**Important:** This feature is only for mobile platforms.

**Figure 89: iOS list view with filter field**

![iOS list view with filter field](image1)

**Figure 90: Android™ list view with filter field**

![Android™ list view with filter field](image2)
Reduce filter usage details

The filter search is case-insensitive.

The value entered in the filter field is compared to all fields of visible columns, except columns of the type TEXT or BYTE. The comparison is based on the formatted value. For example, a MONEY column will display values formatted with the currency symbol. To match values in that column, the user must enter exactly the same value (for example, with the currency symbol and the correct decimal separator). When using COMBOBOX fields, the find searches in the visible values of combobox items.

Only text widgets displaying values are searched. Columns using widgets such as images, radio-groups or checkboxes are not searched. The filter function ignores PHANTOM fields, hidden fields and fields defined with the INVISIBLE attribute.

Only rows in memory can be searched. When using page-mode (ON FILL BUFFER), the built-in filter is disabled. When implementing dynamic tree views, the built-in filter will only search the tree nodes available in the program array.

If the rows are filtered (some value is present in the search field), any non-rowbound action is disabled. On iOS, the action bar is replaced by the search bar.

Disabling the reduce filter

The reduce filter can be disabled with the reduceFilter style attribute:

```
<Style name="Table">
  <StyleAttribute name="reduceFilter" value="no" />
</Style>
```

Summary lines in tables

Table views can display a summary line, to show aggregate values for columns.

To get a summary line in a table, define aggregate field item tags at the bottom of the TABLE container, with the corresponding AGGREGATE form item definitions in the ATTRIBUTES section.

**Important:** This feature is not supported on mobile platforms.
Define the type of the aggregate field with the AGGREGATETYPE attribute: The aggregate value can be automatically computed, or set by program.

To get a global label for the summary line, specify the AGGREGATETEXT attribute at the TABLE level. This aggregate label will appear on the left in the summary line, if no aggregate text is defined at the aggregate field level.

To decorate the summary line, use presentation style attributes such as summaryLineAlwaysAtBottom.

The next example defines a "total" aggregate field for the third column of the table:

```
TABLE (AGGREGATETEXT="Total")
{
  [c1  |c2          |c3         ]
  [c1  |c2          |c3         ]
  [total      ]
}
END

ATTRIBUTES

AGGREGATE total = FORMONLY.total, AGGREGATETYPE=PROGRAM;
```

For details, see Aggregate fields on page 1144.

**Defining the action for a row choice**
The row choice in a TABLE can be associated with a dedicated action.

If using a DISPLAY ARRAY dialog to control a TABLE container, a double-click on a row (for a desktop client), or a tap on a row (for mobile clients) fires a default action.

Row choice action can be customized as described in Defining the action for a row choice on page 1738.

**Using tables on mobile devices**
Table views render in a specific way on mobile devices, in order to take advantage of mobile device ergonomics.

**Unsupported table features**
Some table / list view features are not supported on mobile devices.

The list view features not supported on mobile devices include:

- **Multiple row selection** on page 1752
- **Summary lines in tables** on page 1767
- **List ordering** on page 1764
- **Find function** on page 1764
- **Keyboard seek** on page 1765
- **Columns layout** on page 1763
- **Drag & drop** on page 1819
- **Using IMAGE columns**. (One IMAGECOLUMN can be defined, however)

Note also that there are no column headers/titles in mobile list views.

**Related concepts**

**Built-in table features** on page 1763
Several implicit list handling features are provided by table views.

**Two-column display**
On mobile devices, a TABLE container displays as a list view with the first two columns' content.

While a TABLE container and the corresponding list controller (DISPLAY ARRAY) can define multiple columns, only the first two columns are rendered on a mobile device. The first column defines the main information to be
shown for the row (such as a customer name), while the second column contains additional information (such as a comment, date, address or phone number).

**Figure 91: iOS list view with two-column default rendering**

If the second column contains numeric data or has the `JUSTIFY=RIGHT` attribute, both columns display on a single line with the first column left-aligned and the second column right-aligned.

**Figure 92: iOS list view with side-by-side rendering**
A list view on a mobile device can include an image for each row. To display an image, associate a PHANTOM column to the IMAGECOLUMN attribute of the first column definition. For more details about images in lists, see Displaying column images on page 1761.

**Figure 93: iOS list view with row images**
Related concepts

Record list (DISPLAY ARRAY) on page 1394

The DISPLAY ARRAY instruction provides record list navigation in an application form, with optional record modification actions.

Full and Embedded list views

On mobile devices, table views are displayed as either full screen lists or embedded lists, based on the layout definition.

Full list view

A full list view displays when the table is the only element in a form.

```
LAYOUT TABLE
{ [c1 | c2 ]
}
END
END
```

Figure 94: iOS full list view rendering
Embedded list view

An embedded list view displays when the table is mixed with other form elements. All rows of the table are shown. Scrolling is not possible.

**Tip:** With an embedded list view, consider limiting the number of rows in the program array.

In this example, the table is inside a GRID container:

```
LAYOUT GRID
{| <GROUP g1 >
  | Id: [f1 ]
  | Name: [f2 ]
  | < >
  | <GROUP g2 >
  | <TABLE t1 >
  | [c1 |c2 ]
  | [c1 |c2 ]
  | [c1 |c2 ]
  | < >
  | < >
|}
END END
```

**Figure 95:** iOS embedded list view rendering
The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

**The DOUBLECLICK (tap) action**
On mobile devices, the DOUBLECLICK attribute defines the action to fire when a row is tapped.

By default, no action is fired on mobile devices when the user taps on a row. To fire a dedicated action, add the DOUBLECLICK attribute to the DISPLAY ARRAY dialog and define an ON ACTION action handler.

```plaintext
DISPLAY ARRAY arr TO sr.*
   ATTRIBUTES( DOUBLECLICK=row_select )
   ON ACTION row_select
       CALL process_row(arr_curr())
...
```

Alternatively, you can add a DOUBLECLICK attribute to your TABLE definition in your form file.

**Tip:** We recommend you specify the DOUBLECLICK attribute with the DISPLAY ARRAY dialog, as it is strongly related to the DISPLAY ARRAY dialog.

**Note:**
- On Android™ devices, a long tap on a row only selects the row. The DOUBLECLICK action is not fired.
• For iOS devices, consider using list view decoration options, as described in Row configuration on iOS devices on page 1777.

**Related concepts**

Defining the action for a row choice on page 1768
The row choice in a TABLE can be associated with a dedicated action.

Record list (DISPLAY ARRAY) on page 1394
The DISPLAY ARRAY instruction provides record list navigation in an application form, with optional record modification actions.

**Rowbound actions**
A rowbound action specifies an action to apply to the selected row. Rowbound actions get specific rendering and behavior on mobile devices.

Rowbound actions are action defined with the ROWBOUND action attribute in ON ACTION handlers. Rowbound actions can also be default actions that are implicitly related to the current row, such as the "delete" action.

```plaintext
DISPLAY ARRAY arr TO sr.*
  ... 
  ON ACTION clear_list -- not rowbound 
  ... 
  ON ACTION copy_row ATTRIBUTES(ROWBOUND, TEXT="Copy row") 
  ... 
  ON ACTION check_row ATTRIBUTES(ROWBOUND, TEXT="Check row") 
  ... 
  ON DELETE -- implicitly rowbound 
  ... 
```

**Genero Mobile for Android™ (GMA)**
On Android™ 4 devices, when rowbound actions are defined, each row of a list view shows the three-dot indicator. Tap this icon to bring up a row context menu with options to execute the corresponding rowbound actions. Swipe the row from the right to the left to fire the delete action, it defined.
Figure 96: Android™ list view with rowbound actions

Genero Mobile for iOS (GMI)

On iOS 7 devices, when you swipe your finger from right to left, More… and/or Delete icons show up in the row. Tap More... to bring up a list of rowbound actions to execute. Tap Delete to fire the corresponding delete action code.
Figure 97: iOS list view with rowbound actions

Related concepts
Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

**Close, accept and cancel actions**
The default rendering of the close, accept and cancel actions with a list view depends on the mobile device.

A DISPLAY ARRAY dialog implements the "close", "accept", and "cancel" actions by default. When using a full list view, these actions are default action views. The rendering of these actions vary depending on the type of mobile device. The accept and cancel buttons typically show up on the top of the list view.

For more details, see Action views on mobile devices on page 1678.

**Related concepts**
Default actions in DISPLAY ARRAY on page 1400

**Row configuration on iOS devices**
On iOS devices, table views can be configured to use specific row decorations.

**Note:** The features described in this topic are provided for iOS devices. The decoration attributes are ignored by Genero Mobile for Android™ (GMA)

**The ACCESSORYTYPE attribute**
On iOS devices, the ACCESSORYTYPE attribute used in the DISPLAY ARRAY dialog ATTRIBUTES clause defines the type of icon that appears at the right side of each row.

Possible values for the ACCESSORYTYPE attribute are:

- CHECKMARK
- DETAILBUTTON
- DISCLOSUREINDICATOR

For more details about the ATTRIBUTES syntax, see Syntax of DISPLAY ARRAY instruction on page 1394.

**Checkmark**
When using ACCESSORYTYPE=CHECKMARK, the current row gets a check mark icon on the right hand side.

This decoration is typically used to get a visual indicator for the current row, so the user knows what row will be selected when the DISPLAY ARRAY dialog is validated with an accept (Done) action:

```plaintext
DISPLAY ARRAY arr TO sr.*
   ATTRIBUTES( ACCESSORYTYPE=CHECKMARK )
...```
To customize the application, define the color of the check mark with the *iosTintColor* Window-class style attribute.

**Detail button**

When using `ACCESSORYTYPE=DETAILBUTTON`, each row gets a (i) icon on the right-hand side. To specify what action must be fired when the user taps on the (i) icon, define the `DETAILACTION` in the `DISPLAY ARRAY` attributes, and its corresponding `ON ACTION` handler.

By opening a new window when in the detail action code, a tap on the icon shifts the current window from right to left, to show the new screen.

When tapping on another part of a row, by default, the row becomes then the new current row. To follow typical iOS standards, it is recommended that you also define a `DOUBLECLICK` with its corresponding `ON ACTION` handler, to handle current row selection with a dedicated action. If tapping on any part of a row opens a detail form, use the `DISCLOSUREINDICATOR` solution instead of `DETAILBUTTON`. When selecting a different row, the `AFTER ROW / BEFORE ROW` control blocks are executed before the detail action or double-click action.

```displayarray
DISPLAY ARRAY arr TO sr.*
  ATTRIBUTES ( ACCESSORYTYPE=DETAILBUTTON,
               DETAILACTION=edit_details,
               DOUBLECLICK=select_row )
  ...
  ON ACTION edit_details
    OPEN WINDOW w_details WITH FORM "details"
    INPUT BY NAME arr[i].*
    ...
  END INPUT
  CLOSE WINDOW w_details
  ON ACTION select_row
```
To customize the application, define the color of the disclosure indicator with the `iosTintColor` Window-class style attribute.

**Disclosure indicator**

When using `ACCESSORYTYPE=DISCLOSUREINDICATOR`, each row gets a > gray chevron at the right of each row. This decoration is typically used when tapping the button brings up a list of more choices related to the current row, or to open a detail form to modify the list element.

To execute code when a tapping on a row, define the `DOUBLECLICK` attribute and its corresponding `ON ACTION` handler.

By opening a new window when in the detail action code, a tap on a row shifts the current window from right to left, to show the new screen.

When selecting a different row, the `AFTER ROW / BEFORE ROW` control blocks are executed before the double-click action.

```plaintext
DISPLAY ARRAY arr TO sr.*
    ATTRIBUTES( ACCESSORYTYPE=DISCLOSUREINDICATOR,
                 DOUBLECLICK=row_select )

... ON ACTION row_select
    MENU "Options" ATTRIBUTES(STYLE="dialog")
    COMMAND "Refresh"
    ... COMMAND "Duplicate"
    ... COMMAND "Compress"
    ...
```
COMMAND "Refresh"
...
COMMAND "Synchronize"
...
END MENU
...

Examples
TABLE (table views) usage examples.
Example 1: Simple list view
The form file table.per (grid-based layout):

```
LAYOUT TABLE
{
[c1 |c2 ]
}
END
END
ATTRIBUTES
PHANTOM FORMONLY.key;
c1 = FORMONLY.name, IMAGECOLUMN=image;
PHANTOM FORMONLY.image;
```
The form file `table.per` (stack-based layout):

```
LAYOUT
STACK
  TABLE list1
    PHANTOM FORMONLY.key;
    EDIT FORMONLY.name,
      IMAGECOLUMN=image, TITLE="Name";
    PHANTOM FORMONLY.image;
    EDIT FORMONLY.detail, TITLE="Detail";
END
END
END
```

The program `main.4gl`:

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF RECORD
    key INTEGER,
    name STRING,
    image STRING,
    detail STRING
  END RECORD,
  i INTEGER
FOR i=1 TO 60
  LET arr[i].key = i
  LET arr[i].name = SFMT("Item %1", i)
  IF i MOD 2 THEN
    LET arr[i].image = "file"
  ELSE
    LET arr[i].image = "smiley"
  END IF
  LET arr[i].detail = SFMT("This is item %1", i)
END FOR
OPEN FORM f1 FROM "table"
DISPLAY FORM f1
DISPLAY ARRAY arr TO list1.* ATTRIBUTES(UNBUFFERED,DOUBLECLICK=myselect)
ON ACTION myselect
  MESSAGE "myselect:", arr_curr()
END DISPLAY
END MAIN
```

Understanding scrollgrid views

A scrollgrid view defines a graphical element to display a scrolling list of data records in a set of form fields positioned in a grid.

The scrollgrid is defined as a template for form fields that make up the scroll grid elements. The front end clones this template for each record that fits in the enclosing scrollgrid container. The end user sees a multiple-record view like a list with a vertical scrollbar that can be navigated to select or edit rows, depending on the dialog controlling the scrollgrid.

By default, scrollgrids display a fixed number of visible records, as defined by the number of templates in the grid layout. If the front-end platform allows it, the scrollgrid can be configured to be resizable in height so that if the front end screen or page size grows, the scrollgrid resizes and more records are visible.

![Form with resizable scrollgrid view (GDC desktop front-end)](image)

**Figure 101: Form with resizable scrollgrid view (GDC desktop front-end)**

A usual pattern on the Web is to render information as a responsive tile list, using tiles displayed in pages. A resizable scrollgrid can easily be configured as a responsive tile list.
Scrollgrid view controllers

Scrollgrid views are similar to table views in that they are controlled by a DISPLAY ARRAY or INPUT ARRAY instruction, using a form screen-array bound to a SCROLLGRID container.

When controlled by a DISPLAY ARRAY, the scrollgrid view is by default read-only. However, you can implement modification triggers, to let the end user append, modify and delete rows.

When controlled by an INPUT ARRAY, the scrollgrid view allows immediate data modification: The rows are editable.

Note: A scrollgrid view can also be used with an INPUT or CONSTRUCT dialog: In such case, the user can input field values in the first scrollgrid row only.

You can customize the rendering and the behavior of scrollgrid views with form attributes in the SCROLLGRID container, and in the program using the dialog implementation.

Related concepts

List dialogs on page 1731
Describes how to program dialogs controlling list containers.

Defining scrollgrid in the layout

Define scrollgrid views in the LAYOUT section of the form definition file.

Designing scrollgrid views

The scrollgrid rows are defined as a template within an area delimited by curly brackets.
This is an example of a resizable scrollgrid definition using the `SCROLLGRID` layout item. It is resizable because it has no fixed page size (`WANTFIXEDPAGESIZE=NO`). Only one template is needed to define the records.

The position of the item tags is detected by the form compiler to build the scrollgrid. Item types (widget to be used) and behavior are defined with form items in the `ATTRIBUTES` section.

```plaintext
LAYOUT
SCROLLGRID (WANTFIXEDPAGESIZE=NO)
{
  Id:   [f1    ]
  Name: [f2           ][f3           ]
}
END
END
...
ATTRIBUTES
EDIT f1 = customer.cust_num;
EDIT f2 = customer.cust_fname,
EDIT f3 = customer.cust_lname;
...
```

You can also define `SCROLLGRID` layout tags inside a `GRID` container, beside other layout tags:

```plaintext
LAYOUT
GRID
{
  <SCROLLGRID sg1                      >
  Id:   [f1    ]
  Name: [f2           ][f3           ]
  ...
}
END
END

ATTRIBUTES
SCROLLGRID sg1: scrollgrid1,
  WANTFIXEDPAGESIZE=NO,
  GRIDCHILDRENINPARENT;
...
```

**Important:** Avoid Tab characters (ASCII 9) inside the curly-brace delimited area. If used, Tab characters are replaced with 8 blanks at compilation with `fglform`.

**Height of scrollgrid rows**

The height of scrollgrid rows can be defined within a grid-based layout by adding empty tags underneath (this makes sense only when using widgets that can get a height such as `TEXTEDIT` or `IMAGE`).

In this example, the height of the image item type is defined by the number of rows in the layout section (6 in our example).

```plaintext
LAYOUT
SCROLLGRID (WANTFIXEDPAGESIZE=NO)
{
  Icon [name        ] Index[index ]
  [img                            ]
  [                               ]
  [                               ]
  [                               ]
  [                               ]
  [                               ]
}
```
Defining the rendering type of the scrollgrid

The scrollgrid can be configured to be fixed page size or resizable, depending on requirements or the supported platform:

- To define a scrollgrid with a fixed page size, omit the WANTFIXEDPAGESIZE=NO attribute. The number of visible rows is defined by the number of row templates in the form layout.
- To define a resizable scrollgrid, the WANTFIXEDPAGESIZE=NO is set in the layout to allow the container to stretch vertically. Only one record row template needs to be defined. Then define the initial number of scrollgrid lines with the INITIALPAGESIZE form definition attribute.
- To render a scrollgrid as a paged responsive tile list, the customWidget presentation style is defined and the WANTFIXEDPAGESIZE=NO scrollgrid attribute is used.

For more details, see Controlling scrollgrid rendering on page 1786.

Related concepts

SCROLLGRID container on page 1216
Defines a scrollable grid view widget, in a grid-based layout.

Binding scrollgrids to arrays in dialogs

Program arrays act as data model that are bound to form scrollgrids, when implementing list dialogs.

Identifying list views in program dialogs

In list dialogs such as the INPUT ARRAY or DISPLAY ARRAY, the screen array identifies the record list element in the current form to be bound to the program array used by the dialog.

In this example, the INPUT ARRAY uses the custlist screen array of the form, and binds the custarr program ARRAY with the code:

```
INPUT ARRAY custarr FROM custlist.*
```

The screen array members are associated with the program array record members by position. The order and number of the screen array elements is important as they are bound by position to the members of the program array.

The position of the SCROLLGRID fields, however, can differ from the members of the screen array and program array.

To omit fields in the SCROLLGRID layout, yet include them in the definition of the screen array, and define the fields as PHANTOM fields in the form definition file. The program array can then be defined from the database table definition with the DEFINE LIKE instruction:

```
DEFINE custarr DYNAMIC ARRAY OF RECORD LIKE customer.*
```

The array is usually defined with a flat list of members with ARRAY OF RECORD / END RECORD. However, the array can be structured with sub-records and still be used with a list dialog. This is especially useful when you need to define arrays from database tables, and additional information needs to be managed at runtime (for example to hold image resource for each row, to be displayed with the IMAGECOLUMN attribute):
Defining screen arrays in grid-based layout scrollgrids

When using a grid-based layout, the SCROLLGRID container is bound to a screen array defined in the INSTRUCTIONS section, by the name of the form fields used in the screen array definition.

The form data type and additional properties are defined in the ATTRIBUTES section as form fields:

```
LAYOUT
SCROLLGRID (WANTFIXEDPAGESIZE = NO)
{
  Id:   [f1 ]
  Name: [f2   ][f3   ]
}
END
END
END

ATTRIBUTES
EDIT f1 = customer.cust_num;
EDIT f2 = customer.cust_fname,
EDIT f3 = customer.cust_lname;
...
```

Each form field of the scrollgrid must be grouped in the INSTRUCTIONS section in a SCREEN RECORD definition.

```
INSTRUCTIONS
SCREEN RECORD custlist( cust_num, cust_fname, cust_lname );
END
```

Defining screen arrays in stack-based layout scrollgrids

Since scrollgrids define a grid-based list view, they do not have a stacked view in the sense of TABLE or TREE views.

Related concepts
Variable binding in DISPLAY ARRAY on page 1397
Variable binding in INPUT ARRAY on page 1429

Controlling scrollgrid rendering
Scrollgrid rendering can be controlled by the use of presentation styles and scrollgrid attributes.

Scrollgrid resize control
By default scrollgrids are not resizable and the number of fixed rows is defined by the layout element. The WANTFIXEDPAGESIZE form file attribute controls the vertical resizing of the list elements. Set this attribute to NO, in order to get a resizable scrollgrid:

```
LAYOUT
SCROLLGRID ( WANTFIXEDPAGESIZE=NO )
{
  ...
```
Minimal number of scrollgrid lines

With a resizable scrollgrid, you can define the initial number of rows with the INITIALPAGESIZE form file attribute:

```plaintext
LAYOUT
SCROLLGRID ( WANTFIXEDPAGESIZE=NO, INITIALPAGESIZE=4 )
{
...
```

Note: This is mainly useful in modal windows, to define the initial window size.

Paged scrollgrids (tile list)

A scrollgrid can be rendered as a tile list to fit records horizontally and vertically in a page to respond to the container size when stretched or shrunk.

To enable a paged scrollgrid, in your .4st file, define the customWidget style attribute to the value pagedScrollGrid:

```xml
<Style name="ScrollGrid.paged">
  <StyleAttribute name="customWidget" value="pagedScrollGrid" />
</Style>
```

In the scrollgrid layout definition, use the style name as defined in your styles file:

```plaintext
LAYOUT
SCROLLGRID ( WANTFIXEDPAGESIZE=NO, STYLE="paged" )
{
...
```

See also ScrollGrid style attributes on page 1099

Current row / current cell rendering

In a SCROLLGRID container, the highlighting of the current row (or current cell, when focus granularity is at the cell level) can be controlled with style attributes.

For more details, see Row and cell highlighting in SCROLLGRID on page 1101.

Current row visibility after dialog execution

When the dialog controlling the scrollgrid has finished, the current row may be deselected, depending on the KEEP CURRENT ROW dialog attribute.

Related concepts

Built-in scrollgrid features

Several implicit list handling features are provided by scrollgrid views. Some list features are not supported in scrollgrid.

- Unsupported features on page 1787
- Supported features on page 1788

Unsupported features

Some table / list view features are not supported on scrollgrid container.

The list view features not supported on scrollgrid include:

- Columns layout on page 1763
• List ordering on page 1764

Note: As there are no column headers/titles in scrollgrid list views, column attributes, such as UNSIZABLECOLUMNS, and UNSORTABLECOLUMNS that implement column layout and the built-in list sort, are therefore not supported.

Supported features
The list view provides features that are supported on scrollgrid container.

When a DISPLAY ARRAY or INPUT ARRAY block is combined with a SCROLLGRID, the following list features are supported:

• Find function on page 1764
• Keyboard seek on page 1765
• Reduce filter on page 1766

Defining the action for a row choice
The row choice in a SCROLLGRID can be associated with a dedicated action.

If using a DISPLAY ARRAY dialog to control a scrollgrid, a double-click on a row (for a desktop client), or a tap on a row (for mobile clients) fires a default action.

Row choice action can be customized as described in Defining the action for a row choice on page 1738.

Using scrollgrid on mobile devices
Scrollgrid views render in a specific way on mobile devices, in order to take advantage of mobile device ergonomics.

Unsupported scrollgrid features
Some scrollgrid view features are not supported on mobile devices.

The list view features not supported on mobile devices include:

• Find function on page 1764
• Keyboard seek on page 1765

• The DOUBLECLICK (tap) action on page 1773

Related concepts
Built-in scrollgrid features on page 1787
Several implicit list handling features are provided by scrollgrid views. Some list features are not supported in scrollgrid.

Examples
SCROLLGRID (scrollgrid views) usage examples.

Example 1: Simple scrollgrid view
The form file scrollgrid.per

```plaintext
LAYOUT SCROLLGRID (WANTFIXEDPAGESIZE=NO, INITIALPAGESIZE=4, STYLE="paged")
{
  [f1     ] Id: [f2   ] Name:[f3           ]
  [       ] Details:
  [       ] [f4                            ]
```
The presentation style file contains:

```
<Style name="Scrollgrid.paged" >
  <StyleAttribute name="customWidget" value="pagedScrollGrid" />
</Style>
```

The program `main.4gl`:

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF RECORD
    key INTEGER,
    name STRING,
    image STRING,
    detail STRING
  END RECORD,
  i INTEGER
  FOR i=1 TO 60
    LET arr[i].key = i
    LET arr[i].name = SFMT("Item %1", i)
    IF i MOD 2 THEN
      LET arr[i].image = "file"
    ELSE
      LET arr[i].image = "smiley"
    END IF
    LET arr[i].detail = SFMT("This is item %1", i)
  END FOR
  OPEN FORM f1 FROM "scrollgrid"
  DISPLAY FORM f1
  DISPLAY ARRAY arr TO list1.* ATTRIBUTES(UNBUFFERED,DOUBLECLICK=myselect)
  ON ACTION myselect
    MESSAGE "myselect:", arr_curr()
  END DISPLAY
END MAIN
```

Understanding tree-views

This is an introduction to treeview programming.

Tree-views can be implemented with a DISPLAY ARRAY instruction using a form screen-array bound to a TREE container with tree-view specific attributes. TREE containers are very similar to TABLE containers, except that the first columns are used to display a tree of nodes on the right of the widget.

Important: This feature is not supported on mobile platforms.

The next screen-shot shows a typical file browser using a tree-view. This example implements a DIALOG instruction with two DISPLAY ARRAY sub-dialogs. The first DISPLAY ARRAY sub-dialog controls the tree-view while the second one controls the file list on the right side.

The data used to display tree-view nodes must be provided in a program array and controlled by a DISPLAY ARRAY. It is possible to control a tree view table with a singular DISPLAY ARRAY or with a DISPLAY ARRAY sub-dialog within a DIALOG instruction.

A tree view model is implemented with a flat program array (i.e. a list of rows), where each row defines parent/child node identifiers to describe the structure of the tree; so, the order of the rows matters:

<table>
<thead>
<tr>
<th>Tree structure</th>
<th>parent-id</th>
<th>child-id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Node 1</td>
<td>NULL</td>
<td>1</td>
</tr>
<tr>
<td>Node 1.1</td>

<td>1</td>
<td>1.3</td>
</tr>
<tr>
<td>Node 1.3.1</td>
<td>1.3</td>
<td>1.3.1</td>
</tr>
</tbody>
</table>
Depending on your need, you can fill the program array with all rows of the tree before dialog execution, or you can fill or reduce the list of nodes dynamically upon expand / collapse action events. In the second case, you must provide additional information for each row of the program array, to indicate whether the node has children. A dynamic build of the tree view allows you to implement programs displaying very large trees, for example in a bill of materials application, where thousands of elements can be assembled together.

Tree-views can display additional columns for each node, to show specific row data as in a regular table.

Figure 104: Tree-view with additional columns

**Related concepts**

List dialogs on page 1731
Describes how to program dialogs controlling list containers.

TREE container on page 1218
The TREE container defines the presentation of a list of ordered records in a tree-view widget.

Screen records / arrays on page 1147
Form fields can be grouped in a screen record or screen array definition.

Arrays on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

**Defining a TREE container**

Start a tree-view implementation by defining the TREE container in the form definition file.

Create a form specification file containing a TREE container bound to a screen array. The screen array identifies the presentation elements to be used by the runtime system to display the tree-view and the additional columns.

A TREE container must be present in the LAYOUT section of the form, defining the columns of the tree-view list. The TREE container must hold at least one column defining the node texts (or names). This column will be used on the front-end side to display the tree-view widget. Additional columns can be added in the TREE container to display node information. The TREE container attributes must be declared in the ATTRIBUTES section of the form.

Secondary form fields have to be used to hold tree node information such as icon image, parent node id, current node id, expanded flag and parent flag. While these secondary fields can be defined as regular form fields and displayed in the tree-view list, we recommend that you use PHANTOM fields instead. Phantom fields can be listed in the screen-
array but do not need to be part of the LAYOUT section. Phantom fields will only be used by the runtime system to build the tree of nodes.

Example of tree-view definition using a TREE container:

```
LAYOUT
TREE mytree ( PARENTIDCOLUMN=parentid, IDCOLUMN=id,
              EXPANDEDCOLUMN=expanded, ISNODECOLUMN=isnode )
{
  Tree
  [name                      |desc     ]
  [name                      |desc     ]
  [name                      |desc     ]
  [name                      |desc     ]
  [name                      |desc     ]
} END
END
ATTRIBUTES
EDIT name = FORMONLY.name, IMAGECOLUMN=image;
PHANTOM FORMONLY.image;
PHANTOM FORMONLY.parentid;
PHANTOM FORMONLY.id;
PHANTOM FORMONLY.expanded;
PHANTOM FORMONLY.isnode;
EDIT desc = FORMONLY.description;
END
INSTRUCTIONS
SCREEN RECORD sr( FORMONLY.* );
END
```

Example of tree-view definition using the Tree layout tag inside a GRID container, with a TREE form element to define attributes in the ATTRIBUTES section:

```
LAYOUT
GRID
{
  <Tree tv                             >
    Tree
    [name                      |desc     ]
    [name                      |desc     ]
    [name                      |desc     ]
    [name                      |desc     ]
    [name                      |desc     ]
  </>
} END
END
ATTRIBUTES
TREE tv: mytree,
  PARENTIDCOLUMN=parentid, IDCOLUMN=id,
  EXPANDEDCOLUMN=expanded, ISNODECOLUMN=isnode;
EDIT name = FORMONLY.name, IMAGECOLUMN=image;
PHANTOM FORMONLY.image;
PHANTOM FORMONLY.parentid;
PHANTOM FORMONLY.id;
PHANTOM FORMONLY.expanded;
PHANTOM FORMONLY.isnode;
EDIT desc = FORMONLY.description;
END
INSTRUCTIONS
SCREEN RECORD sr( FORMONLY.* );
```
The first visual column ("name" in example) must be the field defining the node names, and the widget must be an EDIT or LABEL.

Several attributes are used to configure a TREE form element:

- The PARENTIDCOLUMN and IDCOLUMN attributes are respectively used to identify the form field containing the identifiers of the parent and child nodes, defining the structure of the tree. You must specify form field column names, not item tag identifiers (used to reference a form item in the layout section). If these attributes are not specified, the parent node id and node id field names default respectively to "parentid" and "id".
- The EXPANDEDCOLUMN attribute can be used to define the form field holding the flag indicating that a node is expanded (i.e. opened).
- If the ISNODECOLUMN attribute is used, it defines the form field indicating that a node has children, even if the program array does not contain child nodes for that parent node. This attribute must be used to implement dynamic filling of tree-views.
- The IMAGEEXPANDED, IMAGECOLLAPSED and the IMAGELEAF attributes are optional attributes defining global images for expanded, collapsed and leaf nodes. You should use these attributes if you want to display the same icons for all nodes.
- The IMAGEEXPANDED and IMAGECOLLAPSED instruct the runtime system to set a specific icon when a node gets expanded or collapsed. The IMAGELEAF attribute defines the global icon for leaf nodes. This saves the programmer from writing code to display common node images.

Tree-view definition must be completed with form fields declaration. These must be defined in the ATTRIBUTES section. The fields not used for display are declared as PHANTOM fields. The tree-view form fields must be grouped in a screen-array declared in the INSTRUCTIONS section.

The form fields required to declare a tree-view table are the following.

### Table 364: Form fields required to declare a tree-view table

<table>
<thead>
<tr>
<th>Description</th>
<th>Field type</th>
<th>Tree attribute</th>
<th>Mandatory</th>
<th>Default name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text to be displayed for the node</td>
<td>EDIT</td>
<td>N/A</td>
<td>yes</td>
<td>N/A</td>
</tr>
<tr>
<td>Id of the node</td>
<td>PHANTOM</td>
<td>IDCOLUMN</td>
<td>yes</td>
<td>id</td>
</tr>
<tr>
<td>Id of the parent node</td>
<td>PHANTOM</td>
<td>PARENTIDCOLUMN</td>
<td>yes</td>
<td>parentid</td>
</tr>
<tr>
<td>Icon image for a node</td>
<td>PHANTOM</td>
<td>IMAGECOLUMN</td>

<td>EXPANDEDCOLUMN</td>
<td>no</td>
<td>no</td>
</tr>
<tr>
<td>Parent node indicator</td>
<td>PHANTOM</td>
<td>ISNODECOLUMN</td>
<td>no</td>
<td>no</td>
</tr>
</tbody>
</table>

The first three fields (node text, parent id and node id) are mandatory, and that the first visual (non-phantom) field listed in the screen array will be implicitly used to hold the text of tree-view nodes.

Additional fields (like the desc field in this example) can be defined to display details for each node in regular columns, that will appear on the right of the tree widget.

The order of the fields in the screen array of the tree-view does not matter, but it must of course match the order of the corresponding variables in the record-array of the program.

If you need to display node-specific images, define a phantom field to hold node images and attach it to the tree-view definition by using the IMAGECOLUMN attribute. Alternatively you can globally define images for all nodes with the IMAGEEXPANDED, IMAGECOLLAPSED and the IMAGELEAF attributes of the TREE form element.

**Related concepts**

PARENTIDCOLUMN attribute on page 1275
The **PARENTIDCOLUMN** attribute specifies the form field that contains the identifier of the parent node of a tree node.

**IDCOLUMN attribute** on page 1261

The **IDCOLUMN** attribute specifies the form field that contains the identifier of a tree node.

**ISNODECOLUMN attribute** on page 1267

The **ISNODECOLUMN** attribute specifies the form field that indicates whether a tree node has children.

**EXPANDEDCOLUMN attribute** on page 1256

The **EXPANDEDCOLUMN** attribute specifies the form field that indicates whether a tree node is expanded.

**IMAGECOLUMN attribute** on page 1262

The **IMAGECOLUMN** attribute defines the form field containing the image for the current field.

**Form fields** on page 1138

*Form fields* are form elements designed for data input and/or data display.

**Item tags** on page 1155

*Item tags* define the position and size in a grid-based container.

**Screen records / arrays** on page 1147

Form fields can be grouped in a *screen record or screen array* definition.

**Arrays** on page 386

Arrays (static or dynamic) allow to handle an ordered collection of elements.

**Defining the program array for tree-views**

The program array containing the tree-view nodes must use a specific record structure.

In the program code, define a dynamic array of records with the **DEFINE** instruction. The **DISPLAY ARRAY** dialog will use that program array as the model for the tree-view list. A tree of nodes will be automatically built based on the data found in the program array. The front-end can then render the tree of nodes in a tree-view widget.

The members of the program array must correspond to the elements of the screen-array bound to the **TREE** container, by number and data types.

The name of the array members does not matter; the purpose of each member is defined by the name of the corresponding screen-array members declared in the form file. Program array members and screen-array members are bound by position.

The next code example defines a program array with a member structure corresponding to the screen-array defined in the form example of the previous section.

```
DEFINE tree_arr DYNAMIC ARRAY OF RECORD
   name STRING, -- text to be displayed for the node
   pid STRING,  -- id of the parent node
   id STRING,   -- id of the current node
   image STRING, -- name of the image file for the node (can be null)
   expanded BOOLEAN, -- node expansion flag (TRUE/FALSE) (optional)
   isnode BOOLEAN, -- children indicator flag (TRUE/FALSE) (optional)
   description STRING -- user field describing the node
END RECORD
```

The **name**, **pid**, and **id** members are mandatory. These hold respectively the node text, parent and current node identifiers that define the **structure of the tree**.

The **image** member will hold the name of the little icon to be displayed for each node and leaf. You can omit this member, if you do not want to display images, or when then tree defines default images with the **IMAGEEXPANDED**, **IMAGE COLLAPSED** and the **IMAGELEAF** attributes.

The **expanded** member can be used to handle node expansion by program. You can query this member to check whether a node is expanded, or set the value to expand a specific node.
The `isnode` member can be used to indicate whether a given node has children, without filling the array with rows defining the child nodes. This information will be used by front-ends to decorate a node as a parent, even if no children are present. It is recommended that the program then fill the array with child nodes when an expand action is invoked, to implement dynamic tree-views.

The program array can hold more columns (like the `description` field), which can be displayed in regular table columns as part of a node's data.

Remember the order of the program array members must match the screen-array members in the form file, but this order can be different from the column order used in the layout, with the exception of the first column defining the text of nodes (i.e., `name` field in example).

**Related concepts**

**TREE container** on page 1218
The TREE container defines the presentation of a list of ordered records in a tree-view widget.

**Screen records / arrays** on page 1147
Form fields can be grouped in a *screen record* or *screen array* definition.

**Phantom fields** on page 1142
A PHANTOM field defines a screen-record field which is not rendered in the layout (it acts as a hidden field).

**Arrays** on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

**Filling the program array with rows**
This topic describes how to fill a program array for a tree-view.

Once the program array is defined based on the screen-array definition of the tree-view table, fill the array with the tree-view definition.

You can directly fill the program array before the dialog execution. Once the dialog has started, you must use the methods `DIALOG.insertNode()`, `DIALOG.appendNode()` and `DIALOG.deleteNode()`, if you want to modify the tree, otherwise information like *multi-range selection flags* and *cell attributes* will not be synchronized.

Fill the rows in the correct order defining the structure of the tree, to reflect the parent/child relationship of the tree nodes. If a row defines a tree-view node with a parent identifier that does not exist, or if the child row is inserted under the wrong parent row, the orphan row will become a new node at the root of the tree.

In order to fill the program array with database rows defining the tree structure, you will need to write a recursive function, keeping track of the current level of the nodes to be created for a given parent.

The next example shows how to fill the array with data coming from a database table having the following structure:

```sql
CREATE TABLE dbtree (  
id SERIAL NOT NULL,  
parentid INTEGER NOT NULL,  
name VARCHAR(20) NOT NULL  
)
```

The difficulty with fetching a tree from a database table is in the cursor management, which cannot be used recursively. A workaround for this problem is to fetch all the children of a given node at once, then call the function recursively for each of the fetched nodes:

```sql
TYPE tree_t RECORD  
id INTEGER,  
parentid INTEGER,  
name VARCHAR(20)  
END RECORD  

DEFINE tree_arr tree_t  

FUNCTION fetch_tree(pid)  
    DEFINE pid, i, j, n INTEGER  
```
DEFINE a DYNAMIC ARRAY OF tree_t
DEFINE t tree_t

DECLARE cu1 CURSOR FOR SELECT * FROM dbtree WHERE parentid = pid
LET n = 0
FOREACH cu1 INTO t.*
  LET n = n + 1
  LET a[n].* = t.*
END FOREACH

FOR i = 1 TO n
  LET j = tree_arr.getLength() + 1
  LET tree_arr[j].name = a[i].name
  LET tree_arr[j].id = a[i].id
  LET tree_arr[j].parentid = a[i].parentid
  CALL fetch_tree(a[i].id)
END FOR
END FUNCTION

Related concepts
ui.Dialog.insertNode on page 2389
Inserts a new node in the specified tree.

ui.Dialog.appendNode on page 2380
Appends a new node in the specified tree-view.

ui.Dialog.deleteNode on page 2383
Deletes a node from the specified tree-view.

Arrays on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

Controlling a tree-view with DISPLAY ARRAY
A DISPLAY ARRAY dialog needs to be used to control a tree-view.

After the program array has been filled, you must execute a DISPLAY ARRAY dialog.

The next code example implements a DISPLAY ARRAY binding the program array called tree_arr to the sr screen-array, attaching the dialog to the tree table defined in the form:

CALL fill_tree(tree_arr)
DISPLAY ARRAY tree_arr TO sr.* ATTRIBUTES(UNBUFFERED)
  BEFORE ROW
    DISPLAY "Current row is: ", DIALOG.getCurrentRow("sr")
END DISPLAY

It is not possible to use the DISPLAY ARRAY paged mode (ON FILL BUFFER) when the decoration is a tree view list. The dialog needs the complete set of open nodes with parent/child relation to handle the tree view display, with the paged mode only a given window of the dataset is known by the dialog. If you use a the paged mode in DISPLAY ARRAY with a tree view as decoration, the program will raise an error at runtime.

However, tree-views can be filled dynamically with ON EXPAND/ON COLLAPSE triggers.

Related concepts
Dynamic filling of very large trees on page 1797
How to optimize the implementation of large tree-views?

Modifying the tree during dialog execution
The tree-view content can be changed while executing the DISPLAY ARRAY dialog.

During the DISPLAY ARRAY execution, it is possible to modify the content of the tree model (that is the program array), by inserting, adding or removing nodes by program.
However, it is not recommended to directly modify the program array; you must use the dialog class methods 
DIALOG.insertNode(), DIALOG.appendNode() and DIALOG.deleteNode() to modify the tree model instead. By using these methods, the dialog can synchronize internal data, otherwise the tree display would be corrupted.

It is recommended to be in UNBUFFERED mode to get a front-end synchronization of the tree-view content.

**Related concepts**
- [ui.Dialog.insertNode](#) on page 2389
  Inserts a new node in the specified tree.
- [ui.Dialog.appendNode](#) on page 2380
  Appends a new node in the specified tree-view.
- [ui.Dialog.deleteNode](#) on page 2383
  Deletes a node from the specified tree-view.

**Using regular DISPLAY ARRAY control blocks**

Simple table DISPLAY ARRAY control blocks can be used with tree-views.

If needed, you can implement traditional DISPLAY ARRAY control blocks like BEFORE ROW or AFTER ROW:

```plaintext
DISPLAY ARRAY tree_arr TO sr.* ATTRIBUTES(UNBUFFERED)
  BEFORE ROW
    DISPLAY "BEFORE ROW - Current row is: ", DIALOG.getCurrentRow("sr")
  AFTER ROW
    DISPLAY "AFTER ROW - Current row is: ", DIALOG.getCurrentRow("sr")
END DISPLAY
```

**Related concepts**
- [DISPLAY ARRAY control blocks](#) on page 1401
- [DIALOG control blocks](#) on page 1504

**Dialog control blocks** are predefined dialog triggers where you can implement specific code to control the interactive instruction.

**The buffered and unbuffered modes** on page 1618

The buffered and unbuffered mode control the synchronization of program variables and form fields.

**Dynamic filling of very large trees**

How to optimize the implementation of large tree-views?

When a huge tree needs to be displayed, tree data filling can be optimized by creating the nodes on demand. There is no need to fill the complete program array with all possible nodes (down to the last leaf), when only the first levels/branches of the tree are displayed on the screen.

To implement a dynamically filled tree, first define an additional column in the TREE container, to indicate whether a given node has children. That field will be used to render a node with a [+] button, and let the end user click on the node to expand it, even if no child nodes are created yet.

In the DISPLAY ARRAY code, if a node is expanded (or collapsed), the dialog will invoke the ON_EXPAND or ON_COLLAPSE triggers, to let the program add (or remove) rows in the array, to adapt the tree data dynamically by following navigation events.

```plaintext
DEFINE row_index INTEGER
...
DISPLAY ARRAY tree_arr TO sr.* ATTRIBUTES(UNBUFFERED)
  ON_EXPAND (row_index)
    DISPLAY "EXPAND - Expanded row is: ", row_index
    -- Fill with children nodes for tree_arr[row_index]
  ON_COLLAPSE (row_index)
```
The program array can be filled directly before the dialog execution, but once the dialog has started, use dialog methods such as `ui.Dialog.insertNode()` to modify the tree, otherwise information like multi-range selection flags and cell attributes will not be synchronized. This is typically the case when implementing a dynamically-filled tree with `ON EXPAND/ON COLLAPSE` triggers.

**Related concepts**
- [ON EXPAND block](#)
- [ON COLLAPSE block](#)
- [ui.Dialog.insertNode](#)
- [ui.Dialog.appendNode](#)
- [ui.Dialog.deleteNode](#)
- [Example 2: Dynamic tree view (filled on demand)](#)

**Built-in sort and tree-views**
Build-in sort on tree-views might need to be disabled if needed.

By default, the built-in sort is enabled in a `TREE` container; when the end user clicks on column headers, the runtime system sorts the visual representation of the program array. Tree nodes are ordered by levels; the children nodes are ordered inside a given parent node.

This is a powerful built-in feature. However, in some cases, the tree structure must be static (i.e. the order of the nodes must not change) and you don’t want the end user to sort the rows. To prevent the built-in sort, use the `UNSORTABLECOLUMNS` attribute for the `TREE` container definition:

```plaintext
LAYOUT...
END
ATTRIBUTES TREE tv: mytree, UNSORTABLECOLUMNS, ...
...
```

**Related concepts**
- [UNSORTABLECOLUMNS attribute](#)
  - The `UNSORTABLECOLUMNS` attribute indicates that the columns of the table cannot be selected by the user for sorting.
- [List ordering](#)
  - List controllers implement a built-in sort. This feature can be disabled if not required.

**Multi-row selection and tree-views**
Multi-row selection can be used with a `DISPLAY ARRAY` controlling a `TREE` container.

Because of the tree-view ergonomic differences with simple tables, the selection of tree nodes follows some specific rules, compared to multiple-row selection in simple tables:

1. When selecting a range of nodes, only visible nodes will get the selection flag. For example, if you select all nodes with Ctrl-A, and if the root node is collapsed, only the root node will be selected. This applies also when selecting nodes by program with the `ui.Dialog.setSelectionRange()`.
2. Collapsing a node will de-select all child nodes.

**Related concepts**
- [ui.Dialog.setSelectionRange](#)
Sets the row selection flags for a range of rows.

**Multiple row selection** on page 1752
Multiple row selection allows the end user to select several rows within a list of records.

**Drag and drop in tree-views**
Drag and drop is supported with a **DISPLAY ARRAY** controlling a **TREE**.

Use the **ON DRAG** and **ON DROP** interactive blocks, to implement drag and drop within a **DISPLAY ARRAY** controlling a **TREE** container.

The nodes can be moved around in the same tree, can be dropped outside the tree or can be inserted in the tree from external sources.

**Related concepts**
**Drag & drop** on page 1819
Explains programming techniques for the drag & drop feature.

**Examples**
**TREE** (treeview) usage examples.

**Example 1: Static tree view (filled before dialog starts)**

Form file "form1.per":

```
LAYOUT

  - Example 3: Split view using an HBox on page 1817

Understanding split views

Split views refer to the ability to access two forms side by side on a mobile device. This feature is mainly provided for tablet devices, as most phones can only display one window/form at a time.

