax**

```java
com.WebService.CreateStatefulWebService(
    name STRING,
    namespace STRING,
    state state-type )
RETURNING result com.WebService
```

1. `name` is the Web Service identifier.
2. `namespace` is the name space for the Web Service name.
3. `state` is used to identify the state between the client and server.
4. `state-type` is a regular data type or `RECORD` structure.

**Usage**

The `name` and `namespace` must uniquely identify the Web Service across the entire application, when multiple Web Service programs run on the same server. In theory, `namespace+name` must be unique on the internet.

The `state` variable used to identify the state between the client and the server:
• For a WS-Addressing stateful service, the state variable must be a RECORD with the following structure,
  with the W3CEndpointReference variable attribute:

  RECORD ATTRIBUTES(W3CEndpointReference)  
    address STRING, -- The location of the Web Service (for ex: URL)  
    ref RECORD  
    ... (other members defining the state)  
  END RECORD

• For a stateful service based on HTTP cookies, the state variable must be a simple variable defined with
  a basic data type.

  It is up to the programmer to manage the state variable and to restore the service state from a database.

  When creating a stateful Web Service, all published Web Operations require a session in the client request
  excepted those defined as 'initiateSession'.

  In case of error, the method throws an exception and sets the STATUS variable. Depending on the error,
  a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error
  handling in GWS calls (STATUS) on page 2553.

  com.WebService.generateWSDL
  Creates a xml.DomDocument object with the WSDL corresponding to the Web Service object.

  Syntax

  generateWSDL (  
    location STRING )  
  RETURNING result xml.DomDocument

  1. location is the URL where the Web Service will be deployed.

  Usage

  The generateWSDL() method creates a new xml.DomDocument object containing the WSDL data of
  the Web Service object.

  The URL where the Web Service will be deployed must be specified.

  In case of error, the method throws an exception and sets the STATUS variable. Depending on the error,
  a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error
  handling in GWS calls (STATUS) on page 2553.

  com.WebService.publishOperation
  Publishes a Web Operation.

  Syntax

  publishOperation (  
    operation com.WebOperation,  
    role STRING )

  1. operation is the Web Operation object.
  2. role identifies uniquely the Web Operation.

  Usage

  The publishOperation() method publishes the Web Operation specified by the com.WebOperation
  object passed as parameter.
The *role* identifies the operation, if several operations have the same name, by setting the SOAPAction HTTP header. Usually this parameter is set to NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**com.WebService.registerInputHTTPVariable**

Registers the record variable for HTTP input.

**Syntax**

```plaintext
registerInputHTTPVariable(
    http-in http-in-type )
```

1. *http-in* is the HTTP input record variable.
2. *http-in-type* must be a `RECORD` with following structure:

```plaintext
RECORD
    verb STRING,
    url STRING,
    headers DYNAMIC ARRAY OF RECORD
        name STRING,
        value STRING
END RECORD
END RECORD
```

**Usage**

The `registerInputHTTPVariable()` method registers a program variable with a specific structure, that will be filled with the HTTP request headers when a Web Operation arrives.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**com.WebService.registerInputRequestHandler**

Registers the function to be executed on incoming SOAP requests.

**Syntax**

```plaintext
registerInputRequestHandler(
    funcname STRING )
```

1. *funcname* is the name of a program function.

**Usage**

The `registerInputRequestHandler()` method registers a function to be called when an incoming SOAP request is received and before the SOAP engine has processed it.

The callback function must be defined with a unique parameter of type `xml.DomDocument`, and must return the reference to this object, or `NULL`:

```plaintext
FUNCTION myRequestInputHandler( in )
    DEFINE in xml.DomDocument
    ...
    RETURN in
END FUNCTION
```
The input callback function typically modifies the content of the SOAP input request DOM document object passed as parameter.

When returning `NULL` from the input callback function, the output callback function will be called with the default SOAP fault node, which can then be modified.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`com.WebService.registerOutputHTTPVariable`

Registers the record variable for HTTP output.

**Syntax**

```plaintext
registerOutputHTTPVariable(
  http-out http-out-type )
```

1. `http-out` is the HTTP output record variable.
2. `http-out-type` is a `RECORD` with the following structure:

```plaintext
RECORD
  code INTEGER,
  desc STRING,
  headers DYNAMIC ARRAY OF RECORD
    name STRING,
    value STRING
END RECORD
END RECORD
```

**Usage**

The `registerOutputHTTPVariable()` method registers a program variable with a specific structure, that will be used to fill the HTTP response headers when a Web Operation is completed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`com.WebService.registerOutputRequestHandler`

Registers the function to be executed just before the SOAP response is forwarded to the client.

**Syntax**

```plaintext
registerOutputRequestHandler(
  funcname STRING )
```

1. `funcname` is the name of a program function.

**Usage**

The `registerOutputRequestHandler()` method registers a function to be called just after the SOAP engine has processed the request and before the SOAP response is forwarded to the client.

The output callback function must be defined with a unique parameter of type `xml.DomDocument`, and must return the reference to this object:

```plaintext
FUNCTION myRequestOutputHandler( out )
  DEFINE out xml.DomDocument
  ...
```
RETURN out
END FUNCTION

The output callback function typically modifies the content of the SOAP output request DOM document object passed as parameter.

If NULL was returned from the input callback function, the output callback function will be called with the default SOAP fault node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.WebService.registerWSDLHandler
 Registers the function to be executed when a WSDL is generated.

Syntax

```c
registerWSDLHandler(
    funcname STRING )
```

1. `funcname` is the name of a program function.

Usage

The `registerWSDLHandler()` method registers a function to be called when the WSDL of the current Web Service object is generated.

The callback function must be defined with a unique parameter of type `xml.DomDocument`, and must return the reference to this object:

```c
FUNCTION myWSDLHandler( wsdl )
    DEFINE wsdl xml.DomDocument
    ...
    RETURN wsdl
END FUNCTION
```

The callback function typically modifies the content of the WSDL DOM document object passed as parameter.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.WebService.saveWSDL
 Writes to a file the WSDL corresponding to the Web Service object.

Syntax

```c
saveWSDL(
    location STRING )
RETURNING result INTEGER
```

1. `location` is the URL where the Web Service will be deployed.

Usage

The `saveWSDL()` method writes the WSDL data corresponding to the Web Service object.

The URL where the Web Service will be deployed must be specified.
The name of the file will be the name of the Web Service defined by the *name* parameter passed to the `createWebService()` or `createStatefulWebService()` methods.

The method returns 0 if the file was saved, -1 in case of error.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**com.WebService.setComment**

Defines the comment for the Web Service object.

**Syntax**

```java
setComment(
    comment STRING
)
```

1. *comment* is the description of the Web Service.

**Usage**

The `setComment()` method defines the comment associated to a `com.WebService` object.

The comment will be used when generating the WSDL file, as defined by the standard.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**com.WebService.setFeature**

Defines a feature for the current Web Service object.

**Syntax**

```java
setFeature(
    name STRING,
    value STRING
)
```

1. *name* is the name of the Web Service feature.
2. *value* is the value of the feature.

**Usage**

The `setFeature()` method defines a feature for the current Web Service object by specifying a feature name and a value.

The features names are predefined. The second parameter must a a valid value for the specified feature.

**Table 460: Support Web Service features for the setFeature() method**

<table>
<thead>

</tbody>
</table>
The WebOperation class

The `com.WebOperation` class provides an interface to create and manage the operations of a Genero Web Service.

**Important:** This Web Services class is not supported on GMI mobile devices.

The Web Operation can be created as RPC Style or Document Style. Both RPC/Literal and Doc/Literal Styles are WS-I compliant (standards set by the Web Services Interoperability organization).

RPC Style Service (RPC/Literal) is generally used to execute a function, such as a service that returns a stock option. Document Style Service (Doc/Literal) is generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document; this is the MS. Net default. The input or output RECORD cannot have XMLNamespace attributes set on their members.

Calling the appropriate function to create the desired style is the only difference in your Genero code that creates the service. The remainder of the code that describes the service is the same, regardless of whether you want to create an RPC or Document style of service.

Do not use the `setInputEncoded()` and `setOutputEncoded()` methods, as they will specify the RPC/Encoded Style, which is not recommended (see Choosing a Web Service Style).

Since release 2.0 GWS allows you to create RPC Style and Document Style operations in the same Web Service. However, we do not recommend this, as it is not WS-I compliant.

com.WebOperation methods

Methods for the `com.WebOperation` class.

**Table 461: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

</tbody>
</table>
com.WebOperation.addFault

Adds a fault to the current Web Operation definition.

**Syntax**

```java
addFault(
    fault fault-type,
    wsaction STRING )
```

1. *fault* is a program variable defining the fault.
2. *fault-type* is a simple data type, a **RECORD** or an **ARRAY**.
3. *wsaaction* defines the type of action.

**Usage**

Adds a fault the Web Operation can throw during operation processing, where *fault* is any variable previously created as fault of the `com.WebService` object, and *wsaction* the WS-Addressing action identifier if WS-Addressing is supported. If WS-Addressing is not supported, pass NULL as second parameter.

In case of error, the method throws an exception and sets the *STATUS* variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 2553) on page 2553.

com.WebOperation.addInputHeader

Adds an input header for the current Web Operation definition.

**Syntax**

```java
addInputHeader(
    header header-type )
```

1. *header* is a program variable defining the header.
2. *header-type* is a simple data type, a **RECORD** or an **ARRAY**.

**Usage**

This method adds a header to the Web Operation object for input parameters.

In case of error, the method throws an exception and sets the *STATUS* variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 2553) on page 2553.

com.WebOperation.addOutputHeader

Adds an output header for the current Web Operation definition.

**Syntax**

```java
addOutputHeader(
    header header-type )
```

1. *header* is a program variable defining the header.
2. *header-type* is a simple data type, a **RECORD** or an **ARRAY**.
Usage

This method adds a header to the Web Operation object for input parameters.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.WebOperation.CreateDOCStyle

Creates a new Web Operation object with Document style.

Syntax

```java
com.WebOperation.CreateDOCStyle(
    function STRING,
    operation STRING,
    input RECORD,
    output RECORD)
RETURNING result com.WebOperation
```

1. `function` is the name of the program function to be called to process the XML operation.
2. `operation` is the name of the XML operation.
3. `input` is the variable defining the input parameters of the operation (or NULL if there is none).
4. `output` is the variable defining the output parameters of the operation (or NULL if there is none).

Usage

This method creates a Request-Response Document style com.WebOperation object, where `function` is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.WebOperation.CreateRPCStyle

Creates a new Web Operation object with RPC style.

Syntax

```java
com.WebOperation.CreateRPCStyle(
    function STRING,
    operation STRING,
    input RECORD,
    output RECORD)
RETURNING result com.WebOperation
```

1. `function` is the name of the program function to be called to process the XML operation.
2. `operation` is the name of the XML operation.
3. `input` is the input record defining the input parameters of the operation (or NULL if there is none).
4. `output` is the output record defining the output parameters of the operation (or NULL if there is none).

Usage

This method creates a Request-Response RPC style com.WebOperation object, where `function` is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.WebOperation.CreateOneWayDOCStyle
Creates a new Web Operation object with One-Way Document style.

Syntax

```
com.WebOperation.CreateOneWayDOCStyle(
    function STRING,
    operation STRING,
    input RECORD)
RETURNING result com.WebOperation
```

1. function is the name of the program function to be called to process the XML operation.
2. operation is the name of the XML operation.
3. input is the variable defining the input parameters of the operation (or NULL if there is none).

Usage
This method creates a One-Way DOC style com.WebOperation object, where function is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

There is no output parameter to be returned to the client.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.WebOperation.CreateOneWayRPCStyle
Creates a new Web Operation object with One-Way RPC style.

Syntax

```
com.WebOperation.CreateOneWayRPCStyle(
    function STRING,
    operation STRING,
    input RECORD)
RETURNING result com.WebOperation
```

1. function is the name of the program function to be called to process the XML operation.
2. operation is the name of the XML operation.
3. input is the input record defining the input parameters of the operation (or NULL if there is none).

Usage
This method creates a One-Way RPC Style com.WebOperation object, where function is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

There is no output parameter to be returned to the client.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.WebOperation.initiateSession
Defines the Web Operation as session initiator.

Syntax

```java
initiateSession(
    initiator BOOLEAN )
```

1. `initiator` must be `TRUE` to define a session initiator.

Usage

Pass `TRUE` as parameter to `initiateSession()` in order to define the current Web Operation as a session initiator.

A new session must be instantiated in this operation, and must be returned to the client via the `state` variable defined at service creation.

This method works only for `stateful` web services.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
com.WebOperation.setComment
```

Sets the comment for the Web Operation object.

Syntax

```java
setComment(
    comment STRING )
```

1. `comment` is the comment to be set.

Usage

The `setComment()` method defines a comment to the current Web Operation object.

The comment will appear in the WSDL of the service.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
com.WebOperation.setInputAction
```

Sets the WS-Addressing action identifier of the input operation.

Syntax

```java
setInputAction(
    ident STRING )
```

1. `ident` is the WSA action identifier.

Usage

When WS-Addressing is enabled, this method defines the WS-Addressing action identifier of the input operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
**com.WebOperation.setInputEncoded**

Defines the encoding mechanism for Web Operation input parameters.

**Syntax**

```java
setInputEncoded(
    encoded BOOLEAN)
```

1. *encoded* is a boolean defining the encoding mechanism to be used.

**Usage**

When the parameter is `true`, the SOAP Section 5 encoding mechanism is used, `false` indicates the XML Schema mechanism.

The XML Schema mechanism (`false`) is not recommended.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.

**com.WebOperation.setOutputAction**

Sets the WS-Addressing action identifier of the output operation.

**Syntax**

```java
setOutputAction(
    ident STRING)
```

1. *ident* is the WSA action identifier.

**Usage**

When WS-Addressing is enabled, this method defines the WS-Addressing action identifier of the output operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.

**com.WebOperation.setOutputEncoded**

Defines the encoding mechanism for Web Operation output parameters.

**Syntax**

```java
setOutputEncoded(
    encoded BOOLEAN)
```

1. *encoded* is a boolean defining the encoding mechanism to be used.

**Usage**

When the parameter is `true`, the SOAP Section 5 encoding mechanism is used, `false` indicates the XML Schema mechanism.

The XML Schema mechanism (`false`) is not recommended.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.
The WebServiceEngine class

The `com.WebServiceEngine` class provides an interface to manage the Web Services engine.

**Important:** This Web Services class is not supported on GMI mobile devices.

com.WebServiceEngine methods

Methods for the `com.WebServiceEngine` class.

**Table 463: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>com.WebServiceEngine.Flush()</code> RETURNING status INTEGER</td>
<td>Forces the Web Service engine to immediately flush the response of the web service operation.</td>

<tr>
<td><code>com.WebServiceEngine.ProcessServices (timeout INTEGER) RETURNING status INTEGER</code></td>
<td>Specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.</td>
</tr>
</tbody>
</table>
### com.WebServiceEngine.Flush

Forces the Web Service engine to immediately flush the response of the web service operation.

**Syntax**

```plaintext
com.WebServiceEngine.Flush()
RETURNING status INTEGER
```

**Usage**

The `com.WebServiceEngine.flush()` class method allows to return the response inside a high-level web service operation, before the end of the web service function.

When this method is used, any other web operation output parameter changes are ignored.

The `status` returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of `com.WebServicesEngine` on page 2042

**Note:** The return status of the `com.WebServiceEngine.flush()` method has the same meaning as a status returned by `com.WebServiceEngine.ProcessServices()`, with the additional status code -32, meaning that the flush method has been called outside a web operation execution context.

**Note:** `com.WebServiceEngine.ProcessServices()` and `com.WebServiceEngine.HandleRequest()` can return the status code of -31, meaning that the flush function has been called in the last executed web operation.

### Example:

In this code example, the `flush()` method is used to force the response of the web service operation.

```plaintext
DEFINE echoBoolean_in, echoBoolean_out RECORD
   a_boolean BOOLEAN ATTRIBUTES(XMLName="Boolean")
END RECORD

MAIN
   DEFINE ret INTEGER
   ...
   WHILE true
      LET ret = com.WebServiceEngine.ProcessServices(-1)
      CASE ret
         WHEN 0
            DISPLAY "Request automatically processed."
         WHEN -31
            DISPLAY "Operation has been flushed."
         ...
      END CASE
   END WHILE
   ...
END MAIN

FUNCTION echoBoolean()
```
DEFINE ret INTEGER
-- Assign output parameter with input parameter
LET echoBoolean_out.a_boolean = echoBoolean_in.a_boolean
-- Immediate flush of web operation
LET ret = com.WebServiceEngine.flush()
IF ret != 0 THEN
    DISPLAY "ERROR Code : ",ret
    EXIT PROGRAM (1)
END IF
-- Changing the output parameters after flush() would have no effect.
END FUNCTION

com.WebServiceEngine.GetHTTPServiceRequest
Get a handle for an incoming HTTP service request.

Syntax

```java
com.WebServiceEngine.GetHTTPServiceRequest (timeout INTEGER)
RETURNING result com.HTTPServiceRequest
```

1. `timeout` is the timeout in seconds.

Usage

The `com.WebServiceEngine.GetHTTPServiceRequest()` class method returns a `com.HTTPServiceRequest` object to handle an incoming HTTP request, or `NULL` if there was no request during the given period of time.

The `timeout` parameter defines the time in seconds to wait for an incoming request. A value of -1 means infinite wait. When the timeout occurs, the method returns `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

Any new call to this function will raise an error until the previous HTTP request was handled by sending a response back to the client, or destroyed.

The error -15575 can be thrown if the GAS disconnects the Web Services program.

URLs are sent in UTF-8 on the network, if the web services server is not able to convert UTF-8 URLs back to fglrun locale charset, error -15552 will be thrown. As a general advice, run you WS server program in UTF-8.

Example

```java
TRY
    WHILE true
        LET req = com.WebServiceEngine.getHTTPServiceRequest(-1)
        IF req IS NULL THEN
            DISPLAY "HTTP request timeout...: ", CURRENT YEAR TO FRACTION
        ELSE
            CALL req.sendTextResponse(200,NULL,"It works")
        END IF
    END WHILE
CATCH
    IF status == -15575 THEN
        DISPLAY "Disconnected : ",SQLCA.SQLERRM
```
com.WebServiceEngine.GetOption

Returns the value of a Web Service engine option.

Syntax

```java
com.WebServiceEngine.GetOption(
    option STRING )
RETURNING result STRING
```

1. `option` is the name of the option to queried.

Usage

The `com.WebServiceEngine.GetOption()` class method returns the current value of the given the Web Services engine option.

See WebServiceEngine options on page 2040 for the supported options.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

com.WebServiceEngine.HandleRequest

Get a handle for an incoming HTTP service request.

Syntax

```java
com.WebServiceEngine.HandleRequest (
    timeout INTEGER, 
    status INTEGER )
RETURNING result com.HTTPServiceRequest
```

1. `timeout` is the timeout in seconds.
2. `status` is an `INTEGER` variable receiving the method execution status.

Usage

The `com.WebServiceEngine.HandleRequest()` class method returns a `com.HTTPServiceRequest` object to handle an incoming HTTP request, or `NULL` if there was no request during the given period of time.

The `timeout` parameter defines the time in seconds to wait for an incoming request. A value of -1 means infinite wait.

- If there is no request in the given period of time, or if there is an error, the status code is updated by reference, and a `NULL` object is returned.
- If the request is intended to a registered web service, it is processed automatically. The status code is updated by reference and a `NULL` object is returned.
- If the request isn't dedicated to a registered web service, a status code of value 1 is returned by reference, and a valid instance of an `com.HTTPServiceRequest` object, immediately usable to handle the incoming request, is returned.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

Any new call to this function will raise an error until the previous HTTP request was handled by sending a response back to the client, or destroyed.

The status returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of com.WebServicesEngine on page 2042

Note: If the com.WebServiceEngine.Flush() method is used, the return status handling must be done in the web operation function, while com.WebServiceEngine.HandleRequest() will return the code -31, to indicated that a flush was done.

The error -15575 can be thrown if the GAS disconnects the Web Services program.

URLs are sent in UTF-8 on the network, if the web services server is not able to convert UTF-8 URLs back to fglrun locale charset, error -15552 will be thrown. As a general advice, run you WS server program in UTF-8.

com.WebServiceEngine.ProcessServices
Specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

Syntax

```java
    timeout INTEGER
)
RETURNING status INTEGER
```

1. timeout is the timeout in seconds.

Usage

The com.WebServiceEngine.ProcessServices() class method specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

The timeout parameter defines the wait period for an HTTP input request, to process an operation of one of the registered Web Services. The value -1 specifies an infinite waiting time.

The status returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of com.WebServicesEngine on page 2042

The execution status is typically handled in a CASE / END CASE block, to treat all possible execution cases. For a complete example of execution status handling, see Process the requests on page 2485.

Note: If the com.WebServiceEngine.Flush() method is used, the return status handling must be done in the web operation function, while com.WebServiceEngine.ProcessServices() will return the code -31, to indicated that a flush was done.

Get a handle for an incoming HTTP service request.

Syntax

```java
com.WebServiceEngine.SetFaultCode(
    code STRING,
    code_ns STRING
)
```

1. code is the timeout in seconds.
2. `code_ns` is the timeout in seconds.

**Usage**

The `com.WebServiceEngine.SetFaultCode()` class method defines a user SOAP Fault code to be returned to the client, where `code` is the mandatory SOAP Fault code and `code_ns` is the mandatory code namespace.

This method must be called inside a Web Service operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**Syntax**

```java
com.WebServiceEngine.SetFaultCode(
    code STRING
)
```

1. `fault` is the published fault.

**Usage**

The `com.WebServiceEngine.SetFaultDetail()` class method defines the published SOAP Fault to be returned to the client when operation has finished, where `fault` is one of the published variables defined as Fault for that operation.

This method must be called inside a Web Service operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**Syntax**

```java
com.WebServiceEngine.SetFaultDetail(
    fault STRING
)
```

1. `desc` is the description of the fault.

**Usage**

The `com.WebServiceEngine.SetFaultString()` class method defines a user SOAP Fault description to be returned to the client, where `desc` contains the description of the fault.

This method must be called inside a Web Service operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**Syntax**

```java
com.WebServiceEngine.SetFaultString(
    desc STRING
)
```
Sets an option for the Web Service engine.

Syntax

```java
com.WebServiceEngine.SetOption(
    option STRING,
    value STRING )
```

1. `option` is the name of the option to set.
2. `value` is the value of the option to set.

Usage

The `com.WebServiceEngine.SetOption()` class method configures the Web Services engine with options.

See WebServiceEngine options on page 2040 for the supported options.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`com.WebServiceEngine.RegisterService`

Registers a service in the engine.

Syntax

```java
com.WebServiceEngine.RegisterService(
    service com.WebService )
```

1. `service` is the service object to register.

Usage

The `com.WebServiceEngine.RegisterService()` class method registers the `com.WebService` object passed as parameter.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`com.WebServiceEngine.Start`

Starts the Web Service engine.

Syntax

```java
com.WebServiceEngine.Start()
```

Usage

The `com.WebServiceEngine.Start()` class method starts the engine for all registered Web Services.

If you run the Web Services server program in standalone mode, you must set `FGLAPPSERVER`. If you run the Web Services server program through the Genero Application Server, the `FGLAPPSERVER` variable is automatically set by the Genero Application Server. Do NOT manually set `FGLAPPSERVER` in this case.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
WSDL generation options notes
These notes should be reviewed prior to WSDL generation.

1. For the DECIMAL(5,2) data type, when wsdl_decimalsize is TRUE, the generated WSDL file contains the total size and the size of the fractional part of the decimal:

   ```xml
   <types>
   <schema xmlns="http://www.w3.org/2001/XMLSchema">
   <simpleType name="echoDecimal5_2_a_dec5_2_out_FGLDecimal">
   <restriction base="decimal">
   <totalDigits value="5" />
   <fractionDigits value="2" />
   </restriction>
   </simpleType>
   </schema>
   </types>
   <message name="echoDecimal5_2">
   <part name="dec5_2" type="f:echoDecimal5_2_a_dec5_2_in_FGLDecimal" />
   </message>
   ```

   When wsdl_decimalsize is FALSE, the total size and the size of the fractional part are not mentioned:

   ```xml
   <message name="echoDecimal5_2">
   <part name="dec5_2" type="xsd:decimal" />
   </message>
   ```

2. If the WSDL file does not contain the size, the client application has no way of knowing the size. In this case, a default value for the size is generated. For example, the exported server type DECIMAL(5,2) becomes a DECIMAL(32) on the client side.

3. It is better to keep the options wsdl_arraysize, wsdl_stringsize and wsdl_decimalsize set to TRUE so that the client program can do exact type mapping. The default for all three options is TRUE.

4. When setting a facet constraint attribute on a simple data type, the generation of the WSDL will take this attribute into account even if an option has been set to perform the opposite.

5. When setting one facet constraint attribute, all of the default constraint attributes won't be generated anymore unless you specify them as facet constraint attributes.

WebServiceEngine options

Table 464: Options for the com.WebServiceEngine

<table>
<thead>
<tr>
<th>Flag</th>
<th>Client or Server</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>readwritetimeout</td>
<td>Client</td>
<td>Defines the default maximum time in seconds a client, a HTTP request/response and a TCP request/response have to wait before raising an error that the server doesn't return or accept data. A value of -1 means infinite wait. The default is -1.</td>
</tr>
<tr>
<td>connectiontimeout</td>
<td>Client</td>
<td>Defines the default maximum time in seconds a client, a HTTPRequest and a TCRequest have to wait for the establishment of a connection with a server. A value of -1 means infinite wait.</td>

### Table 469: Object methods: Outgoing multipart request

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>setResponseMultipartType(type STRING, start STRING, boundary STRING)</code></td>
<td>Sets HTTP response in multipart mode of given type.</td>
</tr>
<tr>
<td><code>addResponsePart(part-object com.HTTPPart)</code></td>
<td>Adds a new part to the HTTP root part response.</td>
</tr>
</tbody>
</table>

**Syntax**

```java
addResponsePart(part-object com.HTTPPart)
```

**Usage**

Adds a new part to the HTTP root part response. It will be sent after root part has been processed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 2553) on page 2553.

**Syntax**

```java
beginXmlRequest()
```

**Usage**

 Starts an HTTP streaming request.
**RETURNING reader xml.StaxReader**

1. **reader** is a new `xml.StaxReader` object that will be used for streaming.

**Usage**

The `beginXmlRequest()` method starts the streaming HTTP request and returns a `xml.StaxReader` object ready to read the XML from the client.

Supported methods are PUT and POST.

The request Content-Type header must be of the form `*/xml` or `/*/+xml`. For example: `application/xhtml+xml`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

**Syntax**

```java
beginXmlRequest(
    code INTEGER,
    desc STRING)
RETURNING writer xml.StaxWriter
```

1. **code** is the status code of the response.
2. **desc** is the description of the response.
3. **writer** is a new `xml.StaxWriter` the will be used to write the HTTP body.

**Usage**

The `beginXmlResponse()` method starts a HTTP streaming response by sending the a status (**code**) and description (**desc**), followed by the headers previously set, and returns a `xml.StaxWriter` object ready to send XML as the HTTP body.

If the request failed to be read, its content will be discarded; for example, when a request is not well formatted.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `/*/+xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is **NULL**, a default description according to the status code is sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

**com.HTTPServiceRequest.beginXmlResponse**

Starts an HTTP streaming response.
Terminates an HTTP streaming request.

Syntax

```
endXmlRequest(  
    reader xml.StaxReader  )
```

1. `reader` is the `xml.StaxReader` object used for streaming.

Usage

The `endXmlRequest()` method ends the streaming HTTP request by closing the `xml.StaxReader` object passed as parameter.

The `reader` object must be created with the `beginXmlRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

```
com.HTTPServiceRequest.endXmlResponse
```

Terminates an HTTP streaming response.

Syntax

```
endXmlResponse(  
    writer xml.StaxWriter  )
```

1. `writer` is the `xml.StaxWriter` used to write the HTTP body.

Usage

The `endXmlResponse()` method terminates the HTTP streaming response by closing the `xml.StaxWriter` object created by `beginXmlResponse`.

The body of the request is discarded.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

```
com.HTTPServiceRequest.getURL
```

Returns the URL of the HTTP service request.

Syntax

```
getURL()  
    RETURNING result STRING
```
Usage
The `getURL()` method returns the entire URL request containing the host, port, document and query string.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

URLs are sent in UTF-8 on the network. If the query part of the URL cannot be converted from UTF-8 to the fglrun locale charset, STATUS will be set to `-15552`. In this case, the document part of the URL is available, but the query string must be retrieved through `HTTPServiceRequest.readFormEncodedRequest()`. As a general advice, run your WS server program in UTF-8.

### com.HTTPServiceRequest.getMethod

Returns the HTTP method of the service request.

**Syntax**

```java
getMethod()
RETURNING result STRING
```

### Usage

The `getMethod()` method returns the HTTP method of the request (GET, POST, PUT, HEAD, DELETE).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### com.HTTPServiceRequest.getRequestVersion

Returns the HTTP version of the service request.

**Syntax**

```java
getRequestVersion()
RETURNING result STRING
```

### Usage

The `getRequestVersion()` method returns the HTTP version of the request (1.0 or 1.1).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### com.HTTPServiceRequest.getRequestHeader

Returns the value of an HTTP header.

**Syntax**

```java
getRequestHeader( name STRING )
RETURNING result STRING
```

1. `name` is the name of an HTTP header.
**Usage**

The `getRequestHeader()` method returns the value of the HTTP header specified by the `name` parameter, or `NULL` if there is not found.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
com.HTTPServiceRequest.getRequestHeaderCount
Returns number of request headers.
```

**Syntax**

```java
getRequestHeaderCount ()
RETURNING result INTEGER
```

**Usage**

The `getRequestHeaderCount()` method returns the entire URL request containing the host, port, document and query string.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
com.HTTPServiceRequest.getRequestHeaderName
Returns a request header name by position.
```

**Syntax**

```java
getRequestHeaderName (index INTEGER )
RETURNING result STRING
```

1. `index` is the ordinal position of the header.

**Usage**

The `getRequestHeaderName()` method returns the name of the header at the given position.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
com.HTTPServiceRequest.getRequestHeaderValue
Returns a request header value by position.
```

**Syntax**

```java
getRequestHeaderValue (index INTEGER )
RETURNING result STRING
```

1. `index` is the ordinal position of the header.

**Usage**

The `getRequestHeaderValue()` method returns the value of the header at the given position.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.

**com.HTTPServiceRequest.getRequestMultipartType**

Returns the multipart type of an incoming request.

**Syntax**

```java
getRequestMultipartType()  
RETURNING type STRING
```

**Usage**

Returns the multipart type of an incoming request, returns NULL if not a multipart request.

**com.HTTPServiceRequest.getRequestPart**

Returns the HTTPPart object at the specified index position.

**Syntax**

```java
getRequestPart(  
idx INTEGER)  
RETURNING part-object com.HTTPPart
```

1. `idx` is the index position.

**Usage**

Returns the HTTPPart object at the specified index position.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.

Can raise error -15554 (Index is out of bounds).

**com.HTTPServiceRequest.getRequestPartCount**

Returns the number of additional multipart elements.

**Syntax**

```java
getRequestPartCount()  
RETURNING num INTEGER
```

**Usage**

The root multipart is handled via standard `readTextRequest()`, `readXmlRequest()`, `readDataRequest()` and `beginXmlRequest()`.

The number of parts is only available when the entire request has been read.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.
com.HTTPServiceRequest.getRequestPartFromContentID
Returns the HTTPPart object of the given Content-ID value.

Syntax

```java
getRequestPartFromContentID(
   id STRING
) RETURNING part-object com.HTTPPart
```

1. `id` is a Content-ID value.

Usage

Returns the HTTPPart object of the given Content-ID value, returns NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPServiceRequest.hasRequestKeepConnection
Returns TRUE if the connection remains after sending a response.

Syntax

```java
hasRequestKeepConnection()
RETURNING result BOOLEAN
```

Usage

The hasRequestKeepConnection() method returns whether the request expect the connection to stay open after the sending of the response.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPServiceRequest.readDataRequest
Returns the body of a request into a BYTE.

Syntax

```java
readDataRequest(
   body BYTE
)
```

1. `body` is the BYTE variable that will be filled with the request body.

Usage

The readDataRequest() method returns the body of the request in a BYTE.

Supported methods are PUT and POST.

The BYTE variable must be located in memory, and will be filled with the request body. The existing content of the BYTE will be discarded.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.
The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

com.HTTPServiceRequest.readFileRequest

Returns the body of a request into a file.

Syntax

```java
readFileRequest()
RETURNING filename STRING
```

1. `filename` the absolute path to the file containing the HTTP response.

Usage

The `readFileRequest()` method returns the body of the request into a file on the disk.

The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file will be the basename found in the HTTP Content-Disposition Header, if this basename is not specified, the filename will be created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form: `/tmp/ABC/filename_index.ext`, where `index` represents the number of files with the same name on disk.

Supported methods are PUT and POST.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

com.HTTPServiceRequest.readFormEncodedRequest

Returns the string of a GET request with UTF-8 conversion option.

Syntax

```java
readFormEncodedRequest(utf8 BOOLEAN)
RETURNING result STRING
```

1. `utf8` defines if the string must be decoded to the current charset.

Usage

The `readFormEncodedRequest()` method returns the query of a POST "application/x-www-form-urlencoded" request or the query string of a GET request, decoded according to HTML4 or XFORM if `utf8` is TRUE.

**Note:** If the result string contains `&` or `=` XForms special characters, these are doubled as follows: `na&me=va==lue`

If the `utf8` parameter is TRUE, the decoded query string is translated from UTF-8 to the current character set. This may lead to a conversion error.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.
com.HTTPServiceRequest.readTextRequest
Returns the request body as a plain string.

Syntax

```plaintext
readTextRequest ()
     RETURNING result STRING
```

Usage

The `readTextRequest()` method returns the body of the request as a string.
Supported methods are PUT and POST.

The request Content-Type header can be of any form */*. For example: `application/json`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

com.HTTPServiceRequest.readXmlRequest
Returns the request body as an XML document.

Syntax

```plaintext
readXmlRequest ()
     RETURNING result xml.DomDocument
```

Usage

The `readXmlRequest()` method returns the request as an entire XML document, contained in a `xml.DomDocument` object.

Supported methods are PUT and POST.

The request Content-Type header must be of the form */xml or */+xml. For example: `application/xhtml+xml`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

com.HTTPServiceRequest.sendDataResponse
Sends an HTTP response with data of a `BYTE` variable.

Syntax

```plaintext
sendDataResponse (   
    code INTEGER, 
    desc STRING, 
    data BYTE )
```

1. `code` is the status code of the response.
2. `desc` is the description of the response.
3. **data** is the **BYTE** variable containing the data to be sent.

**Usage**

The `sendDataResponse()` method performs the HTTP response by sending the status (**code**) and description (**desc**), followed by the headers previously set and binary data contained in the **BYTE** program variable as body.

It is important for the server to return a correct status **code**, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server should send an HTTP response with the code of 400 (Bad Request). See [HTTP status codes (wikipedia)](http://example.com) for more details about common HTTP response codes.

The **data** parameter is defined as a **BYTE** and must be located in memory and not **NULL**, otherwise the operation fails.

The default Content-Type header is `application/octet-stream`, but it can be changed to any other mime type. For example: `image/jpeg`.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is **NULL**, a default description according to the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](http://example.com) on page 2553.

The **INT_FLAG** variable is checked during GWS API call to handle program interruptions, for more details, see [ Interruption handling in GWS calls (INT_FLAG)](http://example.com) on page 2553.

**送给文件响应**

**Syntax**

```java
sendFileResponse(
    code INTEGER,
    desc STRING,
    filepath STRING
)
```

1. **code** is the status code of the response.
2. **desc** is the description of the response.
3. **filepath** is the path the file containing the data to be send.

**Usage**

The `sendFileResponse()` method performs the HTTP response by sending the status (**code**) and description (**desc**), followed by the headers previously set and the data contained in the specified file as body.

It is important for the server to return a correct status **code**, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server should send an HTTP response with the code of 400 (Bad Request). See [HTTP status codes (wikipedia)](http://example.com) for more details about common HTTP response codes.

If not defined by programmer, the HTTP headers are automatically set as follows:

- **Content-Type** is defined according to the file name extension. If the file extension is not recognized, **Content-Type** defaults to `application/octet-stream`. 
Note: File extensions to Content-Type mapping can be customized in the file FGLDIR/lib/wse/mime.cfg.

• Content-Disposition is set with the base name of the given filename as follows: attachment; filename="basename".

For example, when calling the method as follows:

```text
CALL server.sendFileResponse( 200, NULL, "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP headers of the response will look like:

```text
Content-Type: image/jpg
Content-Disposition: attachment; filename="logo.jpg"
```

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is NULL, a default description according to the status code is sent.

New incoming requests can be retrieved again with the
```java
com.WebServiceEngine.GetHTTPServiceRequest()
```
method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See [Error handling in GWS calls (STATUS)](page 2553).

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see [Interruption handling in GWS calls (INT_FLAG)] on page 2553.

```java
com.HTTPServiceRequest.sendResponse
```
Sends and HTTP response without body.

**Syntax**

```java
sendResponse (  
    code INTEGER,  
    desc STRING )  
```

1. `code` is the status code of the response.
2. `desc` is the description of the response.

**Usage**

The `sendResponse()` method performs the HTTP response by sending the a status (`code`) and description (`desc`), followed by the headers previously set, without a body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server should send an HTTP response with the code of 400 (Bad Request). See [HTTP status codes (wikipedia)] for more details about common HTTP response codes.

If the description is NULL, a default description according to the status code is sent.

New incoming requests can be retrieved again with the
```java
com.WebServiceEngine.GetHTTPServiceRequest()
```
method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See [Error handling in GWS calls (STATUS)] on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see [Interruption handling in GWS calls (INT_FLAG)] on page 2553.
com.HTTPServiceRequest.sendTextResponse
Sends and HTTP response with data from a plain string.

**Syntax**

```java
sendTextResponse(
    code INTEGER,
    desc STRING,
    data STRING )
```

1. `code` is the status code of the response.
2. `desc` is the description of the response.
3. `data` is the string containing the data to be sent.

**Usage**

The `sendTextResponse()` method performs the HTTP response by sending the status (`code`) and description (`desc`), followed by the headers previously set, and text data contained in the string as body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server should send an HTTP response with the code of 400 (Bad Request). See [HTTP status codes (wikipedia)](https://en.wikipedia.org/wiki/List_of_HTTP_status_codes) for more details about common HTTP response codes.

The default Content-Type header is `text/plain`, but it can be changed if of the form `*/*`. For example: `application/json`.

Automatic conversion from locale to user-defined charset is performed when possible, otherwise throws an exception.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is `NULL`, a default description according to the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [*Error handling in GWS calls (STATUS)*](#) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see [*Interuption handling in GWS calls (INT_FLAG)*](#) on page 2553.

com.HTTPServiceRequest.sendXmlResponse
Sends and HTTP response with data from a XML document object.

**Syntax**

```java
sendXmlResponse(
    code INTEGER,
    desc STRING,
    data xml.DomDocument )
```

1. `code` is the status code of the response.
2. `desc` is the description of the response.
3. `data` is the XML document containing the data to be sent.
Usage

The `sendXmlResponse()` method performs the HTTP response by sending the a status (`code`) and
description (`desc`), followed by the headers previously set, and the XML data contained in the passed
`xml.DomDocument` object as body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the
client may fail to interpret the response. For instance, if the request is malformed, the server should send
an HTTP response with the code of 400 (Bad Request). See [HTTP status codes](https://en.wikipedia.org/wiki/List_of_HTTP_status_codes) for more
details about common HTTP response codes.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `*/+xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same
size.

If the description is `NULL`, a default description according to the status code is sent.

New incoming requests can be retrieved again with the

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error,
a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error
handling in GWS calls (STATUS)](https://docs.oracle.com/cd/E19792-01/821-1872/gwsapi/r8211872.htm) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details,
see [Interruption handling in GWS calls (INT_FLAG)](https://docs.oracle.com/cd/E19792-01/821-1872/gwsapi/r8211872.htm) on page 2553.

**Syntax**

```java
setResponseCharset(
    charset STRING
)
```

1. `charset` is the HTTP response character set.

Usage

The `setResponseCharset()` method defines the character set to use when sending an HTTP response.

The server must send a response in a character set that the client understands.

If the response character set is not defined by `setResponseCharset()`, the same character set as the
client request is used, or the implicit ISO-8859-1 charset is used if the character is not defined by the client
request.

The method must be called before sending the response with one of `sendResponse`,
`sendTextResponse`, `sendXmlResponse`, or `beginXmlResponse` and `endXmlResponse` methods.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error,
a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error
handling in GWS calls (STATUS)](https://docs.oracle.com/cd/E19792-01/821-1872/gwsapi/r8211872.htm) on page 2553.

**Syntax**

```java
setResponseHeader(
    name STRING,
    value STRING
)
```

Usage

The `setResponseHeader()` method defines a header for the HTTP response.
value STRING }

1. name is the name of a header to define.
2. value is the value of a header to define.

Usage

The setResponseVersion() method sets (or replaces) the name and value of a HTTP response header.

The Content-Length header cannot be set, because it is computed internally according to the body size.

The method must be called before sending the response with one of sendResponse, sendTextResponse, sendXmlResponse, or beginXmlResponse and endXmlResponse methods.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPServiceRequest.setResponseMultipartType

Sets HTTP response in multipart mode of given type.

Syntax

setResponseMultipartType(
    type STRING,
    start STRING,
    boundary STRING )

1. type is one of the following:
   • form-data: Browser Xform with attachment
   • mixed: Parts are independent
   • related: Parts are dependent (Required for SOAP)
   • alternative: Parts are different type of a same document
   • or any other type
   • NULL: switch multipart mode off
2. start is the Content-ID value of root multipart document. Must be ASCII. (optional)
3. boundary is the string used as multipart boundary. Must be ASCII. (optional)

Usage

Sets HTTP response in multipart mode of given type. Calling one of the standard request method will send the HTTP response as given multipart type, even if no other part has been set.

The root HTTP part must be handled via the standard HTTPServiceRequest methods such as sendTextRequest(), sendXmlRequest(), sendDataRequest() and BeginXmlResponse().

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPServiceRequest.setResponseVersion

Defines the HTTP response version.

Syntax

setResponseVersion(
    version STRING )
1. *version* is the HTTP response version.

**Usage**

The `setResponseVersion()` method defines the HTML response version (1.0 or 1.1).

If not set, the same version as the request is used.

The method must be called before sending the response with one of `sendResponse`, `sendTextResponse`, `sendXmlResponse`, or `beginXmlResponse` and `endXmlResponse` methods.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**HTTP classes**

The HTTP classes manage HTTP client network operations on the client side.

- The `HTTPRequest` class on page 2061
- The `HttpResponse` class on page 2078
- The `HTTPPart` class on page 2085

**The `HTTPRequest` class**

The `com.HTTPRequest` class provides an interface to perform asynchronous XML and TEXT requests over HTTP for a specified URL, with additional XML streaming possibilities, on the client side.

The `STATUS` variable is set to zero after a successful method call.

**com.HTTPRequest methods**

Methods for the `com.HTTPRequest` class.

| **getResponse()**  
  RETURNING result com.HTTPResponse | Waits and returns the response produced by one of request methods. |

Table 474: Object methods of com.HTTPRequest : Multipart methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| **addPart** (  
  *p* com.HTTPPart ) | Adds a new part to the HTTP root part request. |
| **setMultipartType** (  
  *type* STRING,  
  *start* STRING,  
  *boundary* STRING ) | Switch HTTPRequest in multipart mode of given type. |

**com.HTTPRequest.addPart**

Adds a new part to the HTTP root part request.

**Syntax**

```
addPart ( p com.HTTPPart )
```

1. *p* is the HTTPPart object.
Usage

Adds a new part to the HTTP root part request. This part is sent after root part has been processed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### com.HTTPRequest.beginXmlRequest

Starts a streaming HTTP request.

**Syntax**

```
beginXmlRequest()
  RETURNING writer xml.StaxWriter
```

1. `writer` is the `xml.StaxWriter` to be used to write the HTTP request.

**Usage**

The `beginXmlRequest()` starts a streaming HTTP request and returns an `xml.StaxWriter` object ready to send XML to the server.

Supported methods are PUT and POST.

The default Content-Type header is `text/xml`, but it can be changed if of the form */xml or */**+xml. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553

### com.HTTPRequest.clearAuthentication

Removes user-defined authentication.

**Syntax**

```
clearAuthentication()
```

**Usage**

Removes user-defined authentication.

If an `authenticate` entry exists in the FGLPROFILE file, it will be used for authentication, even if the user-defined authentication was removed.

**Important:** The iOS HTTP stack doesn't provide a simple way to handle authentication. The GMI front-end uses the global iOS credential management system, that keeps credential value of previous request according to host and realm, until the keep-alive session is closed. Therefore, doing a `clearAuthentication()` on iOS devices is not working immediately.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### com.HTTPRequest.clearHeaders

Removes all user-defined HTTP request headers.

**Syntax**

```java
clearHeaders()
```

**Usage**

Removes all user-defined HTTP request headers defined with the `setHeader()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPRequest.Create

Creates an new HTTPRequest object from a URL.

**Syntax**

```java
com.HTTPRequest.Create(
    url STRING )
RETURNING result com.HTTPRequest
```

1. `url` is the URL for the HTTP request.

**Usage**

Creates an `com.HTTPRequest` object by providing a mandatory URL with HTTP or HTTPS as protocol.

The `url` parameter can be an identifier of an URL mapping with an optional `alias://` prefix. See FGLPROFILE Configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPRequest.doDataRequest

Performs the request by sending binary data.

**Syntax**

```java
doDataRequest(
    data BYTE )
```

1. `data` is the binary data.

**Usage**

Performs the request by sending binary data contained in the `BYTE` variable.

Supported methods are PUT and POST.

The `BYTE` must be located in memory and not `NULL` otherwise operation fails.

The default Content-Type header is `application/octet-stream`, but it can be changed to any other mime type. For example: `image/jpeg`.

In HTTP 1.1, if the body size is greater than 32k, the request will be sent in several chunks of the same size.
This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2070 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse` on page 2069 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

`com.HTTPRequest.doFileRequest`

Performs the request by sending data contained in a file.

### Syntax

```java
doFileRequest (/filepath STRING )
```

1. `filepath` is the path to the file containing the data to be send.

### Usage

Performs the request by sending data contained in the file passed as parameter. The data is sent as is without any further conversion.

Supported methods are PUT and POST.

If not defined by programmer, the HTTP headers are automatically set as follows:

- **Content-Type** is defined according to the file name extension. If the file extension is not recognized, `Content-Type` defaults to `application/octet-stream`.
  
  **Note:** File extensions to `Content-Type` mapping can be customized in the file `FGLDIR/lib/wse/mime.cfg`.

- **Content-Disposition** is set with the base name of the given `filename` as follows: `attachment; filename="basename"`.

For example, when calling the method as follows:

```java
CALL request.doFileRequest( "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP headers of the POST or PUT will look like:

```plaintext
Content-Type: image/jpeg
Content-Disposition: attachment; filename="logo.jpg"
```

In HTTP 1.1, if the body size is greater than 32k, the request will be sent in several chunks of the same size.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2070 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse` on page 2069 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

**com.HTTPRequest.doFormEncodedRequest**

Performs an "application/x-www-form-urlencoded forms" encoded query.

**Syntax**

```java
doFormEncodedRequest (query STRING, utf8 BOOLEAN )
```

1. `query` is a list of name/value pairs separated by an `&`.
2. `utf8` defines if the query string is UTF-8 encoded.

**Usage**

The `doFormEncodedRequest()` method performs request with an "application/x-www-form-urlencoded forms" encoded query.

Supported methods are GET and POST.

The `query` string is a list of name/value pairs separated by an ampersand (`&`). For example:

```text
name1=value1&name2=value2&name3=value3
```

**Note:** If you need to URL-encode the separator characters `&` and `=`, double them as following: `na&&me=va==lue`.

If the `utf8` parameter is `TRUE`, the query string is encoded in UTF-8 as specified in XForms1.0, otherwise in ASCII as specified in HTML4.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2070 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse` on page 2069 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

**com.HTTPRequest.doRequest**

Performs the HTTP request.

**Syntax**

```java
doRequest ()
```

**Usage**

The `doRequest()` method performs the HTTP request.

Supported methods are GET, HEAD and DELETE.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2070 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going
on, use the `com.HTTPRequest.getLocalResponse` on page 2069 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

**com.HTTPRequest.doTextRequest**

Performs the request by sending an entire string at once.

**Syntax**

```
doTextRequest (  
  data STRING  )
```

1. `data` is a string containing the request.

**Usage**

Performs the request by sending an entire string at once.

Supported methods are PUT and POST.

The default Content-Type header is `text/plain`, but it can be changed if of the form `*/*`. For example: `application/json`.

Automatic character set conversion from the application locale to the user-defined charset is performed. In case of conversion error, the method throws an exception.

**Note**: To avoid character conversion problems when sending text over HTTP, consider setting the same user-define character set as the program defined by the application locale (assuming that the server understands the client application character set).

In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2070 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse` on page 2069 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

**com.HTTPRequest.doXmlRequest**

Performs the request by sending an entire XML document at once.

**Syntax**

```
doXmlRequest (  
  data xml.DomDocument  )
```

1. `data` is the XML document containing the data to be sent.
Usage

The `doXmlRequest()` method performs the request by sending the entire passed `xml.DomDocument` at once.

Supported methods are PUT and POST.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `*/+xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.

The character set used to send the XML data is defined by the encoding attribute in the XML document prolog. It is recommended that you define the HTTP request character set to `NULL` with the `setCharSet()` method, or that you use the same character set that was set in the XML Document.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse()` method to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse()` method to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

`com.HTTPRequest.endXmlRequest`

Terminates a streaming HTTP request.

Syntax

```java
endXmlRequest(
    writer xml.StaxWriter
)
```

1. `writer` is the `xml.StaxWriter` used to write the HTTP request.

Usage

The `endXmlRequest()` method terminates a streaming HTTP request by closing the `xml.StaxWriter` object that was created with the `beginXmlRequest()` method.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse()` method to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse()` method to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

`com.HTTPRequest.getAsyncResponse`
When available, returns the response produced by one of request methods.

Syntax

```java
getAsyncResponse()
RETURNING result com.HTTPResponse
```

Usage

If a response is available, the `getAsyncResponse()` method returns a `com.HTTPResponse` object corresponding to the response that was produced by a call to one of the request methods: `doRequest()`, `doTextRequest()`, `doXmlRequest()`, `doFormEncodedRequest()`, or `beginXmlRequest()` and `endXmlRequest()`.

Unlike `getResponse()`, the `getAsyncResponse()` method is non-blocking: it returns immediately and does not stop the program flow when waiting for a response.

The method returns `NULL` if the HTTP response was not yet received from the server.

This method is typically called just after a `do*Request()` call, and if the returned value is `NULL`, it is called again after a short period of time, to check for a response. Within a dialog, use an `ON IDLE` block to issue a `getAsyncRequest()` every seconds for example.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

```java
com.HTTPRequest.getResponse
```

Waits and returns the response produced by one of request methods.

Syntax

```java
getResponse()
RETURNING result com.HTTPResponse
```

Usage

The `getResponse()` method waits for a response from the server and returns a `com.HTTPResponse` object corresponding to the response that was produced by a call to one of the request methods: `doRequest()`, `doTextRequest()`, `doXmlRequest()`, `doFormEncodedRequest()`, or `beginXmlRequest()` and `endXmlRequest()`.

**Note:** On iOS, a long running HTTP request will display a message box, to let the user cancel the request. If the user cancels the HTTP request, the error `-15578` will be raised. This error can be trapped with `TRY/CATCH`.

Unlike `getAsyncResponse()`, the `getResponse()` method is blocking: it stops the program flow until the HTTP response is received from the server.

Define a response timeout with the `com.HTTPRequest.setTimeOut` method.

**Note:** On iOS devices, when using this method, it is not possible to distinguish different timeouts for the connection and for read/write operation, defined respectively by the `setConnectionTimeOut()` and `setTimeOut()` methods. If both timeouts are defined, the longest timeout will be used for the connection and read/write operations.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

**com.HTTPRequest.removeHeader**
Removes an HTTP header for the request according to a name.

**Syntax**

```java
removeHeader(
    name STRING )
```

1. `name` is the HTTP header name to remove.

**Usage**

The `removeHeader()` method deletes an HTTP header identified by `name`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**com.HTTPRequest.setAuthentication**
Defines the user login and password to authenticate to the server.

**Syntax**

```java
setAuthentication(
    login STRING,
    pass STRING,
    scheme STRING,
    realm STRING )
```

1. `login` is the login name.
2. `pass` is the password.
3. `scheme` defines the method to be used during authentication.
4. `realm` defines the realm.

**Usage**

The `setAuthentication()` method defines the mandatory user login and password to authenticate to the server.

The `scheme` parameter defines the method to be used during authentication. The supported values for the `scheme` parameter are Anonymous, Basic and Digest. The default is Anonymous.

An optional `realm` can be specified.

With Anonymous or Digest authentication, you must re-send the request if you get a 401 or 407 HTTP return code (authorization required)

If a user-defined authentication is set and there is an authenticate entry for this URL in the FGLPROFILE file, the user-defined authentication has priority.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
com.HTTPRequest.setAutoReply
Defines the auto reply option for response methods.

Syntax

```java
setAutoReply (reply BOOLEAN)
```

1. `reply` defines auto-reply when `TRUE`.

Usage

The `setAutoReply()` method defines whether `getResponse()` or `getAsyncResponse()` will automatically perform another HTTP GET request if response contains HTTP Authentication, Proxy Authentication or HTTP redirect data.

Available for GET method and the HTTP HEAD method.

The default is `TRUE`.

**Important:** On iOS devices, `setAutoReply()` is ignored for redirection in synchronous requests: The iOS HTTP stack does not allow to set an auto reply option when doing synchronous requests.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPRequest.setCharset
Defines the character set used when sending text or XML.

Syntax

```java
setCharset (charset STRING)
```

1. `charset` is the character set to use.

Usage

Defines the character set used when sending an HTTP request.

By default, no character set information will be transmitted in the HTTP header. This is also the case when specifying `NULL` as parameter for this method.

If no character set is specified in HTTP headers, ISO8859-1 will implicitly be used as defined by the HTTP standards.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPRequest.setConnectionTimeOut
Defines the timeout for the establishment of the connection.

Syntax

```java
setConnectionTimeOut (timeout INTEGER)
```

1. `timeout` is the number of seconds.
Usage
The setConnectionTimeOut() method sets the time value in seconds to wait for the establishment of the connection, before a break.

The value of -1 means infinite wait.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPRequest.setHeader
Sets an HTTP header for the request.

Syntax

```java
setHeader(
    name STRING,
    value STRING )
```

1. `name` is the HTTP header name.
2. `value` is the HTTP header value.

Usage
The setHeader() method defines an HTTP header with a `name` and `value` for the request.

If a header exists with the same name, it is replaced with the new value.

Setting a header after the body has been sent, or if a streaming operation has been started, will only be taken into account when a new request is reissued.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPRequest.setKeepConnection
Defines if connection is kept open if a new request occurs.

Syntax

```java
setKeepConnection(
    keep BOOLEAN )
```

1. `keep` defines if the connection is kept.

Usage
The setKeepConnection() method defines whether the connection should stay open if a new HTTP request occurs.

The default is FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPRequest.setMaximumResponseLength
Defines the maximum size in Kbyte of a response.

Syntax

```java
setMaximumResponseLength(
    length INTEGER )
```

1. `length` is the maximum size in Kbytes.

Usage

The `setMaximumResponseLength()` method sets the maximum authorized size in Kbytes of the whole response (including headers, body and all control characters), before a break.

The value of -1 means no limit.

**Note:** Setting the maximum response length is ignored for synchronous requests in a Genero Mobile for iOS (GMI) app: The iOS HTTP stack does not allow you to set a maximum response length when doing synchronous requests.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
com.HTTPRequest.setMethod
Sets the HTTP method of the request.
```

Syntax

```java
setMethod(
    method STRING )
```

1. `method` is the HTTP method of the request.

Usage

The `setMethod()` method defines the HTTP method of the request.

Supported methods are GET, PUT, POST, HEAD and DELETE.

The default is GET.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
com.HTTPRequest.setMultipartType
Switch HTTPRequest in multipart mode of given type.
```

Syntax

```java
setMultipartType(
    type STRING,
    start STRING,
    boundary STRING )
```

1. `type` is one of the following:
   - form-data: Browser Xform with attachment
   - mixed: Parts are independent
   - related: Parts are dependent (Required for SOAP)
• alternative: Parts are different type of a same document
• or any other type
• NULL: switch multipart mode off

2. start is the Content-ID value of root multipart document. (optional)
3. boundary is the string used as multipart boundary. (optional)

Usage
Switch HTTPRequest in multipart mode of given type. Calling one of the standard request method will send the HTTP request as given multipart type, even if no other part has been set.

Important: Multipart HTTP requests is not supported on GMI mobile devices.

The root HTTP part is the part handled via the standard HTTPRequest methods such as doTextRequest(), doXmlRequest(), doDataRequest() and beginXmlRequest().

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPRequest.setTimeOut

Defines the timeout for a reading or writing operation.

Syntax

```java
setTimeOut(
    timeout INTEGER
)
```

1. timeout specifies the number of seconds.

Usage

The setTimeOut() method defines a delay in seconds, to wait for a HTTP request read or write operation. If the operation is not terminated after the timeout, it returns immediately with an error.

Use the value of -1 to define an infinite timeout.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPRequest.setVersion

Sets the HTTP version of the request.

Syntax

```java
setVersion(
    version STRING
)
```

1. version is the HTTP version of the request.

Usage

The setVersion() method defines the HTTP version of the request.

Accepted versions are 1.0 and 1.1 (only these two versions are supported).

The default is 1.1.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

Examples

Examples using methods of the com.HTTPRequest class.

Example 1: HTTP GET request

```
IMPORT com

MAIN
DEFINE req com.HTTPRequest
DEFINE resp com.HTTPResponse
TRY
    LET req = com.HTTPRequest.Create("http://localhost:8090/MyPage")
    # Set additional HTTP header with name 'MyHeader', and value 'High Priority'
    CALL req.setHeader("MyHeader","High Priority")
    CALL req.doRequest()
    LET resp = req.getResponse()
    IF resp.getStatusCode() != 200 THEN
        DISPLAY "HTTP Error ("||resp.getStatusCode()||")",
        resp.getStatusDescription()
    ELSE
        DISPLAY "HTTP Response is : ",resp.getTextResponse()
    END IF
CATCH
    DISPLAY "ERROR :",STATUS||" ("||SQLCA.SQLERRM||")"
END TRY
END MAIN
```

Example 2: XForms HTTP POST request

```
IMPORT com
IMPORT xml

MAIN
DEFINE req com.HTTPRequest
DEFINE resp com.HTTPResponse
DEFINE doc xml.DomDocument
TRY
    LET req = com.HTTPRequest.Create("http://localhost:8090/MyProcess")
    CALL req.setMethod("POST") # Perform an HTTP POST method
    # Param1 value is 'hello', Param2 value is 'how are you ?'
    CALL req.doFormEncodedRequest("Param1=hello&Param2=how are you ",FALSE)
    LET resp = req.getResponse()
    IF resp.getStatusCode() != 200 THEN
        DISPLAY  "HTTP Error ("||resp.getStatusCode()||")",
        resp.getStatusDescription()
    ELSE
        # Expect a returned content type of the form */xml
        LET   doc = resp.getXmlResponse()
        DISPLAY   "HTTP XML Response is : ",doc.saveToString()
    END IF
CATCH
    DISPLAY "ERROR :",STATUS||" ("||SQLCA.SQLERRM||")"
END TRY
END MAIN
```
Example 3 : Streaming HTTP PUT request

```plaintext
IMPORT com
IMPORT xml

MAIN
DEFINE req com.HTTPRequest
DEFINE resp com.HTTPResponse
DEFINE writer xml.StaxWriter
TRY
  LET req = com.HTTPRequest.Create("http://localhost:8090/MyXmlProcess")
  CALL req.setMethod("PUT") # Perform an HTTP PUT method
  CALL req.setHeader("MyHeader","Value of my header")
  # Retrieve an xml.StaxWriter to start xml streaming
  LET writer = req.beginXmlRequest()
  CALL writer.startDocument("utf-8","1.0",true)
  CALL writer.comment("My first XML document sent in streaming with
genero")
  CALL writer.startElement("root")
  CALL writer.attribute("attr1","value1")
  CALL writer.endElement()
  CALL writer.endDocument()
  CALL req.endXmlRequest(writer) # End streaming request
  LET resp = req.getResponse()
  IF resp.getStatusCode() != 201 OR resp.getStatusCode() != 204 THEN
    DISPLAY "HTTP Error ("||resp.getStatusCode()||")",
    resp.getStatusDescription()
  ELSE
    DISPLAY "XML document was correctly put on the server"
  END IF
CATCH
  DISPLAY "ERROR :",STATUS||" ("||SQLCA.SQLERRM||")"
END TRY
END MAIN
```

Example 4 : Asynchronous HTTP DELETE request

```plaintext
IMPORT com

MAIN
DEFINE req com.HTTPRequest
DEFINE resp com.HTTPResponse
DEFINE url STRING
DEFINE quit CHAR(1)
DEFINE questionStr STRING
DEFINE timeout INTEGER
TRY
  WHILE TRUE
    PROMPT "Enter http url you want to delete ? 
    FOR url ATTRIBUTES (CANCEL=FALSE)
    LET req = com.HTTPRequest.Create(url)
    CALL req.setMethod("DELETE")
    CALL req.doRequest()
    # Retrieve asynchronous response for the first time
    LET resp = req.getAsyncResponse()
    CALL Update(resp) RETURNING questionStr,timeout
    WHILE quit IS NULL OR ( quit!="Y" AND quit!="N" )
      PROMPT questionStr FOR CHAR quit
      ATTRIBUTES (CANCEL=FALSE,ACCEPT=FALSE,SHIFT="up")
      ON IDLE timeout
      IF resp IS NULL THEN # If no response at first try,
        # retrieve it again
        LET resp = req.getAsyncResponse() # as we now have time
```

```
CALL Update(resp) RETURNING questionStr,timeout
END IF
END PROMPT
END WHILE
IF quit == "Y" THEN
EXIT PROGRAM
ELSE
LET quit = NULL
END IF
END WHILE
CATCH
DISPLAY "ERROR ":STATUS,SQLCA.SQLERRM
END TRY
END MAIN

FUNCTION Update(resp)
DEFINE resp com.HTTPResponse
DEFINE ret STRING
IF resp IS NOT NULL THEN
    IF resp.getStatusCode() != 204 THEN
        LET   ret = "HTTP Error ("||resp.getStatusCode()||") :"||resp.getStatusDescription()||". Do you want to quit ? "
    ELSE
        LET   ret = "HTTP Page deleted. Do you want to quit ? "
    END IF
ELSE
    LET ret = "Do you want to quit ? "
RETURN ret, 1
END IF
END FUNCTION

The HTTPResponse class
The com.HTTPResponse class provides an interface to perform XML and TEXT responses over HTTP, with additional XML streaming possibilities, on the client side.

The STATUS variable is set to zero after a successful method call.

com.HTTPResponse methods
Methods for the com.HTTPResponse class.

Table 475: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>beginXmlResponse()</td>
<td>Starts a streaming HTTP response.</td>

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getMultipartType()</td>
<td>Returns whether a response is multipart or not, and the kind of multipart if any.</td>
</tr>
<tr>
<td>getPart( index INTEGER )</td>
<td>Returns the HTTP part object at the specified index of the current HTTP response.</td>
</tr>
<tr>
<td>getPartCount()</td>
<td>Returns the number of additional parts in the HTTP response.</td>
</tr>
<tr>
<td>getPartFromContentID( id STRING )</td>
<td>Returns the HTTP part object marked with the given Content-ID value as identifier, or NULL if none.</td>
</tr>
</tbody>
</table>
com.HTTPResponse.beginXmlResponse

Starts a streaming HTTP response.

**Syntax**

```
beginXmlResponse()
RETURNING writer xml.StaxWriter
```

1. `writer` is the `xml.StaxWriter` to be used to write the HTTP request.

**Usage**

The `beginXmlResponse()` method the streaming HTTP response and returns a `xml.StaxReader` object ready to read XML from the server.

The Content-Type header must be of the form */xml or */++xml. For example: application/xhtml+xml.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

com.HTTPResponse.endXmlResponse

Performs the HTTP request.

**Syntax**

```
endXmlResponse(
   writer xml.StaxWriter)
```

1. `writer` is the `xml.StaxWriter` used to write the HTTP response.

**Usage**

The `endXmlResponse()` method ends the streaming HTTP response by closing the `xml.StaxWriter` object that was created with the `beginXmlResponse()` method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

com.HTTPResponse.getDataResponse

Returns the entire HTTP response in a BYTE.

**Syntax**

```
getDataResponse(
   data BYTE)
```

1. `data` is a BYTE variable receiving the HTTP response data.
Usage

The `getDataResponse()` method returns the body of an HTTP response into a `BYTE` variable.

The `BYTE` variable must be located in memory, otherwise operation fails.

Returns binary data as response from a server into a `BYTE`.

Previous content is discarded.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

```
com.HTTPResponse.getFileResponse
```

Returns the entire HTTP response in a file on the disk.

Syntax

```
getFileResponse ( )
RETURNING filename STRING
```

1. `filename` is the absolute path to the file containing the HTTP response.

Usage

Reads an HTTP response and creates a file from it.

The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file will be the basename found in the HTTP Content-Disposition Header, if this basename is not specified, the filename will be created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form: `/tmp/ABC/filename_index.ext`, where `index` represents the number of files with the same name on disk.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

```
com.HTTPResponse.getHeader
```

Returns the value of an HTTP header.

Syntax

```
getHeader ( name STRING )
RETURNING result STRING
```

1. `name` is the name of the HTTP header.

Usage

The `getHeader()` method returns the value of the HTTP header specified by the `name` parameter, or `NULL` if not found.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
com.HTTPResponse.getHeaderCount
Returns the number of headers.

Syntax

```
getHeaderCount()
    RETURNING result INTEGER
```

Usage

The `getHeaderCount()` method returns the number of headers of the HTTP response.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPResponse.getHeaderName
Returns the name of a header by position.

Syntax

```
getHeaderName(index)
    RETURNING result STRING
```

1. `index` is the ordinal position of the header.

Usage

The `getHeaderName()` method returns the name of the HTTP response header according to the position passed as parameter.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPResponse.getHeaderValue
Returns the value of a header by position.

Syntax

```
getHeaderValue(index)
    RETURNING result STRING
```

1. `index` is the ordinal position of the header.

Usage

The `getHeaderValue()` method returns the value of the HTTP response header according to the position passed as parameter.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPResponse.getMultipartType
Returns whether a response is multipart or not, and the kind of multipart if any.

**Syntax**

```
getMultipartType()
  RETURNING result STRING
```

**Usage**

Returns whether a response is multipart or not, and the kind of multipart if any.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**com.HTTPResponse.getPartCount**

Returns the number of additional parts in the HTTP response.

**Syntax**

```
getPartCount()
  RETURNING count INTEGER
```

**Usage**

Returns the number of additional parts in the HTTP response. The root part element must be handled via getXmlResponse(), getTextResponse(), getDataResponse() and beginXmlResponse(). In other words, there are getPartCount() + 1 parts if getMultipartType() does not return NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**com.HTTPResponse.getPart**

Returns the HTTP part object at the specified index of the current HTTP response.

**Syntax**

```
getPart(index INTEGER)
  RETURNING part-object com.HTTPPart
```

1. `index` is the index number.

**Usage**

Returns the HTTP part object at the specified index of the current HTTP response.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

Can raise error -15554 (Index is out of bounds).

**com.HTTPResponse.getPartFromContentID**
Returns the HTTP part object marked with the given Content-ID value as identifier, or NULL if none.

**Syntax**

```java
getPartFromContentID(
    id STRING
)
RETURNING part-object com.HTTPPart
```

1. *name* is the name of the HTTP header.

**Usage**

Returns the HTTP part object marked with the given Content-ID value as identifier, or NULL if none.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**com.HTTPResponse.getStatusCode**

Returns the HTTP status code.

**Syntax**

```java
getStatusCode()
RETURNING result INTEGER
```

**Usage**

The `getStatusCode()` method returns the status code for the HTTP response.

When the returned HTTP status code is 401 or 407, authorization is required.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**com.HTTPResponse.getStatusDescription**

Returns the HTTP status description.

**Syntax**

```java
getStatusDescription()
RETURNING result STRING
```

**Usage**

The `getStatusDescription()` method returns a description of the HTTP response status.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**com.HTTPResponse.getTextResponse**

Returns the entire HTTP response in a string.

**Syntax**

```java
getTextResponse()
RETURNING data STRING
```
Usage
The `getTextResponse()` method returns a HTTP response as a entire string.

- The Content-Type header can be of the form */*. For example: application/json.
- Automatic conversion to the locale charset is performed when possible, otherwise throws an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553

```
com.HTTPResponse.getTextResponse
```

Returns the entire HTTP response in a DOM document.

Syntax
```
getXmlResponse ()
RETURNING data xml.DomDocument
```

Usage
The `getXmlResponse()` method returns an HTTP response in a `xml.DomDocument` object.

The Content-Type header must be of the form */xml or */+xml. For example: application/xhtml+xml.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553

Examples
Examples using methods of the `com.HTTPResponse` class.

For examples, see Examples on page 2076.

The HTTPPart class
The `com.HTTPPart` class provides an interface to manage the HTTP attachment sent or received in HTTP.

The `STATUS` variable is set to zero after a successful method call.

```
com.HTTPPart CreateAttachment (
  filename STRING)
RETURNING part-object com.HTTPPart
```
Creates a new HTTPPart object based on given filename located on disk.

```
com.HTTPPart CreateFromData (
  b BYTE)
```
Creates a new HTTPPart object based on given BYTE located in memory.

Table 477: Class methods of `com.HTTPPart`

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CreateAttachment (filename STRING)</code></td>
<td>Creates a new HTTPPart object based on given filename located on disk.</td>
</tr>
<tr>
<td><code>CreateFromData (b BYTE)</code></td>
<td>Creates a new HTTPPart object based on given BYTE located in memory.</td>
</tr>
</tbody>
</table>
### Table 478: Object methods of `com.HTTPPart`

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>RETURNING part-object com.HTTPPart</code></td>
<td></td>
</tr>
<tr>
<td><code>CreateFromDomDocument</code></td>
<td>Creates a new HTTPPart object based on given XML document.</td>
</tr>
<tr>
<td><code>CreateFromString</code></td>
<td>Creates a new HTTPPart object based on given string.</td>
</tr>
</tbody>
</table>

### getAttachment()

**RETURNING filename STRING**

Returns the absolute path to the HTTP part.

### getContentAsData()

**Returns the HTTP part as a BYTE.**

### getContentAsDomDocument()

**Returns the HTTP part as a XML document.**

### getHeader(name STRING)

**RETURNING value STRING**

Setter to handle HTTP multipart headers.

### getContentAsString()

**Returns the HTTP part as a string.**

### setHeader(name STRING, value STRING)

Setter to handle HTTP multipart headers.

---

**com.HTTPPart.CreateFromString**

Creates a new HTTPPart object based on given string.

**Syntax**

```java
CreateFromString(s STRING) RETURNING part-object com.HTTPPart
```

1. `s` is a string
Usage
Creates a new HTTPPart object based on given string. To be used via the addPart() method.

Defaults HTTP multipart headers:

- Content-Type: text/plain
- Content-Transfer-Encoding: 8bits

Notice that the string will be converted during request sending into ISO-8859-1 by default, unless a different charset has been set via setHeader("Content-Type","text/plain; charset=UTF-8") for instance.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPPart.CreateFromDomDocument
Creates a new HTTPPart object based on given XML document.

Syntax

```java
CreateFromDomDocument (x xml.DomDocument) RETURNING part-object com.HTTPPart
```

1. `x` is an XML document.

Usage
Creates a new HTTPPart object based on given XML document. To be used via the addPart() method.

Defaults HTTP multipart headers:

- Content-Type: text/xml; charset=UTF-8
- Content-Transfer-Encoding: 8bits

A different charset can be set with the setHeader method. For example, setHeader("Content-Type","text/plain; charset=ISO-8859-1") sets the charset to ISO-8859-1.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPPart.CreateFromData
Creates a new HTTPPart object based on given BYTE located in memory.

Syntax

```java
CreateFromData (b BYTE) RETURNING part-object com.HTTPPart
```

1. `b` is a BYTE object located in memory.

Usage
Creates a new HTTPPart object based on given BYTE located in memory. To be used via the addPart() method.

Defaults HTTP headers:

- Content-Type: application/octet-stream
- Content-Transfer-Encoding: base64
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**com.HTTPPart.CreateAttachment**

Creates a new HTTPPart object based on given filename located on disk.

**Syntax**

```java
CreateAttachment(
    filename STRING)
RETURNING part-object com.HTTPPart
```

1. *filename* is the name of a file.

**Usage**

Creates a new HTTPPart object based on given filename located on disk. To be used via the `addPart()` method.

The `com.HTTPPart.CreateAttachment()` method automatically sets the following headers for the created HTTPPart object:

- **Content-Type** is defined according to the file name extension. If the file extension is not recognized, **Content-Type defaults to** `application/octet-stream`.

  **Note:** File extensions to Content-Type mapping can be customized in the file `FGLDIR/lib/wse/mime.cfg`.

- **Content-Transfer-Encoding** is set to "binary".

- **Content-Disposition** is set with the base name of the given *filename* as follows: attachment; filename="basename".

For example, when calling the method as follows:

```java
LET part = com.HTTPPart.CreateAttachment( "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP part headers will look like:

```
Content-Type: image/jpeg
Content-Transfer-Encoding: binary
Content-Disposition: attachment; filename="logo.jpg"
```

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**com.HTTPPart.getAttachment**

Returns the absolute path to the HTTP part.

**Syntax**

```java
getAttachment() 
RETURNING filename STRING
```

**Usage**

Returns the absolute path location of the received part file.

The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file will be the basename found in the HTTP Content-Disposition Header, if this basename is not specified, the
filename will be created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form :/tmp/ABC/filename_index.ext, where index represents the number of files with the same name on disk.

If the file is encoded in base64, you can use the Genero Web Services fglpass -dec64 command to convert it back to binary.

It is up to programmer to remove file from the disk when it is no longer needed.

To be used via methods: com.HTTPResponse.getPart on page 2083, com.HTTPResponse.getPartCount on page 2083, and com.HTTPResponse.getPartFromContentID on page 2083

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.HTTPPart.getContentAsData

Returns the HTTP part as a BYTE.

Syntax

```java
getContentAsData ( b BYTE )
```

1. b is a variable holding the BYTE data.

Usage

Returns the HTTP part as a BYTE. BYTE data cannot be returned from a function with a RETURN statement. Therefore, the BYTE parameter must be handled by reference.

To be used via methods: com.HTTPResponse.getPart on page 2083, com.HTTPResponse.getPartCount on page 2083, and com.HTTPResponse.getPartFromContentID on page 2083

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The error -15573 is raised if the part cannot be converted to a Genero BYTE.

com.HTTPPart.getContentAsDomDocument

Returns the HTTP part as a XML document.

Syntax

```java
getContentAsDomDocument ()
RETURNING domDocument xml.DomDocument
```

Usage

Returns the HTTP part as a XML document.

To be used via methods: com.HTTPResponse.getPart on page 2083, com.HTTPResponse.getPartCount on page 2083, and com.HTTPResponse.getPartFromContentID on page 2083

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The error -15573 is raised if the part cannot be converted to a XML DomDocument.

com.HTTPPart.getContentAsString
Returns the HTTP part as a string.

**Syntax**

```
getContentAsString()
  RETURNING str STRING
```

**Usage**

Returns the HTTP part as a string.

To be used via methods: `com.HTTPResponse.getPart` on page 2083, `com.HTTPResponse.getPartCount` on page 2083, and `com.HTTPResponse.getPartFromContentID` on page 2083.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The error -15573 is raised if the part cannot be converted to a Genero string or if the charset is not supported.

**com.HTTPPart.getHeader**

Setter to handle HTTP multipart headers.

**Syntax**

```
getHeader(
  name STRING
)
  RETURNING value STRING
```

1. `name` is the name of the header part.
2. `value` is the value for the header part specified by `name`.

**Usage**

Getter to handle HTTP multipart headers.

Note: In case of related multipart (i.e., the part is multipart/related and set via the `com.HTTPRequest.setMultipartType("related",NULL,NULL)`), it is mandatory to set a unique Content-ID header. To set up a unique Content-ID header, you can use the `security.RandomGenerator.CreateUUIDString` on page 2288 method for that.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**Example**

```
LET val = req.getHeader("MyClientHeader")
```

**com.HTTPPart.setHeader**

Setter to handle HTTP multipart headers.

**Syntax**

```
setHeader(
  name STRING,
  value STRING
)
```
1. `name` is the multipart header name.
2. `value` is the multipart header value (such as HTTP headers).

**Usage**

Setter to handle HTTP multipart headers.

For instance, when you send a multipart image, you should specify the image mime type with this header method. If the image is a png, you have to do `part.setHeader("Content-Type","image/png")`, which lets the peer know the format of the attached file it has to process.

**Note:** In case of related multipart (i.e., the part is multipart/related and set via the `com.HTTPRequest.setMultipartType("related",NULL,NULL)`) it is mandatory to set a unique Content-ID header. To set up a unique Content-ID header, you can use the `security.RandomGenerator.CreateUUIDString` method on page 2288 method for that.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**Example**

```
CALL req.setHeader("MyClientHeader","Hello")
```

**Example**

Examples using methods of the `com.HTTPPart` class.

This example consists of two applications: a client and server exchanging an XML document in multipart with a image as an attachment.

**Client Application**

```java
IMPORT com
IMPORT xml

CONSTANT SERVER_URL = "http://localhost:8090/MultipartMixed/Sample"

MAIN

DEFINE req com.HTTPRequest
DEFINE resp com.HTTPResponse
DEFINE doc xml.DomDocument
DEFINE root xml.DomNode
DEFINE p com.HTTPPart
DEFINE type STRING
DEFINE count INTEGER
DEFINE ind INTEGER

LET req = com.HTTPRequest.Create(SERVER_URL)
CALL req.setMethod("POST")
CALL req.setHeader("MyClientHeader","Hello")
TRY
# Set multipart type
CALL req.setMultipartType("mixed",NULL,NULL)
# Add filename as part
LET p = com.HTTPPart.CreateAttachment("my_picture.png")
# Set attachment Content-Type
CALL p.setHeader("Content-Type","image/png")
# Add part to the request
CALL req.addPart(p)
```
# Perform XML request
CALL req.doXmlRequest(doc)
# Check response
LET resp=req.getResponse()
IF resp.getStatusCode() != 200 THEN
  DISPLAY "HTTP Error ("||resp.getStatusCode()||") ",
  resp.getStatusDescription()
  EXIT PROGRAM (-1)
END IF
IF resp.getStatusDescription() != "OK" THEN
  DISPLAY "HTTP Error ("||resp.getStatusCode()||") ",
  resp.getStatusDescription()
  EXIT PROGRAM (-1)
END IF
# Check whether multipart response or not
LET type = resp.getMultipartType()
IF type IS NULL THEN
  DISPLAY "Failed : Expected multipart in response"
  EXIT PROGRAM (-1)
ELSE
  DISPLAY "Response is multipart of ",type
END IF
# Check response
LET doc = resp.getXmlResponse()
IF doc IS NULL THEN
  DISPLAY "Expected XML document as response"
  EXIT PROGRAM (-1)
ELSE
  DISPLAY "Response is : ",doc.saveToString()
END IF
# Process additional parts
FOR ind = 1 TO resp.getCount()
  LET p = resp.getPart(ind)
  IF p.getAttachment() IS NOT NULL THEN
    DISPLAY "Attached file at ",p.getAttachment()
  ELSE
    DISPLAY "Attached part is ",p.getContentAsString()
  END IF
END FOR
CATCH
  DISPLAY "unexpected exception :",STATUS," ("||SQLCA.SQLERRM||")"
  EXIT PROGRAM (-1)
END TRY
END MAIN

Server Application

IMPORT com
IMPORT xml

MAIN

DEFINE req        com.HTTPServiceRequest
DEFINE url        STRING
DEFINE method     STRING
DEFINE txt        STRING
DEFINE doc        xml.DomDocument
DEFINE type       STRING
DEFINE ind        INTEGER
DEFINE p          com.HTTPPart
CALL com.WebServiceEngine.Start()

LET req = com.WebServiceEngine.getHTTPServiceRequest(-1)
LET url = req.getURL()
IF url IS NULL THEN
  DISPLAY "Failed: url should not be null"
  EXIT PROGRAM (-1)
END IF
LET method = req.getMethod()
IF method IS NULL OR method != "POST" THEN
  DISPLAY "Failed: method should be POST"
  EXIT PROGRAM (-1)
END IF
# Check multipart type
LET type = req.getRequestMultipartType()
IF type IS NULL THEN
  DISPLAY "Failed: expected multipart in request"
  EXIT PROGRAM (-1)
END IF
TRY
  LET doc = req.readXMLRequest()
  DISPLAY "Request is :", doc.saveToString()
CATCH
  DISPLAY "Failed: unexpected error :", STATUS
  EXIT PROGRAM (-1)
END TRY
# Process additional parts
FOR ind = 1 TO req.getRequestPartCount()
  LET p = req.getRequestPart(ind)
  IF p.getAttachment() IS NOT NULL THEN
    DISPLAY "Attached file at ":, p.getAttachment()
  ELSE
    DISPLAY "Attached part is :", p.getContentAsString()
  END IF
END FOR
# Set multipart response type
CALL req.setResponseMultipartType("mixed",NULL,NULL)
# Add XML Part
LET p = com.HTTPPart.CreateAttachment("my_other_picture.jpg")
CALL p.setHeader("Content-Type","image/jpg")
CALL req.addResponsePart(p)
CALL req.sendXmlResponse(200,NULL,doc)
END MAIN

TCP classes
The TCP classes manage TCP client network operations.

• CLASS TCPRequest
• CLASS TCPResponse

The TCPRequest class
The com.TCPRequest class provides an interface to perform asynchronous XML and TEXT requests over TCP, with additional XML streaming possibilities.

Important: This Web Services class is not supported on GMI mobile devices.
com.TCPRequest methods

Methods of the com.TCPRequest class.

Table 479: Class methods of com.TCPRequest

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.TCPRequest.Create(url STRING ) RETURNING result com.TCPRequest</td>
<td>Creates a new TCP request object.</td>
</tr>
</tbody>
</table>

Table 480: Object methods of com.TCPRequest

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>beginXmlRequest() RETURNING writer xml.StaxWriter</td>
<td>Starts a streaming XML request.</td>

<tr>
<td>setConnectionTimeOut(seconds INTEGER )</td>
<td>Defines the connection time out.</td>
</tr>
<tr>
<td>setKeepConnection(on BOOLEAN )</td>
<td>Defines if the TCP connection is kept open after sending a request.</td>
</tr>
<tr>
<td>setMaximumResponseLength()</td>
<td>Defines the time out for read/write operations.</td>
</tr>
</tbody>
</table>
### com.TCPRequest.beginXmlRequest

Starts a streaming XML request.

**Syntax**

```java
beginXmlRequest()
RETURNING writer xml.StaxWriter
```

**Usage**

The `beginXmlRequest()` method begins a streaming HTTP request and returns an `xml.StaxWriter` object ready to send XML to the server.

After sending all the XML data to the server, you must call the `endXmlRequest()` method with the `xml.StaxWriter` object created by the `beginXmlRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

### com.TCPRequest.Create

Creates a new TCP request object.

**Syntax**

```java
com.TCPRequest.Create(
  url STRING )
RETURNING result com.TCPRequest
```

1. `url` is the URL of the TCP request.

**Usage**

This class method creates a new `com.TCPRequest` object according to the URL passed as parameter. The URL must use the TCP or TCPS protocol. Examples of valid URLs include:

- `tcp://localhost:4242/`
- `tcps://localhost:4343/`

The URL can be an identifier of an URL mapping with an optional `alias://` prefix. See FGLPROFILE configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### com.TCPRequest.doDataRequest
Performs the request by sending binary data.

**Syntax**

```java
doDataRequest (data BYTE )
```

1. *data* is the binary data to be send for a TCP request. The *BYTE* variable must be located IN MEMORY.

**Usage**

Performs the TCP request by sending binary data contained in the *BYTE* variable.

**Note:** The *BYTE* variable must be located IN MEMORY.

In case of error, the method throws an exception and sets the *STATUS* variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### Example

```java
IMPORT com
IMPORT XML

MAIN
    DEFINE url STRING
    LET url = "tcp://localhost:4242"
    CALL an_example(url)
END MAIN

FUNCTION an_example(url)
    DEFINE url STRING
    DEFINE req com.TCPRequest
    DEFINE resp com.TCPResponse
    DEFINE ret xml.DomDocument

    TRY
        LET  req = com.TCPRequest.create(url)
        CALL req.doRequest()
        LET  resp = req.getResponse()
        LET  ret = resp.getXmlResponse()
    END TRY
```

Performs a TCP request.

**Syntax**

```java
doRequest ()
```

**Usage**

The `doRequest()` method performs the TCP request.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the *STATUS* variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The *INT_FLAG* variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.
CATCH
   DISPLAY "ERROR : ", STATUS, SQLCA.SQLERRM
EXIT PROGRAM(-1)
END TRY
END FUNCTION

com.TCPRequest.doXmlRequest
Performs a request with a DOM document.

Syntax

doXmlRequest (  
document xml.DomDocument  )

1. document is the DOM document describing the request.

Usage
The doXmlRequest() method performs the TCP request by using the information defined in the xml.DomDocument object passed as parameter.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553

com.TCPRequest.doTextRequest
Performs a request with a string.

Syntax

doTextRequest (  
data STRING  )

1. data is a string describing the request.

Usage
The doTextRequest() method performs the TCP request by using the information defined in string passed as parameter.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553

com.TCPRequest.endXmlRequest
Terminates a streaming TCP request.

Syntax

endXmlRequest (  )
**Usage**

The `endXmlRequest()` method terminates a streaming TCP request performed with the `xml.StaxWriter` object that was created by the `beginXmlRequest()` method.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 2553).

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see [Interruption handling in GWS calls (INT_FLAG)](page 2553).

**com.TCPRequest.getResponse**

Returns the response after performing a TCP request.

**Syntax**

```
getResponse()
```

RETURNS `response` com.TCPResponse

**Usage**

The `getResponse()` method returns a TCP response as a `com.TCPResponse` object, after a call to `doRequest()`, `doXmlRequest()`, `doTextRequest()`, or `beginXmlRequest() / endXmlRequest()` calls.

A call to this method will stop the program flow until the response is received.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 2553).

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see [Interruption handling in GWS calls (INT_FLAG)](page 2553).

**com.TCPRequest.getAsyncResponse**

Returns the response after performing a TCP request, asynchronously.

**Syntax**

```
getAsyncResponse()
```

RETURNS `response` com.TCPResponse

**Usage**

The `getAsyncResponse()` method returns a TCP response as a `com.TCPResponse` object, after a call to `doRequest()`, `doXmlRequest()`, `doTextRequest()`, or `beginXmlRequest() / endXmlRequest()` calls.

Unlike `getResponse()`, the `getAsyncResponse()` method does not stop the program flow: The method returns `NULL` if the response was not yet received.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 2553).
The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

com.TCPRequest.setTimeOut
Defines the time out for read/write operations.

Syntax

```java
setTimeOut (seconds INTEGER )
```

1. `seconds` is the time out in seconds.

Usage

This method defines the time value in seconds to wait for a reading or writing operation, before a break.

If the time out is -1, waits infinitely.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.TCPRequest.setConnectionTimeOut
Defines the connection time out.

Syntax

```java
setConnectionTimeOut (seconds INTEGER )
```

1. `seconds` is the time out in seconds.

Usage

This method defines the time value in seconds to wait for a connection, before a break.

If the time out is -1, waits infinitely.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

com.TCPRequest.setKeepConnection
Defines if the TCP connection is kept open after sending a request.

Syntax

```java
setKeepConnection (on BOOLEAN )
```

1. `on` indicates if the TCP connection must be kept open.

Usage

This method can be used to force the TCP socket to remain open after a send operation, in order to perform subsequent do*Request() calls, without closing the connection (in write mode).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.
com.TCPRequest.setMaximumResponseLength
Defines the time out for read/write operations.

Syntax

```java
setMaximumResponseLength(
    length INTEGER )
```

1. `length` is the max size of a response, in Kbytes.

Usage

This method sets the maximum authorized size in Kbyte of the whole response, before a break.

A length of -1 defines no limit.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

The TCPResponse class

The `com.TCPResponse` class provides an interface to perform XML and TEXT responses over TCP, with additional XML streaming possibilities.

Important: This Web Services class is not supported on GMI mobile devices.

com.TCPResponse methods

Methods of the `com.TCPResponse` class.

Table 481: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>beginXmlResponse()</code></td>
<td>Starts a streaming TCP response.</td>
</tr>
<tr>
<td><code>endXmlResponse(reader)</code></td>
<td>Ends a streaming TCP response.</td>
</tr>
<tr>
<td><code>getDataResponse(data)</code></td>
<td>Returns a TCP response in binary format.</td>
</tr>
<tr>
<td><code>getTextResponse()</code></td>
<td>Returns a TCP response in string format.</td>
</tr>
<tr>
<td><code>getXmlResponse()</code></td>
<td>Returns an entire DOM document as TCP response.</td>
</tr>
</tbody>
</table>

com.TCPResponse.beginXmlResponse
Starts a streaming TCP response.

Syntax

```java
beginXmlResponse()
```
RETURNING reader xml.StaxReader

Usage

Begins the streaming TCP response and returns an xml.StaxReader object ready to read XML from the server.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553

Syntax

```java
com.TCPResponse.endXmlResponse
```

Ends a streaming TCP response.

Usage

Ends a streaming TCP response.

Syntax

```java
endXmlResponse(
    reader xml.StaxReader
)
```

1. `reader` is the STAX reader object created with beginXmlResponse().

Usage

Terminates the streaming TCP response identified by the xml.StaxReader object passed as parameter. This object must have been created with the beginXmlResponse() method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553

Syntax

```java
com.TCPResponse.getDataResponse
```

Returns a TCP response in binary format.

Usage

This method retrieves the TCP response in binary format into the BYTE variable passed as parameter. The method will read the TCP stream, until the peer closes the connection.

Note: The BYTE variable must be located IN MEMORY.

Syntax

```java
getDataResponse(
    data BYTE
)
```

1. `data` is the BYTE variable that will hold the response data in binary format. The BYTE variable must be located IN MEMORY.

Usage

This method retrieves the TCP response in binary format into the BYTE variable passed as parameter. The method will read the TCP stream, until the peer closes the connection.

Note: The BYTE variable must be located IN MEMORY.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553
com.TCPResponse.getTextResponse

Returns a TCP response in string format.

Syntax

```
getTextResponse()
    RETURNING result STRING
```

Usage

This method returns a complete streaming TCP response from the server as a string.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

com.TCPResponse.getXmlResponse

Returns an entire DOM document as TCP response.

Syntax

```
getXmlResponse()
    RETURNING doc xml.DomDocument
```

Usage

This method returns a complete xml.DomDocument as streaming TCP response from the server.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 2553.

Helper classes

The Helper classes provide utility classes.

- The Util class on page 2102

The Util class

The com.Util class provides static helper methods.

This class does not have to be instantiated.

**Important:** This Web Services class is not supported on GMI mobile devices.

com.Util methods

Methods of the com.Util class.

Table 482: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.Util.UniqueApplicationInstance(path STRING)</td>
<td>Checks that the calling application is the only one to run.</td>
</tr>
</tbody>
</table>
# com.Util.UniqueApplicationInstance

Checks that the calling application is the only one to run.

## Syntax

```java
com.Util.UniqueApplicationInstance(
    path STRING)
RETURNING result INTEGER
```

1. `path` is the path to the lock file.

## Usage

This method checks that the calling application is the only one to run, by trying to get an exclusive lock on the given file.

If the lock could be set, the method returns `TRUE`. Otherwise, returns `FALSE` and updates `STATUS` with an error code.

## Specific classes

Several classes support specific features.

- The [APNS class](page 2103)

## The APNS class

The `com.APNS` class implements Apple Push Notification Service APIs.

The `com.APNS` class implements a set of methods to build and handle push messages to be broadcasted by the Apple Push Notification service.

### APNs SSL certificate

Get and configure an SSL certificate to establish secure connections to the Apple Push Notification service.

### Basics

The Apple Push Notification Certificate identifies the push notification service for a given mobile app. This certificate will be created from an App ID (a.k.a. Bundle ID) and is used by the APNs system to dispatch the notification message to the registered devices.

You can create two type of APNs certificates for a given App ID:

- Sandbox (for development and test purpose)
- Production (for deployment)

An APNS push notification provider or an APNS feedback handler needs to establish a secure connection to Apple’s APNs server.

### Get an APNs certificate for your app

In this section we will produce the `myapp.cer` file and `myapp-key.p12` file.

To create an Apple Push Notification Certificate:

1. Log to Apple’s Member Center with you iOS developer or enterprise account,
2. Select Certificates, Identifiers & Profiles,
3. Under Certificates, select the + symbol,
4. Select Apple Push Notification service SSL (Sandbox) for development, or Apple Push Notification service SSL (Production) for production,

5. You need to choose the explicit app ID you want to use for push notifications. Verify before that you enable Push Notification Service for this app ID (go to App IDs section and edit your app ID),

6. Follow the instructions on the page to create a CSR file then click Continue,

7. Your certificate request is now available. Now you can go back to the Development Certificate section still active in your browser and click Choose file,

8. Navigate to the file you just saved and choose that file,

9. Click Generate,

10. Once the certificate is generated, click Download. The certificate will download into your Downloads folder, as a .cer file (for ex: myapp.cer).

11. Double-click this file to install it into Keychain,

12. When done, your new certificate should be listed in the Certificates list,

13. Open your Keychain app and locate the certificate you created, export the private key in p12 format (for ex myapp-key.p12). Note that you will be asked for a password to encode the .p12 file, and for your session password, to exported Keychain files.

Configure Genero to use the APNs certificate

On the Genero push provider server, you will need the public certificate (myapp.crt file) and the private key (myapp-key.pem file) for your app. These files will be referenced in the security.global.certificate and security.global.privatekey entries of FGLPROFILE.

In order to authenticate the APNs server, you will also need the root certificate authority (apple_entrust_root_certification_authority.pem), that can be downloaded from Apple’s web site. This file will be referenced by the security.global.ca entry in FGLPROFILE.

Note: When executing on a Mac, the root certificate (security.global.ca entry) is not required: The Web Services library reads the Keystore of the Mac computer, to authenticate the APNs server.

Create the myapp.crt file (public certificate) from the myapp.cer file, with the openssl x509 command:

```
$ openssl x509 -in myapp.cer -inform der -out myapp.crt
```

Convert the myapp-key.p12 file (containing the private key) to a myapp-key.pem format, with the openssl pkcs12 command:

```
$ openssl pkcs12 -nocerts -in myapp-key.p12 -out myapp-key.pem
```

Note: You need to enter the passphrase for the .p12 file so that openssl can read it. Then you need to enter a new passphrase that will be used to encrypt the .pem file.

FGLPROFILE entries require encrypted private key files, therefore you need to remove the passphrase from the myapp-key.pem file, with the openssl rsa command:

```
$ openssl rsa -in myapp-key.pem -out myapp-key-noenc.pem
```

Set up your FGLPROFILE with the appropriate security.* entries:

```
security.global.ca                   =
  "apple_entrust_root_certification_authority.pem"
security.global.certificate         = "myapp.crt"
security.global.privatekey          = "myapp-key-noenc.pem"
```

In the above example:
1. `apple Entrust root certification authority.pem` is the HTTPS root certificate authenticating the APNs server (if the computer is not a Mac).
2. `myapp.crt` is the public certificate for your app.
3. `myapp-key-noenc.pem` is the private key for your app.

**Note:** If you want to keep the private key encrypted, you need to configure a password agent, as described in Using the password agent

com.APNS methods

Methods of the com.APNS class.

**Table 483: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.APNS.DecodeError (data BYTE)</td>
<td>Decodes content of BYTE data returned from the APNS server in case of error.</td>
</tr>
<tr>
<td>com.APNS.DecodeFeedback (data BYTE, unregs DYNAMIC ARRAY OF RECORD timestamp INTEGER, deviceToken STRING END RECORD)</td>
<td>Decodes content of BYTE data returned from the APNS feedback service.</td>
</tr>
<tr>
<td>com.APNS.EncodeMessage (data BYTE, deviceToken STRING, json STRING, uuid STRING, expiration INTEGER, priority SMALLINT)</td>
<td>Encodes an APNS specific push notification message into a BYTE.</td>
</tr>
</tbody>
</table>

**Syntax**

```java
com.APNS.DecodeError (data BYTE) RETURNING uuid STRING, error INTEGER
```

1. `data` is the BYTE variable containing the error data. This BYTE variable must be located IN MEMORY.
2. `uuid` is a Base64 encoded string containing the push notification identifier.
3. `error` is the APNS error code returned by the server.

**Usage**

This method decodes the content of the BYTE variable passed as a parameter and received as response for a push notification message in the event of an error from the APNs server.

**Note:** This BYTE variable must be located IN MEMORY.
The *uuid* is a binary value that identifies the push notification message. It is returned as a Base64-encoded string.

The *error* returned value defines the APNs error code. For example, error will be set to 10 if the APNs server was shutdown. See the Apple Push Notification Service error reference for more details.

In the case of a decoding error, the method will raise the exception -15566, with details in the SQLCA.SQLERRM register.

**Example**

```sql
DEFINE error_data BYTE,
    uuid STRING,
    error INTEGER
LOCATE error_data IN MEMORY

-- Send push notification message TCP request
...
CALL req.doDataRequest(data)
LET resp = req.getResponse()
TRY
    CALL resp.getDataResponse(error_data)
    CALL com.APNS.DecodeError(error_data)
RETURNING uuid, ecode
...
```

For a complete example, see APNs push provider on page 2109.

---

**com.APNS.DecodeFeedback**

Decodes content of BYTE data returned from the APNs feedback service.

**Syntax**

```sql
com.APNS.DecodeFeedback(
    data BYTE,
    unregs DYNAMIC ARRAY OF RECORD
        timestamp INTEGER,
        deviceToken STRING
    END RECORD
)
```

1. *data* is the BYTE variable containing the feedback data. This BYTE variable must be located IN MEMORY.
2. *unregs* is a structured dynamic array that will contain the list of unregistered device tokens.
   a. *timestamp* is the number of seconds since Unix Epoch (in UTC)
   b. *deviceToken* is a APNS device token that has been unregistered (encoded in Base-64)

**Usage**

Apple recommends to connect frequently to the APNS feedback server in order to verify that your applications are still registered for push notifications.

To get APNS feedback, you must perform a TCP request (using SSL), to the following specific URI:

```
tcps://feedback.push.apple.com:2196
```

The DecodeFeedback() method decodes the content of the BYTE variable, which was passed as a parameter and received as response for the TCP request to the APNS feedback server.
Note: This BYTE variable must be located IN MEMORY.

For the second parameter, this method takes a structured dynamic array that will be filled with the list of unregistered APNS device tokens. It is up to the push program to stop sending push notification messages for these unregistered device tokens.

The timestamp member of an unregs dynamic array element can be used to verify that device tokens have not been re-registered since the feedback entry was generated. This timestamp is returned as a number of seconds since the Unix epoch, in UTC. Use the utilDatetime.fromSecondsSinceEpoch on page 1956 utility API to convert timestamp to a DATETIME value in the current local time.

The deviceToken member of an unregs dynamic array element identifies iOS devices that have been unregistered from the APNS server. Note that these identifier is encoded in Base64.

In the event of a decoding error, the method will raise the exception -15566, with details in the SQLCA.SQLERRM register.

Example

```sql
DEFINE feedback_data BYTE,
    unregs DYNAMIC ARRAY OF RECORD
        timestamp INTEGER,
        deviceToken STRING
    END RECORD,
    i INTEGER

LOCATE feedback_data IN MEMORY

... TCP request to APNS feedback server ...