A split view is composed of a "left pane" and "right pane". In programs, the panes are implemented with window objects displaying forms, which are controlled by parallel dialogs.

Important: This feature is only for mobile platforms.
Split views (controlled by parallel dialogs) are typically used to browse the application data, while modal dialogs are used for data input in a single form. An application based on split views will start with parallel dialogs, and switch to a simple modal dialog when the user chooses to edit application data. Parallel dialog handling is suspended by the runtime system, when a modal dialog executes. For details about parallel dialogs compared to modal dialogs, see What are dialog controllers? on page 1608.

If the application displays several split views simultaneously, implement a navigator pane, to let the end user switch between the different split views.

**Creating split view windows**
The application specifies which window opens in which pane by using the **STYLE** attribute in the **OPEN WINDOW** instruction.

Specify either **LEFT** or **RIGHT** for the **TYPE** attribute, to define a left-hand side pane and a right-hand side pane of the split view respectively.

**Important:** Both left (**TYPE=LEFT**) and right (**TYPE=RIGHT**) split-view windows need to be created.
This example specifies that the window `w_left` (with the form `customer_list`) display in the left pane, and the window `w_right` (with the form `customer_detail`) display in the right pane:

```plaintext
OPEN WINDOW w_left WITH FORM "customer_list" ATTRIBUTES(TYPE=LEFT)
OPEN WINDOW w_right WITH FORM "customer_detail" ATTRIBUTES(TYPE=RIGHT)
```

The window content of both panels will be controlled by parallel dialogs.

**Important:**

Split-view windows must be the root window (after closing the default `SCREEN` window), or direct children of the `NAVIGATOR` window, if it is used. If regular windows are created before split views, these must be closed:

Case 1: Close regular windows created before the split-views:

```plaintext
CLOSE WINDOW screen
OPEN WINDOW w1 WITH FORM "form1"
...
CLOSE WINDOW w1
...
OPEN WINDOW w_left WITH FORM "customer_list" ATTRIBUTES(TYPE=LEFT)
OPEN WINDOW w_right WITH FORM "customer_detail" ATTRIBUTES(TYPE=RIGHT)
```

Case 2: Create split-views as direct `NAVIGATOR` children

```plaintext
CLOSE WINDOW screen
OPEN WINDOW w_main WITH 10 ROWS, 80 COLUMNNS ATTRIBUTES(TYPE=NAVIGATOR)
...
OPEN WINDOW w_left WITH FORM "customer_list" ATTRIBUTES(TYPE=LEFT)
OPEN WINDOW w_right WITH FORM "customer_detail" ATTRIBUTES(TYPE=RIGHT)
```

When using a navigator window, the names of the split view windows must match the action names created in the parallel dialog controlling the options of the navigator pane. For more details, see `Navigator pane` on page 1806.

**Parallel dialogs for split views**

In order to control the left-hand and right-hand split view content, you must implement two parallel dialogs, each dedicated to a pane.

Create each window and start the parallel dialog for that window. Repeat for each window. When all windows have been created and all dialogs started, run the event loop to activate them.

```plaintext
OPEN WINDOW w_left WITH FORM "customer_list"
    ATTRIBUTES(TYPE=LEFT)
START DIALOG d_list_view
OPEN WINDOW w_right WITH FORM "customer_detail"
    ATTRIBUTES(TYPE=RIGHT)
START DIALOG d_detail_view
WHILE fgl_eventLoop()
END WHILE
```

The parallel dialogs must be implemented with a declarative dialog block. See `Parallel dialogs (START DIALOG)` on page 1600 for more details.

For small iOS devices (not tablets), consider using the `ACCESSORYTYPE=DISCLOSUREINDICATOR` in the `DISPLAY ARRAY` dialog, for left-pane controllers.

**Related concepts**

`fgl_eventloop()` on page 2165
Waits for a user interaction event.

**Refreshing a parallel dialog**

To restart a parallel dialog, use `TERMINATE DIALOG + START DIALOG`.

Once the split view parallel dialogs are started, the typically programming pattern to refresh the detail view of the right pane is to restart the detail dialog by executing a `TERMINATE DIALOG` followed by a `START DIALOG`.

The next example shows the case of a list view master (d_list_view dialog) displayed on the left pane, which is bound to a detail view of the right pane (d_detail_view dialog). The detail information must be refreshed when moving to a new row (BEFORE ROW control block):

```dialog
DIALOG d_list_view()
    DISPLAY ARRAY arr TO sr.*
        ATTRIBUTES(ACCESSORYTYPE=DISCLOSUREINDICATOR)
        BEFORE ROW -- in BEFORE ROW, we restart the details view
            CURRENT WINDOW IS w_right
            TERMINATE DIALOG d_detail_view
            LET curr_pa = arr_curr()
            DISPLAY BY NAME arr[curr_pa],*
            DISPLAY SFMT("tapped row %1",arr_curr()) TO info
            START DIALOG d_detail_view
            CURRENT WINDOW IS w_left
        END DISPLAY
END DIALOG
```

**Related concepts**

- **Syntax of the START DIALOG instruction** on page 1603
  Starts the instance of a declarative dialog.

- **Syntax of the TERMINATE DIALOG instruction** on page 1604
  Terminates the instance of a declarative dialog.

**One or two panes**

The same application displays as a split view application with two panes on some devices, yet displays as a single pane on other devices. What controls this?

With split views, you open two windows, assigning one to the left pane and one to the right pane of the split view. Not all mobile devices, however, can display multiple panes on the same screen. While the application code is the same, the mobile client displays either one pane (typical for phones) or two panes (typical for tablets).

If the device only allows a single pane to display, the window in the left pane is the first window displayed.

The rules for single-pane or two-pane display differ depending on the mobile platform:

- **On Android™ devices**, the two-pane mode is activated if the width of the screen is more than 900 dp (density-independent pixels). The width of the screen depends on the orientation; you may notice that you have two panes when the tablet is held in landscape mode (width greater than height), yet only one pane when the tablet is held in portrait mode (height greater than width).

  **Note**: A density-independent pixel (dp) is an abstract unit that is based on the physical density of the screen. The unit is relative to a 160 dpi screen, so one dp is one pixel on a 160 dpi screen. The ratio of dp-to-pixel will change with the screen density, but not necessarily in direct proportion.

- **On iOS devices**:
  - With the iPad, the two-pane mode is activated, regardless of the orientation of the tablet.
  - With the iPhone or iTouch devices, only a single pane displays.
Switching between panes
How to switch between the left and right panes of a split view depends on the mobile platform and the ergonomic standards of that platform.

Switching between panes by program
After creating the split view windows and starting the parallel dialogs to control them, the application program can switch between the left and right panes of a split view by selecting the corresponding window with the CURRENT WINDOW IS instruction.

CURRENT WINDOW IS w_customers

Switching between panes on phone devices
On a mobile device (such as phones) that only displays one split view pane at the time, switching from the left pane to the right pane is handled automatically by the front-end.

Note: The ergonomics and rendering depend on the device's operating system.

When starting the application, the left-pane is displayed first. This pane typically uses a table view controlled by a DISPLAY ARRAY dialog.

On an iOS phone, consider using the ACCESSORYTYPE=DISCLOSUREINDICATOR in the DISPLAY ARRAY dialog of left-pane controllers.

If the end user taps on a row in the list of the left pane, the right pane is automatically shown. To avoid this implicit switch from the left to the right pane, define a DOUBLECLICK = action-name attribute in the DISPLAY ARRAY dialog, and bind this action to an ON ACTION handler which does not change the current window.

Once the right pane is displayed, the user can switch to the left pane:
• On an Android™ phone, press the physical back button.
• On an iOS phone, press the back arrow on the top left of the window.

Important: This automatic "back to left panel" option is only possible if the dialog on the right side does not have a close, cancel or accept action defined. If one of these actions are defined, it will be attached to the back button, and that action will be executed when pressed.

Navigator pane
A navigator pane enables access to several views in an application from a main panel.

For many mobile applications, you will want to provide a view that allows you to show different forms and views that are active at the same time, to expose different functional areas for your application. This can be achieved by providing a top-level navigator with several views, controlled by parallel dialogs.

In order to implement a top-level navigator, create a window with the TYPE=NAVIGATOR attribute and without a form (i.e. using the x ROWS y COLUMNS clause). This window will only be used to display a set of actions views, to let the user switch between views. A view can be implemented as a split view by using a left and right typed window.

Important: The navigator window must be the root window (after closing the default SCREEN window). If regular windows are created before the navigator window, these must be closed:

-- Case 1: Screen window is closed, navigator is the root window
CLOSE WINDOW screen
...
OPEN WINDOW w_main WITH 10 ROWS, 80 COLUMNNS ATTRIBUTES(TYPE=NAVIGATOR)

-- Case 2: Close regular windows created before the navigator window
OPEN WINDOW w1 WITH FORM "form1"
...
CLOSE WINDOW w1
On iOS devices, the navigator window displays in a typical iOS tab bar at the bottom of the screen:

To customize the iOS application, define the color of the iOS tab bar with the `iosTabBarTintColor` and `iosTabBarUnselectedColor` Window-class style attribute.

For example, define a STYLE attribute when creating the window in the program code:

```
OPEN WINDOW tabbar WITH 1 ROWS, 2 COLUMNS
ATTRIBUTES(TYPE=NAVIGATOR, STYLE=mytabbar)
```
Then, in your .f4st style definition file, define a global style for the Window elements, and a specific style to define the colors for the tab bar elements:

```
<StyleList>
  <Style name="Window">
    <StyleAttribute name="windowType" value="normal" />
    <StyleAttribute name="startMenuPosition" value="menu" />
    <StyleAttribute name="iosTintColor" value="blue" />
    <StyleAttribute name="iosNavigationBarTintColor" value="#00366B" />
    <StyleAttribute name="iosToolBarTintColor" value="#00366B" />
    <StyleAttribute name="iosTabBarTintColor" value="#00366B" />
  </Style>
  <Style name="Window.mytabbar">
    <StyleAttribute name="iosTintColor" value="#ffff00" />
    <StyleAttribute name="iosTabBarUnselectedColor" value="#ff0000" />
  </Style>
</StyleList>
```

• On Android™ devices, the navigator window displays in the top of the screen, in the view control of the action bar (2):

The navigator window will be controlled by a dedicated parallel dialog implementing a MENU instruction, with the action handlers to select the related window, when the corresponding action is fired.

**Important:** The name of the actions in the navigator menu must match the name of the corresponding window, which is typically, the left-typed window when using split views.
The next example implements:

- The w_main window, and its corresponding controller, the d_navigator parallel dialog.
- The w_customers window as a left-pane, with the d_customers parallel dialog.
- The w_orders window as a right-pane, with the d_orders parallel dialog.
- The navigator MENU dialog implements the w_customer and w_orders action handlers.

```plaintext
... OPEN WINDOW w_main WITH 10 ROWS, 80 COLUMNNS ATTRIBUTES(TYPE=NAVIGATOR) START DIALOG d_navigator 
OPEN WINDOW w_customers WITH FORM "customers" ATTRIBUTES(TYPE=LEFT) START DIALOG d_customers 
OPEN WINDOW w_orders WITH FORM "orders" ATTRIBUTES(TYPE=RIGHT) START DIALOG d_orders 
... DIALOG d_navigator() 
    MENU 
        ON ACTION w_customers ATTRIBUTES(TEXT="Customers", IMAGE="smiley") 
        CURRENT WINDOW IS w_customers 
        ON ACTION w_orders ATTRIBUTES(TEXT="Orders") 
        CURRENT WINDOW IS w_orders 
    END MENU 
END DIALOG 
```

The functionality is the same on either mobile platforms: providing the user with the ability to navigate between multiple views efficiently. The rendering depends on the platform:

- On an iOS device, navigator window renders as a tab bar, displaying at the bottom of the screen.
- On an Android™ device, navigator window renders as a spinner, which is a drop-down menu in the action bar.

**Rendering an HBox as a split view**

Achieve a split view display with HBOX container and style attribute.

**Note:** This feature is only available with GMA on Android™ devices and the GBC front-end.

By defining a TABLE and a GRID container in a parent HBOX container, it is possible to get a split view display by setting the splitViewRendering style attribute of the HBox class. When using this style attribute, the TABLE displays as a listview on the left of the screen, while the GRID displays as a form on the right.

First define a form with the HBOX container, TABLE and GRID. In the code example below, the HBOX container gets a STYLE attribute referencing a style named "splitview" in the .4st file:

```plaintext
LAYOUT 
HBOX {STYLE="splitview"} 
TABLE 
{ 
[c1 |c2 ] 
[c1 |c2 ] 
[c1 |c2 ] 
[c1 |c2 ] 
} 
END 
GRID 
{ 
First name: [f1 ] 
Last name: [f2 ] 
... 
} 
END 
END 
... 
```
The .4st file may look like the following:

```xml
<StyleList>
  <Style name="HBox.mystyle">
    <StyleAttribute name="splitViewRendering" value="yes" />
  </Style>
  ...
</StyleList>
```

The program must implement a dialog that handles both parts of the splitview. You typically implement a DISPLAY ARRAY to handle the TABLE, and refresh the right part of the screen contained in the GRID, with code in the BEFORE ROW control block:

```4gl
DISPLAY ARRAY arr TO sr.*
  BEFORE ROW
    DISPLAY arr[arrCurr()].first_name TO f_first_name
    DISPLAY arr[arrCurr()].last_name TO f_last_name
END DISPLAY
```

**Related concepts**

- **HBOX container** on page 1197
  Packs child layout elements horizontally.

**Related reference**

- **HBox style attributes** on page 1095
  HBox style presentation attributes apply to an HBox element.

**Examples**

Split views usage examples.

**Example 1: Single split view application**

This application uses a minimum amount of code to describe a typical implementation of parallel dialogs that result in a split view application, with a list in the left pane and the detail for the selected row in the right pane. It uses only one split view.

**main.4gl**

The code in the MAIN block creates the left pane/window and the right pane/window by specifying the TYPE attribute in OPEN WINDOW.

The left window will display a form comprised of a table view of all records (a1_list_view), the other window contains a form with the detail view of a single record from the array (a1_detail_view)

The START DIALOG statements, along with the WHILE fgl_eventLoop() loop, creates the parallel dialog on which a split view depends.

```4gl
DEFINE arr DYNAMIC ARRAY OF RECORD
  id INTEGER,
  name VARCHAR(15),
  date DATE,
  comment VARCHAR(30)
END RECORD
DEFINE curr_pa SMALLINT

MAIN
  CLOSE WINDOW SCREEN
  CALL populate_array()
  OPEN WINDOW w_left WITH FORM "list_view"
      ATTRIBUTES(TYPE=LEFT)
  START DIALOG d_list_view
```
OPEN WINDOW w_right WITH FORM "detail_view"
   ATTRIBUTES(TYPE=RIGHT)
START DIALOG d_detail_view

WHILE fgl_eventLoop()
END WHILE

END MAIN

DIALOG d_list_view()
   DISPLAY ARRAY arr TO sr.*
      ATTRIBUTES(ACCESSORYTYPE=DISCLOSUREINDICATOR)
      BEFORE ROW -- in BEFORE ROW, we restart the details view
      CURRENT WINDOW IS w_right
      TERMINATE DIALOG d_detail_view
      LET curr_pa = arr_curr()
      DISPLAY BY NAME arr[curr_pa].*
      DISPLAY S_FMT("tapped row %1",arr_curr()) TO info
      START DIALOG d_detail_view
      CURRENT WINDOW IS w_left
      END DISPLAY
END DIALOG

DIALOG d_detail_view()
   MENU
      ON ACTION an_action
         MESSAGE "The action an_action was selected!"
      ON ACTION details
         IF edit_details() THEN
            DISPLAY BY NAME arr[curr_pa].*
         END IF
      END IF
   END MENU
END DIALOG

FUNCTION edit_details()
   -- A modal dialog disables all parallel dialogs
   OPEN WINDOW w_details WITH FORM "details"
      ATTRIBUTES(TYPE=POPUP, STYLE="popup")
   LET int_flag=FALSE
   INPUT BY NAME
      arr[curr_pa].name,
      arr[curr_pa].comment
      WITHOUT DEFAULTS
   CLOSE WINDOW w_details
   RETURN (int_flag==FALSE)
END FUNCTION

FUNCTION populate_array()
   DEFINE i INT
   FOR i=1 TO 40
      LET arr[i].id=i
      LET arr[i].name="item "||i
      LET arr[i].date=TODAY
      LET arr[i].comment="item-detail "||i
   END FOR
END FUNCTION
**Left form definition file (list_view.per)**

This form definition file provides the table, or list, of records in the array. Even though four table columns are defined, only two display.

```plaintext
LAYOUT (TEXT="Items")
TABLE
{
    [c1 | c2 ]
}
END
END
ATTRIBUTES
PHANTOM FORMONLY.id;
EDIT c1=FORMONLY.name;
PHANTOM FORMONLY.date;
EDIT c2=FORMONLY.comment;
END
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.*);
END
```

**Right form definition file (detail_view.per)**

This form definition file displays the details for a single record in the array.

```plaintext
LAYOUT (TEXT="Details")
GRID
{
    Id [f01 ]
    Name [f02 ]
    Date [f03 ]
    Comment [f04 ]
    Info [f05 ]
    [b1_details ]
}
END
END
ATTRIBUTES
EDIT f01=FORMONLY.id;
EDIT f02=FORMONLY.name, SCROLL;
EDIT f03=FORMONLY.date;
EDIT f04=FORMONLY.comment, SCROLL;
EDIT f05=FORMONLY.info;
BUTTON b1_details:details,TEXT="Modify details";
END
```

**Detail form definition file (details.per)**

This is a simple form containing two fields that will be used in the program by the `edit_details()` function to modify item details.

```plaintext
LAYOUT (TEXT="Edit details")
GRID
{
    Name:  [f01 ]
    Comment:  [f02 ]
    [ ]
}
END
END
```
Example 2: Multiple split views with navigation bar

This example shows how to write an application that handles two split views, each having a left and right pane, with a top level navigation pane that allows the end user to easily switch between the two split views.

main.4gl

This module implements the window creation and the parallel dialogs to control their content.

The code in the MAIN block creates four windows:

- The main window is the navigation window/pane, defined by the TYPE=NAVIGATION attribute. Only the d_navigator() main dialog is started.
- Two other windows are created for the customer list and details, in the customers() function. This function is called when the main dialog starts. The function checks if the w_customers window exists and if needed, opens the splitview windows and starts the dialogs handling customer records. If windows already exists, it performs a CURRENT WINDOW IS w_customers, to select the customer pane.
- The second window showing orders and its corresponding dialog are created in the orders() function, using the same programming pattern as in the customers() function.
- When the user selects one of the main dialog actions, it calls either the customers(), the orders(), or the params() function, to show the corresponding pane.
- The configuration pane is handled in the params() function, with the corresponding d_params_menu dialog: When selected, the form is in read-only mode by default. The menu implements the "modify" action to edit the parameters. This action will create a modal dialog, that stops temporarily the parallel dialogs.

```plaintext
DEFINE c_arr DYNAMIC ARRAY OF RECORD
  id INTEGER,
  name VARCHAR(30),
  address VARCHAR(100)

    LET o_arr[2].deliv = MDY(2,13,2012)
END FUNCTION

customer_list.per

This is the form defining the customer list, it is used for the left-pane of the customers split view.

LAYOUT (TEXT="Customers")
customer_detail.per
This is the form defining fields to show customer details, it is used for the right-pane of the customers split view.

order_list.per
This is the form defining the order list, it is a single form (not a split view).
Example 3: Split view using an HBox

This app uses a minimum amount of code to show a split view implementation using an hbox container.

**Styles definition file (mystyles.4st)**

For this example, we start with the style file. The style file specifies the `splitViewRendering` attribute for the `HBox` container when the style is set to `mysplitview`.

```xml
<?xml version="1.0" encoding="ANSI_X3.4-1968"?>
<StyleList>
  <Style name="HBox.mysplitview">
    <StyleAttribute name="splitViewRendering" value="yes" />
  </Style>
</StyleList>
```

**Form definition file (splitview.per)**

The form definition file defines a `HBOX` container using the `mysplitview` style. It contains a `TABLE` followed by a `GRID`. The table will become the left pane of the split view app, and the grid will become the right pane of the split view app.

```xml
LAYOUT
  HBOX (STYLE="mysplitview")
    TABLE
      {
        [c1 | c2 ]
        [c1 | c2 ]
        [c1 | c2 ]
        [c1 | c2 ]
      }
    END
  GRID
    {
      <GROUP g1 >
        Name: [lb_name :lb_id ]
        E-mail: [lb_email ]
        Address: [lb_address ]
        City: [lb_city ]
      <
      <GROUP g2 >
        Phone: [lb_phone ]
        Mobile: [lb_mobile ]
      <
    }
  END
END
```

**Attributes**

```xml
{ 
  User [f01 ]
  Auto sync [f02 ]
}
END
```

```xml
EDIT f01=FORMONLY.user_name, SCROLL;
CHECKBOX f02=FORMONLY.auto_sync, NOT NULL,
   VALUECHECKED="Y", VALUEUNCHECKED="N";
END
```
Application (main.4gl)

The application starts by loading the mystyles.4st style file.

After populating the array with our sample data, the splitview.per form is loaded and displayed in the default SCREEN window.

Then, a DISPLAY ARRAY statement takes control, and fills the fields in the grid in the BEFORE ROW trigger, when a new row is selected by the user.

```4gl
DEFINE carr DYNAMIC ARRAY OF RECORD
   cont_id INTEGER,
   cont_name VARCHAR(40),
   cont_address VARCHAR(100),
   cont_city VARCHAR(50),
   cont_phone VARCHAR(20),
   cont_mobile VARCHAR(20),
   cont_email VARCHAR(30)
END RECORD

MAIN
   CALL ui.Interface.loadStyles("mystyles")
   CALL load_samples()
   OPEN FORM f FROM "splitview"
   DISPLAY FORM f
   DISPLAY ARRAY carr TO sr.* ATTRIBUTES(UNBUFFERED)
      BEFORE ROW
         DISPLAY BY NAME carr[arrCurr()].*
      END DISPLAY
   END DISPLAY
END MAIN

FUNCTION load_samples()
   DEFINE i INTEGER
   LET i=0
   LET carr[i:=i+1].cont_id = 982
   LET carr[i].cont_name = "Mike Stanford"
   LET carr[i].cont_address = "5 Marbel St."
   LET carr[i].cont_city = "Balmberg"
   LET carr[i].cont_phone = "8723847234"
```
Drag & drop

Explains programming techniques for the drag & drop feature.

- Examples on page 1823
  - Example 1: Two lists side-by-side with drag & drop on page 1823

Understanding drag & drop

This is an introduction to drag & drop programming.

Drag & drop is a well know feature of graphical applications, allowing the end user to use the mouse to drag an element of a window to another window in the same program or into an external application. The front-end platform/device must support this feature.

Important: This feature is not supported on mobile platforms.

Drag & drop can be implemented in regular tables and tree-views controlled by a singular DISPLAY ARRAY or a DISPLAY ARRAY sub-dialog within a DIALOG instruction. Drag & drop is not supported in other dialog contexts, such as a singular INPUT, INPUT ARRAY or CONSTRUCT.

With drag & drop, end users can:

- Move drag-able objects between lists and tree-views in the same Genero form or program.
- Move drag-able objects between lists and tree-views in different Genero forms and programs.
- Move drag-able objects between other desktop applications and tables/tree-views in Genero programs.

Drag & drop control is implemented in a DISPLAY ARRAY with specific interaction blocks, to handle the events related to the drag and drop operation. These specific blocks will be triggered when drag and drop events arrive from the front-end.

- ON DRAG_START
- ON DRAG_FINISHED
- ON DRAG_ENTER
- ON DRAG_OVER
- ON DROP
Each of these interaction blocks takes a `ui.DragDrop` object as a parameter. A reference variable to that object must be declared before the dialog. In the interaction block, the `ui.DragDrop` object can be used to configure the drag & drop action to take. For example, a "drag enter" event can be refused.

The `ON DRAG_START` and `ON DRAG_FINISHED` triggers apply to the source of the drag & drop operation; the dialog where the object was dragged. The other triggers provide notification to the drop target dialog, used to inform the program when the different drop events occur and to let the target accept or reject the drop action.

This example illustrates the use of a drag & drop interaction block with the `ui.DragDrop` control object:

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER(dnd)
  IF ok_to_drop THEN
    CALL dnd.setOperation("move")
  ELSE
    CALL dnd.setOperation(NULL)
  END IF
...
END DISPLAY
```

Related concepts

- The `DragDrop` class on page 2422
  The `ui.DragDrop` class is used to control the events related to drag & drop events.

**Syntax of drag & drop interaction blocks**

The `ON DRAG* / ON DROP` interaction blocks implement drag & drop operations.

```plaintext
ON DRAG_START ( dnd-object )
ON DRAG_FINISHED ( dnd-object )
ON DRAG_ENTER ( dnd-object )
ON DRAG_OVER ( dnd-object )
ON DROP ( dnd-object )
```

1. `dnd-object` is a variable referencing an object of the class `ui.DragDrop`.

Related concepts

- `ON DRAG_START` block on page 1415
- `ON DRAG_FINISHED` block on page 1416
- `ON DRAG_ENTER` block on page 1416
- `ON DRAG_OVER` block on page 1417
- `ON DROP` block on page 1419

**Default drag & drop operation**

DISPLAY ARRAY dialogs implement a default drag operation.

The `DISPLAY ARRAY` dialog provides a default drag operation, that copies all selected rows to the drag & drop buffer, as a tab-separated list of values.

The user code equivalent to the default drag & drop operation would look like this:

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_START(dnd)
  CALL dnd.setOperation("copy")
```

The ui.DragDrop class is used to control the events related to drag & drop events.

Control block execution order

What is the execution order of drag & drop related dialog control blocks?

The table below shows the order in which the runtime system executes the control blocks related to drag & drop events:

Table 365: Control block execution order for drag & drop events

<table>
<thead>
<tr>
<th>Context / User action</th>
<th>Control block execution order</th>
</tr>
</thead>
<tbody>
<tr>
<td>The user starts to drag an object from the source dialog.</td>
<td>1. <strong>ON DRAG_START</strong> (in source dialog)</td>
</tr>
<tr>
<td>The mouse cursor enters the drop target dialog.</td>
<td>1. <strong>ON DRAG_ENTER</strong> (in target dialog)</td>
</tr>
<tr>
<td>After entering the target dialog, the mouse cursor moves from row to row, or user chooses to change the drop operation (move or copy).</td>
<td>1. <strong>ON DRAG_OVER</strong> (in target dialog)</td>
</tr>
<tr>
<td>The user releases the mouse button over the target dialog.</td>
<td>1. <strong>ON DROP</strong> (in target dialog)</td>
</tr>
<tr>
<td></td>
<td>2. <strong>ON DRAG_FINISHED</strong> (in source dialog)</td>
</tr>
</tbody>
</table>

Handle drag & drop data with MIME types

How to handle MIME types with drag & drop?

If a drag & drop is intended to work only in the same application, data can be passed with variables in the context of the current program. For example, in a program using two tables where the user can drag & drop elements between the two lists, identify the selected rows and update the program arrays accordingly. When drag & drop is limited to the current application, avoid the drop outside the current application.

When a drag & drop operation comes from (or goes to) external applications, data can be of various types/formats: plain text, formatted text, documents, images, sounds, videos, and so on. In order to handle the drag & drop data, you must identify the type of data held in the drag & drop buffer. The type of data in the buffer is identified by the MIME type (Multiple Internet Mail Extensions). MIME types are a widely used internet standard specification, first introduced to identify the content of e-mail attachments.

Only text data can be passed with drag & drop; binary data is not supported. However, you can pass files by using the fgl_getfile() file transfer function, and identify the file with a URI (text-uri-list MIME type). For a working example, see the demos in FGLDIR/demo/DragAndDrop.

Note: When using URI MIME types (for file paths for example), the string returned from the getBuffer() method can contain URL-encoded characters such as %5E, which represents the ^ caret. Therefore, you must URL-decode strings returned from getBuffer() with util.Strings.urlDecode(). When setting the drag & drop buffer content, if required by the front-end platform, the string can be URL-encoded using util.Strings.urlEncode() for setBuffer(). However, URL-encoding file paths for setBuffer() is usually not required.

Example of MIME types:
• text/plain
• text/uri-list
• text/x-vcard

You can also define your own MIME type, as long as it does not conflict with existing standard MIME types. For example:

• text/my-remote-file
• text/my-customer-record

If you do not specify a MIME type when the drag starts, the type defaults to text/plain, and the dialog will by default copy the data from selected rows into the drag & drop buffer. To prevent drag & drop to external applications, you must pass an application-specific MIME type to the `ui.DragDrop.setMimeType()` method, to be sure that other applications do not recognize the MIME type and will deny the drop.

### Preparing the dragged object for external targets

If the program implements drag & drop of objects that can be dropped to external programs, you must specify the MIME type of the object and copy the data to the drag & drop buffer, so that the external application can identify the data format and receive it.

In the `ON DRAG_START` block, you must call the `ui.DragDrop.setMimeType()` method to define the MIME type of the object, and copy the text data into the buffer with the `ui.DragDrop.setBuffer()` method.

This example shows a `DISPLAY ARRAY` dialog preparing the drag & drop buffer to export VCard data from a dragged row:

```plaintext
DEFINE dnd ui.DragDrop
... DISPLAY ARRAY arr TO sr.* ...
... ON DRAG_START(dnd)
    -- Define the MIME type and copy text data to DnD buffer
    CALL dnd.setMimeType("text/x-vcard")
    CALL dnd.setBuffer(buildVCardData( arr[arr_curr()].cid ) )
    CALL dnd.setOperation("copy")
... END DISPLAY
```

### Receiving the dragged object from external sources

This describes how to handle the drop action when the target dialog receives an object dragged from an external source, by identifying the MIME type of the object.

In the `ON DRAG_ENTER` block, you must call the `ui.DragDrop.selectMimeType()` method to check that data is available in a format identified by the MIME type, passed as a parameter. If the type of data is available in the buffer, the method returns `TRUE`. Later, when the dragged object is dropped (`ON DROP`), you can get the previously selected MIME type with `ui.DragDrop.getSelectedMimeType()` before calling `ui.DragDrop.getBuffer()` to retrieve the actual data.

The next example shows the usage of those methods: In `ON DRAG_ENTER`, the program checks available MIME types, and denies the drop operation if the buffer does not hold any of the MIME types that can be treated by the program. In `ON DROP`, the program calls `getSelectedMimeType()` to check what MIME type was selected, retrieves the data with `getBuffer()`, then inserts a new row and puts the data in dedicated fields depending on the MIME type:

```plaintext
DEFINE dnd ui.DragDrop
... DISPLAY ARRAY arr TO sr.* ...
... ON DRAG_ENTER(dnd)
```
-- Set operation to NULL if unexpected MIME type found
CASE
    WHEN dnd.selectMimeType("text/plain")
    WHEN dnd.selectMimeType("text/uri-list")
    OTHERWISE
        CALL dnd.setOperation(NULL)
END CASE

ON DROP (dnd)
    -- Select MIME type and get data from buffer
    LET row = dnd.getLocationRow()
    CALL DIALOG.insertRow("sr", row)
    IF dnd.getSelectMimeType() == "text/plain" THEN
        LET arr[row].text_data = dnd.getBuffer()
    END IF
END

Understanding web components

External graphical components can be integrated into forms by using the WEBCOMPONENT form item type.

A WEBCOMPONENT form field is a form element that defines an area in the form layout to hold an external component, typically not available as a native widget on the front-end platform.

Important: The purpose of a web component form field is not to replace a web browser, PDF viewer, or to implement sub-forms in HTML. A WEBCOMPONENT field must behave as a single form field and integrate with the other standard Genero form fields and form elements.

This section describes how to implement your own web component form fields. Genero provides a set of ready-to-use web components that are available for all front-ends. For more details, see Built-in Web Components on page 1875.

Web component form fields are used to fulfill a specific display and/or input, with advanced and powerful features which can bring added value to your applications. For example, you can find chart and graph widgets, calendar widgets, drawing widgets, and more. Such specialized widgets are not part of the standard GUI toolkits used by Genero front-ends. They need to be integrated as external components with WEBCOMPONENT fields.

Note: Depending on the type of front-end, the web components can have limitations: When using native front-ends (GDC, GMA, GMI), the web components are implemented with a "webview" widget, which is not a fully-featured web browser.
The main web component limitations on native front-ends are:

- lack of plugin support,
- less accurate JavaScript engine,
- lack of advanced HTML+CSS features.

Some web components are free, and some are licensed, so it is recommended that you take the cost into account before integrating a new web component in your application.

Web components can be implemented with two different techniques:

1. **Using an URL specification**, by setting the URL as value of the `WEBCOMPONENT` field at runtime. This is the easiest way to implement a web component. The widget is controlled with URL values by the program, but requires some additional coding to handle URLs, instead of flat field values.

2. **Using an gICAPI object** (based on JavaScript), by defining the `COMPONENTTYPE` attribute in the form file. This kind of web component requires some JavaScript coding, to write a form field "plugin", which is usable in a normal dialog instruction, that behaves as all the other widgets in terms of value setting/getting.

The content and/or behavior of a web component can be controlled in the program code by using the field value. To detect events inside the web component, the program dialogs must implement an `ON CHANGE` control block, that will be fired immediately after a user action on the web component.

**Related concepts**

- [ON CHANGE block](#) on page 1384

**WEBCOMPONENT item type**

Defines a specialized form item that holds an external component.

**WEBCOMPONENT item basics**

The `WEBCOMPONENT` form item defines a form field that will hold an external component, implemented with a front-end plug-in mechanism.

This topic describes the `WEBCOMPONENT` item type in form definition files. For more details see the chapter dedicated to web component programming.

**Defining a WEBCOMPONENT**

The `COMPONENTTYPE` attribute identifies gICAPI external objects to be used for the field. The `PROPERTIES` attribute is typically used to define attributes that are specific to a given gICAPI-based web component. For example, a chart component might have properties to define x-axis and y-axis labels. For more details, see Using a gICAPI web component on page 1835.

If the `COMPONENTTYPE` attribute is not used, the web component will be a URL-based web component. For more details, see Using a URL-based web component on page 1832.

Front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see Common style attributes on page 1083.

**Where to use a WEBCOMPONENT**

A `WEBCOMPONENT` form item can be defined in two different ways:

1. With an item tag and a `WEBCOMPONENT item definition` on page 1238 in a grid-layout container (`GRID`, `SCROLLGRID` and `TABLE`).
2. As a `WEBCOMPONENT stack item` on page 1215 in a `STACK` container.

**Built-in Web Components**

Genero BDL provides a set of ready-to-use web components, that are deployed by default.

For more details, see Built-in Web Components on page 1875.
**Defining the widget size**

The size of a `WEBCOMPONENT` widget can be controlled in grid-based or stack-based layout, based on several attributes such as `SIZEPOLICY` and `STRETCH`.

For more details about image sizing, see Controlling the web component layout on page 1827.

**Related concepts**

- `SIZEPOLICY` attribute on page 1283
  - The `SIZEPOLICY` attribute is a sizing directive based on the content of a form item.

**Controlling the web component layout**

Web components are usually complex widgets displaying detailed information, such as charts, graphs, or calendars. Such widgets are generally resizable. Therefore, the `WEBCOMPONENT` form item must be large and stretchable.

**Note:** By default, a `WEBCOMPONENT` form item is stretchable (STRETCH=BOTH).

As web components are displayed in an individual web viewer, several layout concepts need to be considered:

- The layout attributes of the `WEBCOMPONENT` form item, such as `SIZEPOLICY`, `SCROLLBARS`, `STRETCH` and `HEIGHT`.
- The layout attributes of the HTML root and body element (viewport, height).
- The layout attributes of responsive elements such as SVG content.

**Related concepts**

- `SIZEPOLICY` attribute on page 1283
  - The `SIZEPOLICY` attribute is a sizing directive based on the content of a form item.

- `STRETCH` attribute on page 1286
  - The `STRETCH` attribute specifies how a widget must resize when the parent container is resized.

**Web component in a grid-based layout**

In a grid-bases layout, the item tag of the `WEBCOMPONENT` defines the default dimensions of the web component area:

```xml
LAYOUT
GRID
{
  <GROUP g1>
  [f1][f2]
  [f3]
  ...
  <>
  [f5]
  [ ]
  [ ]
  [ ]
}
END
```

In the **ATTRIBUTES** section, use the `SIZEPOLICY`, `SCROLLBARS` and `STRETCH` attributes, to define the sizing policy of a web component field:

```plaintext
WEBCOMPONENT f5 = FORMONLY.mymap,
  SIZEPOLICY = FIXED,
  STRETCH = BOTH;
```

By default, the `WEBCOMPONENT` widget gets the size of the form item (like SIZEPOLICY=FIXED). When SIZEPOLICY=INITIAL, the web component is scaled to the right size after the first webpage is loaded and stays at that size. When SIZEPOLICY=DYNAMIC, the web component is resized after each load of a new webpage so that no scrollbars should appear.
Related concepts

**WEBCOMPONENT item type** on page 1187
Defines a specialized form item that holds an external component.

**Web component in stack-based layout**

In a stack-based layout, a **WEBCOMPONENT** item is defined with other items in a logical presentation order, without any size information:

```plaintext
LAYOUT
STACK
  GROUP (TEXT="Chart example")
    COMBOBOX FORMONLY.chart_type, NOT NULL,
       INITIALIZER=chart_type_init;
    WEBCOMPONENT FORMONLY.chart,
       COMPONENTTYPE = "chartjs",
       STYLE="regular";
  END
END
```

By default, the **WEBCOMPONENT** widget size will adapt to the content of the web component: It will stretch vertically to the appropriate size, in order to show the complete web component content.

To limit the size of the **WEBCOMPONENT** widget, you can use the **HEIGHT** attribute in the form definition:

```plaintext
WEBCOMPONENT FORMONLY.chart,
   HEIGHT = 5, -- 5 lines
   ...
```

**Note:** If the **HEIGHT** attribute of the web component is defined in the form file, it fixes the widget height, which may result in vertical scrollbars inside the widget. This is like using **SIZEPOLICY=FIXED** for a web component in a grid-based layout.

If the **HEIGHT** attribute is not specified in the .per file, the front-end will take the **height** attribute of the HTML elements of the web component HTML file into account, for example when using a `<canvas />` element:

```html
<body>
  <canvas id="myChart" height="100px" />
</body>
```

**Related concepts**

**WEBCOMPONENT item type** on page 1187
Defines a specialized form item that holds an external component.

**Web component HTML layout**

**Stretchable WEBCOMPONENT form field**

In order to get a stretchable HTML content in your web component, start by defining the **WEBCOMPONENT** form field with the following attributes:

```plaintext
WEBCOMPONENT wc1=FORMONLY.wc1,
   COMPONENTTYPE="mywebcomp",
   SIZEPOLICY=FIXED,
   STRETCH=BOTH,
   SCROLLBARS=NONE;
```
**Viewport zooming on mobile devices**

In order to avoid automatic viewport zooming with mobile applications, consider adding a meta tag with `name='viewport'` in the HTML file of your gICAPI-based web components, with initial and maximal scale attributes set to 1:

```html
<meta name='viewport' content='initial-scale=1.0, maximum-scale=1.0' />
```

**Note:** Don't use such responsive meta tag, if your web component isn't specifically designed to be responsive.

**HTML body auto-resize**

In order to force the resizing of the HTML content to the parent container, use the following CSS style:

```html
<style>
html, body {
  height:100%;
  padding:0;
  margin:0;
  border:0;
}
...
</style>
```

**Controlling SVG layout**

When displaying SVG inside your web component, you need to define how the SVG adapts to the parent container. SVG root elements define their own viewport (width and height attributes), and local layout rules through viewBox and preserveAspectRatio attributes.

For general purpose, do not set the width and height attributes in your root SVG element, and use `preserveAspectRatio="xMidYMid meet"`.

In the CSS style of the HTML page, define CSS styles for a parent div and for the svg root element, depending on the needs (to get scrollbars for example):

```html
<style>
...

.svg_container_nsb {
  overflow: hidden;
}

.svg_container_hsb {
  overflow-x: scroll;
  overflow-y: hidden;
}

.svg_container_vsb {
  overflow-x: hidden;
  overflow-y: scroll;
}

.root_svg_max_h {
  max-height: 100%;
}
```
Control the layout of the svg root element by using the appropriate CSS styles (typically set when building your SVG by program):

SVG adapting to container, no scrollbars in div container (all SVG will be visible):

```html
tag</svg>...
</div>
</body>
```

SVG adapting to container, with vertical scrollbars in the div container (SVG height is much bigger than the width):

```html
tag</svg>...
</div>
</body>
```

SVG adapting to container, with horizontal scrollbars in the div container (SVG width is much bigger than the height):

```html
tag</svg>...
</div>
</body>
```

**Debugging a web component**

**Debugging a Web Component with the GBC front-end**

In order to debug a Web Component when displayed on the GBC front-end, start the debug mode of your browser (for example, in Chrome, hit the F12 key), and use the integrated HTML / JavaScript debugger to inspect the Web Component contents.

**Debugging a Web Component with the GDC front-end**

To enable web component debugging with GDC, define the TCP port where a Chrome browser can connect to, in order to use the QT WebEngine Developer Tools.
With GDC, the web component debug port can be defined with the `--webengine-remote-debugging` command line option, or by setting the `QTWEBENGINE_REMOTE_DEBUGGING` environment variable, before starting the GDC.

**Note:** The command line option takes precedence over the environment variable.

For both the `--webengine-remote-debugging` command line option and the `QTWEBENGINE_REMOTE_DEBUGGING` environment variable, the syntax is:

```
[address:]port
```

**Tip:** The same debugging features of the QT WebEngine Developer Tools are available when using the `--webengine-remote-debugging` command line option, or when using the `QTWEBENGINE_REMOTE_DEBUGGING` environment variable. See QT documentation for more details about debugging features when `QTWEBENGINE_REMOTE_DEBUGGING` is set.

Define a simple `port` number, or a network interface address and port with `address:port`. The `address:port` syntax can be used to control which network interface to export the interface on, to access the developer tools from a remote computer. If no `address` is specified, it defaults to `localhost`.

After starting the Genero program displaying on GDC, the QT WebEngine Developer Tools can be accessed by launching a Chrome browser at the following URL:

- `http://localhost:port` (when the GDC executes on the current host)
- `http://hostname_or_IP:port` (when the GDC executes on a remote machine)

For example, to restrict the access to the debugging tools to the local machine on port 9000, use the value "127.0.0.1:9000". To (theoretically) access from any computer in your network on port 9000, use "0.0.0.0:9000".

**Debugging a Web Component with the GMA front-end**

In order to debug a web component displayed on GMA, you need a Chrome web browser, and an USB cable to plug the device to your computer.

Steps to debug a web component on GMA:

1. Connect your device to your desktop with the USB cable.
2. Stop GMA on the device, if it is already running.
3. Enable debugging option in GMA parameters.
4. Start the application with a web component. This will start GMA with debug service enabled (please wait as the application could take longer to start)
5. Open Chrome on the desktop computer.
6. In the Chrome URL address bar, enter: `chrome://inspect/#devices`
7. On the device, accept the USB debugging.
8. Click on "inspect" link to open the HTML debug window.

**Debugging a Web Component with the GMI front-end**

In order to debug a web component displayed on GMI, you need to setup the Safari® Web Inspector. Check the Apple® development site for more details about enabling the Safari® Web Inspector: [http://developer.apple.com](http://developer.apple.com).

Steps to debug a web component on GMI:

1. On your Mac, open Safari® and make sure the "Develop" option is available. If this option is not available, go to Safari® preferences and enable the option.
2. On the device, go to Settings. In Safari® preferences, go to Advanced and enable the Web Inspector option.
3. Run the app on the device or simulator, or start the program in development mode to display on the GMI front-end.
4. On the Mac, find the connected device/simulator in the Develop menu of Safari® and browse the debuggable components.

**Using a URL-based web component**
This section describes how to add a *URL-based web component* to your application.

To implement an URL-based web component:

URL-based web components are hosted on a third party server and provide a specific service, such as a geographical location on a map. Your application will be dependent on this external service. Consider verifying its permanent availability.

1. Identify the URL of the hosted web component you want to use.
2. In the form file, define a `WEBCOMPONENT` field, without a `COMPONENTTYPE` attribute.
3. In the program, set the URL of the hosted web component in the form field value.
4. In the program, detect user interactions with an `ON CHANGE` control block, and control the URL-based web component with dedicated front calls.

Detailed information about these tasks are provided in the next topics.

**Defining a URL-based web component in forms**

**Adding a WEBCOMPONENT to the form file**

To define a URL-based web component field, add a form field with the `WEBCOMPONENT` item type, without the `COMPONENTTYPE` attribute:

```plaintext
WEBCOMPONENT f001 = FORMONLY.mymap;
```

A web component field is typically defined with the `FORMONLY` prefix, as the data for the field is rarely stored in a database column.

The field type (and its corresponding program variable) must be a character string type. Consider using the `STRING` type to avoid any size limitation for the URL specification.

**Sizing policy for web component fields**

Web components are usually complex widgets displaying detailed information, such as charts, graphs, or calendars, which are generally resizable. Use the appropriate form item attributes to get the expected layout and behavior. For more details, see **Controlling the web component layout** on page 1827.

**Example**

```plaintext
LAYOUT
GRID
{
[wc]
[
[ ]
[
[ ]
[
[ ]
]
]
}
END
END
ATTRIBUTES
WEBCOMPONENT wc = FORMONLY.mychart,
STRETCH = BOTH;
END
```

**Related concepts**

Example 1: URL-based web component using Google maps on page 1834
Specifying the URL source of a web component
The content of URL-based web components is defined by the form field value. It can only be set by program.

Setting the initial URL
When the current form defines a WEBCOMPONENT form item without the COMPONENTTYPE attribute, it is a URL-based web component. The program can set the URL dynamically in field value:

```plaintext
DISPLAY "wc-URL" TO wc-field
```
or with:

```plaintext
DEFINE wc_field STRING
LET wc_field = "wc-URL"
DISPLAY BY NAME wc_field
```
or by using the variable in an INPUT dialog with the UNBUFFERED option:

```plaintext
DEFINE rec RECORD
    name STRING,  
mymap STRING
END RECORD
...
LET rec.mymap = "http://www.openstreetmap.org"
INPUT BY NAME rec.* WITHOUT DEFAULTS
    ATTRIBUTES(UNBUFFERED)
...
```

Once the URL of the web component is defined, the initial URL content is shown by the front-end, and the end user can interact with it.

Changing the URL
During program execution, you can assigning another URL to the web component field value. The content will be updated to show the new URL.

This example implements a MENU dialog with actions that set different URLs to the web component field, changing the content based on the selected action:

```plaintext
MENU "test"
    ON ACTION map_1
        DISPLAY "http://www.openstreetmap.org" TO wc_field
    ON ACTION map_2
        DISPLAY "http://www.wikimapia.org" TO wc_field
    ON ACTION map_3
        DISPLAY "http://maps.google.com" TO wc_field
END MENU
```

Controlling the URL web component in programs
URL-based web components can be controlled with the field value and with front calls.

Detecting user interaction in a web component with ON CHANGE
The content of an URL-based web component is defined by the field value.

When the end user interacts with the content, and if the remote service points to a different URL, the field value changes.

The URL change can be detected by implementing an ON CHANGE control block for the web component field.
**Important:** Due to security rules in modern web browsers, URL-based web components may not trigger `ON CHANGE` block, if the web component URL contains a domain name different from the Genero application. Thus, any changes/navigation in cross domain location cannot be detected in the program. Only HTML pages in the same domain will trigger `ON CHANGE` blocks.

The `ON CHANGE` trigger will be fired immediately when the URL changes:

```plaintext
DEFINE rec RECORD
    num INTEGER,
    name STRING,
    map STRING
END RECORD
...
INPUT BY NAME rec.* WITHOUT DEFAULTS
    ATTRIBUTES(UNBUFFERED)
    ...
    ON CHANGE map
        CALL map_changed(rec.map)
    ...
```

### Controlling URL-based web components with front calls

The web component can be manipulated with specific front calls. The web component-specific front calls are provided in the "webcomponent" front call module.

The `webcomponent.call` is a front call that can be used for general purposes. It takes as parameters the name of the form field, a JavaScript function to call, and optional parameters as required. The JavaScript function must be implemented in the HTML content pointed to by the URL of the web component field. The front call returns the result of the JavaScript function.

```plaintext
DEFINE title STRING
CALL ui.Interface.frontCall("webcomponent", "call",
    ["formonly.url_field", "eval", "document.title"],
    [title] )
```

**Note:** When passing a RECORD or DYNAMIC ARRAY as front call parameter, it will be converted to a JSON string for the JavaScript function.

Some web component providers return key information in the title of the HTML document. The `webcomponent.getTitle` function is another useful `webcomponent` front call that can get the title of the HTML document of the web component:

```plaintext
DEFINE info STRING
CALL ui.Interface.frontCall("webcomponent", "getTitle",
    ["formonly.url_field"], [info] )
```

### Related concepts

  This section describes web component specific front calls.

### Examples

**URL-based Web Components usage examples.**

**Example 1: URL-based web component using Google maps**

This example shows how to implement a simple mobile application using a `WEBCOMPONENT` field interacting with Google maps

The form file: `webcomp.per`

LAYOUT
GRID
{[f1]
[f2]
[f3]
END
ATTRIBUTES
WEBCOMPONENT f1 = FORMONLY.mymap, STRETCH=BOTH;
BUTTONEDIT f2 = FORMONLY.location, ACTION=set_loc;
TEXTEDIT f3 = FORMONLY.value, STRETCH=X;
END

The program file: webcomp.4gl

MAIN
CONSTANT c_gmaps = "http://maps.google.com/
DEFINE rec RECORD
  mymap STRING,
  location STRING,
  value STRING
END RECORD
OPEN FORM f1 FROM "webcomp"
DISPLAY FORM f1
LET rec.location = "Paris"
LET rec.mymap = c_gmaps||"?q="||rec.location
INPUT BY NAME rec.* WITHOUT DEFAULTS
  ATTRIBUTES(UNBUFFERED)
  ON ACTION set_loc
    LET rec.mymap = c_gmaps||"?q="||rec.location
    LET rec.value = rec.mymap
  ON CHANGE mymap
    LET rec.value = rec.mymap
    MESSAGE "URL has changed! "||CURRENT HOUR TO FRACTION(3)
END INPUT
END MAIN

Defining a URL-based web component in forms on page 1832

Using a gICAPI web component
This section describes how to add a gICAPI-based web component to your application.

To implement a gICAPI-based web component:
1. Identify the web component you want to use and get the source code (HTML, JavaScript, CSS).
2. Implement the gICAPI interface script for the web component.
   
   See The gICAPI web component interface script on page 1836 for more details about the gICAPI interface script implementation.

3. Define the location where the front end can find the gICAPI interface files. This depends on the front end technology used by your application.
   
   See Deploying the gICAPI web component files on page 1850 for more details.
4. Define a **WEBCOMPONENT** field in the form file. Use the **COMPONENTTYPE** attribute to define the root HTML file name describing the gICAPI web component.

   See **Defining a gICAPI web component in forms** on page 1853 for more details.

5. Use the web component in the dialog of the program.

   See **Controlling the gICAPI web component in programs** on page 1854 for more details.

6. If image resources are required by your web component, you must provide them as part of the gICAPI web component assets, or provide them from the program with a specific API.

   See **Using image resources with the gICAPI web component** on page 1855 for more details.

**HTML document and JavaScript for the gICAPI object**

A gICAPI web component is identified by an HTML document containing the JavaScript interface (or a reference to the .js file).

The HTML document is defined by the **COMPONENTTYPE** attribute of the **WEBCOMPONENT** form field. The name specified in this attribute will be used to identify the HTML file:

```javascript
WEBCOMPONENT wc = FORMONLY.chart,
COMPONENTTYPE = "mychart"; -- Identifies "mychart.html"
```

The HTML document must reference (or contain) the JavaScript implementing the gICAPI interface:

```html
<!DOCTYPE html>
<html>
<head>
  <title>The title</title>
  <script language="JavaScript" type="text/javascript" src="wc_echo.js"></script>
</head>
<body>
  <div style="background-color:green;width:3000px;height:3000px;" > here
  </div>
</body>
</html>
```

**The gICAPI web component interface script**

The gICAPI web components are controlled on the front-end through a gICAPI interface object, defined in a JavaScript script.

**gICAPI interface basics**

The goal of the gICAPI interface is to manage communication between the program and the web component with a basic API, to handle the interaction events, the focus, and the value of the web component field.

The interface script is written in JavaScript and bound to the **WEBCOMPONENT** form field by using an HTML document as container.
The gICAPI web component API relies on a published global JavaScript object named `gICAPI`.

### gICAPI initialization function

The `onICHostReady()` global function must be implemented, to execute code after the HTML page has been loaded and the `gICAPI` interface has been initialized.

The `gICAPI` object is ready in the context of `onICHostReady()`.

**Important:** The `onICHostReady()` function is only called for the initial HTML page defined by the `WEBCOMPONENT` form item. If you implement JavaScript code that loads another HTML page with a set of `gICAPI` interface functions, these will be ignored. For example, using `window.location='./new-page.html'` will load another HTML page, making all current `gICAPI WEBCOMPONENT` interaction functions invalid.

### Table 366: Function to handle the gICAPI interface

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>onICHostReady( version String )</code></td>
<td>Called when the gICAPI web component interface is ready. The version passed in the parameter allows you to check that your component is compatible with the API, and initialization code can be execute in this function.</td>
</tr>
</tbody>
</table>

The programming interface of the `gICAPI` class is identified by a version number, to make sure that the user code corresponds to the current `gICAPI` implementation. Verify that the runtime version number matches the `gICAPI` version used during development, by checking the value passed as parameter to `onICHostReady()`:

```javascript
var onICHostReady = function(version) {
  if ( version != "1.0" ) {
    alert('Invalid API version');
  }
  ...
}
```

The rest of the `onICHostReady()` function body is used to do some initialization and to assign the `gICAPI.on*()` callback functions as described later in this topic.

### gICAPI field management functions

The `gICAPI` object supports a set of callback functions (like `onFlushData()`) and control functions (like `Action()`), to handle field value changes, properties changes and focus requests.

**Important:** The `gICAPI` object must be instantiated, before defining and assigning these methods. The `gICAPI` object is created and initialized by the web component framework before calling the `onICHostReady()` global
function. Therefore, on* callback methods are typically defined and assigned to the gICAPI object, inside the body of the onICHostReady() function.

```javascript
var onICHostReady = function(version) {
    if ( version != "1.0" ) {
        alert('Invalid API version');
    }
    current_color = "#000000";
    gICAPI.onProperty = function(properties) {
        ...
    }
    ...
}
```

**Note:** The execution order of the gICAPI.on* functions is undefined. For example, the onData() function may be fired before the onProperty() function when the form is initialized. Consider writing code that takes this behavior into account.

**Table 367: Object methods of gICAPI**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action( action String )</td>
<td>Triggers an action event, which will execute the corresponding ON ACTION code. For more details, see gICAPI.Action() on page 1839.</td>
</tr>
<tr>
<td>onData( data String )</td>
<td>Called when the program value of the form field is updated by the runtime system. For more details, see gICAPI.onData() on page 1840.</td>
</tr>
<tr>
<td>onFlushData()</td>
<td>Called when the gICAPI framework needs to send a value to the runtime system. For more details, see gICAPI.onFlushData() on page 1841.</td>
</tr>
<tr>
<td>onFocus( polarity Boolean )</td>
<td>Called when the runtime system / program changes the focus. For more details, see gICAPI.onFocus() on page 1842.</td>
</tr>
<tr>
<td>onProperty( properties String )</td>
<td>Called to get WEBCOMPONENT PROPERTIES attributes. For more details, see gICAPI.onProperty() on page 1843.</td>
</tr>
<tr>
<td>onStateChanged( params [])</td>
<td>Called when the field state changes (for example, when it gets active/inactive) For more details, see gICAPI.onStateChanged() on page 1847.</td>
</tr>
<tr>
<td>SetData( data String )</td>
<td>Registers data to be sent to the program, in order to set the form field value in the program. For more details, see gICAPI.SetData() on page 1848.</td>
</tr>
<tr>
<td>SetFocus()</td>
<td>Generates a focus request. For more details, see gICAPI.SetFocus() on page 1849.</td>
</tr>
</tbody>
</table>

**Related concepts**

- Web component front calls on page 2514
This section describes web component specific front calls.

**gICAPI.Action()**
The gICAPI.Action() function is used to perform an action in the current dialog.

**Purpose of gICAPI.Action()**
Use the gICAPI.Action("action-name") function in order to execute an action in the context of the current dialog.

This function takes the name of the action as parameter. The corresponding ON ACTION handler will be called.

**Note:** Make sure that the parameter passed to gICAPI.action() matches the action name in lowercase letters.

If the named action is not available (if it does not exist, or if it is disabled), the gICAPI.Action() function has no effect.

After calling gICAPI.Action("action-name"), the gICAPI framework will perform a gICAPI.onFlushData() callback (if defined), to let you provide the web component field value with gICAPI.setData().

However, if you do not use the gICAPI.onFlushData() callback, it is also possible to provide the value with gICAPI.setData(), just before calling with gICAPI.Action().

**Example 1: Using gICAPI.SetData() directly before gICAPI.Action()**
The following code executes the "color_selected" action, after setting the value of the WEBCOMPONENT field with gICAPI.SetData():

```javascript
var selectColor = function(c) {
  gICAPI.SetData(c);
  gICAPI.Action("color_selected");
}

// In the HTML code, an element defines the onclick handler as follows:
... onclick="selectColor('#FFFFCC')" ...
```

**Example 2: Using gICAPI.Action() and gICAPI.onFlushData()**
The following code executes the "color_selected" action, and sets the value of the WEBCOMPONENT field with gICAPI.SetData() in the gICAPI.onFlushData() callback:

```javascript
var color = null;

var selectColor = function(c) {
  color = c;
  gICAPI.Action("color_selected");
}

gICAPI.onFlushData = function() {
  gICAPI.SetData(color);
}

// In the HTML code, an element defines the onclick handler as follows:
... onclick="selectColor('#FFFFCC')" ...
```

**Action handler in program code**
In the program code, define an ON ACTION block in a dialog instruction, to execute code when the corresponding web component action is fired.
Note: WEBCOMPONENT actions are not known by the front-end. A default action view will be created for each ON ACTION handler. Consider using the DEFAULTVIEW=NO action attribute, in order to avoid default action views being displayed for your web component actions.

ON ACTION color_selected ATTRIBUTES( DEFAULTVIEW=NO )
  IF rec.webcomp == "#000000" THEN
    LET rec.webcomp = rec.pgcolor
    LET rec.info = NULL
    ERROR "Black color is denied!"
  ELSE
    LET rec.pgcolor = rec.webcomp
    LET rec.info = "Color selected:", rec.pgcolor
  END IF

Related concepts

gICAPI.SetData() on page 1848
The gICAPI.SetData() function registers WEBCOMPONENT field data to be sent to the program.

Purpose of gICAPI.onData()

The gICAPI.onData() function is called each time the WEBCOMPONENT field content modification comes from the program. This occurs for example when the current dialog sets the field value, or when a DISPLAY value TO wc_field instruction is performed.

The gICAPI.onData() function is also used to check that the runtime system has accepted the web component value change, after a call to the gICAPI.SetData() function, when the value needs to be transmitted from the WEBCOMPONENT field to the program.

Handling gICAPI.onData() values

When the gICAPI.onData() function is fired, assign the data value to the web component, or check that the runtime system has validated the value provided with gICAPI.SetData().

The data parameter is a string that contains the field value as provided by the program. It is up to your JavaScript code to interpret the program value to be rendered on the HTML page. For example, the value may just be GPS coordinates, that will be used to display a location on a map. The data is typically serialized as a JSON string.

Note: Use util.JSON classes to serialize / de-serialize structured data (RECORDs or ARRAYs)

If the WEBCOMPONENT field value can be NULL, the onData() function must check for null values as follows:

```javascript
  gICAPI.onData = function(value) {
    if (value == null || value.length == 0) {
      // Process null case.
      ...
    }
    ...
  }
```

Example

The following code example defines the onData() function to set the content on a textarea element:

```javascript
  var onICHostReady = function(version) {
    ...
    gICAPI.onData = function(content) {
      $('#textarea#value').val(content);
    }
  }
```
Related concepts
gICAPI.SetData() on page 1848
The gICAPI.SetData() function registers WEBCOMPONENT field data to be sent to the program.

gICAPI.onFlushData()
The gICAPI.onFlushData() function is executed when the front-end must send the field value to the program.

Purpose of gICAPI.onFlushData()
The gICAPI.onFlushData() function is called when the front-end must sync the WEBCOMPONENT field content with the program.

This occurs when the WEBCOMPONENT field loses the focus, or when calling gICAPI.Action().

Note: If the gICAPI.onFlushData() function is not implemented, the front-end will use the value set from the last gICAPI.SetData() call.

Sending values with gICAPI.onFlushData()
In the gICAPI.onFlushData() function, use gICAPI.SetData() to provide the value to be send to the runtime system.

The gICAPI.onFlushData() function is called when the gICAPI framework requires a field value synchronization, or after gICAPI.Action() is called, to let you provide the value.

After a gICAPI.onFlushData(), the value is sent to program for validation. The runtime system can accept or reject the field value change. In order to detect that the runtime has accepted the value, the gICAPI.onData() function will be called, with the same value as the value provided by gICAPI.SetData(). The web component then receives an indication that the VM has accepted the value change. Note that gICAPI.onData() is also fired when the web component value is changed by the program.

Details about the behavior of gICAPI.onFlushData()
Consider the following facts when implementing gICAPI.onFlushData():

1. If the WEBCOMPONENT field is focused, executing an action will trigger gICAPI.onFlushData()
2. If the WEBCOMPONENT field is focused, and the front-end gives the focus to another element, gICAPI.onFlushData() will be executed.
3. Perform a gICAPI.SetData() call in gICAPI.onFlushData() when needed (for example, if the value of the WEBCOMPONENT field has changed and needs to be sent to the program)
4. Do not use other gICAPI functions such as gICAPI.Action() or gICAPI.SetFocus() in the gICAPI.onFlushData() function.
5. The code inside gICAPI.onFlushData() must be non-blocking and should execute rapidly.

Example
The following code example defines the gICAPI.onFlushData() function to provide the content on a textarea element:

```javascript
var onICHostReady = function(version) {
    ...
    gICAPI.onFlushData = function() {
```
Related concepts
`gICAPI.SetData()` on page 1848

The `gICAPI.SetData()` function registers `WEBCOMPONENT` field data to be sent to the program.

`gICAPI.onFocus()`

The `gICAPI.onFocus()` function is used to detect if the `WEBCOMPONENT` field lost or acquired focus.

Purpose of `gICAPI.onFocus()`

The `gICAPI.onFocus()` function is called when the runtime system gives/grabs the focus to/from the `WEBCOMPONENT` field.

**Note:** The `gICAPI.onFocus()` function is mandatory to implement a `gICAPI` web component.

Focus gain or loss is defined by the `polarity` parameter passed to the `gICAPI.onFocus()` function:

- When the runtime system gives the focus to the `WEBCOMPONENT` field, the `polarity` parameter is `true`.
- When the runtime system grabs the focus from the `WEBCOMPONENT` field, the `polarity` parameter is `false`.

When `polarity` is `true` and HTML elements of the web component can get the focus, the `gICAPI.onFocus()` function must set the focus to the expected element inside the web component.

This function can also be used to handle an internal flag, to know if the web component has got the focus. If the web component has the focus, you can call the `gICAPI.SetData()` function to provide the current value of the `WEBCOMPONENT` field.

When is `gICAPI.onFocus()` called?

The `gICAPI.onFocus(polarity)` function is called with `polarity=true` in the following cases:

- If the current dialog selects the `WEBCOMPONENT` field, as a normal tabbing candidate,
- If the user code executes an explicit `NEXT FIELD` instruction (or equivalent dialog instruction) to the web component,
- If the web component JavaScript code asked to get the focus with `gICAPI.SetFocus()`, and the program has accepted to give the focus to the `WEBCOMPONENT` field.

The `gICAPI.onFocus(polarity)` function is called with `polarity=false` in the following cases:

- If the current dialog gives the focus to another field, as a normal tabbing candidate,
- If the user code executes an explicit `NEXT FIELD` instruction (or equivalent dialog instruction) to move to another field,

**Note:** The `gICAPI.onFocus()` function will not be called with `polarity=false`, if the web component JavaScript code asked the focus with `gICAPI.SetFocus()`, and the program refused to give the focus.

Example

The following code example defines the `gICAPI.onFocus()` function to set an internal flag and give the focus to the textarea:

```javascript
var has_focus;
var onICHostReady = function(version) {
...
```
User interface

```javascript
function gICAPI.onFocus(polarity) {
    has_focus = polarity;
    if (has_focus) {
        $('textarea#value').focus();
    }
    ...
}
```

Related concepts
- **gICAPI.SetFocus** on page 1849
  The `gICAPI.SetFocus()` function must be used to request the focus to the runtime system.
- **gICAPI.SetData** on page 1848
  The `gICAPI.SetData()` function registers WEBCOMPONENT field data to be sent to the program.
- **gICAPI.onProperty**
  The `gICAPI.onProperty()` function is executed when web component properties change.

**Purpose of gICAPI.onProperty**

If defined, the `gICAPI.onProperty()` function is called to get the list of properties of the `<PropertyDict>` AUI node. This node is created in the .42f form file under the form field node, when using the `PROPERTIES` attribute in a WEBCOMPONENT field.

**Note:** `gICAPI.onProperty()` may also be called when `<PropertyDict>` is changed at runtime, after the form was loaded.

This function gets a single string parameter, that holds all current properties defined for the gICAPI web component. The property list is provided as a JSON-formatted string.

**Note:** Each time the `gICAPI.onProperty()` function is called, all properties are provided in the JSON parameter.

For each `gICAPI.onProperty()` call, the complete list of existing properties is passed to the function. In order to detect changes, compare the current set of properties with the new set of properties passed to the `gICAPI.onProperty()` function.

**Converting properties JSON string to a JSON object**

The `gICAPI.onProperty()` function gets a JSON formatted string, that can be converted to a JSON object with `JSON.parse()`.

A typical `gICAPI.onProperty()` function starts as follows:

```javascript
gICAPI.onProperty = function(properties) {
    var properties_object = JSON.parse( properties );
    ...
}
```

**Handling typed property values**

In the `<PropertyDict>` nodes of the AUI tree, attribute type information is not provided. Consequently, if the underlying component expects for example properties with JSON booleans (true/false), your boolean properties need to be identified explicitly and converted to JSON booleans.

In the AUI tree, boolean values are set to '0' or '1'. In JSON, a boolean must be `true` or `false`. 
For example, if you define the following PROPERTIES attribute for the WEBCOMPONENT form field:

```plaintext
PROPERTIES = (
  -- numeric
  height = 500,
  -- string
  theme = "modern",
  -- boolean
  menubar = TRUE,
  statusbar = FALSE,
  -- array
  toolbar = ( "undo redo", "print preview" )
)
```

The resulting JSON string passed to the onProperties() function will look like this:

```json
{
  "height" : "500",
  "theme" : "modern",
  "menubar" : "1",
  "statusbar" : "0",
  "toolbar" : [ "undo redo", "print preview" ]
}
```

Therefore, the JSON string needs to be parsed and some fields must be converted, before it can be used as a JSON object.

In order to replace AUI tree boolean fields to JSON booleans, you can implement a generic function like the following:

```javascript
// Converts the JSON string from onProperty() into a JSON object.
// // The function needs the list of properties that can be booleans.
// // AUI booleans must be converted as follows:
// .per source : PROPERTY ( menubar = FALSE )
// .42f/AUI XML : <Property name="menubar" value="0"/>
// onProperty : 'menubar' : '0'
// JS/JSON : "menubar" : false
//
// var aui_to_json = function(properties, pl_booleans) {
//   var pso = JSON.parse(properties, function (key, value) {
//     if (value && typeof value === 'string') {
//       if ( pl_booleans.indexOf(key) > -1 ) {
//         // Make a real boolean from the string value
//         if (value === "1" || value === "true") {
//           return true;
//         } else if (value === "0" || value === "false") {
//           return false;
//         }
//       }
//     } else if (value === "false") {
//       return false;
//     }
//   })
//   return value;
// });
// return pso;
//
// The above function can then be used in onProperty(), to get a well formatted JSON object of properties.
```
Example 1: Implementing gICAPI.onProperty()

This code example defines a default set of properties, that will be merged with a set of properties passed to the gICAPI.onProperty() function.

Once the new set of properties is created, it is assigned to the underlying web component object referenced here as "component", by using the resetProperties() function. Here we assume that component.resetProperties() expects a valid Java Script object, with JSON arrays and JSON boolean values.

Note: The aui_to_json() function is described in the previous section.

```javascript
var properties = {
  options: [ "fastsearch", "textpattern", "colorpicker" ],
  resize: true,
  menubar: true,
  statusbar: false
};
var onICHostReady = function(version) {
  ...
  gICAPI.onProperty = function(ps) {
    var pso = aui_to_json( ps, ["menubar","toolbar","statusbar"] );
    jQuery.extend(properties, pso);
    component.resetProperties( pso );
  }
  ...
};
```

Example 2: Setting WEBCOMPONENT properties at runtime

This example shows BDL code that can be used to change the PropertyDict AUI node, in order to set the properties of a WEBCOMPONENT field at runtime:

```bddl
PRIVATE FUNCTION _get_property_node(fieldname, tc, property)
  DEFINE fieldname STRING,
     tc STRING, -- "P"=Property or "A"=PropertyArray
     property STRING
  DEFINE tagname STRING,
     w ui.Window,
     f ui.Form,
     n_ff, n_wc, n_pd, n_p om.DomNode,
     nl om.NodeList,
     is_new BOOLEAN
  CASE tc
    WHEN "P" LET tagname = "Property"
    WHEN "A" LET tagname = "PropertyArray"
    OTHERWISE
      DISPLAY "ERROR: Invalid node type: ", tc
    EXIT PROGRAM 1
  END CASE
  LET w = ui.Window.getCurrent() 
  LET f = w.getForm() 
  LET n_ff = f.findNode("FormField", fieldname) 
  LET n_wc = n_ff.getFirstChild() 
  LET n_pd = n_wc.getFirstChild() 
  IF n_pd IS NULL THEN
    LET n_pd = n_wc.createChild("PropertyDict")
```
PUBLIC FUNCTION setProperty(fieldname, property, value)
DEFINE fieldname STRING,
    property STRING,

    EXIT PROGRAM 1
END IF
IF NOT is_new THEN
    -- To rebuild child list, remove prop node, then re-create.
    LET p = n.getParent()
    CALL p.removeChild(n)
    LET n = p.createChild("PropertyArray")
    CALL n.setAttribute("name", property)
END IF
FOR i=1 TO value.getLength()
Related concepts

PROPERTIES attribute on page 1278
The PROPERTIES attribute is used to define a list of widget-specific characteristics.

**gICAPI.onStateChanged()**
The gICAPI.onStateChanged() function is executed when the state of the field changes.

**Purpose of gICAPI.onStateChanged()**
The gICAPI.onStateChanged() function is called when the state of the WEBCOMPONENT field changes. This occurs for example when the field is enabled or disabled when starting/stopping a dialog instruction, or when using the DIALOG.setFieldActive() method, or when the current dialog type changes (when a DISPLAY ARRAY executes a nested INPUT for example).

**Implementing gICAPI.onStateChanged()**
When the gICAPI.onStateChanged() function is fired, set up your WEBCOMPONENT field accordingly, following the state parameters passed to the function.

The gICAPI.onStateChanged() function gets a string representing a JSON structure with all parameters set (like the gICAPI.onProperty() function). Convert this string to a JSON object with JSON.parse(), then use the object properties as follows:

1. **params.active**: The active state of the field (0: field is disabled, 1: field is enabled)
2. **params.dialogType**: The current dialog type (Input, DisplayArray, InputArray, Construct)

**Example**
This code example defines the gICAPI.onStateChanged() function to set up a textarea element:

```javascript
var onICHostReady = function(version) {

  ...

  gICAPI.onStateChanged = function(ps) {
    var params = JSON.parse(ps);
    if (params.active) {
      $('textarea#value').disabled = false;
    } else {
      $('textarea#value').disabled = true;
    }
    ...
    if (params.dialogType == 'Input') {
      ...
    }
  }

  ...
};
```

Related concepts

gICAPI onFocus() on page 1842
The gICAPI.onFocus() function is used to detect if the WEBCOMPONENT field lost or acquired focus.

\[\text{gICAPI.SetData()}\]

The gICAPI.SetData() function registers WEBCOMPONENT field data to be sent to the program.

**Purpose of gICAPI.SetData()**

If the content of the WEBCOMPONENT field needs to be transmitted to the program, use the gICAPI.SetData() function to register the data to be sent to the runtime system.

**Important:** The WEBCOMPONENT field must be the current field (therefore the field must have the focus), otherwise gICAPI.SetData() will be ignored. Use the gICAPI.onFocus() callback function to detect if the WEBCOMPONENT field has the focus.

The data must be a string. It is typically serialized as a JSON string.

**Note:** Data is transmitted as plain text. Sending a large amount of data is not recommended.

**When to use gICAPI.SetData()?**

If the gICAPI.onFlushData() callback function is used, use the gICAPI.SetData() function in this callback function, to provide the WEBCOMPONENT field value. When the WEBCOMPONENT field loses the focus, or when the gICAPI.Action() function is called, the gICAPI framework will call the gICAPI.onFlushData() function implicitly.

The gICAPI.SetData() can also be called outside the context of gICAPI.onFlushData(), or when this callback is not implemented, typically before calling gICAPI.Action(). If no gICAPI.onFlushData() is implemented, the value provided by the last gICAPI.SetData() call will be used.

**Handling NULL values**

In order to send a NULL value, call the gICAPI.SetData() function with JavaScript null as parameter:

```javascript
if (value.length==0) {
    gICAPI.SetData(null);
} else {
    gICAPI.SetData(value);
}
```

**Example**

The following code example registers data to be sent to the runtime system when the gICAPI.onFlushData() callback function is invoked:

```javascript
var onICHostReady = function(version) {
    ...
    gICAPI.onFlushData = function(content) {
        gICAPI.SetData( $('textarea#value').val() );
    }
    ...
};
```

**Related concepts**

- **gICAPI.onData()** on page 1840
- The gICAPI.onData() function is executed when field data is sent by the program.
- **gICAPI.onFocus()** on page 1842
The \texttt{gICAPI.onFocus()} function is used to detect if the \texttt{WEBCOMPONENT} field lost or acquired focus.

\textbf{gICAPI.SetFocus()}

The \texttt{gICAPI.SetFocus()} function must be used to request the focus to the runtime system.

\textbf{Purpose of gICAPI.SetFocus()}

The tabbing order and focus management is controlled by the runtime system and the dialog code (\texttt{NEXT FIELD}). If your \texttt{WEBCOMPONENT} field receives an event that requests the focus, you must first perform a \texttt{gICAPI.SetFocus()} call to determine if the program can put the focus in the field.

\textbf{Focus acknowledgment}

The \texttt{gICAPI.SetFocus()} function is used in conjunction with the \texttt{gICAPI.onFocus()} callback function. If the program can give the focus to the field, \texttt{gICAPI.onFocus()} is called with \texttt{true} as parameter. The \texttt{gICAPI.onFocus()} is not called if one of the following conditions is true:

\begin{itemize}
  \item the current field cannot release the focus because it does not satisfy constraints (\texttt{VERIFY}, data type conversion, and so on),
  \item the dialog code logic prevents focus change (\texttt{AFTER FIELD ...}, \texttt{NEXT FIELD}, etc).
\end{itemize}

A good practice is to define an internal flag, to know if your \texttt{WEBCOMPONENT} field has gained the focus.

\textbf{Example}

The following code example uses the \texttt{gICAPI.SetFocus()} function to get the focus from the runtime system:

```javascript
var has_focus;

var onICHostReady = function(version) {
    has_focus = false;
    ...
    gICAPI.onFocus = function(polarity) {
        has_focus = polarity;
        if (has_focus) {
            $('textarea#value').focus();
        }
    }
    $('textarea#log').on("focus", function() {
        gICAPI.SetFocus();
    });
    ...
};
```

\textbf{Related concepts}

\texttt{gICAPI.onFocus()} on page 1842
The `gICAPI.onFocus()` function is used to detect if the `WEBCOMPONENT` field lost or acquired focus.

**Deploying the gICAPI web component files**
Deploy web component files to the front-end platform before using gICAPI web components.

**Standard Genero gICAPI Web Components**
The Genero BDL package provides a set of common, ready-to-use web components, that can be used in your application.

The Genero BDL Web Components are located in `FGLDIR/webcomponents` and are found by default with any type of front-end configuration.

As these files are part of the `FGLDIR` installation directory, no deployment is required.

**Deploying the HTML document and the JavaScript gICAPI interface**
The gICAPI web component files (main HTML file, additional JavaScript files and other potential assets) must be available on the platform where the front-end executes. Depending on your configuration, Genero supports several solutions to provide the gICAPI web component files from a single location. In a distributed configuration with many individual front-end nodes, consider centralizing the gICAPI files on a server, instead of copying the gICAPI web component files manually to each front-end device.

**Important:** If the main gICAPI HTML document references external JavaScript files, put these files in the same directory as the HTML file referencing them.

**Recommended web component directory layout**
When using the default settings in any configuration (i.e. no `FGLIMAGEPATH` defined, default GAS settings), put the gICAPI web component files under a `webcomponents` directory, along with the other program files, for example:

```
appdir
    appdir/main.42m
    appdir/form1.42f
    appdir/form2.42f
    appdir/webcomponents/3DChart
        appdir/webcomponents/3DChart/3DChart.html
        appdir/webcomponents/3DChart/3DChart.js
        appdir/webcomponents/3DChart/3DChart.css
        appdir/webcomponents/3DChart/icon_close.png
    ...
```

**Deployment methods for front-end types**
Web components assets are deployed with different solutions, depending on the front-end configuration type:

- **Deploying gICAPI assets in direct mode** on page 1851
- **Deploying gICAPI assets with GAS** on page 1851
- **Deploying gICAPI assets on mobile** on page 1852

**Note:** For backward compatibility, the GDC front-end supports also local gICAPI file lookup in the GDC installation directory. However, this solution is deprecated. Consider centralizing the gICAPI web component files on the application server, as described above in the dedicated topics.

**Defining the gICAPI files search path by program**
With older versions, it was possible to use the `setWebComponentPath` on page 2513 front call, to define by program the base URL to the web component files.
Important: This front call is deprecated and only provided for backward compatibility, consider using one of the other mechanisms described in this topic.

Related concepts
Using image resources with the gICAPI web component on page 1855
This section explains how to use image resources in a gICAPI web component.

Deploying gICAPI assets in direct mode
Using GDC, GMI or GMA front-ends in direct mode (not through GAS)

When using a front-end with a direct connection (not through the GAS), web component files can be automatically transferred to the front-end.

Note: Providing gICAPI web component files with the direct mode mechanism simplifies the development process for mobile applications, as you do not have to copy the files to the device.

In direct mode, gICAPI web component assets are typically located in the directory where the MAIN program module resides, under a webcomponents sub-directory. If web component files are located in a different base directory, add the search path to the FGLIMAGEPATH on page 241 environment variable. However, if your application is intended for different front-ends, consider using the recommended gICAPI web component directory layout, to avoid FGLIMAGEPATH for web component assets.

Genero BDL provides a set of standard web components in FGLDIR/webcomponents. These standard web component assets will be implicitly found.

The gICAPI web component files are searched in the following directories:

1. fgldir/webcomponents/component-type/component-type.html
2. appdir/webcomponents/component-type/component-type.html
3. fgldirpath-dir/webcomponents/component-type/component-type.html
4. fgldirpath-dir/component-type.html

Where:

• fgldir is the runtime installation directory on the application server.
• appdir is the directory where the application program resides.
• fgldirpath-dir is one of the base directories defined in FGLIMAGEPATH.
• component-type is the name defined by the COMPONENTTYPE attribute in the form definition file.

If assets such as .js, .css, .png files are referenced by a relative path name in the HTML content, the resources are also transferred via the direct-mode mechanism. If the assets use an absolute path with a concrete URL scheme (such as http://something), the HTML viewer will try to get the resource from the URL location.

For example, if you define the gICAPI web component field as follows:

```plaintext
WEBCOMPONENT wc = FORMOMLY.mychart,
COMPONENTTYPE = "3DChart";
```

If the FGLIMAGEPATH search path contains "/opt/myapp", and the gICAPI files are located under "/opt/myapp/webcomponents/3DChart", the gICAPI web component HTML document will be found on the server at:

• /opt/myapp/webcomponents/3DChart/3DChart.html

Note: For backward compatibility, the GDC front-end is able to find web components locally on the workstation where it executes. However, this solution is deprecated. Consider centralizing your gICAPI web components on the application server.

Deploying gICAPI assets with GAS
Using GDC, GBC front-ends through the GAS

When using the Genero Application Server, the gICAPI web component files must be deployed as part of the application program files.
**Note:** To simplify deployment of gICAPI web components with the GAS, consider using the fglgar utility. For more details, see Packaging web applications on page 2063.

The `.xcf` configuration file of your application can define the base path to search for HTML web component files. This base path is defined by the `WEB_COMPONENT_DIRECTORY` entry of the `EXECUTION` element:

```xml
<Application ...>
  <Execution> ...
    <WEB_COMPONENT_DIRECTORY>$(res.fgldir)/webcomponents;$(application.path)/webcomponents</WEB_COMPONENT_DIRECTORY>
  </Execution>
</Application>
```

While specific web component deployment directories can be defined in the `.xcf` file, consider using the recommended gICAPI web component directory layout.

Genero BDL provides a set of standard web components in `FGLDIR/webcomponents`, that can be found with the default `as.xcf` settings. If you want to use a standard Genero web component with the GAS, and you have defined a specific `WEB_COMPONENT_DIRECTORY` entry in your application `.xcf` configuration file, you must add `$(res.fgldir)/webcomponents` to the `WEB_COMPONENT_DIRECTORY` entry.

The HTML document must be located in a sub-directory below the base path, using the same name as defined by the `COMPONENTTYPE` attribute. As result, the complete path to the HTML document will be:

```
base-path/component-type/component-type.html
```

For example, if the form file defines the `COMPONENTTYPE` attribute as follows:

```xml
WEBCOMPONENT wc = FORMOMLY.mychart,
COMPONENTTYPE = "3DChart";
```

If `application.path` is `"/opt/var/gas/appdata/app/myapp"`, the HTML document will be found in:

- `/opt/var/gas/appdata/app/myapp/webcomponents/3DChart/3DChart.html`

**Note:** The above `.xcf` example shows the default value of the `WEB_COMPONENT_DIRECTORY` parameter that can be inherited by all application configuration nodes. If your gICAPI web component files are located under `appdir/webcomponents`, or if your programs use one of the standard Genero web components provided in `FGLDIR/webcomponents`, there is no need to set the `WEB_COMPONENT_DIRECTORY` element in the `.xcf` file.

### Deploying gICAPI assets on mobile

Using GMI and GMA front-ends, executing app on mobile device

When running the application on mobile (i.e. in embedded mode), the gICAPI web component files (along with other assets) must be deployed on the device: The files will be found locally on the device.

**Note:** In mobile development mode (i.e. in direct mode, when the application runs on a computer and forms display on the GMA or GMI on the mobile device), the gICAPI web component assets are transferred to the device with the direct-mode solution: Web component assets must be located on the computer when the program executes.

If your application is intended for different front-ends, consider using the recommended gICAPI web component directory layout.

Genero BDL provides a set of standard web components in `FGLDIR/webcomponents`. When executing on a mobile device, the standard web component assets will be implicitly found.

In embedded mode, mobile front-ends make a local search for gICAPI web component files in the following order:

1. `fgldir/webcomponents/component-type/component-type.html`
2. `appdir/webcomponents/component-type/component-type.html`
3. `appdir/component-type.html`

Where:

- `fgldir` is the runtime system directory inside the deployed app.
User interface

appdir is the application directory where program files are located.

component-type is the name defined by the COMPONENTTYPE attribute in the form definition file.

For example, if you define a custom gICAPI web component field as follows:

```java
WEBCOMPONENT wc = FORMONLY.mychart,
    COMPONENTTYPE = "3DChart";
```

The gICAPI web component HTML document will be found on the mobile device at:

- `appdir/webcomponents/3DChart/3DChart.html`
- `appdir/3DChart.html`

However, using the second location is not recommended (always use a webcomponents directory).

For more details about `appdir` on mobile devices, see Deploying mobile apps on Android devices on page 3315 and Deploying mobile apps on iOS devices on page 3330.

**Defining a gICAPI web component in forms**

When defining a gICAPI web component in a form specification file, you can also provide a sizing policy and define additional properties.

**Adding a WEBCOMPONENT to the form file**

To define an gICAPI web component field, add a form field with the WEBCOMPONENT item type and the COMPONENTTYPE attribute. The COMPONENTTYPE attribute is mandatory when defining a gICAPI web component; it defines the root HTML file name describing the gICAPI web component.

A web component field is typically defined with the FORMONLY prefix, as the data for the field is rarely stored in a database column.

**Sizing policy for web component fields**

Web components are usually complex widgets displaying detailed information, such as charts, graphs, or calendars, which are generally resizable. Use the appropriate form item attributes to get the expected layout and behavior. For more details, see Controlling the web component layout on page 1827.

**Defining gICAPI web component properties**

Since web component field definitions are generic, you must use the PROPERTIES attribute to set specific parameters for the component.

The PROPERTIES attribute can define a list of:

- simple properties (`name = value`),
- array properties (`name = ( value1, value2, ... )`)
- map/dictionary properties (`name=( name1=value1, name2=value2, ... )`)

where `name` is a simple identifier, and where `values` can be numeric or string literals.

Component properties defined in the PROPERTIES attribute are transmitted to the web component through the onProperty() method of the gICAPI object.

The name of a property defined in the PROPERTIES attribute is converted to lowercase by the form compiler. To avoid mistakes, a good programming pattern is to define properties in lowercase, in both the interface script and in the form definition file. Property names are not checked at compile time, so nonexistent or mistyped properties will be ignored at runtime.

**Example**

```java
WEBCOMPONENT wc = FORMONLY.mychart,
    COMPONENTTYPE = "3DChart";
```

The gICAPI web component HTML document will be found on the mobile device at:

- `appdir/webcomponents/3DChart/3DChart.html`
- `appdir/3DChart.html`

However, using the second location is not recommended (always use a webcomponents directory).

For more details about `appdir` on mobile devices, see Deploying mobile apps on Android devices on page 3315 and Deploying mobile apps on iOS devices on page 3330.
Related concepts

**WEBCOMPONENT item type** on page 1187
Defines a specialized form item that holds an external component.

**Controlling the gICAPI web component in programs**

**Controlling the gICAPI-based web components with ON ACTION**

Once a **WEBCOMPONENT** field is defined in the form file with the **COMPONENTTYPE** attribute pointing to an HTML content file, it can be used as a regular edit field in program dialogs. The data of the gICAPI web component is transmitted with the field value, and usually needs to be serialized and deserialized (typically in JSON), when the data is not a simple scalar value.

When the web component field value is changed in the program, the **onData()** method of the gICAPI object is fired, and you can parse the serialized string in your JavaScript.

In order to detect web component value changes in the program, you need to combine the **gICAPI.setData()** and **gICAPI.Action()** methods, to transmit the value and fire an action, that will be handled by an **ON ACTION** block.

**Note:** The **ON CHANGE** trigger is not executed automatically for gICAPI-based web components, just by using **gICAPI.SetData()**.

The next example serializes and de-serializes a dynamic array using the JSON format:

```plaintext
IMPORT util ...
DEFINE mywc STRING
DEFINE data_array DYNAMIC ARRAY OF RECORD ...
...
INPUT BY NAME mywc, ...
  ATTRIBUTES (WITHOUT DEFAULTS, UNBUFFERED)
  ...
  ON ACTION set_wc_values -- Bound to form button
    LET mywc = util.JSON.stringify( data_array )
  ...
  ON ACTION wc_data_changed -- Triggered by gICAPI.Action()
    CALL util.JSON.parse( mywc, data_array )
...
```

**Important:** All data will be transmitted through the abstract user interface protocol: Transmitting a lot of data will not be efficient and is likely to slow down your application.
Controlling the gICAPI-based web components with properties

Use the **PROPERTIES** attribute in the form specification, to define the configuration of the field. When a property of the web component is modified, the `onProperty()` method of the gICAPI object in the JavaScript will be invoked with the list of properties in JSON notation. Note that the complete property set will be passed, even if a single property is modified.

Controlling gICAPI-based web components with front calls

The web component can be manipulated with specific front calls. The web component-specific front calls are provided in the "webcomponent" front call module.

The `call` front call that can be used for general purposes. It takes as parameters the name of the form field, a JavaScript function to call, and optional parameters as required. The JavaScript function must be implemented in the HTML content of the gICAPI web component field. The front call returns the result of the JavaScript function.