CALL com.APNS.DecodeFeedback(feedback_data, unregs)

FOR i=1 TO unregs.getLength()
    DISPLAY i, " ", unrefs[i].deviceToken
END FOR
```

For a complete example, see APNs feedback handler on page 2110.

com.APNS.EncodeMessage

Encodes an APNS specific push notification message into a BYTE.

Syntax

```
com.APNS.EncodeMessage(  
data BYTE,  
deviceToken STRING,  
json STRING,  
uuid STRING,  
expiration INTEGER,  
priority SMALLINT)  
RETURNING result INTEGER
```

1. data is the BYTE variable holding the APNS message. This BYTE variable must be located IN MEMORY.
2. deviceToken is an APNS device token (encoded in Base-64).
3. json is a JSON string containing the APNS push message data.
4. uuid is the 4 bytes-long push message identifier (encoded in Base64).
5. expiration is a number of seconds since Unix Epoch defining the expiration date of the message.
6. priority is an integer defining the priority of the message.
Usage
This method builds the APNS push notification message into a BYTE variable, for a given device token.

Note: This BYTE variable must be located IN MEMORY.

Note: The size of an APNS notification payload cannot exceed 2 Kilobytes. Make sure that the resulting BYTE variable does not exceed this size limitation. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The APNS push notification message protocol requires some binary data to be encoded in the message content before it is sent to the APNS server with a TCP (over SSL) request, to specific URIs, namely:

- "tcps://gateway.sandbox.apple.com:2195" (for development)
- "tcps://gateway.push.apple.com:2195" (for production)

You need to provide several parameters in order to build the push notification message:

The deviceToken parameter is an APNS device token encoded in Base-64. It's used to identify the target device that must receive the push message. The device token identifies a single iOS device: If you have N devices registered to your push notification provider, you will have N different device tokens. If you want to send one push notification message to all the devices, you must send N different messages, where the only difference between the messages is the device token.

Note: It's in your hands to handle the list of registered device tokens. A device token is assigned to a physical iOS device when the mobile app issues a registerForRemoteNotifications on page 1940 front call. The app must then provide its device token to the push provider program using a method such as a web service mechanism.

Fill the json parameter with a JSON string containing the APNS push message data. For example:

LET json = '{"aps":{"alert":"Hello,
world","sound":"default","badge":1,"content-available":1}}'

See APNS documentation for more details about the JSON content of a message.

The uuid parameter is the 4 bytes-long push message identifier, encoded in Base64. This parameter can be used later to identify the message in push notification errors (com.APNS.DecodeError on page 2105). This parameter can be NULL. To create the uuid parameter, use the security.RandomGenerator.CreateRandomString on page 2287 API, with a size of 4:

LET uuid = security.RandomGenerator.createRandomString(4)

The expiration parameter is a number of seconds since Unix Epoch. It defines the expiration date of the message if it can not be sent by the APNS server to the target devices. This parameter can be NULL, to indicate that there is no expiration date:

LET dt = CURRENT + INTERVAL (10) MINUTE TO MINUTE
LET expiration = util.Datetime.toSecondsSinceEpoch(dt)

The priority parameter can be used to define a priority for the push notification message. Typically, use a value of 10 for immediate, 5 for delayed. This parameter can be NULL. See APNS documentation for more details.

If there's an encoding error, the method will raise the exception -15566, with details in the SQLCA.SQLERRM register.

Example

DEFINE push_data BYTE,
deviceTokenHexa STRING,
dt DATETIME YEAR TO FRACTION(3),
expiration INTEGER,
json_data STRING,
uuid STRING

LOCATE push_data IN MEMORY

LET deviceTokenHexa = "84e3................."

LET dt = CURRENT + INTERVAL (10) MINUTE TO MINUTE
LET expiration = util.Datetime.toSecondsSinceEpoch(dt)
LET json_date = util.JSON.stringify(...)
LET uuid = security.RandomGenerator.createRandomString(4)

CALL com.APNS.EncodeMessage(
    push_data,
    security.HexBinary.ToBase64(deviceTokenHexa),
    json_data,
    uuid,
    expiration,
    10
)

IF LENGTH(push_data) > 2000 THEN
    -- Must reduce the message content...
    RETURN FALSE
END IF

-- Do the TCP request with the push_data variable...

For a complete example, see APNs push provider on page 2109.

APNs examples
APNs push provider

The com.APNS class can be used to implement an APNs push provider.

The following code example implements a push program using the com.APNS API to send a notification message to devices by using the TCP request API. See also com.APNS methods on page 2105 for more details about the APNs API.

Note: An SSL certificate needs to be defined in FGLPROFILE, as described in APNs SSL certificate on page 2103.

Note: The size of the resulting BYTE variable containing the APNS payload cannot exceed 2 Kilobytes.

Important: In order to check that the push message was properly handled by the APNs server, you need to define a TCP request timeout (2 seconds in this example). In case of error, the APNs server will return a response immediately. In case of success, there is not a response from the APNs server. For more details about this protocol, see Apple's APNs documentation.

IMPORT com
IMPORT security

The xml package

The Genero Web Services XML package provides classes and methods to handle any kind of XML documents, including documents with namespaces.

The library provides a W3C-compatible DOM API, integrating additional XML Schema and DTD validation methods. There is also an API compatible with StAX for writing or reading XML documents where performance and speed are important.

Use the IMPORT statement at the top of the module using this library:

IMPORT xml

Note: The DOM API of the com package is designed to handle specific FGL files or to manipulate the user interface tree (the AUI tree). For all other cases/scenarios, we recommend that you use the DOM API of the Web Services xml package.

- The Document Object Modeling (DOM) classes on page 2112
- The streaming API for XML (StAX) classes on page 2178
- XML serialization classes on page 2210
The Document Object Modeling (DOM) classes
The Document Object Modeling (DOM) classes manage XML documents entirely in memory with support of XML Schema and DTD validation.

- **CLASS DomDocument**
  - Features
  - **CLASS DomNode**
  - Types
  - **CLASS DomNodeList**

The DomDocument class
The `xml.DomDocument` class provides methods to manipulate a data tree, following the DOM standards.

The `STATUS` variable is set to zero after a successful method call.

xml.DomDocument methods
Methods for the `xml.DomDocument` class.

<td>Returns the error description at given position.</td>
</tr>
</tbody>
</table>

**xml.DomDocument.appendDocumentNode**

Adds a child DomNode object to the end of the DomNode children for this DomDocument object.

**Syntax**

```javascript
appendDocumentNode(
    node xml.DomNode
)
```

1. `node` is the node to add.

**Usage**

Adds a child `DomNode` object to the end of the DomNode children for this DomDocument object, where `node` is the node to add.

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node and one Document Type node allowed.

**Note:** A fragment is a structure created to receive xml nodes that are not always valid. Once a fragment is added to a valid node, the fragment becomes empty as all nodes are moved from the fragment as a child to the valid node. So developers can work on the fragment until it is added to another node. At that time developers should no more work on the fragment but rather on the valid node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 2553).

**xml.DomDocument.clone**

Returns a copy of a DomDocument object.

**Syntax**

```javascript
clone()
```

**Usage**

Returns a copy of this `DomDocument` object, or `NULL`. 
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.create
Constructor of an empty DomDocument object.

Syntax

```plaintext
xml.DomDocument.create()
RETURNING object xml.DomDocument
```

Usage

Constructor of an empty DomDocument object.

Returns a DomDocument object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

Example

Create a DomDocument without a root node:

```plaintext
xml.domDocument.create()
```

Create a DomDocument with an initial root node named ARoot:

```plaintext
xml.domDocument.create("ARoot")
```

xml.DomDocument.createAttribute
Creates an XML Attribute DomNode object for a DomDocument object.

Syntax

```plaintext
createAttribute(
    name STRING )
RETURNING object xml.DomNode
```

1. name is the name of the XML attribute.

Usage

Creates an XML Attribute DomNode object for a DomDocument object, where name is the name of the XML attribute, cannot be NULL.

Returns a DomNode object, or NULL.

To create a default namespace declaration attribute use xmlns as the name. (Using declareNamespace instead is recommended)

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.createAttributeNS
Creates an XML namespace-qualified Attribute DomNode object for a DomDocument object.

Syntax

```java
createAttributeNS(
    prefix STRING,
    name STRING,
    ns STRING )
RETURNING object xml.DomNode
```

1. `prefix` is the prefix of the XML attribute.
2. `name` is the name of the XML attribute.
3. `ns` is the namespace URI of the XML attribute.

Usage

Creates an XML namespace-qualified Attribute DomNode object for this DomDocument object, where `prefix` is the prefix of the XML attribute, cannot be `NULL`; `name` is the name of the XML attribute, cannot be `NULL`; `ns` is the namespace URI of the XML attribute, cannot be `NULL`.

Returns a `DomNode` object, or `NULL`.

To create a namespace declaration attribute use `xmlns` as the prefix and `http://www.w3.org/XML/1998/namespace` as the namespace. Using `declareNamespace` instead is recommended.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.createCDATASection

Creates an XML CData DomNode object for a DomDocument object.

Syntax

```java
createCDATASection(
    cdata STRING )
RETURNING object xml.DomNode
```

1. `cdata` is the data of the XML CData node.

Usage

Creates an XML CData DomNode object for this DomDocument object, where `cdata` is the data of the XML CData node, or `NULL`. Returns a `DomNode` object, or `NULL`.

Only the characters `#x9`, `#xA`, `#xD`, `[#x20-#xD7FF]`, `[#xE000-#xFFFD]` and `[#x10000-#x10FFFF]` are allowed in the content of an XML CDATASection node.

The character sequence (Double-Hyphen) `--` is not allowed in the content of an XML CDATASection node. The `saveToFile()` and `normalize()` methods will fail if this sequence or characters other than those allowed exist in a CDATASection node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.createComment
Creating an XML Comment DomNode object for a DomDocument object.

**Syntax**

```java
createComment(
    comment STRING )
RETURNING object xml.DomNode
```

1. `comment` is the data of the XML Comment node.

**Usage**

Creating an XML Comment DomNode object for this DomDocument object, where `comment` is the data of the XML Comment node, or NULL.

Returns a DomNode object, or NULL.

Only the characters `#x9`, `#xA`, `#xD`, `[#xE000-#x7FFF]`, and `[#x10000-#x10FFFF]` are allowed in the content of an XML Comment node.

The character sequence (Double-Hyphen) ‘--’ is not allowed in the content of an XML Comment node. The `saveToFile()` and `normalize()` methods will fail if this sequence or characters other than those allowed exist in a Comment node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomDocument.createDocument**

Constructor of a DomDocument with an XML root element.

**Syntax**

```java
xml.DomDocument.createDocument(
    name STRING )
RETURNING object xml.DomDocument
```

1. `name` is the name of the XML Element.

**Usage**

Constructor of a `xml.DomDocument` with an XML root element; where `name` is the name of the XML Element.

Returns a DomDocument object or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomDocument.createDocumentFragment**

Creates an XML Document Fragment DomNode object for a DomDocument object.

**Syntax**

```java
createDocumentFragment()
RETURNING object xml.DomNode
```
Usage

Creates an XML Document Fragment DomNode object for this DomDocument object.

Returns a DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.createDocumentNS

Constructor of a DomDocument with a root namespace-qualified XML root element

Syntax

xml.DomDocument.createDocumentNS(
  prefix STRING,
  name STRING,
  ns STRING )
RETURNING object xml.DomDocument

1. prefix is the prefix of the XML Element or NULL.
2. name is the name of the XML Element.
3. ns is the namespace of the XML Element.

Usage

Constructor of a xml.DomDocument with a root namespace-qualified XML root element where prefix is the prefix of the XML Element or NULL, name is the name of the XML Element, and ns is the namespace of the XML Element. Returns a DomDocument object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

Example

Create a DomDocument with an initial root node named "List" with abc as the prefix and http://www.mysite.com/xmlapi as the namespace:

xml.domdocument.createDocumentNS("abc","List","http://www.mysite.com/xmlapi")

Produces:

<abc:List xmlns:abc="http://www.mysite.com/xmlapi">
[...]
</abc:List>

xml.DomDocument.createDocumentType

Creates an XML Document Type (DTD) DomNode object for a DomDocument object.

Syntax

createDocumentType(
  name STRING,
  publicID STRING,
  systemID STRING,
  internalDTD STRING )
1. *name* is the name of the document type.
2. *publicID* is the URI of the public identifier.
3. *systemID* is the URL of the system identifier (Specifies the file location of the external DTD subset).
4. *internalDTD* is the internal DTD subset.

**Usage**

Creates an XML Document Type (DTD) DomNode object for this DomDocument object; *name* is the name of the document type; *publicID* is the URI of the public identifier or *NULL*; *systemID* is the URL of the system identifier or *NULL* (Specifies the file location of the external DTD subset); *internalDTD* is the internal DTD subset or *NULL*.

Returns a DomNode object, or *NULL* if *internalDTD* is malformed.

**Caution:** Not part of W3C API.

Only internal DTDs are supported.

The public identifier cannot be set without the system identifier.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomDocument.createElement**

Creates an XML Element DomNode object for a DomDocument object

**Syntax**

```java
createElement (  
    name STRING   
)  
RETURNING object xml.DomNode
```

1. *name* is the name of the XML element.

**Usage**

Creates an XML Element DomNode object for this DomDocument object, where *name* is the name of the XML element, cannot be *NULL*.

Returns a DomNode object, or *NULL*.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomDocument.createElementNS**

Creates an XML namespace-qualified Element DomNode object for a DomDocument object.

**Syntax**

```java
createElementNS (  
    prefix STRING,   
    name STRING,  
    ns STRING   
)  
RETURNING object xml.DomNode
```

1. *prefix* is the prefix of the XML element, or *NULL* to use the default namespace.
2. *name* is the name of the XML element.
3. *ns* is the namespace URI of the XML element.

**Usage**

Creates an XML namespace-qualified Element DomNode object for this DomDocument object, where *prefix* is the prefix of the XML element, or NULL to use the default namespace; *name* is the name of the XML element, cannot be NULL; *ns* is the namespace URI of the XML element, cannot be NULL.

Returns a DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomDocument.createEntityReference**

Creates an XML EntityReference DomNode object for a DomDocument object

**Syntax**

```
createEntityReference(
    ref STRING )
RETURNING object xml.DomNode
```

1. *ref* is the name of the entity reference.

**Usage**

Creates an XML EntityReference DomNode object for this DomDocument object, where *ref* is the name of the entity reference.

Returns a DomNode object, or NULL.

An Entity Reference node is read-only and cannot be modified.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomDocument.createNode**

Creates an XML DomNode object from a string for a DomDocument object.

**Syntax**

```
createNode(
    str STRING )
RETURNING object xml.DomNode
```

1. *str* is the string representation of the DomNode to be created.

**Usage**

Creates an XML DomNode object from a string for this DomDocument object; *str* is the string representation of the DomNode to be created.

Returns a xml.DomNode object, or NULL.

**Caution:** Not part of W3C API.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`xml.DomDocument.createProcessingInstruction`

Creates an XML Processing Instruction `DomNode` object for this `DomDocument` object.

**Syntax**

```java
createProcessingInstruction(
    target STRING,
    data STRING )
RETURNING object xml.DomNode
```

1. `target` is the target part of the XML Processing Instruction.
2. `data` is the data part of the XML Processing Instruction.

**Usage**

Creates an XML Processing Instruction `DomNode` object for this `DomDocument` object, where `target` is the target part of the XML Processing Instruction, cannot be `NULL`; `data` is the data part of the XML Processing Instruction, or `NULL`.

Returns a `DomNode` object, or `NULL`.

Only the characters `#x9`, `#xA`, `#xD`, `[#xE000-#xFFFD]` and `[#x10000-#x10FFFF]` are allowed in the content of an XML Processing Instruction node.

The character sequence (Double-Hyphen) `''` is not allowed in the content of an XML Processing Instruction. The `save()` and `normalize()` methods will fail if this sequence or characters other than those allowed exist in a Processing Instruction node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`xml.DomDocument.createTextNode`

Creates an XML Text `DomNode` object for a `DomDocument` object.

**Syntax**

```java
createTextNode(
    text STRING )
RETURNING object xml.DomNode
```

1. `text` is the data of the XML Text node.

**Usage**

Creates an XML Text `DomNode` object for this `DomDocument` object, where `text` is the data of the XML Text node, or `NULL`.

Returns a `DomNode` object, or `NULL`.

Only the characters `#x9`, `#xA`, `#xD`, `[#xE000-#xFFFD]` and `[#x10000-#x10FFFF]` are allowed in the content of an XML Text node. The `save()` and `normalize()` methods will fail if characters other than those allowed exist in a Text node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
xml.DomDocument.declareNamespace
Forces namespace declaration to an XML Element DomNode for a DomDocument object.

**Syntax**

```java
declareNamespace(
    node xml.DomNode,
    alias STRING,
    ns STRING )
```

1. **node** is the XML Element DomNode that carries the namespace definition.
2. **alias** is the alias of the namespace to declare.
3. **ns** is the URI of the namespace to declare.

**Usage**

Forces namespace declaration to an XML Element DomNode for this DomDocument object; **node** is the XML Element DomNode that carries the namespace definition; **alias** is the alias of the namespace to declare, or **NULL** to declare the default namespace; **ns** is the URI of the namespace to declare (can only be **NULL** if alias is **NULL**).

**Caution:** Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.getDocumentElement
Returns the root XML Element DomNode object for this DomDocument object.

**Syntax**

```java
getDocumentElement ()
RETURNING object xml.DomNode
```

**Usage**

Returns the root XML Element DomNode object for this DomDocument object.

Returns a DomNode object, or **NULL**.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.getDocumentNodesCount
Returns the number of child DomNode objects for a DomDocument object.

**Syntax**

```java
getDocumentNodesCount ()
RETURNING count INTEGER
```

**Usage**

Returns the number of child DomNode objects for this DomDocument object.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.getDocumentNodeItem

Returns the child DomNode object at a given position for this DomDocument object.

**Syntax**

```plaintext
getDocumentNodeItem(
    pos INTEGER )
RETURNING object xml.DomNode
```

1. pos is the position of the node to return (index starts at 1).

**Usage**

Returns the child DomNode object at a given position for this DomDocument object where pos is the position of the node to return (Index starts at 1), or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.getElementById

Returns the element that has an attribute of type ID with the given value

**Syntax**

```plaintext
elementById(
    id STRING )
RETURNING object xml.DomNode
```

1. id is the Id value.

**Usage**

Returns the xml.DomNode element that has an attribute of type ID with the given value, or NULL if there is none.

Attributes with the name "ID" or "id" are not of type ID unless so defined with setIdAttribute or setIdAttributeNS. However, there is a specific attribute called xml:id and belonging to the namespace http://www.w3.org/XML/1998/namespace that is always of type ID even if not set with setIdAttributeNS.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.getElementsByTagName

Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name in the entire document.

**Syntax**

```plaintext
elementsByTagName(
    name STRING )
RETURNING object xml.DomNodeList
```

1. name is the name of the XML Element tag to match or "***" to match all tags.
Usage

Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name in the entire document; *name* is the name of the XML Element tag to match, or "*" to match all tags.

Returns a DomNodeList object, or NULL.

The returned list is ordered using a Depth-First pass algorithm.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.getElementsByTagNameNS

Returns a DomNodeList object containing all namespace qualified XML Element DomNode objects with the same tag name and namespace in the entire document

Syntax

```sql
getElementsByTagNameNS (
    name STRING,
    ns STRING
)
RETURNING list xml.DomNodeList
```

1. *name* is the name of the XML Element tag to match or "*" to match all tags.
2. *ns* is the namespace URI of the XML Element tag to match, or "*" to match all namespaces.

Usage

Returns a xml.DomNodeList object containing all namespace qualified XML Element DomNode objects with the same tag name and namespace in the entire document; *name* is the name of the XML Element tag to match, or "*" to match all tags; *ns* is the namespace URI of the XML Element tag to match, or "*" to match all namespaces. Returns a DomNodeList object, or NULL.

The returned list is ordered using a Depth-First pass algorithm.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.getErrorDescription

Returns the error description at given position.

Syntax

```sql
getErrorDescription (
    pos INTEGER
)
RETURNING desc STRING
```

1. *pos* is the position of the error description (index starts at 1).

Usage

Returns the error description at given position. *pos* is the position of the error description (index starts at 1). Returns a string with an error description.

Caution: Not part of W3C API

Example

```sql
FOR i=1 TO doc.getErrorsCount()
```
Displays all the errors encountered in the save, load or validate of `doc` DomDocument.

To display other errors, use the global variable STATUS to get the error code and `err_get(status)` or `sqlca.sqlerrm` to get the description of the error. See error code for more details.

```
FOR i=1 TO doc.getErrorsCount()
    DISPLAY "[", i, "] ", doc.getErrorDescription(i)
END FOR
```

Displays all the errors encountered in the save, load or validate of `doc` DomDocument.

```
xml.DomDocument.getErrorsCount
    Returns the number of errors encountered during the loading, saving or validation of an XML document.

Syntax
    `getErrorsCount()`
    RETURNING `count` INTEGER

Usage
    Returns the number of errors encountered during the loading, the saving or the validation of an XML document.
    Returns the number of errors, or zero if there are none.

    Caution: Not part of W3C API

Example
    FOR i=1 TO doc.getErrorsCount()
        DISPLAY "[", i, "] ", doc.getErrorDescription(i)
    END FOR
```

Displays all the errors encountered in the save, load or validate of `doc` DomDocument.

To display other errors, use the global variable STATUS to get the error code and `err_get(status)` or `sqlca.sqlerrm` to get the description of the error. See error code for more details.

```
xml.DomDocument.getFirstDocumentNode
    Returns the first child DomNode object for a DomDocument object.

Syntax
    `getFirstDocumentNode()`
    RETURNING `object` xml.DomNode

Usage
    Returns the first child DomNode object for this DomDocument object, or NULL.
    In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.getFeature
    Gets a feature for a DomDocument object.

Syntax
    `getFeature(
        `feature` STRING)
1. **feature** is the name of the DomDocument feature.

**Usage**

Gets a feature for the DomDocument object, where *feature* is the name of the DomDocument feature.

Returns the value of the feature.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.getLastDocumentNode

Returns the last child DomNode object for a DomDocument object.

**Syntax**

```
getLastDocumentNode ()
   RETURNING object xml.DomNode
```

**Usage**

Returns the last child DomNode object for this DomDocument object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.getXmlEncoding

Returns the document encoding as defined in the XML document declaration.

**Syntax**

```
getXmlEncoding ()
   RETURNING result STRING
```

**Usage**

Returns the document encoding as defined in the XML document declaration, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.getXmlVersion

Returns the document version as defined in the XML document declaration.

**Syntax**

```
getXmlVersion ()
   RETURNING result STRING
```

**Usage**

Returns the document version as defined in the XML document declaration, which is 1.0. No other versions are supported.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.importNode
Imports a DomNode from a DomDocument object into its new context (attached to a DomDocument object).

**Syntax**

```java
importNode (  
    node xml.DomNode  
    deep INTEGER  
)  
RETURNING object xml.DomNode
```

1. **node** is the node to import.
2. **deep** is a boolean identifying whether to import the node only or the node and all its child nodes.

**Usage**

Imports a DomNode from a DomDocument object into its new context (attached to this DomDocument object), where **node** is the node to import. When **deep** is FALSE only the node is imported; when **TRUE** the node and all its child nodes are imported.

Returns the DomNode object that has been imported to this DomDocument, or **NULL**.

Document and Document Type nodes cannot be imported.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

Inserts a child DomNode object before another child DomNode for this DomDocument object.

**Syntax**

```java
insertBeforeDocumentNode (  
    node xml.DomNode,  
    ref xml.DomNode  
)
```

1. **node** is the node to insert.
2. **ref** is the reference node (the node before which the new node must be inserted).

**Usage**

Inserts a child DomNode object before another child DomNode for this DomDocument object; **node** is the node to insert, **ref** is the reference node (the node before which the new node must be inserted).

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node and one Document Type node allowed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.
Inserts a child DomNode object after another child DomNode for a DomDocument object.

**Syntax**

```sql
insertAfterDocumentNode(
    node xml.DomNode,
    ref xml.DomNode )
```

1. `node` is the node to insert.
2. `ref` is the reference node (the node after which the new node must be inserted).

**Usage**

Inserts a child `DomNode` object after another child `DomNode` for this `DomDocument` object; `node` is the node to insert; `ref` is the reference node (the node after which the new node must be inserted).

**Caution:** Not part of W3C API.

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node and one Document Type node allowed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomDocument.isXmlStandalone**

Returns whether the XML standalone attribute is set in the XML declaration.

**Syntax**

```sql
isXmlStandalone()
    RETURNING result INTEGER
```

**Usage**

Returns whether the XML standalone attribute is set in the XML declaration.

Returns `TRUE` if the standalone attribute in the XML declaration is set to yes.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomDocument.load**

Loads an XML Document into a DomDocument object from a file or an URL.

**Syntax**

```sql
load(
    url STRING )
```

1. `url` is a valid URL or the name of the file.

**Usage**

Loads an XML Document into a DomDocument object from a file or an URL, where `url` is a valid URL or the name of the file.
Only the following kinds of URLs are supported: http://, https://, tcp://, tcps://, file:// and alias://.
See Web services configuration on page 2517 for more details about URL mapping with aliases, and for proxy and security configuration.

See setFeature() to specify how the document can be loaded. HTML parsing is possible when enable-html-compliancy is enabled.

See getErrorsCount() and getErrorDescription() to retrieve error messages related to XML document loading.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

Important: On Mac OS X versions prior to 10.9, the libxml library (used by Genero Web Services classes) has a bug when parsing HTML documents. If you set the HTML compliancy option with CALL doc.setFeature("enable-html-compliancy", TRUE), loading an HTML document with xml.DomDocument.load() may produce additional blank TEXT nodes, because the libxml library loads some ignorable whitespace nodes from the HTML document. Starting with Mac OS X 10.9, the libxml library of the system has fixed this bug.

xml.DomDocument.loadFromPipe

Loads an XML Document into a DomDocument object from a PIPE.

**Syntax**

```plaintext
loadFromPipe ( 
    cmd  STRING )
```

1. *cmd* is the command to read from the PIPE.

**Usage**

Loads an XML Document into a DomDocument object from a PIPE where *cmd* is the command to read from the PIPE.

Caution: Not part of W3C API.

See setFeature() to specify how the document can be loaded. HTML parsing is possible when enable-html-compliancy is enabled.

See getErrorsCount() and getErrorDescription() to retrieve error messages related to XML document loading.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.loadFromString

Loads an XML Document into a DomDocument object from a string.

**Syntax**

```plaintext
loadFromString ( 
    str    STRING )
```

1. *str* is the string to load.

**Usage**

Loads an XML Document into a DomDocument object from a string, where *str* is the string to load.
Caution: Not part of W3C API.

See `setFeature()` to specify how the document can be loaded. HTML parsing is possible when `enable-html-compliancy` is enabled.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document loading.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.DomDocument.normalize
Normalizes the entire Document.
```

### Syntax

```java
normalize()
```

### Usage

Normalizes the entire Document. This method merges adjacent Text nodes, removes empty Text nodes and sets namespace declarations as if the document had been saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document normalization.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.DomDocument.prependDocumentNode
Adds a child DomNode object to the beginning of the DomNode children for a DomDocument object
```

### Syntax

```java
prependDocumentNode(
  node xml.DomNode
)
```

1. `node` is the node to add.

### Usage

Adds a child `DomNode` object to the beginning of the DomNode children for this DomDocument object; `node` is the node to add.

Caution: Not part of W3C API.

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node and one Document Type node allowed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.DomDocument.removeDocumentNode
```
Removes a child DomNode object from the DomNode children for this DomDocument object.

**Syntax**

```java
removeDocumentNode(
    node xml.DomNode )
```

1. *node* is the node to remove.

**Usage**

Removes a child DomNode object from the DomNode children for this DomDocument object, where *node* is the node to remove.

Only Text nodes, Processing Instruction nodes, Element nodes and Document Type nodes allowed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomDocument.save**

Saves a DomDocument object as an XML Document to a file or URL.

**Syntax**

```java
save(
    url STRING )
```

1. *url* is a valid URL or the name of a file.

**Usage**

Saves a DomDocument object as an XML Document to a file or URL, where *url* is a valid URL or the name of the file.

Only the following kinds of URLs are supported: `http://`, `https://`, `tcp://`, `tcps://`, `file:///` and `alias://`. See Web services configuration on page 2517 for more details about URL mapping with aliases, and for proxy and security configuration.

See `setFeature()` to specify how the document can be saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document saving.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomDocument.saveToPipe**

Saves a DomDocument object as an XML Document to a PIPE.

**Syntax**

```java
saveToPipe(
    cmd STRING )
```

1. *cmd* is the command to start the pipe.
Usage
Saves a DomDocument object as an XML Document to a PIPE, where `cmd` is the command to start the pipe.

See `setFeature()` to specify how the document can be saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document saving.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.saveToString
Saves a DomDocument object as an XML Document to a string.

Syntax

```java
saveToString()
RETURNING result STRING
```

Usage
Saves a DomDocument object as an XML Document to a string. Returns the string that will contain the resulting document.

Caution: Not part of W3C API.

See `setFeature()` to specify how the document can be saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document saving.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomDocument.selectByXPath
Returns a DomNodeList object containing all DomNode objects matching an XPath 1.0 expression.

Syntax

```java
selectByXPath(
    expr STRING,
    nslist ... )
RETURNING list xml.DomNodeList
```

1. `expr` is the XPath1.0 expression
2. `nslist` is a list of prefixes bounded to namespaces in order to resolve qualified names in the XPath expression.

Usage
Returns a `xml.DomNodeList` object containing all DomNode objects matching an XPath 1.0 expression. `expr` is the XPath1.0 expression, `nslist` is a list of prefixes bounded to namespaces in order to resolve qualified names in the XPath expression. This list must be filled with an even number of arguments, representing the prefix and its corresponding namespace.

Caution: Not part of W3C API.
Valid example:

```xml
selectByXPath("//d:Record",
    "d",
    "http://defaultnamespace")
selectByXPath("//ns1:Record",
    NULL)
selectByXPath("//ns1:Records/ns2:Record",
    "ns1",
    "http://namespace1",
    "ns2",
    "http://namespace2")
```

Invalid example:

```xml
selectByXPath("//ns1:Record",
    "ns1")
```

This example is invalid because the namespace definition is missing.

If the namespaces list is NULL, the prefixes and namespaces defined in the document itself are used if available.

A namespace must be an absolute URI (ex 'http://', 'file://').

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

`xml.DomDocument.setFeature`

Sets a feature for a DomDocument object.

**Syntax**

```java
setFeature(feature STRING, value STRING)
```

1. **feature** is the name of a DomDocument feature.
2. **value** is the value of a feature.

**Usage**

Sets a feature for the DomDocument object, where **feature** is the name of a DomDocument feature, and **value** is the value of a feature.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

`xml.DomDocument.setXmlEncoding`

Sets the XML document encoding in the XML declaration.

**Syntax**

```java
setXmlEncoding(enc STRING)
```
1. **enc** is the XML document encoding.

**Usage**

Sets the XML document encoding in the XML declaration, or `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```plaintext
exml.DomDocument.setXmlStandalone
Sets the XML standalone attribute in the XML declaration to yes or no in the XML declaration.
```

**Syntax**

```plaintext
setXmlStandalone(
    alone INTEGER
)
```

1. **alone** is a boolean flag.

**Usage**

Sets the XML standalone attribute in the XML declaration to yes or no in the XML declaration, or `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```plaintext
exml.DomDocument.validate
Performs a DTD or XML Schema validation for a DomDocument object.
```

**Syntax**

```plaintext
validate() RETURNING result INTEGER
```

**Usage**

Performs a DTD or XML Schema validation for this DomDocument object. Returns the number of validation errors, or zero if there are none.

**Caution:** Not part of W3C API.

See `setFeature()` to specify what kind of validation to do.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to validation errors.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```plaintext
exml.DomDocument.validateOneElement
Performs a DTD or XML Schema validation of an XML Element DomNode object.
```

**Syntax**

```plaintext
validateOneElement(
    node xml.DomNode
) RETURNING result INTEGER
```
1. *node* is the XML Element DomNode to validate.

**Usage**

Performs a DTD or XML Schema validation of an XML Element DomNode object; *node* is the XML Element DomNode to validate.

Returns the number of validation errors, or zero if there are none.

**Caution:** Not part of W3C API.

See setFeature() to specify what kind of validation to do.

See getErrorsCount() and getErrorDescription() to retrieve error messages related to validation errors.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

Navigation methods usage examples

Examples using the navigation methods of the xml.DomDocument class.

DomDocument navigation functions deal with nodes immediately under the DomDocument object, except for search features. To navigate through all the nodes, you can refer to the navigation functions of the class xml.DomNode.

```xml
<?xml version="1.0" encoding="ISO-8859-1"?><!DOCTYPE CardList SYSTEM "card.dtd"><CardList xml:id="1">
    <!-- demo card --> [...]
</CardList>
```

The first node of the document is `xml-stylesheet`. Use getFirstDocumentNode to get the node. The element at position 2 is the comment `<!-- demo card -->`. Use getDocumentNodeItem function to get the node.

The last node of the document is CardList. Use getLastDocumentNode to get the node.

The number of node of the document is 3. This is result of function getDocumentNodeCount. This function only count the number of children immediately under the DomDocument.

Note that the first line of the example, `<?xml version="1.0" encoding="ISO-8859-1"?>`, is not considered as a node. To access to the information of the first line, use getXmlVersion() and getXmlEncoding functions.

Caution, if the example is in pretty printed format, the results are not the same. There are addition text nodes representing the carriage returns.

```xml
<?xml version="1.0" encoding="ISO-8859-1"?><!DOCTYPE CardList SYSTEM "card.dtd"><CardList xml:id="1">
    <!-- demo card --> [...]
</CardList>
```

See Cautions section for more details.

You can select nodes using their tag names, by XPath, or by their attributes value (if of type ID, xml:id for example). The getElementsByTagName and getElementsByTagNameNS methods return a DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is
restricted to contain objects with the same tag name and/or namespace. The `selectByXPath` method also returns a `DOMNodeList` object, but each node can have a different name.

```xml
getElementsByTagNameNS("message","http://schemas.xmlsoap.org/wsdl/")
```

Get the `message` nodes that have `http://schemas.xmlsoap.org/wsdl/` as the namespace.

```xml
getElementsByTagNameNS("message","*")
```

Get all the `message` nodes, regardless of the namespace they have.

```xml
getElementsByTagName("message")
```

Get all the `message` nodes that do not have any namespace.

```xml
selectByXPath("//xs:element",NULL)
```

Get all the `xs:element` nodes that has a namespace corresponding to prefix `xs`.

```xml
selectByXPath("//Card",NULL)
```

Get all the Card nodes that do not have any namespace.

```xml
getElementById("1")
```

Get the unique node whose attribute of type ID has a value of "1".

**Node creation methods usage examples**

Node creation methods usage examples for the `xml.DomDocument` class.

Creating a node for the `DomDocument` is done in two steps:

- Create the node.
- Add the node to the `DomDocument`.

Each time you create a node, you need to append it at the right place in the `DomDocument`. To add a node to the document use the `DomDocument` management methods or the `DomNode` manipulation methods.

```xml
createNode("<LastName>PATTERSON</LastName><FirstName>Andrew</FirstName>")
```

Creates a structure of nodes.

```xml
createElement("CardList")
```

Produces

```
<CardList>
```

```xml
createElementNS("cny", "Company", "http://www.mysite.com/")
```

Produces `<cny:Company xmlns:cny="http://www.mysite.com/">

See Cautions for more details.

```xml
createAttribute("Country")
```

Creates a `Country` attribute node.

- To set a value to the attribute, use the method `setNodeValue` of the `xml.DomNode` class.
• To add the attribute to an element node, use the method `setAttributeNode` of the xml.DomNode class.

```javascript
createAttributeNS("tw","Town","http://www.mysite.com/cities")
```

**Produces**

```
xmlns:tw="http://www.mysite.com/cities" tw:Town=""
```

• To set a value to the attribute use the method `setNodeValue` of the xml.DomNode class.

• To add the attribute to an element node use the method `setAttributeNodeNS` of the xml.DomNode class.

• For optimization reasons, the namespace is not written aside the attribute until the saving of the DomDocument.

• When accessing the element node, the namespace is not listed in the list of children. In the example above, `tw:Town=""` is in the list of children, not `xmlns:tw="http://www.mysite.com/cities"`.

• To access the namespace during the DomDocument building use the method `normalize` first. Normalize write the namespace declaration at the appropriate place. If there is no previous declaration, it will be accessible as an attribute of this element, otherwise it will be an attribute of one of the ancestors of the element.

```javascript
createTextNode("My Company")
```

Creates a text node.

```javascript
createComment("End of the card")
```

**Produces**

```
<!--End of the card-->
```

```javascript
createCDATASection("<website><a href="www.mysite.com">My Company</a></website>")
```

**Produces**

```
<![CDATA[<website><a href="www.mysite.com">My Company</a></website>]]
```

```javascript
createEntityReference("title")
```

Creates the entity reference `&title;`.

```javascript
createProcessingInstruction("xml-stylesheet", "type="text/xsl" href="card.xsl"")
```

**Produces**

```
<?xml-stylesheet type="text/xsl"href="card.xsl"?>
```

```javascript
createDocumentType("Card", NULL, NULL,"<!ELEMENT Card (lastname, firstname, company, location)>")
```

**Produces**

```
<!DOCTYPE Card [ <!ELEMENT Card (lastname , firstname , company , location)>]>
```

• Only inline DTD are supported. The DTD has to been inserted in the DomDocument at an appropriate place.

```javascript
createDocumentFragment
```

**Is a method that creates a lightweight DomDocument. It represents a subtree of nodes that do not need to conform to well-formed XML rules. This makes DocumentFragment easier to manipulate than a DomDocument.**

```javascript
for i=1 to 5
    let node = doc.createElement("Card")
    call root.appendChild(node) end for
```
This produces a subtree with 5 Card nodes that do not have any root node. Once the subtree is completed, it can be added to the DomDocument object like any other node.

**HTML document usage example**
The HTML language provides tags that allow the user to provide an embedded style sheet (the "style" tag) and to write embedded client side script (the "script" tag). According to the HTML 4.0 specification, the content of these tags must be managed as CDATA section.

**Note:** For more information, see the [HTML 4.0 specification](https://www.w3.org/HTML/).

Because HTML document management via the xml.DomDocument object provides HTML compliancy only (and not strict HTML management), there is a specific way to add these nodes inside a loaded HTML document:

1. Create an element node with the name of the tag to be created.
2. Append that element node to its parent.
3. Create a CDATASection node with the wanted embedded piece of style sheet or piece of script content.
4. Append the CDATASection to the previously created element node.

By following this procedure, the "script" and "style" tags content are recognized as CDATA section content and not TEXT section content and will be preserved. Other methods for adding nodes to the document manage text and therefore will not treat these types of content properly, resulting in invalid HTML code.

### Example

```c
IMPORT XML

MAIN

DEFINE myDoc XML.DomDocument
DEFINE myEltNode, myAttrNode, bodyNode, myCdataNode XML.DomNode
DEFINE nodeLst XML.DomNodeList
DEFINE i INTEGER

TRY
  LET myDoc = XML.DomDocument.create()
  CALL myDoc.setFeature("enable-html-compliancy", 1)
  CALL myDoc.load("testHtml.html")

  LET myEltNode = myDoc.createElement("script")
  LET myCdataNode = myDoc.createCDATASection("document.write("CDATA");")
  LET myAttrNode = myDoc.createAttribute("type")
  CALL myAttrNode.setNodeValue("text/javascript")

  LET nodeLst = myDoc.getElementsByTagName("body")
  LET docNode = nodeLst.getItem(1)

  CALL docNode.appendChild(myEltNode)
  CALL myEltNode.setAttributeNode(myAttrNode)
  CALL myEltNode.appendChild(myCdataNode)

CATCH
  DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
EXIT PROGRAM(-1)
END TRY

END MAIN
```
Load and save methods usage examples
Load and save methods usage examples for the xml.DomDocument class.

You can load an existing xml document. Before loading an xml document you need to create the DomDocument object.

A DomDocument can load files using different URI: http://, https://, tcp://, tcps://, file:// and alias://. Use getErrorsCount() and getErrorDescription() to display errors about the document loading.

```javascript
load("data.xml")
load("http://www.w3schools.com/xml/cd_catalog.xml")
load("https://localhost:6394/ws/r/calculator?WSDL")
load("file:///data/cd_catalog.xml")
load("tcp://localhost:4242/")
load("tcps://localhost:4243/")
load("alias://demo")
```

where demo alias is defined in fglprofile as ws.demo.url = "http://www.w3schools.com/xml/cd_catalog.xml"

```javascript
loadfromstring("<List> <elt>First element</elt> <elt>Second element</elt> <elt>Third element</elt> </List>"
```

Produces a subtree with a root node List and three nodes elt and three textnode.

A DomDocument can be saved at different URI beginning with: http://, https://, tcp://, tcps://, file:// and alias://. Use getErrorsCount() and getErrorDescription() to display errors about the document saving.

```javascript
save("myfile.xml")
save("http://myserver:8080/data/save1.xml")
save("file:///data/save.xml")
save("tcp://localhost:4242/")
save("alias://test")
```

where test alias is defined in fglprofile as ws.test.url = "http://localhost:8080/data/save3.xml"

```javascript
saveToString saves the DomDocument in a string. Use getErrorsCount() and getErrorDescription() to display errors about the document saving
```

normalize function emulates a DomDocument save and load. It can be called at any stage of the DomDocument building. This removes empty Text nodes and sets namespace declarations as if the document had been saved.

Cautions
Cautions when working with the xml.DomDocument class.

Whitespaces, line feeds and carriage returns between elements are represented as text nodes in memory. An XML document written in a single line and a human readable (pretty printed format) do not have the same representation in the DomDocument. Take this under account when navigating in the document.

If a DomNode is not attached to a DomDocument and not referenced by any variable it can be destroyed. If one child of this node is still referenced, this child is not destroyed but its parent and the others node of the subtree are destroyed. To check if a node is attached to a DomDocument use isAttached method.

DomDocument remains in memory if any of its node is still referenced in a variable.
DomDocument Features
A list of features for the `xml DomDocument` class.

## DomDocument features

### Table 492: DomDocument Features

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>format-pretty-print</td>
<td>Formats the output by adding white space to produce a pretty-printed, indented, human-readable form. Possible values are TRUE or FALSE. Default value is FALSE.</td>
</tr>
<tr>
<td>comments</td>
<td>Defines whether the XML comments are kept during the load of a document into a DomDocument object. Possible values are TRUE or FALSE. Default value is TRUE.</td>
</tr>
<tr>
<td>whitespace-in-element-content</td>
<td>Defines whether XML Text nodes that can be considered &quot;Ignorable&quot; are kept during the load of an XML document into a DomDocument object. Possible values are TRUE or FALSE. Default value is TRUE.</td>
</tr>
<tr>
<td>cdata-sections</td>
<td>Defines whether XML CData nodes are kept or replaced by XML Text nodes during the load of an XML document into a DomDocument object. Possible values are TRUE or FALSE. Default value is TRUE.</td>
</tr>
<tr>
<td>expand-entity-references</td>
<td>Defines whether XML EntityReference nodes are kept or replaced during the load of an XML document into a DomDocument object. Possible values are TRUE or FALSE. Default value is FALSE. <strong>Note</strong>: See security issues with expand-entity-references.</td>
</tr>
<tr>
<td>validation-type</td>
<td>Defines what kind of validation should be performed. Possible values are: DTD, Schema. Default is Schema.</td>
</tr>
<tr>
<td>external-schemaLocation</td>
<td>Defines a list of namespace-qualified XML schemas to use for validation on a DomDocument object.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------</td>
<td>------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>Value is a space-separated string of one or several pairs of strings representing the namespace URI of the schema, followed by its location. Examples:</td>
</tr>
<tr>
<td>external-noNamespaceSchemaLocation</td>
<td>Defines a list of XML schemas to use for validation on a DomDocument object. Value is a space-separated string of one or several strings representing the location of a schema. Example:</td>
</tr>
<tr>
<td>schema-uriRecovery</td>
<td>Changes the schema location of an XML schema referenced by import tags in other schemas. Value is a space-separated string of one or several pairs of strings representing the original schema location followed by the new schema location. Example:</td>
</tr>
<tr>
<td></td>
<td>&quot;<a href="http://www.w3.org/2001/xml.xsd">http://www.w3.org/2001/xml.xsd</a> myXML.xsd <a href="http://www.mycompany.com/GWS.xsd">http://www.mycompany.com/GWS.xsd</a> myGWS.xsd&quot;</td>
</tr>
<tr>
<td>load-save-base64-string</td>
<td>Changes methods loadFromString() and saveToString() to handle Base64 strings. Parsing an XML document is done from a BASE64 encoded string, and saving an XML document results in a BASE64 encoded string. Possible values are TRUE or FALSE. Default is FALSE.</td>
</tr>
<tr>
<td>auto-id-attribute</td>
<td>Changes the parsing of an XML document in order to set all unqualified attributes named ID, Id, iD or id to be of type ID. They can then be retrieved with method getElementById() or with an XPath expression without calling setIdAttribute(). Possible values are TRUE or FALSE. Default is FALSE.</td>
</tr>
<tr>
<td>auto-id-qualified-attribute</td>
<td>Changes the parsing of an XML document in order to set all qualified attributes named ID, Id, iD or id to be of type ID. They can then be retrieved with method getElementById() or with an XPath expression without calling setIdAttributeNS().</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>enable-html-compliancy</td>
<td>Changes methods to parse, normalize and save HTML document via the DomDocument object. Possible values are TRUE or FALSE. Default value is FALSE. The HTML parsing isn't namespace qualified, and document is considered as an XML document after loading. <strong>Note:</strong> This feature works only for HTML 4, it is not supported for HTML 5.</td>
</tr>
</tbody>
</table>

**Security issues with expand-entity-references**

For example, in its DTD, the following XML file defines the `myref ENTITY` element referencing the `/etc/passwd` file:

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
<!DOCTYPE foo [ 
  <!ELEMENT foo ANY >
  <!ENTITY myref SYSTEM "file:///etc/passwd" >
]
><foo>&myref;</foo>
```

When loading this XML file with `expand-entity-references` set to TRUE, the resulting DOM document will have a `<foo>` node containing a text node with the content of `/etc/passwd`.

**Examples**

Examples involving the `xml.DomDocument` class.

Example 1: Create a namespace qualified document with processing instructions

To create the following XML document on disk:

```xml
<?Target1 This is my first PI ?>
<MyPre:RootNode xmlns:MyPre="http://www.tempuri.org" >
<MyPre:Element />
</MyPre:RootNode>
<?Target2 This is my last PI ?>
```

Write the following code:

```xml
IMPORT xml

MAIN
  DEFINE doc xml.DomDocument
  DEFINE pi xml.DomNode
  DEFINE node xml.DomNode
  DEFINE elt xml.DomNode
```
# Create a document with an initial namespace qualified root node

# Create a Processing instruction
LET pi = doc.createProcessingInstruction("Target1", "This is my first PI")
# And add it at the begining of the document
CALL doc.prependDocumentNode(pi)

# Create another Processing instruction
LET pi = doc.createProcessingInstruction("Target2", "This is my last PI")
# And add it at the end of the document
CALL doc.appendDocumentNode(pi)

# Retrieve initial root node of the document
LET elt = doc.getDocumentElement()

# Create a new Element node
LET node = doc.createElementNS("MyPre", "Element", "http://www.tempuri.org")
# And add it as child of the RootNode
CALL elt.appendChild(node)

# Then save the document on disk
CALL doc.save("MyFile.xml")

END MAIN

Example 2: Validating a document against XML schemas or a DTD

This code example loads one or more XML schemas or uses an embedded DTD to validate against a XML document:

IMPORT xml

MAIN

DEFINE location STRING
DEFINE xmlfile STRING
DEFINE doc xml.DomDocument
DEFINE ind INTEGER

IF num_args()<2 THEN
    # Checks the number of arguments
    CALL ExitHelp()
ELSE
    LET doc = xml.DomDocument.Create()
    LET xmlfile = arg_val(num_args())
    IF num_args() == 2 AND arg_val(1) == "-dtd" THEN
        # User choosed DTD validation
        CALL doc.setFeature("validation-type", "DTD")
    ELSE
        # User choosed XML Schema validation
        IF arg_val(1) == "-ns" THEN
            # Handle namespace qualified XML schemas
            IF num_args() MOD 2 != 0 THEN
                CALL ExitHelp()
            END IF
            FOR ind = 2 TO num_args()-1 STEP 2
                IF location IS NULL THEN
                    LET location = arg_val(ind) || " " || arg_val(ind+1)
                ELSE
                    LET location = location || " " || arg_val(ind) || 
                          " " || arg_val(ind+1)
                END IF
            END FOR
            TRY
                CALL doc.setFeature("external-schemaLocation", location)
            CATCH
                FOR ind = 1 TO doc.getErrorsCount()
DISPLAY "Schema error ("||ind||") ",doc.getErrorDescription(ind)
END FOR
EXIT PROGRAM (-1)
END TRY
ELSE
# Handle unqualified XML schemas
FOR ind = 1 TO num_args()-1
IF location IS NULL THEN
LET location = arg_val(ind)
ELSE
LET location = location || " " || arg_val(ind)
END IF
END FOR
TRY
CALL doc.setFeature("external-noNamespaceSchemaLocation", location)
CATCH
FOR ind = 1 TO doc.getErrorsCount()
DISPLAY "Schema error ("||ind||") ",doc.getErrorDescription(ind)
END FOR
EXIT PROGRAM (-1)
END TRY
END IF
END IF
END IF
TRY
# Load XML document from disk
CALL doc.load(xmlfile)
CATCH
# Display errors if loading failed
IF doc.getErrorsCount()>0 THEN
FOR ind = 1 TO doc.getErrorsCount()
DISPLAY "LOADING ERROR #"||ind||":",doc.getErrorDescription(ind)
END FOR
EXIT PROGRAM(-1)
ELSE
DISPLAY "Unable to load file ":,xmlfile
EXIT PROGRAM(-1)
END IF
END TRY
TRY
# Validate loaded document
LET ind = doc.validate()
IF ind == 0 THEN
# Successful validation
DISPLAY "OK"
ELSE
# Display validation errors
FOR ind = 1 TO doc.getErrorsCount()
DISPLAY "VALIDATING ERROR #"||ind||":",doc.getErrorDescription(ind)
END FOR
EXIT PROGRAM(-1)
END IF
CATCH
DISPLAY "Unable to validate file ":,xmlfile
EXIT PROGRAM(-1)
END TRY
END MAIN

# Display help
FUNCTION ExitHelp()}
Example

$ fglrun Validator -dtd MyFile.xml
Validates XML file using DTD embedded in the XML file.

$ fglrun Validator Schema1.xsd Schema2.xsd MyFile.xml
Validates unqualified XML file using two unqualified XML schemas.

$ fglrun Validator -ns http://tempuri.org/one Schema1.xsd
http://tempuri.org/two Schema2.xsd MyFile.xml
Validates namespace qualified XML file using two namespace qualified XML schemas.

The DomNode class

The `xml.DomNode` class provides methods to manipulate a node of a DomDocument object.

You can create a DomNode object using creation methods in the `DomDocument` class.

The STATUS variable is set to zero after a successful method call.

xml.DomNode methods

Methods for the `xml.DomNode` class.

Table 493: Object methods: Navigation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getChildrenCount()</code></td>
<td>Returns the number of child DomNode objects for a DomNode object.</td>
</tr>
<tr>
<td><code>getChildrenCount()</code></td>
<td>RETURNING <code>cnt</code> INTEGER</td>
</tr>
<tr>
<td><code>getFirstChild()</code></td>
<td>Returns the first child DomNode object for this XML Element DomNode object.</td>
</tr>
<tr>
<td><code>getFirstChild()</code></td>
<td>RETURNING <code>object</code> xml.DomNode</td>
</tr>
<tr>
<td><code>getFirstChildElement()</code></td>
<td>Returns the first XML Element child DomNode object for this DomNode object.</td>
</tr>
<tr>
<td><code>getFirstChildElement()</code></td>

</tbody>
</table>
xml.DomNode.addPreviousSibling

Adds a DomNode object as the previous sibling of a DomNode object.

Syntax

```plaintext
addPreviousSibling(
    node xml.DomNode
)
```

1. `node` is the node to add.

Usage

Adds a DomNode object as the previous sibling of this DomNode object; `node` is the node to add.

**Caution:** Not part of W3C API.

The DomNode object `node` must be the child of an element or document node; otherwise the operation fails.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.addNextSibling

Adds a DomNode object as the next sibling of a DomNode object.

Syntax

```plaintext
addNextSibling(
    node xml.DomNode
)
```

1. `node` is the node to add.

Usage

Adds a DomNode object as the next sibling of this DomNode object; `node` is the node to add.

**Caution:** Not part of W3C API.

The DomNode object `node` must be the child of an element or document node, otherwise the operation fails.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.appendChild

Adds a child DomNode object to the end of the child list for a DomNode object.

Syntax

```plaintext
appendChild(
    node xml.DomNode
)
```

1. `node` is the node to add
Usage

Adds a child DomNode object to the end of the child list for this DomNode object.

The DomNode object node must be the child of an element or document node; otherwise the operation fails.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.appendChildElement

Creates and adds a child XML Element node to the end of the list of child nodes for an XML Element DomNode object.

Syntax

appendChildElement (  
  name STRING  
)  
RETURNING object xml.DomNode

1. name is the XML Element name.

Usage

Creates and adds a child XML Element node to the end of the list of child nodes for this XML Element DomNode object.

Caution: Not part of W3C API.

Returns the XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.appendChildElementNS

Creates and adds a child namespace qualified XML Element node to the end of the list of child nodes for this XML Element DomNode object.

Syntax

appendChildElementNS (  
  prefix STRING,  
  name STRING,  
  ns STRING  
)  
RETURNING object xml.DomNode

1. prefix is the prefix of the XML Element to add.  
2. name is the name of the XML Element to add.  
3. ns is the namespace URI of the XML Element to add.

Usage

Creates and adds a child namespace qualified XML Element node to the end of the list of child nodes for this XML Element DomNode object.

Caution: Not part of W3C API.

Returns the XML Element DomNode object, or NULL.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.clone**

Returns a duplicate `DomNode` object of a node.

**Syntax**

```java
clone(
    deep INTEGER
) RETURNING object xml.DomNode
```

1. `deep` is a boolean. If `deep` is TRUE, child `DomNode` objects are cloned too; otherwise only the `DomNode` itself is cloned.

**Usage**

Returns a duplicate `DomNode` object of this node. If `deep` is TRUE, child `DomNode` objects are cloned too; otherwise only the `DomNode` itself is cloned.

Returns a copy of this `DomNode` object, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.getAttribute**

Returns the value of an XML Attribute for an XML Element `DomNode` object.

**Syntax**

```java
getAttribute(
    name STRING
) RETURNING value STRING
```

1. `name` is the name of the XML attribute to retrieve.

**Usage**

Returns the value of an XML Attribute for this XML Element `DomNode` object. where `name` is the name of the XML attribute to retrieve.

Returns the XML Attribute value, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.getAttributeNode**

Returns an XML Attribute `DomNode` object for an XML Element `DomNode` object.

**Syntax**

```java
getAttributeNode(
    name STRING
) RETURNING object xml.DomNode
```

1. `name` is the name of the attribute to retrieve.
**Usage**
Returns an XML Attribute `DomNode` object for this XML Element `DomNode` object, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`xml.DomNode.getAttributeNodeItem`  
Returns the XML Attribute `DomNode` object at a given position on this XML Element `DomNode` object.

**Syntax**
```
getAttributeNodeItem(
    pos INTEGER )
RETURNING object xml.DomNode
```

1. `pos` is the position of the node to return.

**Usage**
Returns the XML Attribute `DomNode` object at a given position on this XML Element `DomNode` object, where `pos` is the position of the node to return (Index starts at 1).

Returns the XML Attribute `DomNode` object at the given position, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`xml.DomNode.getAttributeNodeNS`  
Returns a namespace-qualified XML Attribute `DomNode` object for an XML Element `DomNode` object

**Syntax**
```
getAttributeNodeNS(
    name STRING,
    ns STRING )
RETURNING object xml.DomNode
```

1. `name` is the name of the XMLAttribute to retrieve.
2. `ns` is the namespace URI of the XML Attribute to retrieve.

**Usage**
Returns a namespace-qualified XML Attribute `DomNode` object for this XML Element `DomNode` object, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`xml.DomNode.getAttributeNS`  
Returns the value of a namespace qualified XML Attribute for an XML Element `DomNode` object

**Syntax**
```
getAttributeNS(
    name STRING,
    ns STRING )
```

**RETURNING** value STRING

1. *name* is the name.
2. *ns* is the namespace URI of the XML Attribute to retrieve

**Usage**

Returns the value of a namespace qualified XML Attribute for this XML Element DomNode object, where *name* is the name and *ns* is the namespace URI of the XML Attribute to retrieve.

Returns the XML Attribute value, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.getAttributesCount**

Returns the number of XML Attribute DomNode objects on this XML Element DomNode object.

**Syntax**

```
getAttributesCount ()
    RETURNING num INTEGER
```

**Usage**

Returns the number of XML Attribute DomNode objects on this XML Element DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.getChildNodeItem**

Returns the child DomNode object at a given position for a DomNode object.

**Syntax**

```
getChildNodeItem ( pos INTEGER )
    RETURNING object xml.DomNode
```

1. *pos* is the position of the child node in the collection.

**Usage**

Returns the child **DomNode** object at a given position for this DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.getChildrenCount**

Returns the number of child DomNode objects for a DomNode object.

**Syntax**

```
getChildrenCount ()
    RETURNING cnt INTEGER
```
Usage

Returns the number of child DomNode objects for this DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.getElementsByTagName

Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name.

Syntax

```plaintext
getElementsByTagName (name STRING ) RETURNING list xml.DomNodeList
```

1. name is the name of the XML Element tag to match or "***" to match all tags.

Usage

Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name, or NULL; name is the name of the XML Element tag to match, or "***" to match all tags.

The getElementsByTagName and getElementsByTagNameNS methods return a DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is restricted to contain objects with the same tag name and/or namespace.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.getElementsByTagNameNS

Returns a DomNodeList object containing all namespace-qualified XML Element DomNode objects with the same tag name and namespace.

Syntax

```plaintext
getElementsByTagNameNS (name STRING, ns STRING ) RETURNING list xml.DomNodeList
```

1. name is the name of the XML Element tag to match or "***" to match all tags.
2. ns is the namespace URI of the XML Element tag to match or "***" to match any namespace.

Usage

Returns a DomNodeList object containing all namespace-qualified XML Element DomNode objects with the same tag name and namespace, or NULL. name is the name of the XML Element tag to match, or "***" to match all tags; ns is the namespace URI of the XML Element tag to match, or "***" to match any namespace.

The getElementsByTagName and getElementsByTagNameNS methods return a DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is restricted to contain objects with the same tag name and/or namespace.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.
xmlDOMNode.getFirstChild

Returns the first child DomNode object for this XML Element DomNode object.

**Syntax**

```
getFirstChild()
RETURNING object xmlDOMNode
```

**Usage**

Returns the first child DomNode object for this XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xmlDOMNode.getFirstChildElement

Returns the first XML Element child DomNode object for this DomNode object.

**Syntax**

```
getFirstChildElement()
RETURNING object xmlDOMNode
```

**Usage**

Returns the first XML Element child DomNode object for this DomNode object, or NULL.

**Caution:** Not part of W3C API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xmlDOMNode.getLastChild

Returns the last child DomNode object for a XML Element DomNode object.

**Syntax**

```
getLastChild()
RETURNING object xmlDOMNode
```

**Usage**

Returns the last child DomNode object for this XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xmlDOMNode.getLastChildElement

Returns the last child XML element DomNode object for this DomNode object.

**Syntax**

```
getLastChildElement()
RETURNING object xmlDOMNode
```

**Usage**

Returns the last child XML element DomNode object for this DomNode object.
Usage

Returns the last child XML element DomNode object for this DomNode object, or NULL.

Caution: Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.getLocalName

Gets the local name for a DomNode object.

Syntax

getLocalName ()
RETURNING str STRING

Usage

Gets the local name for this DomNode object. If DomNode has a qualified name, only the local part is returned.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.getNamespaceURI

Returns the namespace URI for a DomNode object.

Syntax

getNamespaceURI ()
RETURNING str STRING

Usage

Returns the namespace URI for this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.getNextSibling

Returns the DomNode object immediately following a DomNode object.

Syntax

getNextSibling ()
RETURNING object xml.DomNode

Usage

Returns the DomNode object immediately following this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.getNextSiblingElement
Returns the XML Element DomNode object immediately following a DomNode object.

Syntax

```java
getNextSiblingElement ()
RETURNING object xml.DomNode
```

Usage

Returns the XML Element DomNode object immediately following this DomNode object, or NULL.

**Caution:** Not part of W3C API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```
xml.DomNode.getNodeName
```

Gets the name for a DomNode object.

Syntax

```java
getNodeName ()
RETURNING str STRING
```

Usage

Gets the name for this DomNode object; returns the qualified name of this DomNode object, or NULL. If DomNode does not have a qualified name, the local part is returned.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```
xml.DomNode.getNodeType
```

Gets the XML type for this DomNode object.

Syntax

```java
getNodeType ()
RETURNING str STRING
```

Usage

Gets the XML type for this DomNode object; returns one of the XML DomNode types, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```
xml.DomNode.getNodeValue
```

Returns the value for a DomNode object.

Syntax

```java
getNodeValue ()
RETURNING str STRING
```
Usage

Returns the value for this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.getOwnerDocument**

Returns the DomDocument object containing this DomNode object.

Syntax

```
getOwnerDocument()  
  RETURNING object xml.DomDocument
```

Usage

Returns the DomDocument object containing this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.getParentNode**

Returns the parent DomNode object for this DomNode object.

Syntax

```
getParentNode()  
  RETURNING object xml.DomNode
```

Usage

Returns the parent DomNode object for this DomNode object, or NULL. In the case of a DomDocument node, this method will return NULL (parent is not a DomNode object) but isAttached() will return TRUE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.getPrefix**

Returns the prefix for a DomNode object.

Syntax

```
getPrefix()  
  RETURNING str STRING
```

Usage

Returns the prefix for this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.getPreviousSibling**
Returns the DomNode object immediately preceding a DomNode object.

**Syntax**

```
getPreviousSibling()
    RETURNING object xml.DomNode
```

**Usage**

Returns the DomNode object immediately preceding this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

```
xml.DomNode.getPreviousSiblingElement
    Returns the XML Element DomNode object immediately preceding a DomNode object.
```

**Syntax**

```
getPreviousSiblingElement()
    RETURNING object xml.DomNode
```

**Usage**

Returns the XML Element DomNode object immediately preceding this DomNode object, or NULL.

Caution: Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

```
xml.DomNode.hasAttribute
    Checks whether an XML Element DomNode object has the XML Attribute specified by a specified name.
```

**Syntax**

```
hasAttribute(
    name STRING )
    RETURNING flag INTEGER
```

1. *name* is the object name to check.

**Usage**

Checks whether this XML Element DomNode object has the XML Attribute specified by *name*. Returns TRUE if an XML Attribute with the given name is carried by this XML Element DomNode object, otherwise returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

```
xml.DomNode.hasAttributeNS
```

Checks whether a namespace qualified XML Attribute of a given name is carried by an XML Element DomNode object.

**Syntax**

```sql
hasAttributeNS(
    name STRING,
    ns STRING )
RETURNING flag INTEGER
```

1. *name* the name of the XML Attribute to check
2. *ns* the namespace URI of the XML Attribute to check.

**Usage**

Checks whether a namespace qualified XML Attribute of a given name is carried by this XML Element DomNode object, where *name* the name of the XML Attribute to check; *ns* the namespace URI of the XML Attribute to check. Returns TRUE if an XML Attribute with the given name and namespace URI is carried by this XML Element DomNode object, otherwise returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.hasAttributes**

Identifies whether a node has XML Attribute nodes.

**Syntax**

```sql
hasAttributes()
RETURNING flag INTEGER
```

1. *flag* acts as a boolean.

**Usage**

Returns TRUE if this node has XML Attribute nodes; otherwise, returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.hasChildNodes**

Returns TRUE if a node has child nodes.

**Syntax**

```sql
hasChildNodes()
RETURNING flag INTEGER
```

**Usage**

Returns TRUE if this node has child nodes; otherwise, returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.insertAfterChild**
Inserts a DomNode object after an existing child DomNode object.

**Syntax**

```java
insertAfterChild(
    node xml.DomNode,
    ref xml.DomNode )
```

1. `node` is the node to insert.
2. `ref` is the reference node (the node before which the new node must be inserted).

**Usage**

Inserts a DomNode object after an existing child DomNode object; `node` is the node to insert, `ref` is the reference node (the node before which the new node must be inserted).

**Caution:** Not part of W3C API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.insertBeforeChild**

Inserts a DomNode object before an existing child DomNode object.

**Syntax**

```java
insertBeforeChild(
    node xml.DomNode,
    ref xml.DomNode )
```

1. `node` is the node to insert.
2. `ref` is the reference node (the node before which the new node must be inserted).

**Usage**

Inserts a DomNode object before an existing child DomNode object; `node` is the node to insert, `ref` is the reference node (the node before which the new node must be inserted).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.isAttached**

Returns whether the node is attached to the XML document.

**Syntax**

```java
isAttached()
RETURNING num INTEGER
```

**Usage**

Returns whether the node is attached to the XML document.

**Caution:** Not part of W3C API.

Returns TRUE if this DomNode object is attached to a DomDocument object as a child and was not removed later on; otherwise it returns FALSE.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`xml DomNode.isDefaultNamespace`

Checks whether the specified namespace URI is the default namespace.

**Syntax**

```java
isDefaultNamespace (
    ns STRING )
RETURNING flag INTEGER
```

1. `ns` is the namespace URI to look for.

**Usage**

Checks whether the specified namespace URI is the default namespace, where `ns` is the namespace URI to look for. Returns TRUE if the given namespace is the default namespace, FALSE otherwise.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`xml DomNode.lookupNamespaceURI`

Looks up the namespace URI associated to a prefix, starting from a specified node.

**Syntax**

```java
lookupNamespaceURI (
    prefix STRING )
RETURNING ns STRING
```

1. `prefix` is the prefix to look for.

**Usage**

Looks up the namespace URI associated to a prefix, starting from this node, where `prefix` is the prefix to look for; if NULL, the default namespace URI will be returned. Returns a namespace URI, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`xml DomNode.lookupPrefix`

Looks up the prefix associated to a namespace URI, starting from the specified node.

**Syntax**

```java
lookupPrefix (
    ns STRING )
RETURNING prefix STRING
```

1. `ns` is the namespace URI to look for.

**Usage**

Looks up the prefix associated to a namespace URI, starting from this node, where `ns` is the namespace URI to look for. Returns the prefix associated to this namespace URI, or NULL.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.prependChild**

Adds a child DomNode object to the beginning of the child list for a DomNode object.

**Syntax**

```xml
prependChild(
    node xml.DomNode
)
```

1. *node* is the node to add.

**Usage**

Adds a child DomNode object to the beginning of the child list for this DomNode object; *node* is the node to add.

**Caution:** Not part of W3C API.

The DomNode object node must be the child of an element or document node, otherwise the operation fails.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.prependChildElement**

Creates and adds a child XML Element node to the beginning of the list of child nodes for this XML Element DomNode object.

**Syntax**

```xml
prependChildElement(
    name STRING
    RETURNING object xml.DomNode
)
```

1. *name* is the name of the XML element to add.

**Usage**

Creates and adds a child XML Element node to the beginning of the list of child nodes for this XML Element DomNode object; *name* is the name of the XML element to add.

Returns the XML Element DomNode object, or NULL.

**Caution:** Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.DomNode.prependChildElementNS**

Creates and adds a child namespace-qualified XML Element node to the beginning of the list of child nodes for an XML Element DomNode object.

**Syntax**

```xml
prependChildElementNS(
    name STRING
)
```

**Usage**

Creates and adds a child namespace-qualified XML Element node to the beginning of the list of child nodes for this XML Element DomNode object; *name* is the name of the XML element to add.

Returns the XML Element DomNode object, or NULL.

**Caution:** Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.
```sql
prefix STRING,
name STRING,
ns STRING
)
RETURNING object xmlDOMNode
```

1. `prefix` is the prefix of the XML Element to add.
2. `name` is the name of the XML Element to add.
3. `ns` is the namespace URI of the XML Element to add.

**Usage**

Creates and adds a child namespace-qualified XML Element node to the beginning of the list of child nodes for this XML Element `DOMNode` object.

Returns the XML Element `DOMNode` object, or `NULL`.

**Note:** Not part of W3C API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```sql
xmlDOMNode.removeAllChildren
```

Removes all child `DOMNode` objects from a `DOMNode` object.

**Syntax**

```sql
removeAllChildren()
```

**Usage**

Removes all child `DOMNode` objects from this `DOMNode` object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```sql
xmlDOMNode.removeAttribute
```

Removes an XML Attribute for an XML Element `DOMNode` object.

**Syntax**

```sql
removeAttribute(
    name STRING
)
```

1. `name` is the name of the XML attribute to remove.

**Usage**

Removes an XML Attribute for this XML Element `DOMNode` object, where `name` is the name of the XML attribute to remove. Status is updated with an error code.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```sql
xmlDOMNode.removeAttributeNS
```
Removes a namespace qualified XML Attribute for an XML Element DomNode object

**Syntax**

```java
removeAttributeNS(
    name STRING,
    ns STRING )
```

1. *name* is the name of the XML Attribute to remove.
2. *ns* is the namespace URI of the XML Attribute to remove.

**Usage**

Removes a namespace qualified XML Attribute for this XML Element DomNode object, where name is the name and ns is the namespace URI of the XML Attribute to remove.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.DomNode.removeChild
```

Removes a child DomNode object from the list of child DomNode objects.

**Syntax**

```java
removeChild(  
    node xml.DomNode )
```

1. *node* is the node to remove.

**Usage**

Removes a child DomNode object from the list of child DomNode objects, where node is the node to remove.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.DomNode.replaceChild
```

Replaces an existing child DomNode with another child DomNode object.

**Syntax**

```java
replaceChild(  
    new xml.DomNode,  
    old xml.DomNode )
```

1. *new* is the replacement child.
2. *old* is the child to be replaced.

**Usage**

Replaces an existing child DomNode with another child DomNode object, where old is the child to be replaced and new is the replacement child.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.
xml.DomNode.selectByXPath

Returns a DomNodeList object containing all DomNode objects matching an XPath 1.0 expression.

**Syntax**

```java
selectByXPath(
    expr STRING,
    NamespacesList ...)
RETURNING list xml.DomNodeList
```

1. `expr` is the XPath 1.0 expression.
2. `NamespacesList` is a list of prefixes bounded to namespaces in order to resolve qualified names in the XPath expression.

**Usage**

Returns a DomNodeList object containing all DomNode objects matching an XPath 1.0 expression; `expr` is the XPath 1.0 expression, `NamespacesList` is a list of prefixes bounded to namespaces in order to resolve qualified names in the XPath expression. This list must be filled with an even number of arguments, representing the prefix and the corresponding namespace.

**Caution:** Not part of W3C API.

**Example**

```java
selectByXPath(
    "../../d:Record/*[last()]",
    "d",
    "http://defaultnamespace")
selectByXPath(
    "ns:Record",
    NULL)
selectByXPath(
    "ns1:Records/ns2:Record",
    "ns1",
    "http://namespace1",
    "ns2",
    "http://namespace2")
```

selectByXPath("ns1:Record", "ns1") is invalid because the namespace definition is missing.

If the namespaces list is NULL, the prefixes and namespaces defined in the document itself are used if available.

A namespace must be an absolute URI (ex 'http://', 'file://').

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.setAttribute

Sets (or resets) an XML Attribute for an XML Element DomNode object.

**Syntax**

```java
setAttribute(
    name STRING,
    value STRING )
```
1. *name* is the name of the XML Attribute.
2. *val* is the value of the XML Attribute.

### Usage

Sets (or resets) an XML Attribute for this XML Element DomNode object, where *name* is the name of the XML Attribute and *val* is the value of the XML Attribute.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.DomNode.setAttributeNode(node)
```

Sets (or resets) an XML Attribute DomNode object to an XML Element DomNode object.

#### Syntax

```java
setAttributeNode(
    node xml.DomNode)
```

1. *node* is the XML Attribute DomNode object to set.

### Usage

Sets (or resets) an XML Attribute DomNode object to an XML Element DomNode object, where *node* is the XML Attribute DomNode object to set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.DomNode.setAttributeNodeNS(node)
```

Sets (or resets) a namespace-qualified XML Attribute DomNode object to an XML Element DomNode object.

#### Syntax

```java
setAttributeNodeNS(
    node xml.DomNode)
```

1. *node* is the XML Attribute DomNode object to set.

### Usage

Sets (or resets) a namespace-qualified XML Attribute DomNode object to an XML Element DomNode object, where *node* is the XML Attribute DomNode object to set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.DomNode.setAttributeNS(prefix, name, ns)
```

Sets (or resets) a namespace-qualified XML Attribute for an XML Element DomNode object.

#### Syntax

```java
setAttributeNS(
    prefix STRING, 
    name STRING, 
    ns STRING,
```

value STRING })

1. prefix is the prefix of the XMLAttribute.
2. name is the name of the XML Attribute.
3. ns is the namespace URI of the XML Attribute.
4. val is the value of the XML Attribute.

Usage

Sets (or resets) a namespace-qualified XML Attribute for this XML Element DomNode object, where prefix is the prefix of the XMLAttribute, name is the name of the XML Attribute, ns is the namespace URI of the XML Attribute, and val is the value of the XML Attribute.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.setIdAttribute

Declare (or undeclare) the XML Attribute of given name to be of type ID.

Syntax

```
setIdAttribute(
    name STRING,
    isId INTEGER )
```

1. name is the name of the XML Attribute to set.
2. isId declares whether the attribute is a user-determined ID attribute.

Usage

Declare (or undeclare) the XML Attribute of given name to be of type ID. Use the value TRUE for the parameter isId to declare that attribute for being a user-determined ID attribute, otherwise returns FALSE.

This affects the behavior of getElementById.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNode.setIdAttributeNS

Declare (or undeclare) the namespace-qualified XML Attribute of given name and namespace to be of type ID.

Syntax

```
setIdAttributeNS(
    name STRING,
    ns STRING,
    isId INTEGER )
```

1. name is the name of the XML Attribute to set.
2. ns is the namespace URI of the XML Attribute to set.
3. isId declares whether the attribute is a user-determined ID attribute.
**Usage**

Declare (or undeclare) the namespace-qualified XML Attribute of given name and namespace to be of type ID. Use the value TRUE for the parameter `isID` to declare that attribute for being a user-determined ID attribute, otherwise returns FALSE.

This affects the behavior of `getElementById`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### xmlDOMNode.setNodeValue

Sets the node value for a `DOMNode` object.

**Syntax**

```java
setNodeValue(
    val STRING
)
```

1. `val` is the node value.

### Usage

Sets the node value for this `DOMNode` object, where `val` is the node value.

This method should only be used for nodes that are not parent of other nodes, which means it can be sued for a node of type:

- `ATTRIBUTE_NODE`
- `TEXT_NODE`
- `CDATA_SECTION_NODE`
- `PROCESSING_INSTRUCTION_NODE`
- `COMMENT_NODE`

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### xmlDOMNode.setPrefix

Sets the prefix for a `DOMNode` object.

**Syntax**

```java
setPrefix(
    prefix STRING
)
```

1. `prefix` is the prefix for this `DOMNode` object.

### Usage

Sets the `prefix` for this `DOMNode` object.

This method is only valid on namespace qualified Element or Attribute nodes.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### xmlDOMNode.toString

Returns a string representation of a DomNode object.

Syntax

```
toString()  RETURNING STRING
```

Usage

Returns a string representation of this DomNode object, or NULL

**Caution:** Not part of W3C API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

DomNode types

List of types for the xml.DomNode class.

**Table 499: DomNode types**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ELEMENT_NODE</td>
<td>The DomNode is an XML Element node.</td>
</tr>
<tr>
<td>ATTRIBUTE_NODE</td>
<td>The DomNode is an XML Attribute node.</td>
</tr>
<tr>
<td>TEXT_NODE</td>
<td>The DomNode is an XML Text node.</td>
</tr>
<tr>
<td>CDATA_SECTION_NODE</td>
<td>The DomNode is an XML CData Section node.</td>
</tr>
<tr>
<td>ENTITY_REFERENCE_NODE</td>
<td>The DomNode is an XML Entity Reference node.</td>
</tr>
<tr>
<td>PROCESSING_INSTRUCTION_NODE</td>
<td>The DomNode is an XML Processing Instruction node.</td>
</tr>
<tr>
<td>COMMENT_NODE</td>
<td>The DomNode is an XML Comment node.</td>
</tr>
<tr>
<td>DOCUMENT_TYPE_NODE</td>
<td>The DomNode is an XML DTD node.</td>
</tr>
<tr>
<td>DOCUMENT_FRAGMENT_NODE</td>
<td>The DomNode is an XML Document Fragment node.</td>
</tr>
</tbody>
</table>

Examples

Examples involving the xml.DomNode class.

Example Counting the number of nodes in an XML document

This code example counts the number of nodes of each type.

```
IMPORT XML

DEFINE nbElt INTEGER
DEFINE nbAttr INTEGER
DEFINE nbComment INTEGER
DEFINE nbPI INTEGER
DEFINE nbTxt INTEGER
DEFINE nbCData INTEGER

MAIN
    DEFINE document xml.DomDocument
    DEFINE ind INTEGER
```
# Handle arguments
IF num_args() !=1 THEN
    CALL ExitHelp()
END IF

# Create document, load it, and count the nodes
LET document = xml.DomDocument.Create()
CALL document.load(arg_val(1))
CALL CountDoc(document)

# Display result
DISPLAY "Results: 
DISPLAY " Elements: ",nbElt
DISPLAY " Attributes: ",nbAttr
DISPLAY " Comments: ",nbComment
DISPLAY " PI: ",nbPI
DISPLAY " Texts: ",nbTxt
DISPLAY " CData: ",nbCData

END MAIN

FUNCTION CountDoc(d)
    DEFINE d xml.DomDocument
    DEFINE n xml.DomNode
    LET n = d.getFirstDocumentNode()
    WHILE (n IS NOT NULL )
        CALL Count(n)
        LET n = n.getNextSibling()
    END WHILE
END FUNCTION

FUNCTION Count(n)
    DEFINE n xml.DomNode
    DEFINE child xml.DomNode
    DEFINE next xml.DomNode
    DEFINE node xml.DomNode
    DEFINE ind INTEGER
    DEFINE name STRING
    IF n IS NOT NULL THEN
        IF n.getNodeType() == "COMMENT_NODE" THEN

                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
                    LET useAttributeNSPrefixQ = n.getAttributeUseAttributeNSPrefixQ()
The DomNodeList class

The xml.DomNodeList class provides methods to manipulate a list of DomNode objects.

You can create a DomNodeList object using selection methods in the DomDocument and DomNode classes. The relationship between the DomNode objects in the list depends on the method used to create the DomNodeList object.

The STATUS variable is set to zero after a successful method call.

xml.DomNodeList methods

Methods for the xml.DomNodeList class.

Table 500: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getCount()</td>
<td>Returns the number of DomNode objects in a DomNodeList object.</td>
</tr>
<tr>
<td>getItem(pos INTEGER)</td>
<td>Returns the DomNode object at a given position in a DomNodeList object.</td>
</tr>
</tbody>
</table>

xml.DomNodeList.getCount

Returns the number of DomNode objects in a DomNodeList object.

Syntax

```plaintext
getCount()
RETURNING num INTEGER
```

Usage

Returns the number of DomNode objects in a DomNodeList object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.DomNodeList.getItem

Returns the DomNode object at a given position in a DomNodeList object.

Syntax

```plaintext
getItem(
pos INTEGER)
```

Usage

Returns the DomNode object at a given position in a DomNodeList object.
1. **pos** is the position of the DomNode object to return (index starts at 1).

**Usage**

Returns the **DomNode** object at the given position in this DomNodeList object, where **pos** is the position of the DomNode object to return (Index starts at 1).

Returns NULL when no DomNode object is at the given position.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.

**The streaming API for XML (StAX) classes**

The streaming API for XML (StAX) classes use streaming while managing XML documents.

- **CLASS StaxWriter**
  - Features
  - Example
- **CLASS StaxReader**
  - Event types
  - Features
  - Example

**The StaxWriter class**

The **xml.StaxWriter** class provides methods compatible with StAX (Streaming API for XML) for writing XML documents.

The **STATUS** variable is set to zero after a successful method call.

**xml.StaxWriter methods**

Methods for the **xml.StaxWriter class**.

**Table 501: Class methods: Creation**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>xml.StaxWriter.create()</strong></td>
<td>Constructor of a StaxWriter object.</td>
</tr>
</tbody>
</table>

**Table 502: Object methods: Configuration**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>getFeature</strong> (feature STRING )</td>
<td>Gets a feature of a StaxWriter object.</td>
</tr>
<tr>
<td><strong>setFeature</strong> (feature STRING, value STRING )</td>
<td>Sets a feature of a StaxWriter object.</td>
</tr>
</tbody>
</table>
### Table 503: Object methods: Output

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>close()</td>
<td>Closes the StaxWriter streaming, and releases all associated resources.</td>
</tr>
<tr>
<td>writeTo(url STRING)</td>
<td>Sets the output stream of the StaxWriter object to a file or an URL, and starts the streaming.</td>
</tr>
<tr>
<td>writeToPipe(cmd STRING)</td>
<td>Sets the output stream of the StaxWriter object to a PIPE, and starts the streaming.</td>
</tr>
<tr>
<td>writeToText(txt TEXT)</td>
<td>Sets the output stream of the StaxWriter object to a TEXT large object, and starts the streaming.</td>
</tr>
</tbody>
</table>

### Table 504: Object methods: Document

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dtd(data STRING)</td>
<td>Writes a DTD to the StaxWriter stream.</td>
</tr>
<tr>
<td>endDocument()</td>
<td>Closes any open tags and writes corresponding end tags.</td>
</tr>
<tr>
<td>startDocument(encoding STRING, version STRING, standalone INTEGER)</td>
<td>Writes an XML declaration to the StaxWriter stream.</td>
</tr>
</tbody>
</table>

### Table 505: Object methods: Namespace

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>declareDefaultNamespace(defaultNS STRING)</td>
<td>Binds a namespace URI to the default namespace, and forces the output of the default XML namespace definition to the StaxWriter stream.</td>
</tr>
<tr>
<td>declareNamespace(prefix STRING, ns STRING)</td>
<td>Binds a namespace URI to a prefix, and forces the output of the XML namespace definition to the StaxWriter stream.</td>
</tr>
<tr>
<td>setDefaultNamespace</td>
<td>Binds a namespace URI to the default namespace.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>defaultNS STRING</td>
<td></td>
</tr>
</tbody>
</table>
| setPrefix(  
  prefix STRING,  
  ns STRING ) | Binds a namespace URI to a prefix. |

### Table 506: Object methods: Node

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| attribute(  
  name STRING,  
  value STRING ) | Writes an XML attribute to the StaxWriter stream. |
| attributeNS(  
  name STRING,  
  ns STRING,  
  value STRING ) | Writes an XML namespace qualified attribute to the StaxWriter stream. |
| cdata(  
  data STRING ) | Writes an XML CData to the StaxWriter stream. |
| characters(  
  text STRING ) | Writes an XML text to the StaxWriter stream. |
| comment(  
  data STRING ) | Writes an XML comment to the StaxWriter stream. |
| emptyElement(  
  name STRING ) | Writes an empty XML element to the StaxWriter stream. |
| emptyElementNS(  
  name STRING,  
  ns STRING ) | Writes an empty namespace qualified XML element to the StaxWriter stream. |
| endElement() | Writes an end tag to the StaxWriter stream relying on the internal state to determine the prefix and local name of the last `START_ELEMENT`. |
| entityRef(  
  name STRING ) | Writes an XML EntityReference to the StaxWriter stream. |
| processingInstruction(  
  target STRING,  
  data STRING ) | Writes an XML ProcessingInstruction to the StaxWriter stream. |
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>data</code> STRING )</td>
<td></td>
</tr>
<tr>
<td><code>startElement</code> (</td>
<td>Writes an XML start element to the StaxWriter stream.</td>
</tr>
<tr>
<td>name STRING )</td>
<td></td>
</tr>
<tr>
<td><code>startElementNS</code> (</td>
<td>Writes a namespace-qualified XML start element to the StaxWriter stream.</td>
</tr>
<tr>
<td>name STRING,</td>
<td></td>
</tr>
<tr>
<td>ns STRING )</td>
<td></td>
</tr>
</tbody>
</table>

**xml.StaxWriter.attribute**

Writes an XML attribute to the StaxWriter stream.

**Syntax**

```
attribute(
    name STRING,
    value STRING )
```

1. `name` is the local name of the XML attribute. It cannot be NULL.
2. `value` is the value of the XML attribute. It cannot be NULL.

**Usage**

Attributes can only be written on the StaxWriter stream if it points to a START_ELEMENT or an EMPTY_ELEMENT, otherwise the operation fails with an exception; that is, this method can only be called after a `startElement`, `startElementNS`, `emptyElement`, `emptyElementNS`, or `attribute` and `attributeNS`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxWriter.attributeNS**

Writes an XML namespace qualified attribute to the StaxWriter stream.

**Syntax**

```
attributeNS(
    name STRING,
    ns STRING,
    value STRING )
```

1. `name` is the local name of the XML attribute, cannot be NULL.
2. `ns` is the namespace URI of the XML attribute, cannot be NULL.
3. `value` is the value of the XML attribute, cannot be NULL.

**Usage**

Attributes can only be written on the StaxWriter stream if it points to a START_ELEMENT or an EMPTY_ELEMENT, otherwise the operation fails with an exception; that is, this method can only be called after a `startElement`, `startElementNS`, `emptyElement`, `emptyElementNS`, or `attribute` and `attributeNS`. 
If namespace URI has not been bound to a prefix with one of the methods `setPrefix`, `declareNamespace`, `setDefaultNamespace` or `declareDefaultNamespace`, the operation fails with an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### `xml.StaxWriter.cdata`

Writes an XML CData to the StaxWriter stream.

**Syntax**

```cdata(data STRING)
```

1. `data` is the data contained in the CData section, or NULL.

**Usage**

This method writes XML character data passed as parameter as a CData.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### `xml.StaxWriter.characters`

Writes an XML text to the StaxWriter stream.

**Syntax**

```characters(text STRING)
```

1. `text` is the value to write.

**Usage**

This method writes the character string passed as parameter as a text element.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### `xml.StaxWriter.close`

Closes the StaxWriter streaming, and releases all associated resources.

**Syntax**

```close()
```

**Usage**

This method closes the stream.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
Writes an XML comment to the StaxWriter stream.

**Syntax**

```
comment (
    data STRING
)
```

1. `data` is the data in the XML comment, or NULL.

**Usage**

This method write and XML comment to the stream.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

---

**xml.StaxWriter.create**

Constructor of a StaxWriter object.

**Syntax**

```
xml.StaxWriter.create ()
RETURNS object xml.StaxWriter
```

**Usage**

Returns a new StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

---

**xml.StaxWriter.declareDefaultNamespace**

Binds a namespace URI to the default namespace, and forces the output of the default XML namespace definition to the StaxWriter stream.

**Syntax**

```
declareDefaultNamespace (
    defaultNS STRING
)
```

1. `defaultNS` is the URI to bind to the default namespace. It cannot be NULL.

**Usage**

The stream must point to a START_ELEMENT, and the prefix scope is the current START_ELEMENT / END_ELEMENT pair.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

---

**xml.StaxWriter.declareNamespace**
Binds a namespace URI to a prefix, and forces the output of the XML namespace definition to the StaxWriter stream.

**Syntax**

```
declareNamespace(
    prefix STRING,
    ns STRING )
```

1. *prefix* is the prefix to be bind to the URI, cannot be NULL.
2. *ns* is the URI to bind to the default namespace, cannot be NULL.

**Usage**

The stream must point to a **START_ELEMENT**, and the prefix scope is the current **START_ELEMENT / END_ELEMENT** pair.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxWriter.dtd**

Writes a DTD to the StaxWriter stream.

**Syntax**

```
dtd(
    data STRING )
```

1. *data* is a string representing a valid DTD, cannot be NULL.

**Usage**

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxWriter.emptyElement**

Writes an empty XML element to the StaxWriter stream.

**Syntax**

```
emptyElement(
    name STRING )
```

1. *name* is the local name of the XML empty element, cannot be NULL.

**Usage**

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxWriter.emptyElementNS**

Writes an empty namespace qualified XML element to the StaxWriter stream.

**Syntax**

```
emptyElementNS()```
1. `name` is the local name of the XML empty element, cannot be NULL.
2. `ns` is the namespace URI of the XML empty element, cannot be NULL.

**Usage**

If namespace URI has not been bound to a prefix with one of the functions `setPrefix`, `declareNamespace`, `setDefaultNamespace` or `declareDefaultNamespace`, the operation fails with an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxWriter.endDocument**

Closes any open tags and writes corresponding end tags.

**Syntax**

```java
endDocument()
```

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxWriter.endElement**

Writes an end tag to the StaxWriter stream relying on the internal state to determine the prefix and local name of the last `START_ELEMENT`.

**Syntax**

```java
endElement()
```

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxWriter.entityRef**

Writes an XML EntityReference to the StaxWriter stream.

**Syntax**

```java
entityRef(
    name STRING)
```

1. `name` is the name of the entity, cannot be NULL.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
xml.StaxWriter.getFeature
Gets a feature of a StaxWriter object.

Syntax

```
getFeature(
  feature STRING )
RETURNING str STRING
```

1. `feature` is the name of a feature.

Usage

Returns the feature value. See StaxWriter Features on page 2190.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxWriter.processingInstruction
Writes an XML ProcessingInstruction to the StaxWriter stream

Syntax

```
processingInstruction(
  target STRING,
  data STRING )
```

1. `target` is the target of the Processing Instruction, cannot be NULL.
2. `data` is the data of the Processing Instruction, or NULL.

Usage

Writes an XML ProcessingInstruction to the StaxWriter stream, where `target` is the target of the Processing Instruction, cannot be NULL; `data` is the data of the Processing Instruction, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxWriter.setDefaultNamespace
Binds a namespace URI to the default namespace.

Syntax

```
setDefaultNamespace(
  defaultNS STRING )
```

1. `defaultNS` is the URI to bind to the default namespace, cannot be NULL.

Usage

Binds a namespace URI to the default namespace. The default namespace scope is the current START_ELEMENT / END_ELEMENT pair; `defaultNS` is the URI to bind to the default namespace, cannot be NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.
xml.StaxWriter.setFeature

Sets a feature of a StaxWriter object.

**Syntax**

```java
setFeature(
    feature STRING,
    value STRING )
```

1. `feature` is the name of a feature.
2. `value` is the value of the feature.

**Usage**

Sets a feature of a StaxWriter object, where `feature` is the name of a feature, and `value` is the value of the feature. The features can be changed at any time, but will only be taken into account at the beginning of a new stream (see `writeTo` or `writeToDocument`).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxWriter.setPrefix

Binds a namespace URI to a prefix.

**Syntax**

```java
setPrefix(
    prefix STRING,
    ns STRING )
```

1. `prefix` is the prefix to be bind to the URI, cannot be NULL.
2. `ns` is the namespace URI to be bind to the prefix, cannot be NULL.

**Usage**

The prefix scope is the current `START_ELEMENT / END_ELEMENT` pair.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxWriter.startDocument

Writes an XML declaration to the StaxWriter stream.

**Syntax**

```java
startDocument(
    encoding STRING,
    version STRING,
    standalone INTEGER )
```

1. `encoding` is the encoding of the XML declaration, or NULL to use the default UTF-8 encoding.
2. `version` is the XML version of the XML declaration, or NULL to use the default 1.0 version.
3. `standalone` when TRUE sets the standalone of the XML declaration to "yes", when FALSE sets it to "no" or NULL.
Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

Example

This call:

```java
startDocument("utf-8","1.0",true)
```

Produces:

```xml
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
dtd("note [<!ENTITY writer \"Donald Duck.\"]")
```

xml.StaxWriter.startElement

Writes an XML start element to the StaxWriter stream.

Syntax

```java
startElement (  
    name STRING  )
```

1. `name` is the local name of the XML start element, cannot be NULL.

Usage

All `startElement` methods open a new scope and set the stream to a START_ELEMENT. Writing the corresponding `endElement` causes the scope to be closed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxWriter.startElementNS

Writes a namespace-qualified XML start element to the StaxWriter stream.

Syntax

```java
startElementNS (  
    name STRING,  
    ns STRING  )
```

1. `name` is the local name of the XML start element, cannot be NULL.
2. `ns` is the namespace URI of the XML start element, cannot be NULL.

Usage

All `startElementNS` methods open a new scope and set the stream to a START_ELEMENT. Writing the corresponding `endElement` causes the scope to be closed.

If namespace URI has not been bound to a prefix with one of the functions `setPrefix`, `declareNamespace`, `setDefaultNamespace` or `declareDefaultNamespace`, the operation fails with an exception.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxWriter.writeTo
Sets the output stream of the StaxWriter object to a file or an URL, and starts the streaming.

**Syntax**

```java
writeTo(
    url STRING
)
```

1. `url` is a valid URL or the name of the file that will contain the resulting XML document.

**Usage**

Only the following kinds of URLs are supported:

- `http://`
- `https://`
- `tcp://`
- `tcps://`
- `file://`
- `alias://`

See FGLPROFILE Configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**Examples**

```java
writeTo("printerList.xml")
writeTo("http://myserver:1100/documents/printerList.xml")
writeTo("https://myserver:1100/documents/printerList.xml")
writeTo("alias://printerlist")
```

where `printerlist alias` is defined in fglprofile as `ws.printerlist.url = "http://myserver:1100/documents/ptinterList.xml"`.

xml.StaxWriter.writeToDocument

Sets the output stream of the StaxWriter object to an xml.DomDocument object, and starts the streaming.

**Syntax**

```java
writeToDocument(
    doc xml.DomDocument
)
```

1. `doc` is the empty xml.DomDocument object that will contain the resulting XML document.
**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.StaxWriter.writeToPipe
Sets the output stream of the StaxWriter object to a PIPE, and starts the streaming.
```

**Syntax**

```java
writeToPipe(
    cmd STRING)
```

1. `cmd` is the command to start the PIPE that will get the resulting XML document.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.StaxWriter.writeToText
Sets the output stream of the StaxWriter object to a TEXT large object, and starts the streaming.
```

**Syntax**

```java
writeToText(
    txt TEXT)
```

1. `txt` must be a TEXT lob located in memory that will contain the resulting XML document.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

StaxWriter Features

Features of the `xml.StaxWriter` class.

**Table 507: StaxWriter features**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>format-pretty-print</td>
<td>Formats the output by adding whitespace to produce a pretty-printed, indented, human-readable form. Default value is FALSE.</td>
</tr>
<tr>
<td>smart-ending-elements</td>
<td>Outputs each tag closed with an <code>endElement()</code> call as empty elements if they have no children. Default value is FALSE.</td>
</tr>
</tbody>
</table>
Example
This example uses methods from the xml.StaxWriter class.

```plaintext
IMPORT xml

FUNCTION save(file)
DEFINE file STRING
DEFINE writer xml.StaxWriter
TRY
LET writer = xml.StaxWriter.Create()
CALL writer.setFeature("format-pretty-print",TRUE)
CALL writer.writeTo(file)
CALL writer.startDocument("utf-8","1.0",true)
CALL writer.comment("This is my first comment using a stax writer")
CALL writer.setPrefix("c","http://www.mycompany.com/c")
CALL writer.setPrefix("d","http://www.mycompany.com/d")
CALL writer.setDefaultNamespace("http://www.mycompany.com/d")
CALL writer.setPrefix("eltA","http://www.mycompany.com/d")
CALL writer.startElementNS("root","http://www.mycompany.com/d")
CALL writer.attribute("attr1","value1")
CALL writer.attribute("attr2","value2")
CALL writer.attributeNS("attr3","http://www.mycompany.com/d","value3")
CALL writer.comment("This is a comment using a stax writer")
CALL writer.startElementNS("eltA","http://www.mycompany.com/d")
CALL writer.CData("<this is a CData section>")
CALL writer.endElement() 
CALL writer.startElementNS("eltB","http://www.mycompany.com/c")
CALL writer.characters("Hello world, I'm from the development team")
CALL writer.entityRef("one")
CALL writer.endElement() 
CALL writer.processingInstruction("command1","do what you want")
CALL writer.endElement() 
CALL writer.comment("This is my last comment using a stax writer")
CALL writer.endDocument()
RETURN TRUE
CATCH
DISPLAY "StaxWriter ERROR ":,STATUS, SQLCA.SQLERRM
RETURN FALSE
END TRY
END FUNCTION
```

The StaxReader class
The StaxReader class provides methods compatible with StAX (Streaming API for XML) for reading XML documents.

The STATUS variable is set to zero after a successful method call.

Syntax

```plaintext
xml.StaxReader
```

xml.StaxReader methods
Methods for the xml.StaxReader class.

Table 508: Class methods: Creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml.StaxReader.Create()</td>
<td>Constructor of a StaxReader object.</td>
</tr>
</tbody>
</table>
### Table 509: Object methods: Configuration

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>setFeature</code></td>
<td>Sets a feature of a StaxReader object.</td>
</tr>
<tr>
<td><code>getFeature</code></td>
<td>Gets a feature of a StaxReader object.</td>
</tr>
</tbody>
</table>

```java
setFeature(
    feature STRING,
    value STRING )
```

```java
getFeature(
    feature STRING )
RETURNING str STRING
```

### Table 510: Object methods: Input

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>readFrom</code></td>
<td>Sets the input stream of the StaxReader object to a file or an URL and starts the streaming</td>
</tr>
<tr>
<td><code>readFromDocument</code></td>
<td>Sets the input stream of the StaxReader object to a DomDocument object and starts the streaming</td>
</tr>
<tr>
<td><code>readFromText</code></td>
<td>Sets the input stream of the StaxReader object to a TEXT large object and starts the streaming.</td>
</tr>
<tr>
<td><code>readFromPipe</code></td>
<td>Sets the input stream of the StaxReader object to a PIPE and starts the streaming.</td>
</tr>
<tr>
<td><code>close</code></td>
<td>Closes the StaxReader streaming and releases all associated resources.</td>
</tr>
</tbody>
</table>

```java
readFrom(
    url STRING )
```

```java
readFromDocument(
    doc xml.DomDocument )
```

```java
readFromText(
    txt TEXT )
```

```java
readFromPipe(
    cmd STRING )
```

### Table 511: Object methods: Access

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getEventType</code></td>
<td>Returns a string that indicates the type of event the cursor of the StaxReader object is pointing to.</td>
</tr>
<tr>
<td><code>hasName</code></td>
<td>Checks whether the StaxReader cursor points to a node with a name.</td>
</tr>
<tr>
<td><code>hasText</code></td>
<td>Checks whether the StaxReader cursor points to a node with a text value.</td>
</tr>
<tr>
<td><code>isEmptyElement</code></td>
<td>Checks whether the StaxReader cursor points to an empty element node.</td>
</tr>
</tbody>
</table>

```java
getEventType()        RETURNING eventtype STRING
```

```java
hasName()        RETURNING flag INTEGER
```

```java
hasText()        RETURNING flag INTEGER
```

```java
isEmptyElement()    
```
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RETURNING flag INTEGER</td>
<td></td>
</tr>
<tr>
<td><strong>isStartElement()</strong></td>
<td>Checks whether the StaxReader cursor points to a start element node.</td>
</tr>
<tr>
<td>RETURNING flag INTEGER</td>
<td></td>
</tr>
<tr>
<td><strong>isEndElement()</strong></td>
<td>Checks whether the StaxReader cursor points to an end element node.</td>
</tr>
<tr>
<td>RETURNING flag INTEGER</td>
<td></td>
</tr>
<tr>
<td><strong>isCharacters()</strong></td>
<td>Checks whether the StaxReader cursor points to a text node.</td>
</tr>
<tr>
<td>RETURNING flag INTEGER</td>
<td></td>
</tr>
<tr>
<td><strong>isIgnorableWhitespace()</strong></td>
<td>Checks whether the StaxReader cursor points to ignorable whitespace.</td>
</tr>
<tr>
<td>RETURNING flag INTEGER</td>
<td></td>
</tr>
</tbody>
</table>

**Table 512: Object methods: Document**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>getEncoding()</strong></td>
<td>Returns the document encoding defined in the XML Document declaration, or NULL.</td>
</tr>
<tr>
<td>RETURNING docenc STRING</td>
<td></td>
</tr>
<tr>
<td><strong>getVersion()</strong></td>
<td>Returns the document version defined in the XML Document declaration, or NULL.</td>
</tr>
<tr>
<td>RETURNING version STRING</td>
<td></td>
</tr>
<tr>
<td><strong>isStandalone()</strong></td>
<td>Checks whether the document standalone attribute defined in the XML Document declaration is set to yes.</td>
</tr>
<tr>
<td>RETURNING flag STRING</td>
<td></td>
</tr>
<tr>
<td><strong>standaloneSet()</strong></td>
<td>Checks whether the document standalone attribute is defined in the XML Document declaration.</td>
</tr>
<tr>
<td>RETURNING flag STRING</td>
<td></td>
</tr>
</tbody>
</table>

**Table 513: Object methods: Nodes**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>getPrefix()</strong></td>
<td>Returns the prefix of the current XML node, or NULL.</td>
</tr>
<tr>
<td>RETURNING prefix STRING</td>
<td></td>
</tr>
<tr>
<td><strong>getLocalName()</strong></td>
<td>Returns the local name of the current XML node, or NULL.</td>
</tr>
<tr>
<td>RETURNING localname STRING</td>
<td></td>
</tr>
<tr>
<td><strong>getName()</strong></td>
<td>Returns the qualified name of the current XML node, or NULL.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>getNamespace ()</td>
<td>Returns the namespace URI of the current XML node, or NULL.</td>
</tr>
<tr>
<td>getText ()</td>
<td>Returns as a string the value of the current XML node, or NULL.</td>
</tr>
</tbody>
</table>

**Table 514: Object methods: Processing Instructions**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getPITarget ()</td>
<td>Returns the target part of an XML ProcessingInstruction node, or NULL.</td>
</tr>
<tr>
<td>getPIData ()</td>
<td>Returns the data part of an XML ProcessingInstruction node, or NULL.</td>
</tr>
</tbody>
</table>

**Table 515: Object methods: Attributes**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getAttributeCount ()</td>
<td>Returns the number of XML attributes defined on the current XML node, or zero.</td>
</tr>
<tr>
<td>getAttributeValue (pos INTEGER)</td>
<td>Returns the value of an XML attribute defined at a given position on the current XML node, or NULL.</td>
</tr>
<tr>
<td>findAttributeValue (name STRING, ns STRING)</td>
<td>Returns the value of an XML attribute of a given name and/or namespace on the current XML node, or NULL.</td>
</tr>
</tbody>
</table>
### Table 516: Object methods: Namespace

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>lookupNamespace</strong> (prefix STRING) RETURNING nsuri STRING</td>
<td>Looks up the namespace URI associated with a given prefix starting from the current XML node the StaxReader cursor is pointing to.</td>
</tr>
<tr>
<td><strong>lookupPrefix</strong> (ns STRING) RETURNING prefix STRING</td>
<td>Looks up the prefix associated with a given namespace URI, starting from the current XML node the StaxReader cursor is pointing to.</td>
</tr>
<tr>
<td><strong>getNamespaceCount</strong> () RETURNING num INTEGER</td>
<td>Returns the number of namespace declarations defined on the current XML node, or zero.</td>
</tr>
<tr>
<td><strong>getNamespacePrefix</strong> (pos INTEGER) RETURNING prefix STRING</td>
<td>Returns the prefix of a namespace declaration defined at a given position on the current XML node, or NULL.</td>
</tr>
<tr>
<td><strong>getNamespaceURI</strong> (pos INTEGER) RETURNING nsuri STRING</td>
<td>Returns the URI of a namespace declaration defined at a given position on the current XML node, or NULL.</td>
</tr>
</tbody>
</table>

### Table 517: Object methods: Navigation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>hasNext</strong> () RETURNING flag INTEGER</td>
<td>Checks whether the StaxReader cursor can be moved to a XML node next to it.</td>
</tr>
<tr>
<td><strong>next</strong> ()</td>
<td>Moves the StaxReader cursor to the next XML node.</td>
</tr>
<tr>
<td><strong>nextTag</strong> ()</td>
<td>Moves the StaxReader cursor to the next XML open or end tag.</td>
</tr>
<tr>
<td><strong>nextSibling</strong> ()</td>
<td>Moves the StaxReader cursor to the immediate next sibling XML Element of the current node, skipping all its child nodes.</td>
</tr>
</tbody>
</table>

xml.StaxReader.close
Closes the StaxReader streaming and releases all associated resources.

### Syntax

```
close()
```

### Usage

This method closes the stream.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.Create
Constructor of a StaxReader object.

**Syntax**

```java
xml.StaxReader.Create()
    RETURNING object xml.StaxReader
```

**Usage**

Returns a StaxReader object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.findAttributeValue
Returns the value of an XML attribute of a given name and/or namespace on the current XML node, or NULL.

**Syntax**

```java
findAttributeValue(
    name STRING,
    ns STRING )
    RETURNING value STRING
```

1. `name` is the name of the attribute to retrieve. It cannot be NULL.
2. `ns` is the namespace URI of the attribute to retrieve, or NULL if the attribute is not namespace-qualified.

**Usage**

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.getAttributeCount
Returns the number of XML attributes defined on the current XML node, or zero.

**Syntax**

```java
getAttributeCount()
    RETURNING num INTEGER
```

**Usage**

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.getAttributeLocalName
Returns the local name of an XML attribute defined at a given position on the current XML node, or NULL.

**Syntax**

```
getAttributeNameLocalName (
    pos INTEGER )
RETURNING localname STRING
```

1. `pos` is the position of the attribute to return (Index starts at 1).

**Usage**

This method is only valid on a **START_ELEMENT** node.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.getAttributeNamespace

Returns the namespace URI of an XML attribute defined at a given position on the current XML node, or NULL.

**Syntax**

```
getAttributeNamespace (
    pos INTEGER )
RETURNING nsuri STRING
```

1. `pos` is the position of the attribute to return (Index starts at 1).

**Usage**

This method is only valid on a **START_ELEMENT** node.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.getAttributePrefix

Returns the prefix of an XML attribute defined at a given position on the current XML node, or NULL.

**Syntax**

```
getAttributePrefix (
    pos INTEGER )
RETURNING prefix STRING
```

1. `pos` is the position of the attribute to return (Index starts at 1).

**Usage**

This method is only valid on a **START_ELEMENT** node.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.
Returns the value of an XML attribute defined at a given position on the current XML node, or NULL.

**Syntax**

```sql
getAttributeValue(
    pos INTEGER
) RETURNING value STRING
```

1. `pos` is the position of the attribute to return (Index starts at 1).

**Usage**

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.

**xml.StaxReader.getEncoding**

Returns the document encoding defined in the XML Document declaration, or NULL.

**Syntax**

```sql
getEncoding()
RETURNING docenc STRING
```

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.

**xml.StaxReader.getEventType**

Returns a string that indicates the type of event the cursor of the StaxReader object is pointing to.

**Syntax**

```sql
getEventType()
RETURNING eventtype STRING
```

**Usage**

See *StaxReader Event Types* on page 2208 for the full list of StaxReader event types.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.

**xml.StaxReader.getFeature**

Gets a feature of a StaxReader object.

**Syntax**

```sql
getFeature(
    feature STRING
) RETURNING str STRING
```

1. `feature` is the name of a feature.
**Usage**

See StaxReader Features on page 2208 for the full list of StaxReader features.

Returns the feature value.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.getLocalName

Returns the local name of the current XML node, or NULL.

**Syntax**

```
getLocalName()
RETURNING localname STRING
```

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.getName

Returns the qualified name of the current XML node, or NULL.

**Syntax**

```
getName()
RETURNING name STRING
```

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.getNamespace

Returns the namespace URI of the current XML node, or NULL.

**Syntax**

```
getNamespace()
RETURNING nsuri STRING
```

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.getNamespaceCount

Returns the number of namespace declarations defined on the current XML node, or zero.

**Syntax**

```
getNamespaceCount()
```
Usage
This method is only valid on a `START_ELEMENT` node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.StaxReader.getNamespacePrefix
```

Returns the prefix of a namespace declaration defined at a given position on the current XML node, or NULL.

Syntax

```java
getNamespacePrefix(
    pos INTEGER
) RETURNING prefix STRING
```

1. `pos` is the position of the namespace declaration (Index starts at 1).

Usage
This method is only valid on a `START_ELEMENT` node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.StaxReader.getNamespaceURI
```

Returns the URI of a namespace declaration defined at a given position on the current XML node, or NULL.

Syntax

```java
getNamespaceURI(
    pos INTEGER
) RETURNING nsuri STRING
```

1. `pos` is the position of the namespace declaration (Index starts at 1).

Usage
This method is only valid on a `START_ELEMENT` node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```java
xml.StaxReader.getPIData
```

Returns the data part of an XML ProcessingInstruction node, or NULL.

Syntax

```java
getPIData()
RETURNING data STRING
```
xml.StaxReader.getPITarget
Returns the target part of an XML ProcessingInstruction node, or NULL.

Syntax

```
getPITarget ()
    RETURNING target STRING
```

Usage

This method is only valid on a PROCESSING_INSTRUCTION node.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.getPrefix
Returns the prefix of the current XML node, or NULL.

Syntax

```
getPrefix ()
    RETURNING prefix STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.getText
Returns as a string the value of the current XML node, or NULL.

Syntax

```
getText ()
    RETURNING value STRING
```

Usage

This method is only valid on CHARACTERS, CDATA, SPACE, COMMENT, DTD and ENTITY_REFERENCE nodes. For an ENTITY_REFERENCE, this method returns the replacement value, or NULL if none.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.getVersion
Returns the document version defined in the XML Document declaration, or NULL.

**Syntax**

```
getVersion()
  RETURNING version STRING
```

**Usage**
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxReader.hasName**
Checks whether the StaxReader cursor points to a node with a name.

**Syntax**

```
hasName()
  RETURNING flag INTEGER
```

**Usage**
Returns TRUE if the current XML node has a name, FALSE otherwise. This method returns TRUE for START_ELEMENT and END_ELEMENT, FALSE for all other nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxReader.hasNext**
Checks whether the StaxReader cursor can be moved to a XML node next to it.

**Syntax**

```
hasNext()
  RETURNING flag INTEGER
```

**Usage**
Returns TRUE if there is still an XML node in the stream, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxReader.hasText**
Checks whether the StaxReader cursor points to a node with a text value.

**Syntax**

```
hasText()
  RETURNING flag INTEGER
```
Usage

Returns TRUE if the current XML node has a text value, FALSE otherwise. This method returns TRUE for CHARACTERS, SPACE, CDATA, COMMENT, ENTITY_REFERENCE and DTD, FALSE for all other nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.isCharacters

Checks whether the StaxReader cursor points to a text node.

Syntax

```sql
isCharacters()
RETURNING flag INTEGER
```

Usage

Returns TRUE if the current XML node is a text node, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.isEmptyElement

Checks whether the StaxReader cursor points to an empty element node.

Syntax

```sql
isEmptyElement()
RETURNING flag INTEGER
```

Usage

Returns TRUE if the current XML element node has no children, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.isEndElement

Checks whether the StaxReader cursor points to an end element node.

Syntax

```sql
isEndElement()
RETURNING flag INTEGER
```

Usage

Returns TRUE if the current XML node is an end element node, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.isIgnorableWhitespace
Checks whether the StaxReader cursor points to ignorable whitespace.

### Syntax

```java
isIgnorableWhitespace()
    RETURNING flag INTEGER
```

### Usage

Returns TRUE if the current XML node is an ignorable text node, FALSE otherwise.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### xml.StaxReader.isStandalone

Checks whether the document standalone attribute defined in the XML Document declaration is set to yes.

### Syntax

```java
isStandalone()
    RETURNING flag STRING
```

### Usage

Returns TRUE if the standalone attribute in the XML declaration is set to yes, FALSE otherwise.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### xml.StaxReader.isStartElement

Checks whether the StaxReader cursor points to a start element node.

### Syntax

```java
isStartElement()
    RETURNING flag INTEGER
```

### Usage

Returns TRUE if the current XML node is a start element node, FALSE otherwise.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### xml.StaxReader.lookupNamespace

Looks up the namespace URI associated with a given prefix starting from the current XML node the StaxReader cursor is pointing to.

### Syntax

```java
lookupNamespace(
    prefix STRING
)
    RETURNING nsuri STRING
```

1. `prefix` is the prefix to look for; if NULL the default namespace URI will be returned.
Usage

Returns the namespace URI associated with the prefix, or NULL if there is none.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.lookupPrefix

Looks up the prefix associated with a given namespace URI, starting from the current XML node the StaxReader cursor is pointing to.

Syntax

```
lookupPrefix(
    ns STRING )
RETURNING prefix STRING
```

1. `ns` is the namespace URI to look for. It cannot be NULL.

Usage

Returns the prefix associated with this namespace URI, or NULL if there is none.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.next

Moves the StaxReader cursor to the next XML node.

Syntax

```
next()
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.nextSibling

Moves the StaxReader cursor to the immediate next sibling XML Element of the current node, skipping all its child nodes.

Syntax

```
nextSibling()
```

Usage

The cursor points to the parent end tag if there are no siblings.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.nextTag
Moves the StaxReader cursor to the next XML open or end tag

**Syntax**

```java
nextTag()
```

**Usage**

The cursor points to the end of the document if there is no next XML open or end tag.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxReader.readFrom**

Sets the input stream of the StaxReader object to a file or an URL and starts the streaming

**Syntax**

```java
readFrom(
    url STRING
)
```

1. `url` is a valid URL or the name of the file to read.

**Usage**

Only the following kinds of URLs are supported:

- `http://`
- `https://`
- `tcp://`
- `tcps://`
- `file:///
- `alias://`

See FGLPROFILE Configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxReader.readFromDocument**

Sets the input stream of the StaxReader object to a DomDocument object and starts the streaming

**Syntax**

```java
readFromDocument(
    doc xml.DomDocument
)
```

1. `doc` is an `XML/DomDocument` object that contains an XML document.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.StaxReader.readFromPipe**
Sets the input stream of the StaxReader object to a PIPE and starts the streaming.

Syntax

```java
readFromPipe(
    cmd STRING )
```

1. `cmd` is the command to start the PIPE and where the reader will get the XML from.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.readFromText

Sets the input stream of the StaxReader object to a TEXT large object and starts the streaming.

Syntax

```java
readFromText(
    txt TEXT )
```

1. `txt` must be a TEXT lob located in memory and containing the XML to read.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.setFeature

Sets a feature of a StaxReader object.

Syntax

```java
setFeature(
    feature STRING,
    value STRING )
```

1. `feature` is the name of a feature.
2. `value` is the value of the feature.

Usage

See StaxReader Features on page 2208 for the full list of StaxReader features.

The features can be changed at any time, but will only be taken into account at the beginning of a new stream (see `readFrom` or `readFromDocument`).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.StaxReader.standaloneSet
Checks whether the document standalone attribute is defined in the XML Document declaration.

**Syntax**

```
standaloneSet()
RETURNING flag STRING
```

**Usage**

Returns TRUE if the standalone attribute in the XML declaration is set, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**StaxReader Features**

Features of the `xml.StaxReader` class.

**Table 518: StaxReader Features**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expand-entity-references</td>
<td>Defines whether XML EntityReference nodes are kept or replaced during the parsing of an XML document. Default value is TRUE.</td>
</tr>
</tbody>
</table>

**StaxReader Event Types**

Event types of the `xml.StaxReader` class.

**Table 519: StaxReader event types**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>XML sample</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_DOCUMENT</td>
<td>StaxReader cursor points to the beginning of the XML document.</td>
<td>&lt;?xml version=&quot;1.0&quot; standalone=&quot;no&quot;?&gt;</td>
</tr>
<tr>
<td>END_DOCUMENT</td>
<td>StaxReader cursor has reached the end of the XML document. No additional parsing operation will succeed.</td>
<td></td>
</tr>
<tr>
<td>START_ELEMENT</td>
<td>StaxReader cursor points to an XML start element or empty element node.</td>
<td>&lt;p:elt attr=&quot;val&quot;/&gt; or &lt;p:elt attr=&quot;val&quot;/&gt;</td>
</tr>
<tr>
<td>END_ELEMENT</td>
<td>StaxReader cursor points to an XML end element node.</td>
<td>&lt;/p:elt&gt;</td>
</tr>
<tr>
<td>CHARACTERS</td>
<td>StaxReader cursor points to an XML text node.</td>
<td>... eltA/&gt;This is text&lt;eltB ...</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
<td>XML sample</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------------------------------------------------------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>CDATA</td>
<td>StaxReader cursor points to an XML CDATA node.</td>
<td>&lt;![CDATA[&lt;Hello, world!&gt;]]&gt;</td>
</tr>
<tr>
<td>SPACE</td>
<td>StaxReader cursor points to an XML text node containing only</td>
<td>... eltA/&gt; &lt;eltB ...</td>
</tr>
<tr>
<td>COMMENT</td>
<td>StaxReader cursor points to an XML comment node.</td>
<td>&lt;!-- a comment --&gt;</td>
</tr>
<tr>
<td>DTD</td>
<td>StaxReader cursor points to a DTD string.</td>
<td>&lt;!DOCTYPE A [ &lt;!ELEMENT B (C +)&gt; ]&gt;</td>
</tr>
<tr>
<td>ENTITY_REFERENCE</td>
<td>StaxReader cursor points to an XML entity reference node.</td>
<td>&amp;ref;</td>
</tr>
<tr>
<td>PROCESSING_INSTRUCTION</td>
<td>StaxReader cursor points to an XML processing instruction</td>
<td>&lt;?target data?</td>
</tr>
<tr>
<td>ERROR</td>
<td>StaxReader cursor points to an unexpected XML node.</td>
<td></td>
</tr>
</tbody>
</table>

Example
Example using methods of the xml.StaxReader class.

```
IMPORT xml

FUNCTION parse(file )
DEFINE file STRING
DEFINE event STRING
DEFINE ret INTEGER
DEFINE ind INTEGER
DEFINE reader xml.StaxReader
TRY
  LET reader=xml.StaxReader.Create()
  CALL reader.readFrom(file)
  WHILE (true)
    LET event=reader.getEventType()

END FUNCTION

XML serialization classes
The XML serialization classes convert BDL variables to XML and XML to BDL variables.

- **CLASS Serializer**
  - **Option flags**

The **Serializer class** provides methods to manage options for the serializer engine, and to use the serializer engine to serialize variables and XML element nodes.

This class is a static class and does not have to be instantiated.
The `STATUS` variable is set to zero after a successful method call.

xml.Serializer methods
Methods for the `xml.Serializer` class.

Table 520: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.Serializer.DomToVariable(node xml.DomNode, var fgl-type)</code></td>
<td>Serializes an XML element node into a BDL variable using a DomNode object.</td>
</tr>
<tr>
<td><code>xml.Serializer.GetOption(flag STRING)</code></td>
<td>GETTING value STRING</td>
</tr>
<tr>
<td><code>xml.Serializer.SetOption(flag STRING, value STRING)</code></td>
<td>Sets a global option value for the serializer engine</td>
</tr>
<tr>
<td><code>xml.Serializer.SoapSection5ToVariable(node xml.DomNode, var fgl-type)</code></td>
<td>Serializes an XML element node into a BDL variable in Soap Section 5 encoding.</td>
</tr>
<tr>

<tr>
<td>node xml.DomNode</td>
<td></td>
</tr>
</tbody>
</table>

xml.Serializer.CreateXmlSchemas

Creates XML schemas corresponding to the given variable var, and fills the dynamic array ar with xml.DomDocument objects each representing an XML schema.

**Syntax**

```xml
xml.Serializer.CreateXmlSchemas(
    var fgl-type,
    ar DYNAMIC ARRAY OF xml.DomDocument )
```

1. var is a given variable.
2. ar is a dynamic array of xml.DomDocument objects, each representing an XML schema.

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Serializer.DomToStax

Serializes an XML node object to a StaxWriter object.

**Syntax**

```xml
xml.Serializer.DomToStax(
    node xml.DomNode,
    stax xml.StaxWriter )
```

1. node is an XML DomNode object.
2. stax is a StaxWriter object.

**Usage**

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Serializer.DomToVariable

Serializes an XML element node into a BDL variable using a DomNode object.

**Syntax**

```xml
xml.Serializer.DomToVariable(
    node xml.DomNode,
    var fgl-type )
```
1. `node` is a `DomNode` object of type `ELEMENT_NODE`.
2. `var` is any BDL variable with optional XML mapping attributes.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Serializer.getOption**

Gets a global option value from the serializer engine.

**Syntax**

```plaintext
xml.Serializer.GetOption(
  flag STRING )
RETURNS value STRING
```

1. `flag` is the option flag.

**Usage**

Returns the value of the `flag`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Serializer.setOption**

Sets a global option value for the serializer engine.

**Syntax**

```plaintext
xml.Serializer.SetOption(
  flag STRING, 
  value STRING )
```

1. `flag` is the option flag.
2. `value` is the value of the flag.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Serializer.SoapSection5ToVariable**

Serializes an XML element node into a BDL variable in Soap Section 5 encoding.

**Syntax**

```plaintext
xml.Serializer.SoapSection5ToVariable(
  node xml.DomNode, 
  var fgl-type )
```

1. `node` is a `DomNode` object of type `ELEMENT_NODE`.
2. `var` is any BDL variable with optional XML mapping attributes.
Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Serializer.StaxToDom

Serializes an XML element node into a DomNode object using a StaxReader object.

Syntax

```java
xml.Serializer.StaxToDom(
    stax xml.StaxReader,
    node xml.DomNode )
```

1. `stax` is a StaxReader object where the cursor points to an XML Element node.
2. `node` is a DomNode object of type ELEMENT_NODE or DOCUMENT_FRAGMENT_NODE.

Usage

The resulting XML element node of the serialization process will be appended to the last child of the given node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Serializer.StaxToVariable

Serializes an XML element node into a BDL variable using a StaxReader object.

Syntax

```java
xml.Serializer.StaxToVariable(
    stax xml.StaxReader,
    var fgl-type )
```

1. `stax` is a StaxReader object where the cursor points to an XML Element node.
2. `var` is any BDL variable with optional XML mapping attributes.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Serializer.VariableToDom

Serializes a BDL variable into an XML element node using a DomNode object.

Syntax

```java
xml.Serializer.VariableToDom(
    var fgl-type,
    node xml.DomNode )
```

1. `var` is any BDL variable with optional XML mapping attributes.
2. `node` is a DomNode object of type ELEMENT_NODE or DOCUMENT_FRAGMENT_NODE.
**Usage**

The resulting XML element node of the serialization process will be appended to the last child of the given node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.

```java
xml.Serializer.VariableToSoapSection5
    Serializes a BDL variable into an XML element node in Soap Section 5 encoding.
```

**Syntax**

```java
xml.Serializer.VariableToSoapSection5(
    var fgl-type,
    node xml.DomNode )
```

1. `var` is any BDL variable with optional XML mapping attributes.
2. `node` is a `DomNode` object of type `ELEMENT_NODE` or `DOCUMENT_FRAGMENT_NODE`.

**Usage**

The resulting XML element node of the serialization process will be appended to the last child of the given node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.

```java
xml.Serializer.VariableToStax
    Serializes a BDL variable into an XML element node using a StaxWriter object.
```

**Syntax**

```java
xml.Serializer.VariableToStax(
    var fgl-type,
    stax xml.StaxWriter )
```

1. `var` is any BDL variable with optional XML mapping attributes.
2. `stax` is a `StaxWriter` object.

**Usage**

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 2553.

**Serialization option flags**

Serialization option flags for the `xml.Serializer` class.

**Table 521: Serialization option flags**

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml_ignoretimezone</td>
<td>Defines whether, during the marshalling and un-marshalling process of a BDL DATETIME data</td>
</tr>
<tr>
<td>Flag</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>type, the Serializer should ignore the time zone information. A value of zero means FALSE. The default is FALSE. Throws an exception in case of errors, and updates status with an error code.</td>
</tr>
<tr>
<td>xml_useTypedefinition</td>
<td>Defines whether the Serializer must specify the type of data during serialization. This will add an &quot;xsi:type&quot; attribute to each XML data type. A value of zero means FALSE. The default is FALSE. Throws an exception in case of errors, and updates status with an error code.</td>
</tr>
<tr>
<td>xml_useUtcTime</td>
<td>Defines whether, during the marshalling process of a BDL DATETIME data type, the Serializer should convert it into UTC time. A value of zero means FALSE. The default is FALSE. Throws an exception in case of errors, and updates status with an error code.</td>
</tr>
<tr>
<td>xs_processContents</td>
<td>Defines the way to generate wildcard elements and attributes in XML schemas via the XML schema processContents tag. See Table 522: Values for xs_processContents on page 2216. Throws an exception in case of errors, and updates status with an error code.</td>
</tr>
</tbody>
</table>

Table 522: Values for xs_processContents

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No processContents tag will be generated. (default)</td>
</tr>
<tr>
<td>1</td>
<td>Generation of processContents=&quot;skip&quot;.</td>
</tr>
<tr>
<td>2</td>
<td>Generation of processContents=&quot;lax&quot;.</td>
</tr>
<tr>
<td>3</td>
<td>Generation of processContents=&quot;strict&quot;.</td>

</tbody>
</table>

XML security classes
XML Security classes handle encryption and signature of XML documents entirely in memory with keys and certificates.

Important: The XML security classes are not supported on GMI mobile devices.

- CLASS CryptoKey
  - Keys
- CLASS CryptX509
• CLASS Encryption
• CLASS Signature
  • Digits
  • Transformations
• CLASS KeyStore

The CryptoKey class
The xml.CryptoKey class provides methods to manipulate HMAC, symmetric and asymmetric keys needed for signing, verifying, encrypting and decrypting XML documents or document fragments.

It follows the XML-Signature and XML-Encryption specifications.

The status variable is set to zero after a successful method call.

Important: This class is not supported on GMI mobile devices.

xml.CryptoKey methods
Methods for the xml.CryptoKey class.

Table 523: Class methods: Creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml.CryptoKey.CreateDerivedKey( url STRING ) RETURNING object xml.CryptoKey</td>
<td>Constructor of an empty CryptoKey object intended to be derived before use, and depending on a url.</td>
</tr>
<tr>
<td>xml.CryptoKey.CreateFromNode( url STRING, node xml.DomNode ) RETURNING object xml.CryptoKey</td>

</tr>
<tr>
<td><code>savePublicToString()</code></td>
<td>Save the current xml.CryptoKey's public part in the returned base64 string.</td>
</tr>
<tr>
<td><code>saveToString()</code></td>
<td>Saves the CryptoKey object into a BASE64 string format.</td>
</tr>
</tbody>
</table>

```
Compares a CryptoKey object to a second key.

**Syntax**

```java
compareTo(
    secondKey xml.CryptoKey
) RETURNING flag INTEGER
```

1. `secondKey` is the `xml.CryptoKey` object to use for comparison to the current CryptoKey object.

**Usage**

The method verifies if the keys URL, type, size, usage and value are the same. If they are the same, the two identical keys will produce the same encryption cipher.

The key features are not taken into account during comparison.

Returns TRUE if they are identical, FALSE if they are not identical.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.CryptoKey.computeKey**

Computes the shared secret based on the given modulus, generator, the private key and the other peer's public key. The returned key can be any of symmetric/HMAC or symmetric/encryption key type. It can be used for symmetric signature or symmetric encryption.

**Syntax**

```java
computeKey(
    otherPubKey xml.CryptoKey,
    url STRING
) RETURNING sharedSecret xml.CryptoKey
```

1. `otherPubKey` is the other peer's public key (`xml.CryptoKey`).
2. `url` is the shared secret key type as an url identifier (`STRING`).

**Usage**

**Important:** This method is for Diffie-Hellman key-agreement algorithm only.

In the 3DES case, no key weakness test is done. If the compound shared secret is week, the other peer involed in the communication may raise an error. It depends on the language used on the other side.

In order to be able to compute an AES256 shared secret of the Java™ side, you need to add or relace the files `local_policy.jar` and `US_export_policy.jar` located in `$JDK_HOME/jre/lib/security` by the Java™ Cryptographic Extension correspoinding to your JDK version. You can find this extension at [http://www.oracle.com/technetwork/java/javase/downloads/index.html](http://www.oracle.com/technetwork/java/javase/downloads/index.html).

If the shared secret key length is less than the Diffie-Hellman key length, only the first needed bytes will be taken. For example, if the Diffie-Hellman is 512 bits length and the shared secret is a 3DES key, then only the first 192 bits will be used by the computation. In a 3DES shared secret case, `xml.CryptoKey.computeKey()` is calculated, where in AES shared secret case, the Diffie-Hellman key is truncated.

If the shared secret key length is bigger than the Diffie-Hellman key length, an error is raised.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.Create

Initializes an xml.CryptoKey object. Constructor of an empty CryptoKey object depending on a url.

**Syntax**

```javascript
xml.CryptoKey.Create(  
    url STRING  
)  
RETURNING object xml.CryptoKey
```

1. `url` defines a key identifier according to the XML-Signature and XML-Encryption specification or the Diffie-Hellman specification.

**Usage**

Returns a CryptoKey object or NULL. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.CreateDerivedKey

Constructor of an empty CryptoKey object intended to be derived before use, and depending on a url.

**Syntax**

```javascript
xml.CryptoKey.CreateDerivedKey(  
    url STRING  
)  
RETURNING object xml.CryptoKey
```

1. `url` defines a key identifier according to the XML-Signature and XML-Encryption specification.

**Usage**

Returns a CryptoKey object or NULL. Only symmetric and HMAC keys can be derived. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.CreateFromNode

Constructor of a new CryptoKey object depending on a url and from a XML node, according to the XML-Signature and XML-Encryption specification.

**Syntax**

```javascript
xml.CryptoKey.CreateFromNode(  
    url STRING,  
    node xml.DomNode  
)  
RETURNING object xml.CryptoKey
```

1. `url` defines a key identifier restricted to PUBLIC/PRIVATE keys.
2. `node` is an ELEMENT node whose local name is either:
   - DSAKeyValue or RSAKeyValue and belonging to the XML-Signature namespace http://www.w3.org/2000/09/xmldsig#
   - RSAKeyPair and belonging to the XKMS 2.0 namespace http://www.w3.org/2002/03/xkms#
Usage

Returns a CryptoKey object or NULL.

If the local name is RSAKeyValue or RSAKeyPair, the URL must be a RSA key. If the local name is DSAKeyValue, the URL must be a DSA key.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.deriveKey

Derives the symmetric or HMAC CryptoKey object using the given method identifier and concatenating the optional label, the mandatory seed value and the optional created date as initial random value.

Syntax

deriveKey(
   method STRING,
   label STRING,
   seed STRING,
   created STRING,
   offset INTEGER,
   size INTEGER )

1. method is the identifier of the algorithm to apply to the password and its inputs.
2. label is the optional label input.
3. seed, the mandatory seed input, is the a valid Base64 string representing a random binary data you can obtain with the security.RandomGenerator.CreateRandomNumber on page 2287 helper method.
4. created is the optional created date input.
5. offset is the number of bytes the resulting octet stream must be shifted to obtain the derived key.
6. size defines the number of bytes of the resulting derived key.

Usage

If it is a symmetric key, the size can be 0, or must match the original key according to key identifier.

See Derived keys on page 2232 for more details.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.generateKey

Generates a random key of given size (in bits).

Syntax

generateKey(
   size INTEGER )

1. size is the size of the key to generate.

Usage

For symmetric keys, the size is fixed by the key identifier and cannot be changed. The only authorized values are the real key size or NULL.

For Diffie-Hellman, the input parameter (size INTEGER) is the size of the Diffie-Hellman modulus. If the given size is greater than zero (0), it populates the Diffie-Hellman object by randomly generating a modulus
of the given size and a private key, and computes the public key. The used generator is two (2). If the
given size is zero (0), it completes the Diffie-Hellman object by choosing a private key and computing the
public key according to the previously loaded parameters. For more details on loading parameters, see
Table 534: Object methods: Load and save on page 2236.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error,
a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error
handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.getFeature

Returns the value of the given feature for this CryptoKey object, or NULL.

Syntax

getFeature(
    feature STRING )
RETURNING value STRING

1. feature is the CryptoKey feature.

Usage

Returns NULL if the feature is not set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error,
a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error
handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.getSHA1

Returns the SHA1 encoded key identifier in a base64 encoded STRING.

Syntax

getSHA1()
RETURNING keyId STRING

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error,
a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error
handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.getSize

Returns the size of the key in bits.

Syntax

getSize()
RETURNING size INTEGER

Usage

For a Diffie-Hellman key, returns the size of the key; the size of a Diffie-Hellman key is actually the size
of the modulus. If the modulus is not available (null or equal to zero), the method returns zero. In this
situation, a return of zero does NOT mean the key is corrupt or unusable.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error,
a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error
handling in GWS calls (STATUS) on page 2553.
xml.CryptoKey.getType
Returns the type of key.

**Syntax**

```
getType()
  RETURNING type STRING
```

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.getUrl
Returns the key identifier as an URL, as defined in the XML-Signature and XML-Encryption specification.

**Syntax**

```
getUrl()
  RETURNING keyId STRING
```

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.getUsage
Returns the usage of the key.

**Syntax**

```
getUsage()
  RETURNING usage STRING
```

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.loadBIN
Loads a symmetric or HMAC key from a file in raw format.

**Syntax**

```
loadBIN(
  file STRING )
```

1. `file` is the file name or an entry in the FGLPROFILE file.

**Usage**

Raw format means that the data in the file are read without any transformation, and will be stored as it in the key.
For instance, if you file contains `hello`, it has the same effect as calling `setKey()` with `hello` as parameter.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.CryptoKey.loadDER**

Loads an asymmetric DSA key, an asymmetric RSA key or Diffie-Hellman parameters from a file in DER format.

**Syntax**

```java
loadDER(
    file STRING )
```

1. `file` is the file name or an entry in the FGLPROFILE file.

**Usage**

If the DSA or RSA private key or Diffie-Hellman parameters is protected with a password, the recommended way is to unprotect it with the `openssl` tool and to put the key file on a restricted file system. However, you can use a script or the `fglpass` agent to provide the password to the application.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.CryptoKey.loadFromString**

Loads the given key in BASE64 string format into a CryptoKey object.

**Syntax**

```java
loadFromString(
    str STRING )
```

1. `str` is the string to load.

**Usage**

For Diffie-Hellman, the input parameter is a base64 encoded string containing the Diffie-Hellman parameters. This method populates the Diffie-Hellman key with the modulus and generator in the base64 encoded string. This is useful for the parameters exchange step between two peers.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.CryptoKey.loadPEM**

Loads an asymmetric DSA key, an asymmetric RSA key or Diffie-Hellman parameters from a file in PEM format.

**Syntax**

```java
loadPEM(
    file STRING )
```

1. `file` is the file name or an entry in the FGLPROFILE file.
**Usage**

If the DSA or RSA private key or Diffie-Hellman parameters is protected with a password, the recommended way is to unprotect it with the `openssl` tool and to put the key file on a restricted file system. However, you can use a script or the `fglpass` agent to provide the password to the application.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### xml.CryptoKey.loadPrivate

Loads the private asymmetric RSA key in the given XML document into the private part of this CryptoKey object, according to the XKMS2.0 specification.

**Syntax**

```java
loadPrivate(
    xml xml.DomDocument )
```

1. `xml` is a `DomDocument` object.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### xml.CryptoKey.loadPublic

Loads the public asymmetric RSA or DSA key in the given XML document into the public part of this CryptoKey object, according to the XML-Signature specification for DSA and RSA key value.

**Syntax**

```java
loadPublic(
    xml xml.DomDocument )
```

**Usage**

For Diffie-Hellman, the input parameter is an `xml.DomDocument` object containing a representation of the Diffie-Hellman key. This method populates the Diffie-Hellman object with the parameters and the public key contained in the given `xml.DomDocument` according to the XML-Signature specification for the Diffie-Hellman key values. If the public key node exists in the xml document but is empty, it won't be possible to use the key unless the document contains valid modulus and generator parameters and you call `generateKey` with a size of zero (0). In this case, you won't be in possession of the other peer's public key.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

### xml.CryptoKey.loadPublicFromString

Populate the current CryptoKey object with the passed public key.

**Syntax**

```java
loadPublicFromString(
    pubKeyStr STRING )
```

1. `pubKeyStr` is the public part of the key in base64 form.
**xml.CryptoKey.savePrivate**

Saves the private part of an asymmetric RSA CryptoKey object into a XML document according to the XKMS2.0 specification.

**Syntax**

```java
xml.CryptoKey.savePrivate()
```

**Usage**

Returns an `DomDocument` object containing the private part of an asymmetric RSA key.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.CryptoKey.savePublic**

Saves the public part of an asymmetric RSA or DSA CryptoKey object or the parameters and the public key of the Diffie-Hellman object into a XML document according to the XML-Signature specification for DSA and RSA and Diffie-Hellman key values.

**Syntax**

```java
xml.CryptoKey.savePublic()
```

**Usage**

For Diffie-Hellman, it is useful for the public key exchange between the two peers.

See also the `RetrievalMethod` feature.

Returns an `DomDocument` object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.CryptoKey.savePublicToString**

Save the current `xml.CryptoKey`'s public part in the returned base64 string.

**Syntax**

```java
xml.CryptoKey.savePublicToString()
```

**Usage**

Returns the public part of the key in base64 form (`STRING`).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
xml.CryptoKey.saveToString
Saves the CryptoKey object into a BASE64 string format.

Syntax
```java
saveToString()
    RETURNING str STRING
```

Usage
For Diffie-Hellman, returns the Diffie-Hellman key's modulus and generator in a base64 encoded string. This is useful for the parameters exchange step between the two peers.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.setFeature
Sets or resets the value of a feature for a CryptoKey object.

Syntax
```java
setFeature(
    feature STRING,
    value STRING
)
```

1. `feature` is the name of the feature.
2. `value` is the value to set for the named feature.

Usage
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoKey.setKey
Defines the value of a HMAC or Symmetric key.

Syntax
```java
setKey(
    key STRING
)
```

1. `key` is the value.

Usage
The value can be a password and must be of the size corresponding to the key identifier.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.
Supported kind of keys
Supported kind of keys for the xml.CryptoKey class.

</tbody>
</table>

Derived keys

Key derivation is used on symmetric or HMAC keys to avoid the direct usage of a shared secret password in secured operations. If two parties share a secret password that is successfully hacked by a third party, any future operation becomes unsecure, and the initial two parties do not even realize that their exchanges are unsafe. However, if a different password based on that shared secret password is used for each new secured operation, even if one operation is compromised, it will only unsecure that operation, but not other operations.

The derivation consists of applying an algorithm with some additional inputs (such as a random seed value) to a password in order to obtain another password that is then used in one secured operation. Of course, the algorithm and its additional inputs must also be shared to enable the computation of the same derived key by someone that is intended to decrypt the message.

Note that passwords are often only composed of alphanumeric characters that eases a bit more the job of a hacker, whereas a derived key is composed of any binary data produced by the algorithm used for the derivation.

Examples
Examples using the xml.CryptoKey class.

**Examples:**
- Loading an asymmetric RSA key on page 2233
- Generating a symmetric AES256 key on page 2234
- Setting a HMAC key on page 2234
- Deriving a HMAC key on page 2234
- Computing the shared secret with Diffie-Hellman on page 2235

Loading an asymmetric RSA key

```plaintext
IMPORT xml

MAIN
DEFINE key xml.CryptoKey
LET key = xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#rsa-1_5")
TRY
   CALL key.loadPEM("RSA1024Key.pem")
   CALL key.setFeature("KeyName","MyRsaKey")
   DISPLAY "Key size (in bits) : ",key.getSize() # displays 1024 (bits)
   DISPLAY "Key type : ",key.getType() # displays PRIVATE or PUBLIC
   DISPLAY "Key usage : ",key.getUsage() # displays KEYENCRYPTION
CATCH
   DISPLAY "Unable to load key :",STATUS
```
Generating a symmetric AES256 key

```java
IMPORT xml

MAIN
  DEFINE key xml.CryptoKey
  LET key = xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#aes256-cbc")
  TRY
    CALL key.generateKey(NULL)
    DISPLAY "Key size (in bits) : ",key.getSize() # displays 256 (bits)
    DISPLAY "Key type : ",key.getType() # displays SYMMETRIC
    DISPLAY "Key usage : ",key.getUsage() # displays ENCRYPTION
  CATCH
    DISPLAY "Unable to generate key :",STATUS
  END TRY
END MAIN
```

**Note:** All keys in PEM or DER format were created with the OpenSSL tool.

Setting a HMAC key

```java
IMPORT xml

MAIN
  DEFINE key xml.CryptoKey
  LET key = xml.CryptoKey.Create("http://www.w3.org/2000/09/xmldsig#hmac-sha1")
  TRY
    CALL key.setKey("secretpassword")
    # displays 112 (size of secretpassword in bits)
    DISPLAY "Key size (in bits) : ",key.getSize()
    DISPLAY "Key type : ",key.getType() # displays HMAC
    DISPLAY "Key usage : ",key.getUsage() # displays SIGNATURE
  CATCH
    DISPLAY "Unable to set key :",STATUS
  END TRY
END MAIN
```

**Note:** All keys in PEM or DER format were created with the OpenSSL tool.

Deriving a HMAC key

```java
IMPORT xml
IMPORT com

MAIN
  DEFINE key xml.CryptoKey
  # will contain a random binary data encoded in Base64
  DEFINE seedBase64 STRING
  LET key = xml.CryptoKey.CreateDerivedKey(
    "http://www.w3.org/2000/09/xmldsig#hmac-sha1")
  TRY
    # Creates a random 24 bytes long binary data encoded into a Base64 form
    CALL key.setKey("secretpassword")
```

**Note:** All keys in PEM or DER format were created with the OpenSSL tool.
# Derives the 14 bytes long "secretpassword" into a 64 bytes long key
# from a random 24 bytes long seed value and shifting the resulting key
# from 255 bytes
LET seedBase64 = com.Util.CreateRandomString(24)
CALL key.deriveKey(
   "http://schemas.xmlsoap.org/ws/2005/02/sc/dk/p_sha1",
   NULL, seedBase64, NULL, 255, 64)
# Displays 512 (size of 'secretpassword' derivation in bits)
DISPLAY "Key size (in bits) : ", key.getSize()
# Note: Key is derived and can be used in
# any encryption or signature function
CATCH
   DISPLAY "Unable to derive key ":" , STATUS
END TRY
END MAIN

Note: All keys in PEM or DER format were created with the OpenSSL tool.

Computing the shared secret with Diffie-Hellman

Load the Diffie-Hellman parameters from a PEM file, the other peer's public key from an XML file and
compute the shared secret.

Function generateKey is called with a 0, parameters are already filled.

FUNCTION BuildSharedSecret(DHdoc)
DEFINE myKey, othersPubKey, sharedSecret xml.CryptoKey
DEFINE DHdoc xml.DomDocument
LET myKey =
   xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#DHKeyValue")
LET othersPubKey =
   xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#DHKeyValue")
TRY
   CALL othersPubKey.loadPublic(DHdoc)
   # populate myKey with the parameters previously generated by the
   # other peer.
   CALL myKey.loadPEM("DHParam.pem")
   # Randomly generate a private key and compute the public key. Key
   # length is the parameters length.
   CALL myKey.generateKey(0)
   LET sharedSecret = myKey.computeKey(othersPubKey,
      "http://www.w3.org/2000/09/xmldsig#hmac-sha1")
CATCH
   DISPLAY "ERROR : should not raise exception"
   EXIT PROGRAM (-1)
END TRY
END FUNCTION

The CryptoX509 class
The xml.CryptoX509 class provides methods to manipulate X509 certificates needed for identification of
individual persons, groups or any entities during XML encryption or signature process.

It also provides additional load and save functions to interact with other applications in XML or in BASE64,
such as in WS-Security compliant applications. It follows the XML-Signature and XML-Encryption
specifications.

The STATUS variable is set to zero after a successful method call.

Important: This class is not supported on GMI mobile devices.

xml.CryptoX509.Create
Constructor of an empty CryptoX509 object.

Syntax
```java
xml.CryptoX509.Create()
RETURNING object xml.CryptoX509
```

Usage
Returns a CryptoX509 object or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoX509.CreateFromNode
Constructor of a new CryptoX509 object from a XML X509 certificate node, according to the XML-Signature specification.

Syntax
```java
xml.CryptoX509.CreateFromNode(
   node xml.DomNode )
RETURNING object xml.CryptoX509
```

1. node is an ELEMENT DomNode node with X509Data as local name, and belonging to the XML-Signature namespace http://www.w3.org/2000/09/xmldsig#.
Usage

Returns a CryptoX509 object or NULL.

If the X509 certificate is incomplete, the certificate will be created from the application global certificate list if one of SubjectName or Issuer matches. (See addCertificate for more details.)

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoX509.createPublicKey

Creates a new public CryptoKey object for the given url, from the public key embedded in a certificate.

Syntax

```java
createPublicKey(
  url STRING )
RETURNING object xml.CryptoX509
```

1. *url* is the given *url*.

Usage

Creates a new public CryptoKey object for the given url, from the public key embedded in this certificate if any; NULL otherwise.

Returns a CryptoX509 object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoX509.getFeature

Get the value of a given feature of a CryptoX509 object.

Syntax

```java
getFeature(
  feature STRING )
RETURNING value STRING
```

1. *feature* is a feature of the CryptoX509 object.

Usage

Returns the value of the given feature for this CryptoX509 object, or NULL if feature is not set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoX509.getIdentifier

Gets the identification part of an X509 certificate.

Syntax

```java
getIdentifier()
RETURNING idpart STRING
```
Usage

Returns the identification part of this X509 certificate in a STRING.

Example: /C=FR/ST=France/L=Schiltigheim/O=MC/OU=My Company Name/CN=cert

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoX509.get ThumbprintSHA1
Get the SHA1 encoded thumbprint identifying this X509 certificate.

Syntax

```java
getThumbprintSHA1()
RETURNING setp STRING
```

Usage

Returns the SHA1 encoded thumbprint identifying this X509 certificate in a BASE64 encoded STRING.

Example: CM4y6z7zzLnTGMel1E46RKIKAPI=

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoX509.load
Loads the given XML document with ds:X509Data as root node according to the XML-Signature specification, into the CryptoX509 object.

Syntax

```java
load(
    xml xml.DomDocument )
```

1. xml is a DomDocument object.

Usage

If the X509 certificate in the XML document is incomplete, the certificate will be loaded from the global certificate list if one of SubjectName or Issuer matches.

See the w3.org site for more information on ds:X509Data as root node according to the XML-Signature specification.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoX509.loadDER
Loads a X509 certificate from a file in DER format.

Syntax

```java
loadDER( 
    file STRING )
```

1. file is the filename or an entry in the FGLPROFILE file.
xml.CryptoX509.loadFromString

Loads the given X509 certificate in BASE64 string format into this CryptoX509 object.

**Syntax**

```java
loadFromString(
    str STRING )
```

1. `str` is the X509 certificate in BASE64 string format to load.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

---

xml.CryptoX509.loadPEM

Loads a X509 certificate from a file in PEM format.

**Syntax**

```java
loadPEM(
    file STRING )
```

1. `file` is the filename or an entry in the FGLPROFILE file.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

---

xml.CryptoX509.save

Saves the CryptoX509 certificate into a XML document with ds:X509Data as root node according to the XML-Signature specification.

**Syntax**

```java
save()
```

```java
RETURNING object xml.DomDocument
```

**Usage**

See the w3.org site for more information on ds:X509Data as root node according to the XML-Signature specification.

(See also the RetrievalMethod feature)

Returns an `xml.DomDocument` object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
xml.CryptoX509.saveToString
Saves the CryptoX509 certificate into a BASE64 string format.

Syntax

```
saveToString()
   RETURNING cert STRING
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.CryptoX509.setFeature
Sets or resets the given feature for this CryptoX509 object.

Syntax

```
setFeature(
   feature STRING,
   value STRING )
```

1. `feature` is the feature to be set.
2. `value` is the value to set.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

CryptoX509 Features
Features of the xml.CryptoX509 class.

Table 536: CryptoX509 Features

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X509Certificate</td>
<td>Defines or returns whether the complete X509 certificate is added during XML signature or encryption. Default value is FALSE.</td>
</tr>
<tr>
<td></td>
<td>See specification for details.</td>
</tr>
<tr>
<td>X509SubjectName</td>
<td>Defines or returns whether the subject name of the X509 certificate is added during XML signature or encryption. Default value is FALSE.</td>
</tr>
<tr>
<td></td>
<td>See specification for details.</td>
</tr>
<tr>
<td>X509IssuerSerial</td>
<td>Defines or returns whether the issuer name and serial number of the X509 certificate is added during XML signature or encryption. Default value is FALSE.</td>
</tr>
<tr>
<td></td>
<td>See specification for details.</td>
</tr>
<tr>
<td>Feature</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RetrievalMethod</td>
<td>Defines or returns the URL where the XML form of the X509 certificate will be set during a XML signature, and loaded during a XML verification process, and based on that CryptoX509 object. Default value is NULL, meaning that no retrieval method is used.</td>
</tr>
</tbody>
</table>

**Note:** The XML form of a X509 certificate can be obtain by the `save()` method.

## Examples

**Examples using the `xml.CryptoX509` class.**

**Topics:**

- [Loading a certificate from a PEM file](#) on page 2242
- [Creating a public key for signature verification from a certificate](#) on page 2242
- [Saving the subjectName of a certificate in XML](#) on page 2243

### Loading a certificate from a PEM file

```plaintext
IMPORT xml
MAIN
DEFINE x509 xml.CryptoX509
LET x509 = xml.CryptoX509.Create()
TRY
  CALL x509.loadPEM("Certificate.crt");
  DISPLAY "Id : ",x509.getIdentifier()
CATCH
  DISPLAY "Unable to load certificate : ",STATUS
END TRY
END MAIN
```

**Note:** All certificates in PEM format were created with the OpenSSL tool.

### Creating a public key for signature verification from a certificate

```plaintext
IMPORT xml
MAIN
DEFINE x509 xml.CryptoX509
DEFINE key xml.CryptoKey
LET x509 = xml.CryptoX509.Create()
TRY
  CALL x509.loadPEM("RSA1024Certificate.crt");
CATCH
  DISPLAY "Unable to load certificate : ",STATUS
  EXIT PROGRAM
END TRY
TRY
  LET key = x509.createPublicKey("http://www.w3.org/2000/09/xmldsig#rsa-sha1")
  DISPLAY "Key size (in bytes) : ",key.getSize() # displays 1024 (bits)
  DISPLAY "Key type : ",key.getType() # displays PUBLIC
  DISPLAY "Key usage : ",key.getUsage() # displays SIGNATURE
CATCH
  DISPLAY "Unable to create public key : ",STATUS
END TRY
```
Note: All certificates in PEM format were created with the OpenSSL tool.

Saving the subjectName of a certificate in XML

```xml
IMPORT xml

MAIN
    DEFINE x509 xml.CryptoX509
    DEFINE key xml.CryptoKey
    DEFINE doc xml.DomDocument
    LET x509 = xml.CryptoX509.Create()
    TRY
        CALL x509.loadPEM("RSA1024Certificate.crt");
        CATCH
            DISPLAY "Unable to load certificate :",STATUS
            EXIT PROGRAM
    END TRY
    TRY
        CALL x509.setFeature("X509SubjectName",TRUE)
        LET doc = x509.save()
        CALL doc.setFeature("format-pretty-print",TRUE)
        CALL doc.save("RSAX509SubjectName.xml")
        CATCH
            DISPLAY "Unable to save certificate :",STATUS
    END TRY
END MAIN
```

Note: All certificates in PEM format were created with the OpenSSL tool.

The Signature class
The xml.Signature class provides methods to create detached, enveloped or enveloping XML signatures of one or more references of XML documents or document fragments, and to determine whether a signed referenced document has been modified afterwards.

It follows the XML-Signature specifications.

The STATUS variable is set to zero after a successful method call.

Important: This class is not supported on GMI mobile devices.

xml.Signature methods
Methods for the xml.Signature class.

Table 537: Class methods: Creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml.Signature.Create()</td>
<td>Constructor of a blank Signature object.</td>

**xml.Signature.appendObjectData**

Appends a copy of a XML node `node` to the signature object of index `ind`.

**Syntax**

```java
appendObjectData(
    ind INTEGER,
    node xml.DomNode
)
```

1. `ind` is the index in this Signature object.
2. `node` is the XML `node`.

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Signature.appendReferenceTransformation**

Appends a transformation related to the reference of index `ind`, and is executed before any computation.

**Syntax**

```java
appendReferenceTransformation(
    ind INTEGER,
    trans STRING,
    ...
)
```

1. `ind` is the index in this Signature object.
2. `trans` represents an URL as identifier of the transformation algorithm.

**Usage**

A transformation modifies the reference URI before signing or validating it. Several transformations are executed one after another, and only once the last transformation was applied, is the reference really signed or verified.

Depending on the transformation identifier, additional parameters are necessary.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.
xml.Signature.compute

Computes the signature of all references set in this Signature object.

**Syntax**

```java
compute(
    doc xml.DomDocument )
```

1. `doc` is the XML document.

**Usage**

If the signature type is:

- Enveloping: then `doc` must be NULL because all document fragment references are inside the Signature itself
- Enveloped: then `doc` must be the XML document where the signature must be added afterwards to get a valid enveloped signature
- Detached: then `doc` can be NULL if all references are absolute, otherwise it can be the XML document the fragment references are referencing

See [XML Signature concepts](#) for more details.

Also, see Windows™.NET special recommendation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](#) on page 2553.

xml.Signature.Create

Constructor of a blank Signature object.

**Syntax**

```java
xml.Signature.Create()  
RETURNING sign xml.Signature
```

**Usage**

Returns a Signature object or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](#) on page 2553.

xml.Signature.CreateFromNode

Constructor of a new Signature object from a XML Signature node, according to the XML-Signature specification.

**Syntax**

```java
xml.Signature.CreateFromNode(  
    signode xml.DomNode )  
RETURNING sign xml.Signature
```

1. `sign` is the XML Signature node.

**Usage**

Returns a Signature object or NULL.
The node must be an ELEMENT node with Signature as the local name, and belonging to the XML-Signature namespace http://www.w3.org/2000/09/xmldsig#, as defined here.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.createObject

Creates a new object that will embed additional XML nodes.

**Syntax**

```sql
createObject ()
RETURNING ind INTEGER
```

**Usage**

The returned value represents the index for any further manipulation of this signature object.

**Note:** An object is enveloping additional XML nodes, but is not necessarily signed unless there is a reference on it.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.createReference

Creates a new reference that will be signed with the compute() method

**Syntax**

```sql
createReference (  
  uri STRING,  
  digest STRING )
RETURNING ind INTEGER
```

1. *uri* represents the data to be signed.
2. *digest* is a URL as identifier for the hash algorithm.

**Usage**

The returned value represents the index for any further manipulation of this reference.

The *uri* can be:

- An absolute url such as http://, https://, tcp://, tcps://, file:/// and alias:// (see FGLPROFILE Configuration for more details about URL mapping with aliases), and where the data can be a XML document or any kind of data such as images or html pages.
- NULL to sign the whole document, but only one NULL is allowed in the entire signature.
- A fragment like #tobesigned. Note that a DOM node fragment is identified via the value of an attribute of type ID such as xml:id or any attribute whose type was changed to ID with setIdAttribute() or setIdAttributeNS().

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.getCanonicalization
Returns one of the four canonicalization identifier of the signature.

**Syntax**

```java
getCanonicalization()
    RETURNING ident STRING
```

**Usage**

Returns the canonicalization identifier of the signature.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

---

**xml.Signature.getDocument**

Returns a new `DomDocument` object representing the signature in XML.

**Syntax**

```java
getDocument()
    RETURNING doc xml.DomDocument
```

**Usage**

Returns a `xml.DomDocument` object.

If the type of the signature is `enveloped`, it's up to the user to add it at the right place in the XML document it is intended to sign.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

---

**xml.Signature.getID**

Returns the ID value of the signature.

**Syntax**

```java
getID()
    RETURNING id STRING
```

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

---

**xml.Signature.getObjectCount**

Returns the number of objects in this Signature object.

**Syntax**

```java
getObjectCount()
    RETURNING num INTEGER
```

---
xml.Signature.getObjectId

Returns the ID value of the signature object of index *ind* in this Signature object.

**Syntax**

```java
getObjectId(
    ind INTEGER
) RETURNING id STRING
```

1. *ind* is the index in this Signature object.

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.getReferenceCount

Returns the number of references in this Signature object.

**Syntax**

```java
getReferenceCount () RETURNING num INTEGER
```

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.getReferenceDigest

Returns the digest algorithm identifier of the reference of index *ind* in this Signature object.

**Syntax**

```java
getReferenceDigest(
    ind INTEGER
) RETURNING algo STRING
```

1. *ind* is the index in this Signature object.

**Usage**

Returns the digest algorithm identifier of the reference of index *ind* in this Signature object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.
Returns the ID value of the reference of index \( ind \) in this Signature object, or NULL if there is none.

**Syntax**

```java
getReferenceID(  
    ind INTEGER  
)  
RETURNING  value STRING
```

1. \( ind \) is the index in this Signature object.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.getReferenceTransformation

Gets the transformation identifier related to the reference of index \( ind \) at position \( pos \) in the list of transformation.

**Syntax**

```java
getReferenceTransformation(  
    ind INTEGER,  
    pos INTEGER  
)  
RETURNING  ident STRING
```

1. \( ind \) is the index in this Signature object.
2. \( pos \) is the position in the list of transformation.

**Usage**

Returns the transformation identifier related to the reference of index \( ind \), and at position \( pos \) in the list of transformation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.getReferenceTransformationCount

Returns the number of transformation related to the reference of index \( ind \).

**Syntax**

```java
getReferenceTransformationCount(  
    ind INTEGER  
)  
RETURNING  num INTEGER
```

1. \( ind \) is the index in this Signature object.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.getReferenceURI
Returns the URI of the reference of index \textit{ind} in this Signature object.

**Syntax**

```sql
getReferenceURI(
    \textit{ind} INTEGER 
) RETURNING \textit{uri} STRING
```

1. \textit{ind} is the index in this Signature object.

**Usage**

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 2553.

**xml.Signature.getSignatureMethod**

Returns the algorithm method of the signature.

**Syntax**

```sql
getSignatureMethod()
RETURNING \textit{algo} STRING
```

**Usage**

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 2553.

**xml.Signature.getType**

Returns a string with the type of the Signature object.

**Syntax**

```sql
getType()
RETURNING \textit{str} STRING
```

**Usage**

The string can be \texttt{Detached}, \texttt{Enveloped}, \texttt{Enveloping} or \texttt{Invalid} according to the XML-Signature specification.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 2553.

**xml.Signature.RetrieveObjectDataListFromSignatureNode**

Returns a \texttt{DOMNodeList} containing all embedded XML nodes related to the signature object of index \textit{ind} in the XML Signature node \textit{sign}.

**Syntax**

```sql
xml.Signature.RetrieveObjectDataListFromSignatureNode(
    \textit{sign} xmlDOMNode,
    \textit{ind} INTEGER 
) RETURNING \textit{nodelist} xmlDOMNodeList
```
1. `sign` is the XML Signature node.
2. `ind` is the index of the signature object.

**Usage**

Returns a `DOMNodeList`

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Signature.setCanonicalization**

Sets the canonicalization method to use for the signature.

**Syntax**

```java
setCanonicalization(
  url STRING )
```

1. `url` is one of the four canonicalization identifier.

**Usage**

The default value is the `c14n` method.

**Note:** Windows™ .NET default `c14n` canonicalization method is not compatible with the W3C standard, therefore it is recommended to use the `exc-c14n` method when inter-operating with a Windows™ system.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Signature.setCertificate**

Defines the X509 certificate to be added to the Signature object when signing a document.

**Syntax**

```java
setCertificate(
  cert xml.CryptoX509 )
```

1. `cert` is the X509 certificate to be added.

**Usage**

If NULL, no certificate is added.

During the computation of the signature, some certificate information can be added according to the feature set on that CryptoX509 object. If no features are set, the complete X509 certificate is automatically added.

During the verification of a signature the certificate set with the setCertificate method isn't used. See XML Signature concepts for more details.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Signature.setID**
Sets an ID value for the signature.

Syntax

```java
setId(
   id STRING )
```

1. `id` is the ID value to be set.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.setKey

Defines the key used for signing or validation.

Syntax

```java
setKey(
   key xml.CryptoKey )
```

1. `key` is the `key` to be used for signing or validation.

Usage

Only RSA, DSA or HMAC keys intended for `SIGNATURE` are allowed. During the computation of the signature, some key information can be added according to the `feature` set on that `CryptoKey` object. If no features are set, nothing is added. See XML Signature concepts for more details.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.setObjectID

Sets an ID `value` for the signature object of index `ind`.

Syntax

```java
setObjectID(
   ind INTEGER,
   value STRING )
```

1. `ind` is the index value.
2. `value` is the value to be set.

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.setReferenceID
Sets an ID value for the signature reference of index ind.

Syntax

```python
setReferenceID(
    ind INTEGER,
    value STRING )
```

1. ind is the index value.
2. value is the value to be set.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.signString

Sign the passed string according to the specified key.

Syntax

```python
signString(
    key xml.CryptoKey,
    strToSign STRING
)
RETURNING sig STRING
```

1. key is the key to be used for the signature.
2. strToSign is the string to be sign.

Usage

The key can be a HMAC key, a RSA private key or a DSA private key. The signing process is performed with SHA-1 digest, as recommended by the XmlSec specification.

Returns sig, or the signature in base64 format.

This method does not belong to the XML encryption specification.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.verify

Verifies whether all references in this Signature object haven't changed.

Syntax

```python
verify(
    doc xml.DomDocument )
RETURNING flag INTEGER
```

1. doc is the XML document.

Usage

Returns TRUE if valid, FALSE otherwise.

If the signature type is:

- Enveloping: then doc must be NULL because all document fragment references are inside the Signature itself.
- Enveloped: then doc must be the XML document where the signature was enveloped,
- Detached: then doc can be null if all references are absolute, otherwise it can be the XML document the fragment references are referencing.

See XML Signature concepts for more details.

By default, the validation process uses the CryptoKey set with setKey() to verify the signature. However, if the signature contains a X509 certificate or a X509 retrieval method, it uses the list of trusted certificate, or if the signature contains a RSA or DSA retrieval method, it uses the RSA or DSA public key automatically loaded.

**Note:** See Windows™.NET special recommendation.

Before loading the XML document to verify the signature, you might need to set some options to retrieve the "id" nodes with the xml.DomDocument.setFeature() method:

```
DEFINE doc xml.DomDocument
...
CALL doc.setFeature(feature, TRUE)
... 
```

Here feature must be "auto-id-attribute" if the "id" attribute has no namespace, or "auto-id-qualified-attribute", when "id" has a namespace.

This is especially needed when you encounter error messages such as:

```
Xml security operation failed : libxml2 library function failed :
  expr=xpointer(id('id-1436767651')).
```

Meaning that the parser could not find the "id" attribute in the XML document.

Note that the "auto-id-" features will declare all XML attributes where the name is "id", "ID", "Id" or "$iD$" to be of type ID, and thus be usable via xml.DomDocument.getElementById() method used during signature validation.

If needed, you can also set features for a specific attribute with the xml.DomNode.setIdAttribute() method, or with the xml.DomNode.setIdAttributeNS() method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Signature.verifyString
Verify the signature is consistent with the given key and the original message.

**Syntax**

```
verifyString(
  key xml.CryptoKey,
  signedStr STRING,
  signature STRING )
RETURNING flag INTEGER
```

1. **key** is the key to use for verification.
2. **signedStr** is the signed string in its clear form.
3. **signature** is the signature to be verified.
Usage
The key can be a HMAC key, a RSA private key or a DSA private key. The HMAC key must be the same as the one used for signing. The public RSA and DSA key must be the public key corresponding to the private key used for signing.

Returns 1 when verification is successful; 0 (zero) is returned if verification fails.

This method does not belong to the XML encryption specification.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

XML Signature concepts
The purpose of a signature is to guarantee the integrity of a XML document, that it was not altered, and that it still contains the same data as when it was created. An additional purpose of a signature is to authenticate the author of the document. There are different ways to achieve this guarantee.

Sign and verify with a common shared HMAC key
Use if the sender of the XML document and the receiver share a common secret key.

How to sign
1. Create a HMAC key with the constructor of the CryptoKey class.
2. Set or load the common shared key value in the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

How to verify
1. Create a HMAC key with the constructor of the CryptoKey.
2. Set or load the common shared key value in the CryptoKey object.
3. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
4. Assign the CryptoKey object to the Signature object.
5. Verify the signature validity.

Sign with the originator private RSA or DSA key, and verify with the originator public RSA or DSA key
Use if the receiver of the XML document has the RSA or DSA public key of the sender.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign
1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

How to verify
1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA public key into the CryptoKey object.
3. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
4. Assign the CryptoKey object to the Signature object.
5. Verify the signature validity.

Sign with the originator private RSA or DSA key, and verify with a RSA or DSA retrieval method
Use if the sender of the XML document provides the public RSA or DSA key in XML form (and via http, tcp or a file protocol).

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign
1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Set the RetrievalMethod feature on the CryptoKey object with the URL where the XML form of the public RSA or DSA key is available.
4. Create a blank signature with the constructor of the Signature class.
5. Assign the CryptoKey object to the Signature object.
6. Create one or more references to be signed.
7. Compute the signature.
8. Retrieve the XML signature document from the Signature object.

How to verify
1. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
2. Verify the signature validity.

Note: There is no key nor certificate to set in the Signature object during validation.

Sign with the originator private RSA or DSA key, and verify with the originator X509 certificate associated to the private RSA or DSA key
Use if the receiver of the XML document has the X509 certificate associated to the RSA or DSA private key.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign
1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

How to verify
1. Create a X509 certificate with the constructor of the CryptoX509 class.
2. Load the X509 certificate into the CryptoKey object.
3. Create the RSA or DSA public key from the X509 certificate of the CryptoX509 object.
4. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
5. Assign the CryptoKey object containing the public key to the Signature object.
6. Verify the signature validity.

Sign with the originator private RSA or DSA key, and verify with trusted X509 certificates
Use if the sender of the XML document adds a X509 certificate that was signed by another trusted X509 certificate.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign
1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a X509 certificate with the constructor of the CryptoX509 class.
4. Load the X509 certificate associated to the RSA or DSA private key into the CryptoKey object.
5. Create a blank signature with the constructor of the Signature class.
6. Assign the CryptoKey object to the Signature object.
7. Assign the CryptoX509 object to the Signature object.
8. Create one or more references to be signed.
9. Compute the signature.
10. Retrieve the XML signature document from the Signature object.

How to verify
1. Create a X509 certificate with the constructor of the CryptoX509 class.
2. Load the X509 certificate that was used to sign the originator X509 certificate into the CryptoX509 object.
3. Add the X509 certificate as trusted certificate to the application.
4. Create a signature with the constructor of the Signature class and from a XML signature node obtain after the above compute operation.
5. Verify the signature validity.

Note: Point 1 to 3 can be omitted if entry xml.application.calist has been set in FGLPROFILE file with the trusted certificate.

Note: There is no key nor certificate to set in the Signature object during validation.

Sign with the originator private RSA or DSA key, and verify with a X509 certificate retrieval method and trusted X509 certificates
Use if the sender of the XML document adds a X509 retrieval method that was signed by another trusted X509 certificate.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign
1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a X509 certificate with the constructor of the CryptoX509 class.
4. Set the RetrievalMethod feature on the CryptoX509 object with the URL where the XML form of the originator X509 certificate is available.
5. Create a blank signature with the constructor of the Signature class.
6. Assign the CryptoKey object to the Signature object.
7. **Assign** the CryptoX509 object to the Signature object.
8. **Create** one or more references to be signed.
9. **Compute** the signature.
10. **Retrieve** the XML signature document from the Signature object.

**How to verify**

1. Create a X509 certificate with the **constructor** of the CryptoX509 class.
2. **Load** the X509 certificate that was used to sign the originator X509 certificate into the CryptoX509 object.
3. **Add** the X509 certificate as trusted certificate to the application.
4. Create a signature with the **constructor** of the Signature class and from a XML signature node obtain after the above compute operation.
5. **Verify** the signature validity.

**Note:** Steps 1 - 3 can be omitted if entry `xml.application.calist` has been set in `FGLPROFILE` file with the trusted certificate.

**Note:** There is no key or certificate to set in the Signature object during validation.

---

**Sign with a named key and verify using the keystore**

Use if the sender and the receiver exchange multiple XML documents signed with different keys.

**How to sign**

1. Create a HMAC, RSA or DSA key with the **constructor** of the CryptoKey class.
2. **Set** the HMAC key or **load** the RSA or DSA key in the CryptoKey object.
3. Set the **KeyName feature** with the name identifying the key.
4. Create a blank signature with the **constructor** of the Signature class.
5. **Assign** the CryptoKey object to the Signature object.
6. **Create** one or more references to be signed.
7. **Compute** the signature.
8. **Retrieve** the XML signature document from the Signature object.

**How to verify**

1. Create a HMAC, RSA or DSA key with the **constructor** of the CryptoKey.
2. **Set** the HMAC key or **load** the RSA or DSA key in the CryptoKey object.
3. Set the **KeyName feature** with the name identifying the key.
4. **Register** the key to be used by key name for any signature verification.
5. Create a signature with the **constructor** of the Signature class and from a XML signature node obtain after the above compute operation.
6. **Verify** the signature validity.

**Note:** Steps 1 - 4 should be done once at application startup for each key used in the application. Steps 5 - 6 can then quickly be executed for any XML signature to be checked.

XPathFilter2.0 type (<strong>intersect</strong>, <strong>subtract</strong> or <strong>union</strong>), followed by the XPath expression, followed by NULL or a list of prefix, namespace</td>
<td></td>
</tr>
</tbody>
</table>
This is intended to identify the nodes to be signed using a XPath expression instead of an attribute of type ID, and to perform fast and more complex operations such as intersect, subtract or union.

For instance: The following samples output the entire document without the MyCode node child of the MyElement root node:

```xml
CALL
  s.appendReferenceTransformation(
    i,
    "http://www.w3.org/2002/06/xmldsig-filter2",
    "subtract",
    "/MyElement/MyCode"
)
```

```xml
CALL
  s.appendReferenceTransformation(
    i,
    "http://www.w3.org/2002/06/xmldsig-filter2",
    "subtract",
    "/p1:MyElement/p2:MyCode",
    "p2",
    "/p1",
    "http://www.tempuri.org/ns2",
    "p1",
    "http://www.tempuri.org/ns1"
)
```

See specification for details.

Examples

Examples using the XML Signature class.

- Create a detached signature using a HMAC key on page 2265
- Verify a detached signature using a HMAC key on page 2266
- Create an enveloping signature using a DSA key on page 2267
- Verify an enveloping signature using a X509 certificate on page 2268
- Create an enveloped signature using a RSA key on page 2268
- Verify an enveloped signature using a RSA key on page 2269

Create a detached signature using a HMAC key

```
IMPORT xml

MAIN
  DEFINE doc xml.DomDocument
  DEFINE root xml.DomNode
  DEFINE sig xml.Signature
  DEFINE key xml.CryptoKey
  DEFINE index INTEGER
  # Create DomDocument object
  LET doc = xml.DomDocument.Create()
  # Notice that whitespaces are significant in crytography,
  # therefore it is recommended that you remove unnecessary ones
  CALL doc.setFeature("whitespace-in-element-content",FALSE)
  TRY
```
# Load document to be signed
CALL doc.load("MyDocument.xml")

# Create HMAC key
LET key = xml.CryptoKey.Create("http://www.w3.org/2000/09/xmldsig#hmac-sha1")
CALL key.setKey("secretpassword")

# Create signature object with the key to use
LET sig = xml.Signature.Create()
CALL sig.setKey(key)

# Set XML node to be signed. In our case, the node with attribute 
# 'xml:id="code"
LET index = sig.createReference("#code",
    "http://www.w3.org/2000/09/xmldsig#sha1")

# Set canonicalization method on the XML fragment to be signed.
CALL sig.appendReferenceTransformation(index,
    "http://www.w3.org/2001/10/xml-exc-c14n#")

# Compute detached signature
CALL sig.compute(doc)

# Retrieve detached signature document
LET doc=sig.getDocument()

# Save signature on disk
CALL doc.setFeature("format-pretty-print",TRUE)
CALL doc.save("MyDocumentDetachedSignature.xml")

CATCH
    DISPLAY "Unable to create a detached signature ":",STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Verify a detached signature using a HMAC key

IMPORT xml

MAIN
DEFINE doc xml.DomDocument
DEFINE node xml.DomNode
DEFINE sig xml.Signature
DEFINE key xml.CryptoKey
DEFINE isVerified INTEGER

# Create DomDocument object

    # Verify enveloped signature validity of original document
    LET isVerified = sig.verify(doc)
    # Notice that if something has been modified in the node with
    # attribute 'xml:id="code"' of the original XML document with the
    # enveloped signature, the program will display "FAILED".
    IF isVerified THEN
        DISPLAY "Signature OK"
    ELSE
        DISPLAY "Signature FAILED"
    END IF
CATCH
    DISPLAY "Unable to verify the enveloped signature :",STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

The Encryption class
The xml.Encryption class provides methods to encrypt and decrypt XML documents, nodes or
symmetric keys.

It follows the XML-Encryption specifications.
The STATUS variable is set to zero after a successful method call.

Important: This class is not supported on GMI mobile devices.

xml.Encryption methods
Methods for the xml.Encryption class.

Table 549: Class methods: Creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
### Table 550: Class methods: String encryption and decryption

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.Encryption.DecryptString(key xml.CryptoKey, str STRING)</code></td>
<td>Decrypts the encrypted string <code>str</code> encoded in BASE64, using the symmetric key <code>key</code>, and returns the string in clear text.</td>
</tr>
<tr>
<td><code>xml.Encryption.EncryptString(key xml.CryptoKey, str STRING)</code></td>
<td>Encrypts the string <code>str</code> using the symmetric key <code>key</code>, and returns the encrypted string encoded in BASE64.</td>
</tr>
<tr>
<td><code>xml.Encryption.RSADecrypt(key STRING, enc STRING)</code></td>
<td>Decrypts the BASE64 encrypted string <code>enc</code> using the RSA key <code>key</code> and returns it in clear text.</td>
</tr>
<tr>
<td><code>xml.Encryption.RSAEncrypt(key STRING, str STRING)</code></td>
<td>Encrypts the string <code>str</code> using the RSA key <code>key</code> and returns it encoded in BASE64.</td>
</tr>
</tbody>
</table>

The methods listed in Table 550: Class methods: String encryption and decryption on page 2271 do not belong to the XML encryption specification, but are helper functions to allow BDL application to encrypt and decrypt short passwords with RSA keys, or big strings by using symmetric keys. Notice that a common way to encrypt data is to use symmetric keys, and to use RSA keys to encrypt the symmetric key value.

### Table 551: Object methods: Key and certificate setting

</table>
xml.Encryption.Create
Constructor of an Encryption object.

Syntax
```c
xml.Encryption.Create()
RETURNING enc xml.Encryption
```

Usage
Returns a Encryption object or NULL.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Encryption.decryptElement
Decrypts the EncryptedData DomNode enc using the symmetric key.

Syntax
```c
decryptElement(  
    enc xml.DomNode )
```

1. enc is the encrypted DomNode.

Usage
The encrypted DomNode enc is replaced at the same place in the XML document with the resulting ELEMENT DomNode and its children.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Encryption.decryptElementContent
Decrypts the EncryptedData DomNode enc using the symmetric key.

Syntax
```c
decryptElementContent(  
    enc xml.DomNode )
```

1. enc is the encrypted DomNode.

Usage
The encrypted DomNode enc is replaced at the same place in the XML document with the resulting child nodes.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.
Decrypts the EncryptedData DomNode(enc) using the symmetric key, and returns all its children in one new DOCUMENT_FRAGMENT_NODE node.

**Syntax**

```plaintext
decryptElementContentDetached(
    enc xml.DOMNode
) RETURNING node xml.DOMNode
```

1. `enc` is the encrypted DomNode.

**Usage**

Returns all its children in one new DOCUMENT_FRAGMENT_NODE node.

The resulting child nodes aren't added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the encrypted node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Encryption.decryptElementDetached**

Decrypts the EncryptedData DomNode `enc` using the symmetric key, and returns it in a new ELEMENT node.

**Syntax**

```plaintext
decryptElementDetached(
    enc xml.DOMNode
) RETURNING node xml.DOMNode
```

1. `enc` is the encrypted DomNode.

**Usage**

The resulting DomNode and its children aren't added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the encrypted node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Encryption.decryptKey**

Decrypts the EncryptedKey as root in the given XML document, and returns a new CryptoKey of the given kind.

**Syntax**

```plaintext
decryptKey(
    xml xml.DOMDocument,
    url STRING
) RETURNING key xml.CryptoKey
```

1. `xml` is the DomDocument object.
2. `url` is the string.

**Usage**

Returns a new CryptoKey of the given kind.
Only symmetric or HMAC keys are allowed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Encryption.DecryptString
Decrypts the encrypted string str encoded in BASE64, using the symmetric key key, and returns the string in clear text.

Syntax

```java
xml.Encryption.DecryptString(
    key xml.CryptoKey ,
    str STRING )
RETURNING rstr STRING
```

1. key is the symmetric key to use for decryption.
2. str is the encrypted string for decryption.

Usage

The key must be of usage: encryption.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Encryption.encryptElement
Encrypts the ELEMENT DomNode node and all its children using the symmetric key.

Syntax

```java
encryptElement ( 
    node xml.DomNode )
```

Usage

The ELEMENT DomNode node and all its children are replaced at the same place in the XML document with the resulting EncryptedData node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.Encryption.encryptElementContent
Encrypts all child nodes of the ELEMENT DomNode node using the symmetric key.

Syntax

```java
encryptElementContent ( 
    node xml.DomNode )
```

Usage

The child nodes of the ELEMENT DomNode node are replaced at the same place in the XML document with the resulting EncryptedData node.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```plaintext
xml.Encryption.encryptElementContentDetached
Encrypts all child nodes of the ELEMENT DomNode `node` using the symmetric key, and returns them as one new EncryptedData node.

Syntax

```plaintext
def encryptElementContentDetached(
    node xml.DomNode
) RETURNING rnode xml.DomNode
```

1. `node` is the ELEMENT `DomNode` to encrypt.

Usage

Encrypts all child nodes of the ELEMENT DomNode `node` using the symmetric key, and returns them as one new EncryptedData node.

The resulting DomNode isn't added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the nodes in clear form.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```plaintext
xml.Encryption.encryptElementDetached
Encrypts the ELEMENT DomNode `node` and all its children using the symmetric key, and returns them as one new EncryptedData node.

Syntax

```plaintext
def encryptElementDetached(
    node xml.DomNode
) RETURNING rnode xml.DomNode
```

1. `node` is the ELEMENT `DomNode` to encrypt.

Usage

Encrypts the ELEMENT DomNode `node` and all its children using the symmetric key, and returns them as one new EncryptedData node.

The resulting DomNode isn't added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the nodes in clear form.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

```plaintext
xml.Encryption.encryptKey
Encrypts the given symmetric or HMAC key as an EncryptedKey node and returns it as root node of a new XML document.