```javascript
DEFINE title STRING
CALL ui.Interface.frontCall("webcomponent", "call", 
    ["formonly.mychart", "eval", "document.title"],
    [title] )
```

The `getTitle` function is another useful `webcomponent` front call that can get the title of the HTML document of the web component:

```javascript
DEFINE info STRING
CALL ui.Interface.frontCall("webcomponent", "getTitle", 
    ["formonly.url_field"], [info] )
```

Some providers return key information in the title of the HTML document.

- **call** on page 2514
- **getTitle** on page 2516

Using image resources with the gICAPI web component

This section explains how to use image resources in a gICAPI web component.

Image resources in gICAPI web components

In some cases, web components require image resources, which can be classified as follows:

1. Common (static) image resources, that are part of the gICAPI web component implementation. This category of image resource can be referenced with absolute URLs (retrieved automatically by the HTML viewer), or can be deployed as part of the gICAPI web component assets, when referenced with relative URLs.

2. Private (variable) image resources, that are displayed by the program at runtime. This category of image resource can be referenced with absolute URLs (retrieved automatically by the HTML viewer), or can be provided by using the `ui.Interface.filenameToURI()` / direct-mode mechanism (as described below).

Referencing image resources in HTML

Image resources are typically referenced in HTML within the `<img/>` element, by setting the `src` attribute to a relative or absolute URL:
The following example uses an absolute URL:

```html
<img src="http://www.4js.com/images/smiley.gif" alt="Smiley face" height= "42" width= "42" >
```

This example uses a relative URL:

```html
<img src="smiley.gif" alt="Smiley face" height= "42" width= "42" >
```

The gICAPI web component framework can automatically retrieve image resources. If the value is not an absolute or relative URL that can be resolved by the HTML viewer, the image resources are retrieved from the Genero application using the `ui.Interface.filenameToURI()`/direct-mode mechanism.

**Providing static images in gICAPI web component files**

To provide common static images as assets of your gICAPI web component, provide the image files along with the main HTML file, typically in a dedicated directory. For example, if you define the following directory structure:

```
3DChart/3DChart.html
3DChart/images/redraw.gif
3DChart/images/fetchdata.gif
```

The HTML content of the web component can reference common static images as follows:

```html
<img src="images/redraw.gif" alt="Smiley face" height= "42" width= "42" >
```

**Providing application images from Genero programs**

Some gICAPI web components display variable image resources provided at runtime. For example, a photo gallery web component displaying pictures. Such image resources are usually private to the application.

To use image resources that are not static images part of the gICAPI web component assets:

1. Reference absolute URLs directly in the HTML content (in "src" attributes of image elements) with http:, https: or file: themes, to be retrieved automatically by the HTML viewer, or:
2. Reference image resources in the HTML content with the URI returned from the `ui.Interface.filenameToURI()` method, to provide image files from the platform where the application executes (can be a server or mobile device):
   - When running the application on a server behind the GAS, the `filenameToURI()` method will convert the local file path to a URL that will make the image file available through the GAS.
   - When using a direct connection to the front-end (typical GDC desktop configuration with application running on a server), the file name will be returned as is and the images will then be transmitted through the direct-mode mechanism (using `FGLIMAGEPATH`), as described in **Providing the image resource** on page 1049.
   - When running apps on mobile devices, the `filenameToURI()` method will build the complete path to the local file, based on the list of directories defined in the `FGLIMAGEPATH` environment variable. The image resource is then directly read from the device file system.

Try Example 3: Application images on page 1863, to see this method in practice.

**Examples**

GICAPI Web Component usage examples.

*Example 1: Calling a JavaScript function*

This example shows how to call a JavaScript function with the `webcomponent.call` front call

The form file: `wc_echo.per`

```
LAYOUT
GRID
{
  [wc1                                    ]
  [                                       ]
  [                                       ]
  [ Info: [f1                             ]
    ]
END
END
END
ATTRIBUTES
WEBCOMPONENT wc1 = FORMONLY.mywebcomp,
    COMPONENTTYPE="wc_echo", STRETCH=BOTH;
EDIT f1 = FORMONLY.result;
END
```

The HTML file: `wc_echo.html`

```
<!DOCTYPE html>
<html>
<head>
  <title>The title</title>
  <script language="JavaScript" type="text/javascript" src="wc_echo.js"></script>
</head>
<body>
  <div style="background-color:green;width:3000px;height:3000px;" > here
</div>
</body>
</html>
```

The JavaScript file: `wc_echo.js`

```
var echoString = function(str) {
  return str;
}

var echoObject = function(ostr) {
  var o = JSON.parse(ostr);
  return JSON.stringify(o);
}

var onICHostReady = function(version) {
  if ( version != 1.0 ) {
    alert('Invalid API version');
  }
}
```
The program file: wc_echo.4gl

```plaintext
IMPORT util

MAIN
    DEFINE rec RECORD
        mywebcomp STRING,
        result STRING
    END RECORD

    OPEN FORM f FROM "wc_echo"
    DISPLAY FORM f

    INPUT BY NAME rec.* ATTRIBUTES(UNBUFFERED)
        ON ACTION get_title
            CALL ui.Interface.frontCall("webcomponent","getTitle",
                ["formonly.mywebcomp"],[rec.result])
        ON ACTION echo_string
            LET rec.result = wc_call("formonly.mywebcomp", "echoString",
                "Hello!")
        ON ACTION echo_object
            LET rec.result = wc_call("formonly.mywebcomp", "echoObject",
                '{"id":"235","name":"Doorman"}')
    END INPUT

END MAIN

FUNCTION wc_call(fn,fc,p1)
    DEFINE fn,fc,p1 STRING
    DEFINE res STRING
    TRY
        CALL ui.Interface.frontCall("webcomponent","call",[fn,fc,p1],[res])
    CATCH
        ERROR err_get(status)
        RETURN NULL
    END TRY
    RETURN res
END FUNCTION
```

Example 2: Simple text input

Introduction

This topic describes the different steps to implement a simple gICAPI-based web component.

In this example, we will implement a simple text editor based on a textarea HTML element.

The dialog code implements a couple of triggers to show how the WEBCOMPONENT field interacts with the program.

The HTML file is described in detail, and complete code example with program and form file is available at the end of this topic.

HTML code description

As any HTML source code, the file starts with the typical HTML tags:

```html
<!DOCTYPE html>
<html>
<head>
<meta http-equiv="content-type" content="text/html" charset="utf-8" />
<meta name='viewport' content='initial-scale=1.0, maximum-scale=1.0' />

Note: The "viewport" meta is provided to adjust the viewport size for mobile devices.
```
A bunch of CSS is added to

```html
<style>
html, body {
    height: 100%;
    padding: 0;
    margin: 0;
    border: 0;
    overflow: hidden;
}
textarea#value {
    font-weight: bold;
}
textarea {
    display: block;
    font-family: fixed;
    font-size: 10px;
    padding: 0;
    margin: 0;
    width: 99%;
}
</style>
```

The HTML head is then ended with the typical ending tag:

```html
</head>
```

The body of the HTML file defines a `<textarea>` element and references the external JavaScript files in `<script>` elements:

```html
<body>
<textarea id="value"></textarea>
<script type="text/javascript" src="js/jquery.min.js"></script>
<script type="text/javascript" src="js/wc_simple.js"></script>
</body>
```

Finally, we end the HTML page with the final tag:

```html
</html>
```

**The wc_simple.js file**

The JavaScript code implementing the gICAPI web component starts with some global variables. These variables will hold information that must be persistent during the web component life:

```javascript
var has_focus;
```

The global function `onICHostReady()` will be called by the front end, when the web component interface is ready. The version passed as parameter allows you to check that your component code is compatible with the current gICAPI framework, and to define and assign the `gICAPI.on*` callback methods (these will be defined in the body of the `onICHostReady()` function:

```javascript
var onICHostReady = function(version) {
    if ( version != "1.0" ) {
        alert('Invalid API version');
    }
}```
At this point, the gICAPI interface is ready and the gICAPI object can be used.

The gICAPI.onData() function must be implemented to detect web component value changes done in the program, and to acknowledge SetData() calls:

```javascript
const gICAPI = {}; // Initialize gICAPI object

// gICAPI.onData function
gICAPI.onData = function(content) {
  $('textarea#value').val(content);
}
```

The onFocus() function is used to detect that the web component has got or lost the focus. If the focus is gained, we need to explicitly set the focus to the expected web component element:

```javascript
// gICAPI.onFocus function
gICAPI.onFocus = function(polarity) {
  const has_focus = polarity;
  if (has_focus) {
    $('textarea#value').focus();
  }
}
```

**Note:** The only way to detect that the focus was gained by the web component field, is when onFocus(true) is called.

We bind a function to the window.resize() event in order to reset the size of the textarea element:

```javascript
// Window resize event function
var wc_resize = function() {
  const h = document.body.clientHeight;
  try {
    const log_height = $('textarea#log').height();
    $('textarea#value').height(h - log_height - 10);
  } catch (err) {
  }
}
```

When the textarea element gets the focus, we ask the focus to the runtime system:

```javascript
// Focus event function
$('textarea#value').on("focus", function() {
  gICAPI.SetFocus();
});
```

Implement the gICAPI.onFlushData() function, to provide textarea content, when the front-end needs to send the field value to the runtime system:

```javascript
// gICAPI.onFlushData function
gICAPI.onFlushData = function() {
  gICAPI.SetData( $('textarea#value').val() );
};
```

Setup the web component when the field state changes by implementing the gICAPI.onStateChanged() function:

```javascript
// gICAPI.onStateChanged function
gICAPI.onStateChanged = function(ps) {
  var params = JSON.parse(ps);
```
if ( params.active ) {
  $('textarea#value').attr('disabled', false);
} else {
  $('textarea#value').attr('disabled', true);
}

At the end of the onIHostReady() function, we perform an initial resize:

    wc_resize(); // Force adjustment when starting ...

**Complete source code**

File webcomp.per:

```
LAYOUT (TEXT="Simple web component")
GRID
{  
  Id: [id ]
  [wc ]
  [   ]
  [   ]
  [   ]
  [tx ]
  [   ]
  [   ]
  [   ]
}
END
END

ATTRIBUTES
EDIT id = FORMONLY.id;
WEBCOMPONENT wc = FORMONLY.wc,
  COMPONENTTYPE = "wc_simple",
  SCROLLBARS = NONE,
  STRETCH = BOTH;
TEXTEDIT tx = FORMONLY.info;
END
```

File webcomp.4gl:

```
MAIN
  DEFINE rec
  RECORD
    id INTEGER,
    wc STRING,
    info STRING
  END RECORD

  OPTIONS INPUT WRAP, FIELD ORDER FORM
  OPEN FORM f1 FROM "webcomp"
  DISPLAY FORM f1

  LET rec.id = 123
  LET rec.wc = "Hello, world!"

  INPUT BY NAME rec.* ATTRIBUTES(UNBUFFERED, WITHOUT DEFAULTS)
  BEFORE FIELD wc
```
LET rec.info = "BEFORE FIELD wc=
", rec.wc
ON CHANGE wc
   LET rec.info = "ON CHANGE wc =\n", rec.wc
AFTER FIELD wc
   LET rec.info = "AFTER FIELD wc =\n", rec.wc
ON ACTION show
   LET rec.info = "ON ACTION show wc=\n", rec.wc
ON ACTION disable
   CALL DIALOG.setFieldActive("wc", FALSE)
ON ACTION enable
   CALL DIALOG.setFieldActive("wc", TRUE)
ON IDLE 2
   LET rec.info = "ON IDLE wc=\n ", rec.wc
END INPUT
END MAIN

File wc_simple.html:

<!DOCTYPE html>
<html>
<head>
<meta http-equiv="content-type" content="text/html" charset="utf-8" />
<meta name='viewport' content='initial-scale=1.0, maximum-scale=1.0' />
<style>
html,body {
   height:100%;
   padding:0;
   margin:0;
   border:0;
   overflow:hidden;
}
textarea#value {
   font-weight: bold;
}
textarea {
   display: block;
   font-family: fixed;
   font-size: 10px;
   padding:0;
   margin:0;
   width: 99%;
}
</style>
</head>
<body>
<textarea id="value"></textarea>
<script type="text/javascript" src="js/jquery.min.js"></script>
<script type="text/javascript" src="js/wc_simple.js"></script>
</body>
</html>

File wc_simple.js:

var has_focus = false;

var wc_resize = function() {
   var h = document.body.clientHeight;

try {
    var log_height = $('#textarea#log').height();
    $('#textarea#value').height(h - log_height - 10);
} catch (err) {
}

var onICHostReady = function(version) {
    if (version !== "1.0") {
        alert('Invalid API version');
    }
    gICAPI.onData = function(content) {
        $('#textarea#value').val(content);
    }
    gICAPI.onFocus = function(polarity) {
        has_focus = polarity;
        if (has_focus) {
            $('#textarea#value').focus();
        }
    }
    $(window).resize(function() {
        wc_resize();
    });
    $('#textarea#value').on("focus", function() {
        gICAPI.SetFocus();
    });
    // $('#textarea#value').on("change keyup paste cut", function() {
    // gICAPI.SetData($(this).val());
    // });
    gICAPI.onFlushData = function() {
        gICAPI.SetFlushedData($('#textarea#value').val());
    }
    gICAPI.onStateChanged = function(params) {
        var params = JSON.parse(ps);
        if (params.active) {
            $('#textarea#value').disabled = false;
        } else {
            $('#textarea#value').disabled = true;
        }
    }
    wc_resize(); // Force adjustment when starting ...
}

Example 3: Application images

Introduction
This topic shows how to display application images in a gICAPI-based web component.
In this example, we will focus on the technique to display application images dynamically in gICAPI web component HTML content, by using the `ui.Interface.filenameToURI()` method.
This sample application can be used with any Genero front-end configuration (as a web application with the GAS, in direct (development) mode with GDC/GMA/GMI, or as a mobile app running on a device).
For gICAPI programming basics, see Example 2: Simple text input on page 1858.
The complete code example with program and form file is available at the end of this topic.

**HTML code description**
The HTML source file starts with the typical HTML tags:

```html
<!DOCTYPE html>
<html>
<head>
<meta http-equiv="content-type" content="text/html" charset="utf-8" />
<meta name='viewport' content='initial-scale=1.0, maximum-scale=1.0' />
</head>
<script language="JavaScript">
var onICHostReady = function(version) {
    if ( version != 1.0 )
        alert('Invalid API version');
}
var set_image = function(ressource) {
    var ie = document.getElementsByName("myimage")[0];
    ie.src = ressource;
}
</script>
</head>
<body height="100%" width="100%">
<h2>Testing application images in gICAPI Web Component</h2>
<img name="myimage" />
</body>
</html>
```

The JavaScript code defines the `onICHostReady()` function, and the `set_image()` function, to be called with the `webcomponent.call` front call. The `set_image()` function sets the `src` attribute in the image element:

```
var onICHostReady = function(version) {
    if ( version != 1.0 )
        alert('Invalid API version');
}
var set_image = function(ressource) {
    var ie = document.getElementsByName("myimage")[0];
    ie.src = ressource;
}
```

Close the HTML head element with the `</head>` ending tag:

```html
</head>
```

The body of the HTML page contains two elements:

- an h2 title,
- the image element, identified by a name:

```
<body height="100%" width="100%">
<h2>Testing application images in gICAPI Web Component</h2>
<img name="myimage" />
</body>
```

**Application directory structure**
In order to easily build and install on mobile devices, create the following directory structure:

```
top-dir
    -- fglprofile
    -- main.4gl
    -- main.42m
    -- myform.per
    -- myform.42f
    -- images
        -- image01.jpg
        -- image02.jpg
        -- image03.jpg
```
For more details about building mobile apps from the command line, see Deploying mobile apps on page 3315.

**Providing image files**

Copy some of your favorite images in the "images" directory.

The sample program will scan this directory to fill a combobox and let you choose the image to be displayed:

```java
FUNCTION init_image_list(cb)
DEFINE cb ui.ComboBox
DEFINE h INTEGER,
fn STRING
LET
h=os.Path.dirOpen(os.Path.join(base.Application.getProgramDir(),"images"))
WHILE h > 0
LET fn = os.Path.dirNext(h)
IF fn IS NULL THEN EXIT WHILE END IF
IF fn=="." OR fn==".." THEN CONTINUE WHILE END IF
CALL cb.addItem(fn, fn)
END WHILE
END FUNCTION
```

**Note:** When deployed on a mobile device, the images directory will be part of the application program files. Thus to access the directory you need to add the base.Application.getProgramDir on page 2270 path. For more details, see Directory structure for GMA apps on page 3315 and Directory structure for GMI apps on page 3330.

In the program code, the ON CHANGE image interaction block will perform a front call to set the image resource in the gICAPI web component:

```plaintext
ON CHANGE image
LET rec.uri = ui.Interface.filenameToURI(rec.image)
CALL ui.Interface.frontCall("webcomponent","call",
["formonly.wc","set_image",rec.uri],[])}
```

**FGLIMAGEPATH environment settings**

In order to find image resources when not executing behind a GAS, you need to define the FGLIMAGEPATH environment variable as follows:

```plaintext
$ FGLIMAGEPATH=$PWD/images:.
```

For deployed mobile applications, the FGLIMAGEPATH environment variable must be set in the default fglprofile file, by using the $FGLAPPDIR place holder:

```plaintext
mobile.environment.FGLIMAGEPATH = "$FGLAPPDIR/images:.
```

For more details about FGLIMAGEPATH settings, see Providing the image resource on page 1049.
Complete source code

File myform.per:

LAYOUT

         IF fn=="." OR fn==".." THEN CONTINUE WHILE END IF
         CALL cb.addItem(fn, fn)
      END WHILE
   END FUNCTION
Example 4: Color picker

Introduction

This topic describes the different steps to implement a color picker with a gICAPI-based web component.

In this example, we will implement a simple color picker, that will allow the user the select a color from a predefined set. Colors are drawn as square boxes using SVG graphics, user can change the current selected color with a separate COMBOBOX field, modify the title of the HTML body, and query for the color list with a webcomponent.call front call.

The HTML file is described in detail, and complete code example with program and form file is available at the end of this topic.

HTML code description

As any HTML source code, the file starts with the typical HTML tags:

```html
<!DOCTYPE html>
<html>
<head>
<meta http-equiv="content-type" content="text/html" charset="utf-8" />
<meta name='viewport' content='initial-scale=1.0, maximum-scale=1.0' />
</head>
<body>
<h2>Testing application images in gICAPI Web Component</h2>
<img name="myimage" />
</body>
</html>
```

Note: The "viewport" meta is provided to adjust the viewport size for mobile devices.

The JavaScript code needs to the enclosed in a `<script>` element:

```javascript
var current_color;
```
The global function `onICHostReady()` will be called by the front end, when the web component interface is ready. The version passed as parameter allows you to check that your component code is compatible with the current gICAPI framework, and to define and assign the `gICAPI.on*` callback methods (these will be defined in the body of the `onICHostReady()` function:

```javascript
var onICHostReady = function(version) {
    if ( version != "1.0" ) {
        alert('Invalid API version');
    }

    ... some initialization code ...

gICAPI.onProperty = function(properties) {
    ... see below for function body ...
}

gICAPI.onData = function(data) {
    ... see below for function body ...
}

gICAPI.onFocus = function(polarity) {
    ... see below for function body ...
}
}
```

At this point, the gICAPI interface is ready and the `gICAPI` object can be used.

The `gICAPI.onProperty()` method is called when a web component property changes (properties will be initialized at form creation, or changed during form usage). In this code example, when the property "title" is changed by the program, the element with id="title" is updated with the new title:

```javascript
gICAPI.onProperty = function(properties) {
    try{
        var ps = JSON.parse(properties);
        document.getElementById("title").innerHTML = ps.title;
    }
    catch (err){
        console.error("onProperty(): Invalid JSON string");
    }
}
```

**Note:** The ON ACTION change_title in the dialog code will change the title property after the form initialization, to show that the `gICAPI.onProperty()` function can also be invoked after the web component field creation.

The `showFocusRectangle()` function shows a border around the specified color item (SVG element), following the color identifier passed as parameter and the focus status (focus can be true, false or -1, to keep the current border color and just modify the position of the border):

```javascript
var showFocusRectangle = function(color, focus) {
    // See complete code example for details
}
```
The `changeColor()` function implements a color change, by registering a field value change with `gICAPI.SetData()`, and by triggering a specific action with `gICAPI.Action()`, to inform the program that a color was selected:

```javascript
var changeColor = function(color) {
    current_color = color;
    showFocusRectangle(current_color, true);
    gICAPI.SetData(current_color);
    gICAPI.Action("color_selected");
}
```

Next lines implement the `gICAPI.onFocus()` function, executed when the web component gets or loses the focus. The code distinguishes the case when the focus is gained (by a mouse click on a color item), selecting a new color with a call to `changeColor()`, and the case when the focus is set to the web component by the runtime system. A blue border will be added to the current color item, when the component gets the focus, and the border color is reset to gray when the focus is lost:

```javascript
gICAPI.onFocus = function(polarity) {
    if ( polarity == true ) {
        has_focus = true;
        if (wanted_color != undefined) {
            changeColor(wanted_color);
            wanted_color = undefined;
        } else {
            showFocusRectangle(current_color, true);
        }
    } else {
        has_focus = false;
        showFocusRectangle(current_color, false);
    }
}
```

The `gICAPI.onData()` function must be implemented to detect web component value changes done in the program, and to acknowledge `gICAPI.SetData()` calls. This will be triggered by assigning the `rec.webcomp` variable in the dialog code, typically in the `ON CHANGE color` block, when modifying the combobox value. The `showFocusRectangle()` function moves the focus border to the color item corresponding to the color identifier passed as parameter:

```javascript
gICAPI.onData = function(data) {
    current_color = data;
    showFocusRectangle(current_color, -1);
}
```

The `selectColor()` function will be called through the `onclick` event of the `<rect>` SVG elements representing colors. If the web component does not have the focus yet, the function will call `gICAPI.SetFocus()`, in order to ask the runtime system, if the focus can go to the web component field. If the runtime system accepts to set the focus to the web component field, the `gICAPI.onFocus()` method will be called with `true` as parameter, and will handle the requested color change (using `wanted_color`). If the focus cannot be set to the web component, the `onFocus()` method will not be called:

```javascript
var selectColor = function(color) {
    if (has_focus) {
        changeColor(color);
    } else {
        wanted_color = color;
        gICAPI.SetFocus();
        // Color item change is done in onFocus(), because
        // VM may refuse to set the focus to the wc field.
    }
}
```
**Note:** The only way to detect that the focus was gained by the web component field, is when `onFocus(true)` is called.

End the JavaScript element with the `<script>` ending tag:

```html
</script>
```

Close the HTML head element with the `<head>` ending tag:

```html
</head>
```

The rest of the HTML page defines the graphical elements for the color picker, with a `<h3>` title and an `<svg>` element containing `<rect>` element to show clickable color items. Note the `<rect>` element with `id="focus_rectangle"`, used to show a border for the current color item:

```html
<body height="100%" width="100%">
<h3 id="title">no-title</h3>
<svg id="svg_container" width="230" height="130">
  <rect x="5" y="5" rx="5" ry="5" width="30" height="30"
       id="#FFFFCC"
       style="fill:#FFFFCC;stroke:black;stroke-width:1"
       onclick="selectColor('#FFFFCC')" />
  ...
  <rect x="178" y="73" rx="7" ry="7" width="34" height="34"
       id="focus_rectangle"
       style="fill:none;stroke:gray;stroke-width:3" />
</svg>
</body>
```

Built-in Web Components
Genero provides a set of ready-to-use web components.

- Understanding built-in web components on page 1875
- Built-in web components reference on page 1875
  - The fglrichtext web component on page 1875
    - Examples on page 1881
  - The fglgallery web component on page 1882
    - Examples on page 1888
  - The fgsvgcanvas web component on page 1891
    - Examples on page 1899

Understanding built-in web components
This section describes the available built-in web components and how to use them.

The Genero web components are located in the FGLDIR/webcomponents directory. Additional utility libraries are provided in FGLDIR/src (.4gl sources) and FGLDIR/lib (compiled .42m modules).

Unlike user-defined web components, there is no need to deploy the built-in web components. The built-in web components are available for any type of front-end, including mobile platforms.

Note: Built-in web components are found automatically by the runtime system. There is no need to add the FGLDIR/webcomponents path to the FGLIMAGEPATH environment variable.

Related tasks
Using a giCAPI web component on page 1835
This section describes how to add a giCAPI-based web component to your application.

Built-in web components reference
List of all built-in web components
The fglrichtext web component
The fglrichtext built-in web component implements an HTML text editor.

The fglrichtext built-in web component uses the giCAPI web component framework.
Using images in rich text content

The fglrichtext web component allows insertion of image resources into the text. This can be done with the image option of the toolbar, by copy/paste, or drag&drop operations.

When inserting an image resource from the local platform (for example, with the image option of the toolbar), the complete image content will be inserted as a base64 encoded object in the text.

Note: Inserting huge base64 encoded image data can lead to performance issues.

When inserting an image resource from a copy/paste from a web resource (like an HTML page), only the URL of the image resource is inserted in the text. If this URL is no longer available, the image will disappear from the text.

Defining the fglrichtext web component in the form file

In your .per form definition file, define the HTML text editor as a WEBCOMPONENT form item with the COMPONENTTYPE attribute set to the "fglrichtext" value.

The fglrichtext web component provides its own built-in scrollbars. Therefore, the SCROLLBARS attribute can be set to NONE.

Use SIZEPOLICY=FIXED and STRETCH=BOTH, to get a text editor that is resized with the parent window.

For example:

```
LAYOUT
GRID
{
[rt                 ]
[
   ]
```

Figure 107: fglrichtext web component
Properties of the fglrichtext

The fglrichtext web component supports the following PROPERTIES:

1. toolbar: Defines the toolbar elements layout.
2. autoflush/autoflush_interval: Defines an action and timer for auto flushing the value.
3. spellcheck: Defines the spell checking in the fglrichtext.
4. noteditable: Defines if the fglrichtext is read-only.
5. Properties to define the default font:
   - font_family: Defines the default font family.
   - font_size: Defines the default font size.

   For details, see Specifying the default font on page 1880.
6. Properties to localize fglrichtext labels:
   - labels_toolbar_tooltips: Defines the texts to be displayed for toolbar tooltips.
   - labels_toolbar_link: Defines the labels to be displayed for the link popup dialog.
   - labels_toolbar_linespacing: Defines the texts for line spacing options.
   - labels_toolbar_formatselect: Defines the texts to be format options.

   For details, see Localizing rich text component strings on page 1880.

Configuring the toolbar

Define the controls to be used in the editor toolbar with the toolbar property in the PROPERTIES attribute.

Toolbar items must be separated with a pipe:

```
WEBCOMPONENT rt = FORMONLY.richtext,
...  
PROPERTIES = ( 
  toolbar = "bold|italic|underline|undo|redo|emoji"
), 
...  
```

The fglrichtext web component supports the following toolbar items:

**Table 368: fglrichtext toolbar options**

<table>
<thead>
<tr>
<th>Option name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aligncenter</td>
<td>Centers the current block or image.</td>
</tr>
<tr>
<td>alignjustify</td>
<td>Justifies the current block or image.</td>
</tr>
<tr>
<td>alignleft</td>
<td>Left aligns the current block or image.</td>
</tr>
<tr>
<td>Option name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>alignnone</td>
<td>Removes the alignment of the current block or image and left aligns it.</td>
</tr>
<tr>
<td>alignright</td>
<td>Right aligns the current block or image.</td>
</tr>
<tr>
<td>bold</td>
<td>Applies the bold format to the current selection.</td>
</tr>
<tr>
<td>bullist</td>
<td>Formats the current selection as a bullet list.</td>
</tr>
<tr>
<td>color</td>
<td>Applies text color to selection. This opens a color picker pop-up, allowing you to choose text and/or background color.</td>
</tr>
<tr>
<td>emoji</td>
<td>Opens a picker for selecting an emoji to insert into the field.</td>
</tr>
<tr>
<td>fontselect</td>
<td>Dropdown list with font families to apply to selection.</td>
</tr>
<tr>
<td>fontsizeselect</td>
<td>Dropdown list with font sizes to apply to selection.</td>
</tr>
<tr>
<td>formatselect</td>
<td>Dropdown list with block formats to apply to selection.</td>
</tr>
<tr>
<td>indent</td>
<td>Indents the current list item or block element.</td>
</tr>
<tr>
<td>image</td>
<td>Inserts an image resource found on the local platform.</td>
</tr>
<tr>
<td>insert</td>
<td>Create and delete links.</td>
</tr>
<tr>
<td>italic</td>
<td>Applies the italic format to the current selection.</td>
</tr>
<tr>
<td>linespacing</td>
<td>Defines the line spacing of a selected text.</td>
</tr>
<tr>
<td>numlist</td>
<td>Formats the current selection as a numbered list.</td>
</tr>
<tr>
<td>outdent</td>
<td>Outdents the current list item or block element.</td>
</tr>
<tr>
<td>redo</td>
<td>Redoes the last undo operation.</td>
</tr>
<tr>
<td>removeformat</td>
<td>Removes the formatting from the current selection.</td>
</tr>
<tr>
<td>strikethrough</td>
<td>Applies strike though format to the current selection.</td>
</tr>
<tr>
<td>underline</td>
<td>Applies the underline format to the current selection.</td>
</tr>
<tr>
<td>undo</td>
<td>Undoes the last operation.</td>
</tr>
</tbody>
</table>

**Using the spell checker**

The `fglrichtext` web component can be configured for spell checking with the `spellcheck` property of the `PROPERTIES` attribute:

```
WEBCOMPONENT rt = FORMONLY.richtext,
```
The `spellcheck` property can be set to the following values:

- "browser" (default): This will enable the intrinsic spell checking of the browser.
- "none": No spell checking is required for this rich text field.

**Important:** The `spellcheck` property is supported by the GDC and GBC. It is not supported by GMI or GMA.

**Note:** GDC has specific features regarding spell checking in web components. For example, in GDC 3.10 there is a limited set of supported languages, and if spellcheck is disabled in the web component, enabling the feature in the context menu will have no effect. For more details, see the *Spellchecking in Web Components* topic in the *Genero Desktop Client User Guide*.

### Auto-flushing the rich text content

By default, the text value of an `fglrichtext` field is only flushed to the runtime system, when focus leaves the field or when firing an action.

The `autoflush` property of the `PROPERTIES` attribute allows you to define a user action to be fired every `autoflush_interval` seconds, when the text is changed. The default for `autoflush_interval` is 10 seconds.

**Note:** When the user enters text, the `autoflush` action will be fired every `autoflush_interval` seconds. After the `autoflush` action is sent, if the user does not modify the text, no action will be fired until the user starts again to type text. This way, the network traffic is optimized.

```plaintext
WEBCOMPONENT rt = FORMONLY.richtext,

    PROPERTIES = (
        autoflush = "save_text",
        autoflush_interval = 5  -- Flush every 5 seconds
    ),

...```

In the program code, implement an `ON ACTION` handler using the action name that matches the `autoflush` property of the `WEBCOMPONENT` field. When the action is fired, the rich text will be available in the `WEBCOMPONENT` field value. Use the `UNBUFFERED` dialog mode to have the text automatically copied into the program variable bound to the form field:

```plaintext
INPUT BY NAME rec.richtext, -- Variable bound to the WEBCOMPONENT form field
...          
    ATTRIBUTES(UNBUFFERED) -- To get the input buffer copied into the variable
...          
    ON ACTION save_text ATTRIBUTES(DEFAULTVIEW = NO)
    UPDATE ord_info SET oi_comment = rec.richtext
           WHERE oi_pkey = curr_pkey
...```

Auto-flush can for example be used to implement automatic backup of the text content.

### Defining the rich text field as read-only

Like with the `TEXTEDIT NOTEDITABLE` attribute, it is possible to make the `fglrichtext` web component read-only, by defining the `noteditable` property:

```plaintext
WEBCOMPONENT rt = FORMONLY.richtext,
```
Specifying the default font

Default font attributes can be selected for the fglrichtext web component by using the following properties:

Table 369: Default font properties

<table>
<thead>
<tr>
<th>Property name</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>font_family</td>
<td>Monospace, Sans serif, Serif, Roboto</td>
</tr>
<tr>
<td>font_size</td>
<td>nnnpx</td>
</tr>
</tbody>
</table>

For example:

```plaintext
WEBCOMPONENT rt = FORMONLY.richtext,

... PROPERTIES = (  
  font_family = "Monospace",
  font_size = "25px"
),
...
```

The font_size defines the px unit, otherwise, the property will be ignored.

If the toolbar items fontselect/fontsizeselect are used, they will display the font family and font size defined by the properties, when the fglrichtext initializes.

If the user moves the edit cursor to a text element that uses a different font to the one specified with these attributes, the richtext will reset the current font settings to match that text element.

Localizing rich text component strings

The toolbar button tooltips, combobox items, and popup dialog labels of the fglrichtext web component can be localized with dedicated properties.

Note: Consider using localized strings to define the texts in external string resource files.

For each context, the texts must be provided as a set of JSON formatted key/value pairs, where the key identifies the element to get the text:

```plaintext
label-localization-property = '{ "item-name" : "item-label" [,... ] }'
```

Table 370: Properties for fglrichtext string localization and related item identifiers

<table>
<thead>
<tr>
<th>Property name</th>
<th>Items/Keys</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property name</td>
<td>Items/Keys</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>labels_toolbar_link</td>
<td>&quot;save&quot;, &quot;label&quot;, &quot;edit&quot;, &quot;visit&quot;, &quot;remove&quot;</td>
</tr>
<tr>
<td>labels_toolbar_linespacing</td>
<td>&quot;small&quot;, &quot;normal&quot;, &quot;large&quot;, &quot;huge&quot;</td>
</tr>
<tr>
<td>labels_toolbar_formatselect</td>
<td>&quot;heading&quot;, &quot;normal&quot;</td>
</tr>
</tbody>
</table>

**Note:** For combobox items like with `labels_toolbar_linespacing`, the item/key names must be specified in lowercase ("small":"Petit", not "Small":"Petit"")

For example (not using localized strings):

```javascript
WEBCOMPONENT rt = FORMONLY.richtext,
    ...;
    PROPERTIES = {
        labels_toolbar_tooltips = '{ "aligncenter":"Centré",
            "alignjustify":"Justifié", ... }',
        labels_toolbar_link = '{"save":"OK","label":"Entrez un lien:"}',
        labels_toolbar_linespacing = '{"small":"Petit","normal":"Normal","large":"Grand", ... }',
        labels_toolbar_formatselect = '{"heading":"Titre","normal":"Normal"}',
    },
    ...
```

Example using localized strings:

```javascript
labels_toolbar_tooltips = "%rtlabels.toolbar.tooltips"
```

and then in the .str file:

```javascript
rtlabels.toolbar.tooltips = '{ "aligncenter":"Centré",
    "alignjustify":"Justifié", ... }'
```

Examples

fglrichtext built-in web component usage examples.

**Example 1:** Simple INPUT with fglrichtext

Form definition file `simple_richtext.per`:

```javascript
LAYOUT (TEXT="Rich Text",MINWIDTH=80,MINHEIGHT=20)
GRID
{
    [rt]
    [ ]
    [ ]
    [ ]
    [info]
}
END
END
ATTRIBUTES
WEBCOMPONENT rt = FORMONLY.richtext,
    COMPONENTTYPE = "fglrichtext",
    PROPERTIES = {
        toolbar = "bold|italic|underline|undo|redo",
        spellcheck = "browser",
        autoflush = "savetext",
        autoflush_interval = 30
    },
    SIZEPOLICY = FIXED,
    SCROLLBARS = NONE,
```
STRETCH = BOTH;
EDIT info = FORMONLY.info, SCROLL;
END

Program file simple_richtext.4gl:

MAIN
  DEFINE rec RECORD
    richtext STRING,
    info STRING
  END RECORD

  OPTIONS INPUT WRAP, FIELD ORDER FORM

  OPEN FORM f1 FROM "simple_richtext"
  DISPLAY FORM f1

  INPUT BY NAME rec.*
    ATTRIBUTES(UNBUFFERED, WITHOUT DEFAULTS)
    ON ACTION get_cont ATTRIBUTES(TEXT="Get content")
      LET rec.info = rec.richtext
    ON ACTION set_cont ATTRIBUTES(TEXT="Set content")
      LET rec.richtext = SFMT("<html><body>%1</body></html>",
                                  "<p>This is new text " || current || "</p>"
    LET rec.info = "Text reloaded."
  ON ACTION CLEAR ATTRIBUTES(TEXT="Clear")
    LET rec.richtext = NULL
    LET rec.info = "Text cleared."
  ON ACTION set_focus_to_wc ATTRIBUTES(TEXT="Focus to RichText")
    NEXT FIELD richtext
  ON ACTION set_focus_to_info ATTRIBUTES(TEXT="Focus to info")
    NEXT FIELD info
  ON ACTION savetext ATTRIBUTES(DEFAULTVIEW=NO)
    LET rec.info = "Autoflush occured at: ", CURRENT HOUR TO SECOND
    DISPLAY rec.info
  END INPUT

END MAIN

The fglgallery web component
The fglgallery built-in web component implements a picture gallery, to let the end user select pictures and photos.

The fglgallery built-in web component is a gICAPI web component.

Several rendering modes are supported: Mosaic, List and Thumbnails for basic rendering.
Defining the fglgallery web component in the form file

In your .per form definition file, define the image gallery as a WEBCOMPONENT form item with the COMPONENTTYPE attribute set to the "fglgallery" value.

As the image gallery implements its own navigation controls or scrollbars, the SCROLLBARS attribute can be set to NONE.

Use SIZEPOLICY=FIXED and STRETCH=BOTH, to get an image gallery that resizes with the parent window.

For example:

```
LAYOUT
GRID
{
[ig                     ]
[                       ]
[                       ]
...                      
ATRIBUTES
WEBCOMPONENT ig = FORMONLY.gallery_wc,
COMPONENTTYPE = "fglgallery",
PROPERTIES=(selection="image_selection"),
```
Introducing the `fglgallery.4gl` library

The `fglgallery.4gl` module implements a set of functions to control an fglgallery web component. The source can be found in FGLDIR/src/webcomponents/fglgallery.

Customizing the image gallery

The HTML elements created by fglgallery can be customized with CSS styling.

Default CSS styles for fglgallery are provided in FGLDIR/webcomponents/fglgallery/css/fglgallery.css.

Overwrite or define new style attributes for each fglgallery element type, in a secondary file named FGLDIR/webcomponents/fglgallery/css/fglgallery-custom.css, and uncomment the link in FGLDIR/webcomponents/fglgallery/fglgallery.html to load this custom CSS file after fglgallery.css.

For example, to define a background color for the list display mode, add the following lines in fglgallery-custom.css:

```plaintext
.list-main {
  background-color: black;
}
```

**Note:** Do not modify the default CSS styles in fglgallery.css: This file will be overwritten by a new installation. Use the fglgallery-custom.css file name instead.

fglgallery library initialization and finalization

Library initialization and finalization functions are provided to prepare the library before usage, and free resources when the library is not longer needed:

```plaintext
CALL fglgallery.initialize()
...
CALL fglgallery.finalize()
```

For more details see the initialize() and finalize() functions.

Creating and destroying an image gallery handle

Before using the image gallery web component, you must create a handle with the create() function:

```plaintext
DEFINE id INTEGER
...
LET id = fglgallery.create("formonly.gallery_wc")
```

The create() function takes the WEBCOMPONENT form item name as parameter, and returns the id of the image gallery handle. The image gallery id will be used in subsequent library calls. This technique allows for the manipulation of several image gallery items in the same form, and the use of the library by different callers.

When the image gallery web component is no longer used, destroy the handle with the destroy() function:

```plaintext
CALL fglgallery.destroy(id)
```
The **fglgallery.t_struct_value type**

The ffgallery library provides a user-type to define a variable that will be used to send and receive data from the image gallery web component.

The `fglgallery.t_struct_value` type is a RECORD structure, that holds image selection information:

```plaintext
PUBLIC TYPE t_struct_value RECORD
    current INTEGER,
    selected DYNAMIC ARRAY OF INTEGER
END RECORD
```

In this structure, each picture is identified by its ordinal position in the image gallery.

**Data type for the ffgallery WEBCOMPONENT field**

The ffgallery WEBCOMPONENT field value will be used to exchange image selection information in JSON format. Use STRING as data type for the variable bound to the WEBCOMPONENT field.

The string variable can then be used to map the JSON to the `fglgallery.t_struct_value` record:

```plaintext
DEFINE rec RECORD
    ...  
    gallery_wc STRING,
    ...  
END RECORD
DEFINE 
    ...
INPUT BY NAME rec.* ...
    ...
ON ACTION image_selection
    CALL util.JSON.parse( rec.gallery_wc, struct_value )
    DISPLAY "Current: ", ffgallery.getPath(id, struct_value.current)
    ...
```

**Filling the image gallery with pictures**

In order to add a picture resource to the image gallery, use the `addImage()` function. This function takes three parameters:

1. The id of the image gallery handle,
2. The URL of the picture resource,
3. The text/comment for the picture.

**Important:** When using local application pictures, you need to understand how these pictures are transmitted to the front-end for display inside the WEBCOMPONENT. For more details, see Using image resources with the gICAPI web component on page 1855.

Pictures are identified by their ordinal position in the image gallery.

To add a picture resource that resides on the application server where the program executes, use the `ui.Interface.filenameToURI()` method:

```plaintext
CALL ffgallery.addImage(id,
    ui.Interface.filenameToURI("big_smiley.jpg"),
    "The big smiley.")
```

To add a picture resources that is available as a URL, from the local network or the internet, provide the URL directly:

```plaintext
CALL ffgallery.addImage(id,
```
After adding pictures, display the image gallery with `display()`:

```sql
CALL fglgallery.display(id, FGLGALLERY_TYPE_MOSAIC, FGLGALLERY_SIZE_NORMAL)
```

Or call the `flush()` function, when the image gallery is already displayed:

```sql
CALL fglgallery.flush(id)
```

This flush mechanism allows you to add a set of pictures in one front-end exchange.

**Get the number of pictures in the gallery**

To get the number of pictures that are currently displayed in the gallery, call the `getImageCount()` function:

```sql
DISPLAY fglgallery.getImageCount(id)
```

**Cleaning the image gallery**

Use the `clean()` function to remove all pictures from the image gallery:

```sql
CALL fglgallery.clean(id)
```

**Displaying the image gallery**

To display the image gallery, use the `display()` function. This function takes the image gallery id as parameter, followed by the gallery type and size options:

```sql
CALL fglgallery.display(id, FGLGALLERY_TYPE_MOSAIC, FGLGALLERY_SIZE_NORMAL)
```

**Image gallery type (FGLGALLERY_TYPE_*)**

The type of the image gallery defines the layout / rendering of the gallery. This type is defined by the second parameter of the `display()` function.

For possible values, see the `display()` function reference topic.

**Image gallery size (FGLGALLERY_SIZE_*)**

The size of the images displayed in the gallery is defined by the third parameter of the `display()` function. The size is specified with an abstract option (small, normal, large, etc). This size is related to the current font (the "em" unit is used in HTML).

For possible values, see the `display()` function reference topic.

**Image elements aspect ratio**

All image elements in the fglgallery are displayed with the same size, to align properly when the image resources have different sizes.

By default, image elements are displayed with a square (1:1) aspect ratio.

The aspect ratio can be configured with the `setImageAspectRatio()` function.
Get the picture resource path from a position
To get the picture resource name from an image position, use the `getPath()` function:

```plaintext
LET path = fglgallery.getPath(id, struct_value.current)
```

Get the picture title from a position
To get the title of a picture from an image position, use the `getTitle()` function:

```plaintext
LET title = fglgallery.getTitle(id, struct_value.current)
```

Delete pictures from the image gallery
To remove pictures from the image gallery, use the `deleteImages()` function. This function takes a DYNAMIC ARRAY OF INTEGER as parameter, defining the ordinal positions of the pictures to be deleted:

```plaintext
DEFINE todel DYNAMIC ARRAY OF INTEGER
LET todel[1] = 3
LET todel[2] = 6
CALL fglgallery.deleteImages(id, todel)
```

Single and multiple picture selection
By default, the end user can only select a single picture from the image gallery. With the Mosaic, List and Thumbnails display modes, you can enable multiple picture selection.

Note: Multiple picture selection is not supported with the Light Gallery display mode.

To enable multiple picture selection, use the `setMultipleSelection()` function:

```plaintext
CALL fglgallery.setMultipleSelection(id, TRUE)
```

Picture selection can then be detected with an ON ACTION handler.

Detecting image selection
To implement picture selection in the image gallery component, define the WEBCOMPONENT form field with a "selection" property in the PROPERTIES attribute:

```plaintext
WEBCOMPONENT ig = FORMONLY.gallery_wc,
...
  PROPERTIES = (selection="image_selection"),
...
```

Picture selection is built-in to the fglgallery web component.

In the program code, detect picture selection with an ON ACTION handler defined with an action name that matches the "selection" property of the WEBCOMPONENT field.

When the action is fired, selection information is provided in the WEBCOMPONENT field value as a JSON formatted string similar to: {"current":5,"selected":[4,5]}

Tip: In order to get the selection information directly in the program variable bound to the WEBCOMPONENT field, consider using the UNBUFFERED dialog attribute.

This JSON string can be parsed with the `util.JSON.parse()` method, to fill a variable defined with the `fglgallery.t_struct_value` type:

```plaintext
DEFINE struct_value fglgallery.t_struct_value
...
The selection structure contains a "current" field, to identify the current selected picture, and when the multiple-selection option is enabled, the "selection" field contains the list of picture ids that are selected.

**Define selected pictures by program**

In order to set the current picture, and select or de-select pictures from the program code, use the variable defined with the `fglgallery.t_struct_value` type and assign it as a JSON string to the web component field:

1. Fill the `fglgallery.t_struct_value` variable with the picture ordinal positions,
2. Convert to a JSON string with `util.JSON.stringify()`,
3. Set the `WEBCOMPONENT` field value with the resulting string.

For example, to set picture #3 as current, and select pictures #2, #7 et #15:

```
DEFINE struct_value fglgallery.t_struct_value
...
LET struct_value.current = 3
CALL struct_value.selected.clear()
LET struct_value.selected[1] = 2
LET struct_value.selected[2] = 7
LET struct_value.selected[3] = 15
LET rec.gallery_wc = util.JSON.stringify(struct_value)
```

**Complete fglgallery API reference**

Check the `$FGLDIR/src/webcomponents/fglgallery/fglgallery.4gl` source for more details about the image gallery API.

**Related reference**

The fglsvgcanvas web component
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

Note: This documentation does not explain SVG drawing principles. Before starting with fglsvgcanvas, consider learning SVG, with tutorials found on the internet. It is especially mandatory to properly understand the root SVG viewport / viewBox / preserveAspectRatio concepts.

The fglsvgcanvas built-in web component is a glICAPI web component.

Important: Since SVG allows you to specify coordinates and sizes with units such as "10em", and including the % percentage unit like in "50%", some fglsvxcanvas functions use the STRING type for parameters such as x, y, width, height. In SVG, the decimal separator for numeric values must always be a dot. When computing coordinates and sizes with numeric types such as DECIMAL or when passing decimal values directly to fglsvxcanvas functions, pay attention to numeric to string conversion. By default, the DBMONEY/DBFORMAT settings apply and can produce a comma for the decimal separator. As a general advice, when possible, define a large SVG viewBox (like "0 0 1000 1000"), in order to use only integer numbers for coordinates and sizes, or % percentage units.

The fglsvxcanvas web component HTML page is basically a simple HTML container. It is delivered with the utility library FGLDIR/src/webcomponents/fglsvxcanvas/fglsvxcanvas.4gl, that can be used to produce SVG content.

The programming pattern is based on the built-in om.* API. Create DOM nodes with the utility functions, and construct the root <svg/> element by adding child nodes created from the fglsvxcanvas functions.
Defining the fglsvgcanvas web component in the form file

In the .per form definition file, define the SVG container as a WEBCOMPONENT form item with the COMPONENTTYPE attribute set to the "fglsvgcanvas" value.

Important: The form field name will be used in front calls to identify the SVG canvas.

Since the SVG canvas web component provides built-in scrollbars, the SCROLLBARS attribute can be set to NONE. Use SIZEPOLICY=FIXED and STRETCH=BOTH, to get an SVG canvas that resizes with the parent window.

Additional fglsvgcanvas web component configuration options can be defined with the PROPERTIES attribute (details will be discussed later in this topic).

For example:

```plaintext
LAYOUT
GRID
{
  [cv ]
  [   ]
  [   ]
  ...

ATTRIBUTES
WEBCOMPONENT cv = FORMONLY.canvas,
  COMPONENTTYPE = "fglsvgcanvas",
  PROPERTIES = { selection="item_selection" },
  SIZEPOLICY = FIXED,
  STRETCH = BOTH,
  SCROLLBARS = NONE;
...
```
The fgsvgcanvas.4gl library

SVG can be used to draw complex content such as an agenda or a graph, with advanced SVG concepts such as CSS styles, patterns, nested <svg/> elements, etc.

To simplify SVG programming, Genero BDL provides the FGLDIR/src/webcomponents/fglsvgcanvas/fglsvgcanvas.4gl utility library. This library implements a set of functions that produce common SVG elements.

The fgsvgcanvas.4gl library supports following SVG features:

- Attribute sets
- CSS styles
- Patterns
- Masks
- Filters
- Gradients
- Shapes (rect, circle, polygon, etc)
- Simple text, text on path, text tspan
- Animation
- Clickable elements
- Clipping paths
- RGB color utilities (shade, tint)

fglsvgcanvas library initialization and finalization

Library initialization and finalization functions are provided to prepare the library before usage, and free resources when the library is no longer needed:

```
CALL fgsvgcanvas.initialize()
...  
CALL fgsvgcanvas.finalize()
```

For more details see initialize() on page 2225 and finalize() on page 2223.

Creating an SVG canvas handler

Before creating new SVG element, you need to create the SVG canvas handler, to get an id that will be used in subsequent fgsvgcanvas calls. Define a SMALLINT variable to hold the SVG canvas handler id that is returned by the create() function. This function takes the WEBCOMPONENT field name as attribute, to bind the form field to the SVG canvas handle:

```
DEFINE cid SMALLINT
...  
LET cid = fgsvgcanvas.create("formonly.canvas")
```

Selecting an SVG canvas handler

The SVG canvas is identified by the id returned by the create() function. After creating an SVG canvas, it is automatically defined as the current canvas, and any subsequent calls to an fgsvgcanvas function will apply to that current canvas handler. If you want to manipulate several SVG canvases, select the current canvas with the setCurrent() function:

```
CALL fgsvgcanvas.setCurrent(cid)
```
The root SVG node

The root SVG DOM node is created when calling the `create()` function. However, before drawing your SVG, you need to define essential root SVG attributes.

To define the root SVG attributes, use the `setRootSVGAttributes()` function.

This function returns the root `om.DomNode` of the SVG tree:

```oml
DEFINE root_svg, n om.DomNode
... 
LET root_svg = fglsvgcanvas.setRootSVGAttributes(
  "myrootsvg",
  "10em", "10em", -- viewport
  "0 0 500 500",  -- viewbox
  "xMidYMid meet" -- preserveAspectRatio
) 
... 
```

Specify the following properties to define your root SVG element:

- the viewport defines the viewing area for the SVG image (use NULL, NULL for auto-resize; default unit is px, consider using em unit),
- the viewBox defines the internal coordinate system (with a (0,0,500,200) viewBox, point (250,100) is the middle),
- the parameters to preserve the aspect ratio.

For more details about the `<svg/>` element attributes, see the W3 SVG specification.

Destroying an SVG canvas handler

When the SVG canvas handler is no longer needed (for example, before closing the form/window displaying the corresponding `WEBCOMPONENT`), you can release resources allocated for the SVG handle by calling the `destroy()` function:

```oml
DEFINE cid SMALLINT
... 
LET cid = fglsvgcanvas.create("formonly.canvas") 
... 
CALL fglsvgcanvas.destroy( cid ) 
```

After calling the `destroy()` function, the SVG canvas handler that was created before the destroyed handler, will be set as the new current SVG canvas:

```oml
DEFINE cid1, cid2 SMALLINT
... 
LET cid1 = fglsvgcanvas.create("formonly.canvas1") -- current canvas is cid1 
... 
LET cid2 = fglsvgcanvas.create("formonly.canvas2") -- current canvas is cid2 
... 
CALL fglsvgcanvas.destroy( cid2 ) -- current canvas is cid1 
... 
CALL fglsvgcanvas.destroy( cid1 ) -- no current canvas 
```

Building the SVG DOM tree

After creating the root SVG DOM node with the `setRootSVGAttributes()` function, create other DOM element with fglsvgcanvas functions, and append the child nodes to the root element or sub-elements:

```oml
DEFINE root_svg, n, g om.DomNode
... 
LET n = fglsvgcanvas.svg( ... ) -- creates an <svg/> sub-node. 
```
CALL root_svg.appendChild( n )

LET g = fglsvgcanvas.g( ... ) -- creates a <g/> sub-node.
CALL n.appendChild( g )

Cleaning the SVG canvas
To clean up the SVG canvas content, use the clean() function:

CALL fglsvgcanvas.clean( cid )

Defining CSS styles
SVG supports CSS styling. Styles must be defined in the <defs/> element, and can then be referenced in SVG drawing elements by using the class attribute.

To create styles, start by defining a set of SVG attributes with an om.SaxAttributes object. For attribute names, use the predefined SVGATT_ constants available in the fglsvgcanvas library.

Tip: Define a dynamic array of om.SaxAttributes, to define several reusable attribute sets.

CONSTANT COLORS_OCEAN = 1
CONSTANT COLORS_SAHARA = 2

DEFINE attr DYNAMIC ARRAY OF om.SaxAttributes

LET attr[COLORS_OCEAN] = om.SaxAttributes.create()
CALL attr[COLORS_OCEAN].addAttribute(SVGATT_FILL,           "cyan" )
CALL attr[COLORS_OCEAN].addAttribute(SVGATT_FILL_OPACITY,   "0.3" )
CALL attr[COLORS_OCEAN].addAttribute(SVGATT_STROKE,         "blue" )
CALL attr[COLORS_OCEAN].addAttribute(SVGATT_STROKE_WIDTH,   "5" )
CALL attr[COLORS_OCEAN].addAttribute(SVGATT_STROKE_OPACITY, "0.3" )

LET attr[COLORS_SAHARA] = om.SaxAttributes.create()
CALL attr[COLORS_SAHARA].addAttribute(SVGATT_FILL,          "yellow" )

An SVG attribute set defined in an om.SaxAttributes object can be used in different manners:

1. To explicitly set attributes in an SVG DOM node, with the setAttributes() function.
2. To define a CSS style with a selector and a list of name:value; pairs, with the styleDefinition() function.
3. To set an inline-style in an DOM node, defining a list of name:value; pairs, with the styleAttributeList() function.

To create a set of CSS styles, create a <defs/> SVG element, containing a <style/> element including your attributes sets.

The <style/> element is created with then styleList() function, and each CSS style string is created with the styleDefinition() function, from the om.SaxAttributes objects:

DEFINE defs om.DomNode

LET defs = fglsvgcanvas.defs( NULL )
CALL defs.appendChild( fglsvgcanvas.styleList{
    fglsvgcanvas.styleDefinition(".style_1",attr[STYLE_1])
    | |
    fglsvgcanvas.styleDefinition(".style_2",attr[STYLE_2])
})
Then, you can, for example, define a `<rect/>` element that references the style defined with in the `<defs/>` node:

```java
DEFINE r om.DomNode
LET r = fglsvgcanvas.rect(10,10,30,40,NULL,NULL)
CALL r.setAttribute(SVGATT_CLASS, "style_1")
```

### Displaying the SVG content

After creating the SVG content, it must be sent to the front-end for rendering.

To display the SVG content to the `WEBCOMPONENT` field associated with the SVG canvas handle, use the `display()` function:

```java
CALL fglsvgcanvas.display( cid )
```

### Detecting SVG element selection

To enable clickable SVG elements, define the `WEBCOMPONENT` form field with a "selection" property in the `PROPERTIES` attribute. This property defines the action that will be fired when the user clicks on an SVG element. Use lowercase action names:

```java
WEBCOMPONENT cv = FORMONLY.canvas,
... PROPERTIES = (selection="item_selection"),
... Define clickable SVG elements by using the `<g/>` SVG grouping element. In the group element, define the `SVGATT_ONCLICK`/"onclick" attribute to `SVGVAL_ELEM_CLICKED"elem_clicked(this)".

The `SVGVAL_ELEM_CLICKED"elem_clicked(this)` JavaScript function is predefined in `fglsvgcanvas.html`, and will be fired the action defined by the `selection` property defined by the `WEBCOMPONENT` form field.

The `<g/>` group element (and each child element below the group), must be defined with an "id" attribute, that will be used to identify the clicked elements:

```java
DEFINE root_svg, g, c om.DomNode,
    x INT,
    id STRING
... LET id = "shape_1"
LET g = fglsvgcanvas.g(id)
CALL g.setAttribute(SVGATT_ONCLICK,SVGVAL_ELEM_CLICKED)
LET c = fglsvgcanvas.circle(x,y,s)
CALL c.setAttribute("id",id)
CALL c.setAttribute(SVGATT_STYLE, 'stroke:gray;fill:blue;fill-opacity:0.3' )
CALL g.appendChild( c )
LET c = fglsvgcanvas.circle(x,y,20)
CALL c.setAttribute("id",id)
CALL c.setAttribute(SVGATT_STYLE, 'stroke:gray;fill:yellow;fill-opacity:0.8' )
CALL root_svg.appendChild( g )
```
In the program code, detect SVG element selection with an ON ACTION handler using the action name that matches the "selection" property of the WEBCOMPONENT field. When the action is fired, the id of the selected SVG element is provided in the WEBCOMPONENT field value:

```g4l
DEFINE rec RECORD
    canvas STRING, -- Variable bound to the WEBCOMPONENT form field
    ...
END RECORD
```

```
INPUT BY NAME rec.* ATTRIBUTES(UNBUFFERED)
    ON ACTION item_selection ATTRIBUTES(DEFAULTVIEW = NO)
        DISPLAY "Clicked element:'", rec.canvas
    ...
```

Information about the clicked SVG element is provided in JSON notation, for example:

```json
{"id":"shape_1","source":"action","action":"item_selection"}
```

**Note:** It is also possible to use the `fglsvgcanvas.getItemId()` function to get the id of the clicked SVG element. However, this produces a frontcall that can be avoided, since the element id is available in the WEBCOMPONENT field value. The `getItemId()` function should only be used when the WEBCOMPONENT field does not have the focus, for example to handle mouse hovering events with `mouse_event_focus = false`.

### Detecting mouse hovering SVG events

SVG elements can be defined with the mouse hovering events "onmouseover" and "onmouseout", respectively defined as the `SVGATT_ONMOUSEOVER` and `SVGATT_ONMOUSEOUT` constants in `fglsvgcanvas.4gl` for convenience and code readability.

**Tip:** If you want to implement display effects only, consider using well-known SVG + JavaScript techniques to modify element attributes directly in the web browser context, and thus avoid unnecessary network round-trips. For example, to produce some responsive rendering effect when the mouse goes over an SVG element, you can do following:

```g4l
DEFINE n om.DomNode
LET n = fglsvgcanvas.rect(50,50,20,30,2,2)
CALL n.setAttribute(SVGATT_ONMOUSEOVER,  "evt.target.setAttribute('opacity', '0.5');")
CALL n.setAttribute(SVGATT_ONMOUSEOUT, "evt.target.setAttribute('opacity', '1.0');")
```

The fglsvgcanvas web component can be configured to bind the onmouseover/onmouseout SVG mouse hovering events to ON ACTION handlers and trigger code, when the mouse goes over the SVG elements.

**Important:** When SVG element selection is enabled, the corresponding action has a higher importance as mouse hovering actions: A click on an SVG element will cancel the mouse over / mouse out actions, even if corresponding SVG onmouseover and onmouseout events occurred respectively before and after the onclick SVG event.

This code example defines the web component field properties to handle mouse hovering SVG events:

```g4l
WEBCOMPONENT cv=FORMONLY.canvas,
    ...
    PROPERTIES=(
        ...
        mouse_over = "item_mouse_over",
        mouse_out = "item_mouse_out",
        mouse_event_timeout = 600,
        mouse_event_focus = false
    ),
```

The `mouse_over = "action-name"` property identifies the ON ACTION `action-name` handler to be triggered, when the onmouseover SVG event occurs. Use lowercase to define mouse hovering action names.
The `mouse_out = "action-name"` property identifies the ON ACTION `action-name` handler to be triggered, when the `onmouseout` SVG event occurs. Use lowercase to define mouse hovering action names. Defining the mouse out action is optional.

`mouse_event_timeout = milliseconds` is used to avoid network clogging: This property defines the number of milliseconds to wait before sending the action, after an SVG mouse event has occurred. A JavaScript `setTimeout()` timer is created with this value. The timer is re-initialized each time the event occurs. Default is 500 milliseconds.

`mouse_event_focus = [true | false]` is boolean indicating if the web component must have the focus in order to fire the mouse actions.

When creating your SVG elements, bind mouse hovering SVG events to predefined JavaScript function corresponding to the SVG event. The functions take the current SVG element `(this)` as parameter.

- The `SVGATT_ONMOUSEOVER/"onmouseover"` SVG event must be bound to `SVGVAL_ELEM_MOUSE_OVER/"elem_mouse_over(this)"`.
- The `SVGATT_ONMOUSEOUT/"onmouseout"` SVG event must be bound to `SVGVAL_ELEM_MOUSE_OUT/"elem_mouse_out(this)"`.

For example:

```om
DEFINE n om.DomNode
...
LET n = fglsvgcanvas.rect(x, y, w, h, NULL, NULL)
CALL n.setAttribute(SVGATT_ONMOUSEOVER, SVGVAL_ELEM_MOUSE_OVER)
CALL n.setAttribute(SVGATT_ONMOUSEOUT, SVGVAL_ELEM_MOUSE_OUT)
```

In the dialog code, implement the ON ACTION handlers to execute code, when the actions are fired.

**Note**: If the mouse hovering action requires field focus (`mouse_event_focus=true`), the involved SVG element id is available in the field value, like for the item selection action. If the mouse hovering action can be fired when the web component field does not have the focus, use the `fglsvgcanvas.getItemId()` function to get the id of the SVG element.

```om
... 
ON ACTION item_mouse_over ATTRIBUTES(DEFAULTVIEW = NO)
MESSAGE Sfmt("%1 : mouse over item : %2", CURRENT HOUR TO FRACTION(5), fglsvgcanvas.getItemId(cid) )

ON ACTION item_mouse_out ATTRIBUTES(DEFAULTVIEW = NO)
MESSAGE ""
...
```

### Getting the bounding box of an SVG element

After rendering your SVG, it is possible to get the bounding box of an element.

With elements such as SVG text using a specific font, it is difficult to compute the bounding box of the text, until it has been rendered.

First define a variable with the `fglsvgcanvas.t_svg_rect` type, then (after displaying the SVG with `fglsvgcanvas.display(cid)`), call the `fglsvgcanvas.getBBox(cid, element-id)` function, to get the bounding box of the element identified by `element-id`:

```om
DEFINE rect fglsvgcanvas.t_svg_rect
... 
ON ACTION get_bbox
    CALL fglsvgcanvas.getBBox(cid, "label_23") RETURNING rect.*
    DISPLAY rect.x, rect.y, rect.width, rect.height
```
The bounding box coordinates and size are returned in the current user space.

Note:
If the bounding box is required to place and size SVG element based on the position and size of other elements, consider using SVG scripting instead of the getBBox() function: this will avoid several network roundtrips to render the final SVG image.

For example:

```xml
<svg version="1.1" baseProfile="full"
    xmlns="http://www.w3.org/2000/svg"
    width="500px" height="500px" viewBox="0 0 2000 2000"
    onload="setup()">
    <script type="text/ecmascript">
        // <![CDATA[
        function setup_rect(box,bbox){
            box.setAttributeNS(null, "x", bbox.x - 2);
            box.setAttributeNS(null, "y", bbox.y - 2);
            box.setAttributeNS(null, "width", bbox.width + 4);
            box.setAttributeNS(null, "height", bbox.height + 4);
        }
        function setup(evt){
            setup_rect( document.getElementById("label1Box"), label1.getBBox() );
        }
        // ]]>}
    </script>
    <g id="label1">
        <text x="150" y="250" font-family="Verdana" font-size="55">Hello everybody!</text>
        <rect id="label1Box" stroke="red" stroke-width="3px" fill="none"/>
    </g>
</svg>
```

Dynamic Dialogs

Dialogs can be created at runtime with the ui.Dialog class.

- Understanding dynamic dialogs on page 1903
- Create forms dynamically on page 1904
- Instantiate a dynamic dialog on page 1904
- Defining dialog triggers on page 1906
- Controlling field values on page 1907
- Ending dynamic dialogs on page 1908
- Dynamic multiple dialog on page 1909
- Using dynamic cursors on page 1911
- Additional features on page 1912

Understanding dynamic dialogs

This section provides basics about dynamic dialogs.

The ui.Dialog class can create dialog objects at runtime, to implement generic code controlling forms that are created at runtime, when the data structure is not known at compile time.

Unlike static dialog instructions, dynamic dialogs do not require a data model (that is a program variables containing the values for fields). Dynamic dialogs are created with a list for field definitions that is built at runtime, no static (RECORD) structure is required to instantiate a dynamic dialog.

Important: Dynamic dialogs are provided to resolve specific needs, like implementing a generic zoom window to select a record in a list, and control forms generated at runtime. This feature is not a replacement for regular "static" dialog instructions, used to control the forms defined in form specification files.

Dynamic dialogs use by default the UNBUFFERED mode and WITHOUT DEFAULTS. For more details, see Controlling field values on page 1907.

Dynamic dialogs can be used in conjunction with base.SqlHandle objects, to get database table column information in order to build forms dynamically and define the field list.
**Create forms dynamically**
Dynamic dialogs are typically used with forms that are generated at runtime.

**Purpose of dynamic forms**
Before you instantiate a new `ui.Dialog` object, you must load an existing compiled .42f form, or create a new form dynamically in your program.

Since dynamic dialogs are build at runtime (because form fields are not known at compiled time), the corresponding form is also created (or completed) at runtime.

**Note:** The current form (in the current window) is automatically attached to the new created dialog.

**Dynamic form creation with `createForm()`**
Forms built at runtime must be created with the `ui.Window.createForm()` method, and must contain a valid definition with layout containers, form fields, and screen records.

**Note:** See Genero BDL demos for a complete example of form creation at runtime.

The `createForm()` method will be invoked by using the current window. For the main form of the program, use directly the (empty) `SCREEN` window. For child windows, create the windows without a form by using following syntax:

```plaintext
OPEN WINDOW w1 WITH 1 ROWS, 1 COLUMNS
```

Assuming that there is a current empty window, you can then create the `ui.Form` object, to finally get the `om.DomNode` object to build your form:

```plaintext
DEFINE w ui.Window,
    f ui.Form,
    n om.DomNode
LET w = ui.Window.getCurrent()
LET f = w.createForm("myform")
LET n = f.getNode()
...```

Use `om` classes, to build your form dynamically. A good practice in creating dynamic forms is to write first a .per file, that implements a static version of one of the forms you want to build at runtime. Compile the .per to a .42f and inspect the generated XML file, to understand the structure of the form file.

**COMBOBOX initializers**

Comboxbox initializers are called when executing the `DISPLAY FORM` or `OPEN WINDOW WITH FORM` instructions.

When creating a form dynamically with COMBOBOX fields, the initialization functions are not called. The combobox items must be created as part of the combobox node.

**Related concepts**

The `om package` on page 2429
These topics cover the built-in classes for the om class

**Instantiate a dynamic dialog**
The dynamic dialogs needs to be created with specific `ui.Dialog` methods.

**Defining the dialog object variable**
To reference the dialog object, first declare a variable with the type `ui.Dialog`:

```plaintext
DEFINE d ui.Dialog
```
Defining field names and types

The dynamic dialog creation methods take the list of field definitions as parameter, as a dynamic array with a record structure using two members to define the field name and data type.

Define a dynamic array with the following structure:

```
DEFINE fields DYNAMIC ARRAY OF RECORD
    name STRING,
    type STRING
END RECORD
```

The field definition array will identify form fields and the data types to be used to store the values.

The data types are provided as strings, using the same syntax as a regular Genero type:

```
LET fields[1].name = "formonly.cust_id"
LET fields[1].type = "INTEGER"
LET fields[2].name = "formonly.cust_name"
LET fields[2].type = "VARCHAR(50)"
LET fields[3].name = "formonly.cust_modts"
LET fields[3].type = "DATETIME YEAR TO FRACTION(5)"
```

Note: The type names used by the dynamic dialog API is the same as the type names returned by the 
`base.SqlHandle.getResultType()` method.

Instantiate the dynamic dialog object

When the list of field definition is complete, the next step is to create the dynamic dialog object.

When instantiating a dynamic dialog, the current form is automatically attached to it.

- To create a dynamic dialog handling simple record input (like `INPUT BY NAME`):

  ```
  LET d = ui.Dialog.createInputByName(fields)
  ```

  For more details, see `ui.Dialog.createInputByName` on page 2372.

- To create a dynamic dialog handling query by example (like `CONSTRUCT`):

  ```
  LET d = ui.Dialog.createConstructByName(fields)
  ```

  For more details, see `ui.Dialog.createConstructByName` on page 2370.

- To create a dynamic dialog handling a read-only list (like `DISPLAY ARRAY`):

  ```
  LET d = ui.Dialog.createDisplayArrayTo(fields, "sr_custlist")
  ```

  Note: The `createDisplayArrayTo()` method requires the name of the screen record used to group form fields, as defined in the `INSTRUCTIONS` section of the `.per` form file.

  For more details, see `ui.Dialog.createDisplayArrayTo` on page 2370.

- To create a dynamic dialog handling an editable list (like `INPUT ARRAY FROM`):

  ```
  LET d = ui.Dialog.createInputArrayFrom(fields, "sr_custlist")
  ```

  Note: The `createInputArrayFrom()` method requires the name of the screen record used to group form fields, as defined in the `INSTRUCTIONS` section of the `.per` form file.

  For more details, see `ui.Dialog.createInputArrayFrom` on page 2371.

- To create a dynamic dialog handling a multiple dialog (like `DIALOG / END DIALOG`):

  ```
  LET d = ui.Dialog.createMultipleDialog()
  ```
Then add sub-dialogs with methods such as `ui.Dialog.addInputByName`.
For more details, see `ui.Dialog.createMultipleDialog` on page 2373.

**Defining dialog triggers**
Dialog triggers must be implemented in a **WHILE** loop.

**Dialog trigger identification**
The code implementing dynamic dialogs must be generic. Triggers like `ON ACTION myaction` are identified as a simple string.

**Implicit standard triggers**
Standard dialog triggers such as `BEFORE INPUT`, `BEFORE FIELD field-name`, `AFTER ROW` do not need to be added when creating a dynamic dialog: These triggers are implicitly declared. To react on standard triggers, add a test for the trigger in the event loop.

**Adding user-defined triggers**
Dynamic dialogs can be configured with user-defined triggers, for example to execute code when a specific action is fired.

After creating the dialog object, add user-defined triggers with the `ui.Dialog.addTrigger()` method:

```
DEFINE d ui.Dialog
... CALL d.addTrigger("ON ACTION print")
CALL d.addTrigger("ON DELETE")
...
```

Note that some triggers must be identified with the user-defined action name, as in "ON ACTION print". User-defined triggers will then be handled in the dynamic dialog loop, when the event occurs.

**Handling dialog events**
To implement the "body" of a dynamic dialog, mix a **WHILE** loop with the `ui.Dialog.nextEvent()` method, to handle dialog events.

The **WHILE** loop will act as the main event handler of your dynamic dialog, and will loop, waiting for dialog events until you explicitly exist the loop with an **EXIT WHILE** instruction.

The `nextEvent()` method can return `NULL` in case of dialog error or when the dialog is terminated.

```
DEFINE d ui.Dialog,
    t STRING
... WHILE (t := d.nextEvent()) IS NOT NULL
    CASE t
    WHEN "BEFORE DISPLAY"
        ...
    WHEN "ON ACTION print"
        ...
    WHEN "ON DELETE"
        ...
    WHEN "AFTER DISPLAY"
        ...
    END WHILE
```
The standard triggers such as "BEFORE ROW" and "AFTER FIELD field-name" are equivalent to the trigger found in static dialog control blocks: These allow you to control the behavior of the dynamic dialog.

The user-defined triggers that have been added with the addTrigger() method must also be handled in the dynamic dialog loop.

Inside the WHILE loop, control the behavior of the dialog with the methods provided in the ui.Dialog class. For example, to jump to a different field when the "jump" action is fired:

```
...  
WHEN "ON ACTION jump"
   CALL d.nextField("customer.cust_name")
...  
```

BEFORE/AFTER FIELD handlers must be identified with the field name (without the table/formonly prefix):

```
...  
WHEN "AFTER FIELD cust_name"
   IF LENGTH(d.getFieldValue("customer.cust_name")) < 3 THEN
      ERROR "Customer name is too short"
      CALL d.nextField("customer.cust_name")
   END IF
...  
```

For more details, see the ui.Dialog.nextEvent() method reference.

**Controlling field values**

Fields values in dynamic dialogs can be manipulated dynamically.

**Unbuffered mode is the default**

Dynamic dialogs behave by default in UNBUFFERED mode. When an action is fired and the corresponding trigger handler is executed, the field is validated and the value is available in the corresponding program variable. When changing the variable value by program, the value is automatically displayed to the corresponding form-field.

For more details see The buffered and unbuffered modes on page 1618.

**Default form-field values**

A dynamic input dialog created with ui.Dialog.createInputByName on page 2372 behaves like a static INPUT dialog using the WITHOUT DEFAULTS option: The DEFAULT attribute of the form-field is not used.

A dynamic input array dialog created with ui.Dialog.createInputArrayFrom on page 2371 behaves like a static INPUT ARRAY using the WITHOUT DEFAULTS option: The values set in the internal rows before starting the dialog will be used. However, like with a static INPUT ARRAY, when adding a new row, the DEFAULT attributes of the form-fields are used.

For more details about the WITHOUT DEFAULTS clause, see Form field initialization on page 1622.

**Setting an getting field values**

A dynamic dialog stores field values in internal buffers based on the field definitions provided in the creation method. Access to these values is required, to implement the dynamic dialog.

For example, to set default values before entering the dialog loop, modifying and/or querying values during the dialog loop, and to get the entered values after dialog termination when accepted by the user.

To set or get values of fields controlled by a dynamic dialog, use respectively the ui.Dialog.setFieldValue() and ui.Dialog.getFieldValue() methods.

**Note:** These methods take a form field name as parameter, that can be provided in different notations. See Identifying fields in dialog methods on page 2409 for more details.
When implementing a display array or input array dynamic dialog handling a record list, the set/get field value methods apply to the current row. If you want to set or get field values of a particular row, first move to the row with the `ui.Dialog.setCurrentRow()` method.

This example copies the values from the fields in the current row of a display array dynamic dialog (`d_list`), to the field buffers of a record input dynamic dialog (`d_rec`):

```plaintext
CALL d_list.setCurrentRow("sr_custlist", index)
FOR i=1 TO fields.getLength()
    CALL d_rec.setFieldValue(fields[i].name, d_list.getFieldValue(fields[i].name))
END FOR
```

**Getting query conditions for a field**

A dynamic dialog created with `ui.Dialog.createConstructByName()` handles query by example input (like `CONSTRUCT`).

To generate the SQL condition from the search value entered in a construct field, use the `ui.Dialog.getQueryFromField()` method, by passing the field name as parameter:

```plaintext
LET field_condition = DIALOG.getQueryFromField("customer.cust_name")
```

To build the complete WHERE part for the SELECT statement, iterate through all form fields and concatenate the form field condition by separating with the AND or with the OR operator:

```plaintext
FOR i=1 TO fields.getLength()
    LET field_condition = d.getQueryFromField(fields[i].name)
    IF field_condition IS NOT NULL THEN
        IF where_clause IS NOT NULL THEN
            LET where_clause = where_clause, ", AND "
        END IF
        LET where_clause = where_clause, field_condition
    END IF
END FOR
```

**Ending dynamic dialogs**

Describes how to terminate dynamic dialogs.

**Implementing the accept and cancel actions**

Regular static dialog instructions implement the accept and cancel actions, to respectively validate or abort the dialog. These actions are created automatically for static dialogs, but must be created by hand for dynamic dialogs.

In the case of cancel, you can mimic the behavior of static dialogs by setting the INT_FLAG register to TRUE and then leave the WHILE loop with an EXIT WHILE.

For the accept action, call the `ui.Dialog.accept()` method to validate field input and leave the dialog, and execute an EXIT WHILE in the "AFTER INPUT" event to leave the dialog loop.

For example, to implement the accept and cancel actions for a simple record input:

```plaintext
DEFINE d ui.Dialog,
    t STRING
...
LET d = ui.Dialog.createInputByName(fields)
CALL d.addTrigger("ON ACTION cancel")
CALL d.addTrigger("ON ACTION accept")
...
WHILE (t := d.nextEvent()) IS NOT NULL
```
Case t:
WHEN "ON ACTION cancel"
    LET int_flag = TRUE
    EXIT WHILE
WHEN "ON ACTION accept"
    CALL d.accept()
WHEN "AFTER INPUT"
    EXIT WHILE
END CASE
END WHILE

Terminating the dialog

Some synchronization code needs to be implemented to properly destroy the dynamic dialog.

A dialog needs to be destroyed before closing its corresponding window/form.

In order to terminate a dialog, call the close() dialog method and assign NULL to the ui.Dialog variable referencing the dialog object. This will close the dialog and destroy the corresponding object, if no other variables references it.

When the dialog object is terminated, the corresponding window can also be closed:

```
... WHEN "ON ACTION cancel"
    EXIT WHILE
END WHILE
CALL d.close()
LET d = NULL
CLOSE WINDOW w1
```

Dynamic multiple dialog

Dynamic dialogs allows to create the equivalent of a DIALOG procedural dialog.

Steps to implement a dynamic multiple dialog

The order in which dialog methods are called defines the structure of the dynamic multiple dialog.

To build a dynamic multiple dialog:

1. Create the multiple dialog with createMultipleDialog().
2. Add global dialog triggers with addTrigger().
3. Define the fields for a sub-dialog with a DYNAMIC ARRAY OF RECORD with name and type members.
4. Add the sub-dialog with one of the following methods:
   - addConstructByName()
   - addDisplayArrayTo()
   - addInputArrayFrom()
   - addInputByName()
5. Add sub-dialog triggers with addTrigger(). When calling this method after a sub-dialog item is added, it will create the trigger in the sub-dialog context.
6. Implement the WHILE loop using the nextEvent() method, as for a simple dynamic dialog. However, sub-dialog triggers must be identified with the sub-dialog name.

Identifying global and sub-dialog actions

Sub-dialog actions are added with addTrigger("ON ACTION action-name") in the context of a sub-dialog definition, after calling a method such as addDisplayArrayTo().
In the even loop, the `nextEvent()` method returns sub-dialog actions events with the sub-dialog name prefix, using the "ON ACTION sub-dialog-name.action-name" text form:

```
... 
CALL d.addDisplayArrayTo(, "sr_cust")
CALL d.addTrigger("ON ACTION refresh")
... 
WHILE (t := d.nextEvent()) IS NOT NULL 
  CASE t 
    ...
    WHEN "ON ACTION sr_cust.refresh"
    ...
```

**Identifying sub-dialog triggers**

Sub-dialog triggers such as BEFORE DISPLAY, BEFORE INPUT can be identified in the event loop with the sub-dialog identifier: The `nextEvent()` method returns the event text in the form "trigger-name sub-dialog-name".

For example, when you define the DISPLAY ARRAY-style sub-dialog with the screen record name "sr_cust", the trigger "BEFORE DISPLAY sr_cust" will be generated when the sr_cust list gets the focus (as in a static DIALOG / END DIALOG multiple dialog block):

```
... 
CALL d.addDisplayArrayTo(, "sc_cust")
... 
CALL d.addDisplayArrayTo(, "sc_prod")
... 
WHILE (t := d.nextEvent()) IS NOT NULL 
  CASE t 
    ...
    WHEN "BEFORE DISPLAY sc_cust"
    ...
    WHEN "AFTER DISPLAY sc_cust"
    ...
    WHEN "BEFORE DISPLAY sc_prod"
    ...
    WHEN "AFTER DISPLAY sc_prod"
    ...
```

**Example**

The next example defines a dynamic multiple dialog with a DISPLAY ARRAY and a CONSTRUCT BY NAME sub-dialogs, and adds ON ACTION triggers at global and sub-dialog levels:

```
TYPE t_fields DYNAMIC ARRAY OF RECORD
  name STRING,
  type STRING
END RECORD
DEFINE d ui.Dialog,
list_fields t_fields,
qbe_fields t_fields
... 
OPEN WINDOW w1 WITH FORM "myform"
... 
LET d = ui.Dialog.createMultipleDialog()
-- add global triggers
CALL d.addTrigger("ON ACTION accept")
CALL d.addTrigger("ON ACTION cancel")
... 
-- Add a DISPLAY ARRAY sub-dialog with name "sr_cust" (screen array)
```
CALL d.addDisplayArrayTo(list_fields, "sr_cust")
CALL d.addTrigger("ON ACTION refresh")
...
-- Add CONSTRUCT BY NAME sub-dialog with name "qr_cust"
CALL d.addConstructByName(gbe_fields, "qr_cust")
CALL d.addTrigger("ON ACTION query")
...
WHILE (t := d.nextEvent()) IS NOT NULL
CASE t
  ...
  WHEN "ON ACTION sr_cust.refresh"
    CALL refresh_list(d)
  ...
  WHEN "ON ACTION qr_cust.query"
    CALL exec_query(d)
  ...
  WHEN "ON ACTION accept"
    CALL d.accept()
  WHEN "ON ACTION close"
    EXIT WHILE
  WHEN "AFTER DIALOG" -- after d.accept()
    EXIT WHILE
END CASE
END WHILE
CALL d.close()
LET d = NULL
CLOSE WINDOW w1

Related concepts
Sub-dialog actions in procedural DIALOG blocks  on page 1668
This topic describes how action are differentiated with handlers defined in a procedural DIALOG block.

Using dynamic cursors
Implementing a dynamic dialog based on the database schema.
To write generic code accessing a database, implement the dynamic dialog with field names and types coming from a base.SqlHandle cursor.
The next code example builds a list of fields based on the database table passed as first parameter.
The function scans the result set column names and types of the base.SqlHandle cursor, to build the list of field definitions, that can then be used for the dynamic dialog creation:

FUNCTION build_field_list(dbtable, fields)
  DEFINE dbtable STRING,
       fields DYNAMIC ARRAY OF RECORD
       name STRING,
       type STRING
       END RECORD
  DEFINE h base.SqlHandle,
       i INT

  LET h = base.SqlHandle.create()
  CALL h.prepare("SELECT * FROM " || dbtable)
  CALL h.open()
  CALL h.fetch()
  CALL fields.clear()
  FOR i=1 TO h.getResultCount()
    LET fields[i].name = h.getResultName(i)
    LET fields[i].type = h.getResultType(i)
  END FOR
END FUNCTION
Additional features
Miscellaneous features of dynamic dialogs.

Defining cell attributes
In order to display array cells with colors in a list controlled by a dynamic dialog, you can define a two-dimensional dynamic array to hold cell attributes:

```plaintext
DEFINE attrs DYNAMIC ARRAY OF DIMENSION 2 OF STRING
...
LET attrs[row,col] = "red reverse"
...
CALL d.setArrayAttributes("custlist", attrs)
```

Note: If all cells of the array must get the same display attributes, use a simple DYNAMIC ARRAY OF STRING.

Canvases
Canvases are form drawing areas.

- Understanding canvases on page 1912
- CANVAS item definition on page 1225
- Syntax of canvas nodes on page 1913
- Canvas drawing area on page 1915
- Canvas drawing functions on page 1915
- Examples on page 1916
  - Example 1: Simple canvas on page 1916

Understanding canvases
This is an introduction to CANVAS drawing.

A canvas element defines a drawing area in a form, to show basic colored shapes.

Important: This feature is not supported on mobile platforms.

Canvas can draw lines, rectangles, ovals, circles, texts, arcs, and polygons. Keys can be bound to graphical elements for selection with a right or left mouse click.

In programs, you select a given canvas area by name and you create the shapes in the abstract user interface tree by using the built-in DOM API, or helper functions.

The painted canvas is automatically displayed on the front end when an interactive instruction is executed, such as MENU or INPUT.

Each canvas element is identified by a unique number (id). You can use this identifier to bind mouse clicks to canvas elements.

Note: Consider using Web Components for specific drawing needs (charts, graphics).

Related concepts
CANVAS item definition on page 1225
The CANVAS form item defines an area in which you can draw shapes, in a grid-based layout.

User interface basics on page 1008
This section introduces to the foundation of the Genero user interface.

**CANVAS item definition**
The CANVAS form item defines an area in which you can draw shapes, in a grid-based layout.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```
CANVAS item-tag: item-name [, attribute-list ] ;
```

1. `item-tag` is an identifier that defines the name of the item tag in the layout section.
2. `item-name` identifies the form item.
3. `attribute-list` defines the aspect and behavior of the form item.

**Attributes**

`COMMENT`, `HIDDEN`, `TAG`.

**Usage**

Define the rendering and behavior of a canvas drawing area item tag, with a `CANVAS` element in the `ATTRIBUTES` section.

**Note:** The CANVAS feature is deprecated, consider using the built-in fglsvgcanvas `WEBCOMPONENT`.

**Example**

```
LAYOUT
GRID
{  [cvs1]  
  [     ]  
  ...  
}
END
END

ATTRIBUTES
CANVAS cvs1: canvas1; ... 
```

**Related concepts**

Canvases on page 1912
Canvases are form drawing areas.

**Syntax of canvas nodes**
The AUI tree contains the XML representation of the canvas, with a variety of elements defining shapes.

Canvas areas are defined in forms with the following XML syntax:

```
<Canvas colName="name" >
  | <CanvasArc canvasitem-attribute="value" [...] /> 
  | <CanvasCircle canvasitem-attribute="value"[...] /> 
  | <CanvasLine canvasitem-attribute="value"[...] /> 
  | <CanvasOval canvasitem-attribute="value"[...] /> 
  | <CanvasPolygon canvasitem-attribute="value"[...] /> 
  | <CanvasRectangle canvasitem-attribute="value"[...] /> 
  | <CanvasText canvasitem-attribute="value"[...] /> 
```

Table 371: Types of canvas element

<table>

</tbody>
</table>

**Canvas drawing area**

The canvas area defines a two-dimensional coordinate system to draw elements.

The canvas area represents an abstract drawing page where you define size and location of shapes with coordinates from (0,0) to (1000,1000).

The origin point (0,0), is on the left-bottom of the drawing area.

**Figure 111: Canvas area diagram**

The drawing area is defined in the form file with a `CANVAS` form item. At runtime, you draw the content of canvas areas in the Abstract User Interface tree: In a form defining canvas areas, the Abstract User Interface tree contains empty `<Canvas>` nodes that you can fill with canvas items.

A canvas node is identified in the program by the `name` attribute. You can get the canvas node by name with the `Window.getElement(name)` method.

You cannot drop canvas area nodes, as they are read-only in a form definition.

**Related concepts**

- [CANVAS item definition](#)

The `CANVAS` form item defines an area in which you can draw shapes, in a grid-based layout.

**Canvas drawing functions**

This table describes the helper functions provided to ease canvas usage. Use these functions or use the DOM API to directly create canvas elements in the form. The helper functions are implemented in `FGLDIR/src/fgldraw.4gl`. See the source file for more details.
### Table 373: CANVAS Built-in functions provided for backward compatibility with version 3

<table>
<thead>

<tr>
<td><code>drawButtonRight()</code></td>
<td>Enables right mouse click on a canvas element.</td>
</tr>
<tr>
<td><code>drawClearButton()</code></td>
<td>Disables all mouse clicks on a canvas element.</td>
</tr>
<tr>
<td><code>drawGetClickedItemId()</code></td>
<td>Returns the id of the last clicked canvas element.</td>
</tr>
</tbody>
</table>

### Examples

Canvas usage examples.

**Example 1: Simple canvas**

This topic describes the steps to draw elements in a canvas.

First define a drawing area in the form file with the CANVAS form item type. In this example, the name of the canvas field is 'canvas01'. This field name identifies the drawing area:

```
DATABASE FORMONLY
LAYOUT
GRID
{
    Canvas example:
    [ca01             ]
    [                ]
    [                ]
    [                ]
    [                ]
    [                ]
}
END
```
In programs, you draw canvas shapes by creating canvas nodes in the abstract user interface tree with the DOM API utilities.