Syntax

```plaintext
def encryptKey(
    key xml.CryptoKey
)
1. **key** is the given symmetric or HMAC **key** as an **EncryptedKey** node.

**Usage**

Returns it as root node of a new **XML document**. The key-encryption key must been set otherwise it will fail.

Depending on the feature set on the key-encryption key, the returned XML document will contain an additional KeyInfo node.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Encryption.EncryptString**

Encrypts the string **str** using the symmetric key **key**, and returns the encrypted string encoded in BASE64.

**Syntax**

```java
xml.Encryption.EncryptString(
    key xml.CryptoKey,
    str STRING
) RETURNING rstr STRING
```

1. **key** is the **key**.
2. **str** is the string to be encrypted.

**Usage**

The key must be of usage: **encryption**.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Encryption.getEmbeddedKey**

Get a copy of the embedded symmetric key that was used in the last decryption operation.

**Syntax**

```java
getEmbeddedKey() RETURNING key xml.CryptoKey
```

**Usage**

Returns a copy of the embedded symmetric **key** that was used in the last decryption operation, or NULL if there is none.

An embedded symmetric key is always encrypted, and needs therefore a **key-encryption** key to be set in order to decrypt it.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Encryption.RSADecrypt**
Decrypts the BASE64 encrypted string \textit{enc} using the RSA key \textit{key} and returns it in clear text

\textbf{Syntax}

\begin{verbatim}
xml.Encryption.RSADecrypt(
    key STRING,
    enc STRING )
RETURNING rstr STRING
\end{verbatim}

1. \textit{key} is the file name of a RSA private key in PEM format or an \textit{entry} in the FGLPROFILE file.
2. \textit{enc} is a string that was encrypted with the \texttt{fglpass} tool or with the \texttt{xml.Encryption.RSAEncrypt} method.

\textbf{Usage}

RSA decryption is only intended to short strings that cannot exceed the size of the RSA key minus 12 bytes. For instance, if you have a RSA key of 512 bits, your password cannot exceed \( \frac{512}{8} - 12 = 52 \) bytes. If you need to handle big strings, you must use symmetric keys and the \texttt{DecryptString} method. However, you can use RSA keys to decrypt symmetric key values.

\textbf{Important:} YOU MUST PAY ATTENTION TO RESTRICT ACCESS TO THAT RSA PRIVATE KEY FILE ONLY TO THE PERSON OR GROUP OF PERSON AUTHORIZED.

If the RSA private key is protected with a password the recommended way is to unprotect it with the \texttt{openssl} tool and to put the key file on a restricted file system. But you can also use a script or the \texttt{fglpass agent} to provide the password to the application.

For example, you can encrypt a database password with the \texttt{fglpass} tool and store it in the FGLPROFILE file, then you can decrypt it with the \texttt{base.Application.getResourceEntry} and the \texttt{xml.Encryption.RSADecrypt} method to connect to the database.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (STATUS) on page 2553.

\texttt{xml.Encryption.RSAEncrypt}

Encrypts the string \textit{str} using the RSA key \textit{key} and returns it encoded in BASE64.

\textbf{Syntax}

\begin{verbatim}
xml.Encryption.RSAEncrypt(
    key STRING,
    str STRING )
RETURNING rstr STRING
\end{verbatim}

1. \textit{key} is the file name of a RSA public or private key in PEM format or an \textit{entry} in the FGLPROFILE file.
2. \textit{str} is the string to be encrypted.

\textbf{Usage}

RSA encryption is only intended to short strings that cannot exceed the size of the RSA key minus 12 bytes. For instance, if you have a RSA key of 512 bits, your password cannot exceed \( \frac{512}{8} - 12 = 52 \) bytes. If you need to handle big strings, you must use symmetric keys and the \texttt{EncryptString} method. However, you can use RSA keys to encrypt symmetric key values.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (STATUS) on page 2553.

\texttt{xml.Encryption.setCertificate}
Assigns a copy of the X509 certificate to this Encryption object.

**Syntax**

```
setCertificate(
    cert xml.CryptoX509)
```

1. `cert` is the copy of the X509 certificate.

**Usage**

The certificate will then be added to any further XML document or node encryption.

- NULL is allowed to avoid the certificate being added.
- To encrypt using a certificate, you must use the `createPublicKey` method of the X509 class to obtain the public key embedded in the certificate, and then provide it to the encryption object with above `setKeyEncryptionKey` method.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Encryption.setKey**

Assigns a copy of the symmetric key to this Encryption object.

**Syntax**

```
setKey(
    key xml.CryptoKey)
```

1. `key` is the symmetric **key**.

**Usage**

Any further XML document or node encryption or decryption will use that symmetric key.

When decrypting a XML document that has an embedded symmetric key, the embedded key will be used instead.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (STATUS) on page 2553.

**xml.Encryption.setKeyEncryptionKey**

Assigns a copy of the **key-encryption** key to this Encryption object.

**Syntax**

```
setKeyEncryptionKey(
    key xml.CryptoKey)
```

1. `key` is the **key-encryption** **key**.

**Usage**

Any further XML encryption will use that **key-encryption** key to encrypt the symmetric key set with `setKey()` within the resulting XML, and any further XML decryption will use that **key-encryption** key to decrypt the embedded symmetric key.
• NULL is allowed, meaning that embedded symmetric keys will not be encrypted nor decrypted anymore, assuming that they have been exchanged in another way.
• Only public or private RSA keys, or key-wrap keys are allowed.
• Public RSA keys can encrypt but not decrypt.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

Examples

Examples using the xml.Encryption class.
Encrypt a XML node with a symmetric AES128 key

```xml
IMPORT xml

MAIN
DEFINE doc xml.DomDocument
DEFINE root xml.DomNode
DEFINE enc xml.Encryption
DEFINE symkey xml.CryptoKey
LET doc = xml.DomDocument.Create()
# Notice that white spaces are significant in crytography,
# therefore it is recommended that you remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
# Load XML file to be encrypted
CALL doc.load("XMLFileToBeEncrypted.xml")
LET root = doc.getDocumentElement()
# Create symmetric AES128 key for XML encryption purposes
LET symkey = xml.CryptoKey.Create(
    "http://www.w3.org/2001/04/xmlenc#aes128-cbc")
CALL symkey.setKey(">secretpassword<") # password of 128 bits
CALL symKey.setFeature("KeyName","MySecretKey") # Name the password
    # in order to identify the key (Not mandatory)
# Encrypt the entire document
LET enc = xml.Encryption.Create()
CALL enc.setKey(symkey) # Set the symmetric key to be used
CALL enc.encryptElement(root) # Encrypt
# Save encrypted document back to disk
CALL doc.setFeature("format-pretty-print",TRUE)
CALL doc.save("EncryptedXMLFile.xml")
CATCH
    DISPLAY "Unable to encrypt XML file :",STATUS
END TRY
END MAIN
```

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Decrypt a XML node with a symmetric AES128 key

```xml
IMPORT xml

MAIN
DEFINE doc xml.DomDocument
DEFINE node xml.DomNode
DEFINE enc xml.Encryption
DEFINE symkey xml.CryptoKey
DEFINE list xml.DomNodeList
DEFINE str String
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in crytography,
# therefore it is recommended to remove unnecessary ones
```
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
    # Load encrypted XML file
    CALL doc.load("EncryptedXMLFile.xml")
    # Retrieve encrypted node (if any) from the document
    LET list = doc.getElementsByTagNameNS("EncryptedData","http://www.w3.org/2001/04/xmlenc#")
    IF list.getCount()==1 THEN
        LET node = list.getItem(1)
    ELSE
        DISPLAY "No encrypted node found"
        EXIT PROGRAM
    END IF
    # Check if symmetric key name matches the expected "MySecretKey"
    (Not mandatory)
    LET list = node.selectByXPath("dsig:KeyInfo/dsig:KeyName[position()=1 and text()='MySecretKey']","dsig","http://www.w3.org/2000/09/xmldsig#")
    IF list.getCount()!=1 THEN
        DISPLAY "Key name doesn't match"
        EXIT PROGRAM
    END IF
    # Create symmetric AES128 key for XML decryption purpose
    LET symkey = xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#aes128-cbc")
    CALL symkey.setKey(">secretpassword<") # password of 128 bits
    # Decrypt the entire document
    LET enc = xml.Encryption.Create()
    CALL enc.setKey(symkey) # Set the symmetric key to be used
    CALL enc.decryptElement(node) # Decrypt
    # Save encrypted document back to disk
    CALL doc.setFeature("format-pretty-print",TRUE)
    CALL doc.save("DecryptedXMLFile.xml")
CATCH
    DISPLAY "Unable to decrypt XML file ":STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Encrypt a XML node with a generated symmetric key protected with the public RSA key within a X509 certificate

IMPORT xml

MAIN
    DEFINE doc xml.DomDocument
    DEFINE root xml.DomNode
    DEFINE enc xml.Encryption
    DEFINE symkey xml.CryptoKey
    DEFINE kek xml.CryptoKey
    DEFINE cert xml.CryptoX509
LET doc = xml.DomDocument.Create()
    # Notice that whitespaces are significant in cryptography,
    # therefore it is recommended to remove unnecessary ones
    CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
    # Load XML file to be encrypted
    CALL doc.load("XMLFileToBeEncrypted.xml")
    LET root = doc.getDocumentElement()
    # Load the X509 certificate and retrieve the public RSA key
    # for key-encryption purpose
    LET cert = xml.CryptoX509.Create()
CALL cert.loadPEM("RSA1024Certificate.crt")
LET kek = cert.createPublicKey("http://www.w3.org/2001/04/xmlenc#rsa-1_5")
# Generate symmetric key for XML encryption purpose
LET symkey = xml.CryptoKey.create("http://www.w3.org/2001/04/xmlenc#aes256-cbc")
CALL symkey.generateKey(NULL)
# Encrypt the entire document
LET enc = xml.Encryption.Create()
CALL enc.setKey(symkey) # Set the symmetric key to be used
CALL enc.setKeyEncryptionKey(kek) # Set the key-encryption key to be used for protecting the symmetric key
CALL enc.setCertificate(cert) # Set the certificate to be added (not mandatory)
CALL enc.encryptElement(root) # Encrypt
# Save encrypted document back to disk
CALL doc.setFeature("format-pretty-print",TRUE)
CALL doc.save("EncryptedXMLFile.xml")
CATCH
DISPLAY "Unable to encrypt XML file :",STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Decrypt a XML node encrypted with a symmetric key protected with a private RSA key

IMPORT xml

MAIN
DEFINE doc xml.DomDocument
DEFINE node xml.DomNode
DEFINE enc xml.Encryption
DEFINE symkey xml.CryptoKey
DEFINE kek xml.CryptoKey
DEFINE list xml.DomNodeList
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in cryptography, therefore it is recommended to remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
# Load encrypted XML file
CALL doc.load("EncryptedXMLFile.xml")
# Retrieve encrypted node (if any) from the document
LET list = doc.getElementsByTagNameNS("EncryptedData","http://www.w3.org/2001/04/xmlenc#")
IF list.getCount()==1 THEN
LET node = list.getItem(1)
ELSE
DISPLAY "No encrypted node found"
EXIT PROGRAM
END IF
# Load the private RSA key
LET kek = xml.CryptoKey.create("http://www.w3.org/2001/04/xmlenc#rsa-1_5")
CALL kek.loadPEM("RSA1024Key.pem")
# Decrypt the entire document
LET enc = xml.Encryption.Create()
CALL enc.setKeyEncryptionKey(kek) # Set the key-encryption key to decrypted the protected symmetric key
CALL enc.decryptElement(node) # Decrypt
# Retrieve the embedded symmetric key for further usage and display # info about it
LET symkey = enc.getEmbeddedKey()
DISPLAY "Key size (in bytes) : ", symkey.getSize() # displays 1024
DISPLAY "Key type : ", symkey.getType() # displays SYMMETRIC
DISPLAY "Key usage : ", symkey.getUsage() # displays ENCRYPTION
# Encrypted document back to disk
CALL doc.setFeature("format-pretty-print",TRUE)
CALL doc.save("DecryptedXMLFile.xml")
CATCH
DISPLAY "Unable to decrypt XML file : ", STATUS
END TRY
END MAIN

**Note:** All keys or certificates in PEM or DER format were created with the OpenSSL tool.

### The KeyStore class

The `xml.KeyStore` class provides static methods to handle a key store global to the entire application. It enables to register X509 and trusted certificates, and any kind of key by name for automatic XML signature validation or XML decryption.

The `STATUS` variable is set to zero after a successful method call.

**Important:** This class is not supported on GMI mobile devices.

### xml.KeyStore methods

Methods for the `xml.KeyStore` class.

### Table 555: Class methods

<table>
<thead>
<tr>
<th>Name</th>

</tbody>
</table>

### xml.KeyStore.AddCertificate

Registers the given X509 certificate as a certificate for the application. It will be used when an incomplete X509 certificate is detected during signature or encryption to complete the process by checking the certificate issuer name and serial number.

**Syntax**

```java
xml.KeyStore.AddCertificate(
    cert xml.CryptoX509
)
```

1. `cert` is the X509 certificate to register.
Usage
The method has the same effect as the FGLPROFILE entry xml.keystore.x509list.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.KeyStore.AddKey
Registers the given key by name to the application. It is used for XML signature verification or XML decryption when a key name was specified in the XML KeyInfo node and no other key was set in the Signature or Encryption object.

Syntax

```java
xml.KeyStore.AddKey(
    key xml.CryptoX509
)
```

1. key is the key object xml.CryptoX509 to add to the keystore.

Usage
Registers the given key by name to the application. It is used for XML signature verification or XML decryption when a key name was specified in the XML KeyInfo node and no other key was set in the Signature or Encryption object.

The CryptoKey must have the KeyName feature set, and the name must be unique in the application.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

xml.KeyStore.AddTrustedCertificate
Registers the given X509 certificate as a trusted certificate for the application. It will be used for signature verification if no other certificate was set for that purpose.

Syntax

```java
xml.KeyStore.AddTrustedCertificate(
    cert xml.CryptoX509
)
```

1. cert is the X509 certificate to register.

Usage
Registers the given X509 certificate as a trusted certificate for the application. It will be used for signature verification if no other certificate was set for that purpose.

Has the same effect as the FGLPROFILE entry xml.keystore.caist.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

OM to XML Migration
Information to migrate code that uses the language build-in om package, to the Web Services extensions xml package.

Before you migrate, make sure that you are using the classes from the appropriate package:

- Classes from the om package exist to manipulate the AUI tree.
• Classes from the xml package provide full support for XML document processing, and should be used to manipulate XML documents.

Why would you migrate from om to xml classes and methods?
• You need to be able to utilize a feature (such as a StyleSheet) that requires use of methods from the xml library classes.

OM - XML Mapping

For more information on Genero built-in classes (such as the OM class), refer to Built-in packages on page 1692.

**The security package**

The Genero Web Services security package provides classes and methods to support basic cryptographic features.

Use the IMPORT statement at the top of the module using this library:

```sql
IMPORT security
```

- The RandomGenerator class on page 2287
- The Base64 class on page 2288
- The HexBinary class on page 2294
- The Digest class on page 2299
The RandomGenerator class

The \texttt{security.RandomGenerator} class includes methods for creating random strings or numbers.

\textbf{security.RandomGenerator methods}

Methods of the \texttt{security.RandomGenerator} class.

\textbf{Table 557: Class methods}

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{security.RandomGenerator.CreateRandomNumber()}</td>
<td>Generates a 8-byte strong random number.</td>
</tr>
<tr>
<td>\texttt{security.RandomGenerator.CreateRandomString( size INTEGER )}</td>
<td>Creates a random base64 string.</td>
</tr>
<tr>
<td>\texttt{security.RandomGenerator.CreateUUIDString()}</td>
<td>Creates a new universal unique identifier (UUID).</td>
</tr>
</tbody>
</table>

\texttt{security.RandomGenerator.CreateRandomNumber}

Generates a 8-byte strong random number.

\textbf{Syntax}

\begin{verbatim}
  security.RandomGenerator.CreateRandomNumber()
  RETURNING result BIGINT
\end{verbatim}

1. \texttt{result} is a random big integer.

\textbf{Usage}

Generates a 8-byte strong random number and returns it as a \texttt{BIGINT}.

The generated number can then be used for advanced cryptographic features.

This method is based on openssl, using \texttt{/dev/random} on Unix and \texttt{CryptGenRandom()} on Microsoft Windows, which are following CSPRNG specifications.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 2553.

\texttt{security.RandomGenerator.CreateRandomString}

Creates a random base64 string.

\textbf{Syntax}

\begin{verbatim}
  security.RandomGenerator.CreateRandomString( size INTEGER )
  RETURNING result STRING
\end{verbatim}

1. \texttt{size} is the size of the random string.
2. \texttt{result} is the generated random string in Base64.
Usage

Generates a random binary data of size bytes long and returns it in a STRING encoded in a Base64 form. The size must be greater than 0.

Use this function when randomness is required, such as in xml.CryptoKey.deriveKey() or security.Digest.CreateDigestString().

This method is based on openssl, using /dev/random on Unix and CryptGenRandom() on Microsoft Windows, which are following CSPRNG specifications.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

security.RandomGenerator.CreateUUIDString
Creates a new universal unique identifier (UUID).

Syntax

```
security.RandomGenerator.CreateUUIDString()
```

1. result is the new generated UUID string.

Usage

Generates an universal unique identifier and returns the value as STRING.

The generated strings follows the UUID version 4 specification. Version 4 UUIDs have the form xxxxxxxx-xxxx-4xxx-yxxx-xxxxxxxxxxxx where x is any hexadecimal digit and y is one of 8, 9, A, or B.

Note: This method replaces com.Util.CreateUUIDString().

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The Base64 class

The security.Base64 class includes methods for encoding to base64 or decoding from base64.

security.Base64 methods

Methods of the security.Base64 class.

Table 558: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>

</tr>
<tr>
<td>security.Base64.Xor(b64str1 STRING, b64str2 STRING) RETURNING result STRING</td>
<td>Computes the exclusive disjunction between two base64 encoded strings.</td>
</tr>
</tbody>
</table>

security.Base64.FromByte
Encodes the given BYTE data in base64.

**Syntax**

```
security.Base64.FromByte(
  source BYTE
) RETURNING result STRING
```

1. `source` is the BYTE to be encoded.
2. `result` is the base64 encoded string.
**Usage**

Encodes the given BYTE data in base64 and returns the string.

*Important:* The BYTE must be located in memory.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**security.Base64.FromHexBinary**

Decodes the given hexadecimal string to base64.

**Syntax**

```java
security.Base64.FromHexBinary(
    source STRING
) RETURNING result STRING
```

1. *source* is a string in its hexadecimal form
2. *result* is a string encoded in base64

**Usage**

Decodes the given hexadecimal string and returns it in base64.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**security.Base64.FromString**

Encodes the given string in base64.

**Syntax**

```java
security.Base64.FromString(
    source STRING
) RETURNING result STRING
```

1. *source* is the string to be encoded.
2. *result* is the base64 encoded string.

**Usage**

Encodes the given string and returns it in base64.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**security.Base64.FromStringWithCharset**

Encodes the given string in base64, according to a given charset.

**Syntax**

```java
security.Base64.FromStringWithCharset(
    source STRING,
    charset STRING
) RETURNING result STRING
```
1. *source* is the string to be encoded.
2. *charset* is the character set to be used.
3. *result* is the base64 encoded string.

**Usage**

Encodes the given string and returns it in base64.

Before conversion, the string is converted from the local DVM charset to the specified encoding.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`security.Base64.LoadBinary`

Reads data from a file and encodes to base64.

**Syntax**

```java
security.Base64.LoadBinary (
    path STRING )
RETURNING result STRING
```

1. *path* is the path to the binary file.
2. *result* is a string encoded in base64.

**Usage**

Reads the file located at *path* and encodes these binary data in Base64 format.

For example, this method can be used to send images through a network.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`security.Base64.SaveBinary`

Decodes the given base64 string and writes the data to a file.

**Syntax**

```java
security.Base64.SaveBinary (
    path STRING,
    data STRING )
```

1. *path* is the path to the binary file
2. *data* is a base64 string to be written.

**Usage**

Decodes the given Base64 string and writes the binary data to the file defined by *path*.

This method can be used to save data from a network on the disk.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
security.Base64.ToHexBinary
Decodes the given base64 string to hexadecimal.

Syntax

```
security.Base64.ToHexBinary(
    source STRING )
RETURNING result STRING
```

1. `source` is a string encoded in base64.
2. `result` is a string decoded in hexadecimal.

Usage

Decodes the given base64 string and returns it in its hexadecimal form.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

security.Base64.ToByte
Decodes the given base64 string into a BYTE.

Syntax

```
security.Base64.ToByte(
    source STRING,
    destination BYTE )
```

1. `source` is a string in base64.
2. `destination` is the BYTE to fill with data.

Usage

Decodes the given base64 string and fills the BYTE variable with binary data.

**Important:** The `BYTE` must be located in memory.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

security.Base64.ToString
Decodes the given base64 string.

Syntax

```
security.Base64.ToString(
    source STRING )
RETURNING result STRING
```

1. `source` is a string encoded in base64.
2. `result` is the decoded string.

Usage

Decodes the given base64 string and returns it in its clear (human readable) form.

If the base64 string does not contain a human readable data, the method will raise an exception.
If the base64 string contains bytes sequences that do not match a valid character in the current encoding, the method raises a conversion error.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**security.Base64.ToStringWithCharset**
Decodes the given base64 string, according to a given charset.

**Syntax**

```
security.Base64.ToStringWithCharset(
  source STRING,
  charset STRING )
RETURNING result STRING
```

1. `source` is a string encoded in base64.
2. `charset` is the character set to be used.
3. `result` is the decoded string.

**Usage**
Decodes the given base64 string and returns it in its clear human readable form, according to a given charset.

The original base64 encoded string is first decoded to a string that will be converted from the specified charset to the local DVM charset. In case of charset conversion error, the error -15700 is raised.

If the base64 string does not contain a human readable data, the method will raise an exception.

If the base64 string contains bytes sequences that do not match a valid character in the current encoding, the method raises a conversion error.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**security.Base64.Xor**
Computes the exclusive disjunction between two base64 encoded strings.

**Syntax**

```
security.Base64.Xor(
  b64str1 STRING,
  b64str2 STRING )
RETURNING result STRING
```

1. `b64str1` is a first string encoded in base64.
2. `b64str2` is a second string encoded in base64.
3. `result` is the xor result encoded in base64.

**Usage**
Decodes the two given strings and does an exclusive disjunction between the two binary and returns the result encoded in base64.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.
The HexBinary class

The `security.HexBinary` class includes methods for encoding to hexadecimal or decoding from hexadecimal.

**security.HexBinary methods**

Methods of the `security.HexBinary` class.

### Table 559: Class methods

<table>

</tbody>
</table>

security.HexBinary.FromBase64
Converting a base64 string to the hexadecimal equivalent.

**Syntax**

```java
security.HexBinary.FromBase64(
    source STRING )
RETURNING result STRING
```

1. `source` is a string encoded in base64.
2. `result` is a string decoded in hexadecimal.

**Usage**
Decodes the given base64 string and returns it in its hexadecimal form.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

security.HexBinary.FromByte
Encodes BYTE data in hexadecimal.

**Syntax**

```java
security.HexBinary.FromByte(
    source BYTE )
RETURNING result STRING
```

1. `source` is the BYTE to be encoded in hexadecimal.
2. `result` is the encoded hexadecimal string.

**Usage**
Encodes the given BYTE data in hexadecimal and returns the string.

**Important:** The BYTE must be located in memory.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

security.HexBinary.FromString
Encodes a given string in hexadecimal.

**Syntax**

```java
security.HexBinary.FromString(
```

...
**Usage**

Encodes the given string and returns it in hexadecimal.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**Syntax**

```java
security.HexBinary.FromStringWithCharset (source STRING,
charset STRING )
RETURNING result STRING
```

1. `source` is the source string to be encoded in hexadecimal.
2. `charset` is the character set to be used.
3. `result` is the encoded hexadecimal string.

**Usage**

Encodes the given string and returns it in hexadecimal.

Before conversion, the string is converted from the local DVM charset to the specified encoding.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**Syntax**

```java
security.HexBinary.FromStringWithCharset (source STRING,
charset STRING )
RETURNING result STRING
```

1. `source` is the source string to be encoded in hexadecimal.
2. `charset` is the character set to be used.
3. `result` is the encoded hexadecimal string.

**Usage**

Reads binary data from a file and converts it to hexadecimal.

For example, this method can be used to send images through a network.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

**Syntax**

```java
security.HexBinary.LoadBinary (path STRING )
RETURNING result STRING
```

1. `path` is the path to the binary file.
2. `result` is the string in hexadecimal format.
security.HexBinary.SaveBinary
Decodes an hexadecimal strings and writes the binary data to a file.

Syntax

```java
security.HexBinary.SaveBinary(
    path STRING,
    data STRING )
```

1. `path` is the path to the binary file.
2. `data` is the hexadecimal string to be written.

Usage

Decodes the given hexadecimal string and writes the binary data to the file defined by `path`.

This method can be used to save data from a network on the disk.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

security.HexBinary.ToBase64
Converts an hexadecimal string to the base64 equivalent

Syntax

```java
security.HexBinary.ToBase64(
    source STRING )
RETURNING result STRING
```

1. `source` is a string in its hexadecimal form.
2. `result` is a string encoded in base64.

Usage

Decodes the given hexadecimal string and returns it in base64.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

security.HexBinary.ToByte
Decodes an hexadecimal string into a BYTE variable.

Syntax

```java
security.HexBinary.ToByte(
    source STRING,
    destination BYTE )
```

1. `source` is a string in hexadecimal.
2. `destination` is the BYTE to fill with data.

Usage

Decodes the given hexadecimal string and fills the BYTE variable with binary data.

**Important:** The BYTE must be located in memory.
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (STATUS) on page 2553.

\texttt{security.HexBinary.ToString}
Decodes an hexadecimal string to a clear, human-readable string.

\textbf{Syntax}

\begin{verbatim}
security.HexBinary.ToString(
    source STRING )
RETURNING result STRING
\end{verbatim}

1. \texttt{source} is a string in hexadecimal.
2. \texttt{result} is a human readable string.

\textbf{Usage}
Decodes the given hexadecimal string and returns it in its clear, human readable, form. If the hexadecimal string does not contain a human readable string, the method will raise an exception.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (STATUS) on page 2553.

\texttt{security.HexBinary.ToStringWithCharset}
Decodes an hexadecimal string to a clear, human-readable string, according to a given charset.

\textbf{Syntax}

\begin{verbatim}
security.HexBinary.ToStringWithCharset(
    source STRING,
    charset STRING )
RETURNING result STRING
\end{verbatim}

1. \texttt{source} is a string in hexadecimal.
2. \texttt{charset} is the character set to be used.
3. \texttt{result} is a human readable string.

\textbf{Usage}
Decodes the given hexadecimal string and returns it in its clear human readable form, according to a given charset.

The original hexadecimal encoded string is first decoded to a string that will then be converted from the specified charset to the local DVM charset. In case of charset conversion error, the error -15700 is raised.

If the hexadecimal string does not contain a human readable string, the method will raise an exception.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (STATUS) on page 2553.

\texttt{security.HexBinary.Xor}
Computes the exclusive disjunction between two hexadecimal encoded strings.

\textbf{Syntax}

\begin{verbatim}
security.HexBinary.Xor(
    hexstr1 STRING,
    hexstr2 STRING )
\end{verbatim}
1. hexstr1 is a first string in hexadecimal.
2. hexstr1 is a second string in hexadecimal.
3. result is the xor result encoded in hexadecimal.

Usage

Decodes the two given string and does an exclusive disjunction between the two binary and returns the result in hexadecimal.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

The Digest class

The security.Digest class implements digest algorithms to process data.

The class implements several methods that allow you to add data by pieces and process these data with a specified digest algorithm.

Steps to process data with a digest algorithm:

1. Define the digest algorithm with the security.Digest.CreateDigest method.
3. When all data pieces are added, the buffer can be processed by calling methods like security.Digest.DoBase64Digest or security.Digest.DoHexBinaryDigest.

Alternatively, a simple data string can be processed with the security.Digest.CreateDigestString method.

security.Digest methods

Methods of the security.Digest class.

Table 560: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>security.Digest.addData ( data BYTE )</td>
<td>Adds a data from a BYTE variable to the digest buffer.</td>

<tr>
<td>security.Digest.CreateDigest ( algo STRING )</td>
<td>Creates a SHA1 digest from the given string.</td>
</tr>
<tr>
<td>security.Digest.CreateDigestString( password STRING, randBase64 STRING ) RETURNING result STRING</td>
<td>Creates a digest of the buffered data and returns the result in base64 format.</td>
</tr>
<tr>
<td>security.Digest.DoBase64Digest() RETURNING b64Digest STRING</td>
<td>Creates a digest of the buffered data and returns the result in hexadecimal format.</td>
</tr>
</tbody>
</table>

security.Digest.AddData

Adds a data from a BYTE variable to the digest buffer.

**Syntax**

```plaintext
security.Digest.AddData ( data BYTE )
```

1. `data` is binary data to be added to the digest buffer.

**Usage**

Adds the binary data contained in the given BYTE to the digest context.

After adding all data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

**Important:** The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 2553.

security.Digest.AddBase64Data

Adds a data in base64 format to the digest buffer.

**Syntax**

```plaintext
security.Digest.AddBase64Data ( data STRING )
```

1. `data` is the base64 data string to be added to the digest buffer.

**Usage**

Decodes the given base64 string and adds the binary data to the digest buffer.
After adding all data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`security.Digest.AddHexBinaryData`

Adds a data in hexadecimal format to the digest buffer.

**Syntax**

```java
security.Digest.AddHexBinaryData(
    data STRING )
```

1. *data* is the hexadecimal data string to be added to the digest buffer.

**Usage**

Decodes the given hexadecimal string and adds the binary data to the digest buffer.

After adding all data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`security.Digest.AddStringData`

Adds a data string to the digest buffer.

**Syntax**

```java
security.Digest.AddStringData(
    data STRING )
```

1. *data* is a human-readable character string to be added to the digest buffer.

**Usage**

Adds the specified string data to the digest buffer.

After adding all data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

`security.Digest.AddStringDataWithCharset`

Adds a data string to the digest buffer, after converting to the specified character set.

**Syntax**

```java
security.Digest.AddStringDataWithCharset(
    data STRING,
    charset STRING )
```

1. *data* is a human-readable character string to be added to the digest buffer.
2. *charset* is the charset to be used.
Usage

Adds the specified string data to the digest buffer.

Before adding the string, it is converted from the local DVM charset to the specified encoding.

After adding all data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

security.Digest.CreateDigest

Defines a new digest context by specifying the algorithm to be used.

Syntax

```
security.Digest.CreateDigest (algo STRING)
```

1. `algo` is the digest algorithm to be used.

Usage

Creates and initializes a digest context to compute data digest according to the given algorithm.

Available digest algorithms are:

- "SHA1"
- "SHA224"
- "SHA256"
- "SHA384"
- "SHA512"
- "MD5"

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 2553.

security.Digest.CreateDigestString

Creates a SHA1 digest from the given string.

Syntax

```
security.Digest.CreateDigestString(password STRING, randBase64 STRING)
RETURNING result STRING
```

1. `password` is the password to be digested.
2. `randBase64` is a random string in Base64.
3. `result` is a base64 encoded string.

Usage

Computes the SHA1 digest from a `password` value and an optional `randBase64` random Base64 form string, and returns it into a string encoded in Base64 form.

The random value must be a valid Base64 String. You typically generate this value with the `security.RandomGenerator.CreateRandomString()` method.
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 2553.

\begin{example}
\begin{verbatim}
DEFINE password, digest STRING
...
LET digest =
  security.Digest.CreateDigestString(
    password,
    security.RandomGenerator.CreateRandomString(16) )
\end{verbatim}
\end{example}

\texttt{security.Digest.DoBase64Digest}

Creates a digest of the buffered data and returns the result in base64 format.

\textbf{Syntax}

\begin{verbatim}
security.Digest.DoBase64Digest ()
RETURNING b64Digest STRING
\end{verbatim}

1. \textit{b64Digest} is the digest in base64

\textbf{Usage}

Processes the digest on all data previously added to the context and encodes it in base64.

After that call, the internal buffer is cleaned and ready to be populated again with new data to be digested.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 2553.

\texttt{security.Digest.DoHexBinaryDigest}

Creates a digest of the buffered data and returns the result in hexadecimal format.

\textbf{Syntax}

\begin{verbatim}
security.Digest.DoHexBinaryDigest ()
RETURNING hexBinDigest STRING
\end{verbatim}

1. \textit{hexBinDigest} is the hexadecimal digest.

\textbf{Usage}

Processes the digest on all data previously added to the context and returns it in hexadecimal.

After that call, the internal buffer is cleaned and ready to be populated again with new data to be digested.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 2553.

\textbf{Example}

Computing a hash value of a string.

Program example \texttt{ComputeHash.4gl}:

\begin{verbatim}
IMPORT SECURITY
MAIN
\end{verbatim}
DEFINE result STRING

IF num_args() != 2 THEN
    DISPLAY "Usage: ComputeHash <string> <hashcode>"
    DISPLAY "  string: the string to digest"
    DISPLAY "  hashcode: SHA1, SHA512, SHA384, SHA256, SHA224, MD5"
ELSE
    LET result = ComputeHash(arg_val(1), arg_val(2))
    IF result IS NOT NULL THEN
        DISPLAY "Hash value is ":result
    ELSE
        DISPLAY "Error"
    END IF
END IF

END MAIN

FUNCTION ComputeHash(toDigest, algo)

    DEFINE toDigest, algo, result STRING
    DEFINE dgst security.Digest

    TRY
        LET dgst = security.Digest.CreateDigest(algo)
        CALL dgst.AddStringData(toDigest)
        LET result = dgst.DoBase64Digest()
    CATCH
        DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
        EXIT PROGRAM(-1)
    END TRY

    RETURN result
END FUNCTION

Example execution:

$ fgirun ComputeHash "Hello World" SHA1
Hash value is :Ck1VqNd45Qlq3AZd8XYQLvEhtA=

File extensions

This page describes the file extensions used by the language.

### Genero BDL errors

System error messages sorted by error number.

**Table 562: Genero system error messages**

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-201</td>
<td>A syntax error has occurred. This general SQL error message indicates mistakes in the syntax of an SQL statement. Look for missing or extra punctuation; keywords misspelled, misused, or out of sequence, or a reserved word used as an identifier.</td>
</tr>
<tr>
<td>-204</td>
<td>An illegal floating point number has been found in the statement. A numeric constant that is punctuated like a floating-point number (with a decimal point and/or an exponent starting with e) is unacceptable. Possibly the exponent is larger than can be processed.</td>
</tr>
<tr>
<td>-206</td>
<td>The specified table table-name is not in the database. The database server cannot find a table or view specified in the statement. The table or view might have been renamed or dropped from the database.</td>
</tr>
<tr>
<td>-213</td>
<td>Statement interrupted by user. The database server received an interrupt signal from the user. The statement ended early. A program should roll back the current transaction and terminate gracefully.</td>
</tr>
<tr>
<td>-217</td>
<td>Column column-name not found in any table in the query. The column specified does not exist in the database tables used in this SQL statement.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -235  | Character column size is too big.  
The SQL statement specifies a width for a character data type that is greater than 65,534 bytes.  
If you need a column of this size, use the TEXT data type, which allows unlimited lengths. Otherwise, inspect the statement for typographical errors. |
| -236  | Number of columns in INSERT does not match number of VALUES.  
Each column that is named or implied in an INSERT statement must have a separate value expression. If the statement does not list specific columns, review the definition of the table for the number of columns and their data types. Also check that the list of expressions in the VALUES clause has no extra or missing comma that might result in an incorrect number of values. Be especially careful of long character strings and expressions with parentheses. |
| -239  | Could not insert new row – duplicate value in a UNIQUE INDEX column.  
The row that is being inserted (or being updated to have a new primary key) contains a duplicate value of some row that already exists, in a column or columns that are constrained to have unique values. |
| -244  | Could not do a physical-order read to fetch next row.  
The database server cannot read the data block for this SQL client program. The database server returns this error when a record is locked by another process, and the lock timeout defined by the current program has expired.  
Consider using the `SET LOCK MODE TO WAIT` instruction to define a lock timeout. By default, with most databases, this timeout is zero and error -244 is returned immediately when a lock conflict occurs. If all programs do short transactions (holding locks for a short period of time), it is usually safe to define a lock timeout of 5 to 10 seconds to avoid this SQL error. |
| -250  | Cannot read record from file for update.  
The database server cannot get a row of a table prior to update. |
| -251  | ORDER BY or GROUP BY column number is too big.  
The ORDER BY or GROUP BY clause uses column-sequence numbers, and at least one of them is larger than the count of columns in the select list. |
| -253  | Cannot read record from file for update.  
The database server cannot get a row of a table prior to update. |
| -254  | Too many or too few host variables given.  
The number of host variables that you named in the INTO clause of this statement does not match the number of columns that you referenced in the SQL statement. |
<p>| -255  | Not in transaction. |</p>
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -256   | Transaction not available.  
The database server does not support transactions. |
| -257   | System limit on maximum number of statements exceeded, maximum is count.  
The database server can handle only a fixed number of prepared SQL statements for each user. This limit includes statements that were prepared with the PREPARE statement and cursors that were declared with the DECLARE statement. |
| -259   | Cursor not open.  
The current statement refers to a cursor that has not been opened. Review the logic of the program to see how it failed to execute the OPEN statement before it reached this point. |
| -263   | Could not lock row for UPDATE.  
This statement, probably a FETCH statement that names a cursor declared FOR UPDATE, failed because the row it should have fetched could not be locked. |
| -266   | There is no current row for UPDATE/DELETE cursor.  
The current statement uses the WHERE CURRENT OF cursor-name clause, but that cursor has not yet been associated with a current row. Either no FETCH statement has been executed since it was opened, or the most recent fetch resulted in an error so that no row was returned. Revise the logic of the program so that it always successfully fetches a row before it executes this statement. |
| -268   | Unique constraint constraint-name violated.  
The current statement uses the WHERE CURRENT OF cursor-name clause, but that cursor has not yet been associated with a current row. Either no FETCH statement has been executed since it was opened, or the most recent fetch resulted in an error so that no row was returned. Revise the logic of the program so that it always successfully fetches a row before it executes this statement. |
| -272   | No SELECT permission for table/column.  
The person who created this table has not granted SELECT privilege to your account name or to the public for the table or the column. The owner of the table or the DBA must grant this privilege before you can select data from the table or column. |
| -273   | No UPDATE permission for table/column.  
The person who created this table has not granted UPDATE privilege to your account name or to the public for the table or the column. The owner of the table or the DBA must grant this privilege before you can update a row in this table or update the column. |
<p>| -274   | No DELETE permission for table. |</p>
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The person who created this table has not granted DELETE privilege to your account name or to the public. The owner of the table or the DBA must grant this privilege before you can delete a row in this table.</td>
</tr>
<tr>
<td>-275</td>
<td>The Insert privilege is required for this operation. The Insert access privilege on this table or column is not currently held by your account name, nor by the PUBLIC group, nor by your current role. The owner of the table or the DBA must grant the Insert privilege before you can insert a row into this table.</td>
</tr>
<tr>
<td>-280</td>
<td>A quoted string exceeds 256 bytes. A character literal in this statement exceeds the maximum length. Check the punctuation and length of all quoted strings in the statement. Possibly two missing quotes make a long string out of two short ones. You must revise the statement to use a shorter character string.</td>
</tr>
<tr>
<td>-282</td>
<td>Found a quote for which there is no matching quote. Inspect the current statement, examining the punctuation of all quoted strings.</td>
</tr>
<tr>
<td>-284</td>
<td>A subquery has returned not exactly one row. A subquery that is used in an expression in the place of a literal value must return only a single row and a single column. In this statement, a subquery has returned more than one row, and the database server cannot choose which returned value to use in the expression. You can ensure that a subquery will always return a single row. Use a WHERE clause that tests for equality on a column that has a unique index. Or select only an aggregate function. Review the subqueries, and check that they can return only a single row. This error can also occur when you use a singleton SELECT statement to retrieve multiple rows. You must use the DECLARE/OPEN/FETCH series of statements or the EXECUTE INTO statement to retrieve multiple rows.</td>
</tr>
<tr>
<td>-285</td>
<td>Invalid cursor received by sqlexec. The cursor that this statement uses has not been properly declared or prepared, or the FREE statement has released it, or an automatic re-prepare has been attempted while opening the cursor but that operation failed, leaving the cursor unavailable. Review the program logic to ensure that the cursor has been declared. If it has, and if the DECLARE statement refers to a statement identifier, check that the referenced statement has been prepared.</td>
</tr>
<tr>
<td>-290</td>
<td>Cursor not declared with FOR UPDATE clause. This statement attempts to update with a cursor that was not declared for update. To use a cursor with the UPDATE or DELETE statements, you must declare it FOR UPDATE. Review the program logic to make sure that this statement uses the intended cursor.</td>
</tr>
<tr>
<td>-294</td>
<td>The column column-name must be in the GROUP BY list. In a grouping SELECT, you must list every nonaggregate column in the GROUP BY clause to ensure that a well-defined value exists for each selected column in each grouped row. A column contains either a single aggregate value or a value unique to that group. If a selected column were neither an aggregate nor in the list, two or more values for that column might possibly exist in some group, and the database server</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -307   | Illegal subscript.  
The substring values (two numbers in square brackets) of a character variable are incorrect. The first is less than zero or greater than the length of the column, or the second is less than the first.  
Review all uses of square brackets in the statement to find the error. Possibly the size of a column has been altered and makes a substring fail that used to work. |
| -309   | ORDER BY column or expression must be in SELECT list.  
An expression or column name is in the ORDER BY clause of this SELECT statement, but the expression or column name is not in the select list (the list of values that follows the word SELECT). This action is not supported when a UNIQUE or DISTINCT operator is being used in a query. |
| -316   | Index index-name already exists in database.  
This statement tries to create an index with the name shown, but an index of that name already exists. Only one index of a given name can exist in a single database. |
| -324   | Ambiguous column column-name.  
The column name appears in more than one of the tables that are listed in the FROM clause of this query. The database server needs to know which columns to use.  
Revise the statement so that this name is prefixed by the name of its table (table-name.column) wherever it appears in the query. |
| -329   | Database not found or no system permission.  
The database you tried to connect to is not known by the db server.  
Check database client configuration settings and make sure that there is no spelling error in the name of the database. |
| -330   | Cannot create or rename the database.  
Possibly you tried to create a database with the same name as one that already exists or rename a database to a name that already exists; if so, choose a different name. |
| -349   | Database not selected yet.  
The SQL statement cannot be executed because no current database exists. You must issue a DATABASE or CONNECT TO instruction before executing other SQL statements. |
| -350   | Index already exists on the column (or on the set of columns).  
This CREATE INDEX statement cannot be executed because an index on the same column or combination of columns already exists. For a given collation order, at most two indexes can exist on any combination of columns, one ascending and one descending. |
<p>| -354   | Incorrect database or cursor name format. |</p>
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -360   | Cannot modify a table or view that is also used in subquery.  
        The UPDATE, INSERT, or DELETE statement uses data taken from the same table in a subquery. Because of the danger of entering an endless loop, this action is not allowed, except in the case of an uncorrelated subquery in the WHERE clause of the DELETE or UPDATE statement. |
| -363   | CURSOR not on SELECT statement.  
        The cursor named in this statement (probably an OPEN) has been associated with a prepared statement that is not a SELECT statement.  
        Review the program logic, especially the DECLARE for the cursor, the statement id specified in it, and the PREPARE that set up that statement. If you intended to use a cursor with an INSERT statement, you can only do that when the INSERT statement is written as part of the DECLARE statement. If you intended to execute an SQL statement, do that directly with the EXECUTE statement, not indirectly through a cursor. |
| -366   | The scale exceeds the maximum precision specified.  
        A problem exists with the precision or scale of a DECIMAL or a MONEY data type usage, for example in a DEFINE statement. The first should be declared as DECIMAL(p) or DECIMAL(p,s) where p, the precision (total number of digits) is between 1 and 32, and s, the scale (number of digits to the right of the decimal point) is greater or equal to zero and not greater than p. The MONEY type follows the same rules.  
        Review the DECIMAL or MONEY type definition, and make sure that the precision is in the range [1,32] and that the scale is in the range [0,precision]. |
| -371   | Cannot create unique index on column with duplicate data.  
        This CREATE UNIQUE INDEX statement cannot be completed because the column (or columns) contains one or more duplicate rows. |
| -387   | No connect permission.  
        You cannot access the database that this statement requests because you have not been granted CONNECT privilege to it. Contact a person who has Database Administrator privilege to that database and ask to be granted CONNECT privileges to it. |
| -388   | No resource permission.  
        If you issued a CREATE TABLE, CREATE INDEX, or CREATE PROCEDURE statement, you cannot execute this statement because your account has not been granted the RESOURCE privilege for this database. You need the RESOURCE privilege to create permanent tables, indexes on permanent tables, and procedures. |
<p>| -389   | No DBA permission. |</p>
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -391   | **Cannot insert a null into column column-name.**  
This statement tries to put a null value in the noted column. However, that column has been defined as NOT NULL. Roll back the current transaction. If this is a program, review the definition of the table, and change the program logic to not use null values for columns that cannot accept them. |
| -400   | **Fetch attempted on unopen cursor.**  
This FETCH statement names a cursor that has never been opened or has been closed. Review the program logic, and check that it will open the cursor before this point and not accidentally close it. Unless a cursor is declared WITH HOLD, it is automatically closed by a COMMIT WORK or ROLLBACK WORK statement. |
| -404   | **The cursor or statement is not available.**  
You used a statement that names a cursor that is was destroyed. Review the program logic and check that the cursor specified is declared and opened, but not freed, prior to reaching this statement. |
| -410   | **Prepare statement failed or was not executed.**  
This EXECUTE statement refers to a statement id that has not been prepared. Either no PREPARE statement was done, or one was done but returned an error code. Review the program logic to ensure that a statement is prepared and the PREPARE return code is checked. A negative error code from PREPARE usually reflects an error in the statement being prepared. |
| -412   | **Command pointer is NULL.**  
This statement (probably an EXECUTE or DECLARE) refers to a dynamic SQL statement that has never been prepared or that has been freed. Review the program logic to ensure that the statement has been prepared, the PREPARE did not return an error code, and the FREE statement has not been used to release the statement before this point. |
| -413   | **Insert attempted on unopen cursor.**  
This INSERT statement names a cursor that has never been opened or that has been closed. Review the program logic, and check that it will open the cursor before this point and not accidentally close it. An insert cursor is automatically closed by a COMMIT WORK or ROLLBACK WORK statement. |
| -422   | **Flush attempted on unopen cursor.**  
This FLUSH statement names a cursor that has never been opened or has been closed. Review the program logic to ensure that it will open the cursor before this point and not accidentally close it. An insert cursor is automatically closed by a COMMIT WORK or ROLLBACK WORK. |
| -450   | **Illegal ESQL locator, or uninitialized blob variable in BDL.**  
An SQL statement is using a TEXT or BYTE variable that was not initialized with LOCATE IN FILE or MEMORY. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| LOCATE the TEXT or BYTE variable before using it in SQL statements. | -458 Long transaction aborted.  
The database server ran out of log space in which to record this transaction. A transaction that is not fully recorded cannot be rolled back. To preserve database integrity, the operating system ended the transaction and rolled it back automatically. All changes made since the start of the transaction have been removed. Terminate the application, and replan it so that it modifies fewer rows per transaction. Alternatively, contact the database server administrator to discuss increasing the number or the size of the logical logs. Be prepared to talk about the number of rows being updated or inserted and the size of each row. |
<p>| Invalid statement name or statement was not prepared. | -481 The statement has not been prepared, or the format of the statement name is not valid. A valid statement name does not exceed the maximum length, begins with a letter or underscore, does not contain any blanks or nonalphanumeric characters except underscores. |
| Invalid operation on a non-SCROLL cursor. | -482 You cannot issue a FETCH PRIOR, FETCH FIRST, FETCH LAST, FETCH CURRENT, FETCH RELATIVE n, or FETCH ABSOLUTE n statement with a non-scroll cursor. To do so, you must first declare the cursor as a scroll cursor. |
| Cursor cursor-name not found. | -507 The cursor that is named in the WHERE CURRENT OF clause in this UPDATE or DELETE statement does not exist. Review the spelling of the name. If it is as you intended, check the DECLARE statement to ensure that it has been executed. Also make sure that the cursor has not been freed with the FREE statement or during a failed automatic re-prepare attempt. |
| Statement not available with this database server. | -513 The SQL statement used by the program is not valid for the target database server. Review the code, the SQL instruction cannot be used. |
| The total size of the index is too large or too many parts in index. | -517 All database servers have limits on the number of columns that can be included in an index and on the total number of bytes in a key (the sum of the widths of the columns). This CREATE INDEX statement would exceed that limit for this database server. |
| Table table-name not selected in query. | -522 The table name used in an expression (for example, in the WHERE clause) has not been listed in the clause defining the tables to be used in the query (typically the FROM clause in SELECT statements). |
| Updates are not allowed on a scroll cursor. | -526 For a DECLARE statement, the clause FOR UPDATE is not allowed in conjunction with the SCROLL keyword. |</p>
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -530   | Check constraint constraint-name failed.  
         The check constraint placed on the table column was violated. |
| -535   | Already in transaction.  
         This BEGIN WORK statement is redundant; a transaction is already in progress. If  
         this is a program, review its logic to make sure it has not accidentally failed to end the  
         previous transaction. |
| -551   | The constraint contains too many columns.  
         The total number of columns listed in a UNIQUE, PRIMARY KEY, or FOREIGN KEY  
         clause is limited. The limit depends on the database server in use. |
| -674   | Routine routine-name cannot be resolved.  
         You called a routine that does not exist in the database, you do not have permission to  
         execute the routine, or you called the routine with too few or too many arguments. |
| -681   | Column specified more than once in the INSERT list.  
         The error occurs if the user specifies a column name more than once in the INSERT  
         column list. |
| -691   | Missing key in referenced table for referential constraint  
         constraint-name.  
         A referential constraint has been violated. This condition usually occurs when you are  
         trying to insert a value into or update the value of a column that is part of a referential  
         constraint. The value you are trying to enter does not exist in the referenced (parent-  
         key) column. |
| -743   | Object object_name already exists in database.  
         You are trying to define an object that already exists in the database. |
| -768   | Internal error in routine routine-name.  
         If this internal error recurs, note all circumstances and contact your technical support. |
| -805   | Cannot open file for load.  
         The input file that is specified in this LOAD statement could not be opened.  
         Check the statement. Possibly a more complete pathname is needed, the file does not  
         exist, or your account does not have read permission for the file or a directory in which  
         it resides. |
| -806   | Cannot open file for unload.  
         The output file that is specified in this UNLOAD statement could not be opened.  
         Check the statement. Possibly a more complete pathname is needed; the file exists,  
         but your account does not have write permission for it; or the disk is full. |
| -809   | SQL Syntax error has occurred.  
         The INSERT statement in this LOAD/UNLOAD statement has invalid syntax. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-846</td>
<td>Number of values in load file is not equal to number of columns. The LOAD processor counts the delimiters in the first line of the file to determine the number of values in the load file. One delimiter must exist for each column in the table, or for each column in the list of columns if one is specified. Check that you specified the file that you intended and that it uses the correct delimiter character. An empty line in the text can also cause this error. If the LOAD statement does not specify a delimiter, verify that the default delimiter matches the delimiter that is used in the file. If you are in doubt about the default delimiter, specify the delimiter in the LOAD statement.</td>

<td>-1170</td>
<td><strong>The type of your terminal is unknown to the system.</strong>&lt;br&gt;Check the setting of your TERM environment variable and the setting of your TERMCAP or TERMINFO environment variable.&lt;br&gt;Check with your system administrator if you need help with this action.</td>
</tr>
<tr>
<td>-1202</td>
<td><strong>An attempt was made to divide by zero.</strong>&lt;br&gt;Zero cannot be a divisor.&lt;br&gt;Check that the divisor is not zero. In some cases, this error arises because the divisor is a character value that does not convert properly to numeric.</td>
</tr>
<tr>
<td>-1204</td>
<td><strong>Invalid year in date.</strong>&lt;br&gt;The year in a DATE value or literal is invalid. For example, the number 0000 is not acceptable as the year.&lt;br&gt;Check the value of year.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -1205 | Invalid month in date.  
The month in a DATE value or literal must be a one- or two-digit number from 1 to 12. Check the value of month. |
| -1206 | Invalid day in date.  
The day number in a DATE value or literal must a one- or two-digit number from 1 to 28 (or 29 in a leap year), 30, or 31, depending on the month that accompanies it. Check the value of day. |
| -1210 | Date could not be converted to month/day/year format.  
The DATE type is compatible with the INTEGER type, but not all integer values are valid dates. The range of valid integer values for dates is from -693,594 to +2,958,464. Numbers that are outside this range have no representation as dates. Check the value of the number used to assign the date variable. |
| -1212 | Date conversion format must contain a month, day, and year component.  
When a date value is converted between internal binary format and display or entry format, a pattern directs the conversion. When conversion is done automatically, the pattern comes from the environment variable DBDATE. When it is done with an explicit call to the fmtdate(), rfmtdate(), or USING functions, a pattern string is passed as a parameter. In any case, the pattern string (the format of the message) must include letters that show the location of the three parts of the date: 2 or 3 letters d; 2 or 3 letters m; and either 2 or 4 letters y. Check the pattern string and the value of DBDATE. |
| -1213 | A character to numeric conversion process failed.  
A character value is being converted to numeric form for storage in a numeric column or variable. However, the character string cannot be interpreted as a number. Check the character string. It must not contain characters other than white space, digits, a sign, a decimal, or the letter e. Verify the parts are in the right order. If you are using NLS, the decimal character or thousands separator might be wrong for your locale. |
| -1214 | Value too large to fit in a SMALLINT.  
The SMALLINT data type can accept numbers with a value range from -32,767 to +32,767. To store numbers that are outside this range, redefine the column or variable to use INTEGER or DECIMAL type. |
| -1215 | Value too large to fit in an INTEGER.  
The INTEGER data type can accept numbers with a value range from -2,147,483,647 to +2,147,483,647. Check the other data types available, such as DECIMAL. |
<p>| -1218 | String to date conversion error. |</p>

</tbody>
</table>
| -1313  | SQL statement error number error-num.  
The current SQL statement returned this error code number. |
| -1314  | Program stopped at 'filename', line number line-number.  
At runtime an error occurred in the specified file at the specified line. No .err file is generated.  
Edit your source file, go to the specified line, correct the error, and recompile the file. |
| -1318  | A parameter count mismatch has occurred between the calling function and the called function.  
Either too many or too few parameters were given in the call to the function.  
The call is probably in a different source module from the called functions. Inspect the definition of the function, and check all places where it is called to ensure that they use the number of parameters that it declares. |
| -1320  | A function has not returned the correct number of values expected.  
A function that returns several variables has not returned the correct number of parameters.  
Check your source code and recompile. |
| -1321  | A validation error has occurred as a result of the VALIDATE command.  
The VALIDATE LIKE statement tests the current value of variables against rules that are stored in the syscolval table. It has detected a mismatch.  
Ordinarily, the program would use the WHENEVER statement to trap this error and display or correct the erroneous values. Inspect the VALIDATE statement to see which variables were being tested and find out why they were wrong. |
| -1322  | A report output file cannot be opened: description  
The file that the REPORT TO statement specifies cannot be opened. See the description for more details.  
Check that your account has permission to write such a file, that the disk is not full, and that you have not exceeded some limit on the number of open files. |
| -1323  | A report output pipe cannot be opened.  
The pipe that the REPORT TO PIPE statement specifies could not be started.  
Check that all programs that are named in it exist and are accessible from your execution path. Also look for operating-system messages that might give more specific errors. |
<p>| -1324  | A report output file cannot be written to. |</p>
<table>
<thead>

| -1331  | A row could not be fetched from a temporary report table.  
          Within the report definition, BDL generated SQL statements to select rows from a temporary table. The table was built successfully but now an error occurred while rows were being retrieved from it.  
          Almost the only possible cause is a hardware failure or an error in the database server. Check for operating-system messages that might give more details. |
| -1332  | A character variable has referenced subscripts that are out of range.  
          In the current statement, a variable that is used in taking a substring of a character value contains a number less than one or a number greater than the size of the variable, or the first substring expression is larger than the second.  
          Review the program logic that leads up to this statement to find the cause of the error. |
| -1335  | A report is accepting output or being finished before it has been started.  
          The program executed an OUTPUT TO REPORT or FINISH REPORT statement before it executed a START REPORT.  
          Review the program logic that leads up to this statement to find the cause of the error. |
| -1337  | The variable variable-name has been redefined with a different type or length, definition in module-name-1.4gl, redefinition in module-name-2.4gl.  
          The variable that is shown is defined in the GLOBALS section of two or more modules, but it is defined differently in some modules than in others.  
          Possibly modules were compiled at different times, with some change to the common GLOBALS file between. Possibly the variable is declared as a module variable in some module that does not include the GLOBALS file. |
| -1338  | The function 'function-name' has not been defined in any module in the program.  
          The named function is called from at least one module of the program, but it is defined in none.  
          Verify that the module containing the function is a part of the program, and that the function name is correctly spelled. |
| -1340  | The error log has not been started.  
          The program called the errorlog() function without first calling the startlog() function.  
          Review the program logic to find out the cause of this error. |
| -1349  | Character to numeric conversion error.  
          A character value is being converted to numeric form for storage in a numeric column or variable. However, the character string cannot be interpreted as a number. It |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1353  | Use '!' to edit TEXT and BYTE fields.  
This is a normal message text used outside an error context. |
| -1355  | Cannot build temporary file.  
A TEXT or BYTE variable has been located in a temporary file using the LOCATE statement. The current statement assigns a value into that variable, so BDL attempted to create the temporary file, but an error occurred.  
Possibly no disk space is available, or your account does not have permission to create a temporary file. Look for operating-system error messages that might give more information. |
| -1359  | Read error on blob file 'file-name'.  
The operating system signaled an error during output to a temporary file in which a TEXT or BYTE variable was being saved.  
Possibly the disk is full, or a hardware failure occurred. For more information, look for operating-system messages. |
| -1360  | No PROGRAM= clause for this field.  
No external program has been designated for this field using the PROGRAM attribute in the form-specification file (For Text User Interface mode on ASCII terminals only) |
| -1373  | The field 'field-name' is not in the list of fields in the CONSTRUCT/INPUT statement.  
The built-in function get_fldbuf() or field_touched() has been called with the field name shown. However, input from that field was not requested in this CONSTRUCT or INPUT statement. As a result, the function cannot return any useful value.  
Review all uses of these functions, and compare them to the list of fields at the beginning of the statement. |
| -1374  | SQL character truncation or transaction warning.  
The program set WHENEVER WARNING STOP, and a warning condition arose. If the statement involved is a DATABASE statement, the condition is that the database that was just opened uses a transaction log. On any other statement, the condition is that a character value from the database had to be truncated to fit in its destination. |
| -1375  | SQL NULL value in aggregate or mode ANSI database warning.  
The program set WHENEVER WARNING STOP, and a warning condition arose. If the statement that is involved is a DATABASE statement, the condition is that the database that was just opened is ANSI compliant. On any other statement, the condition is that a null value has been used in the computation of an aggregate value. |
| -1376  | SQL, database server, or program variable mismatch warning.  
The program set WHENEVER WARNING STOP, and a warning condition arose. If the statement that is involved is a DATABASE or CREATE DATABASE statement, the condition is that the database server opened the database. On any other statement,
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1377  | SQL float-to-decimal conversion warning.  
The program set WHENEVER WARNING STOP, and a warning condition arose. The condition is that in the database that was just opened, the database server will use the DECIMAL data type for FLOAT values. |
| -1378  | SQL non-ANSI extension warning.  
A database operation was performed that is not part of ANSI SQL, although the current database is ANSI compliant. This message is informational only. |
| -1396  | A report PRINT FILE source file cannot be opened for reading.  
The file that is named in a PRINT FILE statement cannot be opened.  
Review the file name. If it is not in the current directory, you must specify the full path. If the file exists, make sure your account has permissions to read it. |
| -2017  | The character data value does not convert correctly to the field type.  
You have entered a character value (a quoted string) into a field that has a different data type (for example INTEGER). However, the characters that you entered cannot be converted to the type of the field.  
Re-enter the data. |
| -2024  | There is already a record 'record-name' specified.  
A screen record is automatically defined for each table that is used in the ATTRIBUTES section to define a field. If you define a record with the name of a table, it is seen as a duplicate.  
Check that the record-name of every screen record and screen array is unique in the form specification. |
| -2028  | The symbol 'symbol-name' does not represent a table prefix used in this form.  
In a SCREEN RECORD statement, each component must be introduced by the name of the table as defined in the TABLES section or by the word FORMONLY.  
Review the spelling of the indicated name against the TABLES section, and check the punctuation of the rest of the statement. |
| -2029  | Screen record array 'record-name' has different component sizes.  
The screen record array name has component sizes which either differ from the specified dimension of the array or differ among themselves. This error message appears when one or more of the columns appear a different number of times.  
The dimension of the screen array is written in square brackets that follow its name.  
Verify that the dimensions of the screen array match the screen fields. |
<p>| -2039  | The attributes AUTONEXT, DEFAULT, INCLUDE, VERIFY, RIGHT and ZEROFILL are not supported for BLOB fields. |</p>

<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -4307  | The number of variables and/or constants in the display list does not match the number of form fields in the display destination.  
There must be exactly as many items in the list of values to display as there are fields listed following the TO keyword in this statement.  
Review the statement. |
| -4308  | The number of input variables does not match the number of form fields in the screen input list.  
Your INPUT statement must specify the same number of variables as it does fields.  
When checking this, keep in mind that when you refer to a record using an asterisk or THRU, it is the same as listing each record component individually. |
| -4309  | Printing cannot be done within a loop or CASE statement contained in report headers or trailers.  
BDL needs to know how many lines of space will be devoted to page headers and trailers; otherwise, it does not know how many detail rows to allow on a page. Since it cannot predict how many times a loop will be executed, or which branch of a CASE will be execute, it forbids the use of PRINT in these contexts within FIRST PAGE HEADER, PAGE HEADER, and PAGE TRAILER sections.  
Re-arrange the code to place the PRINT statement where it will always be executed. |
| -4319  | The symbol 'symbol-name' has been defined more than once.  
The variable that is shown has appeared in at least one other DEFINE statement before this one.  
Review your code. If this DEFINE is within a function or the MAIN section, the prior one is also. If this DEFINE is outside any function, the prior one is also outside any function; however, it might be within the file included by the GLOBALS statement. |
| -4320  | The symbol 'symbol-name' is not the name of a table in the specified database.  
The named table does not appear in the database.  
Review the statement. The table name may be spelled wrong in the program, or the table might have been dropped or renamed since the last time the program was compiled. |
| -4322  | The symbol 'symbol-name' is not the name of a column in the specified database.  
The preceding statement suggests that the named column is part of a certain table in the specified database. The table exists, but the column does not appear in it.  
Check the spelling of the column name. If it is spelled as you intended, then either the table has been altered, or the column renamed, or you are not accessing the database you expected. |
<p>| -4323  | The variable 'variable-name' is too complex to be used in an assignment statement. |</p>
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -4324 | The variable 'variable-name' is not a character type, and cannot be used to contain the result of concatenation.  
This statement attempts to concatenate two or more character strings (using the comma as the concatenation operator) and assign the result to the named variable. Unfortunately, it is not a character variable, and automatic conversion from characters cannot be performed in this case.  
Assign the concatenated string to a character variable; then, if you want to treat the result as numeric, assign the string as a whole to a numeric variable. |
| -4325 | The source and destination records in this record assignment statement are not compatible in types and/or length.  
This statement uses asterisk notation to assign all components of one record to the corresponding components of another. However, the components do not correspond. Note that BDL matches record components strictly by position, the first to the first, second to second, and so on; it does not match them by name.  
If the source and destination records do not have the same number and type of components, you will have to write a simple assignment statement for each component. |
| -4328 | The variable 'variable-name' is too complex to be used as the destination of a return from a function.  
The named variable is too complex to be assigned directly in a RETURNING clause.  
Individual members of the complex variable must be returned separately. |
| -4333 | The function 'function-name' has already been called with a different number of parameters.  
Earlier in the program, there is a call to this same function or event with a different number of parameters in the parameter list. At least one of these calls must be in error.  
Examine the FUNCTION statement for the named function to find out the correct number of parameters. Then examine all calls to it, and make sure that they are written correctly. |
| -4334 | The variable 'variable-name' in its current form is too complex to be used in this statement.  
The variable has too many component parts. Only simple variables (those that have a single component) can be used in this statement.  
If variable-name is an array, you must provide a subscript to select just one element. If it is a record, you must choose just one of its components. (However, if this statement permits a list of variables, as in the INITIALIZE statement, you can use asterisk or THRU notation to convert a record name into a list of components) |
| -4335 | The symbol 'field-name' is not an element of the record 'record-name'.
<table>

<tr>
<td>-4358</td>
<td>A FIRST PAGE HEADER has already been specified within this report. Only one FIRST PAGE TRAILER control block is allowed in a REPORT. Search for other FIRST PAGE TRAILER sections and combine all statements in a unique control block.</td>
</tr>
<tr>
<td>-4359</td>
<td>An ON EVERY ROW clause has already been specified within this report. Only one ON EVERY ROW control block is allowed in a REPORT. Search for other ON EVERY ROW sections and combine all statements in a unique control block.</td>
</tr>
<tr>
<td>-4360</td>
<td>An ON LAST ROW clause has already been specified within this report. Only one ON LAST ROW control block is allowed in a REPORT. Search for other ON LAST ROW sections and combine all statements in a unique control block.</td>
</tr>
<tr>
<td>-4361</td>
<td>Group aggregates can occur only in AFTER GROUP clauses. The aggregate functions that apply to a group of rows (GROUP COUNT/PERCENT/SUM/AVG/MIN/MAX) can only be used at the point in the report when a complete group has been processed, namely, in the AFTER GROUP control block. Make sure that the AFTER GROUP block exists and was recognized. If you need the value of a group aggregate at another time (for instance, in a PAGE TRAILER control block), you can save it in a module variable with a LET statement in the AFTER GROUP block.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -4363  | The report cannot skip lines while in a loop within a header or trailer.  
BDL needs to know how many lines of space will be devoted to the page header and trailer (otherwise it does not know how many detail rows to allow on the page). It cannot predict how many times a loop will be executed, so it has to forbid the use of SKIP statements in loops in the PAGE HEADER, PAGE TRAILER, and FIRST PAGE HEADER sections.  
Review the report header or trailer to avoid SKIP in loops. |
| -4369  | The symbol 'symbol-name' does not represent a defined variable.  
The name shown appears where a variable would be expected, but it does not match any variable name in a DEFINE statement that applies to this context.  
Check the spelling of the name. If it is the name you intended, look back and find out why it has not yet been defined. Possibly the GLOBALS statement has been omitted from this source module, or it names an incorrect file. Possibly this code has been copied from another module or another function, but the DEFINE statement was not copied also. |
| -4371  | Cursors must be uniquely declared within one program module.  
In the statement DECLARE cursor-name CURSOR, the identifier cursor-name can be used in only one DECLARE statement in the source file. This is true even when the DECLARE statement appears inside a function. Although a program variable made with the DEFINE statement is local to the function, a cursor within a function is still global to the whole module  
Search for duplicated cursor names and change the name to have unique identifiers. |
| -4372  | The cursor 'cursor-name' has not yet been declared in this program.  
The name shown appears where the name of a declared cursor or a prepared statement is expected; however, no cursor (or statement) of that name has been declared (or prepared) up to this point in the program.  
Check the spelling of the name. If it is the name you intended, look back in the program to see why it has not been declared. Possibly the DECLARE statement appears in a GLOBALS file that was not included. |
| -4374  | This type of statement can only be used within a MENU statement.  
This statement only makes sense within the context of a MENU statement.  
Review the program in this vicinity to see if an END MENU statement has been misplaced. If you intended to set up the appearance of a menu before displaying it, use a BEFORE MENU block within the scope of the MENU. |
| -4375  | The page length is too short to cover the specified page header and trailer lengths.  
A REPORT defines page header and trailer sections with a total number of lines that is not sufficiently less than the specified page length in order to print some detail lines.  
Review the [FIRST] PAGE HEADER and PAGE TRAILER blocks to use less lines or increase the page length. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -4379  | The input file 'file-name' cannot be opened.  
Either the file does not exist, or, on UNIX™, your account does not have permission to read it.  
Possibly the filename is misspelled, or the directory path leading to the file was specified incorrectly. |
| -4380  | The listing file 'file-name' cannot be created.  
The file cannot be created.  
Check that the directory path leading to the file is specified correctly and, on UNIX™ systems, that your account has permission to create a file in that directory. Look for other, more explicit, error messages from the operating system. Possibly the disk is full, or you have reached a limit on the number of open files. |
| -4382  | Record variables that contain array type elements may not be referenced by the ".*" or THROUGH shorthand, or used as a function parameter.  
The .* and THROUGH/THRU notation is used to expand a record with an array member.  
It is allowed to define a record with an array member, but this element must always be used with its full designation of record.array[n]. The .* or THROUGH/THRU notation only expands simple members of the record. |
| -4383  | The elements 'name-1' and 'name-2' do not belong to the same record.  
The two names shown are used where two components of one record are required; however, they are not components of the same record.  
Check the spelling of both names. If they are spelled as you intended, go back to the definition of the record and see why it does not include both names as component fields. |
| -4402  | In this type of statement, subscripting may be applied only to array.  
The statement contains a name followed by square brackets, but the name is not that of an array variable.  
Check the punctuation of the statement and the spelling of all names. Names that are subscripted must be arrays. If you intended to use a character substring in this statement, you will have to revise the program. |
| -4403  | The number of dimensions for the variable 'variable-name' does not match the number of subscripts.  
In this statement, the array whose name is shown is subscripted by a different number of dimensions than it was defined to have.  
Check the punctuation of the subscript. If it is as you intended, then review the DEFINE statement where variable-name is defined. |
<p>| -4410  | There is a numeric constant in the previous line that is too large or too small. |</p>

<td></td>
</tr>
</tbody>
</table>
| **-4464** | The number of columns must match the number of values in the SET clause of an UPDATE statement.  
In an UPDATE statement, the number of values used does not match the number of columns.  
Check for the table definition, then either add or remove values or columns from the UPDATE statement. |
| **-4476** | Record members may not be used with database column substring.  
This statement has a reference of the form name1.name2[...]. This is the form in which you would refer to a substring of a column: table.column[...]. However, the names are not a table and column in the database, so BDL presumes they refer to a field of a record.  
Inspect the statement and determine what was intended: a reference to a column or to a record. If it is a column reference, verify the names of the table and column in the database. If it is a record reference, verify that the record and component are properly defined. |
| **-4477** | The variable 'variable-name' is an array. You must specify one of its elements in this statement.  
You tried to use an array without element specification in a SQL statement.  
Use one of the members of the array. |
| **-4485** | Only blob variables of type BYTE or TEXT may be used in a LOCATE statement.  
The LOCATE statement is using a variable defined with a data type different from BYTE or TEXT.  
Make sure the variables used with LOCATE are defined as BYTE or TEXT. |
| **-4488** | The program cannot CONTINUE or EXIT statement-type at this point because it is not immediately within statement-type statement.  
This CONTINUE or EXIT statement is not appropriate in its context.  
Review your code. Possibly the statement is misplaced, or the statement type was specified incorrectly. |
| **-4489** | A variable used in the above statement must be a global variable.  
A REPORT routine is defining an OUTPUT REPORT TO using a local function variable or report parameter.  
Review the report clause to use a global or module variable instead. |
| **-4490** | You cannot have multiple BEFORE clauses for the same field.  
You cannot specify more than one BEFORE FIELD clause for the same field.  
Review your code to eliminate multiple BEFORE FIELD clauses. |
<p>| <strong>-4491</strong> | You cannot have multiple AFTER clauses for the same field. |</p>

</thead>
</table>
| -6173  | Invalid license number or invalid license key.  
During the license installation, the license number / license key couple does not match.  
Ensure that the license numbers are correct. Upgrade the license software to the latest version available and retry. |
| -6174  | This option is only available for a local license. And resource 'flm.server' was found in your configuration.  
A license server is configured and the user tries to install or uninstall a license using fglWrt.  
Install the license on the license manager (flmprg) Or remove the license manager configuration from fglprofile and install the license locally. |
| -6175  | License number 'license-number' is invalid.  
The license number is not valid.  
Ensure that the license number provided is correct. Upgrade the license software to the latest version available. |
| -6176  | In license server, following problem occurs with license number 'license-number': problem-description  
This is a generic error containing the text of another error.  
Check the error. Contact your support center. |
| -6177  | Following problem occurs with license number 'license-number': description  
This is a generic error containing the text of another error.  
Check the error. Contact your support center. |
| -6178  | Your machine is not allowed to be connected on any of your authorized licenses.  
The CPU license rejects the connection of a new host. All CPU licenses are consumed.  
Contact your support center. |
| -6179  | License validity time is reached. The users control is reactivated.  
The CPU license is time limit is reached. The CPU license is degraded and user control is reactivated.  
Contact your support center. |
| -6180  | CPU limit exceeded. The users control is reactivated.  
The CPU license has less CPUs available than the number of CPUs on the connected host, resulting in one or more hosts running in degraded mode. When running in degraded mode, the number of users allowed is the number of available CPUs in the license * 100 users. User control is activated for license request coming from that host. |
For example, say you have a 5 CPU license and are using the license manager.

- Host A with 2 CPUs connects. It consumes 2 CPUs of the 5 CPU license. 3 CPUs remain free on the license.
- Host B with 2 CPUs connects. It will consume 2 CPUs of the 5 CPU license. 1 CPU remains free on the license.
- Host C with 2 CPU connects. It should consume 2 CPUs, but only 1 CPU remains on the license. User control for Host C is enabled, with 1 CPU (the remaining free CPU) * 100 users allowed.
- Host D connects with N CPU, however there are no CPUs free on the license. Host D is rejected.

In summary, Host A and B can have unlimited sessions, Host C is limited to 100 sessions as the license is degraded by CPU, and any other host is rejected.

In the case of a single host, user control applies to local licenses as well. If Host A has 6 CPUs, yet has a 5 CPU license, it consumes all of the CPUs for the license and run in degraded mode. That means 5 * 100 users are allowed.

<th>Description</th>
</tr>
</thead>
</table>
| -6186  | Demo version initialization.  
This is an information message. |
| -6188  | Your evaluation license period has expired. Contact your support center.  
The software you are using has been installed with a demo license that has expired.  
Contact your software vendor to extend the evaluation period or purchase a permanent license. |
| -6196  | You are not authorized to delete sessions from the license server 'server-name'.  
The command fglWrt -i can only be used with local licenses. If a license server is configured, this error is raised.  
Use the command flmprg instead. |
| -6197  | 'extension-name' extension is not allowed with this license type.  
Generic error indicating that an extension check is rejected. For example, if you are using a non-Informix database, this error will raise if the ODI extension is not set in the license. |
| -6198  | Product identifier does not correspond to the license number.  
This error indicates that a wrong license is installed in the product, such as when you attempt to use a Genero Report Writer (GRW) license when installing the Genero Business Development Language (BDL). This error should not be raised, as fglWrt will reject the installation of a Genero Report Engine (GRE) license when installing Genero BDL, and conversely greWrt will not allow the installation of a Genero BDL license.  
That being said, the installation checks to ensure the license is valid for the product, and raises this error if is not.  
Ensure the proper license is used with the proper package. |
| -6199  | Cannot create directory 'directory-name'. Check installation path and verify your access rights.  
The specified directory can not be created or modified. |
| -6200  | Module 'module-name': The function function-signature-1 will be called as function-signature-2 .  
An incorrect number of parameters are used to call a BDL function.  
Check your source code and recompile your application. |
| -6201  | Module 'module-name': Bad version: Recompile your sources.  
You have compiled your program with an old version. The newly compiled version of your program is not supported.  
Compile all source files and form files again. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6202  | filename 'file-name': Bad magic: Code cannot run with this p code machine.  
You have compiled your program with an old version. The new compiled version of your program is not supported. You might also have a file with the same name as the .42r. You used the fglrun 42r-Name without specifying the extension.  
To resolve this problem, call fglrun with the .42r extension or recompile your application. |
| -6203  | Module 'module-name-1': The function 'function-name' has already been defined in module 'module-name-2'.  
The specified function is defined for the second time in the application. The second occurrence of the function is in the specified module.  
Eliminate one of the two function definitions from your source code. |
| -6204  | Module 'module-name': Unknown op-code.  
An unknown instruction was found in the compiled BDL application.  
Check that the version of the Genero Business Development Language package executing the compiled application is the same as the one that compiled the application. It is also possible that the compiled module has been corrupted. If so, you will need to recompile your application. |
| -6205  | INTERNAL ERROR: Alignment.  
This error is internal, which should not normally occur.  
Contact your Technical Support. |
| -6206  | The 42m module 'module-name' could not be loaded, check FGLLDPATH environment variable.  
The 42m module is not in the current directory or in one of the directories specified by the FGLLDPATH environment variable.  
Set the environment variable FGLLDPATH with the path to the 42m modules to be loaded. |
| -6207  | The dynamic loaded module 'module-name' does not contain the function 'function-name'.  
A BDL module has been changed and recompiled, but the different modules of the application have not been linked afterward.  
Link the new modules together before you execute your application. |
| -6208  | Module 'module-name' already loaded.  
A module was loaded twice at runtime. This can occur because one module has been concatenated with another.  
Recompile and re-link your BDL modules. |
<p>| -6210  | INTERNAL ERROR: exception 2 raised before invoking the exception handler for exception 1. |</p>

</table>
| -6211  | **Link has failed.**  
A problem occurred while linking the BDL program.  
Check for function names, recompile and re-link your BDL modules. |
| -6212  | **Function function-name : local variables size is too large - Allocation failed.**  
A local function variable is too large and runtime could not allocate memory.  
Review the variable data types in the function. |
| -6213  | **Module module-name : Module's variable size is too large - Allocation failed.**  
A module variable is too large and runtime could not allocate memory.  
Review the variable data types in the module. |
| -6214  | **Global variable variable-name size is too large - Allocation failed.**  
A global variable is too large and runtime could not allocate memory.  
Review the variable data types in the globals. |
| -6215  | **Memory allocation failed. Ending program.**  
Runtime could not allocate memory.  
Check for system resources and verify if the OS user is allowed to allocate as much memory as the program needs (check for `ulimits` on UNIX™ systems). |
| -6216  | **The global 'constant-name' has been redefined with a different constant-value.**  
A global constant has been defined twice with a different value.  
A global constant may have only one value. Review your code. |
| -6217  | **The global 'variable-name' has been defined as a constant and a variable.**  
The same symbol was used to define a constant and a variable.  
Use a different name for the constant and the variable. Review your code. |
| -6218  | **No runtime. You must call fgl_start() before calling fgl_call().**  
This error occurs when a C extension has redefined the main() routine, but then does not call fgl_start() to initialize the BDL runtime environment.  
Check the C extension and call fgl_start() before any other operation. |
<p>| -6219  | <strong>WHENEVER ERROR CALL: The error-handler recursively calls itself.</strong> |</p>

| -6319  | **Internal error in the database library. Set FGLSQLDEBUG to get more details.**
An unexpected internal error occurred in the database driver.  
Set the FGLSQLDEBUG environment variable to level 1, 2, 3 or 4 to get detailed debug information. |
| -6320  | **Can't open file 'file-name'.**  
The runtime system tried to open a resource file in FGLDIR but access is denied or file no longer exists.  
Check for file permissions and existence in FGLDIR. |
| -6321  | **No such interface capability: 'feature-name'.**  
The runtime system tried to use a front-end protocol capability, but is not able to use it.  
Check if the front-end is compatible with the runtime system. |
| -6322  | **version-num-1 wrong version. Expecting version-num-2.**  
Some resource files of FGLDIR have been identified as too old for the current runtime system.  
Re-install the runtime system environment. |
| -6323  | **Can't load factory profile 'file-name'.**  
The default fglprofile file located in FGLDIR/etc is missing or is unreadable.  
Check the permission of the file. If the file is missing, reinstall the software. |
| -6324  | **Can't load customer profile 'file-name'.**  
The configuration file defined by the FGLPROFILE environment variable is missing or unreadable.  
Check if the FGLPROFILE environment variable is correctly set and if the file is readable by the current user. |
| -6325  | **Can't load application resources 'file-name'.**  
The directory specified by the fglrun.default entry in FGLDIR/etc/fglprofile is missing or not readable for the current user.  
Check if the entry fglrun.default is correctly set in FGLDIR/etc/fglprofile and if the directory specified is readable by the current user. |
| -6327  | **Internal error in the run time library file library-name.**  
Something unpredictable has occurred, generating an error.

</table>
| -8065  | An interruption was caught during a file transfer.  
An interruption was caught during a file transfer.  
File could not be transferred, you need to redo the operation. |
| -8066  | Network error during file transfer.  
An interrupt was caught during a file transfer.  
Check that your network connection is working properly. |
| -8067  | Could not write destination file for file transfer.  
The runtime system could not write the destination file for a transfer.  
Make sure the file path is correct and check that user has write permissions. |
| -8068  | Could not read source file for file transfer.  
The runtime system could not read the source file to transfer.  
Make sure the file path is correct and check that user has read permissions. |
| -8069  | File transfer protocol error (invalid state).  
The runtime system encountered a problem during a file transfer.  
A network failure has probably raised this error. |
| -8070  | File transfer not available.  
The runtime system could not write the destination file for a transfer.  
Make sure the file path is correct and check that user has write permissions. |
| -8071  | The localized string file 'file-name' is corrupted.  
The shown string resource file is invalid (probably invalid multibyte characters corrupt the file).  
Check for locale settings (LANG), make sure the .str source uses valid characters and recompile it. |
| -8072  | The form file defines several elements of the same type with the same name.  
Review the form file and use unique identifiers. |
| -8073  | Statement must terminate with ';'.  
An ESQL/C preprocessor directive is not terminated with a semicolon.  
Add a semicolon to the end of the directive. |
| -8074  | Invalid 'includes' directive file name.  
An include preprocessor directive is using an invalid file name.  
Check the file name. |
| -8075  | A &elif directive found without corresponding &if, &ifdef or &ifndef directive.  
The preprocessor found an &elif directive with no corresponding &if. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8075 | The compiler plugin name could not be loaded.  
fglcomp could not load the plugin because it was not found.  
Make sure the plugin exists and can be loaded. |
| -8076 | The compiler plugin name does not implement the required interface.  
fglcomp could not load the plugin because the interface is invalid.  
Check if the plugin corresponds to the version of the compiler. |
| -8077 | The attribute 'attribute-name' has been defined more than once.  
The variable attribute shown in the error message was defined multiple times.  
Review the variable definition and remove duplicated attributes. |
| -8078 | The attribute 'attribute-name' is not allowed.  
The variable attribute shown in the error message is not allowed for this type of variable.  
Review the possible variable attributes. |
| -8079 | An error occurred while parsing the XML file.  
The runtime system could not parse an XML file, which is probably not using a valid XML format.  
Check for XML format typos and if possible, validate the XML file with a DTD. |
| -8080 | Could not open xml file.  
The specified XML file cannot be opened.  
Make sure the file exists and has access permissions for the current user. |
| -8081 | Invalid multibyte character has been encountered.  
A compiler found an invalid multibyte character in the source and cannot compile the form or module.  
Check locale settings (LANG) and verify if there are no invalid characters in your sources. |
| -8082 | The item 'item-name' is used in an invalid layout context.  
The form item name is used in a layout part which does not support this type of form item. This error occurs for example when you try to define a BUTTON as a TABLE column.  
Review your form definition file and use correct item types. |
| -8083 | NULL pointer exception.  
The program is using calling a method thru an object variable which is NULL.  
You must assign an object reference to the variable before calling a method. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8084 | Can't open socket: description  
The channel object failed to open a TCP socket. See the description for more details.  
Make sure the IP address and port are correct. |
| -8085 | Unsupported mode for 'open socket'.  
You try to open a channel with an unsupported mode.  
See channel documentation for supported modes. |
| -8086 | The socket connection timed out.  
Socket connect could not be established and timeout expired.  
Check all network layers and try again. |
| -8087 | File error in BYTE or TEXT readFile or writeFile.  
File I/O error occurred while reading from or writing to a file.  
Verify the file name, content and access permissions. |
| -8088 | The dialog attribute 'attribute-name' is not supported.  
A dialog instruction was declared with an ATTRIBUTES clause containing an unsupported option.  
Review the ATTRIBUTES clause and remove unsupported option. |
| -8089 | Action 'action-name' not found in dialog.  
You try to use and action name that does not exist in the current dialog.  
Verify if name of the action is defined by an ON ACTION clause. |
| -8090 | Field 'field-name' already used in this DIALOG.  
The DIALOG instruction binds the same field-name or screen-record multiple times.  
Review all sub-dialog blocks and check the field-names / screen-records. |
| -8091 | The clause 'clause-name' appears more than once.  
You have defined the same dialog control block multiple times. For example, AFTER ROW was defined twice.  
Remove the un-necessary control blocks. |
| -8092 | At least one field for this INPUT ARRAY must be editable.  
An INPUT ARRAY is executed on fields that are read-only. At least one field must be editable and active.  
Review the form specification file or check that at least one field is active. |
| -8093 | Multi-range selection is not available in this context.  
You try to use multi-range selection but it is not possible in the current dialog type.  
Disable this feature. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8094 | Multi-range selection is not available in this context.  
You try to use multi-range selection but it is not possible in the current dialog type.  
Disable this feature. |
| -8095 | Cannot change selection flag for this range of rows.  
An attempt of selection flag modification with DIALOG.setSelectionRange() failed because the range is out of bounds or because there is no multi-range selection available in this context.  
Make sure you can use multi-range selection, and check the start and end index of the range. |
| -8096 | General SQL Warning, check SQLCA.SQLERRD[2] or SQLSTATE.  
The last SQL statement has generated an SQL warning setting the SQLCA.SQLWARN flags.  
Program execution can continue. However, you should take care and check the native SQL code and the SQL message in SQLERRMESSAGE. |
| -8097 | Value too large to fit in a TINYINT.  
The TINYINT data type can accept numbers with a value range from -128 to +127.  
To store numbers that are outside this range, redefine the column or variable to use the SMALLINT or INTEGER type. |
| -8098 | ON FILL BUFFER conflicts with DISPLAY ARRAY as a tree.  
The DISPLAY ARRAY instruction is using a treeview as decoration, but it implements also an ON FILL BUFFER trigger to do paged mode. The paged mode is not possible when using a treeview, because all rows of visible nodes are required (i.e. the dialog cannot display a tree only with a part of the dataset).  
To populate dynamically the array for a treeview, use the ON EXPAND to add new nodes and ON COLLAPSE to remove nodes. |
| -8099 | The form 'form-name' is incompatible with the current runtime version. Rebuild you forms.  
The .42f form was probably compiled with an earlier version as the current runtime system.  
Recompile the form with the fglform compiler corresponding to the current fglrun. |
| -8100 | Attempt to access a closed dialog.  
A call to a DIALOG class method is done with a dialog object that has terminated.  
Review the program logic and call the DIALOG methods only for active running dialogs. |
| -8101 | The TABLE column tag 'tag-name' appears multiple times in the row definition.  
A TABLE column can only be used once in the row definition, you have probably repeated the same screen tag by mistake. |
<table>

Web services

Create a Web service client or server with Genero BDL.

The Genero APIs for creating Web services can be found in the Library section of this manual. See The com package on page 2017 and The xml package on page 2111.

General

These topics provide you with an introduction to Genero Web Services and the information needed to get working with the latest version of the software.

• Introduction to Web Services on page 2408
• SOAP Web Services basics on page 2412
• RESTful Web Services basics on page 2424
• Getting started and examples on page 2424
• Debugging on page 2424
• Platform-specific notes on page 2424
• Known issues on page 2427
• Legal Notices on page 2427

Introduction to Web Services

This topic provides an introduction to Web Services with the Genero Web Services Package (GWS). It is intended to help those using GWS for the first time to understand basic Web Services concepts, and to quickly start their development with the Genero tools.

Concepts

Web services are a standard way of communicating between applications over an intranet or Internet. They define how to communicate between two entities:

• A server that exposes services
• A client that consumes services

Server usage example

A server exposes a "StockQuotation" service that responds to an operation "getQuote". For the "getQuote" operation, the input message is a stock symbol as a string, and the output message is a stock value as a decimal number.

The "getQuote" operation is a function written in Genero BDL, and it is published on the server. This function retrieves the stock value for the stock symbol passed in, and returns it.

Client usage example

The Web service client application calls the function as if it were a local function. It passes the stock symbol in to the function, and stores the returned value in a variable. If the Web Service operation is named WebService_StockQuotation_getQuote and the local variable is svalue, the Web Service is called as follows:

LET svalue = WebService_StockQuotation_getQuote( "MyStockSymbol" )
Service Oriented Architecture (SOA) and web services

Service Oriented Architecture (SOA) is a philosophy of how to connect systems and exchange data to solve business problems. Rather than concentrating on a specific task or transaction, SOA addresses how to use data from various sources, reduce human work, and mitigate the effects of change in a business process and its supporting systems.

The SOA defines the services to be provided; Web Services are the means of implementing those services. Web Services provide a platform-neutral technology to connect multiple systems in a flexible manner, where the platform-neutrality helps insulate the SOA from changes to the underlying systems.

Web Services work by answering requests for information and returning well defined, structured XML documents. Because XML is simple text and Web Services can be invoked via the hypertext transfer protocol (HTTP), it does not matter what platform runs the Web Service, or what platform receives the XML document.

An SOA's resilience to change is accomplished by adhering to good Web Services design practices:

• Build a Web Service that performs a specific task
• Have a rigid structure for the data

Web Services tell exactly how to ask for the information in an XML document written using the Web Services Descriptive Language (WSDL). This self-describing document describes the service the Web Service will perform and how to form the request for its data. Each Web Service must have an associated WSDL document, so that developers and applications know what to expect from the Web Service, and how to invoke it.

Migrating to SOA and web services

Developing an SOA and moving to Web Services is an iterative and evolutionary process. It requires work and diligent design. When switching to Web Services from another integration method, it is recommended to initially focus on shorter term business benefits, targeting an SOA and Web Services project that has tangible goals with measurable benefits.

Once an SOA contains some useful services, these services can be arranged together in a workflow that automates a business process. Web Services can be reused to answer new questions, and implemented as new business services in an SOA. A well-defined Web Service does not contain business logic or business process information. Because each Web Service in an SOA can be called individually to perform a specific task, they can be arranged (orchestrated) together to perform many different business functions. As a result, companies with a mature SOA in place can change business processes through configuring of the orchestration software as opposed to programming individual links between systems.

Planning a web service

When creating a Web Service, you not only have to think of the task at hand, but you should also consider growth. You likely want the Web Service to be flexible; to be able to handle different types of input. Prepare the Web Service for what is probable. Developers should think bigger than the needs of a single application. You should think of reusing existing services, and think how your services can be reused by others.

Security will likely play a larger role than it did previously with existing in-house application infrastructures using programmed links between systems; you will need to become versed in security issues.

Keep the goals of SOA in mind when designing and coding Web Services: Flexibility, Reusability, Interoperability.

Genero web services extension

The Genero Web Services Extension (GWS) is an extension to the Genero Business Development Language. It installs within the Genero Business Development Language directory. The fglgws package includes both Genero Business Development Language and Genero Web Services.
The Genero Application Server is required to manage your Web Services in a deployment environment. It is not required for Web services development, unless you are interested in testing deployment issues.

**Important:** When programming a Web service, your applications must include `IMPORT com` at the top of each module. This imports the Genero Web Services Extension library named `com`:

```
IMPORT com
```

### Web services standards

Web services are platform-independent and programming language-independent. The World Wide Web consortium defines the Web services standards. For more information about these standards, refer to the "Web services" section of their web site at [http://www.w3.org](http://www.w3.org). The Genero Web Services package supports the WSDL 1.1 specification of March 15, 2002 as well as some previous specifications.

The standards involved in what is commonly called "Web services" include XML, XML Schema, SOAP, WSDL, and HTTP.

#### XML

XML (eXtensible Markup Language) defines a machine-independent way of exchanging data. For example, an XML representation of the following BDL data structure:

```
DEFINE Person
RECORD Attribute (XMLName="Person")
  FirstName  VARCHAR(32) Attribute (XMLName="FirstName"),
  LastName   VARCHAR(32) Attribute (XMLName="LastName"),
  Age        INTEGER Attribute (XMLName="Age")
END RECORD
```

Could be:

```xml
<Person>
  <FirstName>John</FirstName>
  <LastName>Smith</LastName>
  <Age>35</Age>
</Person>
```

The record definition allows you to specify XML attributes for data types. This feature was added with Genero 2.00.

#### XML schema

XML Schema defines the elements, entities, and content model of an XML document. For example, for the example document shown in the topic XML on page 2410, the schema could say that the XML document contains an element "Person", and that each "Person" contains one and only one element "FirstName", "LastName", and "Age". The XML Schema has additional capabilities, such as data type control and content restrictions.

An XML Schema allows an XML document to be validated for correctness.

#### SOAP

SOAP (Simple Object Access Protocol) is a high-level communication protocol between a server and the client. It defines the XML data flow between the server and the client. The "StockQuote" service mentioned in the Concepts section exchanges messages using the following syntax:

**Request**

```
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/"><soap:Body>
  <getQuote>
    <stockSymbol>MyCompany</stockSymbol>
  </getQuote>
</soap:Body></soap:Envelope>
```
SOAP relies on a lower-level protocol for the transport layer.

Genero Web Services use SOAP over HTTP, and can also perform low-level XML and TEXT over HTTP communications on the client side. This allows communication between applications using the core Web technology, taking advantage of the large installed base of tools that can process XML delivered plainly over HTTP, as well as SOAP over HTTP.

**WSDL**

The WSDL (Web Services Description Language) file describes the services offered by a server. It contains:

- The description of the operations offered by the server, and each operation's input and output messages.
- The location of the SOAP server.
- Internal connection and protocol details (transport layer, encoding, namespaces, and so on).

A WSDL description is sufficient to provide all the information required to communicate with the SOAP server.

Genero Web Services package provides a tool, fglwsdl, that enables Genero client applications to obtain the WSDL description of a Web Service.

**HTTP**

HTTP (Hypertext Transfer Protocol) is the set of rules for exchanging files (text, graphic images, sound, video, and other multimedia files) on the World Wide Web.

**Web services style options**

The Web Services Style options available for created Genero Web services are WS-I (Web Services Interoperability organization) compliant:

- **RPC Style Service (RPC/Literal)** is generally used to execute a function, such as a service that returns a stock option.
- **Document Style Service (Doc/Literal)** is generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document.
- **RPC Style Service (RPC/Encoded)** is the legacy style, now provided for backwards compatibility. You most likely will not be using the RPC/Encoded style to create new Web Services.
SOAP Web Services basics

Topics in this section are only relevant for Web Services based on the SOAP protocol.

Migration notes

Migrating GWS server applications

What you need to know when migrating GWS server applications.

- Migrating GWS server runners only on page 2412
- Migrating GWS server runners and using new APIs on page 2412
- Operation publication restrictions on page 2413

Migrating GWS server runners only

There is no need to create a special runner for Genero Web Services 2.x. Instead, the GWS 2.x library is imported into your applications. If you want to migrate your existing 1.x GWS Server application to 2.x to avoid the need for a special runner, as well as to take advantage of any bug fixes, take the following steps:

1. Add the following statement at the top of any .4gl module where you have used GWS 1.3x functions:

   ```
   import com
   ```

2. Compile and re-link your GWS Server application (.42r).

   This imports the new GWS com library, and ensures that any GWS 1.3x functions that you have used will be compatible. Your existing Genero 1.3x Client applications, as well as third-party Client applications, will continue to work.

Migrating GWS server runners and using new APIs

If you want to take advantage of the new features and simplify future migrations, you can migrate your Genero Web Services (GWS) Server runner and also use the new GWS 2.x APIs. All the 1.3x publishing functions for all the operations in your application must be replaced with 2.x publishing functions. Since this does not change the interface, all existing Genero 1.3x Client applications, as well as third-party Client applications, will continue to work.

Since 1.3x only supports RPC-Encoded style services, you must use the RPC style functions of the new 2.x APIs as the replacement functions, with setInputEncoded and setOutputEncoded set to true. And, you cannot add XML attributes to the records used as Web Service function parameters.

To replace the fgl_ws_server_publishfunction() statement in an existing GWS Server application; for example:

```
CALL fgl_ws_server_publishfunction(
  "EchoInteger",
  "http://tempuri.org/webservices/types/in", "echoInteger_in",
  "http://tempuri.org/webservices/types/out", "echoInteger_out",
  "echoInteger")
```

1. Add this statement at the top of each module:

   ```
   import com
   ```

2. Define variables for the WebService and WebOperation objects:

   ```
   DEFINE serv com.WebService
   DEFINE op com.WebOperation -- Operation of a WebService
   ```

3. Create the GWS Server object:

   ```
   LET serv = com.WebService.CreateWebService(
     "EchoInteger",
     "http://tempuri.org/webservices")
   ```
4. Use the 2.x publishing functions for each operation:

```java
LET op = com.WebOperation.CreateRPCStyle(
    "echoInteger",
    "EchoInteger",
    echoInteger_in, 
    echoInteger_out)
CALL op.setInputEncoded(true)
CALL op.setOutputEncoded(true)
CALL serv.publishOperation(op, NULL)
```

5. Compile and re-link your GWS Server application (.42r)

GWS 2.x also allows your Server application (.42r) to contain multiple services. If you would like 2.x and 1.3x GWS to coexist in the same .42r executable, replace the existing publishing 1.3x functions.

Operation publication restrictions

If you use a variable as the name of the function to publish, you will have an error message at compile time.

For example:

```java
com.WebOperation.CreateRPCStyle(test, "Add", add_in, add_out)
```

Where `test` is a string variable, `add_in` and `add_out` are input and output records.

At compile time, you get the error message:

```
error:(-9054) Web service function must be a string
```

The function name in parameter can only be a string literal not a string variable.

Since version 2.21, FGL has introduced the concept of PUBLIC/PRIVATE function, there is a risk for a user to publish private functions. Private functions are not always available at runtime.

As a workaround you can add a switch depending on the function name value in order to call the appropriate publication API with the name in a string literal such as following sample:

```java
CASE function_name
    WHEN "Operation1"
        LET op = com.WebOperation.CreateDocStyle(
            "Operation1", "Operation1", op1_in, op1_out)
    WHEN "Operation2"
        LET op = com.WebOperation.CreateDocStyle(
            "Operation2", "Operation2", op2_in, op2_out)
    OTHERWISE
        DISPLAY "ERROR"
END CASE
```

In Java™ or in .NET you cannot publish different numbers of operations for a same service, everything is done at compile time. For instance, when you publish a web service in Java™, only the public methods will be published as operation of the service. There is no way to add or remove some methods at runtime. The only way you have is to create another Java™ class.

Be aware that if you dynamically change the service operations names you are creating a different service, which might be confusing for the web service client.

**Enhance the GWS server application to be WS-I compliant (recommended)**

**Important:** You must be able to change all the Client applications that access your migrated Genero Web Services (GWS) Server.
If you use the Literal styles now available in GWS 2.x for your Web Service, your application will be WS-I compliant. However, the migration techniques still use the RPC/Encoded style (Only RPC/Encoded was supported in GWS 1.3x.). If you can change all the client applications that access your migrated GWS Server, we recommend that you enhance the GWS Server application to be WS-I compliant.

1. Replace the publishing functions in the GWS Server application, but omit the **setInputEncoded** and **setOutputEncoded** lines. The resulting style will be Literal.

2. The enhanced GWS Server will have a new RPC/Literal WSDL that must be used to regenerate the client stub with the **fglwsdl** tool:

   ```
   fglwsdl -o NewClientstub http://localhost:8090/MyCalculator?WSDL
   ```

3. Compile that new client stub, and re-link it with the GWS Client application. This operation must be repeated for each Client application accessing that service.

4. Third party Client applications must also be changed to use the new WSDL.

### Migrating GWS client applications

**Migration from version 1.3x to 2.2x**

If you use a Genero 2.2x runner for the GWS Client application, you must:

1. Regenerate the GWS Client stubs using the **-compatibility** option of the **fglwsdl** tool, so the function prototypes will be compatible:

   ```
   ```

2. Compile the GWS Client stubs and re-link the Client application (.42r).

**Migration from version 2.0x to 2.2x**

You must regenerate all client stubs into your application using the **fglwsdl** tool.

This is mandatory because the generated code is based on the low-level COM and XML APIs and is completely different from versions prior to 2.1x; otherwise, you won’t be able to execute the code.

**Migration from version 2.1x to 2.2x**

It is recommended to regenerate all client stubs into your application using the **fglwsdl** tool.

**Migration from version 2.xx to 2.4x**

It is recommended to regenerate all client stubs into your application using the **fglwsdl** tool.

If you have modified the server location at runtime via the generated global variable in your client application, you MUST apply following modification:

- Prior to version 2.40, you had something like following:

  ```
  LET Calculator_CalculatorPortTypeLocation = "http://host:port/Calculator"
  ```

- Starting with version 2.40, you must have something like following:

  ```
  LET Calculator_CalculatorPortTypeEndPoint.Address.Uri = "http://host:port/Calculator"
  ```

See [Change client behavior at runtime](#).

**Migration from version 2.xx to 3.xx**

It is recommended to regenerate all client stubs into your application using the **fglwsdl** tool.

**Important**: It is mandatory to regenerate the client stubs, to support fault response with HTTP error code of 200.

See [Change client behavior at runtime](#).
**WebService engine options**

In the class `com.WebServiceEngine`, two options have been renamed and two options moved to a new class.

**Renamed options**
The `http_invoketimeout` and `tcp_connectiontimeout` options have been respectively renamed into `readwritetimeout` and `connectiontimeout`, as they are now available for either HTTP or TCP protocol. While the old option names remain for backward compatibility, using the new option names is strongly recommended.

**Moved options**
`xml_ignoretimezone` and `xml_usetypedefinition` options were part of the `com.WebServiceEngine` class. They have been moved to the class `xml.Serializer`, which groups functions on serialization.

**I4GL migration guide**
**Migrate an I4GL web service provider to Genero**

This section explains how to migrate a I4GL web service provider to a Genero application providing the same web service in order to let all clients, already accessing that service, unmodified (excepted for the hostname of course).

**Note:** The migration will be based on the SOA zipcode demo in the I4GL package.

Step 1: Use the I4GL function and the I4GL .4cf configuration file

Use the I4GL .4cf configuration file to get all information about the I4GL web service

For example, the I4GL zipcode demo has following .4cf configuration file:

```plaintext
[SERVICE]
TYPE = publisher
INFORMIXDIR = /dbs/32bits/ifx/11.70.uc2
DATABASE = i4glsoa
CLIENT_LOCALE = en_US.8859-1
DB_LOCALE = en_US.8859-1
INFORMIXSERVER = ol_moscou1170uc2
HOSTNAME = moscou.strasbourg.4js.com
PORTNO = 9876
I4GLVERSION = 7.50.xC4
WSHOME = /dbs/32bits/ifx/11.70.uc2/AXIS2C
WSVERSION = AXIS1.5
TMPDIR = /tmp/zipcodedemo
SERVICENAME = ws_zipcode

[FUNCTION]
NAME = zipcode_details

[INPUT]
[VARIABLE]NAME = pin TYPE = CHAR(10)[END-VARIABLE]
[END-INPUT]

[OUTPUT]
[VARIABLE]NAME = city TYPE = CHAR(100)[END-VARIABLE]
[VARIABLE]NAME = state TYPE = CHAR(100)[END-VARIABLE]
[END-OUTPUT]

[END-FUNCTION]

[DIRECTORY]
NAME = /home/f4gl/fg/i4gl
FILE = soademo.4gl

[END-DIRECTORY]

[END-SERVICE]
```
Then simply copy your I4GL function without any modification into a new Genero file and add the Genero IMPORT com instruction at the beginning of the file.

For example, the I4GL soa demo contains the zipcode_details service (soademo.4gl)

```plaintext
IMPORT com

FUNCTION zipcode_details(pin)

DEFINE state_rec RECORD
    pin CHAR(10),
    city CHAR(100),
    state CHAR(100)
END RECORD,

pin CHAR(10),

sel_stmt CHAR(512);

LET sel_stmt= "SELECT * FROM statedetails WHERE pin = ?";
PREPARE st_id FROM sel_stmt;
DECLARE cur_id CURSOR FOR st_id;
OPEN cur_id USING pin;
FETCH cur_id INTO state_rec.*;
CLOSE cur_id;
FREE cur_id;
FREE st_id;
RETURN state_rec.city, state_rec.state
END FUNCTION

Note: you may need some minor code modification for compatibility.

Step 2: Create a BDL RECORD for the input parameters

Add a new modular BDL record where all members map to one of your I4GL web service input parameter, and keep the parameter order as defined in I4gl .4cf file.

You must then specify the web service input message name via the Genero XML attribute called XMLName, and assign it to the FUNCTION NAME as defined in the I4GL .4cf file.

For example, in the I4GL zipcode demo there is only one parameter: pin. So add the following record at the beginning of the Genero file:

```plaintext
DEFINE zipcode_details_in RECORD ATTRIBUTES(XMLName="zipcode_details")
    pin CHAR(10)
END RECORD
```

Note: Genero Web Services supports complex data type as input parameters.

Step 3: Create a BDL RECORD for the output parameters

Add another modular BDL record where all members map to one of your I4GL web service output parameter, and keep the parameter order as defined in I4GL .4cf file.

You must then specify the web service output message name via the Genero XML attribute called XMLName, and assign it to the FUNCTION NAME as defined in the I4GL .xcf file concatenated to response.

For example, in the I4GL zipcode demo there are two parameters: city and state. So add following record at the beginning of the Genero file:

```plaintext
DEFINE zipcode_details_out RECORD
    ATTRIBUTES(XMLName="zipcode_detailsresponse")
    city CHAR(100),
    state CHAR(100)
END RECORD
```
Note: Genero Web Services supports complex data type as output parameters.

Step 4: Create a BDL wrapper function

Create a Genero BDL wrapper function without any parameters that will then use the input and output record created at Step 2 and 3 to call the I4GL function passing it the parameters retrieved from the records.

For example, in the I4GL zipcode demo there are 1 input and 2 output parameters. So the BDL wrapper function must use these records to call the I4GL function as following:

```plaintext
FUNCTION zipcode_details_g()
    CALL zipcode_details(zipcode_details_in.pin)
    RETURNING zipcode_details_out.city,zipcode_details_out.state
END FUNCTION
```

Step 5: Publish the wrapper function as a Genero web service

Use the COM APIs to publish the I4GL function as a web service based on I4GL .4cf configuration file to get a compatible Genero Web service.

To create a new BDL function in charge of the service publication, you will need the following elements of the I4GL .4cf configuration file:

- The name of the service that is defined in the SERVICENAME entry
- The namespace of the service that is defined as http://www.ibm.com/ concatenated to the FUNCTION NAME
- The name of the function to be published that is defined in the FUNCTION NAME entry

For example, the I4GL zipcode demo has one function published as a Doc/Literal service.

```plaintext
FUNCTION create_zipcode_details_web_service()
    DEFINE serv com.WebService
    DEFINE op   com.WebOperation
    #
    # Create the web service based on the entries of the .4cf file
    #   SERVICENAME: The name of service is 'ws_zipcode'
    #   FUNCTION NAME: The namespace of the service is built from
    #                   the base url 'http://www.ibm.com/' concatenated to
    #                   the NAME of the I4GL function 'zipcode_details'
    #
                                  "http://www.ibm.com/zipcode_details")
    #
    # Create and publish the Doc/Literal web function based on
    # step 2, step 3 and step 4
    # and from the FUNCTION NAME defined in the .4cf file
    #
    LET op = com.WebOperation.CreateDOCStyle("zipcode_details_g",
                                  "zipcode_details",
                                  zipcode_details_in,
                                  zipcode_details_out)
    CALL serv.publishOperation(op,NULL)
    #
    # Register the service into the SOAP engine
    #
    CALL com.WebServiceEngine.RegisterService(serv)
```
Note: I4GL supports only Doc/Literal services.

Note: Genero Web Services can contain several BDL functions in the same service. In other words, you can group several I4GL services into the same Genero service.

Step 6: Create the server

I4GL uses Axis as server for its services, but Genero has its own server programmable via the COM library. Create a new file and add the IMPORT com instruction at beginning of the server file, then simply create the main loop in BDL that will process any incoming HTTP request.

The port of the service defined in the I4GL .4cf configuration file (via the PORTNO entry) can be reused by setting the FGLAPPSERVER environment variable to the same value before to run the server. However, only on development or for tests, on production Genero Web services requires an application server called GAS in charge of load balancing. See the GAS documentation for more details about port configuration for deployment purpose.