Define a variable to hold the DOM node of the canvas and a second to handle children created for shapes:

```plaintext
DEFINE c, s om.DomNode
```

Define a window object variable; open a window with the form containing the canvas area; get the current window object, and then get the canvas DOM node:

```plaintext
DEFINE w ui.Window
OPEN WINDOW w1 WITH FORM "form1"
LET w = ui.Window.getCurrent()
LET c = w.findNode("Canvas","canvas01")
```

Create a child node with a specific type defining the shape:

```plaintext
LET s = c.createChild("CanvasRectangle")
```

Set attributes to complete the shape definition:

```plaintext
CALL s.setAttribute( "fillColor", "red" )
CALL s.setAttribute( "startX", 10 )
CALL s.setAttribute( "startY", 20 )
CALL s.setAttribute( "endX", 100 )
CALL s.setAttribute( "endY", 150 )
```

It is possible to bind keys / actions to Canvas items in order to let the end user select elements with a mouse click. You can assign a function key for left-button mouse clicks with the `acceleratorKey1` attribute, while `acceleratorKey3` is used to detect right-button mouse clicks. The function keys you can bind are F1 to F255. If the user clicks on a Canvas item bound to key actions, the corresponding action handler will be executed in the current dialog. Several canvas items can be bound to the same action keys; In order to identify what items have been selected by a mouse click, you can use the `drawGetClickedItemId()` function of `fgldraw.4gl`. This method will return the AUI tree node id of the Canvas items that was selected (i.e. `s.getId()`).

```plaintext
... Create the Canvas item with s node variable ... 
CALL s.setAttribute( "acceleratorKey1", "F50" )
MENU "test"
   COMMAND KEY (F50)
   IF drawGetClickedItemId() = s.getId() THEN
     ... 
   END IF
... 
END MENU
```

To clear a given shape in the canvas, remove the element in the canvas node:

```plaintext
CALL c.removeChild(s)
```

To clear the drawing area completely, remove all children of the canvas node:

```plaintext
LET s=c.getFirstChild()
WHILE s IS NOT NULL
   CALL c.removeChild(s)
   LET s=c.getFirstChild()
```

- Creating the start menu dynamically on page 1920
- Examples on page 1921
  - Example 1: Start menu in XML format on page 1921
  - Example 2: Start menu created dynamically on page 1921

Understanding start menus
This is an introduction to start menus.

The start menu defines a tree of commands that start programs on the application server where the runtime system executes.

Important: This feature is not supported on mobile platforms.

It is recommended that you create a specific program dedicated to running the start menu. This program must create (or load) a start menu, and then perform an interactive instruction to enter the interaction loop.

The start menu must be defined in the abstract user interface tree under the "UserInterface" root node.

The start menu is unique for a program and cannot be redefined.

When a start menu command is selected by the user, the runtime system automatically starts a child process with the command specified in the command attribute.

Related concepts
The abstract user interface tree on page 1010
The abstract user interface tree is the XML representation of the application forms displayed to the end user.

Syntax of start menu files (.4sm)
A start menu file contains a tree of XML elements defining the application menu to start programs.

Start menus are defined in a .4sm file with the following XML syntax:

```
<StartMenu [startmenu-attribute="value"[...]] >
  group[...]
</StartMenu>
```

where `group` is:

```
<StartMenuGroup group-attribute="value">
  [ ... ]
  <StartMenuSeparator/>
  [ ... ]
</StartMenuGroup>
```

1. `startmenu-attribute` defines a property of the StartMenu.
2. `command-attribute` defines a property of a StartMenuCommand.
3. *group-attribute* defines a property of a `StartMenuGroup`.

</tbody>
</table>

Loading a start menu from an XML file

Start menu XML definition files can be loaded at runtime.

To load a start menu definition file, use the utility method provided by the `ui.Interface` built-in class:

```
CALL ui.Interface.loadStartMenu("standard")
```

Related concepts

`ui.Interface.loadStartMenu` on page 2339

Load the start menu file.

Creating the start menu dynamically

Start menu can be created dynamically with the `om.DomNode` class.

First, get the abstract user interface root node:

```
DEFINE aui om.DomNode
LET aui = ui.Interface.getRootNode()
```

Next, create a node with the "StartMenu" tag name:

```
DEFINE sm om.DomNode
LET sm = aui.createChild("StartMenu")
```

Next, create a "StartMenuGroup" node to group a couple of command nodes:

```
DEFINE smg om.DomNode
LET smg = sm.createChild("StartMenuGroup")
CALL smg.setAttribute("text","Programs")
```

Then, create "StartMenuCommand" nodes for each program and, if needed, add "StartMenuSeparator" nodes to separate entries:

```
DEFINE smc, sms om.DomNode
LET smc = smg.createChild("StartMenuCommand")
CALL smc.setAttribute("text","Orders")
CALL smc.setAttribute("exec","fglrun orders.42r")
LET smc = smg.createChild("StartMenuCommand")
CALL smc.setAttribute("text","Customers")
CALL smc.setAttribute("exec","fglrun customers.42r")
LET sms = smg.createChild("StartMenuSeparator")
LET smc = smg.createChild("StartMenuCommand")
LET smc = sms.createChild("StartMenuCommand")
CALL smc.setAttribute("text","Items")
CALL smc.setAttribute("exec","fglrun items.42r")
```

Related concepts

    RETURN s
END FUNCTION

Window containers (WCI)

WCI containers define window containers to group several programs in a parent multiple document interface presentation.

- Understanding the Window Container Interface on page 1922
- Configuration of WCI parent programs on page 1922
- Configuration of WCI child programs on page 1923
- Implement tabbed WCI containers on page 1924

Understanding the Window Container Interface

This is an introduction to WCI programming.

By default, application windows are displayed independently in separate windows on the front-end window manager. This mode is known as SDI, "Single Document Interface".

The user interface can be configured to group program windows in a parent container. This is known as MDI, "Multiple Document Interface". In Genero, Multiple Document Interface is called WCI: Window Container Interface.

Important: The Window Container Interface is a desktop application feature (for GDC), and is not supported on other front-ends (web and mobile).

The WCI can be used to group several programs together in a parent window. The parent program is the container for the other programs, defined as children of the container. The container program can have its own windows, but this makes sense only for temporary modal windows (with style="dialog").

WCI configuration is done dynamically at the beginning of programs, with methods of the \texttt{ui.Interface} built-in class.

Related concepts

Windows and forms on page 1032
The section describes the concept of windows and forms in the language.

Configuration of WCI parent programs

Programs acting as parent WCI containers must perform WCI configuration calls when they start.

Important: The Window Container Interface is a desktop application feature (for GDC), and is not supported on other front-ends (web and mobile).

The WCI container program is a separate program of a special type, dedicated to contain other program windows. On the front-end, container programs automatically display a parent window that will hold all child program windows that will attach to the container.

The WCI container program must indicate that its type is special (\texttt{ui.Interface.setType()} method), and must identify itself (\texttt{ui.Interface.setName()} method):

\begin{verbatim}
MAIN
    CALL ui.Interface.setName("parent1")
    CALL ui.Interface.setType("container")
    CALL ui.Interface.setText("SoftStore Manager")
    CALL ui.Interface.setSize("600px","1000px")
\end{verbatim}
You can define the initial size of the parent container window with the `ui.interface.setSize(height,width)` method.

When the program is identified as a container, a global window is automatically displayed as an container window. The default toolbar and the default topmenu are displayed and a startmenu can be used. Other windows created by this kind of program can be displayed, inside the container (windowType="normal") or as dialog windows (windowType="modal"). Window styles can be applied to the parent window by using the default style specification (name="Window.main").

**Related concepts**
- The **Interface class** on page 2328
  The `ui.Interface` class provides methods to manipulate the user interface.
- **Toolbars** on page 1327
  Toolbars define a bar of buttons that appears at the top of application forms.
- **Topmenus** on page 1334
  Topmenus define typical pull-down menus that appear at the top of application forms.
- **Start menus** on page 1918
  Start menus define a tree of application programs that can be started.

**Configuration of WCI child programs**
WCI child programs attach to a parent container by defining the WCI container name.

**Important:** The Window Container Interface is a desktop application feature (for GDC), and is not supported on other front-ends (web and mobile).

WCI children programs must attach to a parent container by giving the name of the container program:

```plaintext
MAIN
    CALL ui.Interface.setName("custapp")
    CALL ui.Interface.setType("child")
    CALL ui.Interface.setText("Customers")
    CALL ui.Interface.setContainer("parent1")
    ...
END MAIN
```

Multiple container programs can be used to group programs by application modules.

The client displays a system error and the programs stops when:

- A child program is started, but the parent container is not
- A container program is started twice

When the parent container program is stopped, other applications are automatically stopped by the front-end. This will result in a runtime error -6313 on the application server side. To avoid this, ensure that there are no more running child programs before terminating the parent container program. The WCI container program can query for the existence of children with the `ui.Interface.getChildCount()` and `ui.Interface.getChildInstances()` methods:

```plaintext
MAIN
    CALL ui.Interface.setName("parent1")
    CALL ui.Interface.setType("container")
    CALL ui.Interface.setText("SoftStore Manager")
```
CALL ui.Interface.setSize("600px","1000px")
CALL ui.Interface.loadStartMenu("mystartmenu")

MENU "Main"
  COMMAND "Help" CALL help()
  COMMAND "About" CALL aboutbox()
  COMMAND "Exit"
    IF ui.Interface.getChildCount()>0 THEN
      ERROR "You must first exit the child programs."
    ELSE
      EXIT MENU
    END IF
END MENU
END MAIN

Related concepts

The `ui.Interface` class provides methods to manipulate the user interface.

Implement tabbed WCI containers
WCI container can display child programs in a folder tab.

Important: The Window Container Interface is a desktop application feature (for GDC), and is not supported on other front-ends (web and mobile).

To display the child programs in a folder tab, define the presentation style attribute `tabbedContainer` to `yes`.

With a tabbed window container, the style attribute `tabbedContainerCloseMethod` defines how to close the current page.

Values can be:
- "container" (default), the container has a close button on the top right corner, which closes the current tab.
- "page", each page has its own close button.
- "both", each page and the container have a close button.
- "none", no close button is shown.

The close button is enabled depending on the window style attribute.

Understanding reports

A report can arrange and format the data depending on the instructions used and display the output on the screen, send it to a printer, or store it as a file for future use.

To implement a report, a program must include two distinct components:

- The report driver specifies what data the report includes.
- The report routine formats the data for output.

The report driver retrieves the specified rows from a database, stores their values in program variables, and sends these - one input record at a time - to the report routine. After the last input record is received and formatted, the runtime system calculates any aggregate values based on all the data and sends the entire report to some output device.

Figure 112: Report driver and database cursor

By separating the two tasks of data retrieval and data formatting, the runtime system simplifies the production of recurrent reports and makes it easy to apply the same report format to different data sets.

The report engine supports the following features:

- The option to display report output to the screen, to a printer, to a file or to a SAX handler to transform the output following XML standards. When using the GDC, it is possible to send to report to the local printer configured in GDC, by setting the DBPRINT environment variable to the value "FGLSERVER".
- Full control over page layout, including first page header and generic page headers, page trailers, columnar presentation, and row grouping.
- Facilities for creating the report either from the rows returned by a cursor or from input records assembled from any other source, such as output from several different SELECT statements through the report driver.
- Control blocks to manipulate data from a database cursor on a row-by-row basis, either before or after the row is formatted by the report.
- Aggregate functions that can calculate frequencies, percentages, sums, averages, minimum, and maximum values.
- The USING operator and other built-in functions and operators for formatting and displaying information in output from the report.
- The WORDWRAP operator to format long character strings that occupy multiple lines of output from the report.
- The option to execute other language statements while generating a report.
- Stopping a report in the report definition code, with EXIT REPORT or TERMINATE REPORT.
The report engine supports one-pass reports and two-pass reports. The one-pass requires sorted data to be produced by the report driver in order to handle row grouping with the BEFORE GROUP / AFTER GROUP blocks. The two-pass record handles sort automatically and does not need sorted data from the report driver. During the first pass, the report engine sorts the data and stores the sorted values in a temporary file in the database. During the second pass, it calculates any aggregate values and produces output from data in the temporary files.

**Related concepts**

- XML output for reports on page 1926
  - For better integration with external tools based on XML standards, reports can produce XML output.

### XML output for reports

For better integration with external tools based on XML standards, reports can produce XML output.

The purpose of XML-based reports is to sort and group data, not to decorate. Data decoration and formatting can be done by external tools, or you can redirect the XML report output to a SAX document handler object to process the output and generate for example HTML pages.

- Writing an XML report driver and routine on page 1926
- Structure of XML report output on page 1927
- Conditional statements in XML output on page 1928

### Writing an XML report driver and routine

#### Generating XML output

To produce an XML report, initiate the report with the **START REPORT** instruction followed by the **TO XML HANDLER** clause, to specify the SAX document handler that will process the XML report output:

```
START REPORT order_report
    TO XML HANDLER om.XmlWriter.createFileWriter("orders.xml")
```

In the report routine, you must use the **PRINTX** statement to general XML output:

```
REPORT order_report(rec)
    ...
    FORMAT
        ON EVERY ROW
            PRINTX NAME = order rec.*
    ...
END REPORT
```

The PRINTX instruction takes an optional **NAME** argument to define the name of the XML node.

#### Nested XML reports

If a new report is started with **START REPORT** instruction inside a REPORT routine producing XML, and if there is no destination specified in the **START REPORT** instruction, the sub-report inherits the XML output target of the parent, and sub-report nodes will be merged into the parent XML output:

```
REPORT order_report(rec)
    ...
```
FORMAT
ON EVERY ROW
  PRINTX NAME = order rec.*
  -- Merges sub-report output to parent report XML handler
  START REPORT sub_report
  FOR ...
    OUTPUT TO REPORT sub_report(
    END FOR
  FINISH REPORT sub_report
...
END REPORT

API for global XML handler

The fgl_report_set_document_handler() built-in function can be used to specify a general XML handler, for START REPORT instructions which do not use the TO XML HANDLER clause:

MAIN
...
  CALL
  fgl_report_set_document_handler( om.XmlWriter.createFileWriter("orders.xml") )
  ...
  START REPORT order_report -- Produces XML output to "orders.xml"
  ...
END MAIN

Note: The fgl_report_set_document_handler() function is supported for backward compatibility, it is recommended to use START REPORT ... TO XML HANDLER instead.

Related concepts
The SaxDocumentHandler class on page 2467
The om.SaxDocumentHandler class provides an interface to write an XML filter with events.

Structure of XML report output

The generated XML output contains the structure of the formatted pages, with page header, page trailer and group sections.

Every PRINTX instruction will generate a <Print> node with a list of <Item> nodes containing the data. The XML processor can use this structure to format and render the output as needed.

The output of an XML report will have the following node structure:

<Report ...>
  <PageHeader pageNo="...">
    ...
  </PageHeader>
  <Group>
    <BeforeGroup>
      <Print name="...">
        <Item name="..." type="..." value="..." isoValue="..." />
        <Item name="..." type="..." value="..." isoValue="..." />
        ...
      </Print>
    ...
    </BeforeGroup>
    <OnEveryRow>
      <Print name="...">
        <Item name="..." type="..." value="..." isoValue="..." />
        <Item name="..." type="..." value="..." isoValue="..." />
      ...
      </Print>
    </OnEveryRow>
  </Group>
</Report>
Related concepts

START REPORT on page 1933

The START REPORT instruction initializes a report execution.

Conditional statements in XML output

Principle

If PRINTX commands are used inside program flow control instructions like IF, CASE, FOR, FOREACH and WHILE, the XML output will contain additional nodes to identify such conditional print instructions.

That information can be useful to process an XML report output.

FOR ... END FOR

```xml
<For>
  <ForItem>
    <Print name="...">
      <Item name="..." type="..." value="..." isoValue="..." />
    </Print>
    ...
  </ForItem>
  ...
</For>
```

WHILE ... END WHILE

```xml
<While>
  <WhileItem>
    <Print name="...">
      <Item name="..." type="..." value="..." isoValue="..." />
    </Print>
    ...
  </WhileItem>
  ...
</While>
```
FOREACH ... END FOREACH

```xml
<Foreach>
  <ForeachItem>
    <Print name="...">
      <Item name="..." type="..." value="..." isoValue="..." />
    </Print>
    ...
  </ForeachItem>
  ...
</Foreach>
```

CASE ... END CASE

```xml
<Case>
  <When id="position">
    <Print name="...">
      <Item name="..." type="..." value="..." isoValue="..." />
    </Print>
    ...
  </When>
  ...
</Case>
```

IF ... THEN ... ELSE ... END IF

```xml
<If>
  <IfThen>
    <Print name="...">
      <Item name="..." type="..." value="..." isoValue="..." />
    </Print>
    ...
  </IfThen>
  <IfElse>
    <Print name="...">
      <Item name="..." type="..." value="..." isoValue="..." />
    </Print>
    ...
  </IfElse>
</If>
```

Examples

**Example 1: Nested XML report**

The next code example produces XML output from a main and sub-report:

```c
TYPE t_cust RECORD
  cust_id INTEGER,
  cust_name VARCHAR(30)
END RECORD

TYPE t_ord RECORD
  ord_id INTEGER,
  ord_cust INTEGER,
  ord_date DATE
END RECORD

MAIN
  CALL create_database()
```
CALL run_cust_report()
END MAIN

FUNCTION create_database()

    </OnEveryRow>
  </OnEveryRow>
</Report>
Related concepts

START REPORT on page 1933
The START REPORT instruction initializes a report execution.

The report driver

The report driver retrieves data, starts the report engine and sends the data (as input records) to be formatted by the REPORT routine.

Usage

A report driver can be part of the MAIN program block, or it can be in one or more functions.

The report driver typically consists of a loop (such as WHILE, FOR, or FOREACH) with the following statements to process the report:

Table 378: Report driver statements

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START REPORT</td>
<td>This statement is required to instantiate the report driver.</td>
</tr>
<tr>
<td>OUTPUT TO REPORT</td>
<td>Provide data for one row to the report driver.</td>
</tr>
<tr>
<td>FINISH REPORT</td>
<td>Normal termination of the report.</td>
</tr>
<tr>
<td>TERMINATE REPORT</td>
<td>Cancels the processing of the report.</td>
</tr>
</tbody>
</table>

A report driver is started by the START REPORT instruction. Once started, data can be provided to the report driver through the OUTPUT TO REPORT statement. To instruct the report engine to terminate output processing, use the FINISH REPORT instruction. To cancel a report from outside the report routine, use TERMINATE REPORT (from inside the report routine, you cancel the report with EXIT REPORT).

In order to handler report interruption, the report driver can check if the INT_FLAG variable is TRUE to stop the loop when the user asked to interrupt the report execution.

It is possible to execute several report drivers at the same time. It is even possible to invoke a report driver inside a REPORT routine, which is different from the current driver.

The programmer must make sure that the runtime system will always execute these instructions in the following order:

1. START REPORT
2. OUTPUT TO REPORT
3. FINISH REPORT
Example

```
SCHEMA stores7
MAIN
  DEFINE rcust RECORD LIKE customer.*
  DATABASE stores7
  DECLARE cul CURSOR FOR SELECT * FROM customer
  LET int_flag = FALSE
  START REPORT myrep
    FOREACH cul INTO rcust.*
      IF int_flag THEN EXIT FOREACH END IF
      OUTPUT TO REPORT myrep(rcust.*)
    END FOREACH
  IF int_flag THEN
    TERMINATE REPORT myrep
  ELSE
    FINISH REPORT myrep
  END IF
END MAIN
```

Related concepts

**INT_FLAG** on page 518

INT_FLAG is a predefined variable set to TRUE when an interruption event is detected.

**START REPORT**

The START REPORT instruction initializes a report execution.

**Syntax**

```
START REPORT report-routine
  [ TO to-clause ]
  [ WITH dimension-option [, ...] ]
```

where **to-clause** is one of:

```
| SCREEN             |
| PRINTER            |
| [FILE] filename    |
| PIPE program       |
| IN FORM MODE       |
| IN LINE MODE       |
| XML HANDLER sax-handler-object |
| OUTPUT destination-expr DESTINATION [ program | filename ] |
```

where **dimension-option** is one of:

```
| LEFT MARGIN = m-left    |
| RIGHT MARGIN = m-right  |
| TOP MARGIN = m-top      |
| BOTTOM MARGIN = m-bottom|
| PAGE LENGTH = m-length  |
| TOP OF PAGE = c-top     |
```

1. **report-routine** is the name of the REPORT routine.
2. **filename** is a string expression specifying the file that receives report output.
3. **program** is a string expression specifying a program, a shell script, or a command line to receive report output.
4. **destination-expr** is a string expression that specifies one of: SCREEN, PRINTER, FILE, PIPE, PIPE IN LINE MODE, PIPE IN FORM MODE.
5. **sax-handler-object** is a variable referencing an om.SaxDocumentHandler instance.
6. *m-left* is the left margin in number of characters. The default is 5.
7. *m-right* is the right margin in number of characters. The default is 132.
8. *m-top* is the top margin in number of lines. The default is 3.
9. *m-bottom* is the bottom margin in number of lines. The default is 3.
10. *m-length* is the total number of lines on a report page. The default page length is 66 lines.
11. *c-top* is a string that defines the page-eject character sequence.

**Usage**

The **START REPORT** statement initializes a report. The instruction allows you to specify the report output destination and the page dimensions and margins.

**START REPORT** typically precedes a loop instruction such as **FOR**, **FOREACH**, or **WHILE** in which **OUTPUT TO REPORT** feeds the report routine with data. After the loop terminates, **FINISH REPORT** completes the processing of the output.

```sql
DEFINE file_name VARCHAR(200), page_size INTEGER
...
START REPORT myrep
   TO FILE file_name
   WITH PAGE LENGTH = page_size
```

If a **START REPORT** statement references a report that is already running, the report is re-initialized; any output might be unpredictable.

**Output specification**

The **TO** clause can be used to specify a destination for output. If you omit the **TO** clause, the Genero runtime system sends report output to the destination specified in the report routine definition. If the report routine does not define an **OUTPUT** clause, the report output is sent by default to the report viewer when in GUI mode, or to the screen when in TUI mode.

Report output can be specified dynamically as follows:

- The **TO FILE** option can specify the *filename* as a character variable that is assigned at runtime.
- The **TO PIPE** option can specify the *program* as a character variable that is assigned at runtime.
- The **TO OUTPUT** option can specify the report output with a string expression, described later in detail.

The **SCREEN** option specifies that output is to the report window. The way the report is displayed to the end user depends on whether you are in TUI mode or GUI mode. In TUI mode, the report output displays to the terminal screen. In GUI mode, the report output displays in a dedicated pop-up window called the Report Viewer. When using **REPORT TO SCREEN** in TUI mode, set a **PAGE LENGTH** no larger than the terminal can display, and include **PAUSE** statements in the **FORMAT** section, to let the end user see the output on the screen.

The **PRINTER** option instructs the runtime system to output the report to the device or program defined by the **DBPRINT** environment variable.

When using the **TO PRINTER** clause, if the **DBPRINT** environment variable is set to the value "FGLSERVER", the document is sent to the printer configured in the Genero Desktop Client (GDC).

When using the **FILE** option, you can specify a file name as the report destination. Output will be sent to the specified file. If the file exists, its content will be overwritten by the new report output. The **FILE** keyword is optional, but it's best to include it to make your code more readable.

The **PIPE** option defines a program, shell script, or command line to which the report output must be sent, using the standard input channel. When using the **TUI** mode, you can use the **IN [LINE|FORM] MODE** option to specify whether the program is in line mode or in formatted mode when report output is sent to a pipe.

The **TO OUTPUT** option allows you to specify one of the output options dynamically at runtime. The character string expression must be one of: "SCREEN", "PRINTER", "FILE", "PIPE", "PIPE IN LINE MODE", "PIPE
IN FORM MODE. If the expression specifies "FILE" or "PIPE", you can also specify a filename or program in a character variable following the DESTINATION keyword.

The XML HANDLER option indicates that the report output will be generated as XML and redirected to a SAX-document handler. When using XML output, the report result can be shown in the Genero Report Engine installed on the front-end workstation. See XML output for more details.

When START REPORT without a destination is used inside a REPORT routine producing XML, the sub-report inherits the XML output target of the parent, and sub-report nodes will be merged into the parent XML output.

Page dimensions specification

The WITH clause defines the dimensions of each report page and the left, top, right and bottom margins. The values corresponding to a margin and page length must be valid integer expressions. The margins can be defined in any order, but a comma "," is required to separate two page dimensions options.

- The LEFT MARGIN clause defines the number of blank spaces to include at the start of each new line of output. The default is 5.
- The RIGHT MARGIN clause defines the total number of characters in each line of output, including the left margin. If you omit this but specify FORMAT EVERY ROW, the default is 132.
- The TOP MARGIN clause specifies how many blank lines appear above the first line of text on each page of output. The default is 3.
- The BOTTOM MARGIN clause specifies how many blank lines follow the last line of output on each page. The default is 3.
- The PAGE LENGTH clause specifies the total number of lines on each page, including data, the margins, and any page headers or page trailers from the FORMAT section. The default page length is 66 lines.

In addition to the page dimension options, the TOP OF PAGE clause can specify a page-eject sequence for a printer. On some systems, specifying this value can reduce the time required for a large report to produce output, because SKIP TO TOP OF PAGE can substitute this value for multiple line feeds.

Tip: To produce reports with no page size limit, set margins to zero and use a page length of 1.

OUTPUT TO REPORT

The OUTPUT TO REPORT instruction provides a data row to the report execution.

Syntax

```
OUTPUT TO REPORT report-name ( parameters )
```

1. report-name is the name of the report to which the parameters are sent.
2. parameters is the data that needs to be sent to the report.
Usage

The OUTPUT TO REPORT instruction feeds the report routine with a single set of data values (called an input record), which corresponds usually to one printed line in the report output.

An input record is the ordered set of values returned by the expressions that you list between the parentheses following the report name in the OUTPUT TO REPORT statement. The specified values are passed to the report routine, as part of the input record. The input record typically corresponds to a retrieved row from the database.

The set of values is usually grouped in a RECORD variable and best practice is to define a user defined type (TYPE) in order to ease the variable definitions required in the code implementing the report driver and the report routine definition, for example:

```
SCHEMA stores
  TYPE t_cust RECORD LIKE customer.*
  ... DEFINE r_cust t_cust
  ... OUTPUT TO REPORT cust_report(r_cust.*)
  ... REPORT cust_report(r)
  DEFINE r t_cust
  ...
```

The OUTPUT TO REPORT statement is included within a WHILE on page 352, FOR on page 348, or FOREACH loop, so that the program passes data to the report one input record at a time. The example uses a FOREACH loop to fetch data from the database and pass it as input record to a report:

```
SCHEMA stores
  DEFINE o LIKE orders.*
  ...
  DECLARE order_c CURSOR FOR
    SELECT orders.*
    FROM orders ORDER BY ord_cust
    START REPORT order_list
  FOREACH order_c INTO o.*
    OUTPUT TO REPORT order_list(o.*)
  END FOREACH
  FINISH REPORT order_list
  ...
```

Special consideration is needed when using OUTPUT TO REPORT with row ordering. For example if the report groups rows with BEFORE GROUP OF or AFTER GROUP OF sections, the rows must be ordered by the column specified in these sections, preferably by the report driver to avoid two-pass reports.

If OUTPUT TO REPORT is not executed, none of the control blocks of the report routine are executed, even if the program also includes the START REPORT on page 1933 and FINISH REPORT on page 1937 statements.

The members of the input record that you specify in the expression list of the OUTPUT TO REPORT statement must correspond to elements of the formal argument list in the REPORT definition; in their number and their position. They must be also of compatible data types. At compile time, the number of parameters passed with the OUTPUT TO REPORT instruction is not checked against the DEFINE section in REPORT on page 1941 of the report routine. This is known behavior in the language.

Arguments of the TEXT and BYTE data types are passed by reference rather than by value; arguments of other data types are passed by value. A report can use the WORDWRAP on page 1961 operator with the PRINT on page 1952 statement to display TEXT values. A report cannot display BYTE values; the character string <byte value> in output from the report indicates a BYTE value.

FINISH REPORT
The FINISH REPORT instruction finalizes a report execution.

Syntax

```
FINISH REPORT report-name
```

1. `report-name` is the name of the report to be ended.

Usage

FINISH REPORT closes the report driver. Therefore, it must be the last statement in the report driver and must follow a START REPORT statement that specifies the name of the same report.

FINISH REPORT must be the last statement in the report driver.

FINISH REPORT does the following:

1. Completes the second pass, if report is a two-pass report. These 'second pass' activities handle the calculation and output of any aggregate values that are based on all the input records in the report, such as COUNT (*) or PERCENT (*) with no GROUP qualifier.
2. Executes any AFTER GROUP OF control blocks.
3. Executes any PAGE HEADER, ON LAST ROW, and PAGE TRAILER control blocks to complete the report.
4. Copies data from the output buffers of the report to the destination.
5. Closes the Select cursor on any temporary table that was created to order the input records or to perform aggregate calculations.

Related concepts

TERMINATE REPORT on page 1937
The TERMINATE REPORT instruction cancels a report execution.

EXIT REPORT on page 1952
Cancels the report processing.

Two-pass reports on page 1951
The report engine supports two-pass reports, to order rows automatically.

TERMINATE REPORT
The TERMINATE REPORT instruction cancels a report execution.

Syntax

```
TERMINATE REPORT report-name
```
1. `report-name` is the name of the report to be canceled.

**Usage**

`TERMINATE REPORT` cancels the report processing. It is typically used when the program (or the user) becomes aware that a problem prevents the report from producing part of its intended output, or when the user interrupted the report processing.

`TERMINATE REPORT` has the following effects:

- Terminates the processing of the current report.
- Deletes any intermediate files or temporary tables that were created in processing the report.

The `EXIT REPORT` instruction has the same effect, except that it can be used inside the report definition.

**Related concepts**

- **EXIT REPORT** on page 1952
  - Cancels the report processing.

---

**The report routine**

The *report routine* implements the body of a report, with formatting instructions.

**Syntax 1 (legacy syntax):**

```plaintext
[PUBLIC|PRIVATE] REPORT report-name ( parameter-name [, ...] )
  ↓ define-section ↓
  ↓ output-section ↓
  ↓ sort-section ↓
  ↓ format-section ↓
END REPORT
```

**Syntax 2 (full typed):**

```plaintext
[PUBLIC|PRIVATE] REPORT report-name ( parameter-name data-type
  ↓ Attributes ( attribute ↓ = "value" ↓ [, ...] ) ↓
  ↓ define-section ↓
  ↓ output-section ↓
  ↓ sort-section ↓
  ↓ format-section ↓
END REPORT
```

where `define-section` is:

```plaintext
DEFINE variable-definition [, ...]
```

where `output-section` is:

```plaintext
OUTPUT
  ↓ REPORT TO
  ↓ SCREEN
```
variable-definition follows the DEFINE instruction syntax and declares report-variables.
2. report-variable is the name of a variable declared in the DEFINE section.
3. report-only-fgl-statement is a subset of all the regular language statements.
4. sql-statement is a valid static SQL statement.

Usage

The report definition formats input records. Like the FUNCTION or MAIN statement, it is a program block that can be the scope of local variables. It is not, however, a function; it is not reentrant, and CALL cannot invoke it. The report definition receives data from its driver in sets called input records. These records can include program records, but other data types are also supported. Each input record is formatted and printed as specified by control blocks and statements within the report definition. Most statements and functions can be included in a report definition, and certain specialized statements and operators for formatting output can appear only in a report definition.

Like MAIN or FUNCTION, the report definition must appear outside any other program block. It must begin with the REPORT statement and must end with the END REPORT keywords.
Some statements are prohibited in a REPORT routine control block. For example, it is not possible to use CONSTRUCT, INPUT, DEFER, DEFINE, REPORT, RETURN instructions in a control block of a report.

By default, report routines are public; they can be called by any other module of the program. If a report routine is only used by the current module, you may want to hide that routine to other modules, to make sure that it will not be called by mistake. To keep a report routine local to the module, add the PRIVATE keyword before the report header. Private report routines are only hidden to external modules, all function of the current module can still call local private report routines.

The define section declares the data types of local variables used within the report, and of any variables (the input records) that are passed as arguments to the report by the calling statement. Reports without arguments or local variables do not require a DEFINE section.

The output-section can set margin and page size values, and can also specify where to send the formatted output. Output from the report consists of successive pages, each containing a fixed number of lines whose margins and maximum number of characters are fixed.

The sort-section specifies how the rows have to be sorted. The specified sort order determines the order in which the runtime system processes any GROUP OF control blocks in the FORMAT section.

The format-section is required. It specifies the appearance of the report, including page headers, page trailers, and aggregate functions of the data. It can also contain control blocks that specify actions to take before or after specific groups of rows are processed. (Alternatively, it can produce a default report by only specifying FORMAT EVERY ROW).

The report prototype

When defining a report routine, the report name must immediately follow the REPORT keyword. The name must be unique among function and report names within the program. Its scope is the entire program.

The list of formal arguments of the report must be enclosed in parentheses and separated by commas. These are local variables that store values that the calling routine passes to the report. The compiler issues an error unless you declare their data types in the subsequent DEFINE section of the report routine. You can include a program record in the formal argument list, but you cannot append the .* symbols to the name of the record. Arguments can be of any data type except ARRAY, or a record with an ARRAY member.

When you call a report, the formal arguments are assigned values from the argument list of the OUTPUT TO REPORT statement. These actual arguments that you pass must match, in number and position, the formal arguments of the REPORT routine. The data types must be compatible, but they need not be identical. The runtime system can perform some conversions between compatible data types.

The names of the actual arguments and the formal arguments do not have to match.

You must include the following items in the list of formal arguments:

• All the values for each row sent to the report in the following cases:
• If you include an ORDER BY section or GROUP PERCENT (*) function
• If you use a global aggregate function (one over all rows of the report) anywhere in the report, except in the ON LAST ROW control block
• If you specify the FORMAT EVERY ROW default format
• Any variables referenced in the following group control blocks:
  • AFTER GROUP OF
  • BEFORE GROUP OF

DEFINE section in REPORT
Defines report parameters and local variables.

Syntax
The syntax of the report DEFINE section is the same as for the DEFINE statement, except that you cannot define arrays or array members for records.

Usage
This section declares a data type for each formal argument in the REPORT prototype and for any additional local variables that can be referenced only within the REPORT program block. The DEFINE section is required if you pass arguments to the report or if you reference local variables in the report.

For declaring local report variables, the same rules apply to the DEFINE section as to the DEFINE statement in MAIN and FUNCTION program blocks. There are some differences and exceptions, however:

• Report arguments cannot be of type ARRAY.
• Report arguments cannot be records that include ARRAY members.
• Report local variables are not allocated on the stack at every OUTPUT TO REPORT call: The scope of the variables in the DEFINE section is local to the report routine, but the lifetime is the duration of the program, like module or global variables. In other words, report variables persist across OUTPUT TO REPORT calls.

Data types of local variables that are not formal arguments are unrestricted. You must include arguments in the report prototype and declare them in the DEFINE section, if any of the following conditions is true:

• If you specify FORMAT EVERY ROW to create a default report, you must pass all the values for each record of the report.
• If an ORDER BY section is included, you must pass all the values that ORDER BY references for each input record of the report.
• If you use the AFTER GROUP OF control block, you must pass at least the arguments that are named in that control block.
• If an aggregate that depends on all records of the report appears anywhere except in the ON LAST ROW control block, you must pass each of the records of the report through the argument list.
Aggregates dependent on all records include:

- `GROUP PERCENT(*)` (anywhere in a report).
- Any aggregate without the `GROUP` keyword (anywhere outside the `ON LAST ROW` control block).

If your report calls an aggregate function, an error might result if any argument of an aggregate function is not also a format argument of the report. You can, however, use global or module variables as arguments of aggregates if the value of the variable does not change while the report is executing.

A report can reference variables of global or module scope that are not declared in the `DEFINE` section. Their values can be printed, but they can cause problems in aggregates and in `BEFORE GROUP OF` and `AFTER GROUP OF` clauses. Any references to non-local variables can produce unexpected results, however, if their values change while a two-pass report is executing.

**Related concepts**

- **ORDER BY section in REPORT** on page 1943
  Forces a sort order of unsorted data rows in reports.

- **Two-pass reports** on page 1951
  The report engine supports *two-pass reports*, to order rows automatically.

**OUTPUT section in REPORT**

Specifies report destination and page format options.

**Syntax**

```
OUTPUT
  REPORT TO
    SCREEN
    PRINTER
    FILE filename
    PIPE  IN FORM MODE  IN LINE MODE  program
    LEFT MARGIN m-left
    RIGHT MARGIN m-right
    TOP MARGIN m-top
    BOTTOM MARGIN m-bottom
    PAGE LENGTH m-length
    TOP OF PAGE c-top
```

1. `program` defines the name of a program, shell script, command receiving the output.
2. `filename` defines the file which receives the output of the report.
3. `m-left` is the left margin in number of characters. The default is 5.
4. `m-right` is the right margin in number of characters. The default is 132.
5. `m-top` is the top margin in number of lines. The default is 3.
6. `m-bottom` is the bottom margin in number of lines. The default is 3.
7. `m-length` is the total number of lines on a report page. The default page length is 66 lines.
8. `c-top` is a string that defines the page-eject character sequence.

**Usage**

The `OUTPUT` section can specify the destination and dimensions for output from the report and the page-eject sequence for the printer. If you omit the `OUTPUT` section, the report uses default values to format each page. This section is superseded by any corresponding `START REPORT` specifications.
The OUTPUT section can direct the output from the report to a printer, file, or pipe, and can initialize the page dimensions and margins of report output. If PRINTER is specified, the DBPRINT environment variable specifies which printer.

The START REPORT statement of the report driver can override all of these specifications by assigning another destination in its TO clause or by assigning other dimensions, margins, or another page-eject sequence in the WITH clause.

Because the size specifications for the dimensions and margins of a page of report output that the OUTPUT section can specify must be literal integers, consider defining page dimensions in the START REPORT statement, where you can use variables to assign these values dynamically at runtime.

**Tip:** To produce reports with not page size limit, set margins to zero and use a page length of 1.

### ORDER BY section in REPORT

Forces a sort order of unsorted data rows in reports.

**Syntax**

```
ORDER [ EXTERNAL ] BY report-variable [ DESC | ASC ] [, ...]
```

1. *report-variable* identifies one of the variables passed to the report routine to be used for sorting rows.

**Usage**

When grouping rows in a report, values that the report definition receives from the report driver are significant in determining how BEFORE GROUP OF or AFTER GROUP OF control blocks will process the data in the formatted report output.

The ORDER BY section defines how the variables of the input records are to be sorted. It is required if the report driver does not send sorted data to the report. The specified sort order determines the order in which the runtime system processes any GROUP OF control blocks in the FORMAT section.

If you omit the ORDER BY section, the runtime system processes input records in the order received from the report driver and processes any GROUP OF control blocks in their order of appearance in the FORMAT section. If records are not sorted in the report driver, the GROUP OF control blocks might be executed at random intervals (that is, after any input record) because unsorted values tend to change from record to record.

If you specify only one variable in the GROUP OF control blocks, and the input records are already sorted in sequence on that variable by the SELECT statement, you do not need to include an ORDER BY section in the report.

Specify ORDER EXTERNAL BY if the input records have already been sorted by the SELECT statement used by the report driver. The list of variables after the keywords ORDER EXTERNAL BY control the execution order of GROUP BY control blocks.

Without the EXTERNAL keyword, the report becomes a two-pass report, meaning that the report engine processes the set of input records twice. During the first pass, the report engine sorts the data and stores the sorted values in a temporary table in the database. During the second pass, it calculates any aggregate values and produces output from data in the temporary files.

With the EXTERNAL keyword, the report engine only needs to make a single pass through the data: it does not need to build the temporary table in the database for sorting the data. However, If the report routine contains aggregations functions such as GROUP PERCENT(*), the report will become a two-pass report because such aggregation function needs all rows to compute the value.
The `DESC` or `ASC` clause defines the sort order.

**Related concepts**

**FORMAT section in REPORT**

Defines the formatting directives inside a report routine.