For example, to migrate the I4GL zipcode demo, the service must be created in the server before run the main loop as following:

```gdscript
MAIN
    DEFINE ret INTEGER
    DEFER INTERRUPT
    # Create zipcode_details service
    CALL create_zipcode_details_web_service()
    # Start the server on port set in FGLAPPSERVER
    # (to be set to same value as PORTNO defined in the .4cf file)
    CALL com.WebServiceEngine.Start()
    # Handle any incoming request in a WHILE loop...
    # See <!DOCTYPE concept PUBLIC "-//IBM//DTD DITA IBM Concept//EN" "ibm-concept.dtd">
    <concept id="c_gws_server_tutorial_009" xml:lang="en-us">
        <title>Step 5: Start the GWS server and process requests</title>
        <shortdesc>Once you have registered the Web Service(s), you are ready to start the Genero Web Services (GWS) Server and process the incoming SOAP requests.</shortdesc>
    </concept>
```
Web services | 2419

incoming request. It returns an integer representing the status. The parameter specifies the timeout period (in seconds) for which the method should wait to process a service. The value -1 specifies an infinite waiting time.

```plaintext
# Process each incoming requests (infinite loop)
LET ret = com.WebServiceEngine.ProcessServices(-1)
CASE ret
  WHEN 0
    DISPLAY "Request processed."
  WHEN -1
    DISPLAY "Timeout reached."
  WHEN -2
    DISPLAY "Disconnected from application server."
    EXIT PROGRAM
  WHEN -3
    DISPLAY "Client Connection lost."
  WHEN -4
    DISPLAY "Server interrupted with Ctrl-C."
  WHEN -10
    DISPLAY "Internal server error."
    EXIT PROGRAM
  WHEN -15
    DISPLAY "Server was not started."
    EXIT PROGRAM
  OTHERWISE
    DISPLAY "ERROR: ", STATUS, SQLCA.SQLERRM
END CASE
IF int_flag&lt;&gt;0 THEN
  LET int_flag=0
  EXIT WHILE
END IF
END WHILE

DISPLAY "Server stopped"

END MAIN
```

Note: With Genero Web Services, one server can contain several services. In other words, you can put all your I4GL services into one server.

Step 7: Configure the database

Based on the DATABASE entry in the I4GL .4cf configuration file, use the Genero instruction to connect to the informix database at server startup.
For example, in the I4GL zipcode demo the service access the database called: i4glsoa. So add following instruction at the beginning of the server file created in step 6:

```
DATABASE i4glsoa
MAIN
...
END MAIN
```

Step 8: Compile and run the Genero service

Compile and link the 2 Genero files created above and run your Genero service. It will be directly available for any client, and provide the WSDL when requested via a HTTP GET with WSDL as query string.

Example

The Genero web service is accessible on URL: http://hostname:9876/ws_zipcode and can return the WSDL on URL: http://hostname:9876/ws_zipcode?WSDL.

```
$ fglcomp -M genero_service.4gl
$ fglcomp -M genero_server.4gl
$ fgllink -o genero_zipcode genero_service.42m genero_server.42m
$ export FGLAPPSEVER=9876
$ fgllrun genero_zipcode.42r
```

**Note:** The hostname depends on the machine your Genero application is started.

**Note:** For deploying the service on production you will need the Genero application server (GAS) to load-balance the service. See the GAS documentation about Web Services when deployment is required.

Step 9: Disable Axis support of MTOM/XOP

I4GL is based on Axis Web service for the SOAP layer and sends by default requests in MTOM/XOP. However, Genero Web services doesn't support MTOM/XOP. You must unset the MTOM/XOP feature on your Axis installation if you want your I4GL client applications to communicate with the Genero web service after migration.

For example, the Axis installation contains a file called axis.xml where following line must be removed:

```
<parameter name="enableMTOM" locked="false">true</parameter>
```

Migrate an I4GL web service consumer to Genero

This section explains how to migrate a I4GL web service consumer to a Genero application accessing the same web service. **Notice** that the migration will be based on the soa demo in the I4GL package.

Step 1: Generate the Genero web service stub from an I4GL WSDL

Use the I4GL WSDL located on the Axis server to generate the Genero web service client stub via the tool called fglwsdl.

For example, the WSDL file of the I4GL zipcode demo is located on $INFORMIXDIR/AXIS2C/services/ws_zipcode/zipcode_details.wsdl. So do following command:

```
$ fglwsdl -noFacets zipcode_details.wsdl
```

It will generate these two Genero files:

* `ws_zipcode_zipcode_detailsservice.4gl`
  * It contains the Genero functions to connect to the server in SOAP over HTTP.
  * Take a look into that file if you are interested into Genero HTTP and XML low-level APIs.
• ws_zipcode_zipcode_detailsservice.inc

  • It contains the Genero data types and variables used for XML serialization.
  • Take a look into that file if you are interested into Genero XML to BDL variable mapping.

    **Note:** Option -noFacets is required for this demo because the I4GL CHAR data type will be generated as string in Genero what can lead to XML serialization error if not present.

Step 2: Modify the Genero .inc stubs to fix wrong I4GL WSDL

The I4GL WSDL contains namespace declaration for all I4GL web service data types, but in practice the I4GL axis server doesn't care about namespaces, but Genero does. So you have to open the generated Genero .inc file and remove all attributes called XMLNamespace and XSTypeNamespace.

For example, the generated .inc file from the I4GL WSDL must be modified as following:

```plaintext
#-------------------------------------------
# File: ws_zipcode_zipcode_detailsservice.inc
# GENERATED BY fglwsdl 101601
#-------------------------------------------
# THIS FILE WAS GENERATED. DO NOT MODIFY.
#-------------------------------------------

GLOBALS

... 

#
# TYPE : tzipcode_details
#
TYPE tzipcode_details RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="zipcode_details")
    ,XSTypeNamespace="http://www.ibm.com/zipcode_details")
    pin STRING ATTRIBUTES(XMLName="pin")
END RECORD

#-------------------------------------------

# TYPE : tzipcode_detailsresponse
#
TYPE tzipcode_detailsresponse RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="zipcode_detailsresponse")
    ,XSTypeNamespace="http://www.ibm.com/zipcode_details")
    city STRING ATTRIBUTES(XMLName="city"),
    state STRING ATTRIBUTES(XMLName="state")
END RECORD

#-------------------------------------------

# Operation: zipcode_details
#
# FUNCTION: zipcode_details_g()
#   RETURNING: soapStatus
#   INPUT: GLOBAL zipcode_details
#   OUTPUT: GLOBAL zipcode_detailsresponse
#
# FUNCTION: zipcode_details(p_pin)
#   RETURNING: soapStatus ,p_city ,p_state
#
# FUNCTION: zipcode_detailsRequest_g()
#   RETURNING: soapStatus
#   INPUT: GLOBAL zipcode_details
#
# FUNCTION: zipcode_detailsResponse_g()
#   RETURNING: soapStatus
#   OUTPUT: GLOBAL zipcode_detailsresponse
```

Note: Genero Web Services provides a lot of XML mapping attributes.

Step 3: Include the generated stub into your I4GL application

Add in all I4GL files calling a web service the generated .inc stub with a GLOBALS instruction.

For example, in the I4GL zipcode demo, only the clsloademo.4gl file uses web services. So add following line at beginning of the file:

```
GLOBALS "ws_zipcode_zipcode_detailsservice.inc"
```

Note: This allows access to the Genero global variables and data types used in the web service call, so as the Genero global wsError record to retrieve error codes if any.

Step 4: Modify the I4GL web service function call

The Genero Web service function name is defined in the generated .4gl file and must be used instead of the I4GL function name.

For example, in the I4GL zipcode demo, the web service function name is cons_ws_zipcode and must be renamed to zipcode_details as following:

```
FUNCTION func_cons_ws_zipcode()
  DEFINE state_rec RECORD
    pin CHAR(10),
    city CHAR(100),
    state CHAR(100)
  END RECORD;
  #
  # Genero web service status returning
  # whether web function call was successful or not
  #
  DEFINE soapstatus INTEGER

  #
  # I4GL web service function name is 'cons_ws_zipcode'
  # CALL cons_ws_zipcode("97006")
  # RETURNING state_rec.city, state_rec.state
  # Genero web service function name is 'zipcode_details'
  CALL zipcode_details("97006")
    RETURNING soapstatus, state_rec.city, state_rec.state
  ...
END FUNCTION
```

Note: In Genero Web Services there is an additional returned parameter, soapstatus. If it contains 0 the operation was a success, otherwise an error occurred.
Step 5: Handle Genero web services errors

I4GL web service errors are returned on a non-conventional SOAP fault that cannot be handled in Genero. However, the errors are handled through the additional returned parameter `soapstatus` that must be checked after each web service call. If its value is not zero, an error has occurred and can be retrieved via the global Genero `wsError` record defined in the above generated .inc file.

**Example**

In the Genero Web Service you must check the soap status after each web service call:

```i4gl
FUNCTION func_cons_ws_zipcode()
  DEFINE state_rec RECORD
    pin CHAR(10),
    city CHAR(100),
    state CHAR(100)
  END RECORD;
  DEFINE soapstatus INTEGER

  # Genero web service status returning
  # whether web function call was successful or not
  #
  CALL zipcode_details("97006")
    RETURNING soapstatus, state_rec.city, state_rec.state
  # Check soap status for errors after zipcode_details call
  IF soapstatus<>0 THEN
    # Display error information from the server
    DISPLAY "Error:";
    DISPLAY " code ":,wsError.code
    DISPLAY " ns ":,wsError.codeNS
    DISPLAY " desc ":,wsError.description
    DISPLAY " actor ":,wsError.action
  ELSE
    # Display results
    DISPLAY " SUPPLIED ZIP CODE: 97006 
    RESPONSE FROM WEB SERVICE 
    CITY: ",state_rec.city
    \n    STATE: ",state_rec.state
    \n  END IF
  ... 
END FUNCTION
```

Step 6: Compile and run the Genero client

Then simply compile your modified I4GL application for Genero and execute it. Your application will then connect to the web service passing and returning the parameters as it were only simple BDL function calls.

For example, to compile your I4GL web service application for Genero, you must do the following commands:

```bash
$ fglcomp -M ws_zipcode_zipcode_detailservice.4gl
$ fglcomp -M clsoademo.4gl
$ fgllink -o clsoademo.42r clsoademo.42m
  ws_zipcode_zipcode_detailservice.42m
$ fgllink clsoademo.42r
$ fglrun clsoademo.42r
```
Step 7: Disable Axis support of MTOM/XOP

I4GL is based on Axis Web service for the SOAP layer and sends by default requests in MTOM/XOP. However, Genero Web services doesn't support MTOM/XOP. You must unset the MTOM/XOP feature on your Axis installation if you want your Genero client application to communicate with an I4GL Web service provider.

For example, the Axis installation contains a file called axis.xml where following line must be removed:

```xml
<parameter name="enableMTOM" locked="false">true</parameter>
```

Remark: Standalone Axis server is buggy

The I4GL standalone axis server adds an extra CR LF after the body of the SOAP HTTP post response what leads the Genero client to return the error message: Body content bigger than expected. This is not allowed as defined in HTTP [RFC2616].

**Important:** Notice however that Axis works as expected if loaded from Apache server.

RESTful Web Services basics

Topics in this section are only relevant for Web Services based on the SOAP protocol.

Getting started and examples

Genero Web Services code examples are located in FGLDIR/demo/WebServices, where FGLDIR is the Genero BDL installation directory.

Debugging

The Genero Web Services library gives you the ability to log the data your Web Service application is receiving from or sending to another application by turning on the debug mode.

Debug information is written to the standard error stream of the console; if needed, it can be redirected to a file.

To turn on the debugging feature, set the FGLWSDEBUG environment variable before starting the application.

The level of debugging depends on the value set for the FGLWSDEBUG variable.

Possible values are described in the FGLWSDEBUG environment variable definition.

**Note:** To debug a Web Service application managed by the Application Server, you have to modify the value of the FGLWSDEBUG environment variable in the Application Server configuration file. For more information, refer to the Genero Application Server Manual documentation.

Platform-specific notes

**IBM® AIX®**

- The "IBM® C++ Runtime Environment Components for AIX®" must be installed in order to use Genero Web Services Extension 2.0. See the IBM® support center for more information about downloading the component.

  **Note:** If not installed, you will get the following error message:

  ```
  Could not load C extension library 'com'. Reason: A file or directory in the path name does not exist.
  ```

- Due to an IBM® issue on 64-bit platforms, the openssl library is unable to open the system /dev/urandom device to generate a PRNG number.
You must install the **Entropy Gathering Daemon (a.k.a EGD)** if you need security in your GWS application, and especially if you access a server in HTTPS.

**GMI / iOS Web Services limitations**
Some Web Services classes are not supported on iOS devices (GMI).

**Web Services COM package**
The following com classes are not supported in GMI:

- com.Util
- com.TCPRequest
- com.TCPResponse
- com.WebService
- com.WebOperation
- com.WebServiceEngine *(except for SetOption()/GetOption() methods, for option SoapModuleURI only)*
- com.HTTPServiceRequest

The following methods have a different behavior:

- com.HTTPRequest.setVersion() has no effect, the iOS HTTP stack supports HTTP 1.1 only.
- com.HTTPRequest.getAsyncResponse() is not working asynchronously, it works like com.HTTPRequest.getResponse().
- com.HTTPRequest.setAutoReply() has no effect, the iOS HTTP stack does not provide an auto reply option.
- com.HTTPRequest.setMaximumResponseLength() has no effect, the iOS HTTP stack does not provide a maximum response length option.
- com.HTTPRequest.setConnectionTimeout() and com.HTTPRequest.setTimeout(): the max of both settings is used as timeout by the iOS HTTP stack.

**Web Services XML package**
The following xml classes are not supported in GMI:

**Note:** These classes are currently not supported on iOS, as OpenSSL cannot be used to implement these classes on iOS. OpenSSL is used to implement these classes for other platforms.

- xml.CryptoKey
- xml.CryptoX509
- xml.Signature
- xml.Encryption
- xml.KeyStore

For all other classes of the xml package, methods using an URL parameter accept only a file URI:

- xml.DomDocument.Load()
- xml.DomDocument.save()
- xml.StaxWriter.writeTo()
- xml.StaxReader.readFrom()

If the parameter is not a file URI, these methods can raise runtime exceptions such as -15629, -15630, -15632, -15633.
SOAP protocol

GMI is not able to handle SOAP errors or faults, as the iOS API does not allow a retrieval of an HTTP response body if the server uses an HTTP code of 500. As a result, GMI will not get notified about what went wrong during a remote procedure call.

If the server returns a SOAP error or fault, GMI will raise exception -15559. Modify your call of a remote web service as follows:

```plaintext
DEFINE wsstatus INTEGER
...
LET wsstatus = Webservice_Function_g()
IF wsstatus==-15559 THEN
   MESSAGE "Handle generic SOAP error or fault"
END IF
```

Web Services configuration options

GWS configuration entries of FGLPROFILE are not supported on iOS.
FGLPROFILE entries are described here: FGLPROFILE entries on page 2517.

Long running HTTP request popup

If the `com.HTTPRequest.getResponse()`/`getAsynResponse()` methods take more than 5 seconds to complete, the GMI will show a typical iOS popup message to ask the user if the request must be canceled. If the user cancels the request, the runtime system raises an exception. A progress bar is displayed if the Content-Length for a request is available (i.e. self made uploads and most downloads).

HTTP request compression for POST/PUT

HTTP request compression for POST/PUT is not supported on iOS devices.

Multipart HTTP request

On iOS, multipart HTTP requests are not supported. See `com.HTTPRequest.setMultipartType` on page 2074.

Changing the SOAP client behavior at runtime

The following features have a limited usage on iOS devices:

- HTTP version protocol definition is ignored.
- Connection timeout and read/write timeout are identical.

FGLPROFILE settings for Web Services client

FGLPROFILE settings for Web Services are not supported on iOS:

- Settings for logical names is not supported.
- Settings for HTTP proxy configuration is ignored: Uses device settings.
- Settings for client authentication to server is not supported: Use HTTPRequest API instead.
- Settings for client authentication to proxy is not supported: Uses device settings.
- Settings for server certificate authority is not supported: Uses device KeyChain.
GMA / Android™ Web Services requirements
Requirements to use Web Services on Android platforms.

V3 SSL Certificates
The SSL certificates for secured servers must be of type V3: Android does not support other types of SSL certificates. When creating your own self-signed certificates (to be installed in the “Install from storage” Keystore of Android), make sure that type V3 is used.

Known issues

Forcing RPC style convention when no input message
In RPC style, the convention defines names for input messages and output messages, but if there is no input message, its name cannot be redefined.

To workaround this issue, respect RPC style convention in wsdl, or force RPC convention (on client and server side) by using the -fRPC option of the fglwsdl tool.

Variable names conflicts with library names
The fglwsdl tool can generate variable names conflicting with IMPORT library names.
For example:

```plaintext
DEFINE xml xml.DomDocument
```

will conflict with the xml library, if the code defines also the instruction:

```plaintext
IMPORT xml
```

Concepts
These topics cover various Genero Web Services concepts.

- High-level and low-level web services APIs on page 2428
- SOAP features on page 2428
- Stateful web services on page 2430
- Encryption, base64 and password agent with fglpass tool on page 2437
- HTTP compression on page 2440
- SOAP multipart style requests in GWS on page 2442
High-level and low-level web services APIs

With Genero, we distinguish two type of APIs to implement web services.

- High-level web services are SOAP web services managed on server side with the high-level APIs `WebService` and `WebOperation`, or if you have generated code via the `fglwsdl` tool (client and server side).
- Low-level web services are implemented with `HTTPRequest`, `HTTPResponse` and `HttpServletRequest` classes, where you have to write all the HTTP code of your services by hand.

SOAP features

**SOAP 1.1 and 1.2**

Since 2.40, Genero Web Services (GWS) supports SOAP 1.2. GWS is able to communicate with Web services provided with SOAP 1.1 or SOAP 1.2.

**Server side**

A Genero Web Services server can deliver a service in SOAP 1.1 or SOAP 1.2 using the `com.WebService.setFeature` function.

For example in `$FGLDIR/demo/WebServices/calculator/server/calculatorServer.4gl`, the calculator server offers the service in SOAP 1.1 and SOAP 1.2:

```gln
CALL serv.setFeature("Soap1.1",TRUE)
CALL serv.setFeature("Soap1.2",TRUE)
```

**Client side**

A GWS client can consume a service in SOAP 1.1 or SOAP 1.2.

For example:

- To create a client that consumes the Calculator service in SOAP 1.1 use command:
  ```bash
  ```
- To create a client that consumes the Calculator service in SOAP 1.2 use command:
  ```bash
  ```

Be aware to generate different clients for each SOAP versions. Even if the same operations are provided, the services are using different protocols so the underlying generated stubs are also different.

**SOAP Fault**

Since 2.40, Genero Web Services supports SOAP fault.

For backward compatibility, `fglwsdl` tool provides option `-ignoreFaults` to disable SOAP fault management.

**Server side**

A Genero Web Services server can throw a SOAP fault if any processing error is encountered.

To generate a SOAP fault you need to:

- create the fault variable with `com.WebService.createFault()`
- add it to your operation with `com.WebOperation.addFault`
- use it with `com.WebServiceEngine.SetFaultDetail`
For example in $FGLDIR/demo/WebServices/calculator/server/calculatorServer.4gl, the calculator server has a **divide_by_zero** SOAP fault. The SOAP fault is raised when you try to divide a number by zero. To generate a SOAP fault proceed as follow:

**Create a SOAP fault**

You define the variable to send as a SOAP fault. It can be a simple string like in this example or a complex type. Remember to assign a XMLName to the variable.

```4gl
DEFINE divide_by_zero STRING ATTRIBUTES (XMLName="DividedByZero")
```

Then you inform the service that it can use this fault variable using function `com.WebService.createFault()`.

```4gl
CALL serv.createFault(divide_by_zero,FALSE)
```

**Add the SOAP fault to an operation**

A SOAP fault can be used by an operation to inform the client that an error has occurred. An operation can use different SOAP faults but **only one at a time**.

```4gl
LET op = com.WebOperation.CreateRPCStyle("divide","Divide",divide_in,divide_out)
CALL op.addFault(divide_by_zero,NULL)
```

Here, the SOAP fault is added to the "divide" operation.

**Send the SOAP fault**

Set the values to the fault variable. The fault message is be sent to the client at the end of the operation processing.

```4gl
LET divide_by_zero = "Cannot divide "||divide_in.a||" by zero"
CALL com.WebServiceEngine.SetFaultDetail(divide_by_zero)
```

**Client side**

If a SOAP fault occured the operation returns the SOAP fault number in the operation status. The SOAP fault number is defined in the generated stubs as a BDL constant prefixed with the string `FaultID_`.

**Note:** A SOAP fault can occur in case of HTTP error 200 and 500.

For example in $FGLDIR/demo/WebServices/calculator/client/ws_calculator.inc, **Divide** operation has a SOAP fault that informs the client when a number is divided by zero.

```4gl
# List of Soap fault constants
CONSTANT FaultID_DividedByZero = 1
...
# VARIABLE : DividedByZero
DEFINE DividedByZero STRING ATTRIBUTES (XMLName="DividedByZero",
   XMLNamespace="http://tempuri.org/")
...
# Operation: Divide
# FAULT #1: GLOBALS DividedByZero
```

You can test the operation status code accordingly and display the SOAP fault message.
For example in $FGLDIR/demo/WebServices/calculator/client/calculatorClient.4gl, when the divide operation status is 1, DividedByZero message is displayed.

```
ON ACTION divide
    CALL Divide(op1, op2) RETURNING wsstatus, result, remaind
    CASE wsstatus
        WHEN 0
            DISPLAY BY NAME result, remaind
        WHEN FaultID_DividedByZero
            DISPLAY DividedByZero TO msg
        OTHERWISE
            DISPLAY wsError.description TO msg
    END CASE
```

**Stateful web services**

**Concept**
A stateful service is a service that maintains a context between a web services client and server. It enables the service to keep trace of previous requests from that context, in order to manage different states in the web service server.

Genero Web Services supports two kinds of stateful services:

- Based on the WS-Addressing 1.0 specification to define the XML format used to convey the context from client to the server
- Based on an HTTP session cookie to convey the context from client to the server

The Genero Web Service engine uses a BDL variable defined at stateful service creation via `createStatefulWebService()` as service context. Use that variable to hold a service state in a database.

It is up to the BDL programmer to create, store and remove the service state in the database.

The SOAP engine is responsible for:

- Deserializing the state variable when getting an new incoming request. *The programmer can then read the state variable for any published BDL web service operation and restore the service state corresponding to that variable.*
- Serializing a new instance of the state variable in a web service response for all BDL web service operations set as session initiator via `initiateSession()`. *The programmer must instantiate a new state by filling the state variable and storing it into a database for further use.*

**WS-Addressing 1.0 stateful services**

A stateful service based on WS-Addressing uses the WS-Addressing EndpointReference type as state variable and is independent from the transport layer used. (See [WS-Addressing 1.0 EndpointReferenceType](https://www.w3.org/TR/ws-addressing)). The session state is conveyed from the client to the server as WS-Addressing 1.0 reference parameters.

**Server side**
Perform these steps to create a WS-Addressing stateful service.

**Step 1:** Declare a W3CEndpointReference record to be used as state variable

This record **MUST** have:

- A mandatory member of type STRING, where you can define a different service end point URL, otherwise the current server URL will be used.
- A sub record to contain one or more BDL variables used as state variables and defined as reference parameter in the WS-Addressing 1.0 specification.
For example:

```plaintext
DEFINE EndpointReferenceState RECORD AT(tribute(W3CEndpointReference))
    address STRING, # Mandatory
    ref RECORD # Sub-record Reference parameters containing one
    # or more state variables
    OpaqueID STRING ATtributes(XMLName="OpaqueID"), # Unique ID to
    # identify the service state in the database
    Expiration DATE ATtributes(XMLName="Expiration",
        XMLNamespace="http://tempuri.org") # Session state expiration date
END RECORD
END RECORD
```

You can use a unique ID of a database table to manage the web services sessions in place of OpaqueID.

Step 2: Create a stateful WS-Addressing enabled web service with W3CEndpointReference record as a parameter

The Genero Web Service extension provides a new Web service constructor called `createStatefulWebService()` to perform stateful services. This function works as the stateless constructor, but expects a W3CEndpointReference record as parameter.

For example:

```plaintext
DEFINE serv com.WebService
LET serv = com.WebService.CreateStatefulWebService(  
    "StatefulWSAddressingService","http://4js.com/services",  
    EndpointReferenceState) # Create a stateful service  
    # with a W3CEndpointReference state variable
CALL serv.setFeature("WS-Addressing1.0","REQUIRED") # enable  
    # support of WS-Addressing 1.0
```

Step 3: Publish a web service operation returning the W3CEndpointReference state variable and set it as session initiator

You must define which web service operation will initiate the session on your service and return the W3CEndpointReference state variable.

All other web service operations (not defined as session initiator) will return an error if they don't get reference parameters defined in the W3CEndpointReference state variable as WS-Addressing 1.0 headers.

For example:

```plaintext
DEFINE op com.WebOperation
LET op = com.WebOperation.CreateDocStyle("GetInstance",  
    "GetInstance",NULL,EndpointReferenceState)
CALL op.initiateSession(TRUE)
CALL serv.publishOperation(op=NULL)
```

There is no restriction regarding the input parameter of the web service initiator function, but the output parameter must be the same W3CEndpointReference record passed to the service creation constructor.

It is not required to have a web operation which initiate the session in the same service, but then you have to return the same W3CEndpointReference record in another web service to instantiate the session, such as a Factory service that instantiates all sessions for other stateful services.

Step 4: Create the BDL session initiator function and instantiate a new session

In your BDL function declared as session initiator, you have to:

- Handle the creation of the session
- Fill the state variable before to return from the function
• Store the new session in a database based on the state variable (in order to keep the session across consecutive requests from the same client).

For example:

```plaintext
FUNCTION GetInstance()
    LET EndpointReferenceState.address = NULL
    # Use default endpoint location
    LET EndpointReferenceState.ref.OpaqueID = com.Util.CreateUUIDString()
    # Generate an unique string (can come from a database table id)
    LET EndpointReferenceState.ref.Expiration = CURRENT + INTERVAL HOUR TO HOUR (1)
    # Create expiration date in one hour to discard request after that date
    ... Store OpaqueID into database or use directly a database table entry
    ... to hold the session
END FUNCTION
```

Step 5: Restore the session in any BDL web operation from the W3CEndpointReference record

In any publish BDL web function, the SOAP engine deserializes the WS-Addressing 1.0 reference parameter headers into the W3CEndpointReference sub-record so that you can retrieve the session from the state variable.

For example:

```plaintext
FUNCTION MyFunction()
    IF EndpointReferenceState.ref.OpaqueID IS NULL THEN
        CALL com.WebServiceEngine.SetFaultString("Invalid session id")
        RETURN
    ELSE
        ... Restore the service session based on the OpaqueID state
        ... variable from the database
    END IF
    ... Process the operation
END FUNCTION
```

Client side
Perform these steps to communicate with a stateful web service based on WS-Addressing 1.0.
Step 1: Generate the client stub from your WS-Addressing stateful service

Use the fglwsdl tool as usual. It will detect that the service returns a W3CEndpointReference and generate the appropriate code.

The WSDL imports the WS-Addressing 1.0 schema, so the fglwsdl tool requires an access to the W3C server. Use the option -proxy if you need to connect via a proxy server.

For example:

```plaintext
$ fglwsdl -o ws_stub http://localhost:8090/StatefulWSAddressingService?WSDL
```

The generated .inc file contains a variable of type tWSAGlobalEndpointType to be used to transmit the WS-Addressing 1.0 reference parameters.

Example of a global variable name

```plaintext
DEFINE
    StatefulWSAddressingService_StatefulWSAddressingServicePortTypeEndpoint
tGlobalWSAEndpointType
```
Step 2: Create the MAIN application

In your main application:

1. Import the XML library. This is due to the support of WS-Addressing 1.0 with `IMPORT XML`.
2. Import the generated .inc file with `GLOBALS "ws_stub.inc"`
3. Manage the WS-Addressing 1.0 reference parameters representing the session state (if your client has to handle several instances of a same service).

For example:

```
IMPORT XML # Import the XML library required for WS-Addressing 1.0
GLOBALS "ws_stub.inc" # Import service global definition

TYPE InstanceType DYNAMIC ARRAY OF xml.DomDocument
 # End point WSA reference parameters

DEFINE instance1,instance2,instance3 InstanceType
 # Store the different sessions the client will have to manage

MAIN
...
END MAIN
```

Step 3: Instantiate a new session by calling the web service operation set as session initiator

Call the BDL function generated from the WSDL that is defined as session initiator on the server. This function returns a `W3CEndpointReference` parameter that contains the WS-Addressing 1.0 reference parameters representing the new instance created on server side.

If your application handles several instances, you will have to copy and store those parameters in your application to identify a service instance for further requests.

As the WS-Addressing 1.0 reference parameters are defined as any XML document, they are represented as a dynamic list of `xml.DomDocument` in BDL.

For example:

```
DISPLAY "Creating a new instance ..."
LET wsstatus = GetInstance_g() # call the service session initiator
 # web function
IF wsstatus == 0 THEN
   FOR ind=1 TO
      ns1GetInstanceResponse.return.ReferenceParameters._LIST_0.getLength()
      LET instance1[ind]=
         ns1GetInstanceResponse.return.ReferenceParameters._LIST_0[ind].clone()
      # copy the service returned WS-Addressing 1.0 reference parameters
   END FOR
ELSE
   ... handle soap errors
END IF
```

When creating a new instance, ensure that the `Parameters` member of the generated global variable of type `tWSSAGlobalEndpointType` has been set to NULL, otherwise the server will complain.

Step 4: Call any web service operation with previously returned WS-Addressing 1.0 reference parameters

Before calling any web service operation, you must set the WS-Addressing 1.0 reference parameters returned by a session initiator function to identify the session to the server.
For example:

```IDL
LET StatefulWSAddressingService_StatefulWSAddressingServicePortTypeEndpoint.
    Address.Parameters.* = instance1.*
# assign WS-Addressing 1.0 reference parameters dynamic array by reference
CALL MyFunction("Hello") RETURNING wstatus,ret
# Call web operation MyFunction of instance 1
```

**Stateful services based on HTTP cookies**

A stateful service based on HTTP cookies uses the HTTP transport protocol and its ability to convey cookies, used as session context. **Notice** that it works only if the communication path between the client and the server is performed in HTTP, otherwise it is recommended to use **WS-Addressing stateful services**.

**Server side**

Perform these steps to create an HTTP cookie based stateful service.

Step 1: Declare any BDL simple variable to be used as state variable

For example:

```IDL
DEFINE ServiceState STRING # Unique ID to identify the service state in the database
```

For instance, you can use a unique ID of a database table to manage the web services sessions.

Step 2: Create a stateful web service with state variable as parameter

The Genero Web Service extension provides a new Web service constructor called `createStatefulWebService()` to perform stateful services. This function works as the stateless constructor, but expects a simple state variable as parameter.

**Example**

```IDL
DEFINE serv com.WebService
LET serv =
        "http://4js.com/services",ServiceState)
# Create a stateful service with a simple BDL variable as state variable
```

Step 3: Publish a web service operation defined as session initiator

Define which web service operation will initiate the session on your service and instantiate a new session. All other web service operations (not defined as session initiator) will return an error if they don't get an HTTP cookie called **GSESSIONID**.

For example:

```IDL
DEFINE op com.WebOperation
LET op =
CALL op.initiateSession(true)
CALL serv.publishOperation(op,NULL)
```

There is no restriction on the web service session initiator function regarding to the input and output parameters.

Step 4: Create the BDL session initiator function and instantiate a new session

In your BDL function declared as session initiator, you must:
• Handle the creation of the session.
• Fill the state variable before to return from the function.
• Store the state variable in a database based on the state variable (in order to keep the session across consecutive requests from a same client).

For example:

```clike
FUNCTION GetInstance()
    # Generate an unique string (can come from a database table id)
    LET ServiceState = com.Util.CreateUUIDString()
    ... Store ServiceState value into database or use directly a database table entry to hold the session
END FUNCTION
```

Step 5: Restore the session in any BDL web operation from the state variable

In any publish BDL web function, the SOAP engine deserializes the HTTP Cookie called `GSESSIONID` from the HTTP layer into the state variable. You can then retrieve the session in BDL via that state variable.

For example:

```clike
FUNCTION MyFunction()
    IF ServiceState IS NULL THEN
        CALL com.WebServiceEngine.SetFaultString("Invalid session id")
        RETURN
    ELSE
        ... Restore the service session based on the ServiceState variable from the database
    END IF
    ... Process the operation
END FUNCTION
```

Step 6: Deployment recommendation

When deploying stateful web services based on HTTP cookies, the complete server path will be added into the cookie when first instantiated, so you must pay attention to that URL. In other words, you MUST always call the service via the complete URL containing the service name inside. For instance if your service is named `MyService` and if you GAS configuration file is called `Server.xcf`, the stateful service is accessible at URL: `http://localhost:6394/ws/r/group/Server/MyService`.

**Client side**

Perform the following steps to communicate with a stateful web service based on HTTP cookies.

Step 1: Generate the client stub from your stateful service

Use the `fglwsdl` tool as usual.

For example:

```
$ fglwsdl -o ws_stub http://localhost:8090/StatefulCookieService?WSDL
```

The generated .inc file contains a variable of type `tGlobalEndpointType` to be used to transmit the HTTP Cookie.

**Example of a global variable name**

```
DEFINE StatefulCookieService_StatefulCookieServicePortTypeEndpoint
tGlobalEndpointType
```

Step 2: Create the MAIN application

In your main application:
• Import the generated .inc file with `GLOBALS "ws_stub.inc"`.
• Manage the HTTP cookies representing the session state (if your client has to handle several instances of a same service).

For example:

```
GLOBALS "ws_stub.inc" # Import service global definition

# Store the different sessions the client will have to manage
# in a string
DEFINE instance1,instance2,instance3 String

MAIN
...
END MAIN
```

**Step 3: Instantiate a new session by calling the web service operation set as session initiator**

Call the BDL function generated from the WSDL that was defined as session initiator on the server. This function returns a new HTTP Cookie saved into the `Binding.Cookie` member of the global service variable of type `tGlobalEndpointType`. If your application handles several instances, you will have to copy and store that cookie in your application to identify a service instance for further requests.

For example:

```
DISPLAY "Creating a new instance ...
LET wsstatus = GetInstance_g() # call the service session
# initiator web function
IF wsstatus == 0 THEN
  # copy the service returned HTTP cookie
  LET instance1 =
    StatefulCookieService_StatefulCookieServicePortTypeEndpoint.Binding.Cookie
ELSE
  ... handle soap errors
END IF
```

When creating a new instance, ensure that the `Binding.Cookie` member of the generated global variable of type `tGlobalEndpointType` has been set to NULL, otherwise the server will complain.

**Step 4: Call any web service operation with previously returned HTTP cookie**

Before calling any web service operation, set the HTTP cookie returned by a session initiator function to identify the session to the server.

For example:

```
# use instance1
LET StatefulCookieService_StatefulCookieServicePortTypeEndpoint.Binding.Cookie =
  instance1
# Call web operation MyFunction of instance 1
CALL MyFunction("Hello") RETURNING wsstatus,ret
```

**Step 5: Troubleshooting**

If your Genero application doesn't set the HTTP cookie when accessing a stateful service via the GAS, it is possible that you didn't use the complete URL when accessing the service.

For instance if your service is named `MyService` and if you GAS configuration file is called `Server.xcf`, the stateful service is accessible at URL: `http://localhost:6394/ws/r/group/Server/MyService`. 
Encryption, base64 and password agent with fglpass tool

For security reasons, it is recommended that you avoid storing clear passwords in a file. The Genero Web Services enables the password encryption of a HTTP Authenticate entry in the FGLPROFILE file. The encrypted password is decrypted by the Genero Web Services engine when required.

The fglpass tool

The Genero Web Services package provides a command line tool called fglpass. The fglpass tool can encrypt a password from a X.509 certificate or a RSA private key. The encrypted password is displayed on the console in a Base64 form, composed only of alphanumeric characters, and therefore easily usable in any text file.

See fglpass for more details.

Encrypt a HTTP authenticate password

1. Find the HTTP Authenticate entry with the password you want to encrypt:

   authenticate.myentry.login = "mylogin"
   authenticate.myentry.password = "mypassword"

2. Add the certificate and its private key in the FGLPROFILE file as follows:

   security.mykey.certificate = "MyCertificate.crt"
   security.mykey.privatekey = "MyPrivateKey.pem"

3. Encrypt the password with fglpass:

   $ fglpass -c MyCertificate.crt
   Enter password :mypassword

   The fglpass output looks like the following:

   BASE64 BEGIN
   dB3E5JCVxuoxsR+aOBVfp1jOSwQPt+hdjpMKriWvO2xMd5rFnFEwv+sPPd4w
   /onWviG0M5qubBeS7QULc/ZK0D1aO9/R5RVa5wy1Qu//6vxfyd8NG/
   SFJm1VH63kuyXfiVfq6bHo5+n1QZpVjSHF2msET3S9HTp2Ut4NblP4=BASE64 END

   Note: The encrypted password corresponds to the big suite of alphanumeric characters between BASE64 BEGIN and BASE64 END. The long line of text is wrapped for display purposes only.

4. Replace the clear password with the encrypted one, and specify the key used to encrypt it (mykey in our case):

   authenticate.myentry.login = "mylogin"
   authenticate.myentry.password.mykey = "dB3E5JCVxuoxsR+aOBVfp1jOSwQPt+hdjpMKriWvO2xMd5rFnFEwv+sPPd4w
   /onWviG0M5qubBeS7QULc/ZK0D1aO9/R5RVa5wy1Qu//6vxfyd8NG/
   SFJm1VH63kuyXfiVfq6bHo5+n1QZpVjSHF2msET3S9HTp2Ut4NblP4="

   Note: Do not forget to put quotes around the base64 form; otherwise the '=' character is interpreted during the loading of FGLPROFILE. The long line of text is wrapped for display purposes only.

Encrypt a HTTP authenticate password using a certificate in the Windows™ key store

1. Find the HTTP Authenticate entry with the password you want to encrypt:

   authenticate.myentry.login = "mylogin"
   authenticate.myentry.password = "mypassword"
2. Add the subject of the certificate registered in the Windows™ key store:

```plaintext
security.mykey.subject = "Georges"
```

3. Encrypt the password with `fglpass`:

```bash
$ fglpass -c Georges
Enter password :mypassword
```

The `fglpass` output looks like this:

```
BASE64 BEGIN
dBy3E5JCxuoxsR+aOBVfp1j0SwQPt+hdjpMKriWvO2xMd5rFnFEwv+sPpD4w/onWviG0M5mquBeS7Q0Ut/ZK0D1aO9/R5RVa5wy1Qu//6vxyd8NG/SFJmlVH63kuuyXf1Vf6bHo5+n1Q2pVjSHfF2msET3S9HTpZUt4NbiP4=
BASE64 END
```

**Note:** The encrypted password corresponds to the big suite of alphanumeric characters between BASE64 BEGIN and BASE64 END. The long line of text is wrapped for display purposes only.

4. Replace the clear password with the encrypted one, and specify the key used to encrypt it (`mykey` in our case):

```plaintext
authenticate.myentry.login          = "mylogin"
authenticate.myentry.password.mykey = "dBy3E5JCxuoxsR+aOBVfp1j0SwQPt+hdjpMKriWvO2xMd5rFnFEwv+sPpD4w/onWviG0M5mquBeS7Q0Ut/ZK0D1aO9/R5RVa5wy1Qu//6vxyd8NG/SFJmlVH63kuuyXf1Vf6bHo5+n1Q2pVjSHfF2msET3S9HTpZUt4NbiP4=
```

**Note:** Do not forget to put quotes around the base64 form; otherwise the '=' character is interpreted during the loading of FGLPROFILE. The long line of text is wrapped for display purposes only.

**Use the password agent**

The `fglpass` tool can be started as an agent, to help any BDL application who requires a password to grant access to a private key, by getting it without having to type it. You simply need to enter the password once for each private key at the agent startup, and then any BDL application started on the same machine and with the same user name as the agent itself can get rid of entering the different passwords.

Of course, authentication and data encryption are performed between the BDL application and the agent to guarantee passwords confidentiality, and the passwords are also stored encrypted in the agent memory.

1. To start the password agent at port number **4242** and to serve the BDL applications with the passwords of the private key `RSAKey1.pem` and `DSAKey2.der`, specify the option `-agent`, followed by a colon, followed by the port number where it will be reachable, followed by the list of private keys the agent will handle for all BDL applications.

```bash
fglpass -agent:4242 RSAKey1.pem DSAKey2.der
```

2. The agent will ask you to silently enter the password of the different keys *(the passwords are not displayed to the console when being typed).* In this example, you have:

```
Enter pass phrase for RSAKey1.pem:
```

Followed by:

```
Enter pass phrase for DSAKey2.der:
```
3. Once all keys have been treated, it displays following message to notify that the agent is ready to serve.

Agent started

4. To enable one BDL application to use the password agent capability, set the entry called security.global.agent in the FGLPROFILE file with the port number of the agent.

In our example, with value 4242:

security.global.agent = "4242"

Encrypt a password

The fglpass tool can encrypt a password using an RSA key or certificate, and then encode it in BASE64 form. This allows you to easily add a protected password in the FGLPROFILE file for future use by any BDL application.

1. To encrypt a password from an RSA key and encoded in BASE64, enter:

   fglpass -e -k RSAPub.pem

2. You are prompted to enter the password you want to encrypt.

   Enter password :hello

   The fglpass tool outputs the BASE64 form of the encrypted password on the console.

   BASE64 BEGIN
   Pzk/fNRhetdJDZz5kJNg7P0XET4XsW6bys/fiODvuqxRPh9d/s4loAws65JY0EPb2zytQjxZ/dwaaRzJPYoQmA==
   BASE64 END

   Note: The BASE64 encrypted password is the string between the BASE64 BEGIN and BASE64 END.

Decrypt a password

The fglpass tool can decrypt a BASE64 encoded and encrypted password using the RSA private key that was used to encrypt it or that is associated to a certificate containing the public part of that private key.

1. To decrypt a BASE64 encoded and encrypted password from a RSA private key, enter:

   fglpass -d -k RSAPriv.pem

2. If the RSA key is protected with a password, you are asked to silently enter that password (the password is not displayed to the console when being typed).

   Enter pass phrase for RSAPriv.pem:

3. You are prompted to enter the BASE64 encoded and encrypted password you want to decrypt.

   Enter password :Pzk/fNRhetdJDZz5kJNg7P0XET4XsW6bys/fiODvuqxRPh9d/s4loAws65JY0EPb2zytQjxZ/dwaaRzJPYoQmA==

   The fglpass tool outputs the password in clear text on the console.

   hello

Encode a file in BASE64 form

The fglpass tool can encode a file in BASE64 form.
1. To encode the file *MyFile* in BASE64, enter:

```
fglpass -enc64 MyFile
```

The *fglpass* tool outputs the BASE64 form of the file to the console.

BASE64 BEGIN

c2VjdXJpdHkuZ2xvYmFsLmFnZW50ICAgICAiPSIxMDI0MiINCmNyeXB0byBpbmcuYnVyd2F0aW9uLmNvbmZpYyBzY3J5cHRvLmlkMi5sLmNyeXB0byBwb3J0LmNvbWl0cnkgICAgPSIzMDI0MyINCmNyeXB0byBzdW1zLm9uZyBzcGFjaW50LmNvbWl0cnkgICAgICAgICAgPSIyMDI0NSINCmNyeXB0byBzdW1zLm9uZyBzcGFjaW50LmNvbWl0cnkgICAgICAgICAgICAgID0gIlJTQUMjI5OTkuc2V5Ig0KY3J5cHRvLm1lMi5sLmNyeXB0byBzdW1zLm9uZyBzcGFjaW50LmNvbWl0cnkgICAgICAgICAgICAgICAgID0gIlJTQUMjI5OTkuc2V5Ig0K

BASE64 END

**Note:**
- The BASE64 encoded file is the string between BASE64 BEGIN and BASE64 END.
- You can redirect the output of *fglpass* tool to a file. For example:

```
fglpass -enc64 MyFile > Base64filename
```

### Decode a BASE64 form encoded file

The *fglpass* tool can decode a BASE64 encoded file.

1. To decode a file encoded in BASE64 form, enter:

```
fglpass -dec64 Base64filename
```

The *fglpass* tool outputs the file in clear form on the console.

```
security.global.agent      = "4242"
crypto.id1.key             = "RSA1024Key.pem"
crypto.id2.key             = "RSA2048Key.pem"
crypto.id3.key             = "DSA1024Key.pem"
crypto.id4.key             = "RSA512Protected.pem"
crypto.id5.key             = "DSA512ReallyProtected.pem"
```

**Note:**
- You don't have to remove the BASE64 BEGIN and BASE64 END tags, if they are present in the file, because the *fglpass* tool detects and removes them automatically.
- You can redirect the output of the *fglpass* tool to a file. For example:

```
fglpass -dec64 Base64MyFile > MyFile2
```

### HTTP compression

HTTP compression is a capability that can be built into web servers and web clients to make better use of available bandwidth, and provide greater transmission speeds between both.

There are a variety of places where you can set up HTTP compression.

- You can set up the Web services client to send and receive compressed requests. See [Compression and a Web services client](#) on page 2441.
- You can enable compression for the Web server. Refer to your Web server documentation for details.
- You can enable compression in the Genero Application Server. Compression is enabled by default in `$FGLASDIR/etc/imt.cfg`. Refer to the [Genero Application Server User Guide](#) for more information.
• You can set up the Web services server to send and receive compressed requests. See Compression and a Web services server on page 2442.

Compression and a Web services client
Send and receive compressed requests from a Web services client.

When you create a low-level Web service and do not have any stubs created by fglwsdl, you need to manage it by setting the HTTP headers.

Important: HTTP request compression for POST/PUT is not supported on GMI mobile devices.

Send a compressed request
The method used to set up the client for sending a compressed request depends on whether the Genero Web Services client is a high-level or low-level Web services client. A high-level client is a Genero Web Services client that includes the stub files created by the fglwsdl tool. A low-level client is a Genero Web Services client that does not utilize stub files created by the fglwsdl tool.

Regardless of the type of client, the server must be set up to handle such compression, otherwise the request will be rejected.

Send a compressed request from a high-level client
A high-level client is a Genero Web Services client that includes the stub files created by the fglwsdl tool.

Set the variable Binding.CompressRequest to either "gzip" or "deflate".

```
LET EchoDocStyle_EchoDocStylePortTypeEndpoint.Binding.CompressRequest = "gzip"
```

The Binding.CompressRequest variable is defined in the stub file, specifically the client’s global (inc) file.

```
# # Global Endpoint user-defined type definition #
TYPE tGlobalEndpointType RECORD  # End point
   Address RECORD  # Address
      Uri STRING  # URI
   END RECORD,
   Binding RECORD  # Binding
      Version STRING,  # HTTP Version (1.0 or 1.1)
      Cookie STRING,  # Cookie to be set
      ConnectionTimeout INTEGER,  # Connection timeout
      ReadWriteTimeout INTEGER,  # Read write timeout
      CompressRequest STRING  # HTTP request compression mode (gzip or deflate)
   END RECORD
END RECORD

# # Location of the SOAP endpoint. #
# You can reassign this value at run-time. #

DEFINE EchoDocStyle_EchoDocStylePortTypeEndpoint tGlobalEndpointType
```

Send a compressed request from a low-level client
A low-level client is a Genero Web Services client that does not utilize stub files created by the fglwsdl tool.
Set the `Content-Encoding` field in the request header to either "gzip" or "deflate".

This example sets the `Content-Encoding` field to "gzip", where the request is a `com.HTTPRequest` object.

```java
CALL request.setHeader("Content-Encoding","gzip")
```

**Accept a compressed response**

A Genero Web Services client can accept a compressed request if it sets the `Accept-Encoding` field in the header to "gzip, deflate". These values represent supported compression schema names (called content-coding tokens) separated by commas.

This example sets the `Accept-Encoding` field with the `setHeader` method, where the request is a `com.HTTPRequest` object.

```java
CALL request.setHeader("Accept-Encoding","gzip, deflate")
```

**Compression and a Web services server**

Send and receive compressed requests from a Web services server.

If the Genero Web Services client accepts compression, the Genero Web Services server will reply with a compressed response.

To disable compression, you must disable compression in the Genero Application Server `$FGLASDIR/etc/imt.cfg` file. See the Genero Application Server User Guide for more information.

**SOAP multipart style requests in GWS**

This topic describes multipart support with Genero Web Services

**What is multipart style in SOAP?**

Multipart style SOAP is the ability to send and receive a SOAP request in multiple pieces. The sending of attached files in separate parts of the SOAP request is one example of a multipart style SOAP request.

**Multipart SOAP on the client**

When using a WSDL with multipart style, `fglwsdl` generates a client-side stub handling multipart requests. For more details, see Multipart in the client stub on page 2468.

**Multipart SOAP on the server**

Multipart style is not yet supported with the high-level WS API of Genero.

- It is not possible to write a GWS server handling multipart style SOAP requests with the high-level API.
- When generating code from a WSDL using multipart style, the `fglwsdl` will produce a warning message: WARNING : Unable to manage MIME Mutlipart binding on message 'name', where `name` is the name of the message in XML.

**Implementing multipart using the low-level APIs**

If required, you can implement a WS server handling multipart with the low-level APIs of Genero Web Services. For more details, see `com.HTTPServiceRequest.getRequestMultipartType` on page 2052.
Security

These topics covers security and Genero Web Services.

- Encryption and authentication on page 2443
- Accessing secured services on page 2446
- HTTPS configuration on page 2448
- Certificates in practice on page 2449
- Examining certificates on page 2451
- Troubleshoot common issues on page 2454
- The Diffie-Hellman key agreement algorithm on page 2455

Encryption and authentication

A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

- Secured communications on page 2443
- Certificates on page 2444
- Certificate authorities on page 2445
- Certificates and private keys storage on page 2446

Secured communications

Secured communications are important. If an application wants to send or receive messages from a financial, business, or personnel application on the web, it must be able to authenticate the origin of the message, ensure that no malicious application has altered the original message, and ensure that no third party application can intercept the message.

Suppose that a person named Georges wants to send a message to his bank to transfer some money on the Internet. In this scenario, he faces the following concerns:

1. The privacy of the message, since it includes his account number and the transfer amount.
2. The integrity of the message, since someone might try to modify the original message or substitute a different message in order to transfer the money to another account.
3. The authentication of the message, since the bank must ensure that the message was sent from the right person.

Message privacy

To keep a message private, use a cryptographic algorithm - a technique that transforms a message into an encrypted form unreadable except by those it is intended for. Once it is in this form, the message may only be interpreted through the use of a secret key. There are two kinds of cryptography algorithms: symmetric and asymmetric.

*Symmetric* means the sender and the receiver of a message have to share the same key used to encrypt a clear message into an encrypted form, and then to decrypt it back into the original message. If that key is kept secret, nobody other than the sender and the receiver can read the message. However, the task of choosing a private key before communicating can be problematic.

*Asymmetric* means that there are two different keys working as a key-pair. One key is used to encrypt a message, and the second one is used to decrypt the encrypted message back into its original form. This solves the problem of key sharing in the symmetric cryptography algorithm, and makes it possible to receive secure messages, simply by publishing the key used to encrypt messages (the *public key*), and keeping secret the key used to decrypt messages (the *private key*). Anyone can encrypt a message using the public key, but only the owner of the private key can read it.
Important: The use of an asymmetric key-pair (public and private key), allows Georges to send private messages to his bank, simply by using the bank's public key to encrypt a message. Only the owner of the corresponding private key (the bank in this scenario) is able to read it.

Message integrity
To guarantee the integrity of a message, send a concise summary of the original message. The receiver of the message can create its own summary and compare it to the sender's summary. If they are similar, the message is considered intact, meaning that no third party has modified the original message.

Such a summary is called a message digest and is based on hash algorithms that produce a fixed-length representation of variable-length messages. Message digests are designed to make it very difficult (if not impossible) to determine the original message from a summary.

The message digest must be sent to the receiver in a secure way to assure the message integrity. This is achieved with a digital signature authenticating the sender and containing the sender's message digest.

Important: The use of message digests allows Georges' bank to verify that no one has modified the original message he sent.

Message authentication
To authenticate a message, add a digital signature to that message.

A digital signature is another message, created by encrypting the message digest, along with some other information, with the sender's private key. Anyone with the corresponding public key can decrypt the digital signature. If an application is able to decrypt it, it means the owner of the private key was able to encrypt it, proving that the message comes from this sender and not from someone else.

Once the sender has been authenticated, the receiver can compare the message digest integrated into the digital signature to the one it created from the message it receives, in order to check the message integrity.

Important: The use of digital signatures allows Georges' bank to verify that the message really comes from him.

Certificates
An SSL certificate is a kind of digital identity card that associates the public key with a unique digital thumbprint identifying an individual, a server, or any other entity.

Now that Georges is able to send a secured message to his bank, there is still a problem. How can Georges be sure that the server he is connected to is really the bank's server and not a malicious server?

Georges must be sure that the public key he is using to encrypt his message corresponds to the bank's private key. Similarly, the bank needs to verify that the message signature it receives corresponds to Georges’ signature.

To identify a remote peer, use a certificate - a kind of digital identity card that associates the public key with a unique digital thumbprint identifying an individual, a server, or any other entity (known as the subject). It also includes the identification and signature of the Certificate Authority that issued the certificate, and the period of time during which the certificate is valid. It may have additional information (or extensions) as well as administrative information for the Certificate Authority's use, such as a serial number.

A standard X.509 certificate contains the following standard fields:

• Certificate version
• Serial number of the certificate
• The distinguished name of the certificate issuer
• The distinguished name of the certificate owner
• The validity period of the certificate
• The public key
• The digital signature of the issuer
• Signature algorithm used
• Zero or more certificate extensions

Note:
1. An example of a distinguished name is:
   
   CN=Georges,E=georges@mycompany.com,OU=Sales,O=My Company Name,C=FR,S=France

2. The CN (Common Name) of the distinguished name of the certificate owner corresponds to the certificate subject, and identifies the owner of that certificate.

Certificate authorities
When a certificate authority signs a certificate, it is validating that the certificate is valid.

Each time Georges sends a message to his bank, he will present his own certificate to the bank, and will get the bank’s certificate back. But as every one can create a certificate in the name of Georges, a higher authority that confirms the validity of a certificate is necessary. The bank must be sure it is Georges’ certificate, and that no one else has taken his identity. Similarly, Georges needs an authority that confirms that the certificate coming from the server is really the bank’s certificate.

The solution to validating a certificate is to sign it with a trusted certificate called certificate authority. This is a certificate in which an application creates total confidence concerning the validity of the certificates it has signed. Before signing a certificate, a certificate authority must proceed with a strict identification of the owner of that certificate.

Note: The private key associated to a Certificate Authority must be managed with care, as it is the entity in charge of the validity of all other certificates it has signed.

There are several companies (such as VeriSign, GlobalSign or RSA Security) that have established themselves as certificate authorities and provide the following services over the Internet:

• Verifying certificate requests
• Processing certificate requests
• Issuing and managing certificates

Note: It is also possible to create your own Certificate Authority, but it is up to you to manage it securely.

Root Certificate Authority
A Certificate Authority signed by itself is called a Root Certificate Authority, meaning that the certificate issuer is the same as the certificate subject. Most of the time, such a certificate belongs to a company established as a Certificate Authority, and is used to sign certificate requests coming from different companies that want their own Certificate Authority. If a client certificate is signed by a Certificate Authority previously signed by a Root Certificate Authority, the client certificate can be validated by the Root Certificate Authority even if the Certificate Authority is not present.

For example, if a company wants to buy a Certificate Authority from VeriSign, VeriSign signs that Certificate Authority with its own Root Certificate Authority. The company can then create certificates with the Certificate Authority provided by VeriSign and connect to secure servers without providing them their own Certificate Authority. The secure server, of course, has to know the VeriSign Root Certificate Authority.

Certificate chains
A certificate authority may issue a certificate for another certificate authority. This means that when an application wants to examine the certificate of the issuer, it must check all parent certificates of that issuer until it reaches one it which it has confidence.

The certificate chain corresponds to the number of parent certificate authorities allowed to validate a certificate.
Certificate Authority List

A Certificate Authority List is a list of all certificate authorities considered as trusted by one application, classified by order of importance. Each of these certificates allows the authentication of a certificate presented to that application from a remote peer.

**Note:** With most applications, the Certificate Authority List is a concatenated file of all certificate authorities.

Certificates and private keys storage

The entire concept of security is based on the publication of the public key, and the privacy of the associated private key. For maximum security, it is critical to restrict the access of the private key to the owner of the certificate and associated private key.

**Note:** Some companies provide systems to manage certificates and private keys in complete security.

UNIX™ systems

As the UNIX™ system is already able to restrict the access of a file to only one person, simply restrict access to the private key to the owner of that key to achieve a good level of security. This provides enough security to allow a Genero Web Services client to perform secured communications in the name of the certificate and private key owner, because access to the private key file is granted only if the correct user has logged in.

Windows™ systems

The Windows™ system doesn't provide a reliable and sufficiently strong file access rights policy to secure a file. However, Windows™ has an integrated **key store** system to manage certificates and private keys. It allows the registration and the storage of X.509 certificate authorities, as well as personal X.509 certificates and their associated private keys accessible only if the correct user has logged in. It is recommended that you store the certificate and associated private key in the Windows™ key store instead of in files on the disk.

Accessing secured services

Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web Service.

**Figure 105: Communications options for a client to connect to a Web Service**

- **HTTP**
  - Client connects to a Web Server (or a Web Service) using HTTP as the communication protocol. (**No security, No authentication**).

- **HTTP with Basic Authentication**
  - Client connects to a Web Server using HTTP as the communication protocol, but a valid login and
Web services | 2447

password are required from the Web Server to grant access to the Web Service. (**No security, Weak Authentication**). The login and password are sent in clear text on the communication layer.

**HTTP with Digest Authentication**

Client connects to the Web Server using HTTP as the communication protocol, but a valid login and password are required from the Web Server to grant access to the Web Service. (**No security, Authentication**). The login and password are encoded using a digest algorithm, requiring additional information from the Web Server. This means that the first connection will always fail, but it is necessary in order to return Web Server additional information back to the client.

**HTTPS**

Client connects to a Web Server using HTTPS as the communication protocol. (**Security, No authentication**). The communication channel is encrypted by SSL.

**HTTPS with Basic Authentication**

Client connects to a Web Server using HTTPS as the communication protocol, but a valid login and password are required from the Web Server to grant access to the Web Service. (**Security, Weak Authentication**). The login and password are sent in clear text on the communication layer, but the communication channel is encrypted by SSL.

**HTTPS with Digest Authentication**

Client connects to the Web Server using HTTPS as the communication protocol, but a valid login and password are required from the Web Server to grant access to the Web Service. (**Security, Authentication**). The login and password are encoded using a digest algorithm, requiring additional information from the Web Server. This means that the first connection will always fail, but it is necessary in order to return Web Server additional information back to the client. The communication channel is encrypted by SSL.

To improve communication speed with the cache mechanism, or to restrict internet access to specific clients, Genero Web Services allows a client to connect via proxies. The proxy is in charge of dispatching the client request to the server, and uses the same protocol as that used by the server. So, when a client connects via a proxy to access a HTTP server, the configuration of the HTTP proxy is used, and when the client communicates in HTTPS, the HTTPS proxy configuration is used.

**HTTP proxy**

Client connects via a proxy using HTTP as the communication protocol.

**HTTP proxy with Basic Authentication**

Client connects via a proxy using HTTP as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. The login and password are sent in clear text on the communication layer between client and proxy.

**HTTP proxy with Digest Authentication**

Client connects via a proxy using HTTP as the communication protocol, but a valid login and password are required from the proxy to dispatch
the request to the Web Service. The login and password are encoded using a digest algorithm, requiring additional information from the proxy. This means that the first connection will always fail, but it is necessary in order to return proxy additional information back to the client.

**HTTPS proxy**
Client connects via a proxy using HTTPS as the communication protocol. The communication channel is encrypted by SSL.

**HTTPS proxy with Basic Authentication**
Client connects via a proxy using HTTPS as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. The login and password are sent in clear text on the communication layer between client and proxy, but the communication channel is encrypted by SSL.

**HTTPS proxy with Digest Authentication**
Client connects via a proxy using HTTPS as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. The login and password are encoded using a digest algorithm, requiring additional information from the proxy. This means that the first connection will always fail, but it is necessary in order to return proxy additional information back to the client. The communication channel between client and proxy is encrypted by SSL.

**HTTPS configuration**
If no HTTPS is provided, Genero Web Services (GWS) does the HTTPS request transparently.
For GWS, use an implicit certificate when no HTTP configuration is provided. For stronger security, you can provide HTTPS configuration with your own certificates and CA list.

**The implicit client certificate**
For the implicit certificate, no configuration is required. GWS creates a temporary certificate for the HTTPS request. The temporary certificate is valid for the application session.

**The explicit client certificate**
For the explicit certificate, configure your certificate with fglprofile entries.
For access to a specific site, specify `security.ident.certificate` and `security.ident.privatekey`.
If you use the same certificate across all sites, specify `security.global.certificate` and `security.global.privatekey`.

**Certificate authorities**
Certificate authorities are provided by the system (the operating system keystore). If they are not provided by the system, they are looked for in FGLDIR/web_utilities/certs. Genero Web Services will load the CA from the directories listed in the fglprofile entry "security.global.ca.lookuppath". This entry is a list of directories, separated by a semicolon.
You can configure your CA list with the fglprofile entry `security.global.ca`. 
Mobile platforms
On mobile platforms, no HTTPS configuration is required, because the Web Service library uses the SSL certificates installed in the key database of the device (Keystore for Android™ and Keychain for iOS).

See also GMA / Android Web Services requirements on page 2427.

Certificates in practice
Procedures and tools for creating, importing, and viewing certificates and keys.

- The OpenSSL (openssl) tool on page 2449
- Create a root certificate authority on page 2449
- Create a certificate authority on page 2450
- Create a certificate on page 2450
- Create a certificate authority list on page 2450
- Import a certificate and its private key into the Windows key store on page 2451
- Import a certificate authority into the Windows key store on page 2451
- View a certificate on page 2451
- HTTPS configuration on page 2448

The OpenSSL (openssl) tool
The openssl command line tool creates certificates for the configuration of secured communications.

It requires a configuration file with the default parameters such as the key size or the private key name. OpenSSL is provided with a default configuration file openssl.cnf.

The openssl tool looks for the openssl.cnf file in the directory where it is executed; it stops if the file is not present. To use the openssl tool from any directory, set the OPENSSL_CONF environment variable to specify the location of the configuration file.

For information on how the openssl tool works, refer to the openssl documentation at http://www.openssl.org/docs/apps/openssl.html.

Create a root certificate authority
This procedure allows you to create a root certificate authority.

1. Create the root certificate authority serial file:

   $ echo 01 > MyRootCA.srl

2. Create a CSR (Certificate Signing Request):

   $ openssl req -new -out MyRootCA.csr

   This creates a privkey.pem file containing the RSA private key of that certificate and protected by a password.

3. Remove the password of the private key (Optional):

   $ openssl rsa -in privkey.pem -out MyRootCA.pem

   Note: Removing the password of a certificate authority's private key is not recommended.

4. Create a self-signed certificate from the Certificate Signing Request for a validity period of 365 days:

   $ openssl x509 -trustout -in MyRootCA.csr -out MyRootCA.crt -req -signkey MyRootCA.pem -days 365
**Create a certificate authority**
This procedure allows you to create a certificate authority.

1. Create a CSR (certificate signing request):

   ```bash
   $ openssl req -new -out MyCA.csr
   ```

   This creates a `privkey.pem` file containing the RSA private key of that certificate and protected by a password.

2. Remove the private key password (Optional):

   ```bash
   $ openssl rsa -in privkey.pem -out MyCA.pem
   ```

   **Note:** Removing the password of a certificate authority's private key is not recommended.

3. Create a certificate from the Certificate Signing Request and trusted by the Root Certificate Authority:

   ```bash
   $ openssl x509 -in MyCA.csr -out MyCA.crt -req -signkey MyCA.pem -CA MyRootCA.crt -CAkey MyRootCA.pem -days 365
   ```

   **Note:** If you want an official Certificate Authority, you must send the CSR file to one of the self-established Certificate Authority companies on the Internet (instead of creating it with `openssl`).

**Create a certificate**
This procedure allows you to create a certificate.

1. Create the certificate serial file:

   ```bash
   $ echo 01 > MyCA.srl
   ```

2. Create a CSR (Certificate Signing Request):

   ```bash
   $ openssl req -new -out MyCert.csr
   ```

   This command creates a `privkey.pem` file containing the RSA private key of that certificate and protected by a password.

3. Remove the private key password (Optional):

   ```bash
   $ openssl rsa -in privkey.pem -out MyCert.pem
   ```

4. Create a certificate from the Certificate Signing Request and trusted by the Certificate Authority:

   ```bash
   $ openssl x509 -in MyCert.csr -out MyCert.crt -req -signkey MyCert.pem -CA MyCA.crt -CAkey MyCA.pem -days 365
   ```

   **Note:** If you want an official Certificate, you must send the CSR file to one of the self-established Certificate Authority companies on the Internet (instead of creating it with `openssl`).

**Create a certificate authority list**
This procedure allows you to create a certificate authority list using the `openssl` command.

Concatenate all certificate authorities by order of importance, listing the most important first:

```bash
$ openssl x509 -in MyCA1.crt -text >> CAList.pem
$ openssl x509 -in MyCA2.crt -text >> CAList.pem
```
Import a certificate and its private key into the Windows™ key store
This procedure allows you to import a certificate and its private key.

1. Create a certificate.
   See Create a certificate.

2. Create a specific PKCS12 file containing the certificate and its private key in one file:

   ```
   $ openssl pkcs12 -export -inkey MyCert.pem -in MyCert.crt -out MyCert.p12
   ```

   **Note:** The .p12 generated file is protected by a password and can then be transported without any risk.

3. On a Windows™ system, open this .p12 file and follow the instructions provided.

   **Note:** If you select strong verification during the importation process, a popup displays each time an application accesses the private key asking the user whether the application is allowed to use it.

Import a certificate authority into the Windows™ key store
This procedure allows you to import a certificate authority.

1. Create a certificate authority.
   See Create a certificate Authority.

2. Open the .crt certificate file

3. Click Install Certificate and follow the instructions provided.

   Windows™ automatically places the certificate in the certificate authority list of the key store.

View a certificate
This procedure allows you to view a certificate using the openssl command.

To view a certificate, enter the x509 command:

   ```
   openssl x509 -in MyCompanyCA.crt -noout -text
   ```

Examining certificates
When you receive a URL in https, you are asked to either accept a certificate or the certificate has already been accepted. In the second case, you can still check the server certificate.

- Check the server certificate using FireFox on page 2451
- Check the server certificate using Internet Explorer on page 2452
- Selecting the certificate to add on page 2452
- Missing certificates on page 2453

Check the server certificate using FireFox
This procedure allows you to check the server certificate using FireFox.

1. Type the https URL.
2. Once the page is displayed, click on the padlock.
   The Page Info for the certificate displays.
3. In the Security tab, click on the View button.
   The Certificate Viewer opens.
4. In the Details tab, view the Certificate Hierarchy.
Check the server certificate using Internet Explorer
This procedure allows you to check the server certificate using Internet Explorer.

1. Type the https URL.
2. Once the page is displayed, click on the padlock.
   The Certificate window displays.
3. On the Certification Path, view the certificate hierarchy.

Selecting the certificate to add
The certificate authority (CA) is the authority that validates the server. The certificate to add to the CA list is the authority certificate, not the server certificate.

There are default certificates known by browsers like:

Get the server issuer certificate (and all the parents, grandparents, and so on).

For example, if your server is validated by Thawte, add the Thawte certificate to the list.

To check whether your certificate is the CA certificate, search for the CNs (Common Names) in the .cer files. The CA Subject entry should be the Issuer CN in the server certificate.

```bash
openssl x509 -in server.pem -noout -subject
```

gives:
```
symbol=/C=ZA/ST=Western Cape/L=Cape Town/O=Thawte Consulting cc/OU=CertificationServices Division/ CN=Thawte Server CA /emailAddress=server-certs@thawte.com
```
To convert a .cer certificate to the .pem format used by Genero Web Services:

```bash
openssl x509 -inform DER -in server.cer -outform PEM -out server.crt
```

**Missing certificates**

Sometimes the CA hierarchy described in the server certificate is incomplete or needs another certificate (default ones use by browsers or private ones).

![Certificate Viewer in Firefox Web Browser; Details Tab](image)

**Figure 107: Certificate Viewer in Firefox Web Browser; Details Tab**

When this occurs, you will have this kind of error message when you set FGLWSDEBUG:

```
WS-DEBUG (Security error)
Error with certificate at depth: 3
  issuer = /C=US/O=VeriSign, Inc./OU=Class 3 Public Primary Certification Authority
```
subject = /C=US/O=VeriSign, Inc./OU=Class 3 Public Primary Certification Authority
err 19:self signed certificate in certificate chain
WS-DEBUG END

This means openssl is looking for a third ancestor that is not listed in the hierarchy above. In this example, gatewaybeta.fedex.com only has two ancestors, and none are named “Class 3 Public Primary Certification Authority”. You need to download the root certificates from VeriSign and add “Class 3 Public Primary Certification Authority” in your CA list.

Troubleshoot common issues

You may encounter known (and common) issues when completing the Genero Web Services tutorials or when adding Web services of your own. These issues and their solutions are presented in the following topics.

HTTP 401 error message
An HTTP 401 error message means the server is asking for, but not receiving, authentication (login and password).

This means authenticate.xxx.login and authenticate.xxx.password are not correctly configured. The login and password should be provided in the FGLPROFILE.

Solution:

1. Open the FGLPROFILE used by the application.
2. Add entries for authenticate.xxx.login and authenticate.xxx.password.
3. Save your changes.

Error: Peer certificate is issued by a company not in our CA list
When a client needs to connect to a server with https, the client needs to trust the server it is talking to. So the client needs to included the server CAs (certificate authorities list) to its trusted CAs.

This error means the client CA list is missing a certificate authority in its CA list.

To display the client CA list, use the following command:

```
openssl x509 -in ClientCAList.pem -noout -text
```

Solution:

1. Add the missing CA list to the client CA list.

```
openssl x509 -in MyCompanyCA.crt -text >> ClientCAList.pem
```

Theory:
Usually certificates work in pairs: a public key and a private key.
Web services | 2455

Figure 108: Certificates working in pairs: a public key and a private key

This means that the client has a certificate that can be signed by an authority signed itself by a root authority. Likewise, the server has a certificate that can be signed by an authority signed itself by a root authority. In some instances, a certificate can be signed by itself.

Things to remember:

- The server certificate should have its hostname as CN (Common Name). For example: if you want to access the server https://www.mycompany.com the CN should be www.mycompany.com.
- In client CA list you should have all the CA of the server. In this example you need the server CA (5) and the server CA Root (4). If the server is self-signed then add the server certificate (6) to the client CA list.
- Sometimes, the needed CAs are not listed in the certificates hierarchy. Setting environment variable FGFLWSDEBUG=3, will give you information about the missing CA.

The Diffie-Hellman key agreement algorithm

Diffie-Hellman is a key-agreement algorithm. It allows two peers to agree on the same symmetric key, the shared secret, without exchanging confidential data.

The Diffie-Hellman key agreement algorithm is a method that allows two devices to communicate over a network by establishing a shared secret without exchanging any secret data. Knowing the used key-agreement algorithm, the two devices only need to exchange their public key. Then, using the other peer's public key and its own private key, each device performs the algorithm specific key generation operation to obtain the shared secret. The shared secret is a ready-to-use symmetric key for further signed or encrypted exchanges between the two peers.

Genero Web Services provides several shared secret type for signature, encryption, or key encryption purposes. Using the Diffie-Hellman key agreement algorithm, one of the following types of shared secrets can be computed:

- Symmetric AES128 encryption key
- Symmetric AES192 encryption key
- Symmetric AES256 encryption key
- Symmetric TripleDES encryption key
- Symmetric key wrap AES128 key encryption key
- Symmetric key wrap AES192 key encryption key
- Symmetric key wrap AES256 key encryption key
- Symmetric key wrap TripleDES key encryption key
- Symmetric HMAC-SHA1 signature key
In the Diffie-Hellman key agreement algorithm, two shared constants (called parameters) are used in addition to the private and public key. These two parameters are:

- The modulus (called P): A very big prime number chosen at random.
- The generator (called g): A prime number between two and five. Genero Web Services only uses two (2) for the generator.

If the private key (Priv) is a big number (not necessarily prime) chosen randomly, the public key (Pub) is calculated using P, g, and Priv as follows:

\[
\text{Pub} = g^{\text{Priv}} \mod P
\]

Both devices need to use the same parameters for P and g. There are two ways to ensure this happens: Either P and g are chosen by a third party (such as a security authority) or one of the devices chooses them and sends them to the other peer with its public key.

Genero Web Services allows the Web service to generate the parameters itself, to load them from a string or from a PEM or DER file. The public key and the parameters can also be exchanged using an XML file.

This diagram shows the Diffie-Hellman algorithm steps between two devices, A and B, that need to communicate. Device A is in charge of generating the parameters. The shared secret is labeled K.
Figure 109: The Diffie-Hellman algorithm

For complete details about the mathematical basics underlying the Diffie-Hellman algorithm, see [RFC2631].
It is nearly impossible to get the private key from the public key, even knowing the values of parameters P and g. Therefore, a middle man will not be able to obtain the shared secret K. While devices A and B exchange their public key, and maybe the parameters as well, these values pass through different intermediate points. It is critical that A receives the correct public key from B, and that B receives the correct public key from A, in order to establish a common shared secret. A middle man could corrupt or replace one public key with his own. If that happens, A and B would be able to communicate because they won't compute the same shared secret. No secret data will be exchanged and readable to the middle man. To avoid this situation, one can use Digital Certificate that helps to deliver the public key and the parameters in an authenticated method.

Once the shared secret is established, the Diffie-Hellman public key, private key and parameters are no longer useful. The Diffie-Hellman key agreement algorithm is achieved.

With the library provided as part of Genero Web Services, the shared secret has been computed to fit given specifications such as HMAC, 3DES, AES128, AES192, AES256, KW-3DES, KW-AES128, KW-AES192, or KW-AES256. The shared secret is actually a symmetric key ready to be used in a signature (HMAC) or cipher algorithm. It allows devices A and B to finally communicate via an authenticated (HMAC) or encrypted method.

**SOAP Web Services**

Write a Web Services client or server using the SOAP protocol.

The Genero APIs for creating Web services can be found in the Library section of this manual. See The com package on page 2017 and The xml package on page 2111.

**Writing a Web Services client application**

Create, configure and deploy a Genero Web Services client using the SOAP protocol.

- Steps to write a WS client on page 2458
- Change WS client behavior at runtime on page 2461
- WS client stubs and handlers on page 2464
- Using logical names for service locations on page 2470
- Configure a WS client to connect via an HTTP Proxy on page 2471
- Authenticate the WS client to a server on page 2472
- Authenticate the WS client to a proxy on page 2473
- Configure a WS client to access an HTTPS server on page 2474

**Steps to write a WS client**

The Genero Web Services package (GWS) allows a BDL program to access Web services found on the Internet. GWS supports the WSDL 1.1 specification of March 15, 2002. This example illustrates a client application that accesses the Add operation in the GWS Web Service **MyCalculator**.

See Writing a Web server application on page 2481 for information about the Service.

- Obtaining the WSDL information on page 2458
- Calling a web service on page 2460
- Setting a time period for the response on page 2461
- Handling GWS server errors on page 2461
- Compiling the client application on page 2461

**Obtaining the WSDL information**

To access a remote Web service, you must get the WSDL information from the service provider. Sample services can be found through UDDI registries or on other sites such as XMethods (http://www.xmethods.net).
You can use the `fglwsdl` tool provided by the Genero Web Services package to obtain the necessary WSDL information. The following example obtains the WSDL information for the GWS Service MyCalculator created by the Writing a Web server application on page 2481:

```bash
glwsdl -o Example2Client http://localhost:8090/MyCalculator?WSDL
```

This generates two files:

- `Example2Client.inc` - the globals file containing the definitions of the input and output records, and the prototypes of the operations.
- `Example2Client.4gl` - a module containing the definitions of the functions that can be used in your GWS client application to perform the requested Web Service operation, and the code that manages the Web Service request.

**Note:** The MyCalculator GWS Service must be running on the specified port in order to provide the WSDL information.

The following definitions were generated in the globals file, `Example2Client.inc`:

### Input and Output records

```bdl
DEFINE Add RECORD
  ATTRIBUTES( XMLName="Add", XMLNamespace="http://tempuri.org/webservices" )
  a INTEGER ATTRIBUTES( XMLName="a", XMLNamespace="" ),
  b INTEGER ATTRIBUTES( XMLName="b", XMLNamespace="" )
END RECORD

DEFINE AddResponse RECORD
  ATTRIBUTES( XMLName="AddResponse", XMLNamespace="http://tempuri.org/webservices" )
  r INTEGER ATTRIBUTES(XMLName="r",XMLNamespace="" )
END RECORD
```

Since BDL functions cannot have complex structures as parameters, the data types are defined as global or modular variables.

### Function prototypes for the Operations

This globals file contains the prototype of two functions for the Add operation.

The **Add** function uses input and output parameters, and returns the status and result. This function can only be used if the input and output parameters are not complex structures such as arrays or records. Using this function, developers do not access the global records directly.

The **Add_g** function can be used with the global input and output records. Before calling this function, you must set the values in the variables of the global input record.

```bdl
Operation: Add
# # FUNCTION: Add_g()
# RETURNING: soapStatus
# INPUT: GLOBAL Add
# OUTPUT: GLOBAL AddResponse
# # FUNCTION: Add(p_a, p_b)
# RETURNING: soapStatus ,,p_r
```

See `fglwsdl` on page 1507 and WS client stubs and handlers on page 2464 for more details regarding the `fglwsdl` tool, its output and the generated functions.
**Calling a web service**

### Step 1: Import the COM library of the GWS package

The methods associated with creating and publishing a Web Service are contained in the classes that make up the Genero Web Services Library (com). If you use any of these methods in your client application, you must import the library. Since this example application sets the timeout period that the client will wait for the Service to respond, include the following line at the top of the module:

```
IMPORT com
```

If your generated .inc file uses xml class data types, you need to add `IMPORT xml`.

### Step 2: Specify the globals file

Use a `GLOBALS` statement to specify the generated globals file.

```
GLOBALS "Example2Client.inc"
```

### Step 3: Write the MAIN program block

Provide values for the input and output messages of the operation, and call one of the generated functions. Since the input and output messages are simple integers, we can call the `Add` function.

```
MAIN
  DEFINE op1        INTEGER
  DEFINE op2        INTEGER
  DEFINE result     INTEGER
  DEFINE wsstatus   INTEGER

  LET op1 = 1
  LET op2 = 2
  CALL Add(op1, op2) RETURNING wsstatus, result
  IF wsstatus = 0 THEN
    DISPLAY "Result: ", result
  ELSE
    -- Use the global wsError record
    DISPLAY "Error: ", wsError.description
  END IF
END MAIN
```

Alternatively, we can use the global input and output records directly, calling the `Add_g` function:

```
MAIN
  DEFINE wsstatus INTEGER

  LET Add.a = 1
  LET Add.b = 2
  LET wsstatus = Add_g()
  IF wsstatus != 0 THEN
    -- Use the global wsError record
    DISPLAY "Error ", wsError.Description
  ELSE
    DISPLAY "Result: ", AddResponse.r
  END IF
END MAIN
```

These examples are very basic versions of the code. For complete examples, see the code samples provided with the package in `demo/WebServices`. 
**Setting a time period for the response**

To protect against remote server failure or unavailability, set a timeout value that indicates how long you are willing to wait for the server to respond to your request.

Use the `SetOption()` method of the `WebServiceEngine` class to set the `readwritetimeout` option.

For example, to wait no more than 10 seconds:

```plaintext
CALL com.WebServiceEngine.SetOption( "readwritetimeout", 10 )
```

A timeout value of `-1` means "wait forever". This is the default value.

**Handling GWS server errors**

When a Genero Web Services Service operation returns a status that is non-zero, you can get a more detailed error description from the global record `wsError`.

This record is defined in the `globals` .inc file.

```plaintext
DEFINE wsError RECORD
  code STRING,         -- Short description of the error
  codeNS STRING,       -- The namespace of the error code
  description STRING,  -- Long description of the error
  action STRING        -- internal "SOAP action"
END RECORD
```

**Compiling the client application**

The library file `WSHelper.42m`, included in the `$FGLDIR/lib` directory of the Genero Web Services package, should be linked into every client or server program. Assuming the example client code shown above is in a module named `clientmain.4gl`, you can compile and link the client program:

```plaintext
fglcomp clientmain.4gl
fglcomp Example2Client.4gl
fgllink -o myclient.42r clientmain.42m Example2Client.42m WSHelper.42m
```

**Change WS client behavior at runtime**

Genero Web Services generates a global record called `tGlobalEndpointType` to change the client behavior at runtime without the need to modify any generated client stub. If WS-Addressing 1.0 is enabled, the global generated record is called `tWSAGlobalEndpointType`, and if needed you can also access the HTTP layer via the Request and Response record of the binding section.

- Global Endpoint type definition on page 2461
- WS-Addressing 1.0 Global Endpoint type definition on page 2462
- Change server location on page 2462
- Change the HTTP protocol version on page 2463
- Set an HTTP cookie on page 2463
- Set the connection timeout for a service on page 2463
- Set the read and write timeout for a service on page 2463
- Access HTTP request and response headers for a service on page 2463

**Global Endpoint type definition**

The following global type is used by any generated client stub to allow the programmer to change the client behavior at runtime.

```plaintext
TYPE tGlobalEndpointType RECORD # End point
  Address RECORD # Address
    Uri STRING # URI
  END RECORD, 
  Binding RECORD # Binding
```

Global Endpoint type definition
Description of variables:

- **Address.Uri**: Represents the location of the server.

  **Important**: It replaces the global variable of type STRING generated prior to version 2.40, therefore it is mandatory to regenerate the client stub and to modify the location assignment in your application.

- **Binding.Version**: Represents the HTTP version to use for communication (only 1.0 or 1.1 allowed, default is 1.1).

- **Binding.Cookie**: Represents the HTTP cookie to use for communication (or NULL if there is no cookie to send).

- **Binding.ConnectionTimeout**: Represents the maximum time in seconds to wait for the establishment of the connection to the server.

- **Binding.ReadWriteTimeout**: Represents the maximum time in seconds to wait for a connection read or write operation before breaking the connection.

### WS-Addressing 1.0 Global Endpoint type definition

The following global type is used by any generated client stub where support of WS-Addressing 1.0 is enabled. It allows the programmer to change the client behavior at runtime, and to send additional WS-Addressing 1.0 reference parameters to a server.

If this global type is used in your main application, you must add the `IMPORT xml` instruction.

```plaintext
TYPE tWSAGlobalEndpointType RECORD # End point
  Address RECORD # Address
    Uri STRING, # URI
    Parameters DYNAMIC ARRAY OF xml.DomDocument
      ATTRIBUTES(XMLNamespace="##any",XMLAny) # End point WSA reference parameters
  END RECORD,
  Binding RECORD # Binding
    Version STRING, # HTTP Version (1.0 or 1.1)
    Cookie STRING, # Cookie to be set
    ConnectionTimeout INTEGER, # Connection timeout
    ReadWriteTimeout INTEGER # Read write timeout
  END RECORD
END RECORD
```

Description of variables:

- **Address.Parameters**: Represents the WS-Addressing 1.0 reference parameter to send to a WS-Addressing 1.0 compliant server.

### Change server location

To change the server location at runtime, set the record `Uri` member with a valid URL of another service. All services must respect the same WSDL contract. If you let the variable unset, the client will connect to the server URL defined in the WSDL at code generation time.

Example:

```plaintext
LET Calculator_CalculatorPortTypeEndpoint.Address.Uri =
    http://zeus:1111/mydomain/Calculator
```

You can assign this variable with a URL set in the FGLPROFILE (see Logical Service location).
If you are migrating from a version prior to 2.40, see the migration note.

**Change the HTTP protocol version**

To communicate with a service that speaks only a given version of HTTP, set the record `Version` member with the desired value. If you let the variable unset, the client will communicate in HTTP 1.1.

Example:

```plaintext
LET Calculator_CalculatorPortTypeEndpoint.Binding.Version = "1.0"
```

If you do not want the request to be split into chunks, set the HTTP protocol version to 1.0.

**Important:** On GMI mobile devices, the HTTP protocol version definition is ignored, it will always be version 1.1.

**Set an HTTP cookie**

To send an HTTP cookie to the service, set the record `Cookie` member with the cookie value. If you let the variable unset, the client won’t send any cookie.

Example:

```plaintext
LET Calculator_CalculatorPortTypeEndpoint.Binding.Cookie = "MyCookie=AValue"
```

Unset that variable if you don’t need the cookie to be sent anymore.

**Set the connection timeout for a service**

To change the default timeout value to establish a connection to the service, set the record member `ConnectionTimeout` with the timeout value in seconds.

Example:

```plaintext
LET Calculator_CalculatorPortTypeEndpoint.Binding.ConnectionTimeout = 15
```

**Important:** On GMI mobile devices, the max of `ConnectionTimeout` and `ReadWriteTimeout` will be used.

**Set the read and write timeout for a service**

To change the default time of reading and writing to or from a service, set the record `ReadWriteTimeout` member with the time out value in seconds.

Example:

```plaintext
LET Calculator_CalculatorPortTypeEndpoint.Binding.ReadWriteTimeout = 5
```

**Important:** On GMI mobile devices, the max of `ConnectionTimeout` and `ReadWriteTimeout` will be used.

**Access HTTP request and response headers for a service**

To access HTTP headers exchanged between the Genero client and a web service, you must use following records in the binding section:

- one record called `Request` in order to customize HTTP headers to be sent to a web service
- one record called `Response` in order to retrieve all HTTP headers returned by a web service

```plaintext
TYPE tGlobalEndpointWithHttpLayerType RECORD # End point
    Address RECORD # Address
        Uri STRING # URI
    END RECORD,
    Binding RECORD # Binding
        Version STRING, # HTTP Version (1.0 or 1.1)
```
Cookie STRING, # Cookie to be set
Request RECORD
  Headers DYNAMIC ARRAY OF RECORD # HTTP Headers
  Name STRING,
  Value STRING
END RECORD,
Response RECORD
  Headers DYNAMIC ARRAY OF RECORD # HTTP Headers
  Name STRING,
  Value STRING
END RECORD,
ConnectionTimeout INTEGER,# Connection timeout
ReadWriteTimeout INTEGER # Read write timeout
CompressRequest STRING # HTTP compression mode (gzip or deflate)
END RECORD
END RECORD

Description of additional Request and Response variables:

- **Binding.Request.Headers**: Represents the additional HTTP headers to be sent to the web service. (Notice that client stub headers will replace user ones if the same name).
- **Binding.Response.Headers**: Represents the HTTP headers returned by a web service.

**WS client stubs and handlers**

To access a remote Web Service, you first must get the WSDL information from the service provider. Sample services can be found through UDDI registries (http://www.uddi.org), or on other sites such as XMethods (http://www.xmethods.net).

- **Generating stub files for a GWS Client** on page 2464
- **Handling GWS server errors** on page 2461
- **Global Endpoint user-defined type definition** on page 2465
- **The generated functions** on page 2465
- **The generated callback handlers** on page 2466
- **Example output** on page 2467
- **Using the generated functions** on page 2469

**Generating stub files for a GWS Client**

Use the `fglwsdl` tool to generate the BDL stub from a WSDL URL or file.

The next example requests the Calculator Web Service information from the specified URL, and the output files will have the base name `ws_calculator`:

```
```

For a client application, `fglwsdl` generates two output files, which should not be modified:

- `filename.inc`: the globals file, containing declarations of global variables that can be used as input or output for functions accessing Web Service operations, and the global `wsError` record. In our example, the file is `ws_calculator.inc`.
  
  This file must be listed in a `GLOBALS` statement at the top of any `.4gl` modules that you write for your GWS Client application.

- `filename.4gl`: containing the definitions of the functions that can be used in your GWS client application to perform the requested Web Service operation, and the code that manages the Web Service request. In our example, the file is `ws_calculator.4gl`.
  
  This file must be compiled and linked into your GWS Client application.
Handling GWS server errors
When a Genero Web Services Service operation returns a status that is non-zero, you can get a more detailed error description from the global record wsError.

This record is defined in the globals .inc file.

```plaintext
DEFINE wsError RECORD
  code STRING, -- Short description of the error
  codeNS STRING, -- The namespace of the error code
  description STRING, -- Long description of the error
  action STRING -- internal "SOAP action"
END RECORD
```

Global Endpoint user-defined type definition
The fglwsdl tool generates the globals (inc) file to use for a Web services client. Part of this globals file is a global endpoint user-defined type definition.

```plaintext
# Global Endpoint user-defined type definition

TYPE tGlobalEndpointType RECORD   # End point
  Address RECORD # Address
    Uri STRING                 # URI
    END RECORD,
  Binding RECORD # Binding
    Version STRING,           # HTTP Version (1.0 or 1.1)
    Cookie STRING,            # Cookie to be set
    ConnectionTimeout INTEGER, # Connection timeout
    ReadWriteTimeout INTEGER, # Read write timeout
    CompressRequest STRING     # HTTP request compression mode (gzip or deflate)
    END RECORD
  END RECORD

# Location of the SOAP endpoint.
# You can reassign this value at run-time.
#
DEFINE EchoDocStyle_EchoDocStylePortTypeEndpoint tGlobalEndpointType
```

The CompressRequest entry is of type string. It is NULL by default, meaning that no request is compressed. To compress a request, set this variable to gzip or deflate. The server must support compression, otherwise the request will be rejected.

The generated functions
Genero Web Services (GWS) client functions have the following requirements:

- The function cannot have input parameters.
- The function cannot have return values.
- The function's input message must be defined as a global or module RECORD.
- The function's output message must be defined as a global or module RECORD.

As a result, two types of GWS functions are generated for the Web Service operation that you requested:

- One function type uses global records for the input and output. The names of these functions end in ",_g". Before calling the function in your GWS Client application, you must set the values in the global input record. After the function call, the status of the request is returned from the server, and the output message is stored in the global output record. In addition to performing the desired operation, this function handles the communication for the SOAP request and response, and sets the values in the wsError record as needed.
• The other function type serves as a "wrapper" for the ",g" function. It passes the values of input parameters to the ",g" function, and returns the output values and status received from the ",g" function. Your client application does not need to directly access the global records. This function can only be used if the parameters are simple variables (no records or arrays).

The generated .inc globals file contains comments that list the prototypes of the functions for the GWS operation, and the definitions of the global INPUT and OUTPUT records.

The generated callback handlers

More and more Web Services provide support of the different WS-* specifications. To enable a better interoperability with such services, the fglwsdl tool allows the programmer to modify the SOAP request before it is sent, and to perform additional verifications of the SOAP response before it is returned from the BDL function.

When option -domHandler is used, the fglwsdl tool performs the following two operations at once:

• It generates the client stub based entirely on the DOM API to ease the manipulation of the XML requests and responses.
• It generates additional calls for each operation of a service to execute one of the three callback handlers the programmer has to implement.

Handler definition

There are three kind of callbacks you must implement for each service generated with the -domHandler option.

• The request handler that allows the modification of the entire SOAP request before it is send over the net.

It must be named ServiceName_HandleRequest, where ServiceName is the name of the service according to the different prefix options used during generation.

It must return TRUE if you want the caller function to continue normally or FALSE to return from the caller function with a SOAP error you can define via the wsError record.

```
FUNCTION ServiceName_HandleRequest(operation,doc,header,body)
  DEFINE operation STRING          -- Operation name of the request to be modified.
  DEFINE doc       xml.DomDocument -- Entire XML document of the request
  DEFINE header    xml.DomNode     -- XML node of the SOAP header of the request
  DEFINE body      xml.DomNode     -- XML node of the SOAP body of the request
  CASE operation
    WHEN "Add"  
      ...   -- Use the DOM APIs to modify the request of the Add operation
    WHEN "Sub"  
      ...   -- Use the DOM APIs to modify the request of the Sub operation
    OTHERWISE
      DISPLAY "No modification for operation ":operation
  END CASE
  RETURN TRUE -- Continue normally in Add_g() or Sub_g()
END FUNCTION
```

• The response handler that allows the validation of the entire SOAP response before it is de-serialized into the corresponding record.

It must be named ServiceName_HandleResponse, where ServiceName is the name of the service according to the different prefix options used during generation.

It must return TRUE if you want the caller function to continue normally or FALSE to return from the caller function with a SOAP error you can define via the wsError record.

```
FUNCTION ServiceName_HandleResponse(operation,doc,header,body)
```
FUNCTION ServiceName_HandleResponseFault(operation, doc, header, body)
DEFINE operation STRING -- Operation name of the fault response to be checked.
DEFINE doc xml.DomDocument -- Entire XML document of the fault response
DEFINE header xml.DomNode -- XML node of the SOAP header of the fault response
DEFINE body xml.DomNode -- XML node of the SOAP body of the fault response
CASE operation
  WHEN "Add"
    ... -- Use the DOM APIs to verify the SOAP fault response of the Add operation
  WHEN "Sub"
    ... -- Use the DOM APIs to verify the SOAP fault response of the Sub operation
  OTHERWISE
    DISPLAY "No verification for operation ": operation
END CASE
RETURN TRUE -- Continue normally in Add_g() or Sub_g()
END FUNCTION

Example output
The example Web Service for which the WSDL information was requested, Calculator, has an Add operation that returns the sum of two integers.

The generated file ws_calculator.inc lists the prototype for the Add and Add_g functions, the asynchronous AddRequest_g and AddResponse_g functions, as well as the definitions of the global variables Add and AddResponse:

```plaintext
# Operation: Add## FUNCTION: Add_g() -- Function that uses the global input
#   RETURNING: soapStatus -- An integer where 0 represents success
#   INPUT: GLOBAL Add
```
# OUTPUT: GLOBAL AddResponse
#
# FUNCTION: Add(p_a, p_b)               -- Function with input parameters that
#  RETURNING: soapStatus ,p_r          -- correspond to the a and b variables
#                        -- of the global INPUT record
#                        -- Return values are the status
#                            -- and the value in the r variable
#                            -- of the global OUTPUT record
#
# FUNCTION: AddRequest_g()              -- Asynchronous function that uses
#                        -- global input record
#  RETURNING: soapStatus                -- An integer where 0 represents
#                        -- a previous request was sent
#                        -- and that a response is in progress.
#
# FUNCTION: AddResponse_g()             -- Asynchronous function that uses
#                        -- the global output record
#  RETURNING: soapStatus                -- An integer where 0 represents
#                        -- the response was not
#                        -- yet received, and that a new call
#                        -- should be done later.
#
#VARIABLE : Add   -- defines the global INPUT record
DEFINE Add RECORD ATTRIBUTES(XMLName="Add",
                           XMLNamespace="http://tempuri.org/"
                           a INTEGER ATTRIBUTES(XMLName="a",XMLNamespace=""),
                           b INTEGER ATTRIBUTES(XMLName="b",XMLNamespace="")
END RECORD

# VARIABLE : AddResponse   -- defines the global OUTPUT record
DEFINE AddResponse RECORD ATTRIBUTES(XMLName="AddResponse",
                           XMLNamespace="http://tempuri.org/"
                           r INTEGER ATTRIBUTES(XMLName="r",XMLNamespace="")
END RECORD

Multipart in the client stub
You can generate a client stub for a Web service that has multiple parts.
If the WSDL for a Web service indicates that the Web service uses multiple parts, the client stub generated
will support multiple parts.

For the request
There are as many com.HTTPPart input parameters as parts defined for the input request, plus one
AnyInputParts DYNAMIC ARRAY OF com.HTTPPart parameter, to manage the optional parts a user
can add to the request.
For example:

FUNCTION xxx_g(InputHttpGetPart_1, ..., InputHttpGetPart_n, AnyInputParts)
  DEFINE InputHttpGetPart_1 com.HTTPPart
  ...
  DEFINE InputHttpGetPart_n com.HTTPPart
  DEFINE AnyInputParts DYNAMIC ARRAY OF com.HTTPPart
  ...
RETURN wsstatus
END FUNCTION

For the response
There are as many com.HTTPPart variables are described in the WSDL, plus one AnyOutputParts DYNAMIC ARRAY OF com.HTTPPart to handle the optional parts that may be returned by a service.

For example:

FUNCTION xxx_g()
  DEFINE wsstatus INTEGER
  DEFINE OutputHttpPart_1 com.HTTPPart
  DEFINE AnyOutputParts DYNAMIC ARRAY OF com.HTTPPart
  ...
  RETURN wsstatus, OutputHttpPart_1, AnyOutputParts
END FUNCTION

Using the generated functions
The information obtained from the ws_calculator.inc file allows you to write code in your own .4gl module as part of the Client application, using the Web Service operation Add.

Using parameters and return values
Since the input variables for our example are simple integers, you can call the Add function in your Client application, defining variables for the parameters and return values.

FUNCTION myWScall()
  DEFINE op1 INTEGER
  DEFINE op2 INTEGER
  DEFINE result INTEGER
  DEFINE wsstatus INTEGER
  ...
  LET op1 = 6
  LET op2 = 8
  CALL Add(op1, op2)
    RETURNING wsstatus, result ...
  DISPLAY result

Using global records
You could choose to call the Add_g function instead, using the global records Add and AddResponse directly. If the input variables are complex structures like records or arrays, you are required to use this function.

FUNCTION myWScall()
  DEFINE wsstatus INTEGER
  ...
  LET Add.a = 6
  LET Add.b = 8
  LET wsstatus = Add_g()
  ...
  DISPLAY AddResponse.r

In this case, the status is returned by the function, which has also put the result in the AddResponse global record.