**Syntax**

Default format:

```
FORMAT EVERY ROW
```

Custom format:

```
FORMAT control-block
  [ report-statement
  [ report-only-fgl-statement
  [ sql-statement
  ...
  ...

where control-block can be one of:

```
  [ FIRST ] PAGE HEADER
  [ ] ON EVERY ROW
  [ BEFORE GROUP OF report-variable
  [ AFTER GROUP OF report-variable
  [ PAGE TRAILER
  [ ] ON LAST ROW
```

1. *report-statement* is any report-specific instruction.
2. *report-only-fgl-statement* is any language instruction supported in the report routine.
3. *sql-statement* is any SQL statement supported by the language.
4. *report-variable* is the name of a variable declared in the DEFINE section.

**Usage**

A report definition must contain a `FORMAT` section.
The FORMAT section determines how the output from the report will look. It works with the values that are passed to the REPORT program block through the argument list or with global or module variables in each record of the report. In a source file, the FORMAT section begins with the FORMAT keyword and ends with the END REPORT keywords.

The FORMAT section is made up of the following control blocks:

• FIRST PAGE HEADER
• PAGE HEADER
• PAGE TRAILER
• BEFORE GROUP OF
• AFTER GROUP OF
• ON EVERY ROW
• ON LAST ROW

If you use the FORMAT EVERY ROW, no other statements or control blocks are valid. The EVERY ROW keywords specify a default output format, including every input record that is passed to the report.

Control blocks define the structure of a report by specifying one or more statements to be executed when specific parts of the report are processed.

If a report driver includes START REPORT and FINISH REPORT statements, but no data records are passed to the report, no control blocks are executed. That is, unless the report executes an OUTPUT TO REPORT statement that passes at least one input record to the report; then neither the FIRST PAGE HEADER control block nor any other control block is executed.

Apart from BEFORE GROUP OF and AFTER GROUP OF, each control block must appear only one time.

More complex FORMAT sections can contain control blocks like ON EVERY ROW or BEFORE GROUP OF, which contain statements to execute while the report is being processed. Control blocks can contain report execution statements and other executable statements.

A control block may invoke most language statements, except those listed in prohibited statements.

The BEFORE/AFTER GROUP OF control blocks can include aggregate functions to instruct the report engine to automatically compute such values.

A report-statement is a statement specially designed for the report format section. It cannot be used in any other part of the program.

The sequence in which the BEFORE GROUP OF and AFTER GROUP OF control blocks are executed depends on the sort list in the ORDER BY section, regardless of the physical sequence in which these control blocks appear within the FORMAT section.

**FORMAT EVERY ROW**

Default format specification of a report.

A report routine written with `FORMAT EVERY ROW` formats the report in a simple default format, containing only the values that are passed to the `REPORT` program block through its arguments, and the names of the arguments. You cannot modify the `EVERY ROW` statement with any of the statements listed in report execution statements, and neither can you include any control blocks in the `FORMAT` section.

The report engine uses as column headings the names of the variables that the report driver passes as arguments at runtime. If all fields of each input record can fit horizontally on a single line, the default report prints the names across the top of each page and the values beneath. Otherwise, it formats the report with the names down the left side of the page and the values to the right, as in the previous example. When a variable contains a null value, the default report prints only the name of the variable, with nothing for the value.

The following example is a brief report specification that uses `FORMAT EVERY ROW`. We assume here that the cursor that retrieved the input records for this report was declared with an `ORDER BY` clause, so that no `ORDER BY` section is needed in this report definition:

```sql
DATABASE stores7

REPORT simple( order_num, customer_num, order_date )

DEFINE order_num LIKE orders.order_num,
       customer_num LIKE orders.customer_num,
       order_date LIKE orders.order_date

FORMAT EVERY ROW

END REPORT
```

The example would produce the following output:

<table>
<thead>
<tr>
<th>order_num</th>
<th>customer_num</th>
<th>order_date</th>
</tr>
</thead>
<tbody>
<tr>
<td>1001</td>
<td>104</td>
<td>01/20/1993</td>
</tr>
<tr>
<td>1002</td>
<td>101</td>

<td>04/12/1993</td>
</tr>
<tr>
<td>1005</td>
<td>116</td>
<td>12/04/1993</td>
</tr>
<tr>
<td>1006</td>
<td>112</td>
<td>09/19/1993</td>
</tr>
<tr>
<td>1007</td>
<td>117</td>
<td>03/25/1993</td>
</tr>
<tr>
<td>1008</td>
<td>110</td>
<td>11/17/1993</td>
</tr>
<tr>
<td>1009</td>
<td>111</td>
<td>02/14/1993</td>
</tr>
<tr>
<td>1010</td>
<td>115</td>
<td>05/29/1993</td>
</tr>
<tr>
<td>1011</td>
<td>104</td>
<td>03/23/1993</td>
</tr>
<tr>
<td>1012</td>
<td>117</td>
<td>06/05/1993</td>
</tr>
</tbody>
</table>

**FIRST PAGE HEADER**

Defines the printing commands for the first page of a report.

This control block specifies the action that the runtime system takes before it begins processing the first input record. You can use it, for example, to specify what appears near the top of the first page of output from the report.

Because the runtime system executes the `FIRST PAGE HEADER` control block before generating any output, you can use this control block to initialize variables that you use in the `FORMAT` section.

If a report driver includes `START REPORT` and `FINISH REPORT` statements, but no data records are passed to the report, this control block is not executed. That is, unless the report executes an `OUTPUT TO REPORT` statement that passes at least one input record to the report, neither the `FIRST PAGE HEADER` control block nor any other control block is executed.
As its name implies, you can also use a FIRST PAGE HEADER control block to produce a title page as well as column headings. On the first page of a report, this control block overrides any PAGE HEADER control block. That is, if both a FIRST PAGE HEADER and a PAGE HEADER control block exist, output from the first appears at the beginning of the first page, and output from the second begins all subsequent pages.

The TOP MARGIN (set in the OUTPUT section) determines how close the header appears to the top of the page.

Consider the following notes when programming the FIRST PAGE HEADER control block:

1. You cannot include a SKIP integer LINES statement inside a loop within this control block.
2. The NEED statement is not valid within this control block.
3. If you use an IF...THEN...ELSE statement within this control block, the number of lines displayed by any PRINT statements following the THEN keyword must be equal to the number of lines displayed by any PRINT statements following the ELSE keyword.
4. If you use a CASE, FOR, or WHILE statement that contains a PRINT statement within this control block, you must terminate the PRINT statement with a semicolon (;). The semicolon suppresses any LINEFEED characters in the loop, keeping the number of lines in the header constant from page to page.
5. You cannot use a PRINT filename statement to read and display text from a file within this control block.

Corresponding restrictions also apply to CASE, FOR, IF, NEED, SKIP, PRINT, and WHILE statements in PAGE HEADER and PAGE TRAILER control blocks.

PAGE HEADER
Defines the printing commands for the top of all pages of a report.

This control block is executed whenever a new page is added to the report. The PAGE HEADER control block specifies the action that the runtime takes before it begins processing each page of the report. It can specify what information, if any, appears at the top of each new page of output from the report.

The TOP MARGIN specification (in the OUTPUT section) affects how many blank lines appear above the output produced by statements in the PAGE HEADER control block.

You can use the PAGENO operator in a PRINT statement within a PAGE HEADER control block to automatically display the current page number at the top of every page.

The FIRST PAGE HEADER control block overrides this control block on the first page of a report.

New group values can appear in the PAGE HEADER control block when this control block is executed after a simultaneous end-of-group and end-of-page situation.

The runtime system delays the processing of the PAGE HEADER control block until it encounters the first PRINT, SKIP, or NEED statement in the ON EVERY ROW, BEFORE GROUP OF, or AFTER GROUP OF control block. This order guarantees that any group columns printed in the PAGE HEADER control block have the same values as the columns printed in the ON EVERY ROW control block.

Important: The restrictions that apply to FIRST PAGE HEADER also apply to PAGE HEADER.

Related concepts
FIRST PAGE HEADER on page 1946
Defines the printing commands for the first page of a report.

PAGE TRAILER on page 1948
Defines the printing commands for the tail of all pages of a report.

PRINT on page 1952
Formats and prints a row of data in a report routine.

PRINTX on page 1956
Prints an XML formatted row of data in a report, with an additional identifier for XML outputs.

**PAGE TRAILER**
Defines the printing commands for the tail of all pages of a report.

The **PAGE TRAILER** control block specifies what information, if any, appears at the bottom of each page of output from the report.

The runtime system executes the statements in the **PAGE TRAILER** control block before the **PAGE HEADER** control block when a new page is needed. New pages can be initiated by any of the following conditions:

- PRINT attempts to print on a page that is already full.
- SKIP TO TOP OF PAGE is executed.
- SKIP n LINES specifies more lines than are available on the current page.
- NEED specifies more lines than are available on the current page.

You can use the **PAGE NO** operator in a PRINT statement within a **PAGE TRAILER** control block to automatically display the page number at the bottom of every page, as in this example:

```
PAGE TRAILER
  PRINT COLUMN 28, PAGENO USING "page <<<<"
```

The **BOTTOM MARGIN** specification (in the **OUTPUT** section) affects how close to the bottom of the page the output displays the page trailer.

**Important:** The restrictions that apply to **FIRST PAGE HEADER** also apply to **PAGE TRAILER**.

**Related concepts**

**PRINT** on page 1952
Formats and prints a row of data in a report routine.

**PRINTX** on page 1956
Prints an XML formatted row of data in a report, with an additional identifier for XML outputs.

**BEFORE/AFTER GROUP OF**
Defines printing commands of row grouping sections within a report.

The **BEFORE/AFTER GROUP OF** control blocks specify what action the runtime system takes respectively before or after it processes a group of input records. Group hierarchy is determined by the **ORDER BY** specification in the **SELECT** statement or in the report definition.

A group of records is all of the input records that contain the same value for the variable whose name follows the **AFTER GROUP OF** keywords. This group variable must be passed through the report arguments. A report can include no more than one **AFTER GROUP OF** control block for any group variable.

When the runtime system executes the statements in a **BEFORE/AFTER GROUP OF** control block, the report variables have the values from the first / last record of the new group. From this perspective, the **BEFORE/AFTER GROUP OF** control block can be thought of as the "on first / last record of group" control block.

Each **BEFORE GROUP OF** block is executed in order, from highest to lowest priority, at the start of a report (after any **FIRST PAGE HEADER** or **PAGE HEADER** control blocks, but before processing the first record) and on these occasions:

- Whenever the value of the group variable changes (after any **AFTER GROUP OF** block for the old value completes execution)
Whenever the value of a higher-priority variable in the sort list changes (after any AFTER GROUP OF block for the old value completes execution)

The runtime system executes the AFTER GROUP OF control block on these occasions:

- Whenever the value of the group variable changes.
- Whenever the value of a higher-priority variable in the sort list changes.
- At the end of the report (after processing the last input record but before the runtime system executes any ON LAST ROW or PAGE TRAILER control blocks). In this case, each AFTER GROUP OF control block is executed in ascending priority.

How often the value of the group variable changes depends in part on whether the input records have been sorted by the SELECT statement:

- If records are already sorted, the BEFORE/AFTER GROUP OF block executes before the runtime system processes the first record of the group.
- If records are not sorted, the BEFORE GROUP OF block might be executed after any record because the value of the group variable can change with each record. If no ORDER BY section is specified, all BEFORE/AFTER GROUP OF control blocks are executed in the same order in which they appear in the FORMAT section. The BEFORE/AFTER GROUP OF control blocks are designed to work with sorted data.

You can sort the records by specifying a sort list in either of the following areas:

- An ORDER BY section in the report definition
- The ORDER BY clause of the SELECT statement in the report driver

To sort data in the report definition (with an ORDER BY section), make sure that the name of the group variable appears in both the ORDER BY section and in the BEFORE GROUP OF control block.

To sort data in the ORDER BY clause of a SELECT statement, perform the following tasks:

- Use the column name in the ORDER BY clause of the SELECT statement as the group variable in the BEFORE GROUP OF control block.
- If the report contains BEFORE or AFTER GROUP OF control blocks, make sure that you include an ORDER EXTERNAL BY section in the report to specify the precedence of variables in the sort list.

If you specify sort lists in both the report driver and the report definition, the sort list in the ORDER BY section of the REPORT takes precedence. When the runtime system starts to generate a report, it first executes the BEFORE GROUP OF control blocks in descending order of priority before it executes the ON EVERY ROW control block. If the report is not already at the top of the page, the SKIP TO TOP OF PAGE statement in a BEFORE GROUP OF control block causes the output for each group to start at the top of a page.

If the sort list includes more than one variable, the runtime system sorts the records by values in the first variable (highest priority). Records that have the same value for the first variable are then ordered by the second variable and so on until records that have the same values for all other variables are ordered by the last variable (lowest priority) in the sort list.

The ORDER BY section determines the order in which the runtime system processes BEFORE GROUP OF and AFTER GROUP OF control blocks. If you omit the ORDER BY section, the runtime system processes any GROUP OF control blocks in the lexical order of their appearance within the FORMAT section.

If you include an ORDER BY section, and the FORMAT section contains more than one BEFORE GROUP OF or AFTER GROUP OF control block, the order in which these control blocks are executed is determined by the sort list in the ORDER BY section. In this case, their order within the FORMAT section is not significant because the sort list overrides their lexical order.

The runtime system processes all the statements in a BEFORE GROUP OF or AFTER GROUP OF control block on these occasions:

- Each time the value of the current group variable changes.
- Each time the value of a higher-priority variable changes.
How often the value of the group variable changes depends in part on whether the input records have been sorted. If the records are sorted, AFTER GROUP OF executes after the runtime system processes the last record of the group of records; BEFORE GROUP OF executes before the runtime system processes the first records with the same value for the group variable. If the records are not sorted, the BEFORE GROUP OF and AFTER GROUP OF control blocks might be executed before and after each record because the value of the group variable might change with each record. All the AFTER GROUP OF and BEFORE GROUP OF control blocks are executed in the same lexical order in which they appear in the FORMAT section.

In the AFTER GROUP OF control block, you can include the GROUP keyword to qualify aggregate report functions like AVG(), SUM(), MIN(), or MAX():

```plaintext
AFTER GROUP OF r.order_num
  PRINT r.order_date, 7 SPACES,
    r.order_num USING"###", 8 SPACES,
    r.ship_date, " ",
    GROUP SUM(r.total_price) USING"$$,$$$,$$$.&"
AFTER GROUP OF r.customer_num
  PRINT 42 SPACES, "-------------------"
  PRINT 42 SPACES, GROUP SUM(r.total_price) USING"$$,$$$,$$$.&"
```

Using the GROUP keyword to qualify an aggregate function is only valid within the AFTER GROUP OF control block. It is not valid, for example, in the BEFORE GROUP OF control block.

After the last input record is processed, the runtime system executes the AFTER GROUP OF control blocks before it executes the ON LAST ROW control block.

**Related concepts**
- Two-pass reports on page 1951
  The report engine supports two-pass reports, to order rows automatically.
- PRINT on page 1952
  Formats and prints a row of data in a report routine.
- PRINTX on page 1956
  Prints an XML formatted row of data in a report, with an additional identifier for XML outputs.

**ON EVERY ROW**
Defines printing commands for each row in a report.

The ON EVERY ROW control block specifies the action to be taken by the runtime system for every input record that is passed to the report definition.

The runtime system executes the statements within the ON EVERY ROW control block for each new input record that is passed to the report. The following example is from a report that lists all the customers, their addresses, and their telephone numbers across the page:

```plaintext
ON EVERY ROW
  PRINT r.fname, " ", r.lname, " ",
    r.address1, " ", r.cust_phone
```

The runtime system delays processing the PAGE HEADER control block (or the FIRST PAGE HEADER control block, if it exists) until it encounters the first PRINT, SKIP, or NEED statement in the ON EVERY ROW control block.

If a BEFORE GROUP OF control block is triggered by a change in the value of a variable, the runtime system executes all appropriate BEFORE GROUP OF control blocks (in the order of their priority) before it executes the ON EVERY ROW control block. Similarly, if execution of an AFTER GROUP OF control block is triggered by a change in the value of a variable, the runtime system executes all appropriate AFTER GROUP OF control blocks (in the reverse order of their priority) before it executes the ON EVERY ROW control block.

**Related concepts**
- PRINT on page 1952
Formats and prints a row of data in a report routine.

PRINTX on page 1956
Prints an XML formatted row of data in a report, with an additional identifier for XML outputs.

**ON LAST ROW**
Defines the printing commands of the last row in a report.

The **ON LAST ROW** control block specifies the action that the runtime system is to take after it processes the last input record that was passed to the report definition and encounters the **FINISH REPORT** statement.

The statements in the **ON LAST ROW** control block are executed after the statements in the **ON EVERY ROW** and **AFTER GROUP OF** control blocks if these blocks are present.

When the runtime system processes the statements in an **ON LAST ROW** control block, the variables that the report is processing still have the values from the final record that the report processed. The **ON LAST ROW** control block can use aggregate functions to display report totals.

**Related concepts**
PRINT on page 1952
Formats and prints a row of data in a report routine.

PRINTX on page 1956
Prints an XML formatted row of data in a report, with an additional identifier for XML outputs.

**Prohibited report routine statements**

Language statements that have no meaning inside a report definition routine are prohibited. These statements are some of the statements that are not valid within any control block of the **FORMAT** section of a **REPORT** program block, such as interactive statements (**CONSTRUCT**, **INPUT**, **DIALOG**, **MENU**), program block definitions (**FUNCTION**, **REPORT**), and some flow control instructions like **RETURN**.

A compile-time error is issued if you attempt to include any of these statements in a control block of a report. You can call a function that includes some of these statements, but this is not recommended.

**Related concepts**
Report instructions on page 1952
The report instruction listed in this section can appear only in control blocks of the **FORMAT** section of a report routine.

**Two-pass reports**

The report engine supports **two-pass reports**, to order rows automatically.

The one-pass report requires sorted data to be produced by the report driver in order to handle before/after groups properly. The two-pass report handles sorts internally and does not need sorted data from the report driver. During the first pass, the report engine sorts the data and stores the sorted values in a temporary file in the database. During the second pass, it calculates any aggregate values and produces output from data in the temporary files.

A report is defined as a two-pass report if it includes any of the following items:

- An **ORDER BY** section without the **EXTERNAL** keyword.
- The **GROUP PERCENT(*)** aggregate function anywhere in the report.
- Any aggregate function that has no **GROUP** keyword in any control block other than **ON LAST ROW**.

Two-pass reports create temporary tables. The **FINISH REPORT** statement uses values from these tables to calculate any global aggregates, and then deletes the tables. Since two-pass reports create temporary tables, the report engine requires a database connection, and the database server must support temporary tables with indexes.

Consider avoiding two-pass reports when a regular report is possible.
Related concepts
ORDER BY section in REPORT on page 1943
Forces a sort order of unsorted data rows in reports.

ON LAST ROW on page 1951
Defines the printing commands of the last row in a report.

FINISH REPORT on page 1937
The FINISH REPORT instruction finalizes a report execution.

Report instructions
The report instruction listed in this section can appear only in control blocks of the FORMAT section of a report routine.

- EXIT REPORT on page 1952
- PRINT on page 1952
- PRINTX on page 1956
- NEED on page 1957
- PAUSE on page 1957
- SKIP on page 1958

EXIT REPORT
Cancels the report processing.

Syntax
EXIT REPORT

Usage
EXIT REPORT cancels the report processing. It must appear in the FORMAT section of the report definition. It is useful after the program (or the user) becomes aware that a problem prevents the report from producing part of its intended output.

EXIT REPORT has the following effects:
- Terminates the processing of the current report.
- Deletes any intermediate files or temporary tables that were created in processing the report.

You cannot use the RETURN statement as a substitute for EXIT REPORT. An error is issued if RETURN is encountered within the definition of a report.

Related concepts
FORMAT section in REPORT on page 1944
Defines the formatting directives inside a report routine.

FUNCTIONS on page 353
Describes user defined functions.

PRINT
Formats and prints a row of data in a report routine.

Syntax
PRINT
expression
| COLUMN left-offset  |
| PAGENO           |
| LINENO           |
| num-spaces SPACES |
| [GROUP] COUNT(*) [ WHERE condition ] |
| [GROUP] PERCENT(*) [ WHERE condition ] |
| [GROUP] AVG( variable ) [ WHERE condition ] |
| [GROUP] SUM( variable ) [ WHERE condition ] |
| [GROUP] MIN( variable ) [ WHERE condition ] |
| [GROUP] MAX( variable ) [ WHERE condition ] |
| char-expression WORDWRAP RIGHT MARGIN rm |
| FILE "file-name" |

1. *expression* is any legal language expression.
2. *left-offset* is described in COLUMN.
3. *num-spaces* is described in SPACES.
4. *char-expression* is a string expression or a TEXT variable.
5. *filename* is a string expression, or a quoted string, that specifies the name of a text file to include in the output from the report.

**Usage**

The PRINT instruction is used in a report routine to output a line of data.

The PRINT statement can include character data in the form of an ASCII file, a TEXT variable, or a comma-separated expression list of character expressions in the output of the report. (For TEXT variable or file name, you cannot specify additional output in the same PRINT statement.)

If a BYTE value is used in the PRINT statement, the output will show the "<byte value>" text for this element when the report output is regular text. If the report output is XML, the BYTE value is converted to Base64 before it is written to the output stream.

PRINT statement output begins at the current character position, sometimes called simply the current position. On each page of a report, the initial default character position is the first character position in the first line. This position can be offset horizontally and vertically by margin and header specifications and by executing any of the following statements:

- The SKIP statement moves it down to the left margin of a new line.
- The NEED statement can conditionally move it to a new page.
- The PRINT statement moves it horizontally (and sometimes down).

Unless you use the keyword CLIPPED or USING, values are displayed with widths (including any sign) that depend on their declared data types.

**Table 379: Default print width for data types**

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default Print Width</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>N/A</td>

<td>Length current value in the variable.</td>
</tr>
<tr>
<td>TEXT</td>
<td>Length current value in the variable.</td>
</tr>
<tr>
<td>VARCHAR</td>
<td>Length current value in the variable.</td>
</tr>
</tbody>
</table>

Unless you specify the FILE or WORDWRAP option, each PRINT statement displays output on a single line. For example, this fragment displays output on two lines:

```sql
PRINT fname, lname
PRINT city, "", state, " ", zip-code
```

If you terminate a PRINT statement with a semicolon. However, you suppress the implicit LINEFEED character at the end of the line. The next example has the same effect as the PRINT statements in the previous example:

```sql
PRINT fname;
PRINT lname
PRINT city, "", state, " ", zip-code
```

The expression list of a PRINT statement returns one or more values that can be displayed as printable characters. The expression list can contain report variables, built-in functions and operators. Some of these can appear only in a REPORT program block such as PAGENO, LINENO, PERCENT.

If the expression list applies the USING operator to format a DATE or MONEY value, the format string of the USING operator takes precedence over the DBDATE, DBMONEY, and DBFORMAT environment variables.

The PRINT FILE statement reads the contents of the specified filename into the report, beginning at the current character position. This statement permits you to insert a multiple-line character string into the output of a report. If filename stores the value of a TEXT variable, the PRINT FILE file-name statement has the same effect as specifying PRINT text-variable. (But only PRINT variable can include the WORDWRAP operator)

Aggregate report functions summarize data from several records in a report. The syntax and effects of aggregates in a report resemble those of SQL aggregate functions but are not identical.

The expression (in parentheses) that SUM(), AVG(), MIN(), or MAX() takes as an argument is typically of a number or INTERVAL data type; ARRAY, BYTE, RECORD, and TEXT are not valid. The SUM(), AVG(), MIN() , and MAX() aggregates ignore input records for which their arguments have null values, but each returns NULL if every record has a null value for the argument.

The GROUP keyword is an optional keyword that causes the aggregate function to include data only for a group of records that have the same value for a variable that you specify in an AFTER GROUP OF control block. An aggregate function can only include the GROUP keyword within an AFTER GROUP OF control block.

The optional WHERE clause allows you to select among records passed to the report, so that only records for which the boolean expression is TRUE are included.
Example

The following example is from the FORMAT section of a report definition that displays both quoted strings and values from rows of the customer table:

```
FIRST PAGE HEADER
PRINT COLUMN 30, "CUSTOMER LIST"
SKIP 2 LINES
PRINT "Listings for the State of ", thisstate
SKIP 2 LINES
PRINT "NUMBER", COLUMN 12, "NAME", COLUMN 35, "LOCATION",
       COLUMN 57, "ZIP", COLUMN 65, "PHONE"
SKIP 1 LINE
PAGE HEADER
PRINT "NUMBER", COLUMN 12, "NAME", COLUMN 35, "LOCATION",
       COLUMN 57, "ZIP", COLUMN 65, "PHONE"
SKIP 1 LINE
ON EVERY ROW
PRINT customer_num USING "###&", COLUMN 12, fname CLIPPED,
       1 SPACE, lname CLIPPED, COLUMN 35, city CLIPPED, ",",
       state, COLUMN 57, zip-code, COLUMN 65, phone
```

Records allow structured program variables definitions.

Arrays on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

**PRINTX**

Prints an XML formatted row of data in a report, with an additional identifier for XML outputs.

**Syntax**

\[
\text{PRINTX [NAME = identifier] expression}
\]

1. *identifier* is the name to be used in the XML node.
2. *expression* is any legal language expression.

**Usage**

The PRINTX statement is similar to PRINT, except that when XML is produced by the report, the XML print element will be named as specified. If the NAME clause is omitted or the report is run in non-XML mode, then PRINTX does exactly the same as PRINT.

To generate XML output, you must redirect the report output into a SAX document handler with the TO XML HANDLER clause of START REPORT:

```
START REPORT orders_report
   TO XML HANDLER om.XmlWriter.createFileWriter("orders.xml")
```

Note that when using XML output, BYTE values are converted to Base64 before they are printed with the PRINTX instruction.

**Example**

```
REPORT (fname, lname, ...)
   DEFINE fname VARCHAR(20),
         lname VARCHAR(20)
...
FORMAT
   ...
   ON EVERY ROW
       PRINTX NAME=customer fname, lname
...
```

With the above code, the variable names will appear in the graphical report designer as "customer.fname" and "customer.lname".

**Related concepts**

  The START REPORT instruction initializes a report execution.
- **The SaxDocumentHandler class** on page 2467
  The om.SaxDocumentHandler class provides an interface to write an XML filter with events.
- **PRINT** on page 1952
Formats and prints a row of data in a report routine.

Expressions on page 293
Shows the possible expressions supported in the language.

NEED
Specifies the number of rows needed in a report section.

Syntax

```
NEED num-lines LINE[S]
```

1. `num-lines` is the number of lines.

Usage

This statement has the effect of a conditional SKIP TO TOP OF PAGE statement, the condition being that the number to which the integer expression evaluates is greater than the number of lines that remain on the current page.

The NEED statement can prevent the report from dividing parts of the output that you want to keep together on a single page. In this example, the NEED statement causes the PRINT statement to send output to the next page unless at least six lines remain on the current page:

```
AFTER GROUP OF r.order_num
  NEED 6 LINES
  PRINT " ", r.order_date, " ", GROUP SUM(r.total_price)
```

The LINES value specifies how many lines must remain between the line above the current character position and the bottom margin for the next PRINT statement to produce output on the current page. If fewer than LINES remain on the page, the report engine prints both the PAGE TRAILER and the PAGE HEADER.

The NEED statement does not include the BOTTOM MARGIN value when it compares LINES to the number of lines remaining on the current page. NEED is not valid in FIRST PAGE HEADER, PAGE HEADER, or PAGE TRAILER blocks.

Related concepts

SKIP on page 1958
Skips a given number of lines in a report.

PRINT on page 1952
Formats and prints a row of data in a report routine.

FIRST PAGE HEADER on page 1946
Defines the printing commands for the first page of a report.

PAGE HEADER on page 1947
Defines the printing commands for the top of all pages of a report.

PAGE TRAILER on page 1948
Defines the printing commands for the tail of all pages of a report.

PAUSE
Pauses a report displayed to the screen.

Syntax

```
PAUSE "comment" 
```

1. `comment` is an optional comment to be displayed.
Usage

Output is sent by default to the screen unless the START REPORT statement or the OUTPUT section specifies a destination for report output.

The PAUSE statement can be executed only if the report sends its output to the screen. It has no effect if you include a TO clause in either of these contexts:
- In the OUTPUT section of the report definition.
- In the START REPORT statement of the report driver.

Include the PAUSE statement in the PAGE HEADER or PAGE TRAILER block of the report. For example, the following code causes the runtime system to skip a line and pause at the end of each page of report output displayed on the screen:

```
PAGE TRAILER
  SKIP 1 LINE
  PAUSE "Press return to continue"
```

Related concepts

- **START REPORT** on page 1933
  The START REPORT instruction initializes a report execution.
- **OUTPUT section in REPORT** on page 1942
  Specifies report destination and page format options.
- **PAGE HEADER** on page 1947
  Defines the printing commands for the top of all pages of a report.
- **PAGE TRAILER** on page 1948
  Defines the printing commands for the tail of all pages of a report.

```
SKIP
```

Skips a given number of lines in a report.

Syntax

```
SKIP { num-lines LINE[S] | TO TOP OF PAGE }
```

1. `num-lines` is the number of lines.

Usage

The SKIP statement allows you to insert blank lines into report output or to skip to the top of the next page as if you had included an equivalent number of PRINT statements without specifying any expression list.

The LINE and LINES keywords are synonyms in the SKIP statement.

Output from any PAGE HEADER or PAGE TRAILER control block appears in its usual location.

The SKIP `num LINES` statement cannot appear within a CASE statement, a FOR loop, or a WHILE loop.

The SKIP TO TOP OF PAGE statement cannot appear in a FIRST PAGE HEADER, PAGE HEADER or PAGE TRAILER control block.

Example

```
FIRST PAGE HEADER
  PRINT "Customer List"
  SKIP 2 LINES
  PRINT "Number       Name               Location"
  SKIP 1 LINE
PAGE HEADER
```
PRINT "Number        Name               Location"
SKIP 1 LINE
ON EVERY ROW
  PRINT r.customer_num, r.fname, r.city

Related concepts
PRINT on page 1952
Formats and prints a row of data in a report routine.
FIRST PAGE HEADER on page 1946
Defines the printing commands for the first page of a report.
PAGE HEADER on page 1947

PAGE TRAILER on page 1948
Defines the printing commands for the tail of all pages of a report.

Report operators
Report operators can be used to print dynamic report information.
• LINENO on page 1959
• PAGENO on page 1960
• SPACES on page 1960
• WORDWRAP on page 1961

LINENO
Contains the current line number in a report.

Syntax
LINENO

Usage
This operator takes no operand but returns the value of the line number of the report line that is currently printing.
The report engine calculates the line number by calculating the number of lines from the top of the current page, including the TOP MARGIN.

Example
In this example, a PRINT statement instructs the report to calculate and display the current line number, beginning in the tenth character position after the left margin:

  ON EVERY ROW
    IF LINENO > 9 THEN
      PRINT COLUMN 10, "Line:", LINENO USING "<<<"
    END IF

Related concepts
START REPORT on page 1933
The **START REPORT** instruction initializes a report execution.

### PAGENO

Contains the current page number in a report.

**Syntax**

```
PAGENO
```

**Usage**

This operator takes no operand but returns the number of the page the report engine is currently printing.

You can use **PAGENO** in the **PAGE HEADER** or **PAGE TRAILER** block, or in other control blocks to number the pages of a report sequentially.

**Example**

If you use the SQL aggregate **COUNT(*)** in the **SELECT** statement to find how many records are returned by the query, and if the number of records that appear on each page of output is both fixed and known, you can calculate the total number of pages, as in this example:

```sql
FIRST PAGE HEADER
    SELECT COUNT(*) INTO cnt FROM customer
    LET y = cnt/50 -- Assumes 50 records per page
    ON EVERY ROW
        PRINT COLUMN 10, r.customer_num, ...
    PAGE TRAILER
        PRINT PAGE PAGENO USING "<<" OF cnt USING "<<"
```

If the calculated number of pages was 20, the first page trailer would be:

```
Page 1 of 20
```

**PAGENO** increments with each page, so the last page trailer would be:

```
Page 20 of 20
```

**Related concepts**

- **PAGE HEADER** on page 1947
- Defines the printing commands for the top of all pages of a report.
- **PAGE TRAILER** on page 1948
- Defines the printing commands for the tail of all pages of a report.

### SPACES

Generates the given number of blank characters.

**Syntax**

```
num-spaces SPACES
```

1. **num-spaces** is the number of spaces.

**Usage**

This operator returns a string of blanks, equivalent to a quoted string containing the specified number of blank spaces.

In a **PRINT** statement, these blanks are inserted at the current character position.
Its operand must be an integer expression that returns a positive number, specifying an offset (from the current character position) no greater than the difference (right margin - current position). After PRINT SPACES has executed, the new current character position has moved to the right by the specified number of characters.

Outside PRINT statements, SPACES and its operand must appear within parentheses: \((n \text{ SPACES})\).

**Example**

```
ON EVERY ROW
  LET s = (6 SPACES), "=ZIP"
  PRINT r.fname, 2 SPACES, r.lname, s
```

**Related concepts**

*PRINT* on page 1952
Formats and prints a row of data in a report routine.

*Integer expressions* on page 296
This section covers integer expression evaluation rules.

**WORDWRAP**

Splits a character string to match a given margin limit.

**Syntax**

```
WORDWRAP [ RIGHT MARGIN position ]
```

1. *position* defines the temporary right margin, as a number of characters, counting from the left.

**Usage**

The *WORDWRAP* operator automatically wraps successive segments of long character strings onto successive lines of report output. Any string value that is too long to fit between the current position and the right margin is divided into segments and displayed between temporary margins:

- The current character position becomes the temporary left margin.
- Unless you specify *RIGHT MARGIN*, the right margin defaults to 132, or to the size value from the *RIGHT MARGIN* clause of the *OUTPUT* section or *START REPORT* instruction.

Specify *WORDWRAP RIGHT MARGIN* _integer_ to set a temporary right margin as a number of characters, counting from the left edge of the page. This value cannot be smaller than the current character position or greater than right margin defined for the report. The current character position becomes the temporary left margin. These temporary values override the specified or default left and right margins of the report.

After the PRINT statement has executed, any explicit or default margins defined in the *RIGHT MARGIN* clause of the *OUTPUT* section or *START REPORT* instruction are restored.

The following PRINT statement specifies a temporary left margin in column 10 and a temporary right margin in column 70 to display the character string that is stored in the variable called *mynovel*:

```
PRINT COLUMN 10, mynovel WORDWRAP RIGHT MARGIN 70
```

The data string can include printable ASCII characters. It can also include the TAB (ASCII 9), LINEFEED (ASCII 10), and ENTER (ASCII 13) characters to partition the string into words that consist of substrings of other printable characters. Other non-printable characters might cause runtime errors. If the data string cannot fit between the margins of the current line, the report engine breaks the line at a word division, and pads the line with blanks at the right.

From left to right, the report engine expands any TAB character to enough blank spaces to reach the next tab stop. By default, tab stops are in every eighth column, beginning at the left-hand edge of the page. If the next tab stop or a string of blank characters extends beyond the right margin, the report engine takes these actions:
1. Prints blank characters only to the right margin.
2. Discards any remaining blanks from the blank string or tab.
3. Starts a new line at the temporary left margin.
4. Processes the next word.

The report engine starts a new line when a word plus the next blank space cannot fit on the current line. If all words are separated by a single space, this action creates an even left margin. The following rules are applied (in descending order of precedence) to the portion of the data string within the right margin:

- Break at any LINEFEED, or ENTER, or LINEFEED, ENTER pair.
- Break at the last blank (ASCII 32) or TAB character before the right margin.
- Break at the right margin, if no character farther to the left is a space, ENTER, TAB, or LINEFEED character.

The report engine maintains page discipline under the WORDWRAP option. If the string is too long for the current page, the report engine executes the statements in any page trailer and header control blocks before continuing output onto a new page.

For Japanese locales, a suitable break can also be made between the Japanese characters. However, certain characters must not begin a new line, and some characters must not end a line. This convention creates the need for KINSOKU processing, whose purpose is to format the line properly, without any prohibited word at the beginning or ending of a line.

Reports use the wrap-down method for WORDWRAP and KINSOKU processing. The wrap-down method forces down to the next line characters that are prohibited from ending a line. A character that precedes another that is prohibited from beginning a line can also wrap down to the next line. Characters that are prohibited from beginning or ending a line must be listed in the locale. The runtime system tests for prohibited characters at the beginning and ending of a line, testing the first and last visible characters. The KINSOKU processing only happens once for each line. That is, no further KINSOKU processing occurs, even if prohibited characters are still on the same line after the first KINSOKU processing.

**Related concepts**

**Report aggregate functions**

Report aggregate functions can be used to compute data.

- COUNT on page 1962
- PERCENT on page 1963
- SUM on page 1964
- AVG on page 1965
- MIN on page 1965
- MAX on page 1966

**COUNT**

Counts a number of rows in a report based on a condition.

**Syntax**

```
|GROUP| COUNT(*) | WHERE condition |
```
1. *condition* is a boolean expression evaluated to compute the aggregate value.

**Usage**

This aggregate report instruction returns the total number of records qualified by the optional *WHERE* condition.

The *WHERE* condition is evaluated after any *OUTPUT TO REPORT* execution. Even if it is typically used in *AFTER GROUP OF* blocks, the aggregate expression is not evaluated in that block: Changing values of the *WHERE* clause in the *AFTER GROUP context will not have an immediate effect.

Using the *GROUP* keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the *AFTER GROUP OF* control block.

**Example**

The following fragment of a report definition uses the *AFTER GROUP OF* control block and *GROUP* keyword to form sets of records depending on how many items are in each order. The last *PRINT* statement calculates the total price of each order, adds a shipping charge, and prints the result. Because no *WHERE* clause is specified here, *GROUP SUM()* combines the *total_price* of every item in the group included in the order.

```
AFTER GROUP OF number
  SKIP 1 LINE
  PRINT 4 SPACES, "Shipping charges for the order: ",
            ship_charge USING "$$$.&&"
  PRINT 4 SPACES, "Count of small orders: ",
            GROUP COUNT(*) WHERE total_price < 200.00 USING "##,###"
  SKIP 1 LINE
  PRINT 5 SPACES, "Total amount for the order: ",
            ship_charge + GROUP SUM(total_price) USING "$$,$$$,$$$,,&&"
```

**Related concepts**

*OUTPUT TO REPORT* on page 1935
The *OUTPUT TO REPORT* instruction provides a data row to the report execution.

*BEBEFORE/AFTER GROUP OF* on page 1948
Defines printing commands of row grouping sections withing a report.

*PRINT* on page 1952
Formats and prints a row of data in a report routine.

*Report engine configuration* on page 1967
Report engine behavior can be controlled with *FGLPROFILE* settings.

*NULL* on page 502
The *NULL* constant is provided as the "nil" value.

*Two-pass reports* on page 1951
The report engine supports *two-pass reports*, to order rows automatically.

**PERCENT**
Calculated the percentage of rows matching a condition.

**Syntax**

```
[GROUP] PERCENT(*) [WHERE condition]
```

1. *condition* is a boolean expression evaluated to compute the aggregate value.

**Usage**

This aggregate report instruction returns the percentage of the total number of records qualified by the optional *WHERE* condition.
Using the GROUP keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the AFTER GROUP OF control block.

This aggregate instruction makes a two-pass report when not using the GROUP keyword and is used in any control block other than ON LAST ROW, or when using the GROUP PERCENT(*) anywhere in the report.

**Related concepts**

BEFORE/AFTER GROUP OF on page 1948  
Defines printing commands of row grouping sections withing a report.

Report engine configuration on page 1967  
Report engine behavior can be controlled with FGLPROFILE settings.

NULL on page 502  
The NULL constant is provided as the "nil" value.

Two-pass reports on page 1951  
The report engine supports two-pass reports, to order rows automatically.

**SUM**

Calculates the total of a report parameter based on a condition.

**Syntax**

```plaintext
[GROUP] SUM(expression) [WHERE condition]
```

1. expression is the expression to be computed.
2. condition is a boolean expression evaluated to compute the aggregate value.

**Usage**

This aggregate report instruction evaluates as the total of expression among all records or among records qualified by the optional WHERE clause and any GROUP specification.

Using the GROUP keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the AFTER GROUP OF control block.

Input records for which the expression evaluates to NULL values are ignored.

By default, if all input record values are NULL, the result of the aggregate is NULL. However, you can control this behavior and force the runtime system to return zero instead of NULL with the report.aggregateZero FGLPROFILE parameter.

This aggregate instruction makes a two-pass report when not using the GROUP keyword and is used in any control block other than ON LAST ROW.

**Related concepts**

BEFORE/AFTER GROUP OF on page 1948  
Defines printing commands of row grouping sections withing a report.

Report engine configuration on page 1967  
Report engine behavior can be controlled with FGLPROFILE settings.

NULL on page 502  
The NULL constant is provided as the "nil" value.

Two-pass reports on page 1951
The report engine supports **two-pass reports**, to order rows automatically.

### AVG

Calculates the average of a report parameter base on a condition.

**Syntax**

```plaintext
[GROUP] AVG(expression) [WHERE condition]
```

1. *expression* is the expression to be computed.
2. *condition* is a boolean expression evaluated to compute the aggregate value.

**Usage**

This aggregate report instruction evaluates as the average (that is, the arithmetic mean value) of expression among all records or among records qualified by the optional WHERE clause and any GROUP specification.

Using the GROUP keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the AFTER GROUP OF control block.

Input records for which the *expression* evaluates to NULL values are ignored.

By default, if all input record values are NULL, the result of the aggregate is NULL. However, you can control this behavior and force the runtime system to return zero instead of NULL with the report.aggregateZero FGLPROFILE parameter.

This aggregate instruction makes a two-pass report when not using the GROUP keyword and is used in any control block other than ON LAST ROW.

**Related concepts**

- BEFORE/AFTER GROUP OF on page 1948
  Defines printing commands of row grouping sections within a report.
- Report engine configuration on page 1967
  Report engine behavior can be controlled with FGLPROFILE settings.
- NULL on page 502
  The NULL constant is provided as the "nil" value.
- Two-pass reports on page 1951
  The report engine supports two-pass reports, to order rows automatically.

### MIN

Calculates the minimum value of a report parameter according to a condition.

**Syntax**

```plaintext
[GROUP] MIN(expression) [WHERE condition]
```

1. *expression* is the expression to be computed.
2. *condition* is a boolean expression evaluated to compute the aggregate value.

**Usage**

For number, currency, and interval values, `MIN(expression)` aggregate report instruction returns the minimum value for *expression* among all records or among records qualified by the WHERE clause and any GROUP specification.

For DATETIME or DATE data values, greater than means later and less than means earlier in time. Character strings are sorted depending on their first character. If your program is executed in the default (U.S. English) locale, for
character data types, greater than means after in the ASCII collating sequence, where a> A> 1, and less than means before in the ASCII sequence, where 1< A< a.

Using the GROUP keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the AFTER GROUP OF control block.

Input records for which the expression evaluates to NULL values are ignored.

By default, if all input record values are NULL, the result of the aggregate is NULL. However, you can control this behavior and force the runtime system to return zero instead of NULL with the report.aggregateZero FGLPROFILE parameter.

This aggregate instruction makes a two-pass report when not using the GROUP keyword and is used in any control block other than ON LAST Row.

Related concepts
BEFORE/AFTER GROUP OF on page 1948

NULL on page 502
The NULL constant is provided as the "nil" value.
Two-pass reports on page 1951
The report engine supports two-pass reports, to order rows automatically.

MAX
Calculates the maximum value of a report parameter according to a condition.

Syntax

\[ \text{GROUP} \] \text{MAX(expression)} \ [\text{WHERE} \ condition] \]

1. expression is the expression to be computed.
2. condition is a boolean expression evaluated to compute the aggregate value.

Usage
For number, currency, and interval values, the MAX(expression) aggregate report instruction returns the maximum value for expression among all records or among records qualified by the WHERE clause and any GROUP specification.

For DATETIME or DATE data values, greater than means later and less than means earlier in time. Character strings are sorted depending on their first character. If your program is executed in the default (U.S. English) locale, for character data types, greater than means after in the ASCII collating sequence, where a> A> 1, and less than means before in the ASCII sequence, where 1< A< a.

Using the GROUP keyword causes the aggregate instructions to include only data of the current group of records that have the same value for the variable that you specify in the AFTER GROUP OF control block.

Input records for which the expression evaluates to NULL values are ignored.

By default, if all input record values are NULL, the result of the aggregate is NULL. However, you can control this behavior and force the runtime system to return zero instead of NULL with the report.aggregateZero FGLPROFILE parameter.

This aggregate instruction makes a two-pass report when not using the GROUP keyword and is used in any control block other than ON LAST Row.

Report engine behavior can be controlled with FGLPROFILE settings.

**NULL** on page 502

The NULL constant is provided as the "nil" value.

**Two-pass reports** on page 1951

The report engine supports *two-pass reports*, to order rows automatically.

---

### Report engine configuration

Report engine behavior can be controlled with FGLPROFILE settings.

By default, aggregate instructions such as `SUM()` return a NULL value if all input record values are NULL.

You can force the report engine to return a zero decimal value with the following FGLPROFILE setting:

```
Report.aggregateZero = {true|false}
```

When this entry is set to true, the `SUM()`, `AVG()`, `MAX()` and `MIN()` aggregate functions return zero when all values are NULL.

Default value of the configuration parameter is false (i.e. aggregate functions evaluate to null if all items are null)

When using `GROUP` aggregates with this entry is set to true, the aggregate instruction will still return NULL in the first `AFTER GROUP OF` output of the report. Zero values will be returned starting from second group output. This behavior is expected, for backward compatibility with older versions.

It is not recommended to use the `Report.aggregateZero` entry if you don't need that specific behavior.

fglrun

The fglrun tool is the runtime system program that executes p-code programs.

Syntax

```
fglrun [options] program [argument [...]]
```

1. **options** are described in Table 380: fglrun options on page 1968.
2. **program** is a .42r or .42m p-code program.
3. **argument** is an argument passed to the program

Options

Table 380: fglrun options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V or --version</td>
<td>Display version information for the tool.</td>
</tr>
<tr>
<td>-h or --help</td>
<td>Displays options for the tool. Short help.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -i \mbcs \ | Displays information.  
- \mbcs \ displays information about multibyte character set settings. |
<p>| -d | Start in debug mode. See Integrated debugger on page 2029 for more details. |
| -e \extfile,...\ | Specify a C extension module to be loaded. This option can take a comma-separated list of extensions. |
| -l | Link p-code modules together, see Compiling source files on page 1998. |
| -o \proname.42r|libname.42x \ | Output file specification when using the -l link option, it can be a 42r program or a 42x library. |
| -b | Displays compiler version information of the module, see Compiling source files on page 1998. |
| -P | Generate profiling information to stderr (UNIX™ only). See Program profiler on page 2053. |
| -M | Display a memory usage diagnostic when program ends. See Check runtime system memory leaks on page 403. |
| -m | Check for memory leaks. If leaks are found, displays memory usage diagnostic and stops with status 1. See Check runtime system memory leaks on page 403. |
| --java-option=option | Passes Java runtime options when initializing the JNI interface. See Java Interface for more details. |
| --print-imports | Loads the specified modules and prints all IMPORT FGL instructions used in each module. See Compiling source files on page 1998. |
| --start-guilog=logfile | Log all GUI protocol exchange in a file. The GUI log file can then be replayed with the --run-guilog option. If the log file contains a %p placeholder, it is replaced by the current process id. |
| --run-guilog=logfile | Replays a GUI log created with the --start-guilog option. |
| --gui-listen=port | Instructs the runtime system to listen to a TCP port for incoming GUI connections. For more details see Connecting with a front-end on page 1017. |
| --module-size | Shows the amount of limited pcode size for a module. The next argument must be a .42m module. |
| --merge-cov name.4gl [name.42m.cov] | Merges FGLCOV coverage data files with source files to produce a readable file name.4gl.cov module. If the .42m.cov file is not located beside the source file, you can specify the full path with the second optional file path. See Source code coverage on page 2056. |</p>
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--program-size</td>
<td>Shows the amount of limited pcode size for an entire program. The next argument must be a .42r program file.</td>
</tr>
<tr>
<td>--trace</td>
<td>Starts the program by printing function call stack trace with parameter and return values. For more details, see Execution trace on page 2060.</td>
</tr>
</tbody>
</table>

**Usage**

The fglrun command line tool executes p-code programs, for example:

```mermaid
  fglrun myprogram.42r -x 123
```

The program file must contain the MAIN routine.
The arguments passed to the program can be queried with the arg_val() built-in function.
The .42r or .42m extension is optional:

```mermaid
  fglrun myprogram -x 123
```

**Note:** First fglrun tries to find the program file with the name provided in the command line. If the file is not found, the extension is removed (if it is present in the provided file name), and a new search is done by adding the .42r extension. If the file is still not found, fglrun tries with the .42m extension. This means that a program file myprogram.42m will be found and loaded, even if you pass myprogram.42r to fglrun. Specify program files without a .42r or .42m extension, to avoid mistakes and simplify migration from .42r linked programs to .42m-only modules (using IMPORT FGL).

**Related concepts**

Executing programs on page 520
There are different ways to execute compiled programs, depending on the configuration and the development or production context.

fglform

The fglform tool compiles form specification files into XML formatted files used by programs.

**Syntax**

```mermaid
  fglform [options] form-name.[per]
```

1. **options** are described in Table 381: fglform options on page 1970.
2. **form-name.[per]** is the form specification file. The .per extension is optional.

**Options:**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>-U ident</td>
<td>Undefines the macro 'ident'. See Source preprocessor on page 2019 for more details.</td>
</tr>
</tbody>
</table>

**Usage**

The `fglform` command line tool compiles a `.per` form specification file into a `.42f` compiled version:

```plaintext
fglform custform.per
```

The `.per` extension is optional, if not used, `fglform` will automatically search for files with this extension.

The `.42f` compiled version is an XML formatted file used by programs when a form definition is loaded with the `OPEN FORM` or `OPEN WINDOW WITH FORM` instructions.

**Related concepts**

Form specification files on page 1132
Form specification files are the source files defining the layout and content of application forms.

Compiling source files on page 1998
Describes how to build the runtime files from source files.

`fglcomp` on page 1972
The `fglcomp` tool compiles `.4gl` source files into `.42m` p-code modules.

**fgl2p**

The `fgl2p` tool compiles source files and assembles p-code modules into a `.42r` program or a `.42x` library.

**Syntax**

To create a library:

```plaintext
fgl2p [options] -o outfile.42x [pcmod.42m | srcfile.4gl] [...]
```
To create a program:

```bash
fgl2p [options] -o outfile.42r pcmod.42m srcfile.4gl library.42x [...]
```

1. options are described in Table 382: fgl2p options on page 1972.
2. outfile.42r is the name of the program to be created.
3. outfile.42x is the name of the library to be created.
4. pcmod.42m is a p-code module compiled with fglcomp.
5. source.4gl is a program source file.
6. library.42x is the name of a library to be linked.

**Options**

**Table 382: fgl2p options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V</td>
<td>Display version information for the tool.</td>
</tr>
<tr>
<td>-h</td>
<td>Displays options for the tool. Short help.</td>

<tr>
<td>-o outfile.ext</td>
<td>Output file specification, where ext can be 42r for a</td>
</tr>
<tr>
<td></td>
<td>program or 42x for a library.</td>
</tr>
<tr>
<td>otheroption</td>
<td>Other options are passed to the linker or compiler.</td>
</tr>
</tbody>
</table>

**Usage**

The fgl2p command line tool can compile .4gl source files and link .42m p-code modules together, to create a .42x library or a .42r program file.