See Tutorial: Writing a Client Application for more information. The demo/WebServices subdirectory of your Genero installation directory contains complete examples of Client Applications.
Using asynchronous calls

If you don't want your application to be blocked when waiting for the response to a request, you should first call **AddRequest_g**: this will send the request using the global **Add** record to the server. It returns a status of 0 (zero) if everything goes well, -1 in case of error, or -2 if you tried to resend a new request before the previous response was retrieved.

```
FUNCTION sendMyWScall()
  DEFINE wsstatus INTEGER
  ...
  LET Add.a = 6
  LET Add.b = 9
  LET wsstatus = AddRequest_g()
  IF wsstatus <> 0 THEN
    DISPLAY "ERROR ", wsError.code
  END IF
  ...
```

You can then call **AddResponse_g** to retrieve the response in the **AddResponse** global record of the previous request. If returned status is 0 (zero) the response was successfully received, -1 means that there was an error, and -2 means that the response was not yet received and that the function should be called later.

```
FUNCTION retrieveMyWScall()
  DEFINE wsstatus INTEGER
  ...
  LET wsstatus = AddResponse_g()
  CASE wsstatus
    WHEN -2
      DISPLAY "No response available, try later"
    WHEN 0
      DISPLAY "Response is :", AddResponse.r
    OTHERWISE
      DISPLAY "ERROR ", wsError.code
  END CASE
  ...
```

You can mix the asynchronous call with the synchronous one as they are using two different requests. In other words, you can perform an asynchronous request with **AddRequest_g**, then a synchronous call with **Add_g**, and then retrieve the response of the previous asynchronous request with **AddResponse_g**.

**Important**: In development mode, a single BDL Web Service server can only handle one request at a time, and several asynchronous requests in a row without retrieving the corresponding response will lead to a deadlock. To support several asynchronous requests in a row, it is recommended that you are in deployment mode with a GAS as the front end.

Using logical names for service locations

Genero Web Services, starting with version 2.00, provides a repository for Web Service locations using FGLPROFILE. To achieve maximum flexibility, you can map a logical reference used by your Web Services Client application to an actual URL. This is subject to the network configuration and access rights management of the deployment site.

**Important**: On GMI mobile devices, FGLPROFILE settings for logical names are not supported.

- FGLPROFILE entry on page 2471
- Logical reference in the client application on page 2471
- Logical reference in the URL on page 2471
FGLPROFILE entry

The following entry in the FGLPROFILE file maps the logical reference "myservice" to an actual URL:

```
ws.myservice.url = "http://www.MyServer.com/cgi-bin/fglccgi.exe/ws/r/MyWebService"
```

Logical reference in the client application

When you generate a Client stub from WSDL information using the tool fglwsdl, a global variable for the URL of the Web Service is contained in the .inc file.

For example:

```
# Location of the SOAP server.
# You can reassign this value at run-time.
# DEFINE Calculator_CalculatorPortTypeEndpoint tGlobalEndpointType
```

You can assign a logical name to this global variable in your Web Services Client application:

```
LET Calculator_CalculatorPortTypeEndpoint.Address.Uri = "alias://myservice"
```

When the Client application accesses the Service, the actual location will be supplied by the entry in FGLPROFILE on the Client machine. This allows you to provide the same compiled .42r application to different customers. The entries in FGLPROFILE on each customer's machine would customize the Web Service location for that customer.

If you are migrating from a version prior to 2.40, see migration note.

Logical reference in the URL

When you deploy a Genero Web Service with a GAS behind a Web Server, the service can be accessed by two different URLs. You can use a logical name in the URL, mapping the actual location of the Web Service in FGLPROFILE, depending on the location of the client machine.

For example:

- For internal Clients: `http://zeus:6394/ws/r/myservice`
- For Clients using the Web: `http://www.myServer.com/...`

These two URLS could be mapped in the FGLPROFILE file on the Client machine, each specifying the location of the Service.

Configure a WS client to connect via an HTTP Proxy

Configuration steps to connect via a HTTP proxy.

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.

1. Add the location of the proxy to fglprofile with the proxy.http.location entry.

Add the entry `proxy.http.location` to your fglprofile. For the value, provide the IP address of the HTTP proxy and the port number where the HTTP proxy is listening, separated by a colon. For example, to have a client connect via a HTTP proxy located at the IP address "10.0.0.170" and listening on port number "8080", add this entry to your fglprofile:

```
proxy.http.location = "10.0.0.170:8080"
```

**Note:** To configure the client to connect via an HTTPS proxy, replace `http` with `https`.

2. Define the list of host names the client will **not** have to connect to via a proxy with the `proxy.http.list` entry.
Add the entry `proxy.http.list` to your `fglprofile`. For the value, provide a semi-colon separated list of clients. For example, to exclude all hosts beginning with "www.mycompany.com" or "www.google." from connecting via a HTTP proxy, add this entry to your `fglprofile`:

```
proxy.http.list = "www.mycompany.com;www.google."
```

**Configure a WS client to use IPv6**

Configuration steps to customize IPv6 for a WS client.

A Web Services client program can access to a WS server using IPv6.

URLs that map to IPv6 addresses will be automatically handled by the Web Services library. It is also possible to specify an IPv6 address directly as URL in your BDL code by enclosing the address in square brackets, for example:

```
LET myURL = "http://[fe80::20c:29ff:fe05:9ca3]:80/index.html"
```

By default, the WS library will automatically use IPv6 addresses if available, and fallback to IPv4 otherwise. To overcome the default behavior, you can specify explicitly the IP version.

Indeed, the platform where WS client programs execute must support IPv6.

1. If needed, force the IP version with the `ip.global.version` entry in `fglprofile`, by specifying "4" for IPv4 or "6" for IPv6.
   
   For example, to force IPv4 (when IPv6 is available):
   
   ```
ip.global.version = "4"
```

2. When using IPv6 for link-local addresses, if several network interfaces exist on the machine, you can explicitly specify what interface must be used with the `ip.global.v6.interface.name` or `ip.global.v6.interface.id` entry in `fglprofile`.

   In order to specify the IPv6 network interface by name, use:
   
   ```
ip.global.v6.interface.name = "eth0"
```

   **Important:** The `ip.global.v6.interface.name` entry is not supported on Microsoft™ Windows™ platforms.

   In order to specify the IPv6 network interface by id, use:
   
   ```
ip.global.v6.interface.id = "2"
```

**Authenticate the WS client to a server**

Configuration steps to authenticate the client to a server (HTTP authentication).

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: Use the `com.HTTPRequest.setAuthentication` on page 2071 API instead.

1. Add HTTP authenticate entries to `fglprofile`.

   To connect to a server with HTTP Authentication, define the client login and password with the same values as registered on the server side. These entries must be defined with an unique identifier (`httpauth` in this example) to define a HTTP Authentication with "mylogin" as login and "mypassword" as password:

   ```
authenticate.httpauth.login = "mylogin"
authenticate.httpauth.password = "mypassword"
```

   See [RFC2617] for more details.

2. Encrypt the password.

   Due to security leaks, it is recommended that you NOT have a password in clear text. The Genero Web Services package provides the tool `fglpass`, which encrypts a password with a certificate that is readable only with the associated private key. To encrypt the HTTP authentication password:
a) Encrypt the clear text password with \texttt{fglpass} using the client certificate.

   \begin{verbatim}
   $ fglpass -e -c MyClient.crt
   Enter password :mypassword
   \end{verbatim}

   \textbf{Note:} \texttt{fglpass} outputs the encrypted password on the console but can be redirected to a file.

b) Modify the HTTP authentication password entry by specifying the security configuration to use to decrypt it (id1 in our case)

   \begin{verbatim}
   authenticate.id2.password.id1="HWTFu8QE2t3e5D4joy7js8mB95oOGTzLmcAor9j5DS+C
   loil1GCiwZ9eWpfnIWS0N9IwoiJheYxfnu20uaGGmniUGiHxT634lePXNSicu32Nt1Vp9t6Rcs0
   wN/p9a6D4XtiD9iHW7iQvXhqC9uamd3gI9Q3GhHwXOMM1Y//c8Y="
   \end{verbatim}

   \textbf{Note:} Hard returns have been added to the code sample above, for the purpose of printing and viewing within this document. The value for authenticate.id2.password.id1 is a single string with no spaces.

   \textbf{Note:} The size of the encrypted password depends on the size of the public key, and can change according to the certificate used to encrypt it.

3. Configure the client to authenticate to a server.

   As a client is able to connect to different servers that do not know the client with the same login and password, it is necessary to specify the login and password that correspond to each server.

   To authenticate the client known as "myclient" and with the password \texttt{passphrase} by the server \texttt{myserver}, add the following entry:

   \begin{verbatim}
   ws.myserver.authenticate = "httpauth"
   \end{verbatim}

   \textbf{Authenticate the WS client to a proxy}

   Configuration steps to authenticate the client to a proxy (proxy authentication).

   \textbf{Important:} On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.

1. Add an HTTP authenticate entry to fglprofile.

   To connect via a proxy with HTTP Proxy Authentication, it is necessary to define the client login and password as registered on the HTTP proxy.

   The following two entries must be defined with an unique identifier (\texttt{proxyauth} for our example) to define a HTTP Proxy Authentication with \texttt{myapplication} as login and \texttt{mypassword} as password:

   \begin{verbatim}
   authenticate.proxyauth.login = "myapplication"
   authenticate.proxyauth.password = "mypassword"
   \end{verbatim}

   See [RFC2617] for more details.

2. For proxy authentication, an entry must be made to the HTTP proxy configuration in order to authenticate a client.

   To authenticate a client known as \texttt{myapplication} and with \texttt{mypassword} as password by the HTTP Proxy, add the following entry to the HTTP proxy configuration:

   \begin{verbatim}
   proxy.http.authenticate = "proxyauth"
   \end{verbatim}

   \textbf{Note:} To authenticate the client to a HTTPS proxy, replace \texttt{http} with \texttt{https}. 

Configure a WS client to access an HTTPS server
Configuration steps to access a server in HTTPS.

To configure access to an HTTPS server, you will need to configure for the client certificate, configure for the certificate authority list, and the add additional entries for the server to the fglprofile.

Important: On GMI mobile devices, FGLPROFILE settings are ignored: The device KeyChain must hold the server certificate authority.

1. Configure for the client certificate. See Configure for the client certificate on page 2474.
2. Configure for the certificate authority list. See Configure for the certificate authority list on page 2475.
3. Add configuration entries for the server to fglprofile.

The Genero Web Services client needs a set of configuration entries that specify the security configuration and the HTTP authentication when accessing an HTTPS server. The following entries must be defined with an unique identifier (such as myserver):

```
ws.myserver.url = "https://www.MyServer.com/cgi-bin/fglccgi.exe/ws/r/MyWebService"
ws.myserver.security = "id1"
```

(line breaks added for document readability)

- The unique identifier myserver can be used in the BDL client code in place of the actual URL.
- The security entry value (id1 in this example) must match the unique identifier defined by the client security entry created in 3 on page 2475.

Configure for the client certificate
You generate a client certificate and configure your application to use the client certificate generated. For production systems, you add the configuration details to fglprofile.

During development, if you do not have the certificate information in your fglprofile, Genero creates a certificate for you. When you move into production, however, the server provides a certificate for you, and you need to add the certificate information to the fglprofile.

1. Create the root certificate authority.
   a) Create the root certificate authority serial file.
   
   $$ echo 01 > MyCompanyCA.srl $$
   b) Create the Root Authority's Certificate Signing Request and private key.
   
   $$ openssl req -new -out MyCompanyCA.csr -keyout MyCompanyCA.pem $$
   c) Create the Root Certificate Authority for a period of validity of 2 years.
   
   (line breaks added for document readability)
   $$ openssl x509 -trustout -in MyCompanyCA.csr -out MyCompanyCA.crt -req -signkey MyCompanyCA.pem -days 730 $$
   (line breaks added for document readability)
   
   Note: The private key file (MyCompanyCA.pem) of a Root Certificate Authority must be handled with care. This file is responsible for the validity of all other certificates it has signed. As a result, it must not be accessible by other users.

2. Create the client's X.509 certificate and private key.
   a) Create the client serial file.
   
   $$ echo 01 > MyClient.srl $$
   b) Create the client's Certificate Signing Request and private key.
   
   $$ openssl req -new -out MyClient.csr $$
Note: By default, openssl outputs the private key in the privkey.pem file.

c) Remove the password from the RSA private key.

$ openssl rsa -in privkey.pem -out MyClient.pem

Note: The key is also renamed in MyClient.pem.

d) Create the client's Certificate trusted by the Root Certificate Authority (self-signed X.509 certificate valid for a period of 1 year).

(line breaks added for document readability)

$ openssl x509 -in MyClient.csr -out MyClient.crt -req -signkey MyClient.pem -CA MyCompanyCA.crt -CAkey MyCompanyCA.pem -days 365

Note: Most servers do not check the identity of the clients. For these servers, the client's certificate does not necessary need to be trusted; it is only used for data encryption purpose. If, however, the server performs client identification, you must trust a Certificate Authority in which it has total confidence concerning the validity of the client's certificates.

Note: The purpose of the client's Certificate is to identify the client to any server; therefore the subject of the certificate must correspond to the client's identity as it is known by the servers.

Note: To import the certificate in a keystore you can create a pkcs12 certificate.

3. Add the client's security configuration to fglprofile.

The client security entry defines the certificate and the associated private key used by the Genero Web Services client during communication with an HTTPS communication. The security entry must be defined with an unique identifier (id1 in this example).

security.id1.certificate = "MyClient.crt"
security.id1.privatekey = "MyClient.pem"

Note: If the private key is protected with a password, you must remove it or create a script that returns the password on demand.

A client certificate is created and your application is configured to use it. The client certificate is not self-signed but issued by a company, created with a root certificate.

Configure for the certificate authority list
When a client accesses a server with a certificate, the server sends back its certificate. The client needs to check to see if that certificate is trusted. This is done using a certificate authority list.

1. Create the client's certificate authority list.

   a) Save the certificate of the HTTPS server to disk.

      Type the server's URL in your Internet browser. When prompted, save the certificate to disk.

   b) Create the client's Certificate Authority List from the certificate that you saved to disk.

      $ openssl x509 -in ServerCertificate.crt -text >> ClientCAList.pem

      Note: All trusted certificate authorities are listed. All other certificates that were trusted by the Root Certificate Authority will also be considered as trusted by the client.

2. Set the global certificate authority list in fglprofile.

The global certificate authority list entry defines the file containing the certificate authority list used by the Genero Web Services client to validate all certificates coming from the different servers it will connect to.

security.global.ca = "ClientCAList.pem"
If `security.global.ca` is not defined, Genero Web Services will look to see whether the operating system has a keystore, otherwise `security.global.ca.lookuppath` will be used.

The client application is configured to use the appropriate certificate authority list to validate a server’s certificate.

**Writing a Web Services server application**

These topics cover creating a Genero Web Services server using the SOAP protocol.

- [Writing a Web services server function](#) on page 2476
- [WS server stubs and handlers](#) on page 2478
- [Writing a Web server application](#) on page 2481
- [Get HTTP headers information at WS server side](#) on page 2489
- [Choosing a web services style](#) on page 2491
- [Web services server program deployment](#) on page 2513
- [Configuring the apache web server for HTTPS](#) on page 2514

**Writing a Web services server function**

Writing a Web service with Genero is quite simple. You create a standard Genero function and publish it as a Web function (Web services operation) using methods from the classes in the COM library. There are restrictions on the function - input and output parameters are not allowed. By using global or module variables, however, to work around this exception.

See also [Tutorial: Writing a GWS Server Application](#)

The steps for writing a Web Services function:

1. [Define the input parameters](#) on page 2476
2. [Define the output parameters](#) on page 2477
3. [Write the BDL function](#) on page 2477
4. [Create and publish the Web services operation](#) on page 2477

**Define the input parameters**

As stated in the introduction, input parameters in Genero Web Service operations are not allowed. However, each Web Function can have one global variable or module variable that defines the input message of the function. This variable must be a record in which each field represents one of the input parameters of the Web Function.

The name of each field corresponds to the name used in the SOAP request. These fields are filled with the contents of the SOAP request by the Web Services engine just before executing the corresponding BDL function.

**Example**

```bdl
DEFINE add_in RECORD
    a INTEGER,
    b INTEGER
END RECORD
```

**Note:** Genero version 2.0 allows you to add optional attributes to the definition of data types. You can use attributes to map the BDL data types in a Genero application to their corresponding XML data types. See [Attributes to Customize XML Mapping](#) for additional information.
Define the output parameters

Output parameters in Genero Web Functions are not allowed, but each Web Function can have one global variable or module variable that defines the output message of the function. This message must be a record where each field represents one of the output parameters of the Web Function.

The name of each field corresponds to the name used in the SOAP request. These fields are retrieved from the Web Services engine immediately after executing the BDL function, and sent back to the client.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFINE add_out RECORD</td>
</tr>
<tr>
<td>r INTEGER</td>
</tr>
<tr>
<td>END RECORD</td>
</tr>
</tbody>
</table>

**Note:** GWS 2.0 allows you to add optional attributes to the definition of data types. You can use attributes to map the BDL data types in a Genero application to their corresponding XML data types. See Attributes to Customize XML Mapping for additional information.

Write the BDL function

A Web Function is a normal BDL function that uses the input and output records that you have defined.

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>FUNCTION add()</td>
</tr>
<tr>
<td>LET add_out.r = add_in.a + add_in.b</td>
</tr>
<tr>
<td>END FUNCTION</td>
</tr>
</tbody>
</table>

Create and publish the Web services operation

Methods are available in the Genero Web Services library (com) to:

- Define the Web Service, by creating a WebService object
- Define the Web Services operation for your function, by creating a WebOperation object
- Publish the operation - associate it with the Web Service object that you defined.

The com library must be imported into each module of a Web Services Server application.

The following abbreviated example is from the Web Services Server tutorial:

```sql
IMPORT com
...
FUNCTION createservice() |
  DEFINE serv com.WebService # A WebService
  DEFINE op com.WebOperation # Operation of a WebService

  --Create WebService object
  "http://tempuri.org/webservices")

  --Create WebOperation object
  LET op = com.WebOperation.CreateRPCStyle("add", "Add", add_in, add_out)

  --Publish the operation, associating it with the WebService object
  CALL serv.publishOperation(op,NULL)
...
END FUNCTION
```
See the Web Services Server tutorial and Choosing a Web Service Style for complete examples and explanations.

**WS server stubs and handlers**

To access a remote Web Service, you first must get the WSDL information from the service provider. Sample services can be found through UDDI registries (http://www.uddi.org), or on other sites such as XMethods (http://www.xmethods.net).

**Generating files for a GWS server**

You can write a Genero Web Services Server application for a Web Service that you have created; see Tutorial: Writing a Server Application.

If you want to make sure your Web Service is compatible with that of a third-party (an accounting application vendor, for example), you can use the fglwsdl tool to obtain the WSDL information that complies with that vendor's standards, and to generate corresponding files that can be used in your GWS Server application.

This example requests the Calculator Web Service information from the specified URL, and the output files will have the base name "ws_calculator".

```bash
```

For a server application, fglwsdl generates two files, which should not be modified:

- **filename.inc** - the globals file, containing declarations of global variables that can be used as input or output to functions accessing the Web Service operations. In our example, the file is `ws_calculatorService.inc`.
  - This file must be listed in a GLOBALS statement at the top of any .4gl modules that you write for your GWS Server application.
- **filename.4gl** - containing a function that creates the service described in the WSDL, publishes the operations of the service, and registers the service. In our example, the file is `ws_calculatorService.4gl`.
  - This file must be compiled and linked into your GWS Server application.

**Server handlers**

The COM library enables to intercept high-level web services operation on server side. You can now define three BDL functions via the following methods of the web service class. They will be executed at different steps of a web service request processing in order to modify the SOAP request, response or the generated WSDL document before or after the SOAP engine has processed it. This helps handle WS-* specifications not supported in the web service API.

- Method `registerWSDLHandler()`
- Method `registerInputRequestHandler()`
- Method `registerOutputRequestHandler()`

All three kinds of BDL callback functions must conform to this prototype:

```gd
FUNCTION CallbackHandler( doc xml.DomDocument )
    RETURNING xml.DomDocument
```

**Example 1: Modify the generation of a WSDL**

Register your handler with:

```gd
CALL serv.registerWsdllHandler("WSDLHandler")
```
where serv is of class com.WebService and WSDLHandler is the following function:

```plaintext
FUNCTION WSDLHandler(wsdl)
  DEFINE wsdl Xml.DomDocument
  DEFINE node Xml.DomNode
  DEFINE list Xml.DomNodeList
  DEFINE ind INTEGER
  DEFINE name STRING
  # Add a comment
  LET node = wsdl.createComment(
    "First modified WSDL via a BDL callback function")
  CALL wsdl.prependDocumentNode(node)
  # Rename input and output parameter in UPPERCASE
  LET list = wsdl.selectByXPath("
    //wsdl:definitions/wsdl:types/xsd:schema/
    xsd:complexType/xsd:sequence/xsd:element/xsd:complexType/
    xsd:sequence/xsd:element",NULL)
  -- first input parameter for selectByXPath above
  -- one string, no spaces!
  FOR ind=1 TO list.getCount()
    LET node = list.getItem(ind)
    LET name = node.getAttribute("name")
    LET name = name.toUpperCase()
    CALL node.setAttribute("name",name)
  END FOR
  RETURN wsdl
END FUNCTION
```

If NULL is returned from the callback function, an HTTP error will be sent and the ProcessServices() returns error code -20.

**Example 2: Change the SOAP incoming request**

Register your handler with:

```plaintext
CALL serv.registerInputRequestHandler("InputRequestHandler")
```

where serv is of class com.WebService and InputRequestHandler is this function:

```plaintext
FUNCTION InputRequestHandler(in)
  DEFINE in Xml.DomDocument
  DEFINE ind INTEGER
  DEFINE node Xml.DomNode
  DEFINE copy Xml.DomNode
  DEFINE tmp Xml.DomNode
  DEFINE parent Xml.DomNode
  DEFINE name STRING
  DEFINE list Xml.DomNodeList
  # Change input parameter below myrecord in lower case
  # to follow high-level web service
  LET list = in.SelectByXPath("//SOAP:Envelope/SOAP:Body/fjs:EchoDOCRecordRequest/fjs:myrecord/*",
   "SOAP","http://schemas.xmlsoap.org/soap/envelope/",
   "fjs","http://www.mycompany.com/webservices")
  FOR ind = 1 TO list.getCount()
    LET node = list.getItem(ind)
    LET parent = node.getParentNode()
    LET name = node.getLocalName()
    LET copy = in.createElementNS(node.getPrefix(),
      name.toLowerCase(),node.getNamespaceURI())
    LET tmp = node.getFirstChild()
    LET tmp = tmp.clone(true)
```
CALL copy.appendChild(tmp)
CALL parent.replaceChild(copy,node)
END FOR
RETURN in
END FUNCTION

If NULL is return from the callback function, a SOAP fault will be sent (but can be changed from the output handler) and the ProcessServices() returns error code -18.

Example 3: Modify the SOAP outgoing request

Register your handler with:

CALL serv.registerOutputRequestHandler("OutputRequestHandler")

where serv is of class com.WebService and OutputRequestHandler is this function:

FUNCTION OutputRequestHandler(out)
DEFINE out Xml.DomDocument
DEFINE ind INTEGER
DEFINE node Xml.DomNode
DEFINE copy Xml.DomNode
DEFINE tmp Xml.DomNode
DEFINE parent Xml.DomNode
DEFINE name STRING
DEFINE list Xml.DomNodeList
# Change output parameter below myrecord in uppercase
# before sending back to the client
FOR ind = 1 TO list.getCount()
LET node = list.getItem(ind)
LET parent = node.getParentNode()
LET name = node.getLocalName()
LET copy = out.createElementNS(node.getPrefix(),name.toUpperCase(), node.getNamespaceURI())
LET tmp = node.getFirstChild()
LET tmp = tmp.clone(true)
CALL copy.appendChild(tmp)
CALL parent.replaceChild(copy,node)
END FOR
RETURN out
END FUNCTION

If NULL is return from the callback function, a SOAP fault will be sent and the ProcessServices() returns error code -19.

Example output

In the generated file ws_calculatorService.inc, the definitions of the variables for the input and output record are the same as those generated for the Web Service Client application:

#VARIABLE : Add -- defines the global INPUT record
DEFINE Add RECORD ATTRIBUTES(XMLName="Add",
XMLNamespace="http://tempuri.org/")
   a INTEGER ATTRIBUTES(XMLName="a",XMLNamespace=""),
   b INTEGER ATTRIBUTES(XMLName="b",XMLNamespace="")
END RECORD

# VARIABLE : AddResponse -- defines the global OUTPUT record
The generated file `ws_calculatorService.4gl` contains a single function that creates the Calculator service, creates and publishes the service operations, and registers the Calculator service:

```gl
FUNCTION Createws_calculatorService()
    DEFINE service com.WebService
    DEFINE operation com.WebOperation
    ...  # Create Web Service
    LET service = com.WebService.CreateWebService("Calculator",
        "http://tempuri.org/")
    # Publish Operation : Add
    LET operation = com.WebOperation.CreateRPCStyle("Add","Add",
        Add,AddResponse)
    CALL service.publishOperation(operation,"")  ...  # Register Service
    CALL com.WebServiceEngine.RegisterService(service)
    RETURN 0
END FUNCTION
```

**Writing your functions**

The `ws_calculatorService.4gl` file provides you with the global input and output records and function names that allow you to write your own code implementing the `Add` operation. Your new code should not be written in the generated modules. For example, do not add your own version of the `Add` function to the generated `ws_calculatorService.4gl` module; it can be included in your module containing the `MAIN` program block, or in a separate module to be included as part of the Web server application. The function must use the generated definitions for the global input and output records.

In your version of the operation, this function adds 100 to the sum of the variables in the input record:

```gl
FUNCTION Add()
    LET AddResponse.r = (Add.a + Add.b) + 100
END FUNCTION
```

See [Tutorial: Writing a Server application](tutorial_url) for more information. The `demo/WebServices` subdirectory of your Genero installation directory contains complete examples of Server Applications.

**Writing a Web server application**

This tutorial guides you through the steps to create a Server application for a Genero Web Service that can be accessed over the web by Client applications. A complete example is provided at `$FGLDIR/demo/WebServices`.

You can write your Server application based on input/output records that you have defined. Or, you can use the `fglwSDL` tool to include third-party WSDL information in your Server application.

**Including the web services library**

The methods associated with creating and publishing a Web Service are contained in the classes that make up the Genero Web Services Library (com). Include this line at the top of each module of your GWS Server application to import the library:

```gl
IMPORT com
```
Example 1: Writing the entire server application

You can define a Web Service in your application and write definitions for the input and output records that will be used by the Service. This example illustrates a Service that has one operation, Add, to provide the sum of two numbers.

- Step 1: Define input and output records on page 2482
- Step 2: Write a BDL function for each service operation on page 2482
- Step 3: Create the service and operations on page 2482
- Step 4: Register the service on page 2484
- Step 5: Start the GWS server and process requests on page 2484

Step 1: Define input and output records

Based on the desired functionality of the operations that you plan for the Service, define the input and output records for each operation. BDL functions that are written to implement a Web Service operation cannot have input parameters or return values. Instead, each function's input and output message must be defined as a global or module RECORD.

The Input message

The fields of the global or module record represent each of the input parameters of the Web Function. The name of each field in the record corresponds to the name used in the SOAP request. These fields are filled with the contents of the SOAP request by the Web Services engine just before executing the corresponding BDL function.

The Output message

The fields of the global or module record represent each of the output parameters of the Web Function. The name of each field in the record corresponds to the name used in the SOAP request. These fields are retrieved from the Web Services engine immediately after executing the BDL function, and sent back to the client.

Your Genero Web Services service has one planned operation that adds two integers and returns the result. The input and output records are defined as follows:

```
GLOBALS
DEFINE
  add_in RECORD   # input record
    a INTEGER,
    b INTEGER
END RECORD,
  add_out RECORD  # output record
    r INTEGER
END RECORD
END GLOBALS
```

Step 2: Write a BDL function for each service operation

You will need to write a function to implement each operation, using the input and output global records.

To implement your Add operation:

```
#User Public Functions
FUNCTION add()
  LET add_out.r = add_in.a + add_in.b
END FUNCTION
```

Step 3: Create the service and operations

The Genero Web Services library (com) provides classes and methods that allow you to use Genero BDL to configure a Web Service and its operations.
• **WebService** - this is a container for web operations.
• **WebOperation** - describes the operation.

**Define variables for the WebService and WebOperation objects**

```vbscript
FUNCTION createservice()
  DEFINE serv  com.WebService    # A WebService
  DEFINE op    com.WebOperation  # Operation of a WebService
END
```

**Choose a Namespace**

XML uses namespaces to group the element and attribute definitions, and to avoid conflicting names. In practice, a namespace must be a unique identifier (URI: Uniform Resource Identifier). If you do not know the unique identifier to use, your company's Web site domain name is guaranteed to be unique (such as "www.mycompany.com"); then, append any string.

Examples of valid namespaces for the fictional My Company company:

- "http://www.mycompany.com/MyServices"
- "http://www.mycompany.com/any_string"

Another option (for testing only) is to use the temporary namespace "http://tempuri.org/".

**Create the WebService object**

Call the constructor method of the *WebService* class. The parameters are:

1. Service name
2. Valid namespace

This example uses the temporary namespace and creates a Service named "MyCalculator".

```vbscript
LET serv =
```

**Create the WebOperation object**

A WebService object can have multiple operations. The operations can be created in RPC style or Document style by calling the corresponding constructor method of the *WebOperation* class. The parameters are:

1. the name of the BDL function that is executed to process the XML operation
2. the name you wish to assign to the XML operation
3. the input record defining the input parameters of the operation (or NULL if there is none)
4. the output record defining the output parameters of the operation (or NULL if there is none)

To create the operation for the previously defined `add` function in RPC style:

```vbscript
LET op = com.WebOperation.CreateRPCStyle("add", "Add", add_in, add_out)
```

To create the operation for the previously defined `add` function in Document style:

```vbscript
LET op = com.WebOperation.CreateDOCStyle("add", "Add", add_in, add_out)
```

Mixing RPC style and Document style operations in the same service is not recommended, as it is not WS-I compliant. See [Web Services Styles](#) for additional information about styles.

The rest of the code in your application is the same, regardless of the Web Services style that you have chosen.
Publish the operation

Once an operation is defined, it must be associated with its corresponding WebService (the operation must be published). The publishOperation method of the WebService object has the following parameters:

- the WebOperation to be published
- a string to identify the operation if several operations have the same name; if this is NULL, the default value is an empty string

For example, to publish the Add operation of the Calculator service, which was defined as op:

```
CALL serv.publishOperation(op,NULL)
```

Step 4: Register the service

Once the Service and operations are defined and the operations are published, the WebService and WebOperation objects have completed their work. Registering a service puts the Genero DVM in charge of the execution of all the operations of that service - dispatching the incoming message to the right service, returning the correct output, and so on. The same service may be registered at different locations on the Web.

The WebServiceEngine is a global built-in object that manages the Server part of the Genero DVM. Use the RegisterService class method of the WebServiceEngine class. The parameter is:

1. The name of the WebService object

To register the Calculator service example created in Step 3: Create the service and operations on page 2482:

```
CALL com.WebServiceEngine.RegisterService(serv)
END FUNCTION
```

Note: If you wanted to create a single GWS Server DVM containing multiple Web Services, you could define additional input and output records and repeat steps 2 through 6 for each Web Service. In Step 5: Start the GWS server and process requests on page 2484, a GWS Server DVM is started, containing as many Web Services as you have defined. See Web services server program deployment on page 2513 for additional discussion of GWS Services and GWS Servers.

Step 5: Start the GWS server and process requests

Once you have registered the Web Service(s), you are ready to start the Genero Web Services (GWS) Server and process the incoming SOAP requests.

The GWS Server is located on the same physical machine where the application is being executed (In other words, where fglrun executes).

This is the MAIN program block of your application.

Define a variable for status

Define a variable to hold the returned status of the request:

```
MAIN
DEFINE ret INTEGER
```

Call the function that you created, which defined and registered the service and its operations:

```
CALL createservice()
```
Start the GWS Server

Use the Start class method of the WebServiceEngine class to start the server.

```
CALL com.WebServiceEngine.Start()
```

Process the requests

This example uses the ProcessServices method of the WebServiceEngine class to process each incoming request. It returns an integer representing the status. The parameter specifies the timeout period (in seconds) for which the method should wait to process a service. The value -1 specifies an infinite waiting time.

```
WHILE TRUE
    # Process each incoming requests (infinite loop)
    LET ret = com.WebServiceEngine.ProcessServices(-1)
    CASE ret
        WHEN 0
            DISPLAY "Request processed."
        WHEN -1
            DISPLAY "Timeout reached."
        WHEN -2
            DISPLAY "Disconnected from application server."
            EXIT PROGRAM
        WHEN -3
            DISPLAY "Client Connection lost."
        WHEN -4
            DISPLAY "Server interrupted with Ctrl-C."
        WHEN -10
            DISPLAY "Internal server error."
            EXIT PROGRAM
        WHEN -15
            DISPLAY "Server was not started."
            EXIT PROGRAM
        OTHERWISE
            DISPLAY "ERROR: ", STATUS, SQLCA.SQLERRM
    END CASE
    IF int_flag<>0 THEN
        LET int_flag=0
    EXIT WHILE
    END IF
END WHILE
DISPLAY "Server stopped"
END MAIN
```

**Note:** For testing purposes only, the GWS Server can be started in standalone mode. In a production environment, the Genero Application Server (GAS) is required to manage your application. For deployment, the GWS Server application must be added to the GAS configuration. See **Adding Applications** in the Genero Application Server User Guide.

Example 2: Writing a server using third-party WSDL (the fglwsdl tool)

To write a Web Service that is compatible with the specification of the input and output records defined by a third-party (for example, a vendor of manufacturing software, or a WSDL specialist in your company) you can use the fglwsdl tool to obtain the WSDL information and generate a part of the Server application. See fglwsdl on page 1507 for a complete description of the tool and its use.

- **Step 1:** Get the WSDL description and generate files on page 2486
- **Step 2:** Write a BDL function for your service operation on page 2487
- **Step 3:** Create service, start server and process requests on page 2487
Step 1: Get the WSDL description and generate files

This tutorial uses fglwsdl and the Calculator Service defined in Example 1: Writing the entire server application on page 2482 to obtain the WSDL information and generate two corresponding BDL files:

- the globals file, containing declarations of global variables that can be used as input or output to functions accessing the Web Service operations.
- a .4gl file containing a function that creates the service described in the WSDL, publishes the operations of the service, and registers the service.

```
fglwsdl -s -o example1 http://localhost:8090/MyCalculator?WSDL
```

Note: the MyCalculator Genero Web Services Service created in Example 1: Writing the entire server application on page 2482 must be running in order to obtain the WSDL information.

The generated globals file

The globals file example1Service.inc provides the definition of the global input and output records as described in the Step 1: Define input and output records on page 2482 of the Example 1: Writing the entire server application on page 2482 of the Example 1: Writing the entire server application GWS Server program. The names of the input and output records have been assigned by fglwsdl, in accordance with the Style of the Web Service MyCalculator (created as RPCStyle in the Example1 program). Do not modify this file.

Input and output records:

```
# VARIABLE : Add
DEFINE Add RECORD
  ATTRIBUTES( XMLName="Add",
    xmlns="http://tempuri.org/webservices"
  )
a INTEGER ATTRIBUTES(XMLName="a",xmlns="" ),
b INTEGER ATTRIBUTES(XMLName="b",xmlns="" )
END RECORD

# VARIABLE : AddResponse
DEFINE AddResponse RECORD
  ATTRIBUTES( XMLName="AddResponse",
    xmlns="http://tempuri.org/webservices"
  )
r INTEGER ATTRIBUTES(XMLName="r",xmlns="" )
END RECORD
```

The generated .4gl file

The example1Service.4gl file contains a single function that creates the service, publishes the operation, and registers the Service. The Web Service Style that is created is determined by the style specified in the WSDL information. The functions in this file accomplish the same tasks as Step 3: Create the service and operations on page 2482 and Step 4: Register the service on page 2484 of Example 1. Do not modify this file.

```
# example1Service.4gl
# Generated file containing the function Createexample1Service

IMPORT com
GLOBALS "example1Service.inc"

# FUNCTION Createexample1Service
#   RETURNING soapstatus
FUNCTION Createexample1Service()
DEFINE service com.WebService
DEFINE operation com.WebOperation
# Set ERROR handler
WHENEVER ANY ERROR GOTO error
```
# Create Web Service

LET service = com.WebService.CreateWebService(
    "MyCalculator",
    "http://tempuri.org/webservices"
)

# Operation: Add
# Publish Operation: Add
LET operation = com.WebOperation.CreateRPCStyle(
    "Add",
    "Add",
    Add,
    AddResponse
)

CALL service.publishOperation(operation,""

# Register Service
CALL com.WebServiceEngine.RegisterService(service)
RETURN 0

# ERROR handler
LABEL error:
RETURN STATUS

# Unset ERROR handler
WHENEVER ANY ERROR STOP

END FUNCTION

Step 2: Write a BDL function for your service operation

Using the information from these generated files, the Add operation from Example 1: Writing the entire server application on page 2482 is rewritten to have different functionality but to still be compatible with the WSDL description of the operation. This step accomplishes the same thing as Step 2: Write a BDL function for each service operation on page 2482 in Example 1. In this version of the add operation, the sum of the two numbers in the input record is increased by 100.

```gd
# my_function.4gl               -- file containing the function definition
IMPORT com                      -- import the Web Services library
GLOBALS "example1Service.inc"   -- use the generated globals file
# User Public Functions
FUNCTION add()                  -- new version of the add function
    LET AddResponse.r = (Add.a + Add.b)+ 100  -- the global input and output records are used
END FUNCTION
```

Step 3: Create service, start server and process requests

Create your own Main module that calls the function from the generated .4gl file to create the service, and then starts the Genero Web Services Server and manages requests as in Step 5: Start the GWS server and process requests on page 2484 of Example 1: Writing the entire server application on page 2482.

```gd
# example2main.4gl file          -- contains the MAIN program block
IMPORT com
GLOBALS "example1Service.inc"

MAIN
    DEFINE create_status INTEGER
    DEFER INTERRUPT
    CALL Createexample1Service()   -- call the function generated in example1Service.4gl
    RETURNING create_status
    IF create_status <> 0 THEN
        DISPLAY "error"
    END IF
```
ELSE
    # Start the server and manage requests
    CALL ManageService()
END IF

END MAIN

FUNCTION ManageService()
    DEFINE ret INTEGER
    CALL com.WebServiceEngine.start()
    WHILE TRUE
        # continue as in Step 5 of Example 1
        ...
    END WHILE
END FUNCTION

Compiling GWS server applications

The library file WSHelper.42m, included in the $FGLDIR/lib directory of the Genero Web Services package, should be linked into every GWS Server application.

If your application uses the fglwsdl tool to generate information, link the .4gl generated file into the application.

Examples

Compiling the Example 1: Writing the entire server application on page 2482 program:

fglcomp example1.4gl
fgllink -o example1.42r example1.42m WSHelper.42m

Compiling the Example 2: Writing a server using third-party WSDL (the fglwsdl tool) on page 2485 program:

fglcomp example2main.4gl my_function.4gl example1Service.4gl
fgllink -o example2.42r example2main.42m my function.42m
example1Service.42m WSHelper.42m

Testing the GWS service in stand-alone mode

For testing and development purposes only, the Genero Web Services Server application can be executed directly, without using the Genero Application Server (GAS).

1. Use the Genero fglrun command to execute the GWS Server application, which must reside on the same machine:

fglrun <gws application>

This will start the GWS Server on the port specified by the FGLAPPSERVER environment variable. If this environment variable is not set for the user, port number 80 is used. For example, if FGLAPPSERVER is set to 8090, the server will be started on that port.

   Note: The user must not set the FGLAPPSERVER variable in production environments, since the port number is selected by the Genero Application Server.

2. Obtain the WSDL information for your Service and write a test Client application. If the GWS Server in step 1 was started on your local machine, for example, the command to get the WSDL information would be:

fglwsdl -o <test-client> http://localhost:8090/<service-name>?WSDL
**Configuring the Genero application server for the GWS Application**

The final step is to configure the Genero Application Server (GAS) to handle the GWS application. In a production environment, Genero Web Services becomes a part of a global application architecture handled by the application server of the **GAS** package. See [Web services server program deployment](#) on page 2513, as well as *Adding Applications* in the GAS manual.

**Making the GWS service available**

Once you compile and deploy your Genero Web Services Server application (see [Web services server program deployment](#) on page 2513), it can be used by others to obtain the WSDL information and write a client application that accesses your Genero Web Service. See [Steps to write a WS client](#) on page 2458.

Your company can provide the location of the GWS Server to potential users of your Web Service in various ways. For example:

- Provide the location on a company web site
- Register the Web Service with UDDI (Universal Description, Discovery, and Integration) - the XML-based registry providing Internet listings for companies worldwide
- Communicate directly with your potential users

**Get HTTP headers information at WS server side**

In high level web services, we now give access to the HTTP headers request and response.

The web service can get information from the request headers and reply with custom headers and status.

1. Declare variables to receive or send HTTP headers.
2. Register these variables to the web service server.

**Declare variables to receive or send HTTP headers**

The variable for the request headers:

```gen
DEFINE http_in RECORD
  verb STRING,
  url STRING,
  headers DYNAMIC ARRAY OF RECORD
    name STRING,
    value STRING
  END RECORD
END RECORD
```

After the web service operation has been processed, the variable is set to NULL.

The variable for the response headers:

```gen
DEFINE http_out RECORD
  code INTEGER,
  desc STRING,
  headers DYNAMIC ARRAY OF RECORD
    name STRING,
    value STRING
  END RECORD
END RECORD
```

After the web service operation has been processed, the variable is set to NULL.

**Note:** While the variables must follow the structure shown, the variable name can be any name you choose.

The web service engine headers have precedence. For example, if you set the "Content-Length" value, the one that is taken into account is the one defined by the Genero Web Services engine.
Register the variables to the server

This code example uses two methods, which use the defined variables:

- `com.WebService.registerInputHttpVariable(http_in)` where `http_in` is the RECORD variable for the request headers.
- `com.WebService.registerOutputHttpVariable(http_out)` where `http_out` is the RECORD variable for the response headers

Example

```plaintext
FUNCTION CreateService()

DEFINE serv com.WebService # WebService
DEFINE op com.WebOperation # Operation of a WebService

TRY
  # Create a Web Service
  LET serv = com.WebService.CreateWebService("EchoHttpHeadersService", Namespace)

  # Create Document Style Operations
  # EchoDOCRecord
  LET op = com.WebOperation.CreateDOCStyle("echoDocRecord", "EchoDOCRecord", echoRecordDoc_in, echoRecordDoc_out)

  CALL serv.publishOperation(op,NULL)

  # Register HTTP input
  CALL serv.registerInputHttpVariable(http_in)

  # Register HTTP output
  CALL serv.registerOutputHttpVariable(http_out)

  # Register service
  CALL com.WebServiceEngine.RegisterService(serv)
  DISPLAY "EchoHttpHeadersService Service registered"
CATCH
  DISPLAY "Unable to create 'EchoHttpHeadersService' Web Service : ", STATUS||" ("||SQLCA.SQLERRM||")"
  EXIT PROGRAM (-1)
END TRY
END FUNCTION

FUNCTION echoDocRecord()

DEFINE ind INTEGER
DEFINE ok BOOLEAN

  # Check incoming VERB
  IF http_in.verb != "POST" THEN
    LET http_out.code = 400
    LET http_out.desc = "Bad request: method should be POST"
    RETURN
  END IF

  # Check incoming query string
  IF http_in.url.getIndexOF("?MyQuery=OK",1)<=0 THEN
```
LET http_out.code = 400
LET http_out.desc = "Bad request: URL should have MyQuery=OK"
RETURN
END IF

# Check incoming header called MyPersonal
LET ok = FALSE
FOR ind = 1 TO http_in.headers.getLength()
  DISPLAY ind||"# ",http_in.headers[ind].name,
    ",=",http_in.headers[ind].value
  IF http_in.headers[ind].name == "MyPersonal" THEN
    IF http_in.headers[ind].value == "Header" THEN
      LET ok = TRUE
    END IF
  END IF
END FOR
IF NOT ok THEN
  LET http_out.code = 400
  LET http_out.desc = "Bad request: expected additional header called MyPersonal"
  RETURN
END IF

# assign the output record
LET echoRecordDoc_out.MyRecord.MyInt =
  echoRecordDoc_in.MyRecord.MyInt
LET echoRecordDoc_out.MyRecord.MyFloat =
  echoRecordDoc_in.MyRecord.MyFloat

# Add MyPersonalHeader=MyPersonalValue http headers
LET http_out.headers[1].name = "MyPersonalHeader"
LET http_out.headers[1].value = "MyPersonalValue"

END FUNCTION

**Choosing a web services style**

Genero Web Services 2.0 allows you to create Web Services operations in the following styles:

**Table 563: Web Services Styles**

<table>
<thead>
<tr>
<th>Web Services Style</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RPC Style Service (RPC/Literal)</td>
<td>Generally used to execute a function, such as a service that returns a stock option.</td>
</tr>
<tr>
<td>Document Style Service (Doc/Literal)</td>
<td>Generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document; this is the MS.Net default. Both RPC/Literal and Doc/Literal Styles are WS-I compliant (Web Services Interoperability organization).</td>
</tr>
<tr>
<td>RPC Style Service (RPC/Encoded)</td>
<td>Provided only for backwards compatibility with older versions of web services already published. Important: This style is deprecated by the WS-I organization, and is not recommended, as most Web Service</td>
</tr>
</tbody>
</table>
Web Services Style | Description
---|---
| | implementations won’t support it in the future.

The style of service to be created is specified in the Genero application for the Web Service, using the following methods of the `WebOperation` class from from the Web Services COM Library (`com`). The parameters are the same for both methods:

1. The name of the BDL function that is executed to process the Web Service operation
2. The name you wish to assign to the Web Service operation
3. The input record defining the input parameters of the operation (or NULL if there is none)
4. The output record defining the output parameters of the operation (or NULL if there is none)

```plaintext
LET op = com.WebOperation.CreateRPCStyle("add","Add", add_in, add_out)
LET op = com.WebOperation.CreateDOCStyle("checkInvoice", "CheckInvoice", invoice_in, invoice_out)
```

Calling the appropriate function for the desired style is the only difference in your Genero code that creates the service. The remainder of the code that describes the service is the same, regardless of whether you want to create an RPC or Document style of service.

**Important:** Do not use the `setInputEncoded()` and `setOutputEncoded()` methods of the `WebService` class from the Web Services COM Library (`com`), as they apply only to RPC/Encoded Style, which is not recommended.

**Note:** If you add headers to your RPC Style service, choose the Literal serialization mechanism by setting the `encoded` parameter of the `createHeader()` method to FALSE:

```plaintext
CALL serv.createHeader(var,FALSE)
```

**Note:** GWS release 2.0 allows you to create RPC Style and Document Style operations in the same Web Service. However, we do not recommend this, as it is not WS-I compliant.

**How Do I … ?**

These topics provide you with the information needed to perform specific tasks related to Genero Web Services using the SOAP protocol.

**Tip:** See here for other Web services "How Do I … ?“ topics.

- Fix Genero 2.10 to 2.11 WSDL generation issue on page 2492
- How to handle WS security on page 2494

**Fix Genero 2.10 to 2.11 WSDL generation issue**

How to convert a WSDL generated from a Genero 2.11 (or later) application to a WSDL as generated by Genero 2.10.

Since Genero 2.11, each BDL variable generates a associated named complexType in the WSDL and references it. While this does not impact the Web service, some tools will generate additional client stubs to follow the WSDL definition with the named complexType. As a result, any client program written from a WSDL generated in 2.10 must be reviewed if it uses a WSDL generated in 2.11 or later.

If you do not want to modify your application, you can use the WSDL conversion tool program to remove the named complexType and add the unnamed equivalent as child node of the parameter variable of all Web service operations, as if the WSDL would have been generated in 2.10.
**WSDL conversion tool**

This program reads a WSDL, looks for all named complexType used in all the web operation parameters and modifies them in order to have unnamed complexType instead.

```
IMPORT XML
MAIN
DEFINE
doc xml.DomDocument,
    list, elist, tlist xml.DomNodeList,
    node, enode, nnode xml.DomNode,
    i, j, k, idx INTEGER,
    ename, tname STRING

IF num_args() <> 1 THEN
    CALL display_help()
    RETURN 0
END IF

TRY
    LET doc = xml.DomDocument.Create()
    CALL doc.setFeature("whitespace-in-element-content",FALSE)
    CALL doc.load(arg_val(1))
    # get the list of input/output message
    # check if their names (x) are defined as elements with types (y)
    # if yes then
    # copy the complextype y definition to element name x
    # and remove the complexe type y definition
    # for example:
    # message
    # <wsdl:message name="is_OKIn">
    # <wsdl:part name="parameters" element="fjs:is_OKRequest" />
    # </wsdl:message>
    # <wsdl:message name="is_OKOut">
    # <wsdl:part name="parameters" element="fjs:is_OKResponse" />
    # </wsdl:message>
    # element
    # <xsd:element name="is_OKResponse"
    #    type="s1:is_OKResponse_is_OKResponse" />
    # type
    # <xsd:complexType name="is_OKRequest_is_OKRequest">
    LET list =
        doc.selectByXPath("//wsdl:part[@name='parameters']/@element",
            "wsdl","http://schemas.xmlsoap.org/wsdl/")
    IF list IS NULL THEN
        DISPLAY "Nothing to convert."
    END IF
    FOR i=1 TO list.getCount()
        LET node = list.getItem(i)
        LET ename = node.getNodeValue()
        LET idx = ename.getIndexOf(":",1)
        IF idx <> 0 THEN
            LET ename = ename.subString(idx+1,ename.getLength())
        END IF
        # get the element
        LET elist =
            doc.selectByXPath("//xsd:element[@name='" || ename || "]",
                "xsd","http://www.w3.org/2001/XMLSchema")
        IF elist IS NOT NULL THEN
            FOR j=1 TO elist.getCount()
                LET enode = elist.getItem(j)
                LET tname = enode.getAttribute("type")
                CALL enode.removeAttribute("type")
            END FOR
        END IF
    END FOR
END TRY
```
Example of use:

$ fglrun Convert Genero2_21.wsdl
$ Document is saved in result.wsdl

How to handle WS security

Genero Web Services does not entirely manage WS-Security. We provide XML APIs to help the development of Web Services with security.

Introduction

This topic describes how to handle WS Security using the demo wssecuritymessage. It is a sample that you can adapt to your needs. The demo will be enhanced to illustrate new features that will be introduced to fully support WS-Security.

The demo involves three clients exchanging secured messages. Those clients post and retrieve messages on a secured server. Each client is identified by a certificate and sign their messages.

We assume that you are familiar with security concepts described in topic "Encryption and Authentication Concepts".

The demo assumes that all the clients have sent their public keys to the other clients and to the server. Those keys are kept in each host's (server or clients) keystore. The certificates included in this package
are provided for demonstration purposes only. As they are distributed with this package, anybody using this product can decrypt the messages exchanged. Do NOT use them in production.

**Server side**

We provide 3 handlers to handle WS Security:

- Method `com.WebService.registerWSDLHandler()` to modify the wsdl to add WS policy.

In this demo, a received message is processed:

1. Identify the sender and validate the sender (search in keystore)
2. Decrypt the symmetric key with the server private key
3. Decrypt the body
4. Check the signature with the sender public key
5. Store the message in the box (thanks to the "To" field, "subject" and "message")
6. Create the outgoing message
7. Sign the outgoing message
8. Encrypt the outgoing message with a generated symmetric key. This symmetric key is then encrypted with the client public key.

**Client side**

The client consists in sending a message and retrieving messages clients sent to it.

Before that, create the client stub from the wsdl:

- `fglwsdl -domHandler myservice.wsdl`

The client stub reference handlers:

- `SecureMessageBox_HandleRequest`
- `SecureMessageBox_HandleResponse`
- `SecureMessageBox_HandleResponseFault`

For more details about client SOAP handlers see [Client stub and handlers](#).

What to do when a message is sent:

- Sign and encrypt the request for the server (WS-Security)
  - sign with client private key
  - encrypt with server public key
- Send key information in the request
  - key to identify the sender/client
  - key to identify the recipient/server
  - key used to encrypt the data (usually a symmetric key encrypted by the recipient public key)
- If the message has to be encrypted for the final recipient (XML-Security)
  - sign the message
  - encrypt the message

What to do to retrieve messages:

- Identify the sender and validate the sender (search in keystore)
- Identify the recipient (should be the server itself)
- Decrypt the request
- Check the signature
- Retrieve messages for the recipient
**SOAP security standards**

The policy documentation can be found [here](#).

The demo policy is divided into sections (make sure that the naming are correct and that the structure is understandable):

- **Security bindings** on page 2496
- **SOAP message security options** on page 2498
- **SignedParts** on page 2498
- **EncryptedParts** on page 2498

WS Security section begins with:

```xml
```

It defines rules:

```xml
<wsp:ExactlyOne>
</wsp:ExactlyOne>
```

Only one assertion should be fulfilled.

```xml
<wsp:All>
</wsp:All>
```

All the assertions should be fulfilled.

**Security bindings**

There are 3 types of security binding:

- TransportBinding
- SymmetricBinding
- AsymmetricBinding

The current demo uses the Asymmetric binding.

**Asymmetric Binding**

This section is divided in sub sections:

- InitiatorToken
- RecipientToken
- AlgorithmSuite
- Layout
- Additional assertions

AsymmetricBinding is the root node for protection description.

```xml
```

**InitiatorToken**

InitiatorToken is the message sender (client)

For example:

```xml
<sp:InitiatorToken>
  <wsp:Policy>
  </wsp:Policy>
</sp:InitiatorToken>
```
Note: The value for the sp:IncludeToken attribute is one contiguous string with no spaces. For this document, it is shown covering two lines.

The token is used for the message signature from initiator to recipient and encryption from recipient to initiator.

The initiator key is a X509 certificate that is always sent to the recipient.

sp:IncludeToken attribute indicates if the token must be included.

IncludeToken/AlwaysToRecipient means each requests sent to the recipient must include the initiator token. But the token should not be included in messages from recipient to initiator.

The token must send its Thumbprint Reference.

The token must be of type X509 version 1 as defined in "X509 token profile 1.0".

What should be done in BDL is described in Client Side section.

To retrieve the thumbprint reference you can use the API function xml.CryptoX509.getThumbprintSHA1.

To create the x509 certificate use an appropriate tool like openssl.

RecipientToken

RecipientToken is the message receiver (server)

Note: The value for the sp:IncludeToken attribute is one contiguous string with no spaces. For this document, it is shown covering two lines.

The token is used for encryption from initiator to recipient, and for the message signature from recipient to initiator.

The recipient key is a X509 certificate that is never sent to the initiator.

sp:IncludeToken attribute indicates if the token must be included.

IncludeToken/Never means the token should not be included in any requests between the initiator and the recipient.

Instead the recipient ThumbprintReference is sent.

The token must be of type X509 version 3 as defined in "X509 token profile 1.0".

What should be done in BDL is described in Server Side section. To retrieve the thumbprint reference you can use the API function xml.CryptoX509.getThumbprintSHA1. To create the appropriate certificate use an appropriate tool like openssl.
AlgorithmSuite

AlgorithmSuite tells which algorithm is used to encrypt the data.

```xml
<sp:AlgorithmSuite>
  <wsp:Policy>
    <sp:TripleDesRsa15 />  
  </wsp:Policy>
</sp:AlgorithmSuite>
```

TripleDesRsa15 refers to key http://www.w3.org/2001/04/xmlenc#tripledes-cbc.

Layout

Layout describes the way information are added to the message header.

```xml
<sp:Layout>
  <wsp:Policy>
    <sp:Strict />  
  </wsp:Policy>
</sp:Layout>
```

For example, with Strict layout, token that are included in the message must be declared before use. For more details on the rules to follow see the security policy specifications section 7.7.

Additional Assertions

PartsToSign

```xml
<sp:OnlySignEntireHeadersAndBody />  
```

The assertion means if there is any signature on the header or the body it should be on the entire header and the entire body not on their child element.

SOAP message security options

```xml
  <sp:MustSupportRefKeyIdentifier />  
  <sp:MustSupportRefIssuerSerial />  
</sp:Wss10>
```

- MustSupportRefKeyIdentifier means that initiator and recipient are able to generate and process key identifier reference.
- MustSupportRefIssuerSerial means that initiator and recipient are able to generate and process issuer and token serial reference.

SignedParts

The SignedParts section tells which part of the message should be signed.

```xml
  <sp:Body />  
</sp:SignedParts>
```

- Only the body needs to be signed

EncryptedParts

The section EncryptedParts tells which part of the message should be encrypted.

```xml
```

- Only the body needs to be signed
• sp:Body indicates the body message needs to be encrypted

Encrypt the body using the algorithm referenced in assertion AlgorithmSuite:

• create an encryption key using TripleDesRsa15 algorithm (i.e. generate a TripleDES symmetric key and then encrypt it with a RSA1.5 public key) like example2 in crypto key chapter that uses AES256.
• encrypt the body with the created key

To find the exact syntax of security message read the specifications "Web Services Security: SOAP Message Security 1.0".

RESTful Web Services

While RESTful Web Services are supported, the RESTful Web Services documentation is not yet completed.

The Genero APIs for creating Web services can be found in the Library section of this manual. See The com package on page 2017 and The xml package on page 2111.

How Do I … ?

These topics provide you with the information needed to perform specific tasks related to Genero Web Services (SOAP or RESTful).

Tip: See here for SOAP-specific “How Do I … ?” topics.

• Call Java APIs from Genero in a SOA environment on page 2499
• Call .NET APIs from Genero in a SOA environment on page 2504
• Compute a hash value from a BDL string on page 2511

Call Java APIs from Genero in a SOA environment

How to call a Java library from Genero in a SOA environment, using Genero and Java Web services.

This can easily be done using the Java JAX-WS framework on a server, and a Genero application for the client part.

Note: There is no strong linkage between Genero and a java JVM.

These topics are presented as a tutorial that uses a Java barcode creation library to build a picture from a code.

Recommendation

The usage of Genero Web Services to call a Java™ service is recommended in a SOA environment. It enables several Genero applications to connect to a centralized Java™ service without the need to start a new JVM for each running Genero application. It also provides more flexibility because there is no strong linkage between Genero and the Java™ virtual machine. You can for instance upgrade the Java™ service without changing anything in your Genero code.
However, due to the XML serialization process and the HTTP transport protocol in Web Services, there can be some performance issues. So if your main concern is performance, it is recommended to use the Genero Java™ bridge.

**Prerequisites**

- A JRE 1.5 or above
- The Java™ barcode library (available [here](#))
  - You must add these JARs to the Java™ CLASSPATH: barcode.jar and BarcodeReader.jar
  - The trial version has some functions partially implemented.
- Download the JAX-WS framework from the Sun metro project [here](#); add this JAR to the java CLASSPATH: webservices-tools.jar

**Using the barcode library**

The barcode library is composed of two libraries:

- A library for building a barcode image from a numeric code
- A library for reading a barcode image to return the numeric code

This section depends on the library you want to use in Genero.

In our tutorial, we create two functions called **buildImage** and **readImage**.

This is the Java™ implementation:

```java
buildImage( type : String, code : String) : byte[]

try {
    Barcode builder=new Barcode();
    builder.setType(GetBarcodeBuilderType(type));
    builder.setData(data);
    builder.setAddCheckSum(true);
    ByteArrayOutputStream out=new ByteArrayOutputStream();
    if (builder.createBarcodeImage(out)) {
        byte[] ret = out.toByteArray();
        return ret;
    } else {
        return null;
    }
} catch (Exception e) {
    return null;
}
```

```java
readImage( type : String, img : byte[]) : String

try {
    File f=new File("tmp.jpg");
    FileOutputStream stream=new FileOutputStream(f);
    stream.write(img);
    stream.close();  String[] datas =
    BarcodeReader.read(f, GetBarcodeReaderType(type));
    if (datas==null) {
        return null;
    } else {
        String ret = datas[0];
        return ret;
    }
} catch (Exception e) {
    return null;
}
```
The following two functions convert the type of a code bar to the type expected by the library:

```java
private int GetBarcodeBuilderType(String str) {
    if (str.equals("CODABAR")) {
        return Barcode.CODABAR;
    }
    else if (str.equals("CODE11")) {
        return Barcode.CODE11;
    } else if (str.equals("CODE128")) {
        return Barcode.CODE128;
    } else if (str.equals("CODE128A")) {
        return Barcode.CODE128A;
    } else if (str.equals("CODE128B")) {
        return Barcode.CODE128B;
    } else if (str.equals("CODE128C")) {
        return Barcode.CODE128C;
    } else if (str.equals("CODE2OF5")) {
        return Barcode.CODE2OF5;
    } else if (str.equals("CODE39")) {
        return Barcode.CODE39;
    } else if (str.equals("CODE39EX")) {
        return Barcode.CODE39EX;
    } else if (str.equals("CODE93")) {
        return Barcode.CODE93;
    } else if (str.equals("CODE93EX")) {
        return Barcode.CODE93EX;
    } else if (str.equals("EAN13")) {
        return Barcode.EAN13;
    } else if (str.equals("EAN13_2")) {
        return Barcode.EAN13_2;
    } else if (str.equals("EAN13_5")) {
        return Barcode.EAN13_5;
    } else if (str.equals("EAN8")) {
        return Barcode.EAN8;
    } else if (str.equals("EAN8_2")) {
        return Barcode.EAN8_2;
    } else if (str.equals("EAN8_5")) {
        return Barcode.EAN8_5;
    } else if (str.equals("INTERLEAVED25")) {
        return Barcode.INTERLEAVED25;
    } else if (str.equals("ITF14")) {
        return Barcode.ITF14;
    } else if (str.equals("ONECODE")) {
        return Barcode.ONECODE;
    } else if (str.equals("PLANET")) {
        return Barcode.PLANET;
    } else if (str.equals("POSTNET")) {
        return Barcode.POSTNET;
    } else if (str.equals("RM4SCC")) {
        return Barcode.RM4SCC;
    } else if (str.equals("UPCA")) {
        return Barcode.UPCA;
    } else if (str.equals("UPCE")) {
        return Barcode.UPCE;
    } else {
        return -1;
    }
}

private int GetBarcodeReaderType(String str) {
    if (str.equals("CODABAR")) {
        return BarcodeReader.CODABAR;
    }
    else if (str.equals("CODE11")) {
        return BarcodeReader.CODE11;
    }
Calling Java™ from Genero

The integration of one or several Java™ libraries with multiple methods in a Genero application can be performed, as described in the following topics.

Step 1: Write a new java class

Instead of writing the functions in 4GL, you simply need to write them in a Java™ class with the methods you want to use in 4GL. In our example, the two functions are buildImage and readImage. And of course, don't forget to import the necessary Java™ import instructions.

```java
import com.barcodelib.barcodereader.BarcodeReader;
import com.barcodelib.barcode.Barcode;
import java.io.*;
import javax.jws.*;
import javax.jws.soap.SOAPBinding;
import javax.xml.ws.Endpoint;

public class BarcodeService {
    public byte[] buildImage(String type, String data) {
        if (str.equals("CODE128")) {
            return BarcodeReader.CODE128;
        } else if (str.equals("CODE39")) {
            return BarcodeReader.CODE39;
        } else if (str.equals("CODE39EX")) {
            return BarcodeReader.CODE39EX;
        } else if (str.equals("CODE93")) {
            return BarcodeReader.CODE93;
        } else if (str.equals("DATAMATRIX")) {
            return BarcodeReader.DATAMATRIX;
        } else if (str.equals("EAN13")) {
            return BarcodeReader.EAN13;
        } else if (str.equals("EAN8")) {
            return BarcodeReader.EAN8;
        } else if (str.equals("INTERLEAVED25")) {
            return BarcodeReader.INTERLEAVED25;
        } else if (str.equals("ITF14")) {
            return BarcodeReader.ITF14;
        } else if (str.equals("ONECODE")) {
            return BarcodeReader.ONECODE;
        } else if (str.equals("PLANET")) {
            return BarcodeReader.PLANET;
        } else if (str.equals("POSTNET")) {
            return BarcodeReader.POSTNET;
        } else if (str.equals("QRCODE")) {
            return BarcodeReader.QRCODE;
        } else if (str.equals("RM4SCC")) {
            return BarcodeReader.RM4SCC;
        } else if (str.equals("RSS14")) {
            return BarcodeReader.RSS14;
        } else if (str.equals("RSSLIMITED")) {
            return BarcodeReader.RSSLIMITED;
        } else if (str.equals("UPCA")) {
            return BarcodeReader.UPCA;
        } else if (str.equals("UPCE")) {
            return BarcodeReader.UPCE;
        } else {
            return -1;
        }
    }
}
```
Notice that if you want the service to run standalone, you must also add following the main method to tell the system the port number on which the service will run:

```java
public static void main(String[] args) {
    String endpointUri = "http://localhost:9090/";
    Endpoint.publish(endpointUri, new BarcodeService ());
    System.out.println("BarcodeService started at " + endpointUri);
}
```

**Step 2: Transform the Java™ class in a web service**

To transform the previous java class in a Web Service, simply add a WebService annotation:

```java
@WebService(targetNamespace = http://www.mycompany.com/barcode ",
    name="Barcode",
    serviceName="BarcodeService")
public class BarcodeService{
    ...
}
```

This defines all public and non static methods of the class as operations of the BarcodeService Web Service.

**Step 3: Start the service**

Compile the previously created java class, and run it.

Commands to compile and execute the service in standalone mode:

```sh
$ javac BarcodeService.java
$ java BarcodeService
```

Once the service is started, it is ready to accept requests and you can also retrieve its WSDL at following URL:

http://localhost/9090/BarcodeService?WSDL

**Note:** If you want the service to be started on a web server, you must deploy it first using Eclipse or the Web Server deployment tools.

**Step 4: Generate BDL stub to access the Java™ library**

Use the fglwsdl tool to generate the client stub to access the BarcodeService:

```sh
$ fglwsdl http://localhost:9090/BarcodeService?WSDL
```

This will create two .4gl files that must be compiled and linked into your BDL application in order to call the Java™ barcode library functions. These files contain the BDL interface to access the Java™ library where you will find the two functions, readImage and buildImage, defined in BDL.

**Step 5: Modify your BDL application**

The last step is to modify the existing application where you want to use the Java™ library, by calling the BDL functions generated in the stub. Then compile your application and the previously generated stubs, and link everything together.
Your application is now ready to use the different features of your Java™ library.

**Example program**

This program calls the `buildImage` function of the Barcode Java™ library.

```glossary
GLOBALS "BarcodeService_BarcodePort.inc"

MAIN

DEFINE wsstatus INTEGER

IF num_args() != 3 THEN
    CALL ExitHelp()
END IF

LET ns1buildImage.arg0 = arg_val(1)
LET ns1buildImage.arg1 = arg_val(2)
LOCATE ns1buildImageResponse.return IN MEMORY

LET wsstatus = buildImage_g()
IF wsstatus <> 0 THEN
    DISPLAY "Error ("||wsError.code||") : ",wsError.description
ELSE IF
    IF ns1buildImageResponse.return IS NULL THEN
        DISPLAY "Encoding failed"
    ELSE
        CALL ns1buildImageResponse.return.writeFile(arg_val(3))
    END IF
END IF

FREE ns1buildImageResponse.return

END MAIN

FUNCTION ExitHelp()
    DISPLAY arg_val(0)||" <type> <data> <filename>"
    DISPLAY "type : barcode type such as EAN8 or CODE128"
    DISPLAY "data : data to be encoded with a barcode [0-9A-D]"
    DISPLAY "filename : resulting image filename"
    DISPLAY "example : createImage EAN8 12358723A mybarcode.jpg"
EXIT PROGRAM (-1)
END FUNCTION
```

**Conclusion**

In a SOA environment, you can call any Java™ library from Genero using Web Services, and without a strong dependency to a JVM. This follows SOA principles - it allows you to reuse the Java™ library in another BDL application without any new development, you can update the Java™ part without recompiling any .4gl source, and integrate any function available from a SOA platform.

**Call .NET APIs from Genero in a SOA environment**

How to call a .NET library from Genero in a SOA environment, using Genero and Web services, and IIS and Visual Studio .NET.

There is no strong linkage between Genero and .NET. You can call a .NET library from a non-Windows Genero platform.

These topics are presented as a tutorial that uses a .NET barcode creation library to build a picture from a numeric code, and C# as the development language. This works with any .NET language.
Prerequisites

- IIS (Internet Information Services) Web server
- Visual Studio Professional Edition C#
  - Visual Studio in only needed for development. Once the service is built, you can deploy on any IIS Web Server.
- The .NET barcode library (available [here](#))
  - The trial version has some functions partially implemented.
  - The .NET library is called BarcodeLib.Barcode.dll, and must be added to the Visual Studio Project.

Using the barcode library

This section depends on the library you want to use in Genero. In our tutorial, we create one function called `buildImage`. This is the C# implementation:

```csharp
buildImage( type : String, code : String) : byte[]
```

```csharp
Linear barcode = new Linear();
barcode.Data = code;
barcode.Type = GetBarcodeBuilderType(type);
barcode.AddChecksum = true;
// save barcode image into your system
barcode.ShowText = true;
byte[] ret = barcode.drawBarcodeAsBytes();
if (ret != null) return ret;
else return null;
```

You will also need to convert the type of a code bar to the right type as expected by the library. Therefore, you will need this function.

```csharp
private BarcodeType GetBarcodeBuilderType(String str)
{
    if (str.Equals("CODABAR")) {
        return BarcodeType.CODABAR;
    } else if (str.Equals("CODE11")) {
        return BarcodeType.CODE11;
    } else if (str.Equals("CODE128")) {
        return BarcodeType.CODE128;
    } else if (str.Equals("CODE128A")) {
        return BarcodeType.CODE128A;
    } else if (str.Equals("CODE128B")) {
        return BarcodeType.CODE128B;
    } else if (str.Equals("CODE128C")) {
        return BarcodeType.CODE128C;
    } else if (str.Equals("CODE2OF5")) {
        return BarcodeType.CODE2OF5;
    } else if (str.Equals("CODE39")) {
        return BarcodeType.CODE39;
    } else if (str.Equals("CODE39EX")) {
        return BarcodeType.CODE39EX;
    } else if (str.Equals("CODE93")) {
        return BarcodeType.CODE93;
    } else if (str.Equals("EAN13")) {
        return BarcodeType.EAN13;
    } else if (str.Equals("EAN13_2")) {
        return BarcodeType.EAN13_2;
    } else if (str.Equals("EAN13_5")) {
        return BarcodeType.EAN13_5;
    } else if (str.Equals("EAN8")) {
        return BarcodeType.EAN8;
    } else if (str.Equals("EAN8_2")) {
```

```csharp
```
Calling .NET from Genero

Step 1: Create an ASP.NET Web Service Application

Start Visual Studio, and create a new web project with the name BarCodeService.

Figure 110: Visual Studio New Project; ASP .NET Web Service Application selected

Step 2: Rename the generated files

Rename the generated class called Service1 with an appropriate name such as BarCode, and the file Service1.asmx to BarCodeService.asmx, for instance. The .asmx file is the file that is accessible from the IIS web server once the application is deployed. The .asmx file also contains a reference to the default
generated class, Service1, which must also be renamed to the new name (BarCode in our tutorial), in case Visual Studio didn't make the change automatically.

The class view after renaming the class:

![Class View; BarCode selected]

Figure 111: Class View; BarCode selected

The file view after renaming the asmx file:

![File View; BarCodeService selected]

Figure 112: File View; BarCodeService selected

Step 3: Add the barcode library as a reference

Right-click on the solution explorer, select Add Reference and use the Browse panel to enter the location of the barcode library called BarcodeLib.Barcode.dll:
Note: By default, the barcode library will be copied to the right place when deploying on the IIS web server.

Step 4: Add the buildImage method

Remove the default generated HelloWorld method, and create the buildImage method.

Add the three using instructions to import the barcode library, and to declare buildImage as a WebMethod. Use the GetBarcodeBuilderType() method to convert a string to a code as expected by the barcode library.

```csharp
using BarcodeLib;
using BarcodeLib.Barcode;
using BarcodeLib.Barcode.Linear;

namespace BarCodeService
{
    /// <summary>
    /// Summary description for Service1
    /// </summary>
    [WebService(Namespace = "http://tempuri.org/")]
    [WebServiceBinding(ConformsTo = WsiProfiles.BasicProfile1_1)]
    [ToolboxItem(false)]
    // To allow this Web Service to be called from script, using ASP.NET
    {
        [WebMethod]
        public byte[] buildImage(String type, String code)
        {
            try
            {
                Linear barcode = new Linear();
                barcode.Data = code;
                barcode.Type = GetBarcodeBuilderType(type);
                barcode.AddCheckSum = true;

                // save barcode image into your system
                barcode.ShowText = true;
            }
```
byte[] ret = barcode.drawBarcodeAsBytes();
if (ret != null) return ret;
else return null;
}
catch (Exception e)
{
    return null;
}
}

---

**Figure 113: BarCodeService.BarCode**

**Step 5: Publish the service**

Build the entire application, right-click on the solution, and select the publish operation. This will copy all necessary files to your IIS web server and make your application available at an URL, depending on where you deploy it on your IIS web server.
In our tutorial, the service will be located at the root of the server. In other words, it will be available at 

Figure 114: Publish Web dialog

Step 6: Generate .4gl stub to access the .NET library

Use the fglwsdl tool to generate the client stub to access the BarcodeService, as follows:

```
$ fglwsdl http://localhost/BarCodeService.asmx?WSDL
```

This will create two .4gl files, which must be compiled and linked into your BDL application in order to call
the .NET barcode library functions. These files contain the BDL interface to access the .NET library where
you will find the function buildImage, defined in BDL.

Step 7: Modify your BDL application

Modify your existing application, where you want to use the .NET library, by calling the BDL functions
generated in the stub. Then compile your application and the previously generated stubs, and link
everything together.

Your application is now ready to use the different features of your .NET library.

Example BDL program

This program calls the buildImage function of the Barcode .NET library.

```
GLOBALS "BarCode_BarCodeSoap.inc"
MAIN
  DEFINE wsstatus INTEGER
  IF num_args() != 3 THEN
    CALL ExitHelp()
  END IF
  LET buildImage.type = arg_val(1)
  LET buildImage.code = arg_val(2)
  LOCATE buildImageResponse.buildImageResult IN MEMORY
  LET wsstatus = buildImage_g()
  IF wsstatus <> 0 THEN
    DISPLAY "Error ("||wsError.code||") : ",wsError.description
```
ELSE
    IF buildImageResponse.buildImageResult IS NULL THEN
        DISPLAY "Encoding failed"
    ELSE
        CALL buildImageResponse.buildImageResult.writeFile(arg_val(3))
    END IF
END IF
FREE buildImageResponse.buildImageResult
END MAIN

FUNCTION ExitHelp()
    DISPLAY arg_val(0) || " <type> <data> <filename>"
    DISPLAY "type : barcode type such as EAN8 or CODE128"
    DISPLAY "data : data to be encoded with a barcode [0-9A-D]"
    DISPLAY "filename : resulting image filename"
    DISPLAY "exemple : createImage EAN8 12358723A mybarcode.jpg"
    EXIT PROGRAM (-1)
END FUNCTION

Conclusion
It is quite easy to interact with a .NET library from Genero using .NET Visual Studio and the web services. Of course you also need an IIS web server installed on your Windows system. This means that you can, in the same Genero application, interact with .NET and Java libraries without any strong linkage between Genero and the third party libraries you want to use. This meets the SOA principles that provide more flexibility to your entire BDL application.

You can integrate any new library from another vendor, without the risk of conflicts between different libraries that could happen if you had to link everything together in C or Java.

You can upgrade a third party library without recompiling the BDL application, which will still work.

You can use all these third party libraries in other BDL or other applications.

Compute a hash value from a BDL string
How to compute a hash value of a BDL string using the security.Digest API.

Signing a XML document is nothing more than computing a hash over a fragment of XML. If you set the string you need to hash in an XML node, and use the correct XPath expression, the security.Digest API will do it for you.

Some special characters are escaped in XML. If you use one of them, the computed hash value will be wrong because the result is actually computed over the escaped string. The special characters to be aware of are: ",', &< and >.

Sample code
Then uses the security.Digest API to compute a XML digital signature for the content of the root node, or in other words the string you wish to hash, using a XPath expression.

And finally, retrieves the hash value from the signature and returns it.
The computed hash value is encoded in Base64, so you may have additional conversion to do.

IMPORT SECURITY

MAIN

DEFINE result STRING

IF num_args() != 2 THEN
DISPLAY "Usage: ComputeHash <string> <hashcode>"
DISPLAY "  string: the string to digest"
DISPLAY "  hashcode: SHA1, SHA512, SHA384, SHA256, SHA224, MD5"
ELSE
  LET result = ComputeHash(arg_val(1), arg_val(2))
  IF result IS NOT NULL THEN
    DISPLAY "Hash value is: ", result
  ELSE
    DISPLAY "Error"
  END IF
END IF
END MAIN

FUNCTION ComputeHash(toDigest, algo)

DEFINE toDigest, algo, result STRING
DEFINE dgst security.Digest
TRY
  LET dgst = security.Digest.CreateDigest(algo)
  CALL dgst.AddStringData(toDigest)
  LET result = dgst.DoBase64Digest()
CATCH
  DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
  EXIT PROGRAM(-1)
END TRY
RETURN result
END FUNCTION

Example of usage:
$ fglrun ComputeHash "Hello, world !!!" SHA1
$ Hash value is: Ck1VqNd45QIvq3AZd8XYQLvEhtA=

Example
Computing a hash value of a string.

Program example ComputeHash.4gl:

IMPORT SECURITY

MAIN

DEFINE result STRING

IF num_args() != 2 THEN
  DISPLAY "Usage: ComputeHash <string> <hashcode>"
  DISPLAY "  string: the string to digest"
  DISPLAY "  hashcode: SHA1, SHA512, SHA384, SHA256, SHA224, MD5"
ELSE
  LET result = ComputeHash(arg_val(1), arg_val(2))
  IF result IS NOT NULL THEN
    DISPLAY "Hash value is: ", result
  ELSE
    DISPLAY "Error"
  END IF
END IF
END MAIN

FUNCTION ComputeHash(toDigest, algo)
DEFINE toDigest, algo, result STRING
DEFINE dgst security.Digest

TRY
  LET dgst = security.Digest.CreateDigest(algo)
  CALL dgst.AddStringData(toDigest)
  LET result = dgst.DoBase64Digest()
CATCH
  DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
  EXIT PROGRAM(-1)
END TRY

RETURN result
END FUNCTION

Example execution:
$fglrun ComputeHash "Hello World" SHA1
Hash value is :Ck1VqNd45Qlqv3AZd8XYQLvEnhA=

Deploy a Web Service

Web services server program deployment

Introduction
In a production environment, Genero Web Services becomes a part of a global application architecture handled by the Genero Application Server (GAS). The GWS DVMs are managed by the GAS.

This architecture takes care of:

- Security issues
- Scalability
  - Load management
  - Balancing of the Web service requests amongst the available virtual machines
- Runtime monitoring

GAS configuration

For deployment, the GWS Server application must be added to the GAS configuration. See Adding Applications in the GAS manual.

The web services application can be added to the GAS in different ways:

- GWS Server application implementing a single Web Service.

  This application could be deployed on various physical machines. A Genero Web Services VMProxy (GWSPProxy) is started on each machine where the GWS Server application is executed, to manage the requests for a service and manage the DVMs that handle the requests. A single VMProxy can communication with multiple GWS DVMs, and manage the load balancing.

- GWS Server application implementing multiple Web Services.

  The GWSPProxy would manage the client requests, dispatching the request to the appropriate DVM and the appropriate web service.

  Note: A Web Service Server must be stateless; several instances of the same Service can be created to support load balancing.
The basic deployment strategy can be implemented in varying permutations, depending on your business needs and the volume of requests.

**Figure 115: Deployment strategy**

- Using the World Wide Web, a Web Service client requests WSDL information for a particular Web Service from the Web Server.
- The Web Service client uses this information to make a Web Service request from the Web Server.
- The Web server passes the request to the GAS dispatcher.
- The GAS dispatcher starts a GWSProxy, which will be in charge of the pool of DVMs that will serve the web service application.
- The GWSProxy will start the number of DVMs specified by the START element defined for the web service application.

For a more detailed explanation of the Services Pool for web services, refer to the *GAS Architecture* topic in the Genero Application Server manual.

**Access the web services server from a client application**

To reach the web service from the internet, client applications must use the following URL form:

```
http://host_name/ws/r/app_id
```

1. *host_name* defines the web server host name where the GAS is running.
2. *app_id* is the XCF file of the GAS web services application.

**Configuring the apache web server for HTTPS**

The first three steps are for the creation of all X.509 certificates.

- **Step 1: Create the Root Certificate Authority**
- **Step 2: Create the server’s certificate and private key**
- **Step 3: Create the server’s certificate authority list**

The next three steps are for server configuration.

- **Step 4: Register the server as a Web Service in the GAS**
- **Step 5: Configure apache for HTTPS**
- **Step 6: Configure apache for HTTP basic authentication**

**Step 1: Create the root certificate authority**

- Create the root certificate authority serial file:

```
$ echo 01 > MyCompanyCA.srl
```
• Create the Root Authority's Certificate Signing Request and private key:

```bash
$ openssl req -new -out MyCompanyCA.csr -keyout MyCompanyCA.pem
```

• Create the Root Certificate Authority for a period of validity of 2 years:

```bash
$ openssl x509 -trustout -in MyCompanyCA.csr -out MyCompanyCA.crt -req -signkey MyCompanyCA.pem -days 730
```

**Note:** The private key file *(MyCompanyCA.pem)* of a RootCertificate Authority must be handled with care. This file is responsible for the validity of all other certificates it has signed. As a result, it must not be accessible by other users.

**Step 2: Create the server’s certificate and private key**

• Create the server’s serial file:

```bash
$ echo 01 > MyServer.srl
```

• Create the server’s Certificate Signing Request and private key:

```bash
$ openssl req -new -out MyServer.csr
```

**Note:** By default, openssl outputs the private key in the *privkey.pem* file.

• Remove the password from the private key:

```bash
$ openssl rsa -in privkey.pem -out MyServer.pem
```

**Note:** The key is also renamed in *MyServer.pem*.

• Create the server’s Certificate trusted by the Root Certificate Authority:

```bash
$ openssl x509 -in MyServer.csr -out MyServer.crt -req -signkey MyServer.pem -CA MyCompanyCA.crt -CAkey MyCompanyCA.pem
```

**Note:** The purpose of the server’s Certificate is to identify the server to any client that connects to it. Therefore, the subject of that server’s certificate must match the hostname of the server as it is known on the network; otherwise the client will be suspicious about the server's identity and stop the communication. For instance, if the URL of the server is `https:///www.MyServer.com/cgi-bin/fglccgi.exe/ws/r/MyWebService`, the subject must be `www.MyServer.com`.

**Step 3: Create the server’s certificate authority list**

• Create the server’s Certificate Authority List:

```bash
$ openssl x509 -in MyCompanyCA.crt -text >> ServerCAList.pem
```

**Note:** As the server trusts only the Root Certificate Authority, the list contains only that one certificate authority; all other certificates that were trusted by the Root Certificate Authority will also be considered as trusted by the server.

**Step 4: Register the server as a web service in the GAS**

As the Web Server is in charge of the complete HTTPS protocol with all the clients, there is no additional GAS configuration needed to add security. Simply register the BDL server to the list of Web Services of the GAS. For more information, refer to the *Genero Application Server User Guide*.

For more details, see *Web services server program deployment* on page 2513.
Step 5: Configure apache for HTTPS

You must configure Apache to support HTTPS by adding the required modules. Please refer to the Apache Web server documentation for more information.

- For the Apache 1.3 manual, go to [http://httpd.apache.org/docs/1.3](http://httpd.apache.org/docs/1.3).
- For the Apache 2.0 manual, go to [http://httpd.apache.org/docs/2.0/](http://httpd.apache.org/docs/2.0/).

Once the Apache Web server supports HTTPS, you must change or add the following directives to the apache configuration file:

- Set the Apache Web server Certificate Authority List directive created in Step 4:
  ```
  SSLCACertificateFile D:/Apache-Server/conf/ssl/ServerCAList.pem
  ```
- Set the Apache Web server Certificate and associated private key directives created in Step 2:
  ```
  SSLCertificateFile D:/Apache-Server/conf/ssl/MyServer.crt
  SSLCertificateKeyFile D:/Apache-Server/conf/ssl/MyServer.pem
  ```
- Require the Apache Web server to verify the validity of all client certificates:
  ```
  SSLVerifyClient require
  ```

**Note:** The Apache Web server must be started on a machine where the host is the same as the one defined in the subject of the server’s certificate (www.MyServer.com in our case).

Step 6: Configure apache for HTTP basic authentication

You must configure Apache to support HTTP basic authentication by adding the required modules. Please refer to the Apache Web server documentation for more information.

- For the Apache 1.3 manual, go to [http://httpd.apache.org/docs/1.3](http://httpd.apache.org/docs/1.3).
- For the Apache 2.0 manual, go to [http://httpd.apache.org/docs/2.0/](http://httpd.apache.org/docs/2.0/).

Once the Apache Web server supports HTTP basic authentication, you must:

1. Add an user to the Apache Web server basic authentication file with the same login and password as defined for the client.

   Apache provides the tool **htpasswd** that you can use to create the file and add the user. To add the user **mylogin** with the password **mypassword** to a new file called **myusers**:
   ```
   $ htpasswd -c myusers mylogin mypassword
   ```

   **Note:** To add additional users, remove the option `-c`.

2. Add an Apache Web server location directive that enables you to group several directives for one URL. (In our case, the URL is /cgi-bin/fglcgi.exe/ws/r/MyWebService).

   The following example (based on Apache 2.0) defines the HTTP authentication type (Basic), with a user file (user-basic) containing the login and password of those who are allowed to access the service.

   ```
   <Location /cgi-bin/fglcgi.exe/ws/r/MyWebService>
   AllowOverride None
   Order allow,deny
   Allow from all
   # # Basic HTTP authenticate configuration #
   AuthName "Top secret"
   AuthType Basic
   AuthUserFile "D:/Apache-Server/conf/authenticate/myusers"
   Require valid-user # Means any user in the password file
   </Location>
   ```
For more information about Apache Web server directives, refer to the Apache Web Server manual.

Reference

These topics are the reference guides for Genero Web Services.

- Web services configuration on page 2517
- Attributes to customize XML serialization on page 2525
- Error handling in GWS calls (STATUS) on page 2553
- Interruption handling in GWS calls (INT_FLAG) on page 2553
- Server API functions - version 1.3 only on page 2554
- Configuration API functions - version 1.3 only on page 2560
- Using fglwSDL to generate code from WSDL or XSD schemas on page 2563

Web services configuration

The Genero Web Services secured communication and the support of XML-Security is based on the OpenSSL engine. It allows a BDL Web Services client, or a BDL application using the **com** or **xml** API, to communicate with any secured server over HTTP or HTTPS, and to handle encrypted and/or signed XML document in BDL coming from any other application.

The configuration is defined from entries in the **fglprofile** file. When using BDL Web Services on server side, it is the Web Server that is in charge of the BDL Web Services server security, not the BDL server application itself. You must refer to your Web Server manual to secure the server part of the Web Services.

**Note:** This is useful for deployment purposes, as no additional code modification is necessary, even if the location of the different servers changes, or if different cryptography keys or X509 certificates are necessary for a same application but intended to several customers with their own needs.

FGLPROFILE entries

The **fglprofile** entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

**Important:** Web Services FGLPROFILE configuration options are not supported on GMI mobile devices.

- HTTPS and password encryption on page 2517
- Basic or digest HTTP authentication on page 2519
- Proxy configuration on page 2520
- Server configuration on page 2521
- XML configuration on page 2522

HTTPS and password encryption

The following table lists the FGLPROFILE entries specifying the security certificates and algorithms the Web Services client uses for HTTPS and password encryption. These entries specify how an application using the low-level **com** or **xml** APIs performs secured communications.

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>security.global.script</td>
<td>Filename of a script executed each time a password of a private key is required by the client. The security script accepts one argument corresponding to the filename of the private key for which the password is required, and must</td>
</tr>
<tr>
<td>Entry</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>security.global.agent</td>
<td>Port number where the fglpass agent is waiting for requests. It returns the password that grants access to a private key when needed by a BDL application. The DVM and the fglpass agent perform authentication and exchange encrypted data over the local host network only. Refer to Using the password agent for details. This entry cannot be used if security.global.agent is set.</td>
</tr>
</tbody>
</table>
| security.global.protocol | The SSL protocol to use for secured communications. Possible values are:  
|                          | • TLSv1.2  
|                          | • TLSv1.1  
|                          | • TLSv1 (version 1.0)  
|                          | • SSLv3  
|                          | • SSLv23 (The default, enabling all supported protocols)                                                                                                                                                                                                                                                                                                                                                                                               |
| security.global.ca       | Filename of the Certificate Authority list, with the concatenated PEM-encoded third party X.509 certificates considered as trusted, and in order of preference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| security.global.windowsca | If set to true, build the Certificate Authority list from the Certificate Authorities stored in the Windows™ key store. This entry is only valid on Windows™ systems where security.global.ca is not set.                                                                                                                                                                                                                                                                                                                                                       |
| security.global.cipher   | The list of encryption, digest, and key exchange algorithms the client is allowed to use during a secured communication. If this entry is omitted, all algorithms are supported. For more details about cipher, refer to www.openssl.org.                                                                                                                                                                                                                                                                                                                                            |
| security.global.certificate | Filename of the PEM-encoded client X.509 certificate to be used for any secured connection if not redefined in a specific server configuration.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| security.global.privatekey | Filename of the PEM-encoded private key associated to the above X509 certificate and to be used for any secured connection if not redefined in a specific server configuration.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| security.global.keyssubject | The subject string of a X.509 certificate and its associated private key registered in the Windows™ key store to be used for any secured connection if return the correct password or the client stops. For script examples, see Windows™ Password Script Example or UNIX™ Password Script Example. This entry cannot be used if security.global.agent is set.                                                                                                                                                                                                                                                                                                                                 |
not redefined in a specific server configuration. This entry is valid only on Windows™ systems.

**security.ident.certificate**
Filename of the PEM-encoded client X.509 certificate.

**security.ident.privatekey**
Filename of the PEM-encoded private key associated to the above X.509 certificate.

**security.ident.keyssubject**
The subject string of a X.509 certificate and its associated private key registered in the Windows™ key store. This entry is valid only on Windows™ systems.

**Note:**

1. The `ident` keyword must be replaced with your own identifier, and all necessary entries must be set. See FGLPROFILE setting.
2. If an entry is defined more than once, only the last occurrence is taken into account.

**Basic or digest HTTP authentication**

The following table lists the FGLPROFILE entries that specify the login and password to use in the case of HTTP authentication to a server or a proxy. The entries also specify the login and password to use in an application using the low-level `com` or `xml` API.

Table 565: HTTP basic or digest Authentication FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>authenticate.ident.login</code></td>
<td>The login identifying the client to a server during HTTP Authentication.</td>
</tr>
<tr>
<td><code>authenticate.ident.password</code></td>
<td>The password validating the login of a client to a server during HTTP Authentication. As passwords should never be in clear text, it is recommended that you encrypt them with the <code>fglpass</code> tool. For more information, see FGLPROFILE password encryption.</td>
</tr>
<tr>
<td><code>authenticate.ident.realm</code></td>
<td>The string identifying the server to the client during HTTP Authentication. If the string does not match the server’s string, authentication fails. This parameter is optional, but it is recommended that you check the server identity, especially if the server’s location is suspicious.</td>
</tr>
<tr>
<td><code>authenticate.ident.scheme</code></td>
<td>One of the following strings representing the different HTTP Authentication mechanisms.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Anonymous</strong> (default value) - The client does not know anything about the server, and performs a first request to retrieve the server authentication mechanism. It then uses the login and password to authenticate to the server using the Basic or Digest mechanism, depending on the server returned value.</td>
</tr>
</tbody>
</table>
• **Basic** - The client authenticates itself to the server at first request, by sending the login and the password using the Basic authentication mechanism.

• **Digest** - The client performs a first request without any login and password, to retrieve the server information before authenticating itself to the server in a second request using the Digest mechanism.

**Note:**

1. The `ident` keyword must be replaced with your own identifier, and all necessary entries must be set. See FGLPROFILE setting.

2. If an entry is defined more than once, only the last occurrence is taken into account.

**Proxy configuration**

The following table lists the FGLPROFILE entries that specify how the Web Services client communicates with a proxy. The entries specify the way an application using the low-level `com` or `xml` API communicates with a proxy.

**Table 566: Proxy Configuration FGLPROFILE entries**

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>proxy.http.location</code></td>
<td>Location of the HTTP proxy defined as <code>host:port</code> or <code>ip:port</code>. If the port is omitted, the port 80 is used.</td>
</tr>
<tr>
<td><code>proxy.http.list</code></td>
<td>The list of beginning host names, separated with semicolons, for which the Web Services client does not go via the HTTP proxy.</td>
</tr>
<tr>
<td><code>proxy.http.authenticate</code></td>
<td>The HTTP Authenticate identifier the Web Services client uses to authenticate itself to the HTTP proxy.</td>
</tr>
<tr>
<td><code>proxy.https.location</code></td>
<td>Location of the HTTPS proxy defined as <code>host:port</code> or <code>ip:port</code>. If the port is omitted, the port 443 is used.</td>
</tr>
<tr>
<td><code>proxy.https.list</code></td>
<td>The list of beginning host names, separated with semicolons, for which the Web Services client does not go via this HTTPS proxy.</td>
</tr>
<tr>
<td><code>proxy.https.authenticate</code></td>
<td>The HTTP Authenticate identifier the Web Services client uses to authenticate itself to the HTTPS proxy.</td>
</tr>
</tbody>
</table>

**Note:** If an entry is defined more than once, only the last occurrence is taken into account.

**IPv6 configuration**

The following table lists the FGLPROFILE entries that specify how the Web Services client uses the IPv6 network protocol.
Table 567: IPv4 and IPv6 FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip.global.version</td>
<td>Defines the IP version to be used. Possible values are &quot;4&quot; (IPv4) or &quot;6&quot; (IPv6). By default, when this entry is not defined, the WS library will try to use IPv6 and fallback to IPv4, according to the operating system.</td>
</tr>
<tr>
<td>ip.global.v6.interface.name</td>
<td>Defines the name of the network interface to be used for IPv6 link-local addresses. For example, this entry can get values such as &quot;eth0&quot;, &quot;en0&quot;, &quot;ethernet_5&quot;.</td>
</tr>
<tr>
<td>ip.global.v6.interface.id</td>
<td>Defines the id of the network interface to be used for IPv6 link-local addresses. For example, this entry can get values such as &quot;1&quot;, &quot;2&quot;, &quot;11&quot;.</td>
</tr>
</tbody>
</table>

**Important:** This entry is not supported on Microsoft™ Windows™ platforms.

**Note:** If an entry is defined more that once, only the last occurrence is taken into account.

**Server configuration**

The following table lists the FGLPROFILE entries that specify the correct way a Web Services client connects to an end point (usually a server). Notice that the entries specify also the way an application using the low-level com or xml API connects to an end point.

Table 568: Server Configuration FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ws.ident.url</td>
<td>The endpoint URL of the server. By using a wildcard in the URL, you can create a URL base that applies to multiple server applications. URLs that have the same URL base can share server configuration (such as authentication and HTTPS). See Wildcards in the URL base on page 2524.</td>
</tr>
<tr>
<td>ws.ident.cipher</td>
<td>The list of encryption, digest and key exchange algorithms the client is allowed to use during a secured communication to that server. It overwrites the global definition.</td>
</tr>
<tr>
<td>ws.ident.verifyserver</td>
<td>If set to true, the client performs a strict server identity validation. If not fulfilled, it stops the communication; otherwise no server identity verification is performed. The default value is true.</td>
</tr>
<tr>
<td>ws.ident.security</td>
<td>The security identifier the client uses to perform an HTTPS communication to the server.</td>
</tr>
<tr>
<td>ws.ident.authenticate</td>
<td>The HTTP authenticate identifier the client uses to authenticate itself to the server.</td>
</tr>
</tbody>
</table>

**Note:**
1. The `ident` keyword must be replaced with your own identifier. All necessary entries, depending on the remote server's configuration, must be set. See FGLPROFILE setting.

2. You can use the unique identifier in the .4gl code instead of the server URL, with the `alias://` prefix. For example, `alias://ident`.

3. If an entry is defined more than once, only the last occurrence is taken into account.

XML configuration

The following table lists the FGLPROFILE entries that control XML to Genero values conversion, and XML cryptography key or certificate mapping.

**Table 569: XML configuration FGLPROFILE entries**

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.keystore.calist</code></td>
<td>The list of PEM-encoded third party X.509 certificates, separated with semicolons, of the Certificate Authority considered as trusted, in order of preference.</td>
</tr>
<tr>
<td><code>xml.keystore.x509list</code></td>
<td>The list of PEM-encoded third party X.509 certificates, separated with semicolons, to be used to find out the correct X.509 certificate when getting an incomplete one in a XML signature or an encrypted XML document.</td>
</tr>
<tr>
<td><code>xml.ident.key</code></td>
<td>The filename of a cryptography key. For instance <code>RSA.pem</code>, <code>DSA.der</code> or <code>HMAC.bin</code>.</td>
</tr>
<tr>
<td><code>xml.ident.x509</code></td>
<td>The filename of a cryptography x509 certificate. For instance <code>Cert.crt</code>.</td>
</tr>
<tr>
<td><code>xml.serializer.supportEmptyStrings</code></td>
<td>Controls empty string XML nodes conversion to Genero STRING values.</td>
</tr>
<tr>
<td></td>
<td>The default is <code>false</code>, empty XML tags are converted to <code>NULL</code>.</td>
</tr>
<tr>
<td></td>
<td>If set to <code>true</code>, an empty XML tag is converted to an empty STRING value. As result, in Genero, the <code>LENGTH()</code> function will return zero and the <code>IS NULL</code> comparison operator will evaluate to <code>FALSE</code>.</td>
</tr>
<tr>
<td></td>
<td>Note that this entry only works for the STRING data type, and if the tag is not present, the STRING is set to <code>NULL</code>.</td>
</tr>
<tr>
<td>`xml.signature.prefix = &quot;prefix&quot;</td>
<td>Defines the prefix for an XML Signature.</td>
</tr>
<tr>
<td></td>
<td>Use &quot;&lt;none&gt;&quot; to specify no prefix.</td>
</tr>
<tr>
<td></td>
<td>By default, the XML Signature prefix is &quot;dsig&quot;..</td>
</tr>
<tr>
<td>`xml.encryption.prefix = &quot;prefix&quot;</td>
<td>Defines the prefix for an XML Encrypted data.</td>
</tr>
<tr>
<td></td>
<td>Use &quot;&lt;none&gt;&quot; to specify no prefix.</td>
</tr>
<tr>
<td></td>
<td>By default, the XML Encrypted data prefix is &quot;xenc&quot;..</td>
</tr>
</tbody>
</table>
Note:
1. The ident keyword must be replaced with your own identifier. See FGLPROFILE sample 2.
2. You can use the unique identifier in the .4gl code instead of the filename.
3. If an entry is defined more than once, only the last occurrence is taken into account.

Examples
Windows™ password script example

```лож
@echo off
REM -- Windows password script
IF "%1" == "Cert/MyPrivateKeyA.pem" GOTO KeyA
IF "%1" == "Cert/MyPrivateKeyB.pem" GOTO KeyB
GOTO end
:KeyA
ECHO PasswordA
GOTO end
:KeyB
ECHO PasswordB
GOTO end
:end
GOTO :EOF
```

UNIX™ password script example

```лож
# UNIX password script
if [ "$1" == "Cert/MyPrivateKeyA.pem" ]
then
    echo PasswordA
fi
if [ "$1" == "Cert/MyPrivateKeyB.pem" ]
then
    echo PasswordB
fi
```

FGLPROFILE sample

The following is an FGLPROFILE sample, configured for a connection to a HTTPS server via a proxy, and with HTTP and Proxy Authentication.

```лож
# Security configuration
security.global.script = "Cert/password.sh"
security.global.ca = "Cert/CAList.pem"
security.global.cipher = "HIGH" # Use only HIGH encryption ciphers
security.mykey.certificate = "Cert/MyCertificateA.crt"
security.mykey.privatekey = "Cert/MyPrivateKeyA.pem"

# Proxy HTTP Authentication
authenticate.proxyauth.login = "myapplication"
authenticate.proxyauth.password = "mypswd"
authenticate.proxyauth.scheme = "Basic"

# HTTPS Proxy configuration
proxy.https.location = "10.0.0.170"
proxy.https.list = "www.mycompany.com;www.mycompany.com"
proxy.https.authenticate = "proxyauth"

# Server HTTP Authentication
authenticate.serverauth.login = "mylogin"
authenticate.serverauth.password = "password"

# Server configuration
FGLPROFILE sample 2

The following is an FGLPROFILE sample, configured for XML cryptography and using the fglpass agent to get the private key passwords.

```plaintext
# Security configuration
security.global.agent     = "4444"

# Crypto configuration
xml.keystore.calist     = "RSARootCertificate.crt;DSARootCertificate.crt"
xml.keystore.x509list   = "RSA1024Certificate.crt;DSA1024Certificate.crt"
xml.id1.x509            = "RSA1024Certificate.crt"
xml.id2.x509            = "DSA1024Certificate.crt"
xml.id3.key             = "RSA1024Key.pem"
xml.id4.key             = "DSA1024Key.der"
xml.id5.key             = "HMAC.bin"
```

Wildcards in the URL base

By using a wildcard in the URL, you can create a URL base that applies to multiple server applications. URLs that have the same URL base can share server configuration (such as authentication and HTTPS).

To create a URL base, add a wildcard (/*) to the end of a URL in the fglprofile entry. A server application that starts with this URL (and that is not explicitly defined elsewhere) shares the configuration with other applications that also start with the same base URL. If an application has its own server configuration explicitly defined, it uses its specific entries instead of those defined by the wildcard configuration.

Consider this excerpt from a hypothetical fglprofile:

```plaintext
authenticate.auth.login     = "xxx"
authenticate.auth.password  = "yyy"
authenticate.auth.scheme    = "Basic"
security.sec.certificate    = "client.crt"
security.sec.privatekey     = "client.pem"
ws.myapp.url                = "http://mycompany.com/sample/*"
ws.myapp.authenticate       = "auth"
ws.myapp.security           = "sec"
ws.thirdapp.url             = "http://mycompany.com/sample/application3"
ws.thirdapp.authenticate    = "auth3"
```

Based on this example:

- Requests to "http://mycompany.com/sample/application1" and "http://mycompany.com/sample/demos/shoppingcart" use the same authentication and HTTPS configuration.
- A request to "http://mycompany.com/sample/application3" uses its specific authentication "auth3". No security configuration is defined for this URL, nor does it fall back on the shared security configuration defined for the base URL.

Note: This applies to:
- `com.HTTPRequest.Create` on page 2065 `com.HTTPRequest.Create()`
Attributes to customize XML serialization

See The Serializer class on page 2210 for information on setting serialization options when mapping BDL and XML data.

BDL to/from XML type mappings

Starting with Genero 2.0, you can add optional attributes to the definition of program variables to be used for XML serialization. These attributes can be used to map a BDL data type used in the input or output message of a Genero Web Service application to a specific XML data type, rather than using the default.

For example, if an XML Schema boolean data type is required for an application, and the corresponding BDL type is a SMALLINT, you can use an attribute to map the BDL SMALLINT variable to the XML boolean.

The following example uses the XSDBoolean attribute to map a BDL SMALLINT variable to an XML Schema boolean type, and assigns an uppercase name as the XMLName attribute:

```asciidoc
GLOBALs
DEFINE invoice_out RECORD
  ok SMALLINT ATTRIBUTES(XSDBoolean,XMLName="OK")
END RECORD
END GLOBALs
```

If you assign your own XMLName attributes, be sure to respect the conventions when using the RPC Service Style.

See the Tutorial: Writing a GWS Server application for additional information about input and output messages.

Default BDL/XML mapping

By default, Genero Web Services maps BDL variables in the input or output messages of a WS application to their corresponding XML data types, enabling values to be passed between applications and Web Services. The XML data types conform to the standard XML Schema Definition (XSD):

Table 570: Default XML Mapping

<table>
<thead>
<tr>
<th>data type of BDL variable</th>
<th>Default XML data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>xsd:base64binary</td>
</tr>
<tr>
<td>CHAR</td>
<td>xsd:string</td>
</tr>
<tr>
<td>DATE</td>
<td>xds.date</td>
</tr>
<tr>
<td>DATETIME YEAR TO FRACTION(1-5)</td>
<td>xsd:dateTime</td>
</tr>
<tr>
<td>DATETIME YEAR TO SECOND</td>
<td>xsd:dateTime</td>
</tr>
<tr>
<td>DATETIME YEAR TO HOUR</td>
<td>xsd:dateTime</td>
</tr>
<tr>
<td>DATETIME YEAR TO MINUTE</td>
<td>xsd:dateTime</td>
</tr>
<tr>
<td>DATETIME YEAR TO YEAR</td>
<td>xsd:gYear</td>
</tr>
<tr>
<td>DATETIME YEAR TO MONTH</td>
<td>xsd:gYearMonth</td>
</tr>
<tr>
<td>data type of BDL variable</td>
<td>Default XML data type</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td>DATETIME YEAR TO DAY</td>
<td>xsd:date</td>
</tr>
<tr>
<td>DATETIME MONTH TO MONTH</td>
<td>xsd:gMonth</td>
</tr>
<tr>
<td>DATETIME MONTH TO DAY</td>
<td>xsd:gMonthDay</td>
</tr>
<tr>
<td>DATETIME DAY TO DAY</td>
<td>xsd:gDay</td>
</tr>
<tr>
<td>DATETIME HOUR TO HOUR</td>
<td>xsd:time</td>
</tr>
<tr>
<td>DATETIME HOUR TO MINUTE</td>
<td>xsd:time</td>
</tr>
<tr>
<td>DATETIME HOUR TO SECOND</td>
<td>xsd:time</td>
</tr>
<tr>
<td>DATETIME HOUR TO FRACTION(1-5)</td>
<td>xsd:time</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>xsd:decimal</td>
</tr>
<tr>
<td>FLOAT</td>
<td>xsd:double</td>
</tr>
<tr>
<td>INTEGER</td>
<td>xsd:int</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>xsd:duration</td>
</tr>
<tr>
<td>SMALLFLOAT</td>
<td>xsd:float</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>xsd:short</td>
</tr>
<tr>
<td>STRING</td>
<td>xsd:string</td>
</tr>
<tr>
<td>TEXT</td>
<td>xsd:string</td>
</tr>
<tr>
<td>VARCHAR</td>
<td>xsd:string</td>
</tr>
<tr>
<td>TINYINT</td>
<td>xsd:byte</td>
</tr>
<tr>
<td>BIGINT</td>
<td>xsd:long</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>xsd:boolean</td>
</tr>
</tbody>
</table>

In addition, the Web Service Style that you use determines what default XMLName attributes are assigned to variables.

**Type mapping attributes**

The attributes listed in this table cannot have values.

**Table 571: Mapping between simple BDL and XML data types**

<tr>
<td>XSDUnsignedLong</td>
<td>Map BDL DECIMAL to XML Schema unsignedLong.</td>
</tr>
<tr>
<td>XSDUnsignedShort</td>
<td>Map BDL INTEGER or BIGINT to XML Schema unsignedShort.</td>
</tr>
</tbody>
</table>

**XSDAnySimpleType**

Map BDL STRING or VARCHAR to XML Schema anySimpleType.

**XSDAnyType**

Map BDL STRING or VARCHAR to XML Schema anyType.

**XSDAnyURI**

Map BDL STRING or VARCHAR to XML Schema anyURI.

**XSDBase64binary**

Map BDL BYTE to XML Schema base64binary.

**Example**

```
DEFINE myVar RECORD
   ATTRIBUTES(XMLName="Root")
      val1 BYTE
        ATTRIBUTES(XSDBase64binary,XMLName="Val")
```
XSDBoolean
Map BDL BOOLEAN, SMALLINT or INTEGER to XML Schema boolean.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XSDBoolean,XMLName="Val")
END RECORD

<Root>
  <Val>true</Val>
</Root>

XSDByte
Map BDL TINYINT, SMALLINT or BIGINT to XML Schema byte.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 SMALLINT ATTRIBUTES(XSDByte,XMLName="Val")
END RECORD

<Root>
  <Val>-126</Val>
</Root>

XSDDate
Map BDL DATE or DATETIME to XML Schema date.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATE ATTRIBUTES(XSDDate,XMLName="Val")
END RECORD

<Root>
  <Val>2006-06-29+01:00</Val>
</Root>

XSDDateTime
Map BDL DATETIME to XML Schema dateTime.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME ATTRIBUTES(XSDDateTime,XMLName="Val")
END RECORD
XSDDecimal
Map BDL DECIMAL to XML Schema decimal.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(5,3) ATTRIBUTES(XSDDecimal,XMLName="Val")
END RECORD

تسوي
<br />
<br />
XSDDouble
Map BDL FLOAT to XML Schema double.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 FLOAT ATTRIBUTES(XSDDouble,XMLName="Val")
END RECORD

تسوي
<br />
<br />
XSDDuration
Map BDL INTERVAL to XML Schema duration.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTERVAL DAY TO SECOND
  ATTRIBUTES(XSDDuration,XMLName="Val")
END RECORD

تسوي
<br />
<br />
XSDEntities
Map BDL STRING or VARCHAR to XML Schema ENTITIES.

XSDEntity
Map BDL STRING or VARCHAR to XML Schema ENTITY.
**XSDFloat**

Map BDL SMALLFLOAT to XML Schema `float`.

```
Example

DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 SMALLFLOAT ATTRIBUTES(XSDFloat,XMLName="Val")
END RECORD

<Root>
    <Val>126.435</Val>
</Root>
```

**XSDGDay**

Map BDL DATETIME to XML Schema `gDay`.

```
Example

DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DATETIME DAY TO DAY ATTRIBUTES(XSDGDay,XMLName="Val")
END RECORD

<Root>
    <Val>---25</Val>
</Root>
```

**XSDGMonth**

Map BDL DATETIME to XML Schema `gMonth`.

```
Example

DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DATETIME MONTH TO MONTH ATTRIBUTES(XSDGMonth,XMLName="Val")
END RECORD

<Root>
    <Val>---12</Val>
</Root>
```

**XSDGMonthDay**

Map BDL DATETIME to XML Schema `gMonthDay`.

```
Example

DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DATETIME MONTH TO DAY ATTRIBUTES(XSDGMonthDay,XMLName="Val")
END RECORD

<Root>
    <Val>---12-31</Val>
```
XSDGYear
Map BDL DATETIME to XML Schema gYear.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
   val1 DATETIME YEAR TO YEAR Attributes(XSDGYear,XMLName="Val")
END RECORD

<Root>
   <Val>2006</Val>
</Root>

XSDGYearMonth
Map BDL DATETIME to XML Schema gYearMonth.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
   val1 DATETIME YEAR TO MONTH Attributes(XSDGYearMonth,XMLName="Val")
END RECORD

<Root>
   <Val>2006-06</Val>
</Root>

XSDHexBinary
Map BDL BYTE to XML Schema hexBinary.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
   val1 BYTE Attributes(XSDHexBinary,XMLName="Val")
END RECORD

<Root>
   <Val>0FB6</Val>
</Root>

XSDID
Map BDL STRING or VARCHAR to XML Schema ID.

XSDIDREF
Map BDL STRING or VARCHAR to XML Schema IDREF.

XSDIDREFS
Map BDL STRING or VARCHAR to XML Schema IDREFS.

XSDInt
Map BDL INTEGER or BIGINT to XML Schema int.
Example

DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val INTEGER ATTRIBUTES(XSDInt,XMLName="Val")
END RECORD

<Root>
    <Val>-1258</Val>
</Root>

XSDInteger

Map BDL DECIMAL to XML Schema integer.

Example

DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val DECIMAL(32,0) ATTRIBUTES(XSDInteger,XMLName="Val")
END RECORD

<Root>
    <Val>12678</Val>
</Root>

XSDLanguage

Map BDL STRING or VARCHAR to XML Schema language.

XSDLong

Map BDL BIGINT or DECIMAL to XML Schema long.

Example

DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val DECIMAL(19,0) ATTRIBUTES(XSDLong,XMLName="Val")
END RECORD

<Root>
    <Val>1267488</Val>
</Root>

XSDNCName

Map BDL STRING or VARCHAR to XML Schema NCName.

XSDName

Map BDL STRING or VARCHAR to XML Schema Name.

XSDNegativeInteger

Map BDL DECIMAL to XML Schema negativeInteger.

Example

DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val DECIMAL(32,0) ATTRIBUTES(XSDNegativeInteger,XMLName="Val")
XSDNMTOKEN
Map BDL STRING or VARCHAR to XML Schema NMToken.

XSDNMTOKENS
Map BDL STRING or VARCHAR to XML Schema NMTokens.

XSDNonNegativeInteger
Map BDL DECIMAL to XML Schema nonNegativeInteger.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
val1 DECIMAL(32,0)
ATTRIBUTES(XSDNonNegativeInteger,XMLName="Val")
END RECORD

<Root>
  <Val>1589</Val>
</Root>

XSDNonPositiveInteger
Map BDL DECIMAL to XML Schema nonPositiveInteger.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
val1 DECIMAL(32,0)
ATTRIBUTES(XSDNonPositiveInteger,XMLName="Val")
END RECORD

<Root>
  <Val>-8574</Val>
</Root>

XSDNormalizedString
Map BDL STRING or VARCHAR to XML Schema normalizedString.

XSDnotation
Not supported.

XSDPositiveInteger
Map BDL DECIMAL to XML Schema positiveInteger.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
val1 DECIMAL(32,0)
ATTRIBUTES(XSDPositiveInteger,XMLName="Val")
XSDQName
Map BDL STRING or VARCHAR to XML Schema QName.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 SMALLINT ATTRIBUTES(XSDShort,XMLName="Val")
END RECORD
```

XSDShort
Map BDL SMALLINT or BIGINT to XML Schema short.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 SMALLINT ATTRIBUTES(XSDShort,XMLName="Val")
END RECORD
```

XSDString
Map BDL STRING, CHAR, TEXT or VARCHAR to XML Schema string.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 STRING ATTRIBUTES(XSDString,XMLName="Val")
END RECORD
```

XSDTime
Map BDL DATETIME to XML Schema time.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DATETIME ATTRIBUTES(XSDTime,XMLName="Val")
END RECORD
```

XSDToken
Map BDL STRING or VARCHAR to XML Schema token.

XSDUnsignedByte
Map BDL SMALLINT or BIGINT to XML Schema unsignedByte.
Example

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 SMALLINT ATTRIBUTES(XSDUnsignedByte,XMLName="Val")
END RECORD

<Root>
    <Val>254</Val>
</Root>
```

**XSDUnsignedInt**

Map BDL BIGINT or DECIMAL to XML Schema `unsignedInt`.

Example

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DECIMAL(32,0) ATTRIBUTES(XSDUnsignedInt,XMLName="Val")
END RECORD

<Root>
    <Val>1267896754</Val>
</Root>
```

**XSDUnsignedLong**

Map BDL DECIMAL to XML Schema `unsignedLong`.

Example

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DECIMAL(32,0) ATTRIBUTES(XSDUnsignedLong,XMLName="Val")
END RECORD

<Root>
    <Val>12678967543233</Val>
</Root>
```

**XSDUnsignedShort**

Map BDL INTEGER or BIGINT to XML Schema `unsignedShort`.

Example

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 INTEGER ATTRIBUTES(XSDUnsignedShort,XMLName="Val")
END RECORD

<Root>
    <Val>65535</Val>
</Root>
```

**XML facet constraint attributes**

The following attributes are facet constraints depending on the XSD data type used on a simple BDL variable to restrict the allowed value-space.
(Notice that some attributes are allowed only on some XSD data types).

Several facet constraints can be set on the same data type, and a mandatory values is expected (for example, `XSDMinLength="8"`).

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSDLength</td>
<td>Define the exact number of XML character or bytes.</td>
</tr>
<tr>
<td>XSDMinLength</td>
<td>Define the minimum number of XML character or bytes.</td>
</tr>
<tr>
<td>XSDMaxLength</td>
<td>Define the maximum number of XML character or bytes.</td>
</tr>
<tr>
<td>XSDEnumeration</td>
<td>Define a list of allowed values separated by the character</td>
</tr>
<tr>
<td>XSDWhiteSpace</td>
<td>Perform a XML string manipulation before serialization or deserialization.</td>
</tr>
<tr>
<td>XSDPattern</td>
<td>Define the regular expression the value has to match.</td>
</tr>
<tr>
<td>XSDMinInclusive</td>
<td>Define the inclusive minimum value according to the data type where it is set.</td>
</tr>
<tr>
<td>XSDMaxInclusive</td>
<td>Define the inclusive maximum value according to the data type where it is set.</td>
</tr>
<tr>
<td>XSDMinExclusive</td>
<td>Define the exclusive minimum value according to the data type where it is set.</td>
</tr>
<tr>
<td>XSDMaxExclusive</td>
<td>Define the exclusive maximum value according to the data type where it is set.</td>
</tr>
<tr>
<td>XSDTotalDigits</td>
<td>Define the total number of digits.</td>
</tr>
<tr>
<td>XSDFractionDigits</td>
<td>Define the number of digits of the fraction part.</td>
</tr>
</tbody>
</table>

**XSDLength**

Restrict the length of the data to the exact number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

**Note:**

1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater than XSDMinLength.
2. XSDMaxLength cannot be used with XSDLength.

**Example**

```sql
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDLength="12",
XMLName="MyString")

DEFINE myByte BYTE ATTRIBUTES(XSDBase64Binary, XSDLength="8000",
XMLName="MyPicture")
```
**XSDMinLength**
Restrict the length of the data to the minimum number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

**Note:**
1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater than XSDMinLength
2. XSDMaxLength cannot be used with XSDLen

**Example**

```plaintext
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDMinLength="12", XMLName="MyString")

DEFINE myByte BYTE ATTRIBUTES(XSDBase64Binary, XSDMinLength="8000", XMLName="MyPicture")
```

**XSDMaxLength**
Restrict the length of the data to the maximum number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

**Note:**
1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater than XSDMinLength
2. XSDMaxLength cannot be used with XSDLen

**Example**

```plaintext
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDMaxLength="12", XMLName="MyString")

DEFINE myByte BYTE ATTRIBUTES(XSDBase64Binary, XSDMaxLength="8000", XMLName="MyPicture")
```

**XSDEnumeration**
Restrict the allowed value-space to a list of values separated by the characters |.

**Note:**
1. To escape the separator character, simply double it like the following ||
2. This attribute can be set on any simple BDL variable excepted on XSDBoolean.

**Example**

```plaintext
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDEnumeration="one|two|three|four", XMLName="MyString")

DEFINE myDec DECIMAL(3,1) ATTRIBUTES(XSDDecimal, XSDEnumeration="12.1|11.8|-24.7", XMLName="MyDecimal")
```
XSDWhiteSpace
Perform a XML string manipulation before serialization or deserialization according to one of the three allowed values:

- **preserve**: the XML string is not modified.
- **replace**: the XML string is modified by replacing each \n, \t, \r by a single space.
- **collapse**: the XML string is modified by replacing each \n, \t, \r by a single space, then each sequence of several spaces are replaced by one single space. Leading and trailing spaces are removed too.

**Note:**

1. The whiteSpace facet is always performed before any other facet constraints, or serialization or deserialization process.
2. For any BDL variable excepted STRING, CHAR and VARCHAR, only collapse is allowed.

**Example**

```
DEFINE myStr STRING ATTRIBUTES(XSDString,
     XSDWhiteSpace="replace",
     XMLName="MyString")

DEFINE myDec DECIMAL(3,1) ATTRIBUTES(XSDDecimal,
     XSDWhiteSpace="collapse", XMLName="MyDecimal")
```

XSDPattern
Define a regular expression the value has to match to be serialized or deserialized without any error.

**Note:**

1. The regular expression is defined in the XML Schema Part 2 specification available here.
2. Backslash characters in a regular expression must be escaped by duplicating it.

**Example**

```
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDPattern="A.*Z",
     XMLName="MyString")

DEFINE myZipCode INTEGER ATTRIBUTES(XSDInt, XSDPattern="[0-9]{5}",
     XMLName="MyZipCode")

DEFINE myOtherZipCode INTEGER ATTRIBUTES(XSDInt,
     XSDPattern="\d{5}", XMLName="myOtherZipCode") # regex is \d{5}
see note
```

XSDMinInclusive
Define the minimum inclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

**Note:** The minimum value cannot exceed the implicit minimum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the minimum value is -32768.

**Example**

```
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort,
     XSDMinInclusive="-1000",
```
XSDMaxInclusive

Define the maximum inclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

**Note:** The maximum value cannot exceed the implicit maximum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the maximum value is 32767.

**Example**

```xml
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort,
  XSDMaxInclusive="1000",
  XMLName="MyCode")

DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal,
  XSDMaxInclusive="299.99",
  XMLName="MyRate")
```

XSDMinExclusive

Define the minimum exclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

**Note:** The minimum value cannot exceed or be equal to the implicit minimum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the minimum value is -32768.

**Example**

```xml
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort,
  XSDMinExclusive="-1000",
  XMLName="MyCode")

DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal,
  XSDMinExclusive="100.01",
  XMLName="MyRate")
```

XSDMaxExclusive

Define the maximum exclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

**Note:** The maximum value cannot exceed or be equal to the implicit maximum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the maximum value is 32767.

**Example**

```xml
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort,
  XSDMaxExclusive="1000",
  XMLName="MyCode")
```

```xml
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal,
  XSDMaxExclusive="299.99",
  XMLName="MyRate")
```
XSDTotalDigits
Define the maximum number of digits allowed on a numeric data type, fraction part inclusive if there is one.

Note:
1. The total digits value cannot be equal or lower than 0.
2. On a BDL decimal, the total digits value cannot be lower than the precision of the BDL decimal itself.
3. Notice that a decimal without any precision and scale value is a decimal(16), therefore the total digits value must be equal or greater than 16.

Example

```define myCode SMALLINT ATTRIBUTES(XSDShort, XSDTotalDigits="4", XSDMaxExclusive="1000", XMLName="MyCode")```

```define myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDTotalDigits="5", XSDMaxExclusive="299.99", XMLName="MyRate")```

XSDFractionDigits
Define the maximum number of digits allowed on the fraction part of a numeric data type.

Note:
1. The fraction digits value set on a BDL data type without XSDDecimal set, can only be 0.
2. On a BDL DECIMAL, the fraction digits value cannot be lower than the scale of the BDL DECIMAL itself, and must be lower than the XSDTotalDigits value if set.

Example

```define myCode SMALLINT ATTRIBUTES(XSDShort, XSDFractionDigits="0", XSDMaxExclusive="1000", XMLName="MyCode")```

```define myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDTotalDigits="5", XSDFractionDigits="3", XSDMaxExclusive="299.99", XMLName="MyRate")```

Customizing XML serialization
The following attributes are used to change the default serialization of BDL into XML, and vice-versa. Some of these attributes cannot have values; for the others a value is mandatory.

The following attributes cannot have values:
### Table 573: XML Serialization customizing - Attributes that cannot have values

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLOptional</td>
<td>Define whether the variable can be missing.</td>
</tr>
<tr>
<td>XMLElement</td>
<td>Map a BDL simple data type to an XML Element.</td>
</tr>
<tr>
<td>XMLAttribute</td>
<td>Map a BDL simple data type to an XML Attribute.</td>
</tr>
<tr>
<td>XMLBase</td>
<td>Set the base type of an XML Schema simpleContent.</td>
</tr>
<tr>
<td>XMLAll</td>
<td>Map a BDL Record to an XML Schema all structure.</td>
</tr>
<tr>
<td>XMLChoice</td>
<td>Map a BDL Record to an XML Schema choice structure.</td>
</tr>
<tr>
<td>XMLSequence</td>
<td>Map a BDL Record to an XML Schema sequence structure.</td>
</tr>
<tr>
<td>XMLSimpleContent</td>
<td>Map a BDL Record to an XML Schema simpleContent structure.</td>
</tr>
<tr>
<td>XSComplexType</td>
<td>Map a BDL Record type definition to an XML Schema complexType.</td>
</tr>
<tr>
<td>XMLList</td>
<td>Map a one-dimensional array to an XML Schema list.</td>
</tr>
<tr>
<td>XMLSelector</td>
<td>Define which member of an XMLChoice record is selected.</td>
</tr>
<tr>
<td>XMLAny</td>
<td>Map a Xml.DomDocument object to a wildcard XML element node.</td>
</tr>
<tr>
<td>XMLAnyAttribute</td>
<td>Map a BDL one-dimensional dynamic array of a record with 3 strings to XML wildcard attributes.</td>
</tr>
</tbody>
</table>

Values are mandatory for the following attributes: (for example, `XMLName="myname"`)

### Table 574: XML Serialization customizing - Attributes that must have values

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLName</td>
<td>Define the XML Name of a variable in an XML document.</td>
</tr>
<tr>
<td>XMLNamespace</td>
<td>Define the XML Namespace of a variable in an XML document.</td>
</tr>
<tr>
<td>XMLType</td>
<td>Force the XML type name of a variable.</td>
</tr>
<tr>
<td>XLMTypenamespace</td>
<td>Force the XML type namespace of a variable.</td>
</tr>
<tr>
<td>XSTypename</td>
<td>Define the XML Type Name of a BDL type definition.</td>
</tr>
<tr>
<td>XSTypenamespace</td>
<td>Define the XML Type Namespace of a BDL type definition.</td>
</tr>
<tr>
<td>XMLElementNamespace</td>
<td>Define the default XML namespace of all children defined as XMLElement in a Record.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Definition</td>
</tr>
<tr>
<td>------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>XMLAttributeNamespace</td>
<td>Define the default XML namespace of all children defined as XMLAttribute in a Record.</td>
</tr>
</tbody>
</table>

**XMLElement (Optional)**

Map a BDL simple data type to an XML Element.

**Note:** The attribute cannot be set on a type definition.

**Example**

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 INTEGER ATTRIBUTES(XMLElement, XSDunsignedShort, XMLName="Val1"),
    rec RECORD ATTRIBUTES(XMLName="Rec")
        val2 FLOAT ATTRIBUTES(XMLElement, XMLName="Val2"),
        val3 STRING ATTRIBUTES(XMLElement, XMLName="Val3")
    END RECORD
END RECORD

<Root>
    <Val1>148</Val1>
    <Rec1>
        <Val2>25.8</Val2>
        <Val3>Hello world</Val3>
    </Rec1>
</Root>
```

**XMLAttribute**

Map a BDL simple data type to an XML Attribute.

**Note:**
1. The attribute cannot be set on a type definition.
2. The attribute can only be set on a RECORD's member.

**Example**

```dpl
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 INTEGER ATTRIBUTES(XMLAttribute, XSDunsignedShort, XMLName="Val1"),
    rec RECORD ATTRIBUTES(XMLName="Rec")
        val2 FLOAT ATTRIBUTES(XMLAttribute, XMLName="Val2"),
        val3 STRING ATTRIBUTES(XMLElement, XMLName="Val3")
    END RECORD
END RECORD

<Root Val1="148">
    <Rec1 Val2="25.8">
        <Val3>Hello world</Val3>
    </Rec1>
</Root>
```

**XMLBase**

Define the simple BDL variable used as the base type of an XML Schema `simpleContent` structure.
The attribute can be set on one and only one member of a RECORD defined with the `XMLSimpleContent` attribute.

**XMLAll**

Map a BDL Record to an XML Schema all structure.

The order in which the record members appear in the XML document is not significant.

```
Example

DEFINE myall RECORD ATTRIBUTES(XMLAll,XMLName="Root")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT  ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  val3  STRING  ATTRIBUTES(XMLName="Val3")
END RECORD

<Root Val2="25.8">
  <Val3>Hello world</Val3>
  <Val1>148</Val1>
</Root>
```

**XMLChoice**

Map a BDL Record to an XML Schema choice structure. The choice of the record's member is performed at runtime, and changes dynamically according to a mandatory member. This specific member must be of type SMALLINT or INTEGER, and have an `XMLSelector` attribute set. The XMLChoice attribute also supports a "nested" value that removes the surrounding XML tag.

**Note:**

1. Valid selector values are indexes referring to members considered as XML element nodes. All other values will raise XML runtime errors.
2. Nested choice records cannot be defined as main variables; there must always be a surrounding variable.

```
Example

DEFINE mychoice RECORD ATTRIBUTES(XMLChoice,XMLName="Root")
  val1  INTEGER  ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT    ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  sel   SMALLINT ATTRIBUTES(XMLSelector),
  val3  STRING   ATTRIBUTES(XMLName="Val3")
END RECORD

Case where "sel" value is 4

<Root Val2="25.8">
  <Val3>Hello world</Val3>
</Root>

Case where "sel" value is 1

<Root Val2="25.8">
  <Val1>148</Val1>
```
Nested example:

```bdl
DEFINE myVar RECORD ATTRIBUTES (XMLName="Root")
    val1  INTEGER   ATTRIBUTES (XMLName="Val1"),
    val2  FLOAT     ATTRIBUTES (XMLAttribute, XMLName="Val2"),
    choice RECORD ATTRIBUTES (XMLChoice="nested")
        choice1  INTEGER ATTRIBUTES (XMLName="ChoiceOne"),
        choice2  FLOAt  ATTRIBUTES (XMLName="ChoiceTwo"),
        nestedSel SMALLINT ATTRIBUTES (XMLSelector)
    END RECORD,
    val3  STRING    ATTRIBUTES (XMLName="Val3")
END RECORD
```

Case where "nestedSel" value is 1

```xml
<Root Val2="25.8">
    <Val1>148</Val1>
    <ChoiceOne>6584</ChoiceOne>
    <Val3>Hello world</Val3>
</Root>
```

Case where "nestedSel" value is 2

```xml
<Root Val2="25.8">
    <Val1>148</Val1>
    <ChoiceTwo>85.8</ChoiceTwo>
    <Val3>Hello world</Val3>
</Root>
```

**XMLSequence (Optional)**

Map a BDL RECORD to an XML Schema sequence structure. The order in which the record members appear in the XML document must match the order of the BDL RECORD. The XMLSequence attribute also supports a “nested” value that removes the surrounding XML tag.

**Note:** Nested sequence records cannot be defined as main variables; there must always be a surrounding variable.

**Example**

```bdl
DEFINE mysequence RECORD ATTRIBUTES (XMLSequence, XMLName="Root")
    val1  INTEGER   ATTRIBUTES (XMLName="Val1"),
    val2  FLOAT     ATTRIBUTES (XMLName="Val2"),
    val3  STRING    ATTRIBUTES (XMLName="Val3")
END RECORD
```

```xml
<Root Val2="25.8">
    <Val1>-859</Val1>
    <Val3>Hello world</Val3>
</Root>
```

Nested example:

```bdl
DEFINE myVar RECORD ATTRIBUTES (XMLName="Root")
    val1  INTEGER   ATTRIBUTES (XMLName="Val1"),
    val2  FLOAT     ATTRIBUTES (XMLName="Val2"),
    sequence RECORD ATTRIBUTES (XMLSequence="nested")
        seq1   INTEGER   ATTRIBUTES (XMLName="SeqOne"),
    END RECORD,
```
**XMLSimpleContent**

Map a BDL RECORD to an XML Schema `simpleContent` structure.

**Note:** One member must have the XMLBase attribute; all other members must have an XMLAttribute attribute. If not, the compiler complains.

**Example**

```plaintext
DEFINE mysimpletype RECORD
  ATTRIBUTES(XMLSimpleContent, XMLName="Root")
  base STRING ATTRIBUTES(XMLBase),
  val1 INTEGER ATTRIBUTES(XMLAttribute, XMLName="Val1"),
  val2 FLOAT ATTRIBUTES(XMLAttribute, XMLName="Val2")
END RECORD

<Role Val2="25.8">
  <Val1>148</Val1>
  <SeqOne>6584</SeqOne>
  <SeqTwo>85.597</SeqTwo>
  <Val3>Hello world</Val3>
</Root>
```

**XSComplexType**

Map a BDL RECORD type definition to an XML Schema `complexType`.

**Note:** You can have one member as a nested sequence or choice, or as an XMLList array with a nested sequence or choice as the array's elements; all other members must have an XMLAttribute attribute. If not, the compiler complains.

**Example**

```plaintext
TYPE mycomplextype RECORD ATTRIBUTES(XSComplexType,
  XSTypeName="MyComplexType", XSTypeNamespace="http://tempuri.org")
  name DYNAMIC ARRAY ATTRIBUTES(XMLList) OF RECORD
    ATTRIBUTES(XMLSequence="nested")
    firstname STRING ATTRIBUTES(XMLName="FirstName"),
    lastname STRING ATTRIBUTES(XMLName="LastName")
  ,
  date DATE ATTRIBUTES(XMLAttribute, XMLName="Date")
END RECORD

<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  targetNamespace="http://tempuri.org"
  elementFormDefault="qualified">
  <xsd:complexType name="MyComplexType">
    <xsd:sequence maxOccurs="unbounded">
      <xsd:element name="FirstName" type="xsd:string" />
      <xsd:element name="LastName" type="xsd:string" />
    </xsd:sequence>
  </xsd:complexType>
</xsd:schema>
```
XMLList

Map a one dimensional array to an XML Schema element that has more than one occurrence.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES/XMLName="Root")
  val1 INTEGER ATTRIBUTES/XMLName="Val1"),
  list DYNAMIC ARRAY ATTRIBUTES/XMLList) OF STRING
  ATTRIBUTE/XMLName="Element"),
  val2 FLOAT ATTRIBUTES/XMLName="Val2")
END RECORD

<Root>
  <Val1>148</Val1>
  <Element>hello</Element>
  <Element>how</Element>
  <Element>are</Element>
  <Element>you</Element>
  <Val2>0.58</Val2>
</Root>
```

**Note:** It is not possible to define an XMLList attribute on a main array.

XMLSelector

Define the index of the candidate among all members of an XMLChoice record that will be serialized or deserialized at runtime.

The index starts at 1.

The selector data type must be a SMALLINT or a INTEGER.

XMLAny

Map a Xml.DomDocument object to a wildcard XML element:

```plaintext
DEFINE myVar RECORD ATTRIBUTES/XMLName="Root",XMLNamespace="http://tempuri.org")
  val1 INTEGER ATTRIBUTES/XMLName="Val1")
  any Xml.DomDocument ATTRIBUTES/XMLAny,XMLNamespace="##other")
  val2 FLOAT ATTRIBUTES/XMLName="Val2")
END RECORD

<pre:Root xmlns:pre="http://tempuri.org">
  <pre:Val1>148</pre:Val1>
  <pre2:Doc xmlns:pre2="http://www.mycompany.com">
    <pre2:Element>how</pre2:Element>
    <pre2:Element>are</pre2:Element>
    <pre2:Element>you</pre2:Element>
  </pre2:Doc>
  <pre:Val2>
    0.58</pre:Val2>
</pre:Root>
```

**Note:** Associated with XMLAny, the XMLNamespace attribute requires either:
• A list of space-separated URIs to accept each attribute belonging to one of this namespace URI as a wildcard attribute.
• The value `##any` to accept any attribute as a wildcard attribute.
• The value `##other` to accept any attribute not in the main schema namespace as a wildcard attribute.

For example:

• If XMLNamespace=“http://tmpuri.org http://www.mycompany.com”, then only the XML documents belonging to one of those namespaces will be accepted and serialized (or de-serialized) into the Xml.DomDocument object.
• If XMLNamespace=“##any”, then any XML document will be accepted and serialized (or de-serialized) into the Xml.DomDocument object.
• If XMLNamespace=“##other”, then any XML document not belonging to the targetNamespace of the XML Schema where the any definition is used will be accepted and serialized (or de-serialized) into the Xml.DomDocument object.

**XMLAnyAttribute**

Map a one-dimensional dynamic array to wildcard XML attributes.

### Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
  XMLNamespace="http://tempuri.org")
  val1 INTEGER ATTRIBUTES(XMLName="Val1"),
  val2 FLOAT   ATTRIBUTES(XMLName="Val2"),
  attr  STRING  ATTRIBUTES(XMLName="Attr", XMLAttribute),
  any   DYNAMIC ARRAY ATTRIBUTES(XMLAnyAttribute,
    XMLNamespace="##other")OF RECORD
    ns  STRING,
    name  STRING,
    value  STRING
  END RECORD
END RECORD
```

```xml
<pre:Root xmlns:pre="http://tempuri.org" pre:Attr="10"
  xmlns:pre2="http://www.mycompany.com" pre2:AnyAttr1="10"
  pre2:AnyAttr2="">
  <pre:Val1>148</pre:Val1>
  <pre:Val2>0.58</pre:Val2>
</pre:Root>
```

**Note:**

1. The attribute `XMLAnyAttribute` is only allowed on a one-dimensional dynamic array of a record with three members of type STRING. The first member is for the namespace of the wildcard attribute, the second member is for the name of the wildcard attribute, and the third member is for the value of the wildcard attribute. The name cannot be null.

2. Associated with the XMLAnyAttribute, the XMLNamespace attribute requires either:
   • A list of space-separated URIs to accept each attribute belonging to one of the namespace URIs as a wildcard attribute.
   • The value `##any` to accept any attribute as a wildcard attribute.
   • The value `##other` to accept any attribute not in the main schema namespace as a wildcard attribute.

For example:
• If XMLNamespace="http://tmpuri.org http://www.mycompany.com", then only the attributes belonging to one of those namespaces will be accepted and serialized (or deserialized) into the array.
• If XMLNamespace="##any", then any attribute will be accepted and serialized (or deserialized) into the array.
• If XMLNamespace="##other", then any attributes not belonging to the targetNamespace of the XML Schema where the anyAttribute definition is used will be accepted and serialized (or deserialized) into the array.

XMLName
Define the name of a variable in an XML document.

Note: The attribute cannot be set on a type definition.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT,
  val3  INTEGER ATTRIBUTES(XMLName="Val3")
END RECORD

<Root>
  <Val1>148</Val1>
  <val2>0.5</val2>
  <Val3>-18547</Val3>
</Root>

XMLNamespace
Define the namespace of a variable in an XML document.

Note:
1. If the attribute is set on a Record, by default all members defined as XMLElement of that record are in the same namespace.
2. If the attribute is set on an Array, by default all elements defined as XMLElement of that array are in the same namespace.
3. The attribute cannot be set on a type definition.

Example
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
XMLNamespace="http://tempuri.org")
  attr1 INTEGER ATTRIBUTES(XMLAttribute,XMLName="Attr1"),
  val1  FLOAT   ATTRIBUTES(XMLName="Val1", XMLNamespace="http://www.mycompany.com"),
  val2  INTEGER ATTRIBUTES(XMLName="Val2"),
  attr2 STRING  ATTRIBUTES(XMLAttribute, XMLName="Attr2",
                            XMLNamespace="http://anyuri.org")
END RECORD

<fjs1:Root xmlns:fjs1="http://tempuri.org" Attr1="158"
xmlns:fjs3="http://anyuri.org" fjs3:Attr2="Hello">
  <fjs2:Val1 xmlns:fjs2="http://www.mycompany.com">0.5</fjs2:Val1>
</fjs1:Root>
XMLType

Force the XML type name of a variable by adding xsi:type at serialization or by checking xsi:type at deserialization.

**Note:** The attribute must be used with the XMLTypenamespace attribute; otherwise, the compiler complains.

**Example**

```bdl
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
   XMLNamespace="http://tempuri.org")
   val1  FLOAT   ATTRIBUTES(XMLName="Val1"),
   val2  INTEGER ATTRIBUTES(XMLName="Val2",
      XMLType="MyRecord",
      XMLTypenamespace="http://mynamespace.org")
END RECORD

<fjs1:Root xmlns:fjs1="http://tempuri.org">
   <fjs1:Val1>0.5</fjs1:Val1>
   <fjs1:Val2 xmlns:fjs2="http://mynamespace.org" xsi:type="fjs2:MyRecord">-18547</fjs1:Val2>
</fjs1:Root>
```

XMLTypenamespace

Force the XML type namespace of a variable by adding xsi:type at serialization or by checking xsi:type at de-serialization.

**Note:** The attribute must be used with the XMLType attribute; otherwise the compiler complains.

**Example**

```bdl
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
   XMLNamespace="http://tempuri.org")
   val1  FLOAT   ATTRIBUTES(XMLName="Val1"),
   val2  INTEGER ATTRIBUTES(XMLName="Val2",
      XMLType="MyRecord",
      XMLTypenamespace="http://mynamespace.org")
END RECORD

<fjs1:Root xmlns:fjs1="http://tempuri.org">
   <fjs1:Val1>0.5</fjs1:Val1>
   <fjs1:Val2 xmlns:fjs2="http://mynamespace.org" xsi:type="fjs2:MyRecord">-18547</fjs1:Val2>
</fjs1:Root>
```

XSTypename

Define the XML Schema name of a BDL type definition.

**Note:**

1. The attribute must be used with the XSTypenamespace attribute; otherwise the compiler complains.
2. The attribute is only allowed on a type definition.

**Example**

```bdl
TYPE myType RECORD ATTRIBUTES(XMLSequence,
    XSTypeName="MyFirstType",
    XSTypeNamespace="http://tempuri.org" )
    val1  FLOAT   ATTRIBUTES(XMLElement,XMLName="Val1"),
    val2  INTEGER
    ATTRIBUTES(XMLElement,XMLName="Val2",XMLOptional),
    attr  STRING  ATTRIBUTES(XMLAttribute,XMLName="Attr")
END RECORD
```

```xml
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    targetNamespace="http://tempuri.org"
    elementFormDefault="qualified">
    <xsd:complexType name="MyFirstType">
        <xsd:sequence>
            <xsd:element name="Val1" type="xsd:double" />
            <xsd:element name="Val2" type="xsd:int" minOccurs="0" />
        </xsd:sequence>
        <xsd:attribute name="Attr" type="xsd:string" use="required" />
    </xsd:complexType>
</xsd:schema>
```

**XSTypenamespace**

Define the XML Schema namespace of a BDL type definition.

**Note:**

1. The attribute must be used with the XSType attribute; otherwise the compiler complains.
2. The attribute is only allowed on a type definition.

**Example**

```bdl
TYPE myType RECORD ATTRIBUTES(XMLChoice,
    XSTypeName="MyFirstChoice",
    XSTypeNamespace="http://tempuri.org" )
    val1  FLOAT   ATTRIBUTES(XMLElement,XMLName="Val1"),
    val2  INTEGER
    ATTRIBUTES(XMLElement,XMLName="Val2",XMLOptional),
    attr  STRING  ATTRIBUTES(XMLAttribute,XMLName="Attr",XMLOptional),
    set   INTEGER ATTRIBUTES(XMLSelector)
END RECORD
```

```xml
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    targetNamespace="http://tempuri.org"
    elementFormDefault="qualified">
    <xsd:complexType name="MyFirstChoice">
        <xsd:choice>
            <xsd:element name="Val1" type="xsd:double" />
            <xsd:element name="Val2" type="xsd:int" minOccurs="0" />
        </xsd:choice>
        <xsd:attribute name="Attr" type="xsd:string" />
    </xsd:complexType>
</xsd:schema>
```
**XMLElementNamespace**

Define the default namespace of all members of a record also defined as XML elements.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
   XMLNamespace="http://tempuri.org",
   XMLElementNamespace="http://www.mycompany.com")
val1 FLOAT ATTRIBUTES(XMLElement,XMLName="Val1"),
val2 INTEGER ATTRIBUTES(XMLElement,XMLName="Val2"),
attr STRING ATTRIBUTES(XMLAttribute,XMLName="Attr"),
END RECORD

<fjs1:Root xmlns:fjs1="http://tempuri.org" Attr="Hello"
   xmlns:fjs2="http://www.mycompany.com">
   <fjs2:Val1>0.5</fjs2:Val1>
   <fjs2:Val2>-18547</fjs2:Val2>
</fjs1:Root>
```

**XMLAttributeNamespace**

Define the default namespace of all members of a record also defined as XML attributes.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
   XMLNamespace="http://tempuri.org",
   XMLAttributeNamespace="http://www.mycompany.com")
val1 FLOAT ATTRIBUTES(XMLElement,XMLName="ValOne"),
val2 FLOAT ATTRIBUTES(XSDdouble,XMLName="ValTwo",XMLOptional)
END RECORD

<fjs1:Root xmlns:fjs1="http://tempuri.org"
   fjs2:Attr1="Hello", xmlns:fjs2="http://www.mycompany.com"
   <fjs1:Val1>0.5</fjs1:Val1>
   <fjs1:Val2>-18547</fjs1:Val2>
</fjs1:Root>
```

**XMLOptional**

Define whether the variable can be missing or not. It specifies how a NULL value is interpreted in XML.

**Note:**

1. The attribute cannot be set on a type definition.
2. The attribute cannot be set if the main variable is not a RECORD.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
val1 INTEGER ATTRIBUTES(XSDint,XMLName="ValOne"),
val2 FLOAT ATTRIBUTES(XSDdouble,XMLName="ValTwo",XMLOptional)
```
Error handling in GWS calls (STATUS)

In case of problem, the methods of GWS classes can throw an exception and set the STATUS variable with the appropriate error number.

By default, the program will stop if an exception is thrown. You can trap the GWS errors with a WHENEVER ERROR handler or with a TRY/CATCH block. In the next example, the readTextRequest() API is surrounded by a TRY/CATCH block:

```plaintext
DEFINE req com.HTTPServiceRequest,
data STRING
...
LET req = com.WebServiceEngine.getHTTPServiceRequest(5)
TRY
...
CALL req.readTextRequest() RETURNING data
...
CATCH
CALL show_err(SFMT("Unexpected HTTP request read exception: %1", STATUS))
END TRY
```

For some errors, a human-readable description of the error code is available in the SQLCA.SQLERRM register.

Interruption handling in GWS calls (INT_FLAG)

Genero Web Services (GWS) tests INT_FLAG to check if an application has been interrupted.

If INT_FLAG is set to TRUE, the DVM interrupts the GWS function processing and an exception is raised with error code -15553.

Important: Set the INT_FLAG register to FALSE before calling a GWS function. For example, after a dialog was stopped with a cancel action, the INT_FLAG is set to TRUE. If you do not reset INT_FLAG to FALSE, the next GWS function may be canceled.

As a general rule, surround GWS calls with a TRY/CATCH block (or WHENEVER ERROR handler), to detect both communication errors and interruptions.

```plaintext
TRY
 LET INT_FLAG=FALSE
...
 CALL req.sendXMLRequest(doc)
...
CATCH
 CASE STATUS
 WHEN -15553 -- TCP socket error
 IF INT_FLAG THEN
  MESSAGE "An interruption occurred."
```
Server API functions - version 1.3 only

The following table lists the APIs to create a Web Services server in BDL.

**Note:** These functions are valid for backwards compatibility, but they are not the preferred way to handle Genero Web Services. See the GWS COM Library classes and methods.

Table 575: APIs to create a Web Services server in BDL (version 1.3 only)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fgl_ws_server_setNamespace()</td>
<td>Defines the namespace of the service on the Web.</td>
</tr>
<tr>
<td>fgl_ws_server_start()</td>
<td>Creates and starts the Web Service server.</td>
</tr>
<tr>
<td>fgl_ws_server_publishFunction()</td>
<td>Publishes the BDL function as a Web Function.</td>
</tr>
<tr>
<td>fgl_ws_server_generateWSDL()</td>
<td>Generates the WSDL file.</td>
</tr>
<tr>
<td>fgl_ws_server_process()</td>
<td>Waits for and processes incoming SOAP requests.</td>
</tr>
<tr>
<td>fgl_ws_server_setFault()</td>
<td>Sets the SOAP fault string for a Web Function.</td>
</tr>
<tr>
<td>fgl_ws_server_getFault()</td>
<td>Retrieves the fault string that was set for a Web Function, for testing purposes.</td>
</tr>
</tbody>
</table>

**fgl_ws_server_setNamespace() (version 1.3)**

**Purpose**

This function defines the namespace of the service on the Web and must be called first, before all other functions of the API.

**Syntax**

FUNCTION fgl_ws_server_setNamespace(namespace VARCHAR)

**Parameters**

- **namespace** is the name of the namespace.

**Return values**

- None

**Example**

```sql
CALL fgl_ws_server_setNamespace("http://tempuri.org")
```
fgl_ws_server_start() (version 1.3)

Purpose
This function creates and starts the server. For development or testing purposes, you may start a Web Service server as a single server where only one request at a time will be able to be processed. For deployment, you may start a Web Service server with an application server able to handle several connections at one time using a load-balancing algorithm. The value of the parameter passed to the function determines which method is used.

Syntax

FUNCTION fgl_ws_server_start(tcpPort VARCHAR)

Parameters

• tcpPort is a string representing either:
  • the socket port number (for a single Web Service server)
  • the host and port value separated by a colon (for a Web Service server connecting to an application server). The value of port is an offset beginning at 6400.

  Note: If the FGLAPPSERVER environment variable is set, the tcpPort value is ignored, and replaced by the value of FGLAPPSERVER.

Return values

• None

Examples:
To start a standalone Web Service server:

CALL fgl_ws_server_start("8080") # A single Server is listening
# on port number: 8080

To start a Web Service server attempting to connect to an application server:

CALL fgl_ws_server_start("zeus:5") # The server attempt to connect
# to an application server
located
# on host zeus and listening
# on the port number 6405

Possible runtime errors

• -15504: PORT_ALREADY_USED
• -15514: PORT_NOT_NUMERIC
• -15515: NO_AS_FOUND
• -15516: LICENSE_ERROR

fgl_ws_server_publishFunction() (version 1.3)

Purpose
This function publishes the given BDL function as a Web-Function on the Web.
Syntax

```
FUNCTION fgl_ws_server_publishFunction(
    operationName VARCHAR,
    inputNamespace VARCHAR,
    inputRecordName VARCHAR,
    outputNamespace VARCHAR,
    outputRecord VARCHAR,
    functionName VARCHAR)
```

Parameters

- `operationName` is the name by which the operation will be defined on the Web. The name is case sensitive.
- `inputNamespace` is the namespace of the incoming operation message.
- `inputRecordName` is the name of the BDL record representing the Web Function input message or "" if there is none.
- `outputNamespace` is the namespace of the outgoing operation message.
- `outputRecord` is the name of the BDL record representing the Web Function output message or "" if there is none.
- `functionName` is the name of the BDL function that is executed when the Web Service engine receives a request with the operation name defined above.

Return values

- None

Example

```
CALL fgl_ws_server_publishFunction(
    "MyWebOperation",
    "http://www.tempuri.org/webservices/", "myfunction_input",
    "http://www.tempuri.org/webservices/", "myfunction_output",
    "my_bdl_function")
```

Possible runtime errors

- -15503: FUNCTION_ALREADY_EXISTS
- -15501: FUNCTION_ERROR
- -15502: FUNCTION_DECLARATION_ERROR
- -15512: INPUT_VARIABLE_ERROR
- -15513: OUTPUT_VARIABLE_ERROR
- -15503: BDL_XML_ERROR
- -15518: INPUT_NAMESPACE_MISSING
- -15519: OUTPUT_NAMESPACE_MISSING

`fgl_ws_server_generateWSDL()` (version 1.3)

Purpose

This function generates the WSDL file according to the BDL-server program.

Syntax

```
FUNCTION fgl_ws_server_generateWSDL(
```
Parameters

- `serviceName` is the name of the web service.
- `serviceLocation` is the URL of the server.
- `fileName` is the name of the file that will be generated.

Return values

- `resultStatus` is a status containing:
  - 0 if the file has been correctly generated.
  - Any other values if the operation has failed.

Example

```sql
DEFINE mystatus INTEGER

LET mystatus=fgl_ws_server_generateWSDL(
"CustomerService",
"http://localhost:8080",
"C:/mydirectory/myfile.wsdl")

IF mystatus=0 THEN
  DISPLAY "Generation of WSDL done..."
ELSE
  DISPLAY "Generation of WSDL failed!"
END IF
```

`fgl_ws_server_process()` (version 1.3)

Purpose

This function waits for an incoming SOAP request for a given time (in seconds) and then processes the request, or returns, if there has been no request during the given time. If a DEFER INTERRUPT or DEFER QUIT instruction has been defined, the function returns even if it is an infinite wait.

Syntax

```sql
FUNCTION fgl_ws_server_process(timeout INTEGER)
  RETURNING resultStatus INTEGER
```

Parameters

- `timeout` is the maximum waiting time for an incoming request (or -1 for an infinite wait)

Return values

- `resultStatus` is a status containing:
  - 0 Request has been processed
  - -1 Timeout has been reached
  - -2 The application server asks the runner to shutdown
• -3 A client connection has been unexpectedly broken
• -4 An interruption has been raised
• -5 The HTTP header of the request was incorrect
• -6 The SOAP envelope was malformed
• -7 The XML document was malformed

Example

```lisp
DEFER INTERRUPT
DEFINE mystatus INTEGER
LET mystatus=fgl_ws_server_process(5)# wait for 5 seconds # for incoming request
  IF mystatus=0 THEN
    DISPLAY "Request processed."
  END IF
  IF mystatus=-1 THEN
    DISPLAY "No request."
  END IF
  IF mystatus=-2 THEN # terminate the application properly
    EXIT PROGRAM # if connected to application server
  END IF
  IF mystatus=-3 THEN
    DISPLAY "Client connection unexpectedly broken."
  END IF
  IF mystatus=-4 THEN
    DISPLAY "Server process has been interrupted."
  END IF
  IF mystatus=-5 THEN
    DISPLAY "Malformed or bad HTTP request received."
  END IF
  IF int_flag<>0 THEN
    LET int_flag=0
    EXIT PROGRAM
  END IF
```

fgl_ws_server_setFault() (version 1.3)

Purpose

This function can be called in a published Web-Function in order to return a SOAP fault string to the client at the end of the function's execution.

Syntax

```lisp
FUNCTION fgl_ws_server_setFault(faultMessage VARCHAR)
```

Parameters

• `faultMessage` is a string containing the SOAP Fault string that will be returned to the client.

Return values

• None

Example

```lisp
CALL fgl_ws_server_setFault(
```
fgl_ws_server_getFault() (version 1.3)

**Purpose**
This function retrieves the last fault string the user has set in a Web-Function, or an empty string if there is none.

**Note:** This function is only for testing the Web Services functions before they are published on the Web.

**Syntax**
```plaintext
FUNCTION fgl_ws_server_getFault()
RETURNING faultMessage VARCHAR
```

**Parameters**
- None

**Return values**
- `faultMessage` is the string containing the SOAP Fault string.

**Example**
```plaintext
DEFINE div_input RECORD
  a INTEGER,
  b INTEGER
END RECORD

DEFINE div_output RECORD
  result INTEGER
END RECORD

FUNCTION TestServices()
  DEFINE string VARCHAR(100)
  ...
  # Test divide by zero operation
  LET div_input.a=15
  LET div_input.b=0
  CALL service_operation_div()
  LET string=fgl_ws_server_getFault()
  DISPLAY "Operation div error: ", string
  ...
END FUNCTION

FUNCTION service_operation_div()
  ...
  IF div_input.b = 0 THEN
    CALL fgl_ws_server_setFault("Divide by zero")
    RETURN
  END IF
  ...
END FUNCTION
```
Configuration API functions - version 1.3 only

The following table lists those configuration API functions that can modify the behavior of the Web Services engine for the client as well as for the server.

**Note:** These functions are valid for backwards compatibility, but they are not the preferred way to handle Genero Web Services. See the COM Library classes and methods.

Table 576: Configuration API functions for Web Services engine behavior modification

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fgl_ws_setOption()</td>
<td>Sets an option flag with a given value.</td>
</tr>
<tr>
<td>fgl_ws_getOption()</td>
<td>Returns the value of an option flag.</td>
</tr>
</tbody>
</table>

**fgl_ws_setOption()**

This function sets an option flag with a given value, changing the global behavior of the Web Services engine.

Syntex

```FUNCTION fgl_ws_setOption(optionName VARCHAR,  
                           optionValue INTEGER)```

Parameters

- `optionName` is one of the global flags.
- `optionValue` is the value of the flag.

Return values

- None

**Example**

```
CALL fgl_ws_setOption("http_invoketimeout", 5)
```

Possible runtime errors

- -15511: INVALID_OPTION_NAME

**fgl_ws_getOption()**

This function returns the value of an option flag.

Syntax

```FUNCTION fgl_ws_getOption(optionName VARCHAR)  
       RETURNING optionValue INTEGER```

Parameter

- `optionName` is one of the global flags.
Return values

- `optionValue` is the value of the flag.

Example

```plaintext
DEFINE value INTEGER
LET value=fgl_ws_getOption("http_invoketimeout")
```

Possible runtime errors

- -15511: INVALID_OPTION_NAME

Option flags

Table 577: Option flags

<table>
<thead>
<tr>
<th>Flags</th>
<th>Client or Server</th>
<th>Commentary</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>http_invoketimeout</code></td>
<td>Client</td>
<td>Defines the maximum time in seconds a client has to wait before the client connection raises an error because the server is not responding. A value of -1 means that it has to wait until the server responds. The default value is -1.</td>
</tr>
<tr>
<td><code>tcp_connectiontimeout</code></td>
<td>Client</td>
<td>Defines the maximum time in seconds a client has to wait for the establishment of a TCP connection with a server. A value of -1 means infinite wait. The default value is 30 seconds except for Windows™, where it is 5 seconds.</td>
</tr>
<tr>
<td><code>soap_ignoretimezone</code></td>
<td>Both</td>
<td>Defines if, during the marshalling and unmarshalling process of a BDL DATETIME data type, the SOAP engine should ignore the time zone information. A value of zero means false. The default value is false.</td>
</tr>
<tr>
<td><code>soap_usetypedefinition</code></td>
<td>Both</td>
<td>Defines if the Web Services engine must specify the type of data in all SOAP requests. This will add an &quot;xsi:type&quot; attribute to each parameter of the request. A value of zero means false.</td>

</tbody>
</table>

**WSDL generation option notes**

1. For a BDL type **DECIMAL(5,2)**, when **wsdl_decimalsize** is TRUE, the generated **WSDL** file contains the total size and the size of the fractional part of the decimal:

```xml
<types>
  <schema xmlns="http://www.w3.org/2001/XMLSchema"
    targetNamespace="http://www.mycompany.com/types/">
    <simpleType name="echoDecimal5_2_a_dec5_2_out_FGLDecimal">
      <restriction base="decimal">
        <totalDigits value="5" />
        <fractionDigits value="2" />
      </restriction>
    </simpleType>
  </schema>
</types>

<message name="echoDecimal5_2">
  <part name="dec5_2" type="f:echoDecimal5_2_a_dec5_2_in_FGLDecimal" />
</message>
```

When **wsdl_decimalsize** is FALSE, the total size and the size of the fractional part are not mentioned:

```xml
<message name="echoDecimal5_2">
  <part name="dec5_2" type="xsd:decimal" />
</message>
```
2. If the WSDL file does not contain the size, the client application has no way of knowing the size. In this scenario, a default value for the size is generated. For example, the exported server type \texttt{DECIMAL(5,2)} becomes a \texttt{DECIMAL(32)} on the client side.

3. It is better to keep the options \texttt{wsdl_arraysize}, \texttt{wsdl_stringsize} and \texttt{wsdl_decimalsize} set to \texttt{TRUE} (default) so that the BDL client application can do an exact type mapping.

**Using \texttt{fglwsdl} to generate code from WSDL or XSD schemas**

This section covers the different options of the \texttt{fglwsdl} tool. This tool is used to generate .4gl code from WSDL / XSD schemas.

**Generate TYPE definitions from global XML elements or attributes**

If a WSDL or a XSD has global XML elements or attributes defined with an inlined type, the -\textit{fInlineTypes} option of \texttt{fglwsdl} generates a \texttt{TYPE} definition representing that inline type, using the original WSDL/XSD name of the element or attribute, concatenated with the string ‘GlobalAttributeType’ or ‘GlobalElementType’.

For example, when using \texttt{fglwsdl -fInlineTypes}, the following schema:

```xml
<xs:element name="getAlertListRequestFlow">
  <xs:complexType>
    <xs:sequence>
      <xs:element name="getAlertListRequest" type="amp:getAlertListRequest" />
    </xs:sequence>
  </xs:complexType>
</xs:element>
```

Will produce:

```perl
TYPE tgetAlertListRequestFlowGlobalElementType RECORD
  ATTRIBUTES(XMLSequence)
    getAlertListRequest tgetAlertListRequest
      ATTRIBUTES(XMLName="getAlertListRequest")
  END RECORD
DEFINE getAlertListRequestFlow tgetAlertListRequestFlowGlobalElementType
  ATTRIBUTES(XMLName="getAlertListRequestFlow")
END RECORD
```

Instead of:

```perl
DEFINE getAlertListRequest Flow RECORD
  ATTRIBUTES(XMLName="getAlertListRequestFlow",XMLSequence)
    getAlertListRequest Request tgetAlertListRequest
      ATTRIBUTES(XMLName="getAlertListRequest")
  END RECORD
```
Mobile applications

These topics cover programming subjects about mobile applications

- Types of Genero Mobile apps on page 2564
- Language limitations on page 2570
- Environment variables on mobile on page 2570
- App localization on page 2570
- Apps user interface on page 2571
- Database support on mobile devices on page 2579
- Web Services on mobile devices on page 2581
- Accessing device functions on page 2581
- Debugging a mobile app on page 2582
- Deploying mobile apps on page 2584
- Push notifications on page 2611

Types of Genero Mobile apps

A mobile app is an app that runs on a mobile device, such as a tablet or a phone. There are different types of mobile apps.

When you are developing your app, and you execute the app on your development machine for display on a device or emulator, you are running the app in development mode.

When you follow the procedure to deploy your application to the device for testing or to distribute your app to your end users, you have a deployed app. A deployed app might be an app that executes irrespective of network availability, it might be an app that accesses device peripherals, it might be an app that requires network access.

Here are the categories, or application types, for deployed apps.

Standalone apps

A standalone app has the DVM and display client entirely on the mobile device. This app executes irrespective of network availability and can access device peripherals such as the camera, contacts, email, calendar, GPS, and storage via exposed APIs (front calls). For database needs, this app can only connect to a local SQLite database.

Note: The DVM refers to the dynamic virtual machine, which is the process that runs the app.
Figure 116: Standalone app

**Partially-connected apps**

A *partially-connected app* has the DVM and display client entirely on the mobile device, yet this app includes items that require a network connection. This app must be able to run when no network connection is available. This app uses a network API to talk to any back-end.

Examples include:

- Web Services performed with JSON over HTTP; use RESTful methods to write data synchronization routines. With this example, business logic executes within the device’s Virtual Machine and the user is able to store captured data to a local SQLite database. When the network becomes available, the user synchronizes the stored data with the remote server’s database.

  **Note:** As of Genero Mobile 1.1, you can also write a Web Service using SOAP.

- A web component that runs Google Maps.

This app first operates without a network connection, and must be able to run without a network connection. Once network connectivity is restored, the app can perform network-dependent tasks such as synchronizing with a remote database, make a web service call, or use a web component.

If you are using GMI, and the device goes into standby mode, the application does not run in the background and activities with the network are suspended.
Client-server apps

With a client-server app or connected app, the bulk of the app runs on a remote server and the display client sits on the mobile device.

As with any deployed app, this app first starts on the mobile device; the DVM for the deployed app runs on the mobile device. The role of the deployed app, however, is to connect to a remote corporate server as an online terminal. It is the deployed app that launches the remote application using the runOnServer frontcall. The remote application’s DVM and business logic reside on the remote server, somewhere in the network. The remote application is not limited to a SQLite database.

In the event that the network is interrupted, the Genero Mobile client app is suspended until service resumes.

Figure 118: Client-server app

Mobile development mode

Setup a development environment to display app forms on a mobile front-end.

In a command-line development environment, the runtime system (DVM) executes the application code on the development machine, displaying app forms through a mobile front-end installed on a device or emulator.

This is the typical configuration used in a development environment. Once the app development is complete, you can build the real mobile app to be deployed on devices, as described in Deploying mobile apps on page 2584.

Genero mobile development client for Android

Set up a development environment to display app forms on an Android device.

Using the GMA front-end on Android™ devices

To display Genero application forms on an Android™ device in development mode (with programs executing on a computer), the GMA front-end app must be installed on the device (or emulator).

Note: With the GMA front-end installed on the mobile device, you can perform a classic GUI connection based on FGLSERVER.

Building the GMA front-end application

Before building the GMA front-end, fulfill the prerequisites to build an Android app as described in Building Android apps with Genero on page 2586.

Get the GMA package (for ex, fjs-gma-1.20.05-build201602101754.zip), extract the APK archive for your device type. Plug your devices via USB cable to the computer to copy and install the GMA front-end APK, or use the gmabuildtool command with the test option:

```
$ . ~/genero/devel/fgl/mobile/java-1.8.env
$ . ~/genero/devel/fgl/mobile/android-sdk.env
$ mkdir /tmp/gma
$ cd /tmp/gma
$ unzip ~/Download/fjs-gma-1.20.05-build201602101754-allos.zip
Archive:  ~/Download/fjs-gma-1.20.05-build201602101754-allos.zip
... inflating: fjs-gma-1.20.05-build201602101754-d32a040.apk
inflating: fjs-gma-1.20.05-build201602101754-d32x040.apk
...
$ gmabuildtool test --test-apk ./fjs-gma-1.20.05-build201602101754-d32a040.apk
...
```

Once the GMA front-end is installed on the device, make sure that WIFI is enabled and start the GMA app. The main GMA screen shows the IP address of the device and the TCP port it is listening to (0=6400).

On the development machine, define the FGLSERVER environment variable with the IP address of the device.

Now you are ready to run your app on the server and display on the Android device.
Genero mobile development client for iOS

Set up a development environment to display app forms on an iOS device.

Installing the GMI front-end on iOS devices

To display Genero application forms on the device, the GMI front-end must be installed on your iOS devices (or emulators).

Genero supports two types of GMI front-end apps for iOS:

- The ready-to-use “Genero Mobile Development Client” for iOS, available through the App Store.

  **Important:** Due to Apple limitations, the Genero Mobile Development Client app is not allowed to listen to a TCP port to provide a GUI service. In order to establish the GUI front-end connection, the front-end must connect to the runtime system running on the development machine.

- A self-made GMI front-end, using the gmibuildtool to build a GMI front-end app with your own Apple developer account.

  **Note:** With this configuration, you can perform a classic GUI connection based on FGLSERVER.

Using the Genero Mobile Development Client for iOS

Go to the App Store and search for “Genero Mobile”, select and install the "Genero Mobile Development Client".

Once the GMI development client is installed on the device, make sure that WIFI is enabled and start the GMI app.

  **Note:** Because of iOS app limitations defined by Apple, an app shipped on the App Store cannot listen to a TCP port to provide a GUI service. In order to display Genero form on the GMI development client, you will have to establish the GUI connection from the device to the server, after starting the fglrun process with the --gui-listen option.

The main GMI screen shows a URL field to let you enter the IP address / hostname and the TCP port the runtime system will listen to.

  **Note:** Make sure that the firewall on the development machine allows incoming connections for the TCP port number specified with the --gui-listen fglrun option.

Start the application on the development server, by using the fglrun --gui-listen=portnum command:

```bash
fglrun --gui-listen=6500 main.42m
```

On the iOS device, enter the following in the URL field:

```
fgl://dev-server-hostname:6500
```

Then tap the [Connect] button to establish the GUI connection.

Build your own GMI front-end

In order to use the classic GUI connection mode with fglrun connecting to the mobile front-end via FGLSERVER, it is possible to create your own GMI front-end, with your own Apple certificate and provisioning profile.

  **Note:** As with other iOS apps, a self-made GMI front-end can only be created on a Mac OS/X computer.
The generated GMI can then be deployed on your device or simulator. The GMI front-end will listen on the port 6400, to display applications running on a server through the FGLSERVER setting.

Before creating your own GMI front-end, fulfill the prerequisites to build an iOS app as described in Building iOS apps with Genero on page 2598.

In order to build your own GMI front-end:

1. Make sure that the gmibuildtool is available (if not done yet, extract the fjs-flgmi*.zip archive into FGLDIR).
2. Go to the FGLDIR/demo/MobileDemo/gmiclient directory.
3. Delete the complete build directory if it exists (can be done with a make clean command).
4. Make the GMI app with make (program files like main.42m file must exist).
5. Build the GMI front-end:
   - To build only the GMI front-end (GMI.app directory) for the simulator, execute the gmibuildtool command without any parameter:
     
     ```
     $ gmibuildtool
     ```
   - To build and install the GMI front-end on the simulator, first make sure that the simulator is started (open -a simulator command), then execute the gmibuildtool command with following parameters:
     
     ```
     $ gmibuildtool --device booted
     ```
   - To build only the GMI front-end IPA for devices, get a development certificate and provisioning profile and execute the gmibuildtool command with following parameters:
     
     ```
     $ gmibuildtool \
     --device phone \
     --certificate "iPhone Developer" \
     --provisioning "~/Library/MobileDevice/Provisioning Profiles/myapp.mobileprovision"
     ```
     The generated IPA file can be found in the build subdirectory. This IPA file can be installed on your devices by using iTunes.
   - To build and install the GMI front-end on the device plugged to your Mac, get a development certificate and provisioning profile, and the exact device name (with the instruments -s command) and execute the gmibuildtool command with following parameters:
     
     ```
     $ gmibuildtool \
     --device "Mike's iPhone 6 (9.0)" \
     --certificate "iPhone Developer" \
     --provisioning "~/Library/MobileDevice/Provisioning Profiles/myapp.mobileprovision"
     ```
     Once the GMI front-end is installed on the device, make sure that WIFI is enabled and start the GMI app.

     The main GMI screen shows the IP address of the device and the TCP port it is listening to (0=6400).

     On the development machine, define the FGLSERVER environment variable with the IP address of the device.

     Now you are ready to run your app on the server and display on the iOS device.
Language limitations

Parts of the Genero language are not supported on mobile devices.

**Important:** This topic is provided as a quick glance at Genero Business Development Language limitations in mobile applications. Details can be found in the BDL reference topics.

The following language options have limited support:

- The **RUN** instruction has limited support on mobile platforms.
  - The **RUN** instruction is not supported on mobile devices, because of operating system limitations.
  - **RUN command WITHOUT WAITING** is not supported when programs run on an application server and display on a mobile device, because the Genero GUI protocol is not able to handle multiple connections at the same time.

The following language features are not supported.

- The **INPUT ARRAY** instruction is not supported.
- The **base.Channel.openPipe** method is not supported.

Environment variables on mobile

You may need to set environment variables for your app.

**Set environment variables**

Set environment variables for your app must be done in an **fglprofile** file. This **fglprofile** file must be located beside the main program module.

To add an environment variable for your mobile app, use the following syntax:

```
mobile.environment.DBFORMAT="$:,::"
```

Any existing environment variable setting is overwritten by the value set (using `mobile.environment.envvarname`) in the **fglprofile** file.

For more details, see Setting environment variables in FGLPROFILE (mobile) on page 173.

**Note:** Environment variables set in an FGLPROFILE file are only read when the deployed application runs the mobile device. They are not read during development mode (i.e. when the VM runs on the development machine and the mobile client displays on the device). The FGLPROFILE environment variable settings are only for the VM component and are ignored by the GMA/GMI front-end component.

App localization

Mobile apps can be designed to display localized texts according to the current language selected on the device.

Localized string files (.42s) must be deployed in directories matching the language identifiers (en for English, zh_TW for simplified Chinese, etc), beside the program module.

The list of .42s files required by the application must be defined in the unique **fglprofile** configuration file located beside the program module of your application.

For more details, see Localized string files on mobile devices on page 336 and Deploying mobile apps on page 2584.
App execution

Mobile apps are started and stopped, and can switch between foreground and background states when running.

App execution modes

On iOS and on Android, standalone Genero apps are installed and started on the device as other apps. However, if a permanent network connect is available (WIFI), it is possible to have a lightweight app installed on the device, that executes the real application code on a server, displaying forms on the device.

For more details, see Starting programs on a mobile device on page 394.

Android app state

The foreground / background state of Android apps can be controlled with a presentation style attribute which applies to the UserInterface class: androidKeepForeground.

For more details, see Controlling Android app states (GMA) on page 394.

Apps user interface

This section includes topics about user interface programming for mobile.

In general, the user interface of a mobile app written in Genero displays and reacts as a desktop or web application, while simultaneously respecting the device operating system look-and-feel. There are parts of the interface, however, that display and react in a specific way.

Take a look at each of the user interface items in this chapter, to understand how they are portrayed in a mobile app. A user interface feature not listed means there is nothing mobile-specific to its display or behavior.

Action rendering

How actions are rendered varies between OS type of the mobile device.

The top and/or bottom parts of the mobile app screen is dedicated to displaying default action views to the user. A default action view is an implicit graphical item that can be tapped to fire the corresponding action.

The default action views are rendered on the mobile device according to platform-specific standards, which are covered in Rendering default action views on mobile on page 1281.
Figure 119: Action rendering example on an Android device
Images and icons

For this topic, an image can refer to the *IMAGE* item type or the icons used in the app.

**Image format support**

Mobile apps written in Genero supports all image formats supported by the device OS, however each platform has its own restrictions on which image formats it supports:

- Android image format support
- iOS image format support

Mobile devices have a much higher pixel density (a higher resolution) than classic desktop monitors. An image which looks nice on a desktop can appear small or as an upscaled image on a mobile device.

**Providing the image resource**

Genero supports different solutions to provide the image data in a mobile app, depending on the need (button icon, application picture, etc). To understand how to get image resource on mobile apps with Genero, see *Providing the image resource* on page 784.

**Image sizing on mobile devices**

The *IMAGE* item type defines an area for the display of an image on a form.
Image layout and sizing can be controlled with form item attributes to adapt to the type of mobile device. For more details, see Controlling the image layout on page 783.

Default action icons

In general, you want the icons used for your mobile app to be the standard icons used by all apps for the mobile platform. Genero is set up to use such icons by default. For more details, see Rendering default action views on mobile on page 1281.

Genero also supports icon centralization based on TTF icons, to get a global consistent look and feel for all your mobile apps. For more details, see Providing the image resource on page 784.

Keyboard type

Depending on the data being entered, a mobile device should display the keyboard that is appropriate for the data.

There are a variety of keyboard types for mobile devices. A field dedicated to phone number input should display a keyboard easing phone number input.

The KEYBOARDHINT form field attribute provides a hint regarding the kind of data the form field contains. Valid values include DEFAULT, EMAIL, NUMBER, and PHONE:

```
ATTRIBUTES
EDIT f01 = customer.cust_phone, KEYBOARDHINT = PHONE;
...
```

Although Genero mostly respects the provided hint, the variable data type that is bound to the form field is also examined, to determine what keyboard to display:

- If the field is defined as a DATE or DATETIME field, the date picker displays regardless of the KEYBOARDHINT setting.
- If the field is a TEXT data, a text keyboard displays regardless of the KEYBOARDHINT setting.

For more details, see KEYBOARDHINT attribute on page 976.

List views

Form tables in a mobile app render as list views.

List views are commonly used in mobile apps to present an indexed list of items or selectable list of options. They are also used to let users navigate through hierarchically structured data.

List views are displayed as either full list views or embedded list views.

The list view only displays the first two columns' content and any associated row image, regardless of the number of columns defined.

No column header/title is displayed in mobile list views. Thus the mobile user cannot manipulate columns (hide, reorder, resize, or sort).

With full list views, the built-in reduce filter allows the user to filter the rows displayed.

The JUSTIFY attribute of the second column can influence how the rows are displayed.

Various options affect the rendering and behavior, by defining TABLE container attributes, DISPLAY ARRAY dialog attributes and ON ACTION handler attributes.

For complete details on implementing table views in a mobile app, see Using tables on mobile devices on page 1364.
Split views

Split views refer to the ability to access two forms side by side on a mobile device.

Side by side views on mobile apps

Many mobile apps offer a specific form layout, splitting the screen in two in order to show a list of the left side and a detail form on the right side. Such kind of layout can be implemented in Genero with the Split views on page 1397.

Differences in how split views are handled by the clients

There are differences between the Genero Mobile for iOS (GMI) and Genero Mobile for Android (GMA) implementations of split views and parallel dialogs, to include:

- When the application displays in a single pane or in two panes.
- How a user switches between the two panes.

There are also differences in how the split view renders between GMA and GMI.

With Genero Mobile for Android:

- The navigator pane renders as a menu in the left-hand side of the title bar.
- All buttons are merged.
- The title is not displayed when there is a navigator pane. If there is no navigator pane, the title of the current window is displayed.
With Genero Mobile for iOS:

- The navigator pane renders along the bottom of the app.
- Each window has its own title and its own buttons.

**Figure 122: The stores2 demo rendered on an iOS device**

### Toolbars

Toolbars allow to control over where actions display (and in what order).

For desktop applications, the toolbar is a series of buttons typically contained in a toolbar object, located at the top of the form. For Genero mobile apps, the toolbars are rendering according to the mobile platform standards.

**Table 578: Mobile platform differences for toolbars**

<table>
<thead>
<tr>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genero Mobile for Android does not have toolbars. The action views appear in the Android <strong>action bar</strong>. Toolbar action views are listed first and ordered as they are defined in the toolbar, followed by the action views from the action panel. Disabled actions are greyed out.</td>
<td>The toolbar items render in the iOS toolbar pane. The <code>iosSeparatorStretch</code> toolbar style attribute can be used to stretch the separators to give more space between actions. Disabled actions are greyed out.</td>
</tr>
</tbody>
</table>

For more information, see [Toolbars on mobile devices](#) on page 1028. Default action views are rendered on mobile devices according to the rules covered in [Rendering default action views on mobile](#) on page 1281.

### Topmenus

Topmenus provide a hierarchical menu in the app.

The rendering of a TOPMENU depends on the mobile operating system.
Table 579: Genero Mobile and topmenus

<table>
<thead>
<tr>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Navigation drawer for Android" /></td>
<td><img src="image" alt="Menu button for iOS" /></td>
</tr>
</tbody>
</table>

**Figure 123: Navigation drawer for Android**

A navigation drawer is visible in the action bar if a topmenu is available to the displayed form. The navigation drawer is a panel to the left of the app icon (seen as three bars). Tap and the navigation drawer transitions in from the left edge of the screen and displays the app’s main navigation actions.

Restricted to two levels.

**Figure 124: Menu button for iOS**

A menu button is visible in the navigation bar if a topmenu is available to the displayed form. There are no restrictions on the number of levels.

For complete details on implementing top menus in your app, see Topmenus on page 1030.

**Front call support**

Genero Mobile provides front calls to interface with the device capabilities.

Use front calls to access mobile devices capabilities. For example, with the mobile/takePhoto front call, you can open the camera app of the device to take a picture.

**Note:** In a classical Genero client/server configuration, a frontcall is a remote procedure call that involves a round-trip between the front-end and the server where the application executes. For a standalone mobile app, this does not cause any latency. For a server-side app (i.e. runOnServer), however, latency can result.

The details for each frontcall can be found in Built-in front calls on page 1887.

**Color and theming**

Mobile applications must follow the platform colors and theming.

**User interface design on mobile devices**

Genero BDL provides several ways to define colors and styles for a mobile app. This section introduces features that can be used to customize your mobile app and adapt to the target platform user interface design. As a general rule, avoid to use non-standard ergonomics and decorations, using defaults to let Genero render your forms according to the platform standards. For example, the GMA front-end will use Google material design on Android devices.

**Defining TTF icon colors**

By default, TTF icons get the color of the platform theme. A default color can be defined for all TTF icons of a window with the defaultTTFColor style attribute. In order to define a color for a specific icon, add an #RGB color specification in your image to font glyph mapping file.

For more details, see Using a simple image name (centralized icons) on page 785

**App color theme on Android**

Android apps can be created with a specific color theme following the Google material design.

When building the APK with the gmabuildtool, you can specify the general app colors with the --build-app-colors option.
For more details, see Define app's color theme on page 2590.

Decorate iOS UI elements

This section describes the presentation style attributes that are supported for iOS devices.

Foreground colors

In order to define the foreground color for items used in the iOS navigation bar, toolbar, and some items in the forms (Buttons, SpinEdit, Radiogroups, and row checkmark and disclosure indicators in list views), the `iosTintColor` style attribute can be used at Window level:

```xml
<StyleList>
  <Style name="Window">
    <StyleAttribute name="iosTintColor" value="white" />
  </Style>
</StyleList>
```

Background colors

Background color of iOS specific elements can be defined with the following style attributes at the Window level:

- `iosTabBarTintColor`
- `iosToolbarTintColor`
- `iosNavigationBarTintColor`

For example:

```xml
<StyleList>
  <Style name="Window">
    <StyleAttribute name="iosTintColor" value="white" />
    <StyleAttribute name="iosNavigationBarTintColor" value="blue" />
    <StyleAttribute name="iosToolBarTintColor" value="blue" />
  </Style>
</StyleList>
```

iosTintColor inheritance

The `iosTintColor` style attribute can be used at Window level to defined the text color for Tabbar and Toolbar elements.

However, when defining the text color at Window level, it has an impact on the form elements such as Folder, Button, SpinEdit and RadioGroup too. For example, if you set `iosTintColor` to white at the window level, Folder, Button, SpinEdit and RadioGroup element will appear as if they were hidden.

To avoid this, set another text color at the Form element level, as shown in the next .4st style file:

```xml
<StyleList>
  <Style name="Window">
    <StyleAttribute name="iosTintColor" value="white" />
    <StyleAttribute name="iosNavigationBarTintColor" value="blue" />
    <StyleAttribute name="iosToolBarTintColor" value="blue" />
  </Style>

  <Style name="Form">
    <StyleAttribute name="iosTintColor" value="blue" />
  </Style>
</StyleList>
```
Important: Note that in the above example, the `iosToolBarTintColor` and `iosNavigationBarTintColor` define respectively the background color for the iOS navigation bar and the iOS toolbar.

For a complete description of these attributes, see Style attributes reference on page 818.

### Database support on mobile devices

On the device, a Genero app can use SQL for data management.

#### Databases supported on mobile devices

Only SQLite can be used on mobile devices. SQLite has a small footprint, is free and readily available.

The database driver (dbmsqt) and the SQLite library are built into the runtime system for mobile Genero apps. No database driver specification is required when running on mobile.

To read more about SQLite programming, see Using SQLite database in mobile apps on page 2579.

#### Synchronizing data with a central database

When local mobile app data needs to be synchronized with a central database, you must write your own synchronization routines using Web Services. You must implement a back-end service to collect mobile database updates and to send central database changes back to the mobile app.

Important: If you are using GMI, and the device goes into standby mode, the application does not run in the background and activities with the network are suspended. If you are synchronizing data with the server, and the device goes into standby, the synchronization is suspended until the device resumes from standby. If you have a long synchronization, you need to either disable the sleep to allow the synchronization to complete, or accept that the synchronization will suspend when the device goes into standby mode.

### Using SQLite database in mobile apps

On the device, Genero Mobile uses the SQLite database only.

#### Running an app in development mode

When running an app in development mode (where the app runs on a computer), you can use any database server that Genero supports for the operating system of the server-side app.

#### Running an app on a mobile device

When running the application on the device, only SQLite can be used. The database must be created at the first application execution, or it must be delivered as the default database in the `.ipa` or `.apk` package.

#### Locale character set and length semantics

SQLite stores data in UTF-8 codeset, mobile apps will by default run in UTF-8 and with character length semantics (`FGL_LENGTH_SEMANTICS=CHAR`).

#### Creating the database

Mobile applications usually create their database at first execution. The SQLite database file must be created in the application sandbox, in a writable directory. If the database file does not exist in the current working directory (`os.Path.pwd()`), create an empty file and then perform a `CONNECT TO` instruction.

For more details, see Creating a database from programs on page 417.
Providing a default database

SQLite database file format is cross-platform. Instead of creating the database the first time the application starts, you might want to prepare a default database file in your development environment, and include it in the .ipa/.apk package.

Data types with SQLite

SQLite does not have strict data type checking as traditional databases. If you define a table column as a DECIMAL, you can still store character values in that column. Pay attention to this SQLite specific feature, to avoid invalid storage and type conversion errors in your application.

Consider using the following data types for maximum portability, especially when data needs to be synchronized with a central database server, where the data types must match to the types used in the mobile application: CHAR, VARCHAR, DATE, DATETIME YEAR TO MINUTE, DATETIME YEAR TO FRACTION(3), DECIMAL, SMALLINT, INTEGER, BIGINT, BYTE, TEXT.

Optimizing data changes

SQLite can be slow at doing commits, due to the data integrity technique used for transactions. Since each INSERT/UPDATE/DELETE statements acts as an individual transaction (i.e., auto-commit), there will be as many transactions/commits as data manipulation statements. For example, it takes about 10 seconds to insert 1000 rows on an Intel core i7 2.60GHz CPU / 5400.0 RPM HDD computer.

When executing code that modifies a lot of rows (for example, when inserting default data at first application execution, or when doing synchronization with a central database), enclose the SQL statements within a BEGIN WORK/COMMIT WORK transaction block to speed up the process:

```sql
BEGIN WORK
FOR i=1 TO mylog.getLength()
   -- INSERT / UPDATE / DELETE statements
END FOR
COMMIT WORK
```

Enforcing foreign key constraints

SQLite 3.6.19 and + support foreign key constraints, with ON DELETE CASCADE and ON UPDATE CASCADE options. By default, however, foreign key constraints are not enforced. Each application must explicitly turn on the feature with a PRAGMA command. Immediately after the database connection, you can perform the PRAGMA command in an EXECUTE IMMEDIATE statement:

```sql
CONNECT TO connstr AS "c1"
EXECUTE IMMEDIATE "PRAGMA foreign_keys = ON"
```

Truncating the SQLite database file

By default, when deleting rows, SQLite keeps the unused database file pages for future storage. As result, when deleting a large amount of data, the database file might be larger than necessary. Consider truncating the database file with the VACUUM SQL command (in an EXECUTE IMMEDIATE statement), if disk space is limited and when a lot of database rows were deleted.

Depending on the application, the VACUUM command can be executed:

- when starting the application, just after connecting to the database,
- after doing a large database operation (such as a synchronization with a central database),
- as a manual option that the user can trigger.

For example, after connecting to the database:

```sql
CONNECT TO connstr AS "c1"
```
EXECUTE IMMEDIATE "VACUUM"

Sharing database files between Android apps

Two different Android apps (each packaged as a separate .apk) execute in their own sandbox, but have access to the storage area (SD-CARD) and therefore could share a common database file.

SQLite handles concurrent access to the same database file by setting a lock on the entire db file when modifying data (INSERT/UPDATE/DELETE). By default, if a writer process locks the file, other processes must wait until the lock owner process completes its transaction and releases the lock.

Because of Informix compatibility, Genero BDL uses a default lock timeout or zero (i.e., not waiting for locks to be released). As result, when writing to a database file that is locked by another process, if the isolation level is SERIALIzATION (the default with SQLite), an application will get the SQL error -244.

To avoid this problem, you must change the default lock timeout with the SET LOCK MODE instruction, after starting the database session:

```
CONNECT TO connstr AS "c1"
SET LOCK MODE TO 5 -- seconds
```

The second process will then wait until the first process releases the lock. If transactions are short (milliseconds), having processes waiting for each other is transparent to the user.

Accessing device functions

Mobile apps can access device functions by using front calls.

Mobile applications typically want to access device functions such as geolocation, multimedia content (photos, videos), messaging (contacts database, email, sms).

This can be easily achieved by using front calls dedicated to mobile features. Note that some functions are platform specific, for example to launch an Android activity, or access to iOS device settings.

As a general rule, execute your front call in a TRY / CATCH block to catch errors:

```
DEFINE status STRING,
    latitude, longitude FLOAT
TRY
    CALL ui.Interface.frontCall("mobile", "getGeolocation",
        [], [status, latitude, longitude] )
CATCH
    ERROR "Could not get coordinates..."
END TRY
```

For more details, see Genero Mobile common front calls on page 1931, Genero Mobile Android front calls on page 1946, Genero Mobile iOS front calls on page 1950.

Web Services on mobile devices

Web Services can be used within mobile applications.

Genero Mobile for Android

Requirements for Web Services on Android platforms:

- V3 SSL Certificates

For complete details about the requirements for Web Services on GMA, see GMA / Android Web Services requirements on page 2427
Genero Mobile for iOS

Requirements for Web Services on iOS platforms:

- Some `com` classes are not supported.
- Some methods of the `com.HTTPRequest` class have a different behavior on GMI.
- Some `xml` classes are not supported.
- For supported classes of the `xml` package, methods using an URL parameter accept only a file URI.
- SOAP errors and faults are not handled; an application may handle the error -15559.
- GWS configuration entries of FGLPROFILE are not supported.
- A long running HTTP request popup displays after some seconds, giving the user the option to cancel the request.
- HTTP request compression for POST/PUT is not supported.
- Multipart HTTP requests are not supported.
- Limited configuration of SOAP client.

For complete details about limitations for Web Services on GMI, see GMI / iOS Web Services limitations on page 2425.

Debugging a mobile app

Different solutions are available to debug a mobile app.

Debugging a mobile app in development mode

When executing a mobile app program on a server, displaying the user interface on a mobile front-end defined by FGLSERVER, it is possible to debug the BDL code with the `fglrun -d` option:

```
$ export FGLSERVER=device-ip-address
$ fglrun -d main.42m
```

For more details, see Starting fglrun in debug mode on page 1537.

AUI protocol debugging

With app running on a server or on the device, it is possible to show AUI protocol exchanges in the console running the program on the server, by setting the FGLGUIDEBUG environment variable to 1. When this variable set, you can watch user interface events that occur during program execution and how they are treated by the runtime system.

To set the FGLGUIDEBUG environment variable for an app running on the device, use an FGLPROFILE fglrun.environment entry. The output can be inspected with the program logs as described later in this section.

For more details, see FGLGUIDEBUG on page 184.

AUI protocol logging in development mode

With app running on a server, it can be useful to log AUI protocol exchanges between the runtime system and the mobile front-end, to inspect the content, or replay a scenario. This is possible with the `--start-guilog` and `--run-guilog` options of fglrun:

```
$ fglrun --start-guilog=casel.log
```

The AUI protocol log file produced by the `--start-guilog` option can then be shared for analysis.

For more details, see Front-end protocol logging on page 759.
Debugging a mobile app running on the device

When executing the mobile app on a device, and if the app has been created with debug mode, it is possible to establish a connection to the runtime system executing on the mobile device, by using the fglldb command line tool.

**Important:** On iOS devices, after installing the app, you need to enable the debug port in the app settings, otherwise the app will not listen to the debug port.

For example:

```
$ fglldb -m 192.168.1.23:6400
108 DISPLAY ARRAY contlist TO sr.*
```

This way you can debug an app running on a device, by using the source code located on the server where the fglldb command is executed.

For more details, see Debugging on a mobile device on page 1538.

Building mobile apps in debug mode

In order to enable debug features of an app running on a mobile device, you need to build the app in debug mode:

- For Android:
  
  The gmabuildtool provides the `--mode debug` option, to create a debug version of the APK.
  
  For more details, see Building Android apps with Genero on page 2586.

- For iOS:
  
  The gmibuildtool provides the `--mode debug` option, to create a debug version of the IPA. The certificate defined in the provisioning profile must be a development certificate.

  **Note:** After installing the debug version of the app on your iOS device, you need to enable the debug port in the app settings.

  For more details, see Building iOS apps with Genero on page 2598.

Browse the AUI tree created on the mobile front-end side

The content of the Abstract User Interface tree created on the mobile front-end side can be inspected from a web browser, when the app has been created with debug mode, or in development mode by executing the app on a server and displaying on the device.

To inspect AUI tree, open a web browser and enter the following URL:

```
http://device-ip-address:6480 (or 6400)
```

For more details, see Inspecting the AUI tree of a front end on page 751.

Viewing embedded app program logs

The program logs of an app running on a device can be viewed in a browser, if the app was created in debug mode. VM messages (runtime errors, standard output and standard error) are available. This feature is not available if the app is build in release mode.

To inspect program logs, open a web browser and enter the following URL:

```
http://device-ip-address:6480 (or 6400)
```

A menu will then appear in the web page, where you can choose the VM output to be inspected.
Deploying mobile apps

This section describes how to build and deploy mobile apps with Genero.

• Deploying mobile apps on Android devices on page 2584
• Deploying mobile apps on iOS devices on page 2596
• Running mobile apps on an application server on page 2607

Deploying mobile apps on Android™ devices

This section contains information to create a mobile application to be deployed on Android devices.

Directory structure for GMA apps

Platform-specific rules need to be considered when deploying on Android devices (GMA).

The application sandbox

On Android devices, applications are deployed in an application sandbox. The application can access and store data outside of its space, but then the data is also accessible by the other applications.

Directory structure for a GMA application

Inside its application sandbox, an Android app uses the following directory structure:

```
appdir/
   |-- main.42m                             --
   |-- *.42m                               --
   |-- *.42f                               --
   |-- fglprofile                          --
   |   ...                                 --
   |-- *.42s                              --
   |-- de/                                 --
   |   |-- *.42s                           --
   |-- fr/                                 --
   |   |-- *.42s                           --
   |-- zh/                                 --
   |   |-- *.42s                           --
   |   ...                                 --
   |   ... other resource files/dirs ...    --
   |   ...                                 --
   |-- webcomponents                      --
   |   |-- component-type                 --
   |       |-- component-type.html         --
   |       |-- other-web-comp-resource     --
   |   ...                                 --
   |-- appdata/                           --
   |   |-- ... writable app files ...     --

tmpdir/                                  --
   |-- ... temporary files ...            --
```

Program files directory (appdir)

Application program files (.42m, .42f, and so on) need to be deployed in the appdir application base directory.
The program files directory can be found in programs with the `base.Application.getProgramDir` on page 1710 method.

**Important:** On Android, the program files directory returned by the `base.Application.getProgramDir()` method is the same directory as the default working directory, returned by `os.Path.pwd()`.

The `FGLAPPDIR` environment variable is automatically set to the `appdir` directory.

**Program name (MAIN)**

When deploying on mobile devices, the name of the program file must be `main.42m` or `main.42r`.

**Note:** When using the command-line app build scripts, the name of the program file must be `main.42T`. When using Genero Studio, the packaging script takes care of renaming this file, if you have not named it `main`.

As with other program files, the "MAIN" module must be located under the `appdir` application program directory.

**Working directory**

On Android devices, the default current working directory is the `appdir` directory, and can be used for writable files.

The current working directory can be found in programs with the `os.Path.pwd` on page 2012 method.

Files that need to be writable (such as SQLite database files) can be created directly under the `appdir` directory. However, to better organize application files, create sub-directories such as `appdir/appdata`, keeping original files directly under the `appdir` directory. For example, create the application database under `os.Path.pwd() || "/database"`.

**Temporary directory (`tmpdir`)**

A temporary directory is available for the application.

In order to find the temporary directory for the app, use the `standard.feInfo` front call, with the "dataDirectory" parameter.

To create a temporary file name, use the `os.Path.makeTempName()` method.

**Language directories for localized strings**

When the app starts, the appropriate `.42s` string files will be loaded from the directory corresponding to the current language settings of the mobile device. String files to be loaded can be defined in app's `fglprofile`, or you can use the main program name to avoid `fglprofile` settings.

For each language supported by your application, a directory must exist under `appdir`, with a name including the locale codes. Consider also providing default string files (in English for ex) directly under `appdir`, in case if the regional settings of the device do not match one of the locale directories of the app, otherwise the application will stop with error `-8006`.

For example:

- `appdir/mystrings.42s`
- `appdir/fr/mystrings.42s`
- `appdir/de/mystrings.42s`

For more details, see [Localized string files on mobile devices](#) on page 336.
Deploying a custom fglprofile file

If you need to set fglprofile entries for your mobile application, create a file with the name fglprofile, and deploy it under the appdir directory, along with the other program files.

See Understanding FGLPROFILE on page 167 for more details about fglprofile settings.

Creating the initial database file

When a mobile application starts for the first time, it typically creates a new database, or copies an existing database template file from the file directory (base.Application.getProgramDir on page 1710) to the working directory (os.Path.pwd on page 2012).

Note: Different database file names should be used for the original and final application database, as folders pointed by base.Application.getProgramDir() and os.Path.pwd() can be the same on Android devices.

For more details about database creation on mobile devices, see Creating a database from programs on page 417.

Building Android™ apps with Genero

Genero provides a command-line tool to create applications for Android devices.

Basics

Genero mobile apps for Android are distributed as APK packages like any other Android app. Genero provides a command line tool to build the APK package for your mobile application. For testing purposes, the tool can also deploy and automatically launch the app on a specific device or simulator. The tool has also an option to update the Android SDK.

Note: This documentation section implies that you are familiar with Android app programming concepts and requirements. For example, you will need the Android SDK tools to be installed (and up to date) to build your Android apps. For more details, visit the Android developer site at https://developer.android.com.

Prerequisites

Before starting the command line tool to build or deploy the app, fulfill the following prerequisites:

• The Genero BDL development environment (FGLDIR) must be installed on the computer to compile your program files.
• The Java JDK must be installed. The minimum required version is 1.7.
• The Android SDK must be installed (the buildtool uses the "Gradle" utility).

Note: The first time the Android tools are called, they will automatically check for updates. Therefore, you need an internet connection.
• All Android SDK packages required by GMA must be downloaded. In order to download the required Android SDK packages, execute the gmabuildtool updatesdk command.

Note: Execute the gmabuildtool updatesdk command every time a new version of the GMA buildtool and GMA binary archive is installed.
• The GMA buildtool and the GMA binary archive must be installed.

The GMA buildtool and GMA binary archive are provided in the GMA distribution archive (fjs-gma-*.zip).

To setup the GMA buildtool perform the following steps:

1. Create a dedicated directory (gma-install-dir) and extract the content of the fjs-gma-*.zip. This will contain the gmabuildtool command. Add the gma-install-dir directory to your PATH environment variable.
2. Create a directory (gma-scaffold-project) for the GMA binary archive, and extract gma-install-dir/artifacts/fjs-gma-*android-scaffolding.zip into this directory. This directory will be specified with the --build-project option of gmabuildtool.
   • Android specific app resources such as icons (in all required sizes) are required, along with the application program files.
   • If you plan to publish your app on Google Play, register to Google Play as a developer and create a Google Play project.

Environment settings
Define the following environment variables before starting the command-line buildtool:
   • Android SDK env settings (ANDROID_HOME, PATH)
   • Java JDK env settings (JAVA_HOME, PATH)

Update the Android SDK with the GMA buildtool
After a fresh installation of the GMA buildtool and GMA binary archive, upgrade the Android SDK and download all Android SDK packages required by GMA, by executing the gmabuildtool updatesdk command:

```bash
gmabuildtool updatesdk
   --android-sdk /use/local/32bits/android-sdk/r22.6.2
```

The Android SDK installation directory is required for the SDK update, and is found in ANDROID_HOME environment variable, or with the --android-sdk option.

If you need to specify a proxy to download the Android SDK, use the --proxy-host and --proxy-port options:

```bash
gmabuildtool updatesdk
   --proxy-host amadeus --proxy-port 3232
   ...
```

Eventually, use the --no-install-extras option, to skip installation of extra SDK modules such as Google’s driver for windows and the HAXM for windows and OS X:

```bash
gmabuildtool updatesdk
   --no-install-extras
   ...
```

Building and deploying with the GMA buildtool
The gmabuildtool build ... command creates the APK from a set of files, and according to the options passed as parameter.

```bash
gmabuildtool build
   ... build options ...
```

Once the APK file is created, use the gmabuildtool test --test-apk command to install the app on the Android device plugged to the computer, and start the app automatically.

```bash
gmabuildtool test
   --test-apk path-to-the-apk-file
```

For a complete description of command options, see gmabuildtool on page 2592.
Cleaning the scaffold files

The build process is optimized to avoid a complete APK rebuild every time you invoke the GMA buildtool: When application program file changes are detected, the GMA buildtool will create archive files that can be reused in the next build if no changes are detected. However, files used for the optimized build might be corrupted, for example in case of user interruption or graddle build failure.

In this situation, you can use the --clean option of the gmabuildtool build ... command, to cleanup the scaffold build directory, and continue with a fresh build:

```
gmabuildtool build --clean
... build options ...
```

Using an options file

To simplify option specication, create an file with the list of options to be passed to the gmabuildtool with the --input-options argument. The options file must contain a line for each option/value peer:

```
$ cat myoptions.txt
--build-output-apk-name MyApp
--build-app-name MyApp
--build-app-package-name com.example.myapp
...
$ gmabuildtool --input-options ./myoptions.txt
```

Elements used to building the Android app

The gmabuildtool build command builds the Android APK package from the following:

- The GMA binary archive, containing the GMA front end and the FGL runtime system.

  Note: You must unzip the fjs-gma-**-android-scaffolding.zip file.

- The compiled application program and resource files (.42m, .42f, etc) (--build-app-genero-program* options),
- The prefix for the APK file name to be generated (--build-output-apk-name option),
- The name of the app (--build-app-name option),
- The version code of the app (--build-app-version-code option),
- The version name of the app (--build-app-version-name option),
- Android app specific resources:
  - Android app icons (all sizes) (--build-app-icon* options).
  - Android app specifics (to sign the app, not required in development mode):
  - The keystore alias, used with the keytool to generate the keystore file (--build-jarsigner-alias option).
  - The keystore file, generated from keytool (for the --build-jarsigner-keystore option).

Generate the keystore file to sign your app

In order to build an APK that can be deployed on the market (Google Play), you need to sign your Android app.

First, you need to generate a keystore file with the keytool Android utility.

The keystore file and keystore alias will be used by the gmabuildtool to sign the APK with the jarsigner utility. These signing credentials are passed to the buildtool with the --build-jarsigner-keystore and --build-jarsigner-alias options.

For more details, see manual Android application signing.
Generated APK file name

The file name of the APK package is formed from:

1. the APK file name prefix defined by the --build-output-apk-name option (by default, "app"),
2. the target type (-arm or -x86),
3. if building a debug version, the --debug suffix,
4. the .apk file extension.

For example, if the APK file name prefix is MyApp and the target architecture is arm in debug mode, the resulting APK file name will be: MyApp-arm-debug.apk.

Default build directory structure

For convenience, the buildtool supports a default directory structure to find all files required to build the APK:

```
top-dir
|-- main.42m and other program files, as described in Directory structure for GMA apps on page 2584
    |-- gma
        |-- project
        |   ...
        |-- temp
        |   ...
        |-- ic_app_hdpi.png
        |-- ic_app_mdpi.png
        |-- ic_app_xhdpi.png
        |-- ic_app_xxhdpi.png
        |   ...
```

In the above directory structure:

1. top-dir is the top directory of the default structure. It will typically hold your application program files. The program files directory can be specified with the --build-app-genero option.
2. top-dir/gma is the default directory containing the GMA binary archive, the temp directory and the app icons.
3. top-dir/gma/project must contain the unzipped GMA binary archive (fjs-gma-*-android-scaffolding.zip). This directory can be specified with the --build-project option.

Android permissions

In order to use a device feature such as the camera, an Android app must be created by specifying the corresponding Android permissions. Furthermore, Android distinguishes "normal" and "dangerous" permissions. While both type of permissions just need to be specified when building the app, "dangerous" permissions require a user validation: A popup dialog will appear to let the user confirm that the dangerous feature can be accessed. Before Android 6, dangerous permissions defined by the app were asked at app installation. Starting with Android 6, dangerous permissions must be asked by the app code on demand.

Android permissions required for the built-in front calls are automatically set by GMA, which ask automatically user confirmation if the permission is dangerous. For example, if the app code makes a chooseContact front call, the GMA will automatically ask the user for the Android permission to access the contacts database, and set the corresponding permission on confirmation. When building your app, there is no need to specify permissions required for built-in front calls.

Other permissions (not involved by built-in front calls) need to be defined when building the app, and "dangerous" permissions need to be asked to the user when needed. In order to ask the user for a given permission, the app must use the askForPermission front call.
Mobile applications can be specified with the `--build-app-permissions` option of the gmabuildtool. Define the list of permissions as a single argument, by using the comma as separator.

For example:

```
gmabuildtool build \
... \
   --build-app-permissions android.permission.READ_CALENDAR,... \ 
...```

Android permissions listed below are defined by default by GMA and therefore do not need to be specified when building your app. For "dangerous" permissions, the GMA will automatically ask the user to access the feature, when corresponding front call is performed:

- **Normal permissions set by default in GMA (no user confirmation required):**
  - android.permission.INTERNET
  - android.permission.ACCESS_NETWORK_STATE
  - android.permission.CHANGE_NETWORK_STATE
  - android.permission.ACCESS_WIFI_STATE
  - android.permission.WAKE_LOCK
  - com.google.android.c2dm.permission.RECEIVE
  - packageName.permission.C2D_MESSAGE

- **Dangerous permissions set by default in GMA (requires user confirmation):**
  - android.permission.ACCESS_FINE_LOCATION
  - android.permission.ACCESS_COARSE_LOCATION
  - android.permission.READ_CONTACTS
  - android.permission.GET_ACCOUNTS
  - android.permission.MOUNT_FORMAT_FILESYSTEMS
  - android.permission.READ_LOGS
  - android.permission.READ_PHONE_STATE
  - android.permission.WRITE_EXTERNAL_STORAGE
  - android.permission.READ_EXTERNAL_STORAGE

Other permissions required by the app but not listed here need to be specified when building your app, and if the permission enters in the "dangerous" category, the app code must issue an `askForPermission` front call before using the feature. For a complete list of Android permissions, see Android's Manifest permissions.

**Define app's color theme**

Android apps can be created with a color theme defined by four basic colors to customize your app, that can be defined with the `--build-app-colors` option.

**Note:** This feature is only available with Android 5.0 / SDK 21 and higher. With older versions of Android, the colors specified with the `--build-app-colors` option will not take effect.

The value provided to the `--build-app-colors` option must be a comma-separated list of four hexadecimal RGB colors.

The position of the color defines its purpose:

1. Primary color: This is the main color used in the app.
2. Primary dark color: This is the color used for the status bar and the navigation bar.
3. Accent color: This is the color used for widgets and table lines.
4. Action bar text color: This is the foreground color for the texts in the action bar.

By default, the color theme is the Genero purple color.
For example, to define a red color theme, use the following combination:

```
$ gmabuildtool build
  ... 
  --build-app-colors "#F44336,#B71C1C,#EF9A9A,#FFFFFF" 
  ...
```

For more details about Android color schemes, see Android Colors

### Debug and release versions

Android apps can be generated in a debug or release version. Release versions are prepared for distribution on Google Play, while debug versions are used in development. In debug mode, the app installed on the device will listen on the debug TCP port to allow `fgldb -m` connections.

Debug or release mode can be controlled with the `--build-mode` option of the `gmabuildtool` command:

```
$ gmabuildtool build 
  --build-mode debug 
  ...
```

By default the app is built in release mode.

### Building an Android app with gmabuildtool

Follow the next steps to setup a GMA app build directory in order to create an Android app, based on the default directory structure:

1. Create the root distribution directory (`top-dir`)
2. Copy compiled program files (.42m, .42f, fglprofile, application images, web component files, etc) under `top-dir`.
3. Copy the default English .42s compiled string resource file under `top-dir`.
4. Create non-English language directories (fr, ge, ...) under `top-dir` and copy the corresponding .42s files.
5. Copy default application data files (database file for ex) under `top-dir`.
6. Create the `top-dir/gma` directory.
7. Copy Android app resources (icons) under `top-dir/gma`.

Once the build directory is prepared, issue the following commands to build the APK:

```
$ cd top-dir 
$ gmabuildtool build 
  --android-sdk /home/mike/android/sdk 
  --build-project /home/mike/work/example/scaffold_project 
  --build-apk-outputs /home/mike/work/example/outputs 
  --build-output-apk-name MyApp 
  --build-app-name MyApp 
  --build-app-package-name com.example.myapp 
  --build-app-version-code 1002 
  --build-app-version-name "10.02" 
  --build-jarsigner-alias android_alias 
  --build-jarsigner-keystore /home/mike/work/example/sign/android.keystore 
  --build-mode release 
  --build-app-permissions android.permission.ACCESS_WIFI_STATE,android.permission.CALL_PHONE
```

**Important:** The directory specified with the `--build-project` option must contain the unzipped GMA binary archive (`fjs-gma-*-android-scaffolding.zip`).
Building an app with GMA custom extensions

The gmabuildtool build command supports APK creation for applications using GMA custom extensions written in Java.

Before building the APK package, create the custom GMA binary archive with your extensions, as described in Packaging custom Java extensions for GMA on page 1595.

When your custom GMA binary archive is complete, build the APK package with the gmabuildtool build command. Use the --build-project option to specify the path to the Android Studio project that was used to build your custom GMA binary archive:

```bash
$ gmabuildtool build
...  
--build-project /home/mike/android_project/mycustgma
...  
```

**Note:** Other options have to be specified as for a regular build using the original standard GMI binary archive.

Deploy and launch the app

After building the APK package, for testing purposes, you can deploy and launch your app from the command line with the gmabuildtool test command.

**Note:** The test command is provided for development only. To deploy your app in production for several devices, use the regular publication channel of Android apps.

In order to deploy and launch the app, you must provide:

1. the path to the APK file

There must be only one Android device connected or running Android emulator.

```bash
$ gmabuildtool test \  
--test-apk /home/mike/work/example/outputs/MyApp-arm-debug.apk
```

gmabuildtool

The gmabuildtool is a utility to create and test applications for an Android devices.

Syntax

```
gmabuildtool { build | test | updatesdk } \ [options]
```

1. **build** is the command to build an APK package.
2. **test** is the command to deploy and launch an app.
3. **updatesdk** is the command to update the Android SDK to download packages required by GMA.
4. **options** are described in Table 580: gmabuildtool options on page 2592.

Options

**Table 580: gmabuildtool options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Short option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--android-sdk path</td>
<td>-as</td>
<td>The path to the Android SDK installation directory. If not specified, defaults to the ANDROID_HOME environment variable.</td>

<tr>
<td></td>
<td></td>
<td>By default, the color theme is the Genero purple color.</td>
</tr>
<tr>
<td>--build-app-genero-program-main path</td>
<td>-bgpm</td>
<td>Relative path to the main module of the application (can be .xcf, .42m or .42r).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Defaults to main.42m.</td>
</tr>
<tr>
<td>--build-app-genero-program path</td>
<td>-bgp</td>
<td>Defines the path to the application program files (.42m, .42f, etc)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The contents of this directory will be zipped and bundled inside APKs. This option can handle an already zipped Genero program archive.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If not specified, defaults to the current working directory.</td>
</tr>
<tr>
<td>--build-app-icon-hdpi path</td>
<td>-bih</td>
<td>Defines the path to application icon in hdpi.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default is ./gma/ic_app_hdpi.png, in the current working directory.</td>
</tr>
<tr>
<td>--build-app-icon-mdpi path</td>
<td>-bim</td>
<td>Defines the path to application icon in mdpi.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default is ./gma/ic_app_mdpi.png, in the current working directory.</td>
</tr>
<tr>
<td>--build-app-icon-xhdpi path</td>
<td>-bixh</td>
<td>Defines the path to application icon in xhdpi.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default is ./gma/ic_app_xhdpi.png, in the current working directory.</td>
</tr>
<tr>
<td>--build-app-icon-xxhdpi path</td>
<td>-bixxh</td>
<td>Defines the path to application icon in xxhdpi.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Default is ./gma/ic_app_xxhdpi.png, in the current working directory.</td>
</tr>
<tr>
<td>--build-app-name app-name</td>
<td>-bn</td>
<td>Application name.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If not specified, the application name defaults to the current working directory.</td>
</tr>
<tr>
<td>Option</td>
<td>Short option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>--build-app-package-name name</td>
<td>-bpn</td>
<td>APK package name. The package name should be formatted as &quot;com.organization-name.app-name&quot;. If not specified, the application package name defaults to com.example.current-working-directory.</td>
</tr>
<tr>
<td>--build-app-permissions permissions</td>
<td>-ba</td>
<td>Android application permissions. The list of permissions is provided as a comma separated list of android.permission.* identifiers. For more details, see Android permissions on page 2589.</td>
</tr>
<tr>
<td>--build-app-version-code version-code</td>
<td>-bvc</td>
<td>Application version code. For example: 100915 The value of this option must be an integer (do not use decimal numbers).</td>
</tr>
<tr>
<td>--build-app-version-name version-name</td>
<td>-bvn</td>
<td>Application version name. For example: 10.09.15 This will be the actual app version visible on devices.</td>
</tr>
<tr>
<td>--build-apk-outputs path</td>
<td>-bo</td>
<td>Defines the destination folder where the APK packages must be created.</td>
</tr>
<tr>
<td>--build-distribution path</td>
<td>-bd</td>
<td>Distribution folder path. Used to have a location to store the extracted scaffold folder, and be able to build GMA APKs if the project folder is an extension project. Default is ./gma/temp, in the current working directory.</td>
</tr>
<tr>
<td>--build-jarsigner-alias alias</td>
<td>-bja</td>
<td>Jarsigner alias. This is the alias provided to the keystore utility to build the keystore file to sign the app. Used when APK artifacts are signed.</td>
</tr>
<tr>
<td>--build-jarsigner-keypass keypass</td>
<td>-bjk</td>
<td>Jarsigner keypass. Specifies the password used to protect the private key of the keystore entry addressed by the alias specified in the --build-jarsigner-alias option. The password is required when using jarsigner to sign a JAR file. Used when APK artifacts are signed.</td>
</tr>
<tr>
<td>--build-jarsigner-keystore path</td>
<td>-bjks</td>
<td>Jarsigner keystore path. This is the path to the keystore file generated by the keystore utility to sign the app.</td>
</tr>
<tr>
<td>Option</td>
<td>Short option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>--build-jarsigner-storepass storepass</code></td>
<td>-bjs</td>
<td>Jarsigner storepass. Used when APK artifacts are signed. Specifies the password that is required to access the keystore.</td>
</tr>
<tr>
<td>`--build-mode [release</td>
<td>debug]`</td>
<td>-bm</td>
</tr>
<tr>
<td><code>--build-output-apk-name name</code></td>
<td>-ban</td>
<td>Defines the prefix for the APK packages names. By default, this prefix is &quot;app&quot;. The file name of the APK package is formed from: 1. the APK file name prefix defined by the <code>--build-output-apk-name</code> option (by default, &quot;app&quot;), 2. the target type (-arm or -x86), 3. if building a debug version, the -debug suffix, 4. the .apk file extension. For example, if the APK file name prefix is MyApp and the target architecture is arm in debug mode, the resulting APK file name will be: MyApp-arm-debug.apk.</td>
</tr>
<tr>
<td><code>--build-project path</code></td>
<td>-bp</td>
<td>Defines the path to the directory containing the original (unzipped) GMA binary archive files, or the directory containing the Android Studio project, when building a customized GMA. <strong>Note:</strong> When using the original GMA binary archive, the zip file must be uncompressed before executing the build. Default is ./gma/project, in the current working directory.</td>
</tr>
<tr>
<td>`--build-types [x86</td>
<td>arm</td>
<td>x86,arm]`</td>
</tr>
<tr>
<td><code>--clean</code></td>
<td>-c</td>
<td>Clean the scaffold build directory before a rebuild. This option can be used with the <code>build</code> command, to cleanup the scaffold directories containing the application files, before a new build. To be used in case if the previous build was interrupted or has failed.</td>
</tr>
<tr>
<td>Option</td>
<td>Short option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>--input-options path</td>
<td>-i</td>
<td>Path to the file containing gmabuildtool options. Define all options in a file and pass the file to the gmabuildtool command with the --input-options argument. The options file must use the following format: option-name option-value ...</td>
</tr>
<tr>
<td>--java-home path</td>
<td>-jh</td>
<td>Java home path. Default is JAVA_HOME.</td>
</tr>
<tr>
<td>--no-install-extras</td>
<td>-uN</td>
<td>Avoid installation of extra SDK modules when using the updatesdk command.</td>
</tr>
<tr>
<td>--proxy-host host</td>
<td>-ph</td>
<td>Defines the proxy host for the updatesdk command.</td>
</tr>
<tr>
<td>--proxy-host port</td>
<td>-pp</td>
<td>Defines the proxy port for the updatesdk command.</td>
</tr>
<tr>
<td>--test-apk path</td>
<td>-ta</td>
<td>Path to the APK file to deploy and launch with the test command.</td>
</tr>
<tr>
<td>--help</td>
<td>-h</td>
<td>Display the list of options.</td>
</tr>
<tr>
<td>--verbose-fine</td>
<td>-v</td>
<td>Verbose mode (level 1)</td>
</tr>
<tr>
<td>--verbose-finer</td>
<td>-vv</td>
<td>Verbose mode (level 2)</td>
</tr>
<tr>
<td>--verbose-finest</td>
<td>-vvv</td>
<td>Verbose mode (level 3) - shows all possible logs.</td>
</tr>
<tr>
<td>--version</td>
<td>-V</td>
<td>Display GMA build tool version.</td>
</tr>
</tbody>
</table>

Deploying mobile apps on iOS devices
This section contains information to create a mobile application to be deployed on iOS devices.

Directory structure for GMI apps
Platform-specific rules need to be considered when deploying on iOS devices (GMI).

The application sandbox
On iOS devices, program interactions with the file system are limited to the directories inside the app's sandbox.

Directory structure for a GMI application
Inside its application sandbox, an iOS app uses the following directory structure:

```
appdir/
  |-- main.42m
  |-- *.42m
  |-- *.42f
```
Program files directory (appdir)

Application program files (.42m, .42f, as well as other program resources) need to be deployed in the appdir directory.

**Important:** On iOS, the application program directory is read-only. Only the "Documents" directory is writable.

The program files directory can be found in programs with the base.Application.getProgramDir on page 1710 method.

The FGLAPPDIR environment variable is automatically set to the appdir directory.

Program name (MAIN)

When deploying on mobile devices, the name of the program file must be main.42m or main.42r.

**Note:** When using the command-line app build scripts, the name of the program file must be main.42?. When using Genero Studio, the packaging script takes care of renaming this file, if you have not named it main.

As with other program files, the "MAIN" module must be located under the appdir application program directory.

Working directory

The current working directory for an iOS application is typically a writable "Documents" directory, in the private folder of the app. For example, the path to the working directory can be "/private/var/mobile/.../Documents".

The current working directory can be found in program with the os.Path.pwd on page 2012 method.

**Note:** Any file access without an absolute path will be relative to the current working directory.

Files that need to be writable (such as SQLite database files) must be created or copied from the program files directory into the working directory. Copy must be done by the app at first execution, by
using `base.Application.getProgramDir` on page 1710, to find the program files directory, and `os.Path.pwd()`, to find the working directory.

**Temporary directory (`tmpdir`)**

A temporary directory is available for the application.

In order to find the temporary directory for the app, use the `standard.felInfo` front call, with the "dataDirectory" parameter.

To create a temporary file name, use the `os.Path.makeTempName()` method.

**Language directories for localized strings**

When the app starts, the appropriate .42s string files will be loaded from the directory corresponding to the current language settings of the mobile device. String files to be loaded can be defined in app's `fglprofile`, or you can use the main program name to avoid `fglprofile` settings.

For each language supported by your application, a directory must exist under `appdir`, with a name including the locale codes. Consider also providing default string files (in English for ex) directly under `appdir`, in case if the regional settings of the device do not match one of the locale directories of the app, otherwise the application will stop with error `-8006`.

For example:

```
appdir/mystrings.42s
appdir/fr/mystrings.42s
appdir/de/mystrings.42s
```

For more details, see [Localized string files on mobile devices on page 336](#).

**Deploying a custom fglprofile file**

If you need to set `fglprofile` entries for your mobile application, create a file with the name `fglprofile`, and deploy it under the `appdir` directory, along with the other program files.

See [Understanding FGLPROFILE on page 167](#) for more details about `fglprofile` settings.

**Creating the initial database file**

When a mobile application starts for the first time, it typically creates a new database, or copies a existing database template file from the `appdir` program file directory (`base.Application.getProgramDir` on page 1710) to the working directory (`os.Path.pwd` on page 2012).

For more details about database creation on mobile devices, see [Creating a database from programs on page 417](#).

**Building iOS apps with Genero**

Genero provides a command-line tool to build applications for iOS devices.

**Basics**

Genero mobile apps for iOS are distributed as IPA packages like any other iOS app. Genero provides a command line tool to build the .ipa package for your mobile application, or the .app directory for simulators.

**Note:** This documentation section assumes that you are familiar with iOS app programming concepts and requirements. In order to build your apps, you must have an Apple developer account, as well as certificates and provisioning profiles to deploy your apps. For more details, visit the Apple developer site at [https://developer.apple.com](https://developer.apple.com).
Prerequisites

Before starting the command line tool to build or deploy the app, fulfill the following prerequisites:

- The Genero BDL development environment (FGLDIR) must be installed on the Mac computer to compile your program files.
- The GMI build tool must be installed and available (check that the gmibuildtool command is available).
  
  **Note:** The GMI build tool is provided as a ZIP archive (fjs-fglgmi-*.zip) that must be extracted directly into FGLDIR.
  
  **Important:** When re-installing a new GMI archive, remove all "build" directories created by the gmibuildtool.

- An Apple developer account, device identifiers (UDID) and corresponding identifiers to sign your iOS app (certificate, bundle id, provisioning profile).
  
  **Important:** The UDID is the identifier of your physical device, it can be found with the instruments -s command when the device is plugged to the Mac. When deploying on a physical device, make sure that the UDID of the device is listed in the Apple Developer account that is used to generate the provisioning profiles.

- XCode must be installed on your Mac OS X computer (utilities from XCode toolchain are required).
  
  **Note:** Make sure that the installed XCode version supports the iOS versions of your mobile devices. As a general rule, update the XCode and iOS to the latest versions.

- iOS app resources such as icons and launch images (in all required sizes).

Finding the UDID of the plugged device

In order to find the UDID of the device plugged to your Mac, execute the instruments -s command, and identify the line describing your physical device:

```
$ instruments -s
Known Devices:
  fraise [55D6D6C1-DE87-52F0-865E-3C6DC79F13D7]
Fourjs2 iPod touch (9.1) [78b7452fa9462c98c3bc7047da344314fd032004]
  iPad 2 (9.0) [19CDA827-CA55-46F1-9376-BF61E2ECFDBB]
  iPad Air (9.0) [F55E1207-C42B-472E-BD76-5B5AE46DE77A]
  iPad Air 2 (9.0) [A0E8C4CD-67CD-42CB-84DF-9C75AC773293]
  ...
Known Templates:
  "Activity Monitor"
  "Allocations"
  ...
```

In the above output, the UDID of the iPod is 78b7452fa9462c98c3bc7047da344314fd032004.

Environment settings

Before starting the command-line build tool,

- Make sure that XCode tools are available (try xcodebuild from the command line)

Creating the GMI front-end for development purpose

Four Js is not allowed to provide a ready-to-use front-end component for iOS devices, because of iOS app limitations defined by Apple: An iOS app shipped on the App Store cannot listen to a TCP port to provide a GUI service. Therefore, you will have to create your own GMI front-end, with your own Apple certificate and provisioning profile. The generated GMI can then be deployed on your device or simulator for development purpose listening on the port 6400, to display applications running on a server (FGLSERVER).

In order to build your own GMI front-end:
1. Make sure that the gmibuildtool is available (if not done yet, extract the fjs-fglgi*.zip archive into FGLDIR).
2. Go to the FGLDIR/demo/MobileDemo/gmiclient directory.
3. Delete the complete build directory if it exists (can be done with a make clean command).
4. Make the GMI app with make (program files like main.42m file must exist).
5. Build the GMI front-end:
   • In order to build only the GMI front-end (GMI.app directory) for the simulator, execute the gmibuildtool command without any parameter:
     ```
     $ gmibuildtool
     ```
   • In order to build and install the GMI front-end on the simulator, first make sure that the simulator is started (open -a simulator command), then execute the gmibuildtool command with following parameters:
     ```
     $ gmibuildtool --device booted
     ```
   • In order to build only the GMI front-end IPA for devices, get a development certificate and provisioning profile and execute the gmibuildtool command with following parameters:
     ```
     $ gmibuildtool \
     --device phone \
     --certificate HGRW8... \
     --provisioning "/Library/MobileDevice/Provisioning Profiles/myapp.mobileprovision"
     ```
     The generated IPA file can be found in the build subdirectory. This IPA file can be installed on your devices by using iTunes.
   • In order to build and install the GMI front-end on the device plugged to your Mac, get a development certificate and provisioning profile, and the exact device name (with the instruments -s command) and execute the gmibuildtool command with following parameters:
     ```
     $ gmibuildtool \
     --device "Mike's iPhone 6 (9.0)" \
     --certificate HGRW8... \
     --provisioning "/Library/MobileDevice/Provisioning Profiles/myapp.mobileprovision"
     ```

**Specifying the target to build and deploy the iOS app**

The gmibuildtool command can build and install iOS apps for the simulator or for physical devices.

The build and/or install action is controlled by the --device option:

• By default, when not specifying the --device option, a GMI.app directory is created for the simulator.
• When specifying the --device booted option, the GMI.app directory is created and the app is installed on the booted simulator.
• When specifying the --device phone option, the GMI.app directory and .ipa file are created.
• When specifying the --device physical-device-name option (with a real physical device name plugged on your Mac), the GMI.app directory and .ipa file are created and the app is installed on the device.

By default, the generated GMI.app directory and .ipa archive can be found in $PWD/build subdirectories. However you can specify the destination IPA file with the --output option.

**Elements used to build the iOS app**

The gmibuildtool command builds the iOS app package from the following:
• The GMI binary archive, containing the GMI front end and the FGL runtime system library,
  
  **Note:** These files are provided in the fjs-fglgmi-*.zip archive that must be extracted
directly under FGLDIR.

  **Important:** When re-installing a new GMI archive, remove all "build" directories created by
the gmibuild tool.

• The compiled application program and resource files (.42m, .42f, etc).

  **Note:** The application program files must include a main.42m or main.42r module.

• The display name of the app (--app-name parameter),
• The version of the app (--app-version parameter),
• The debug or release mode (--mode parameter),
• The certificate (to sign the app) (--certificate parameter),
• The bundle Identifier (--bundle-id parameter),
• The app provisioning profile (.mobileprovision file) (--provisioning parameter),
• iOS app specific resources:
  • App icons (--icons parameter),
  • Launch images (--launch-images parameter) or launch storyboard file (--storyboard
    parameter).

For a complete description of command options, see gmibuild tool on page 2604.

**Default build directory structure**

For convenience, the build tool supports a default directory structure to find all files required to build the
app:

```
top-dir
   |-- main.42m and other program files, as described in Directory structure
      for GMI apps on page 2596
   |-- gmi
      |-- Info.plist
      |-- LaunchScreen.storyboard
      |-- Default@2x.png
      |-- Default-568h@2x.png
      |-- Default-Landscape.png
      |-- Default-Landscape-667h@2x.png
      |-- Default-Landscape-736h@3x.png
      |-- Default-Landscape@2x.png
      |-- Default-Portrait.png
      |-- Default-Portrait-736h@3x.png
      |-- Default-Portrait-667h@2x.png
      |-- Default-Portrait@2x.png
      ...  
      |-- icon_29x29.png
      |-- icon_40x40.png
      |-- icon_57x57.png
      |-- icon_58x58.png
      |-- icon_72x72.png
      |-- icon_76x76.png
      |-- icon_80x80.png
      |-- icon_120x120.png
      |-- icon_152x152.png
```
In the above directory structure:

1. `top-dir` is the top directory of the default structure. It will typically hold your application program files. A different program files directory can be specified with the `--program-files` option.
2. `top-dir/gmi` is the default directory containing the app resource files such as icons:
   a. `Info.plist` is the Information Property List File that will be used to build the app. Some properties will be overwritten by `gmibuildtool` options like `--app-name` and `--app-version`.
   b. `LaunchScreen.storyboard` is the default storyboard file for the app launch screen. This file can be specified with the `gmibuildtool --storyboard` option.
   c. `Default-*.*.png` are the app launch image files. The directory to find launch images can be specified with the `gmibuildtool --launch-images` option.
   d. `icon_*.*.png` are the app icon files. The directory to find icons can be specified with the `gmibuildtool --icons` option.

Debug and release versions

iOS apps can be generated in a debug or release version. Release version are prepared for distribution on the App Store, while debug versions are used in development.

In debug mode, the app installed on the device can listen on the debug TCP port to allow `fgldb -m` connections, after enabling the debug port in the app settings.

Debug or release mode must be specified in the command line with the `--mode debug` or `--mode release` option. Additionnally, if you want to deploy on a physical device, you need to use a provisioning profile corresponding to the debug or release mode:

- In debug mode, the certificate must be a development certificate.
- In release mode, the certificate must be a distribution certificate.

Defining the app version and build number

Apple distinguishes the app version number of a bundle (visible to the end user), from the build version number of a bundle (called a release version number in Apple docs).

You specify the app version number with the `--app-version` option of the `gmibuildtool` command. This option sets the `CFBundleVersion` property of the `Info.plist` file, and must match the version specified in iTunes Connect.

In order to distinguish multiple builds (Apple's term is "releases") of the same app version number, define the build version number of your app with the `--build-number` option. This option sets the `CFBundleShortVersionString` property of the `Info.plist` file. For a given app version, you need to increase this build number, to be able to upload a new binary on iTunes Connect.

**Note:** If you do not specify the `--build-number` option, the build version number defaults to the app version specified with the `--app-version` option.

Defining app properties in the ./gmi/Info.plist file

iOS app are created with a set of properties that are essential configuration information for a bundled executable. These properties are defined in the "Information Property List File", an XML formatted file, named `Info.plist` by convention.

Most important `Info.plist` properties are defined with `gmibuildtool` options such as `--app-name` and `--app-version`. However, you may need to define other properties that are out of the scope of the build tool. For example: background modes, device capabilities, screen orientations, permanent wifi, etc.
In order to define specific app properties, setup an Info.plist file in top-dir/gmi directory, before executing the gmibuildtool. Properties covered by the build tool will be overwritten, while any other property defined in the top-dir/gmi/Info.plist file will be left untouched.

For more details about the Info.plist file structure, see Apple developer site page about Information Property List File.

Building an iOS app with gmibuildtool

Follow the next steps to setup a GMI app build directory in order to create an iOS app, based on the default directory structure:

1. Create the root distribution directory (top-dir)
2. Copy compiled program files (.42m, .42f, fglprofile, application images, web component files, etc) under top-dir.
3. Copy the default English .42s compiled string resource file under top-dir.
4. Create non-English langage directories (fr, ge, ...) under top-dir and copy the corresponding .42s files.
5. Copy default application data files (database file for ex) under top-dir.
6. Create the top-dir/gmi directory.
7. Copy iOS app resources (icons, launch screen, storyboard) under top-dir/gmi.
8. If needed, create an top-dir/gmi/Info.plist file, to define specific iOS app properties.

Once the build directory is prepared, issue the following commands:

```bash
$ cd top-dir
$ gmibuildtool
   --output myapp.ipa \
   --app-name "My App" \
   --app-version "v3.1.6" \
   --bundle-id "com.example.mycompany.myapp" \
   --mode release \
   --certificate HGRW8...\n   --provisioning "~/Library/MobileDevice/Provisioning Profiles/myapp.mobileprovision" \
   --device phone
```

Building a GMI app with C extensions or custom front calls

In order to create an iOS app using C extensions written in Objective-C as in Implementing C-Extensions for GMI on page 1619, you need to setup a Makefile calling the FGLDIR/lib.Makefile-gmi generic makefile.

In your Makefile, define the following variables to be passed to the generic makefile:

- **APPNAME**: Defines the display name of the app.
- **BUNDLE_IDENTIFIER**: Defines the Bundle Id (or App Id) of the app.
- **IDENTITY**: Defines the certificate to be used for this app.
- **PROVISIONING_PROFILE**: Defines the provisioning profile generated for this app.
- **USEREXTENSION**: Defines the lib name containing the C extensions.
- **TARGET**: Defines the device where the app must be installed (can be phone or simulator).

Custom Makefile example:

```makefile
... 
all: $(MODULES) $(FORMS) ...
run: all userextension.dylib
    fglrun -e userextension main
```
userextension.dylib: userextension.c
  fglmkext $? 
...

GMI_OPTIONS = \
  APPNAME=MyApp \n  BUNDLE_IDENTIFIER=com.mycomany.myapp \n  IDENTITY=HGRW8... \n  PROVISIONING_PROFILE=~/Library/MobileDevice/Provisioning\ Profiles/myapp.mobileprovision \n  USEREXTENSION=userextension.o \n  TARGET=phone 

GMI_MAKE = make -f $(FGLDIR)/lib/Makefile-gmi $(GMI_OPTIONS)

  gmi.all: all 
    $(GMI_MMAKE) all

  gmi.install: all 
    $(GMI_MMAKE) install

  gmi.uninstall: 
    $(GMI_MMAKE) uninstall

  gmi.info: 
    $(GMI_MMAKE) info

  gmi.clean: 
    ~$(GMI_MMAKE) clean

The same technique can be used to build apps that must include custom front calls. For complete examples, see FGLDIR/demo/MobileDemo/userextension and FGLDIR/demo/MobileDemo/userfrontcall

gmibuildtool
The gmibuildtool is a utility to create and test applications for an iOS devices.

Syntax

gmibuildtool [options]

1. options are described in Table 581: gmibuildtool options on page 2604.

Options

Table 581: gmibuildtool options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--app-name application-name</td>
<td>Display name of the mobile app. This option can be specified to define the display name of the app, it sets the CFBundleDisplayName property in the Info.plist file. If not specified, the name defaults to &quot;Noname&quot;.</td>
</tr>
<tr>
<td>--app-version application-version</td>
<td>Defines app version visible to the users on the App Store.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>This option is mandatory and sets <strong>CFBundleVersion</strong> properties in the <strong>Info.plist</strong> file.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If the <strong>--build-number</strong> option is not used, <strong>--app-version</strong> will also set the both the <strong>CFBundleShortVersionString</strong> property.</td>
</tr>
<tr>
<td></td>
<td>In iTunes Connect, you define the version of your app, that must match the <strong>CFBundleVersion</strong> property in the <strong>Info.plist</strong> file of the app. If these versions do not match, the app cannot be published. Once the app is visible on App Store, the version specified in iTunes Connect shows up in the &quot;Version&quot; section of the application page.</td>
</tr>
<tr>
<td></td>
<td>The app version number should be a string comprised of three period-separated integers. For example: &quot;1.4.2&quot;</td>
</tr>
<tr>
<td><strong>--bundle-id bundle-identifier</strong></td>
<td>Defines the Bundle Identifier (a.k.a. App Id) for the app. This option is mandatory and sets the <strong>CFBundleIdentifier</strong> property in the <strong>Info.plist</strong> file.</td>
</tr>
<tr>
<td></td>
<td>A bundle identifier is the unique identifier of your app, to let iOS recognize new app versions. When developing for the simulator, you can choose your own identifier. When creating an application for the App Store, the bundle identifier must be registered with Apple.</td>
</tr>
<tr>
<td></td>
<td>If not specified, the name defaults to &quot;noname&quot; (for prototyping).</td>
</tr>
<tr>
<td><strong>--build-number build-number</strong></td>
<td>Defines the build number used to upload a new binary of the same app version. This option must be used to distinguish different builds for the same app version. It sets the <strong>CFBundleShortVersionString</strong> property in the <strong>Info.plist</strong> file.</td>
</tr>
<tr>
<td></td>
<td>The build number needs to be incremented in order to upload a new binary version of the same app version in iTunes Connect.</td>
</tr>
<tr>
<td></td>
<td>If this option is not used, the build number defaults to the version specified with the <strong>--app-version</strong> option.</td>
</tr>
<tr>
<td></td>
<td>The build number is a string comprised of three period-separated integers. For example: &quot;1.4.2&quot;</td>
</tr>
<tr>
<td><strong>--certificate identity</strong></td>
<td>Name of a certificate to sign the app. This option is mandatory to build apps for a physical device or for the app store. The certificate can be found in the Keychain access program, in the &quot;Common Name&quot; field of the certificate panel. The command <strong>security find-identity -v</strong> can be used to list all available certificates.</td>
</tr>
<tr>
<td><strong>--device device-name</strong></td>
<td>Defines the name of a device or simulator.</td>
</tr>
<tr>
<td></td>
<td>• By default, when not specifying the <strong>--device</strong> option, a <strong>GMI.app</strong> directory is created for the simulator.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>• When specifying the <strong>--device booted</strong> option, the GMI.app directory is created and the app is installed on the booted simulator.</td>
</tr>
<tr>
<td></td>
<td>• When specifying the <strong>--device phone</strong> option, the GMI.app directory and .ipa file are created.</td>
</tr>
<tr>
<td></td>
<td>• When specifying the <strong>--device physical-device-name</strong> option (with a real physical device name plugged on your Mac), the GMI.app directory and .ipa file are created and the app is installed on the device.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: Use the <code>instruments -s XCode</code> command to find the list of available devices (simulators or connected devices).</td>
</tr>
<tr>
<td><strong>--help</strong></td>
<td>Display the help of the command tool.</td>
</tr>
<tr>
<td><strong>--icons icons-dir</strong></td>
<td>Provides the directory where the application icons are located.</td>
</tr>
<tr>
<td></td>
<td>By default, the application icons directory is <code>current-working-dir/gmi</code>.</td>
</tr>
<tr>
<td></td>
<td>The name of the app icon files must be: <code>icon_57x57.png</code>, <code>icon_72x72.png</code>, <code>icon_29x29.png</code>, <code>icon_40x40.png</code>, <code>icon_120x120.png</code>, <code>icon_152x152.png</code>, <code>icon_58x58.png</code>, <code>icon_76x76.png</code>, <code>icon_80x80.png</code></td>
</tr>
<tr>
<td><strong>--launch-images launch-images-dir</strong></td>
<td>The directory where launch images are located.</td>
</tr>
<tr>
<td></td>
<td>By default, the launch images directory is <code>current-working-dir/gmi</code>.</td>
</tr>
<tr>
<td></td>
<td><strong>Note</strong>: This option is ignored if the <strong>--storyboard</strong> option is provided.</td>
</tr>
<tr>
<td></td>
<td>The name of the image files must be: <code>Default.png</code>, <code>Default@2x.png</code>, <code>Default-568h@2x.png</code>, <code>Default-Portrait-667h@2x.png</code>, <code>Default-Landscape-667h@2x.png</code>, <code>Default-Portrait-736h@3x.png</code>, <code>Default-Landscape-736h@3x.png</code>, <code>Default-Portrait.png</code>, <code>Default-Landscape.png</code>, <code>Default-Portrait@2x.png</code>, <code>Default-Landscape@2x.png</code>.</td>
</tr>
<tr>
<td></td>
<td>Each file name corresponds to a device type (you may not need to provide all files if you target only recent iOS devices), see Apple Developer documentation for more details about launch images.</td>
</tr>
<tr>
<td>**--mode {debug</td>
<td>release}**</td>
</tr>
<tr>
<td></td>
<td>By default, the mode is <code>debug</code>.</td>
</tr>
<tr>
<td></td>
<td><strong>Note that the provisioning profile must correspond:</strong></td>
</tr>
<tr>
<td></td>
<td>• <strong>--mode debug</strong>: Development provisioning profile.</td>
</tr>
<tr>
<td></td>
<td>• <strong>--mode release</strong>: Distribution provisioning profile.</td>
</tr>
<tr>
<td><strong>--output ipa-file-name</strong></td>
<td>Path to output IPA and APP files to be generated.</td>
</tr>
</tbody>
</table>
Running mobile apps on an application server

From the mobile device, programs can be started remotely on an application server, and displayed on the device.

Purpose of remote application execution for mobile devices

Remote applications displayed on a mobile device allow the use of the processor, memory, storage and software resources available on a server, for mobile users.

**Note:** Executing remote/server applications for display on a mobile device requires a reliable and constant network connection. If the network connection fails, the application will stop, as with other client/server Genero front-ends.

Server applications can only be started through the Genero Application Server (GAS), by using the UA protocol available since version 3.00. You must set up and configure the GAS for the programs you want to start remotely. See the GAS documentation for more details.

**Note:** Applications executed on the GAS server must use the UTF-8 encoding. Mobile front-ends will reject any attempt to display forms of an application using an encoding other than UTF-8.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--program-files program-dir</code></td>
<td>Path to Genero BDL program files (.42m, .42f, etc). By default, the program files directory is the current work directory. Following files are automatically excluded: *.4gl, *.per, *.msg, *.str, *.sch, [Mm]akefile, *.42d, [Mm]akefile, *.chdmo, *.xib, build/ (the build directory), gmi/ (this folder is the default location of LaunchScreens and AppIcons). If the file gmiignore exists, then this file contains additional files to be ignored.</td>
</tr>
<tr>
<td><code>--provisioning provisioning-file</code></td>
<td>Path to the provisioning profile (.mobileprovision). The provisioning profile is mandatory to build apps for a physical device or for the app store. Provisioning profiles can be found in $HOME/Library/MobileDevice/Provisioning\ Profiles/</td>
</tr>
<tr>
<td><code>--storyboard storyboard-file</code></td>
<td>Path to the storyboard file, to get a splash screen to be displayed when the app starts. This file is an alternative for Launch Screens (<code>--launch-images</code> option). This option is mandatory if you do not provide launch images with the <code>--launch-images</code> option. The default storyboard is an empty screen.</td>
</tr>
</tbody>
</table>
Implementing the embedded mobile app

Create a small application to be deployed on the mobile device, which then starts the application(s) on an GAS server.

The server application is started from the embedded application through the runOnServer front call. The embedded mobile application can be a very simple MAIN / END MAIN program, only performing the "runOnServer" front call.

For example, this is the very minimal embedded application, starting a program on the GAS:

```plaintext
MAIN
  CALL ui.interface.frontcall("mobile","runOnServer",
      ["http://myappserver:6394/ua/r/myapp"],[])
END MAIN
```

When the remote application starts, the graphical user interface displays on the mobile device.

The runOnServer front call returns when the called application ends, control goes back to the initial application executing on the mobile device.

**Note:** In development context, it is possible to execute the parent starter app on a server, display on a mobile device with FGLSERVER on page 188 set properly, and use the runOnServer front call. Because starting remote GAS applications is done with a front call, this configuration mimics an embedded starter app running on the device.

Using the runOnServer front call

The application executed on the server-side is identified by the first parameter of the runOnServer front call. This application must be delivered by the Genero Application Server. The parameter must contain an "ua/r" URL syntax (the UA protocol introduced with the GAS 3.00).

For example: http://myappserver:6394/ua/r/myapp

The URL may contain a query string, with parameters for the application to be executed by the GAS.

If needed, you can add a second argument to define a timeout as a number of seconds. The embedded application will wait for the remote application to start, until the timeout expired. If no timeout parameter is specified, or when zero is passed, the timeout is infinite.

In case of failure (application not found, timeout expired), the front call raises the runtime error -6333 and the HTTP status code of the request can be found in the error message details. Use a TRY/CATCH block to check if the execution the server application was successful:

```plaintext
MAIN
  TRY
    CALL ui.interface.frontcall("mobile","runOnServer",
      ["http://myappserver:6394/ua/r/myapp"],[])
  CATCH ERROR err_get(STATUS)
  END TRY
END MAIN
```

Subsequent server-side application runs are allowed; the last active application will display on the device. However, it is not possible to navigate between started applications. Therefore, an application started with the runOnServer front call must only use the RUN instruction to start sub-programs. RUN WITHOUT WAITING is not supported.
Passing parameters to the server application

If needed, the embedded app can pass arguments to the server application by using parameter specification in the URL string, with the \?Arg=value1&Arg=value1\... notation:

```
DEFINE params, base, complete_url STRING
LET params = "Arg=verbose&Arg=5677"
LET url = "http://myappserver:6394/ua/r/myapp"
LET complete_url = base || "?" || params
```

The remote program can retrieve the parameters with the \arg_val()\ built-in function.

**Note:** It is not needed to URL-encode the string passed to the \runOnServer\ front call.

See the GAS documentation (\AllowUrlParameters\ attribute) about passing parameters in the application URL.

This is an example of an embedded application to be deployed on the mobile device, which passes parameters to a server-side application:

```
IMPORT util

MAIN
  DEFINE arr DYNAMIC ARRAY OF STRING, x INT
  MENU "test"
  COMMAND "runOnServer"
    CALL arr.clear()
    LET arr[1] = "first argument"
    LET arr[2] = "second argument"
    LET x = do_run("http://10.0.40.29:6394/ua/r/test1", 10, arr)
  COMMAND "exit"
  EXIT MENU
END MENU

FUNCTION do_run(url,timeout,params)
  DEFINE url STRING,
       timeout SMALLINT,
       params DYNAMIC ARRAY OF STRING
  DEFINE i, r INTEGER, tmp STRING
  LET r = 0
  LET tmp = url
  FOR i=1 TO params.getLength()
    LET tmp = tmp || IIF(i==1,"?","&") || "Arg=" || params[i]
  END FOR
  TRY
    CALL ui.interface.frontcall("mobile","runOnServer",[tmp,timeout],[])
  CATCH
    ERROR err_get(STATUS)
    LET r = -1
  END TRY
  RETURN r
END FUNCTION
```

A sample server-side application:

```
MAIN
  MENU "Prog1"
  COMMAND "arg1" MESSAGE "Arg 1 = ", arg_val(1)
  COMMAND "arg2" MESSAGE "Arg 2 = ", arg_val(2)
  COMMAND "arg3" MESSAGE "Arg 3 = ", arg_val(3)
  COMMAND "Quit" EXIT MENU
END MENU
```
Sharing files between embedded and server app

If files need to be shared between the embedded application and the server application, the application running on the GAS can only access the `data-directory` directory, in the sandbox of the embedded application that executes the "runOnServer" front call.

This matters when using file handling APIs such as `fgl_putfile()` and `fgl_getfile()` or front calls like `takePhoto` and `launchURL`.

The `data-directory` on the mobile device can be found with the `feInfo/dataDirectory` front call. In both the embedded app and the app running on the server, this front-call will return the same directory.

The following workflow can be used:

1. Before starting the server application with a `runOnServer` front call, the embedded app must copy files to the `data-directory`.
2. While executing, the server application can retrieve files from the `data-directory` with `fgl_getfile()`, and send its own files to the `data-directory`, with `fgl_putfile()`.
3. When the server application terminates, the embedded app can read files the server application left in the `data-directory`.

**Note:** If several remote applications are started successively on the server with a `RUN` instruction, make sure to not overwrite files written by other server programs.

In order to write code for the embedded app, that can be executed in development mode (running on a server) and on the mobile device, you can adapt to the execution context: Make a simple file copy when executing on the mobile device, or do an `fgl_putfile()` call, when running on the development server. Check the execution context with the `base.Application.isMobile()` method.

This example, in the embedded app on the mobile device, copies a file from the device private directory to the `data-directory`:

```plaintext
IMPORT os
...
CALL mobile_copy_to_data_dir("myfile.txt")
...
FUNCTION mobile_copy_to_data_dir(fn)
    DEFINE fn, dd, dst STRING, r INT
    CALL ui.interface.frontcall("standard","feInfo",["dataDirectory"],[dd])
    -- Always use / as path sep for Android/iOS dirs.
    LET dst = dd || "/" || os.Path.basename(fn)
    IF base.Application.isMobile() THEN
        -- Executing on device: make a simple copy to data-dir
        LET r = os.Path.copy(fn, dst)
        MESSAGE SFMT("COPY status = %1", r)
    ELSE
        -- Executing on dev server: make a file transfer to data-dir
        CALL fgl_putfile(fn, dst)
    END IF
END FUNCTION
```

**Note:** We do not use the `os.Path.join()` method here because it would add the path separator according to the operating system where the application is executed. This would not be a problem when executing on the mobile device or Unix-like platforms. However, when running on a Windows platform, the `os.Path.join()` method would join the directory and the file name with a backslash, and the resulting path would not fit Android or iOS directory path specification for the `data-directory`. 
In the server application, use the `fgl_getfile()` function, to transfer a file from the mobile device `data-directory` to the local server disk:

```plaintext
IMPORT os
...
CALL server_get_from_data_dir("myfile.txt", "/tmp/server_file.txt")
...
FUNCTION server_get_from_data_dir(fn, dst)
  DEFINE fn, dst, dd, src STRING
  CALL ui.interface.frontcall("standard","feInfo","["dataDirectory"]",[dd])
  --- Use / as path sep for Android/iOS dirs!
  LET src = dd || "/" || fn
  CALL fgl_getfile(src, dst)
END FUNCTION
```

Similarly, in the server application, use the `fgl_putfile()` function, to copy a file from the server application to the `data-directory` of the embedded app:

```plaintext
IMPORT os
...
CALL server_put_to_data_dir("/tmp/server_file.txt", "myfile.txt")
...
FUNCTION server_put_to_data_dir(src, fn)
  DEFINE src, fn, dd, dst STRING
  CALL ui.interface.frontcall("standard","feInfo","["dataDirectory"]",[dd])
  --- Use / as path sep for Android/iOS dirs!
  LET dst = dd || "/" || fn
  CALL fgl_putfile(src, dst)
END FUNCTION
```

**Push notifications**

This section describes how to implement push notification with Genero.

A push notification is a short message sent by a central server entity to an app installed on a mobile device. In order to be notified, the app+device must register itself to a push service (a global service such as Google Cloud Messaging), and register also to a push provider (part of the custom application). To indicate that fresh information is available, notifications are sent by push providers to the push service, which broadcasts notifications to registered devices. The apps can then get details about the notification and display a little hint to the end user. Enterprise mobile applications can use push notifications to produce urgent and important updates for users.
Figure 125: This figure describes the workflow for a push notification (items in yellow are the components that can be implemented with Genero BDL)

Workflow:
1. The app registers to the push service.
2. The push service generates a unique token to identify the device+app and returns this token to the app.
3. The app transmits the token to the token maintainer.
4. The token maintainer stores the new token in a database.
5. Some event occurs in the global application workflow that requires a push notification to warn all registered devices/apps.
6. The push provider reads the database for registered tokens.
7. The push provider sends push notification requests to the push service.
8. The push service broadcasts the notification messages to all registered devices.

There are several push notification mechanisms available. This chapter covers the Google Cloud Messaging (GCM) and Apple Push Notification services (APNs).

Common components can be implemented on the same code base for both GCM and APNs push notification mechanisms: The mobile app and the token maintainer.

**Google Cloud Messaging (GCM)**

Follow this procedure to implement push notification with GCM.

**Introduction to GCM push notification**

The push notification solution described in this section is based on the Google Cloud Messaging service. Familiarize yourself with GCM by visiting the [https://developers.google.com/cloud-messaging](https://developers.google.com/cloud-messaging) web site.

Google Cloud Message services allow push servers to send notification message data to registered Android™ or iOS devices.

The system involves the following actors:

- The Google Cloud Message service (GCM):
GCM provides push server and client identification. It also handles all aspects of queuing of messages and delivery to the target application running on registered devices.

- The registration tokens maintainer:
  A Web Services server program maintaining the database of registration tokens with application user information. This program must listen to new device registration events and store them in a database. The push server program can then query this database to build the list of registration tokens to identify the devices to be notified.

- The push server program:
  Implemented by a third-party service or as a Genero BDL program using the Web Services API. This push server program will send notification messages to GCM with two connection servers (HTTP and XMPP).

- Devices running the Genero app registered to the push notification server:
  Registered devices use the push notification client API to register, get notification data and unregister from the service.

  Note: The database used to store registration tokens must be a multi-user database (do not use SQLite for example), since two distinct programs will use the database.

Creating a GCM project
To initiate a push notification service dedicated to your applications, you must first create a Google Cloud Messaging project on the Google web site. Creating a GCM project will give you the API Key and the Sender ID. The API Key is the authentication key to access Google services. The Sender ID identifies your GCM project; this id will be used by your mobile app to indicate that it wants to get messages from this GCM project.

To get details about GCM project creation, visit: https://developers.google.com/cloud-messaging.

To create a GCM project and get the API Key and Sender ID, follow the steps at: https://developers.google.com/cloud-messaging/android/client#get-config.

Write down the API Key and the Sender ID generated for you, as these will be used later on.

Implementing the registration tokens maintainer
To handle device registrations on the server side of your application, the same code base can be used for GCM and other token-based frameworks.

For more details, see Implementing a token maintainer on page 2623.

Implementing the push server
The push server will produce application notification messages that will be transmitted to the GCM service. The GCM service will then send them to all mobile devices registered to the service with the Sender ID.

  Important: The size of an GCM notification content cannot exceed 4 Kilobytes. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The push server will use RESTful HTTP POST requests to send notifications through the GCM service to the following URL:

"https://gcm-http.googleapis.com/gcm/send".

The HTTP POST header must contain the following attributes:

```
Content-Type: application/json
Authorization: key=API_Key
```
where API_key is the API Key obtained during GCM project creation.

The push server program can be implemented with the Web Services API to make RESTful requests as follows:

```
IMPORT com
IMPORT util

FUNCTION gcm_send_notif_http(api_key, notif_obj)
  DEFINE api_key STRING,
  notif_obj util.JSONObject

  DEFINE req com.HTTPRequest,
  resp com.HTTPResponse,
  req_msg STRING

  TRY
    LET req = com.HTTPRequest.Create("https://gcm-http.googleapis.com/gcm/send")
    CALL req.setHeader("Content-Type", "application/json")
    CALL req.setHeader("Authorization", SFMT("key=%1", api_key))

    CALL req.setMethod("POST")
    LET req_msg = notif_obj.toString()
    IF req_msg.getLength() >= 4096 THEN
      LET res = "ERROR : GCM message cannot exceed 4 kilobytes"
      RETURN res
    END IF
    CALL req.doTextRequest(req_msg)
    LET resp = req.getResponse()
    IF resp.getStatusCode() != 200 THEN
      DISPLAY SFMT("HTTP Error (%1) %2", 
        resp.getStatusCode(), 
        resp.getStatusDescription())
    ELSE
      DISPLAY "Push notification sent!"
    END IF
  CATCH
    DISPLAY SFMT("ERROR : %1 (%2)", STATUS, SQLCA.SQLERRM)
  END TRY

END FUNCTION
```

The body of the HTTP POST request must be a JSON formatted record using a structure similar to the following example:

```
{
  "collapse_key": "stock_update",
  "time_to_live": 108,
  "delay_while_idle": true,
  "data":
  {
    "stock_change":
    {
      "stock_id": "STK-034",
      "timestamp": "2015-02-24 15:10:34.18345",
      "item_count": 15023
    },
  },
  "registration_ids": [ "APA91b...", "Hun4MxP...", "5ego..." ]
}
```
Note: This notification message uses the "registration_ids" attribute to provide a list of devices to be notified. If you want to notify a single device, use the "to" attribute instead of "registration_ids", and pass a single registration token instead of a JSON array.

For more details about the JSON request structure in a GCM HTTP POST, see https://developers.google.com/cloud-messaging/http.

By convention, if the "data" member of the JSON request defines a "genero_notification" member, the front-end will show graphical notification (popup hint) with the "title", "content" and the "icon" values.

Note: With GMA, the icon should be packaged in the APK and should be accessible by name (as the gma_ic_genero.png in the drawable folders)

For example:

```json
...
"data": {
  "genero_notification": {
    "title": "Stock has changed",
    "content": "New stock information will be retrieved from the backend server...",
    "icon": "stock_update"
  },
  ...
},
"registration_ids": ["APA91b...", "Hun4MxP...", "5ego..."
}
```

The next code example implements a function that creates the JSON object, which can be passed to the gcm_send_notif_http() function described above. The only purpose of this notification message is to test the "genero_notification" popup hint. The function takes an array of registration tokens as a parameter, which will be used to set the "registration_ids" attribute:

```java
FUNCTION gcm_simple_popup_notif(reg_ids, notif_obj, popup_msg)
  DEFINE reg_ids DYNAMIC ARRAY OF STRING,
       notif_obj util.JSONObject,
       popup_msg STRING
  DEFINE data_obj, popup_obj util.JSONObject
  CALL notif_obj.put("registration_ids", reg_ids)
  LET data_obj = util.JSONObject.create()
  LET popup_obj = util.JSONObject.create()
  CALL popup_obj.put("title", "Notification message!")
  CALL popup_obj.put("content", popup_msg)
  CALL popup_obj.put("icon", "genero")
  CALL data_obj.put("genero_notification", popup_obj)
  CALL data_obj.put("other_info", "Additional data...")
  CALL notif_obj.put("data", data_obj)
END FUNCTION
```

The gcm_simple_popup_notif() and gcm_send_notif_http() functions can then be used as follows:

```java
IMPORT com
```
IMPORT util

MAIN
    CONSTANT api_key = "xyz..."
    DEFINE reg_ids DYNAMIC ARRAY OF STRING,
        notif_obj util.JSONObject
    LET reg_ids[1] = "APA91bHun..."
    LET reg_ids[2] = "B4AA2q7xa..."
    LET notif_obj = util.JSONObject.create()
    CALL gcm_simple_popup_notif(reg_ids, notif_obj, "This is my message!")
    CALL gcm_send_notif_http(api_key, notif_obj)
END MAIN

In order to use the tokens database maintained by a token maintainer program, your GCM push server can collect registration tokens as shown in the following example:

FUNCTION gcm_collect_tokens(reg_ids)
    DEFINE reg_ids DYNAMIC ARRAY OF STRING
    DEFINE rec RECORD
        id INTEGER,
        sender_id VARCHAR(150),
        registration_token VARCHAR(250),
        badge_number INTEGER,
        app_user VARCHAR(50),
        reg_date DATETIME YEAR TO FRACTION(3)
    END RECORD
    DECLARE c1 CURSOR FOR
        SELECT * FROM tokens
        WHERE sender_id IS NOT NULL -- In case if APNs tokens remain in the db
    CALL reg_ids.clear()
    FOREACH c1 INTO rec.*
        CALL reg_ids.appendElement()
        LET reg_ids[reg_ids.getLength()] = rec.registration_token
    END FOREACH
END FUNCTION

The above function can then be used by another function to send the push message to all registered devices:

FUNCTION gcm_send_text(api_key, the_text)
    DEFINE api_key, the_text STRING
    DEFINE reg_ids DYNAMIC ARRAY OF STRING,
        notif_obj util.JSONObject,
        info_msg STRING
    CALL gcm_collect_tokens(reg_ids)
    IF reg_ids.getLength() == 0 THEN
        RETURN "No registered devices..."
    END IF
    LET notif_obj = util.JSONObject.create()
    CALL gcm_simple_popup_notif(reg_ids, notif_obj, the_text)
    LET info_msg = gcm_send_notif_http(api_key, notif_obj)
    RETURN info_msg
END FUNCTION

Handle push notifications in mobile apps
To handle push notifications in mobile apps, the same code base can be used for GCM and other token-based frameworks.
For more details see Handling notifications in the mobile app on page 2629.

Apple Push Notification Service (APNs)

Follow this procedure to implement push notification with APNs.

Introduction to APNs push notification

The push notification solution described in this section is based on the Apple Push Notification Service. Familiarize yourself with APNs by visiting the Apple Push Notification Service web site.

Apple Push Notification service allows push servers to send notification message data to registered iOS (and OS X) devices.

The APNs service transports and routes a remote notification from a given provider to a given device. A notification is a short message built from two pieces of data: the device token and the payload.

Note: Each device needs to be identified by its device token, and the provider must send individual notification messages for each registered device.

The system involves the following actors:

- The Apple Push Notification Service (APNs):
  APNs provides push server and client identification. It also handles all aspects of message queuing and delivery to the target applications running on registered devices. The APNs system includes a feedback service that can be queried to check for devices that have unregistered and no longer need to be notified.

- The device tokens maintainer:
  A Web Services server program maintaining the database of device tokens, with application user information. This program must listen to new device registration events, store them in a database, and from time to time query the APNs feedback service to check for unregistrations.

- The push provider:
  This program will send notification messages to the APNs server by using the `com.APNS` class and TCP request API. The push provider program will query the device token database to know which devices need to be notified.

- Devices running the Genero app registered to the push notification server:
  Registered devices use the push notification client API to register, get notification data and unregister from the service.

  Note: The database used to store device tokens must be a multi-user database (do not use SQLite for example), since two distinct programs will use the database.

APNS push notification security

iOS apps must be created with an Apple certificate for development or distribution, linked to an App ID (or Bundle ID) with push notification enabled. The provisioning profile used when building the IPA must be linked to the App ID with push enabled. Certificate, provisioning and bundle id must be specified to the GMI build tool.

To create the push provider linked to your app, usually you need to create two Apple Push Notification certificates linked to your App ID (you select the App ID when you create a push certificate in the Apple member center): One certification for development and another for distribution. For more details about the push provider certificates, see APNs SSL certificate on page 2103.

Check also Apple Push Notification documentation for more details about certificate requirements for push notifications.
Identifying target devices

Each APNs client device is identified by a device token. A device token is an opaque identifier of a device that APNs gives to the device when an app registers itself for push notification. It enables APNs to locate in a unique manner the device on which the client app is installed. The device shares the device token with the push provider. The push provider must produce notification messages for each device by including the device token in the message structure.

**Important**: The mobile app obtains its device token by registering to the APNs service with the registerForRemoteNotifications call. It is then in charge of sending its device token to the push provider; typically through a RESTful request. The push provider must collect and store the device tokens, as they need to be specified in a push notification message send by the push provider.

Notification content (payload)

In a notification message, the payload is a JSON-defined property list that specifies how the user of an app on a device is to be alerted.

**Important**: The size of an APNS notification payload cannot exceed 2 Kilobytes. Make sure that the resulting BYTE variable does not exceed this size limitation. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The payload must contain a list of "aps" records. Each "aps" record represents a notification message to be displayed as a hint on the device (for example, by adding a badge number to the app icon). The "aps" records can also contain custom data in a separate set of JSON attributes.

In the Genero mobile app, the notification messages are obtained by using the getRemoteNotifications call, after a notification push action was detected with an ON ACTION handler.

**Important**: When an iOS app is in background, silent push notifications can occur, but notification message data (i.e. the payload) may not be available. In such case, GMI is able to detect that a notification arrived (i.e. when the app badge number is greater than zero) and raise the notification pushed action, but the getRemoteNotifications front call will return no message data (data return param is NULL). If such case, implement a fallback mechanism (based on RESTful web services for example), to contact the push notification provider and retrieve the message information.

Example of notification record list (JSON array) returned by the getRemoteNotifications front call:

```json
[
   {
      "aps": {
         "alert": "My first push",
         "badge": 1,
         "sound": "default",
         "content-available": 1
      }
   },
   {
      "aps": {
         "alert": {
            "title": "Push",
            "body": "My second push"
         },
         "badge": 2,
         "sound": "default",
         "content-available": 1
      }
   }
]
```
Badge number handling

With APNs, badge number handling is in charge of the application code: The push provider sends a badge number in the payload records, the app can check the message content, and must communicate with a server component, to indicate that the notification message has been consumed. The server program can then maintain a badge number for each registered device, decrementing the badge number.

In order to set or query the badge number for your app, use the following front calls:

- `setBadgeNumber (iOS)` on page 1952
- `getBadgeNumber (iOS)` on page 1951

In this tutorial, badge numbers are stored on the server database. The token maintainer handlers requests from apps to sync the badge number for a given device token, and the push provider program reads the database to set the badge number in the notification payload. When the app consumes messages, it queries and resets the app badge number with the `getBadgeNumber/setBadgeNumber` front calls, and informs the token maintainer to sync the badge number in the central database.

Communication channels

A provider communicates with Apple Push Notification service over a binary network interface, using a streaming TCP socket design in conjunction with binary content:

- The binary interface of the APNs development environment is available through the URL `gateway.sandbox.push.apple.com` on port 2195.
- The binary interface of the APNs production environment is available through the URL `gateway.push.apple.com` on port 2195.
- The binary interface of the APNs feedback service is available through the URL `feedback.push.apple.com` on port 2196.

For each interface, use TLS (or SSL) to establish a secured communication channel. The SSL certificate required for these connections is obtained from Apple's Member Center.

To establish a TLS session with APNs, an Entrust Secure CA root certificate must be installed on the provider’s server. If the server is running OS X, this root certificate is already in the keychain. On other systems the certificate might not be available.

Creating an APNs certificate for the app

The Apple Push Notification Certificate identifies the push notification service for a given mobile app. This certificate will be created from an App ID (a.k.a. Bundle ID) and is used by the APNs system to dispatch the notification message to the registered devices.

For more details, see APNs SSL certificate on page 2103.

Implementing the device tokens maintainer

To handle device registrations on the server side of your application, the same code base can be used for APNs and other token-based frameworks.

For more details, see Implementing a token maintainer on page 2623.
Implementing the push provider

The push provider will produce application notification messages that will be transmitted to the APNs service. The APNs service will then spread them to all registered mobile devices, identified by their device token.

To send notification messages, the push provider must build binary messages by using the com.APNS API, provided by the Web Services library, and send TCP message requests over SSL to the following URLs:

- "tcps://gateway.sandbox.apple.com:2195" (for development)
- "tcps://gateway.push.apple.com:2195" (for production)

**Note:** In order to establish a secure connection to the APNs framework an SSL certificate needs to be defined in FGLPROFILE, as described in APNs SSL certificate on page 2103.

To send a notification message, the push provider must know the device tokens of the registered devices/applications.

**Note:** A distinct notification message must be sent for each registered device.

The following example demonstrates how to implement a function to send an APNs notification message. The function takes a device token and a JSON object as parameters. First, build the binary data with the com.APNS.EncodeMessage() method, then POST the data with a com.TCPRequest.doDataRequest() method. In case of success, the TCP request timeout will occur (APNs service only responds immediately in case of error), then use the com.TCPResponse.getDataResponse() method, to get status information. See com.APNS.EncodeMessage() for more details about notification message creation.

```java
IMPORT com
IMPORT security
IMPORT util

FUNCTION apns_send_notif_http(deviceTokenHexa, notif_obj)
  DEFINE deviceTokenHexa STRING,
       notif_obj util.JSONObject
  DEFINE req com.TCPRequest,
         resp com.TCPResponse,
         uuid STRING,
         ecode INTEGER,
         dt DATETIME YEAR TO SECOND,
         exp INTEGER,
         data, err BYTE,
         res STRING

  LOCATE data IN MEMORY
  LOCATE err IN MEMORY

  LET dt = CURRENT + INTERVAL(10) MINUTE TO MINUTE
  LET exp = util.Datetime.toSecondsSinceEpoch(dt)

  TRY
      LET req = com.TCPRequest.create( "tcps://gateway.push.apple.com:2195" )
      CALL req.setKeepConnection(true)
      CALL req.setTimeout(2) # Wait 2 seconds for APNs to return error code
      LET uuid = security.RandomGenerator.createRandomString(4)
      CALL com.APNS.EncodeMessage( data,
                                    security.HexBinary.ToBase64(deviceTokenHexa),
                                    notif_obj.toString(),
                                    uuid,
                                    exp)
exp,
  10
)
IF LENGTH(data) > 2000 THEN
  LET res = "ERROR : APNS payload cannot exceed 2 kilobytes"
  RETURN res
END IF
CALL req.doDataRequest(data)
TRY
  LET resp = req.getResponse()
  CALL resp.getDataResponse(err)
  CALL com.APNS.DecodeError(err) RETURNING uuid, ecode
  LET res = SFMT("APNS result: UUID: %1, Error code: %2", uuid, ecode)
CATCH
  CASE STATUS
    WHEN -15553 LET res = "Timeout Push sent without error"
    WHEN -15566 LET res = "Operation failed ": SQLCA.SQLERRM
    WHEN -15564 LET res = "Server has shutdown"
    OTHERWISE LET res = "ERROR :", STATUS
  END CASE
END CATCH
END TRY
END TRY
RETURN res
END FUNCTION

The next code example implements a function that creates the JSON object defining notification content (payload). That object can be passed to the `apns_send_notif_http()` function described above:

FUNCTION apns_simple_popup_notif(notif_obj, msg_title, user_data, badge_number)
  DEFINE notif_obj util.JSONObject,
  msg_title, user_data STRING,
  badge_number INTEGER
  DEFINE aps_obj, data_obj util.JSONObject
  LET aps_obj = util.JSONObject.create()
  CALL aps_obj.put("alert", msg_title)
  CALL aps_obj.put("sound", "default")
  CALL aps_obj.put("badge", badge_number)
  CALL aps_obj.put("content-available", 1)
  CALL notif_obj.put("aps", aps_obj)
  LET data_obj = util.JSONObject.create()
  CALL data_obj.put("other_info", user_data)
  CALL notif_obj.put("custom_data", data_obj)
END FUNCTION

The `apns_simple_popup_notif()` and `apns_send_notif_http()` functions can then be used as follows:

IMPORT com
IMPORT util

MAIN
  DEFINE reg_ids DYNAMIC ARRAY OF STRING,
  notif_obj util.JSONObject,
  i INTEGER
LET notif_obj = util.JSONObject.create()
CALL gcm_simple_popup_notif(notif_obj, "This is my message!", 1)

LET reg_ids[1] = "APA91bHun..."
LET reg_ids[2] = "B4AA2q7xa..."
...
FOR i=1 TO reg_ids.getLength()
    DISPLAY gcm_send_notif_http(reg_ids[i], notif_obj)
END FOR
END MAIN

In order to use the tokens database maintained by a token maintainer program, your APNs push provider can collect device tokens as shown in the example below. Note that the dynamic array contains token ids and badge numbers:

FUNCTION apns_collect_tokens(reg_ids)
    DEFINE reg_ids DYNAMIC ARRAY OF RECORD
        token STRING,
        badge INTEGER
    END RECORD
    DEFINE rec RECORD
        id INTEGER,
        sender_id VARCHAR(150),
        registration_token VARCHAR(250),
        badge_number INTEGER,
        app_user VARCHAR(50),
        reg_date DATETIME YEAR TO FRACTION(3)
    END RECORD,
    x INTEGER
    DECLARE c1 CURSOR FOR
        SELECT * FROM tokens
        WHERE sender_id IS NULL -- In case if GCM tokens remain in the db
    CALL reg_ids.clear()
    FOREACH c1 INTO rec.*
        LET x = reg_ids.getLength() + 1
        LET reg_ids[x].token = rec.registration_token
        LET reg_ids[x].badge = rec.badge_number
    END FOREACH
END FUNCTION

In order to handle badge numbers for each registered device, implement a function to update badge numbers in database:

FUNCTION save_badge_number(token, badge)
    DEFINE token STRING,
    badge INT
    UPDATE tokens SET
        badge_number = badge
    WHERE registration_token = token
END FUNCTION

The above functions can then be used to send a push message to all registered devices:

FUNCTION apns_send_message(msg_title, user_data)
    DEFINE msg_title, user_data STRING
    DEFINE reg_ids DYNAMIC ARRAY OF RECORD
        token STRING,
        badge INTEGER
    END RECORD,
    notif_obj util.JSONObject,
```sql
info_msg STRING,
new_badge, i INTEGER
CALL apns_collect_tokens(reg_ids)
IF reg_ids.getLength() == 0 THEN
    RETURN "No registered devices..."
END IF
LET info_msg = "Send:"
FOR i=1 TO reg_ids.getLength()
    LET new_badge = reg_ids[i].badge + 1
    CALL save_badge_number(reg_ids[i].token, new_badge)
    LET notif_obj = util.JSONObject.create()
    CALL apns_simple_popup_notif(notif_obj, msg_title, user_data, new_badge)
    LET info_msg = info_msg, "\n",
    apns_send_notif_http(reg_ids[i].token, notif_obj)
END FOR
RETURN info_msg
END FUNCTION
```

See also Provider Communication with Apple Push Notification Service.

Handle push notifications in mobile apps

To handle push notifications in mobile apps, the same code base can be used for APNs and other token-based frameworks.

For more details see Handling notifications in the mobile app on page 2629.

Implementing a token maintainer

The token maintainer is a BDL Web Services server program that handles push token registration from mobile apps.

Basics

In order to implement a push notification mechanism, you need to set up a server part (token maintainer and push notification server), in conjunction with a push notification framework such as Google Cloud Messaging (GCM) or Apple Push Notification service (APNs). In addition, you need to handle notification events in your mobile app. This section describes how to implement the token maintainer, the server program that maintains the list of registered devices (i.e. registration tokens for GCM or device tokens for APNs).

**Note:** The max length of a push client token can vary according to the push framework provider. If you need to store registration tokens in a database, check the max size for a token and consider using a large column type such as `VARCHAR(250)`.

The same code base can be used for Android (using GCM) and iOS (using APNs) applications: The token maintainer will basically handle RESTful HTTP requests coming from the internet for token registration and token un-registration. For each of these requests, the program will insert a new record or delete an existing record in a dedicated database table.

**Note:** The database used to store tokens must be created before starting the token maintainer program. By default, the program uses SQLite (dbmsqt) and the name of the database is "tokendb". To create this SQLite database, simply create an empty file with this name.

The push provider/server program can then query the tokens table to build the list of target devices for push notifications.

In the context of APNS, the token maintainer must also handle badge numbers for each registered device: When consuming notification messages, the iOS app must inform the token maintainer that the badge number has changed. This function is implemented with the "badge_number" command.
The token maintainer is a Web Services server program which must be deployed behind a GAS to handle load balancing. You can, however, write code to test your program in development without a GAS.

The act of registering/unregistering push tokens is application specific: When registering tokens, you typically want to add application user information. Genero BDL allows you to implement a token maintainer in a simple way.

**Note:** When executing this token maintainer program with APNs, you must pass the "APNS" command line argument to execute APNs feedback queries.

### MAIN block and database creation

Start with the MAIN block, and the connection to a database. In this tutorial, we use SQLite as the database. The program will automatically create the database file and the tokens table if it does not yet exist.

```plaintext
... MAIN CALL open_create_db() CALL handle_registrations() END MAIN

FUNCTION open_create_db() DEFINE dbsrc VARCHAR(100),
  x INTEGER
LET dbsrc = "tokendb+driver='dbmsqt'"
CONNECT TO dbsrc WHENEVER ERROR CONTINUE
SELECT COUNT(*) INTO x FROM tokens WHENEVER ERROR STOP
IF SQLCA.SQLCODE<0 THEN
  CREATE TABLE tokens {
    id INTEGER NOT NULL PRIMARY KEY,
    sender_id VARCHAR(150),
    registration_token VARCHAR(250) NOT NULL UNIQUE,
    badge_number INTEGER NOT NULL,
    app_user VARCHAR(50) NOT NULL, -- UNIQUE
    reg_date DATETIME YEAR TO FRACTION(3) NOT NULL
  }
END IF
END FUNCTION
```

### Handling registration and unregistration requests

The next function is typical Web Service server code using the Web Services API to handle RESTful requests. Note that the TCP port is defined as a constant that is used to set FGLAPPSERVER automatically when not running behind the GAS:

```plaintext
IMPORT util IMPORT com

CONSTANT DEFAULT_PORT = 9999

MAIN ...
  CALL handle_registrations()
END MAIN

FUNCTION handle_registrations() DEFINE req com.HTTPServiceRequest,
  url, method, version, content_type STRING,
reg_data, reg_result STRING
IF LENGTH(fgl_getenv("FGLAPPSERVER"))==0 THEN
  -- Normally, FGLAPPSERVER is set by the GAS
  DISPLAY SFMT("Setting FGLAPPSERVER to %1", DEFAULT_PORT)
  CALL fgl_setenv("FGLAPPSERVER", DEFAULT_PORT)
END IF
CALL com.WebServiceEngine.Start()
WHILE TRUE TRY
  LET req = com.WebServiceEngine.getHTTPServiceRequest(20)
  CATCH
    IF STATUS==-15565 THEN
      CALL show_verb("TCP socket probably closed by GAS, stopping
process...")
      EXIT PROGRAM 0
    ELSE
      STATUS
      DISPLAY "Unexpected getHTTPServiceRequest() exception: ",
      DISPLAY "Reason: ", SQLCA.SQLERRM
      EXIT PROGRAM 1
    END IF
  END TRY
  IF req IS NULL THEN -- timeout
    DISPLAY SFMT("HTTP request timeout...: %1", CURRENT YEAR TO
    FRACTION)
    CALL check_apns_feedback()
    CALL show_tokens()
    CONTINUE WHILE
  END IF
  LET url = req.getURL()
  LET method = req.getMethod()
  IF method IS NULL OR method != "POST" THEN
    IF method == "GET" THEN
      CALL req.sendTextResponse(200,NULL,"Hello from token
      maintainer...")
    ELSE
      DISPLAY SFMT("Unexpected HTTP request: %1", method)
      CALL req.sendTextResponse(400,NULL,"Only POST requests
      supported")
    END IF
    CONTINUE WHILE
  END IF
  LET version = req.getRequestVersion()
  IF version IS NULL OR version != "1.1" THEN
    DISPLAY SFMT("Unexpected HTTP request version: %1", version)
    CONTINUE WHILE
  END IF
  LET content_type = req.getRequestHeader("Content-Type")
  IF content_type IS NULL
    OR content_type NOT MATCHES "application/json*" -- ;Charset=UTF-8
    THEN
    DISPLAY SFMT("Unexpected HTTP request header Content-Type: %1",
    content_type)
    CALL req.sendTextResponse(400,NULL,"Bad request")
    CONTINUE WHILE
  END IF
TRY
  CALL req.readTextRequest() RETURNING reg_data
CATCH
  DISPLAY SFMT("Unexpected HTTP request read exception: %1", STATUS)
END TRY
LET reg_result = process_command(url, reg_data)
CALL req.setResponseCharset("UTF-8")
CALL req.setResponseHeader("Content-Type","application/json")
Processing registration and unregistration commands

The next function is called when a RESTful request is to be processed. The URL will define the type of command to be executed by the server:

- If the URL contains "/token_maintainer/register", a new token must be inserted in the database.
- If the URL contains "/token_maintainer/unregister", an existing token must be deleted from the database.

```sql
FUNCTION process_command(url, data)
  DEFINE url, data STRING
  DEFINE data_rec RECORD
    sender_id VARCHAR(150),
    registration_token VARCHAR(250),
    app_user VARCHAR(50)
  END RECORD,
  p_id INTEGER,
  p_ts DATETIME YEAR TO FRACTION(3),
  result_rec RECORD
    status INTEGER,
    message STRING
  END RECORD,
  result STRING
  LET result_rec.status = 0
  TRY
    CASE
      WHEN url MATCHES "*/token_maintainer/register"
        CALL util.JSON.parse( data, data_rec )
        SELECT id INTO p_id FROM tokens
          WHERE registration_token = data_rec.registration_token
          IF p_id > 0 THEN
            LET result_rec.status = 1
            LET result_rec.message = SFMT("Token already registered:
            [%1]", data_rec.registration_token)
            GOTO pc_end
        END IF
        SELECT MAX(id) + 1 INTO p_id FROM tokens
        IF p_id IS NULL THEN LET p_id=1 END IF
        LET p_ts = util.Datetime.toUTC(CURRENT YEAR TO FRACTION(3))
        INSERT INTO tokens
          VALUES( p_id, data_rec.sender_id,

END FUNCTION

Showing the current registered tokens

The following function is called after a WebServiceEngine timeout, when no request is to be processed. Its purpose is just to show the current list of registered tokens in a server log (stdout):

FUNCTION show_tokens()
  DEFINE rec RECORD
    id INTEGER,
    sender_id VARCHAR(150),
    registration_token VARCHAR(250),
    badge_number INTEGER,
    app_user VARCHAR(50),
    reg_date DATETIME YEAR TO FRACTION(3)
  END RECORD
  DECLARE c1 CURSOR FOR SELECT * FROM tokens ORDER BY id
  FOREACH c1 INTO rec.*
    IF rec.sender_id IS NULL THEN
      LET rec.sender_id = ".(null)"
    END IF
    DISPLAY "   
      rec.id, ": 
        rec.app_user[1,10], "/ 
        rec.sender_id[1,20], "/ 
        rec.badge_number USING "<<<&", 
        rec.registration_token[1,20], "/ "
  END FOREACH
  IF rec.id == 0 THEN
    DISPLAY "No tokens registered yet..."
APNs feedback checking

When using Apple Push Notification service, the device token maintainer can also handle device unregistration by querying the APNs feedback service. The APNs feedback service will provide the list of device tokens that are no longer valid because the app on the devices has unregistered.

**Note:** When using the APNs feedback service, an SSL certificate needs to be defined in FGLPROFILE as described in APNs SSL certificate on page 2103.

To get the list of device tokens failed for remote notifications, send HTTP POST request to the following URL:

```
tcps://feedback.push.apple.com:2196
```

The token maintainer can use this service to clean up the token database.

The next function is called after a timeout when no request needs to be processed by the token maintainer:

```java
FUNCTION check_apns_feedback()
DEFINE req com.TCPRequest,
resp com.TCPResponse,
feedback DYNAMIC ARRAY OF RECORD
    timestamp INTEGER,
    deviceToken STRING
END RECORD,
timestamp DATETIME YEAR TO FRACTION(3),
token VARCHAR(250),
i INTEGER,
data BYTE

IF arg_val(1)!="APNS" THEN RETURN END IF
DISPLAY "Checking APNS feedback service..."

LOCATE data IN MEMORY

TRY
    LET req = com.TCPRequest.create( "tcps://feedback.push.apple.com:2196" )
    CALL req.setKeepConnection(true)
    CALL req.setTimeout(2)
    CALL req.doRequest()
    LET resp = req.getResponse()
    CALL resp.getDataResponse(data)
    CALL com.APNS.DecodeFeedback(data,feedback)
    FOR i=1 TO feedback.getLength()
        LET timestamp =
            util.Datetime.fromSecondsSinceEpoch(feedback[i].timestamp)
            util.Datetime.toUTC(timestamp)
        LET token = feedback[i].deviceToken
        DELETE FROM tokens
            WHERE registration_token = token
            AND reg_date < timestamp
    END FOR
CATCH
    CASE STATUS
        WHEN -15553 DISPLAY "APNS feedback: Timeout: No feedback message"
        WHEN -15566 DISPLAY "APNS feedback: Operation failed :", SQLCA.SQLERRM
        WHEN -15564 DISPLAY "APNS feedback: Server has shutdown"
        OTHERWISE DISPLAY "APNS feedback: ERROR :",STATUS
```
Handling notifications in the mobile app

This topic describes how to handle push notification in the app running on mobile devices.

Basics

In order to implement a push notification mechanism, you need to set up a server part (token maintainer and push notification server), in conjunction with a push notification framework such as Google Cloud Messaging (GCM) or Apple Push Notification service (APNs). In addition, you need to handle notification events in your mobile app. This section describes how to implement push notification in the app with the push notification API available in Genero BDL.

The same code base can be used to handle push notifications for Android (using GCM) and iOS (using APNs) devices. Only the content of the notification message will have to be processed with specific code, as the structure of the message differs according to standards defined by the push notification framework.

Genero API for push notifications

Genero BDL provides an API to handle push notification on mobile apps. Dedicated front calls are available to register to a push server, fetch push notification data, and unregister:

- registerForRemoteNotifications on page 1940
- getRemoteNotifications on page 1936
- unregisterFromRemoteNotifications on page 1945

To detect when a notification message arrives from the push server, a specific action called notificationpushed must be used by app code on a ON ACTION handler. This special action is referenced as a predefined action.

Android app permissions for GCM push notifications

Android apps using push notification services need specific permissions (Android manifest), such as:

- android.permission INTERNET
- android.permission.GET ACCOUNTS
- android.permission.WAVE LOCK
- com.google.android.c2dm.permission.RECEIVE
- application-package-name.permission.C2D_MESSAGE where application-package-name is the Android package name of your app (for example, com.mycompany.pushclient)

Permissions will be automatically set when building the Android APK packages with the GMA build tool, according to the package name specified with the --build-app-package-name option.

See the GCM documentation for more details about required permissions for push notifications.

iOS app certificates for APNS push notifications

iOS apps must be created with an Apple certificate for development or distribution, linked to an App ID (or Bundle ID) with push notification enabled. The provisioning profile used when building the IPA must be linked to the App ID with push enabled. Certificate, provisioning and bundle id must be specified to the GMI build tool.
Handling push notification in the app

To handle push notifications in your mobile app, perform the following steps:

1. Register to the push service and get the registration token
2. Send the push notification token to your token maintainer
3. Handle notification events with the `notificationpushed` action
4. Eventually un-register from the push servers

1 - Registering to the push service and to the push provider

Register the app to the push notification service with the "registerForRemoteNotifications" front call.

- When using GCM, you must provide Sender ID to identify the GCM project.
- When using APNs, you can leave the Sender ID to NULL.

**Note:** The app does not need to register for notification each time it is restarted: Even if the app is closed, the registration is still active until the `unregisterFromRemoteNotifications` front call is performed. At first execution, an app will typically ask if the user wants to get push notifications and register to the push service if needed. To disable push notification, apps usually implement an option that can be disabled (to unregister) and re-enabled (to register again) by the user. On Android, that the app must register for notification each time it is upgraded.

**Important:**

When an app restarts, if notifications are pending and the app has already registered for push notification in a previous execution, the `notificationpushed` action will be raised as soon as a dialog with the corresponding `ON ACTION` handler activates. The app should then perform a `getRemoteNotifications` front call as in the regular case, to get the pending notifications pushed to the device while the app was off.

However, special consideration needs to be given to iOS devices. When push notification arrives for an iOS app that has not started, there is no mechanism to wake up the app and get the push data. Therefore, when the user starts the app from the springboard, there will never have any push data available. Depending on the context, implement the following programming patterns to solve this problem:

1. If the push notification contains a badge number, the app can verify if the badge is greater than 0 (with the `getBadgeNumber` front call) in order to perform a `getRemoteNotifications` front call. Even if there is no data available with the front call, the app should directly ask the server push provider to get last push data.
2. If the push notification does not contain badge numbers, the app should always perform a `getRemoteNotification` front call when it starts. If there is no push data available from the front call, the app should ask the server push provider if there is push data available. This is by the way also recommended when receiving a `notificationpushed` action during application life time.
3. If the user starts the app from the Notification Center, the app is launched with push data transmitted from the system, and the `notificationpushed` action is sent. The app should perform the `getRemoteNotifications` front call and get the push data.

The `registerForRemoveNotifications` front call will return a registration token for the app which will be used by the push server (a.k.a push provider).

- When using GCM, the returned identifier is the GCM "registration token".
- When using APNs, the returned identifier is the APNs "device token".

```
CONSTANT GCM_SENDER_ID = "<enter your GCM Sender ID ('' for APNs)>
```

...
LET rec.tm_host = "https://pushreg.example.orion"
LET rec.tm_port = 4930
LET rec.app_user = "mike"

LET rec.registration_token = register(GCM_SENDER_ID, rec.app_user)

FUNCTION register(sender_id, app_user)
    DEFINE sender_id STRING,
    app_user STRING
    DEFINE registration_token STRING
    TRY
        CALL ui.Interface.frontCall("mobile", "registerForRemoteNotifications",
            [ sender_id ], [ registration_token ] )
        IF tm_command( "register", sender_id, registration_token, app_user,
            0 ) < 0 THEN
            RETURN NULL
        END IF
    CATCH
        MESSAGE "Registration failed."
        RETURN NULL
    END TRY
    MESSAGE SFMT("Registration succeeded (token=%1)", registration_token)
    RETURN registration_token
END FUNCTION

2 - Sending a push notification token to your token maintainer

Once registered to the GCM or APNs service, the app must also register to the push server or push provider by sending the token obtained in step 1.

This is typically done by using a RESTful HTTP POST, sending the token (along with additional application user information) to a dedicated server program that maintains the list of registered devices/tokens.

The device token maintainer can be implemented in BDL as a Web Service program, as described in Implementing a token maintainer on page 2623.

In this tutorial, the tm_command() function implements token registration (as well as badge number handling for APNS):

IMPORT com
IMPORT util

... LET rec.tm_host = "https://pushreg.example.orion"
LET rec.tm_port = 4930 ...

FUNCTION tm_command( command, sender_id, registration_token, app_user,
    badge_number )
    DEFINE command STRING,
    sender_id STRING,
    registration_token STRING,
    app_user STRING,
    badge_number INTEGER
    DEFINE url STRING,
    json_obj util.JSONObject,
    req com.HTTPRequest,
    resp com.HTTPResponse,
    json_result STRING,
result_rec RECORD
  status INTEGER,
  message STRING
END RECORD

TRY
  LET url = SFMT( "http://%1:%2/token_maintainer/%3",
                  rec.tm_host, rec.tm_port, command )
  LET req = com.HTTPRequest.create(url)
  CALL req.setHeader("Content-Type", "application/json")
  CALL req.setMethod("POST")
  CALL req.setConnectionTimeOut(5)
  CALL req.setTimeOut(5)
  LET json_obj = util.JSONObject.create()
  CALL json_obj.put("sender_id", sender_id)
  CALL json_obj.put("registration_token", registration_token)
  CALL json_obj.put("app_user", app_user)
  CALL json_obj.put("badge_number", badge_number)
  CALL req.doTextRequest(json_obj.toString())
  LET resp = req.getResponse()
  IF resp.getStatusCode() != 200 THEN
    MESSAGE SFMT("HTTP Error (%1) %2",
                  resp.getStatusCode(),
                  resp.getStatusDescription())
    RETURN -2
  ELSE
    LET json_result = resp.getTextResponse()
    CALL util.JSON.parse(json_result, result_rec)
    IF result_rec.status >= 0 THEN
      RETURN 0
    ELSE
      MESSAGE SFMT("Notification maintainer message:
                    %1",
                    result_rec.message)
      RETURN -3
    END IF
  END IF
END TRY
END FUNCTION

When the app is declared as push notification client to the push server, continue with the normal program flow.

3 - Handling push notification events

To get and handle notification events, the current active dialog must implement the notificationpushed special action.

In the ON ACTION block for this action, query for notification messages by using the "getRemoteNotifications" front call, (passing the Sender ID as parameter when using GCM, for APNs the Sender ID must be NULL). This front call returns a JSON string containing a list of notification messages to be processed:

...  
DIALOG ...
...
  ON ACTION notificationpushed
    CALL handle_notification(sender_id)
  ...
END DIALOG ...
...
When using APNS, the app must handle the badge numbers attached to the device token. The app must:

1. Query the current badge number with the `getBadgeNumber` front call.
2. Compute the new badge number according to the number of notifications consumed.
3. Reset the badge number with the `setBadgeNumber` front call.
4. Inform the token maintainer to sync the badge number in the central database.

The following function handles badge numbers for the app:

```plaintext
FUNCTION setup_badge_number(consumed)
DEFINE consumed INTEGER
DEFINE badge_number INTEGER
TRY -- If the front call fails, we are not on iOS...
    CALL ui.Interface.frontCall("ios", "getBadgeNumber", [],
        [badge_number])
CATCH
    RETURN
END TRY
END FUNCTION
```
4 - Unregistering the app from push notification

If the app no longer wants to get push notifications, unregister from the push provider (using a RESTful POST, in the `regunreg_token()` function), and unregister from the push service by using the "unregisterFromRemoteNotifications" front call.

- When using GCM, you must pass the GCM Sender ID as parameter.
- When using APNs, the parameter must be NULL.

```plaintext
LET rec.tm_host = "https://pushreg.example.orion"
LET rec.tm_port = 4930

CALL unregister(GCM_SENDER_ID, rec.registration_token, rec.app_user)

FUNCTION unregister(sender_id, registration_token, app_user)
  DEFINE sender_id STRING,
         registration_token STRING,
         app_user STRING
  IF tm_command( "unregister", sender_id, registration_token, app_user, 0 ) < 0 THEN
    RETURN
  END IF
  TRY
    CALL ui.Interface.frontCall(
        "mobile", "unregisterFromRemoteNotifications",
        [ sender_id ], [ ]
    )
  CATCH
    MESSAGE "Un-registration failed (broadcast service)."
    RETURN
  END TRY
  MESSAGE "Un-registration succeeded"
END FUNCTION
```