```bash
fgl2p -o myprog.42r module1.4gl module2.42m lib1.42x
```

This tool is provided for convenience, in order to create programs or libraries in one command line. It uses the fglcomp and the fgllink tools to compile and link modules together.

**Related concepts**

Compiling source files on page 1998

Describes how to build the runtime files from source files.

**fglcomp**

The fglcomp tool compiles .4gl source files into .42m p-code modules.

**Syntax**

```bash
fglcomp [options] module.4gl
```

1. options are described in Table 383: fglcomp options on page 1973.
2. module.4gl is the program source file. The .4gl extension is optional.

</tr>
<tr>
<td>--java-option=option</td>
<td>Passes Java runtime options when initializing the JNI interface. See Java Interface for more details.</td>
</tr>
</tbody>
</table>

**Usage**

The fglcomp command line tool compiles a .4gl into a .42m p-code module:

```
fglcomp customers.4gl
```

If a compilation error occurs, the compiler generates an error file with an .err extension. The error file contains the original source code with error messages. Use the option -M to display the error messages to standard error instead of producing the .err file.

**Arguments for the -W option**

The -W option can be used to check for wrong language usage, that must be supported for backward compatibility. When used, this option helps to write better source code.

**Note:** Warnings are written to stderr.

The warning argument can be used as follows:

- `-W all` enables all warning flags.
- `-W error` makes the compiler stop if any warning is raised, as if an error occurred.
- `-W to-err-file` writes warnings to the .err file when this file is produced. By default warnings go to the stderr stream.
- `-W unused` displays a message for all unused variables.
- `-W return` displays a warning if the same function returns different number of values with several RETURN statements.
- `-W stdsql` displays a message for all non-portable SQL statements or language instructions.
- `-W print` displays a message when the PRINT instruction is used outside a REPORT.
- `-W implicit` warns on references to undeclared functions. A function is undeclared if not defined in the current module or in any imported module. This warning is silently ignored if IMPORT FGL is not used.
- `-W apidoc` prints a warning for invalid source documentation tags when using the --build-doc option.
The `-W` option also supports the negative form of arguments by using the `no-` prefix as in: `no-return`, `no-unused`, `no-stdsql`. You might need to use these negative forms in order to disable some warning when using the `-W all` option:

```bash
fglcomp -Wall -Wno-stdsql customers.4gl
```

Switches will be enabled/disabled in the order of appearance in the command line.

**Related concepts**

- **Compiling source files** on page 1998
  - Describes how to build the runtime files from source files.
- **fglform** on page 1970
  - The `fglform` tool compiles form specification files into XML formatted files used by programs.

**fgllink**

The `fgllink` tool assembles p-code modules produced with `fglcomp` into a `.42r` program or a `.42x` library.

**Syntax**

To create a library:

```bash
fgllink [options] -o outfile.42x module.42m [...]
```

To create a program:

```bash
fgllink [options] -o outfile.42r { module.42m | library.42x } [...]
```

1. `options` are described in Table 384: `fgllink` options on page 1975.
2. `outfile.42r` is the name of the program to be created.
3. `outfile.42x` is the name of the library to be created.
4. `module.42m` is a p-code module compiled with `fglcomp`.
5. `library.42x` is the name of a library to be linked.

**Options**

**Table 384: `fgllink` options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-V</code> or <code>--version</code></td>
<td>Display version information for the tool.</td>
</tr>
<tr>
<td><code>-h</code> or <code>--help</code></td>
<td>Displays options for the tool. Short help.</td>
</tr>
<tr>
<td><code>-e extfile[,...]</code></td>
<td>Specify a C extension module to be loaded. This option can take a comma-separated list of extensions.</td>
</tr>
<tr>
<td>`-o { progname.42r</td>
<td>libname.42x }`</td>
</tr>
<tr>
<td><code>otheroption</code></td>
<td>Other options are passed to <code>fglrun</code> for linking.</td>
</tr>
</tbody>
</table>

**Usage**

The `fgllink` command line tool links `.42m` p-code modules together to create a `.42x` library or a `.42r` program file.

```bash
fgllink -o myprog.42x module1.42m module2.42m lib1.42x
```

**Note:** `fgllink` is a wrapper calling `fglrun` with the `-l` option.
**Related concepts**

*Compiling source files* on page 1998
Describes how to build the runtime files from source files.

**fglmkmsg**
The `fglmkmsg` tool compiles `.msg` message files into a binary version used by programs.

**Syntax**

```bash
fglmkmsg [options] srcfile [outfile]
```

1. `options` are described in Table 385: `fglmkmsg` options on page 1976.
2. `srcfile` is the source message file.
3. `outfile` is the destination file.

**Options**

**Table 385: `fglmkmsg` options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V</td>
<td>Display version information for the tool.</td>
</tr>
<tr>
<td>-h</td>
<td>Displays options for the tool. Short help.</td>
</tr>
<tr>
<td>-r msgfile</td>
<td>De-compiles a binary message file.</td>
</tr>
</tbody>
</table>

**Usage**
The `fglmkmsg` command line tool compiles a `.msg` message file into a `.iem` compiled version:

```bash
fglmkmsg mess01.msg
```

For backward compatibility, you can specify the output file as second argument:

```bash
fglmkmsg mess01.msg mess01.iem
```

The `.iem` compiled version can be used by BDL programs, for example, when the `HELP` clause is used in a `MENU` or `INPUT` instruction.

**Related concepts**

*Message files* on page 1059
Message files centralize strings and larger texts identified by a number, that can be used in programs.

**fglmkext**
The `fglmkext` tool compiles and links a user C Extension.

**Syntax**

```bash
fglmkext [options] source.c [...]
```

1. `options` are described in Table 386: `fglmkext` options on page 1977.
2. `source` is a C source file implementing C extension functions.
Options

Table 386: fglmkext options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V</td>
<td>Display version information for the tool.</td>
</tr>
<tr>
<td>-h</td>
<td>Displays options for the tool. Short help.</td>
</tr>
<tr>
<td>-o libname</td>
<td>Output file specification, defines the C Extension library name.</td>
</tr>
</tbody>
</table>

Usage

The fglmkext command line tool compiles and links a C Extension library.

The command can be used with a single source file, the name of the library will default to the name of the specified source:

```
fglmkext myext.c
```

If a single C source file is provided, must define the usrFunctions C extension interface structure as well as the functions to be used from a BDL program.

In order to specify a library name, use the -o option, several C source files can also be specified. For example, on a UNIX platform:

```
fglmkext -o mycext.so module_a.c module_b.c
```

Related concepts

Creating C-Extensions on page 2110

Custom C-Extensions must be provided to the runtime system as Shared Objects (.so) on UNIX™, and as Dynamically Loadable Libraries (.DLL) on Windows®.

fgldb

The fgldb tool is an interface program for remote debugging.

Syntax 1: Debugging an application running on a server

```
fgldb -p process-id
```

1. `process-id` is the process identifier of the fglrun process.

Syntax 2: Debugging an app running on a mobile device

```
fgldb -m host[:port]
```

1. `host` is the host (or IP address) of the mobile device where the program executes, default is "localhost".
2. `port` is the TCP port number to connect to, default is 6400.

Options

Table 387: fgldb options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V</td>
<td>Display version information for the tool.</td>
</tr>
</tbody>
</table>
**Option** | **Description**
---|---
-h | Displays options for the tool.
-p process-id | Attach to a running process to debug
-m host[[:port]] | Attach to a running process to debug

**Usage**

The `fgldb` command line tool is an interface for remote debugging, attaching to a Genero program running on a server or on a mobile device (or mobile emulator).

**Related concepts**

- Attaching to a running program on page 2031
  It is possible to remotely start the debugger for a program running on the same computer.
- Debugging on a mobile device on page 2032
  It is possible to remotely start the debugger for an app running on a mobile device.

**fgldbsch**

The `fgldbsch` tool generates the database schema files from an existing database.

**Syntax**

```
fgldbsch -db dbname [options]
```

1. `dbname` is the name of the database from which the schema is to be extracted.
2. `options` are described in Table 388: `fgldbsch` options on page 1978.

**Options**

**Table 388: `fgldbsch` options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V</td>
<td>Display version information for the tool.</td>
</tr>
<tr>
<td>-h</td>
<td>Displays options for the tool. Short help.</td>
</tr>
<tr>
<td>-H</td>
<td>Display long help.</td>
</tr>
<tr>
<td>-v</td>
<td>Enable verbose mode (display information messages).</td>
</tr>
<tr>
<td>-ct</td>
<td>Display data type conversion tables.</td>
</tr>
<tr>
<td>-cx dbtype</td>
<td>Display data type conversion table for the give database type.</td>
</tr>
<tr>
<td>-db dbname</td>
<td>Specify the database as <code>dbname</code>. This option is required to generate the schema files.</td>
</tr>
<tr>
<td>-dv dbdriver</td>
<td>Specify the database driver to be used.</td>
</tr>
<tr>
<td>-un user</td>
<td>Define the user name for database connection as <code>user</code>.</td>
</tr>
<tr>
<td>-up pswd</td>
<td>Define the user password for database connection as <code>pswd</code>.</td>
</tr>
<tr>
<td>-ow owner</td>
<td>Define the owner of the database tables as <code>owner</code>.</td>
</tr>
<tr>
<td>-cv string</td>
<td>Specify the data type conversion rules by character positions in <code>string</code>.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-of name</td>
<td>Specify output files prefix, default is database name.</td>
</tr>
<tr>
<td>-tn tabname</td>
<td>Extract the description of a specific table.</td>
</tr>
<tr>
<td>-ie</td>
<td>Ignore tables with columns having data types that cannot be converted.</td>
</tr>
<tr>
<td>-cu</td>
<td>Generate upper case table and column names.</td>
</tr>
<tr>
<td>-cl</td>
<td>Generate lower case table and column names.</td>
</tr>
<tr>
<td>-cc</td>
<td>Generate case-sensitive table and column names.</td>
</tr>
<tr>
<td>-sc</td>
<td>Extract shadow columns.</td>
</tr>
<tr>
<td>-st</td>
<td>Extract system tables.</td>
</tr>
<tr>
<td>-om</td>
<td>Run schema extractor in old fglschema mode (accepts -c and -r options)</td>
</tr>
</tbody>
</table>

**Usage**

The `fgldbsch` command line tool extracts the schema description for any database supported by the product. The `.sch` schema file is mandatory to compiler forms or source modules using the `SCHEMA` instruction.

**Related concepts**

*Database schema* on page 476

Defines database table structures with column type information to be reused in program variable definitions.

**fglmkstr**

The `fglmkstr` tool compiles `.str` localized string resource files.

**Syntax**

```
fglmkstr [options] source-file[.str]
```

1. `options` are described in Table 389: `fglmkstr options` on page 1979.
2. `source-file` is the `.str` string file. You can omit the file extension.

**Options**

**Table 389: fglmkstr options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V</td>
<td>Display version information for the tool.</td>
</tr>
<tr>
<td>-h</td>
<td>Displays options for the tool. Short help.</td>
</tr>
</tbody>
</table>

**Usage**

The `fglmkstr` command line tool is used to compile `.str` localized string files into `.42s` files.

**Related concepts**

*Localized strings* on page 430
Localized strings provide a means of writing applications in which the text of strings can be customized on site.

fglwsdl

The fglwsdl tool produces web services stub files for client or server programs (from WSDL / XSD).

Syntax

fglwsdl command [options] parameter

1. command indicates what operation must be done by fglwsdl.
2. options are described in Commands and options on page 1980.
3. parameter depends on the command used.

Commands and options

Table 390: fglwsdl commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V</td>
<td>Display version information</td>

</tr>
<tr>
<td>-c [options]</td>
<td>Generate client stub (default) to be used in a GWS client application.</td>
</tr>
<tr>
<td>wsdl-spec</td>
<td>wsdl-spec is the name of a WSDL description file or the URL of a WSDL</td>
</tr>
<tr>
<td></td>
<td>description for a published web service.</td>
</tr>
<tr>
<td></td>
<td>The options are listed in Table 391: WSDL Options on page 1980 and Table</td>
</tr>
<tr>
<td>-s [options]</td>
<td>Generate server stub to be used in a GWS server application.</td>
</tr>
<tr>
<td>wsdl-spec</td>
<td>wsdl-spec is the name of a WSDL description file or the URL of a WSDL</td>
</tr>
<tr>
<td></td>
<td>description for a published web service.</td>
</tr>
<tr>
<td></td>
<td>The options are listed in Table 391: WSDL Options on page 1980 and Table</td>
</tr>
<tr>
<td>-x [options]</td>
<td>Generate BDL data types from a XML schema (XSD).</td>
</tr>
<tr>
<td>xsd-spec</td>
<td>xsd-spec is the name of an XML schema file or the URL of an XSD schema</td>
</tr>
<tr>
<td></td>
<td>resource on the web.</td>
</tr>
<tr>
<td>-regex regex</td>
<td>Validate the value against the regex regular expression described in XML</td>
</tr>
<tr>
<td>value</td>
<td>schema specification.</td>
</tr>
</tbody>
</table>

Table 391: WSDL Options

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-o file</td>
<td>Specify a base name for the output files.</td>
</tr>
<tr>
<td>-n service</td>
<td>Generate only for the given service name and port type.</td>
</tr>
<tr>
<td>port</td>
<td></td>
</tr>
<tr>
<td>-b binding</td>
<td>Generate only for the given binding.</td>
</tr>
</tbody>
</table>
Options | Description
---|---
-prefixed name | Add name as the prefix of the generated web service functions, variables and types. (name can contain %s for servicename, %p for portname and %f for filename)
-compatibility | Generate a Genero 1.xx compatibility client stub.
-fRPC | Force RPC convention; use RPC Convention to generate the code, regardless of what the WSDL information contains.
-fRPCNamespace | Generate code to support the namespace attribute for RPC parameters.
-disk | Save WSDL and all dependencies from an URL on the disk. **Note:** To generate code at the same time, you must use the option -c, -s, or both. Otherwise, no code is generated.
-domHandler | Generates the use of DOM in the client stub and calls to callback handlers.
-alias | Generates FGLPROFILE Logical names in place of URLs for the client stub.
-soap11 | Generates only client and server stubs supporting SOAP 1.1 protocol.
-soap12 | Generates only client and server stubs supporting SOAP 1.2 protocol.
-ignoreFaults | Do not generate extra code to handle soap faults.
-wsa <yes|no> | Force support of WS-Addressing 1.0 if yes, disable support of WS-Addressing 1.0 if no, otherwise support WS-Addressing 1.0 according to the WSDL definition.
-mtom <yes|no> | Override the WSDL MTOM policy with this option. If yes, generates the stub with MTOM support. If no, generates the stub without MTOM support. This option can be applied to the client side or server side.

Table 392: XSD Options

Options | Description
---|---
-o file | Name of the output file. If file has no extension, .inc is added.
-n name [ns] | Generate only for the given variable name and namespace (if there is one).
-prefixed name | Add name as the prefix of the generated data types.
-disk | Save XSD and all dependencies from an URL on the disk. **Note:** No code is generated.
- hexb64AsString | Generate all XSD base64 and hexBinary type as 4GL STRING.

If the WSDL has a Message Transmission Optimization Mechanism (MTOM) policy, the tool generates any xsd:base64Binary and xsd:hexBinary as a STRING data type with the XMLOptimizedContent attribute (instead of a BYTE data type). The STRING represents a file name on disk, that will be handled as a SOAP-attached file.

**Tip:** This option is useful for avoiding loading a file into a BYTE each time you want to send a big file.

If the WSDL does not have an MTOM policy, the tool generates any xsd:base64Binary and xsd:hexBinary as a STRING data type (instead of a BYTE data type). The programmer is responsible to set a base64 or hexbinary value to the STRING in order to avoid a XML serialization error with the peer, as that last one expects a base64 or an hexbinary value.
### Table 393: Common options

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-comment</td>
<td>Add XML comments to the generation.</td>
</tr>
<tr>
<td>-fArray</td>
<td>Force XML array generation instead of XML list when possible. If the WSDL contains an XML definition of a BDL list, generate a BDL array matching the same definition.</td>
</tr>
<tr>
<td>-fInheritance</td>
<td>Force generation of XML choice records for all inheritance types found in the schemas, otherwise only for abstract types and elements.</td>
</tr>
<tr>
<td>-fInlineTypes</td>
<td>Force generation of TYPE definitions for all global inlined types found in the schemas.</td>
</tr>
<tr>
<td>-noFacets</td>
<td>Don’t generate facet constraints restricting the value-space of simple data type.</td>
</tr>
<tr>
<td>-legacyTypes</td>
<td>Don’t generate BIGINT, TINYINT and BOOLEAN data types.</td>
</tr>
<tr>
<td>-ignoreMixed</td>
<td>Ignore attribute mixed=&quot;true&quot; in XML schemas when generating code.</td>
</tr>
<tr>
<td>-ext schema</td>
<td>Add an external schema. See option <code>-extDir</code>.</td>
</tr>
<tr>
<td>-extDir directory</td>
<td>Add all external schema files ending with .xsd in the directory.</td>
</tr>
<tr>
<td>Note:</td>
<td>External schemas for dependencies won’t be included in the WSDL description or in the XSD schema if their location attributes are missing. Use this option to add a missing external schema for a WSDL or XSD dependency.</td>
</tr>
<tr>
<td>-noValidation</td>
<td>Disable XML schema validation warnings.</td>
</tr>
<tr>
<td>-autoNsPrefix nb</td>
<td>Automatic prefix generation for variables and types using a substring of the namespace by removing the nb first elements (-1 means only the last element). For example: If a variable belongs to the namespace <a href="http://www.mycompany.com/Global/Service">http://www.mycompany.com/Global/Service</a>, a value of -1 will give Service as a prefix, and a value of 1 will give Global_Service as a prefix.</td>
</tr>
<tr>
<td>-nsPrefix ns value</td>
<td>Add value as prefix of the generated variables and types belonging to namespace ns (supersede the -prefix and the -autoNsPrefix option, and can be called several times).</td>
</tr>
</tbody>
</table>

### Table 394: Network options (when specifying an URL)

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-noHTTP</td>
<td>Disable HTTP - search for the WSDL description or the XML schema and its dependencies on the client instead of the internet. Useful, for example, if a company has restricted access to the internet.</td>
</tr>
<tr>
<td>-proxy location</td>
<td>Connect via proxy where location is host[:port] or ip[:port].</td>
</tr>
<tr>
<td>-pAuth login pass</td>
<td>Proxy authentication login and password.</td>
</tr>
<tr>
<td>-hAuth login pass</td>
<td>HTTP authentication login and password.</td>
</tr>
<tr>
<td>-cert cert</td>
<td>File of the X509 PEM-encoded certificate for HTTPS purpose.</td>
</tr>
<tr>
<td>-key key</td>
<td>File of the PEM-encoded private key for HTTPS purpose.</td>
</tr>
<tr>
<td>-wCert cert</td>
<td>Certificate name in the Windows™ keystore for HTTPS purpose (Windows™ only).</td>
</tr>
<tr>
<td>-CA list</td>
<td>A filename with the list of concatenated X509 PEM-encoded certificate authorities. (On Windows™, if not set, the Certificate Authority list of the key store is used).</td>
</tr>
</tbody>
</table>
Usage

The fglwsl command line tool produces the WSDL description of a web service that will be accessed by a GWS client application, or to define a WSDL description to creating a corresponding GWS server application. The tool generates the BDL data types from XML schemas (also known as XSD).

To access a remote web service, you must get the WSDL information from the service provider. Sample services can be found through UDDI registries (http://www.uddi.org), or on other sites such as XMethods (http://www.xmethods.net).

Related concepts
WS client stubs and handlers on page 3152
WS server stubs and handlers on page 3164

fglpass

The fglpass tool allows you to encrypt passwords.

Syntax

fglpass [options]

1. options are described in fglpass options.

Options

Table 395: fglpass options

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V</td>
<td>Display version information</td>
</tr>
<tr>
<td>-Vssl</td>
<td>Display OpenSSL version</td>

<td>Windows® certificate name to encrypt the password</td>
</tr>
<tr>
<td>-c cert</td>
<td>File of the PEM-encoded certificate to encrypt the password</td>
</tr>
<tr>
<td>-k key</td>
<td>File of the PEM-encoded private key to encrypt or decrypt the password</td>
</tr>
<tr>
<td>-enc64 file</td>
<td>File to be BASE64 encoded (result to stdout)</td>
</tr>
<tr>
<td>-dec64 file</td>
<td>BASE64 encoded file to be decoded (result to stdout)</td>
</tr>
<tr>
<td>-agent:port files</td>
<td>Start password agent on specified port to serve the list of private key files</td>
</tr>
</tbody>
</table>
### Command

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-gid</td>
<td>When executing <code>fglpass</code> in agent mode (with <code>-agent</code> option), allows authentication to be performed for all users belonging to the group of current users executing the command.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Requires the FGLPROFILE entry <code>security.global.agent.gid=true</code> for <code>fglrun</code>.</td>
</tr>
</tbody>
</table>

#### Usage

The `fglpass` command line tool allows you to:

- Encrypt a password using a RSA key or X.509 certificate and encode it in BASE64 form.
- Run a password agent that returns (in a protected way) the passwords that grant access to the different private keys used in all your applications.
- Encode a file in BASE64 form and decode it back.

For security reasons, it is recommended to avoid storing clear passwords in a file, or leave private keys unprotected without a password. The `fglpass` command can be used to encrypt passwords.

**Related concepts**

Encryption, base64 and password agent with `fglpass` tool on page 3117

#### fglWrt

Use the `fglWrt` tool to manage product licenses.

**Tip:** Limitations regarding the use of the `fglWrt` tool are discussed in the *Genero Licensing* manual.

#### Syntax

```
fglWrt [options]
```

1. `options` are described in Table 396: `fglWrt` options on page 1984.

#### Options

**Table 396: fglWrt options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V</td>
<td>Display version information for the tool.</td>
</tr>
<tr>
<td>-h</td>
<td>Displays options for the tool. Short help.</td>
</tr>
<tr>
<td>-l license</td>
<td>Installs a license.</td>
</tr>
<tr>
<td>-m key</td>
<td>Maintenance key specification.</td>
</tr>
<tr>
<td>-u</td>
<td>Check for active users.</td>
</tr>
<tr>
<td>-k key</td>
<td>Installation key for license validation.</td>
</tr>
<tr>
<td>-d</td>
<td>Remove current installed license.</td>
</tr>
<tr>
<td>-i</td>
<td>Clears the list of registered user sessions.</td>
</tr>
</tbody>
</table>
## Option Description

-\( a \) \( \text{option} \)

Check or view options, possible options are:

- `ps`: Shows processes on this machine.
- `cpu`: Shows number of CPU in the computer.
- `hostname`: Shows name of this machine.
- `info license`: Shows license information.
- `info stat`: Shows statistics of license server.
- `info users`: Shows all registered active users.
- `info up`: Shows if license server is up.

### Usage

The `fglNrt` command line tool is used to install, upgrade or delete licenses.

If no license is installed, it is not possible to use Genero Business Development Language.

#### fglgar

The `fglgar` is a tool for packaging applications for deployment as standalone on a server or on any Web server with Genero Application Server (GAS).

### Syntax

```bash
fglgar [options]
```

### Syntax with commands

```bash
fglgar command [options]
```

### fglgar commands

The `fglgar` tool supports three commands:

- `fglgar gar [options]`
  
  The `gar` command creates a Genero Archive file. Options are described in Table 398: `fglgar gar options` on page 1986.

- `fglgar war [options]`
  
  The `war` command creates a Java Web Archive (WAR) file embedding a Genero Archive and GAS in a jar file (JGAS). It also provides the option to add a customized Genero Browser Client (GBC). Options are described in Table 399: `fglgar war options` on page 1987.

- `fglgar run [options]`
  
  The `run` command executes a Genero Archive application previously packaged as a `war` file. Options are described in Table 400: `fglgar run options` on page 1987.
## Options

### Table 398: fglgar gar options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h --help</td>
<td>Displays help for the gar command.</td>
</tr>
<tr>
<td>-v --verbose</td>
<td>Displays the verbose output of additional information.</td>
</tr>
<tr>
<td>-q --quiet</td>
<td>Operates in silent mode</td>
</tr>
<tr>
<td>-o output_file_path</td>
<td>The relative or absolute path to the archive file to create. If not specified, the archive defaults to the name of current directory where the command is run.</td>
</tr>
<tr>
<td>--output output_file_path</td>
<td>Directory to archive.</td>
</tr>
<tr>
<td>--input-source directory</td>
<td>Specifies the Genero Archive resource directory where the application's public images are found. (These are common or can be shared by all your applications.)</td>
</tr>
<tr>
<td>--resource directory</td>
<td>Specifies Genero Archive application trigger execution component. (Optional).</td>
</tr>
<tr>
<td>--trigger-component component_name</td>
<td>Specifies Genero Archive application trigger execution component. (Optional).</td>
</tr>
<tr>
<td>--deploy-trigger command</td>
<td>(Optional) Specifies the Genero Archive trigger command to deploy the application. Generates a MANIFEST file, if none exists. Raises errors if a MANIFEST already exists.</td>
</tr>
<tr>
<td>--undeploy-trigger command</td>
<td>(Optional) Specifies the Genero Archive trigger command to undeploy the application. Generates a MANIFEST file, if none exists. Raises errors if a MANIFEST already exists.</td>
</tr>
<tr>
<td>--application application_file</td>
<td>Specifies the application configuration or executable file. If you specify executable (42r or 42m) files instead of xcf file, xcf files are created automatically based on default configuration defined in the GAS as.xcf file. Multiple applications may be specified. Generates a MANIFEST file, if none exists. Raises errors if a MANIFEST already exists.</td>
</tr>
<tr>
<td>--service application_file</td>
<td>Specifies the service configuration file or executable. If you specify executable (42r or 42m) files instead of xcf file, xcf files are created automatically based on default configuration defined in the GAS as.xcf file. Multiple applications may be specified. Generates a MANIFEST file, if none exists. Raises errors if a MANIFEST already exists.</td>
</tr>
</tbody>

<td><code>-E log.file.path=</code>'pwd'`</td>
</tr>
</tbody>
</table>
**Usage**

The `fglgar` command line tool is used to create Genero archive (`gar`), or Java Web archive (`war`) files. You can use it for the following methods of application deployment:

- You can deploy Web applications or services in a `gar` file on any Web server where the GAS is installed.
- You can deploy Genero applications and services on a Java EE server like Apache Tomcat® or Glassfish (via `war`) and then with the browser you can access your applications and services.
- You can also run Web applications or services in a Java servlet (`war`) as standalone on a machine (without any Java EE Web server) and access your applications and services via a browser.

In other words, the `fglgar` tool allows you to develop, package, and test your Web application or service on a browser without GAS being installed on the server.

**Important:**

- The FGLGWS needs to be installed on the server to interpret the Genero 4GL applications and services.
- You need a Java Runtime Environment (JRE) version that is at least version 1.8 or greater.

For usage options, run the command `fglgar` without any other parameters or with the help (`-h`) option.

**Tip:** For help with using a specific command, for example `gar`, running `fglgar gar --help`, is the same as running `fglgar gar --help`.

**Related concepts**

Packaging web applications on page 2063
Describes methods of packaging the runtime files and resources of your web applications and services using the `fglgar` tool.

---

**fpi**

The `fpi` tool displays product version information.

**Syntax:**

```
fpi [options]
```

1. `options` are described in Table 401: `fpi options` on page 1988.

**Options**

**Table 401: fpi options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-V</td>
<td>Display version information for the Genero BDL package.</td>
</tr>
<tr>
<td>-h</td>
<td>Displays options for the tool.</td>
</tr>
<tr>
<td>-l or --list</td>
<td>List version information for all Genero BDL command line tools.</td>
</tr>
</tbody>
</table>

**Usage**

The `fpi` command line tool can be used to list version information for all command line tools available in the Genero BDL package.
gmabuildtool

The gmabuildtool is a utility to create and test applications for an Android™ device.

Syntax

\[
\text{gmabuildtool command [option [...]]}
\]

1. \textit{command} can be one of the following:
   - \texttt{updatesdk}: updates the Android™ SDK, to download packages required by GMA.
   - \texttt{scaffold}: manages scaffold archives.
   - \texttt{build}: builds an APK package.
   - \texttt{test}: deploys and launches an app on the device or emulator.
2. \textit{option} can be a general or command-specific option, as described in Options on page 1989.

Known issues

\textbf{Important:} When using \texttt{gmabuildtool updatesdk} on Microsoft™ Windows® platforms, the "tools" package of Android™ SDK cannot be updated due to an SDK manager bug. The workaround is to download and install a new Android™ SDK. This problem exists for example with Android™ SDK 26.0.2, and may be solved in higher SDK versions.

Options

Table 402: General gmabuildtool options

<table>

</tbody>
</table>
| --build-app-colors color-list | -bc | Define the Android™ color theme for the app (Android™ 5.0+/SDK 21+)
The value must be a comma-separated list of four hexadecimal RGB colors: #F44336,#B71C1C,#EF9A9A,...
The position of the RGB value in the color list defines its purpose:
1. colorPrimary: The main color used in the app.
2. primaryDark: The color used for the status bar and the navigation bar.
3. accent: The accent color used for widgets and table lines.
4. actionBarText: The foreground color for the texts in the action bar.
5. primaryText: The text color for items in the whole application.
6. windowBackground: The window background color.
7. navigationBarBackground: The background color of the bottom bar.
By default, the color theme is the Genero purple color. |
| --build-app-genero-program-main path | -bgpm | Relative path to the main module of the application (can be .xcf,.42m or .42r).
Defaults to main.42m |
| --build-app-genero-program path | -bgp | Defines the path to the application program files (.42m,.42f,etc)
The contents of this directory will be zipped and bundled inside APKs. This option can handle an already zipped Genero program archive.
If not specified, defaults to the current working directory.
**Note:** The path defined by this option is used as base directory for other options such as --build-project and application icon resources options.
|
| --build-app-icon-hdpi path | -bih | Defines the path to application icon in hdpi.
Default is top-dir/gma/ic_app_hdpi.png, where top-dir is defined by the --build-app-genero-program option. |
| --build-app-icon-mdpi path | -bim | Defines the path to application icon in mdpi.
Default is top-dir/gma/ic_app_mdpi.png, where top-dir is defined by the --build-app-genero-program option. |
| --build-app-icon-xhdpi path | -bixh | Defines the path to application icon in xhdpi.
Default is top-dir/gma/ic_app_xhdpi.png, where top-dir is defined by the --build-app-genero-program option. |
<table>
<thead>
<tr>
<th>Option</th>
<th>Short option</th>
<th>Description</th>

</tr>
<tr>
<td><code>--build-app-name app-name</code></td>
<td><code>-bn</code></td>
<td>Application name. If not specified, the application name defaults to the current working directory.</td>
</tr>
<tr>
<td><code>--build-app-package-name name</code></td>
<td><code>-bpn</code></td>
<td>APK package name. It is recommended to format the package name as &quot;com.organization-name.app-name&quot;. If not specified, the application package name defaults to <code>com.example.current-working-directory</code>.</td>
</tr>
<tr>
<td><code>--build-app-permissions permissions</code></td>
<td><code>-ba</code></td>
<td>Android™ application permissions. The list of permissions is provided as a comma separated list of <code>android.permission.*</code> identifiers. For more details, see Android permissions on page 3321.</td>
</tr>
<tr>
<td><code>--build-app-version-code version-code</code></td>
<td><code>-bvc</code></td>
<td>Application version code. For example: 100915. The value of this option must be an integer (do not use decimal numbers).</td>
</tr>
<tr>
<td><code>--build-app-version-name version-name</code></td>
<td><code>-bvn</code></td>
<td>Application version name. For example: 10.09.15. This will be the actual app version visible on devices.</td>
</tr>
<tr>
<td><code>--build-apk-outputs path</code></td>
<td><code>-bo</code></td>
<td>Defines the destination folder where the APK packages must be created.</td>
</tr>
<tr>
<td><code>--build-cordova cordova-plugin-names</code></td>
<td><code>-bco</code></td>
<td>Defines Cordova plugins to be embedded in the app package. When specifying multiple cordova plugins, use the comma (,) as separator. The name of the plugin must match the Git repository name. It is case-sensitive. Note: To get the list of available Cordova plugins, use the <code>gmabuildtool scaffold --list-plugins</code> command. For further information, see Cordova plugins on page 3370.</td>
</tr>
<tr>
<td><code>--build-force-scaffold-update</code></td>
<td><code>-bfsu</code></td>
<td>Forces to re-create the app project directory with the original GMA scaffold directory (defined by <code>--build-project</code>).</td>

<tr>
<td>Option</td>
<td>Short option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>--build-jarsigner-alias alias</td>
<td>-bja</td>
<td>Jarsigner alias. This is the alias provided to the <code>keystore</code> utility to build the keystore file to sign the app. Used when APK artifacts are signed.</td>
</tr>
<tr>
<td>--build-jarsigner-keypass keypass</td>
<td>-bjk</td>
<td>Jarsigner keystore path. Specifies the password used to protect the private key of the keystore entry addressed by the alias specified in the <code>--build-jarsigner-alias</code> option. The password is required when using jarsigner to sign a JAR file. Used when APK artifacts are signed.</td>
</tr>
<tr>
<td>--build-jarsigner-keystore path</td>
<td>-bjks</td>
<td>Jarsigner keystore path. This is the path to the keystore file generated by the <code>keystore</code> utility to sign the app. Used when APK artifacts are signed.</td>
</tr>
<tr>
<td>--build-jarsigner-storepass storepass</td>
<td>-bjs</td>
<td>Jarsigner storepass. Specifies the password that is required to access the keystore. Used when APK artifacts are signed.</td>
</tr>
<tr>
<td>--build-mode {release</td>
<td>debug}</td>
<td>-bm</td>
</tr>
<tr>
<td>--build-output-apk-name name</td>
<td>-ban</td>
<td>Defines the prefix for the APK packages names. By default, this prefix is &quot;app&quot;. The file name of the APK package is formed from: 1. The APK file name prefix defined by the <code>--build-output-apk-name</code> option (by default, &quot;app&quot;), 2. When building a debug version, the <code>--debug</code> suffix, 3. The <code>.apk</code> file extension. For example, if the APK file name prefix is <code>MyApp</code> and is a debug package, the resulting APK file name will be: <code>MyApp-debug.apk</code>. Defines the path to the directory containing the original GMA binary archive files (i.e. scaffolding), or the directory containing the Android™ Studio project, when building a customized GMA. Default is <code>top-dir/gma/project</code>, where <code>top-dir</code> is defined by the <code>--build-app-genero-program</code> option. Forces a silent build, by answering yes to all questions asked during the build process. By default, the user must answer to the build questions by yes/no.</td>
</tr>
<tr>
<td>--build-project path</td>
<td>-bp</td>
<td></td>
</tr>
<tr>
<td>--build-quietly</td>
<td>-bq</td>
<td></td>
</tr>
</tbody>
</table>
Option | Short option | Description
--- | --- | ---
--build-status-icon-hdpi path | -bsh | Status icon path for hdpi (high dots per inch) size.
The default path is `top-dir/gma/ic_status_hdpi.png`, where `top-dir` is defined by the `--build-app-genero-program` option.
If this option is not specified, yet you provide default files under the gma directory named like those defined for the default path, your package will use these files. If you don't provide any status icon files, the default files are used.

--build-status-icon-mdpi path | -bsm | Status icon path for mdpi (medium dots per inch) size.
The default path is `top-dir/gma/ic_status_mdpi.png`, where `top-dir` is defined by the `--build-app-genero-program` option.
If this option is not specified, yet you provide default files under the gma directory named like those defined for the default path, your package will use these files. If you don't provide any status icon files, the default files are used.

--build-status-icon-xhdpi path | -bsxh | Status icon path for xhdpi (extra-high dots per inch) size.
The default path is `top-dir/gma/ic_status_xhdpi.png`, where `top-dir` is defined by the `--build-app-genero-program` option.
If this option is not specified, yet you provide default files under the gma directory named like those defined for the default path, your package will use these files. If you don't provide any status icon files, the default files are used.

Related concepts

Building Android apps with Genero on page 3317
Genero provides a command-line tool to create applications for Android™ devices.

gmibuildtool

The gmibuildtool is a utility to create and test applications for an iOS devices.

Syntax

```
   gmibuildtool [options]
```

1. options are described in Options on page 1995.
Options

Table 407: gmibuildtool options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--app-name application-name</td>
<td>Display name of the mobile app. This option can be specified to define the display name of the app, it sets the CFBundleDisplayName property in the Info.plist file. If not specified, the name defaults to &quot;Noname&quot;.</td>
</tr>
</tbody>
</table>
| --app-version application-version | Defines app version visible to the users on the App Store. This option is mandatory and sets CFBundleVersion properties in the Info.plist file.  
Note: If the --build-number option is not used, --app-version will also set the both the CFBundleShortVersionString property. 
In iTunes® Connect, you define the version of your app, that must match the CFBundleVersion property in the Info.plist file of the app. If these versions do not match, the app cannot be published. Once the app is visible on App Store, the version specified in iTunes® Connect shows up in the "Version" section of the application page. 
The recommendation for the app version number is that it is a string comprised of three period-separated integers. For example: "1.4.2" |
| --bundle-id bundle-identifier | Defines the Bundle Identifier (a.k.a. App Id) for the app. This option is mandatory and sets the CFBundleIdentifier property in the Info.plist file. 
A bundle identifier is the unique identifier of your app, to let iOS recognize new app versions. When developing for the simulator, you can choose your own identifier. When creating an application for the App Store, the bundle identifier must be registered with Apple. If not specified, the name defaults to "noname" (for prototyping). |
| --build-cordova cordova-plugin-names | Defines Cordova plugins to be embedded in the app package. 
When specifying multiple cordova plugins, use the comma (,) as separator. 
The name of the plugin must match the Git repository name. It is case-sensitive.  
Note: To get the list of available Cordova plugins, use the gmibuildtool --list-plugins command. |
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| --build-number build-number | Defines the build number used to upload a new binary of the same app version.  
This option must be used to distinguish different builds for the same app version. It sets the CFBundleShortVersionString property in the Info.plist file.  
The build number needs to be incremented in order to upload a new binary version of the same app version in iTunes® Connect.  
If this option is not used, the build number defaults to the version specified with the --app-version option.  
The build number is a string comprised of three period-separated integers. For example: "1.4.2" |
| --certificate identity | Name of a certificate to sign the app.  
This option is mandatory to build apps for a physical device or for the app store.  
The certificate can be found in the Keychain® access program, in the "Common Name" field of the certificate panel.  
The command security find-identity -v can be used to list all available certificates. |
| --crypto [yes|no]      | Enables GWS cryptographic APIs based on the OpenSSL library. When using this option, the OpenSSL library is embedded into the resulting .ipa file.  
The default is yes. |
| --device device-name   | Defines the name of a device or simulator.  
• By default, when not specifying the --device option, a GMI.app directory is created for the simulator.  
• When specifying the --device booted option, the GMI.app directory is created and the app is installed on the booted simulator.  
• When specifying the --device phone option, the GMI.app directory and .ipa file are created.  
• When specifying the --device physical-device-name option (with a real physical device name plugged on your Mac), the GMI.app directory and .ipa file are created and the app is installed on the device.  
**Note**: Use the instruments -s Xcode® command to find the list of available devices (simulators or connected devices). |
| --extension-libs       | Specify the libraries to use when compiling and linking the app.  
This option is used when you want to provide your own C extension or custom front calls. |
<p>| --help                 | Display the help of the command tool. |</p>
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--icons icons-dir</td>
<td>Provides the directory where the application icons are located. By default, the application icons directory is <code>current-working-dir/gmi</code>. The name of the app icon files must be: icon_57x57.png, icon_72x72.png, icon_29x29.png, icon_40x40.png, icon_120x120.png, icon_152x152.png, icon_58x58.png, icon_76x76.png, icon_80x80.png</td>
</tr>
<tr>
<td>--install [yes</td>
<td>no]</td>
</tr>
<tr>
<td>--install-plugins github-url</td>
<td>This option installs additional plugins in the GMI installation directory.</td>
</tr>
<tr>
<td>--launch-images launch-images-dir</td>
<td>The directory where launch images are located. By default, the launch images directory is <code>current-working-dir/gmi</code>. <strong>Note:</strong> This option is ignored if the <code>--storyboard</code> option is provided. The name of the image files must be: Default.png, <a href="mailto:Default@2x.png">Default@2x.png</a> <a href="mailto:Default-568h@2x.png">Default-568h@2x.png</a>, <a href="mailto:Default-Portrait-667h@2x.png">Default-Portrait-667h@2x.png</a> <a href="mailto:Default-Landscape-667h@2x.png">Default-Landscape-667h@2x.png</a>, <a href="mailto:Default-Portrait-736h@3x.png">Default-Portrait-736h@3x.png</a>, <a href="mailto:Default-Landscape-736h@3x.png">Default-Landscape-736h@3x.png</a>, <a href="mailto:Default-Portrait@2x.png">Default-Portrait@2x.png</a>, <a href="mailto:Default-Landscape@2x.png">Default-Landscape@2x.png</a>. Each file name corresponds to a device type (you may not need to provide all files if you target only recent iOS devices), see Apple® Developer documentation for more details about launch images.</td>
</tr>
<tr>
<td>--list-plugins</td>
<td>This option lists the shipped plugins and additional plugins installed in the GMI installation directory.</td>
</tr>
<tr>
<td>--mode [debug</td>
<td>release]</td>
</tr>
</tbody>
</table>

Note: This option is ignored if the `--storyboard` option is provided. The name of the image files must be: Default.png, Default@2x.png Default-568h@2x.png, Default-Portrait-667h@2x.png Default-Landscape-667h@2x.png, Default-Portrait-736h@3x.png, Default-Landscape-736h@3x.png, Default-Portrait@2x.png, Default-Landscape@2x.png. Each file name corresponds to a device type (you may not need to provide all files if you target only recent iOS devices), see Apple® Developer documentation for more details about launch images.
<table>

**Related concepts**

Building iOS apps with Genero on page 3332
Genero provides a command-line tool to build applications for iOS devices.

**Compiling source files**

Describes how to build the runtime files from source files.

- Compiling form specification files (.per) on page 1999
- Compiling message files on page 1060
- Compiling string resource files on page 436
- Compiling program code files (.4gl) on page 2001
Compiling form specification files (.per)

The .per form definition files must be compiled to .42f XML files, in order to be loaded by the runtime system.

Understanding .per source compilation

Form specification files (with .per file extension) must be compiled to runtime form files (with .42f file extension) by using the fglform tool.

Compiled form files are XML independent from the platform and processor architecture.

The following lines show a compilation in a UNIX™ shell session:

```bash
$ cat form.per
LAYOUT
GRID
{
    [f01   ]
}
END
END
ATTRIBUTES
f01 = FORMONLY.field1;
END

$ fglform form.per

$ ls -s form.42f
  4 form.42f
```

Automatic compilation of imported modules

When compiling a .per module that includes other forms with the FORM instruction, fglform will automatically compile the included forms, if the .per source is more recent as the .42f file. The included forms can be located in a different directory as the main form.

For more details, see FORM clause on page 1196.

Handling fglform compiler errors

If an error occurs, the compiler writes an error file with the .err extension.

```bash
$ cat form.per
LAYOUT
GRID
{
}

$ fglform form.per
The compilation was not successful. Errors found: 1.
The file 'form.err' has been written.

$ cat form.err
LAYOUT
GRID
```
With the -M option, you can force the compiler to display an error message instead of generating an .err error file (line break added for documentation readability):

```
$ fglform -M form.per
form.per:4:1:4:1: error:(-6803)
    A grammatical error has been found at '}', expecting SCR_TEXT.
```

### Produce compiler warnings with -W

By default, the compiler does not raise any warnings. You can turn on warnings with the -W option:

```
$ cat form.per
LAYOUT
GRID

{ [f01 ] }
END
END
ATTRIBUTES
f01 = FORMONLY.field1, WIDGET="COMBO";
END
```

```
$ fglform -Wall form.per
form.per:9: warning (-8005) Deprecated feature: The WIDGET attribute is obsolete
```

### Compiling message files

The .msg message files must be compiled to .iem binary files, in order to be loaded by the runtime system.

In order to use message files in a program, the message source files (with .msg extension) must be compiled with the fglmkmsg on page 1976 utility to produce compiled message files (with .iem extension).

The following command line compiles the message source file mess01.msg:

```
fglmkmsg mess01.msg
```

This creates the compiled message file mess01.iem.

For backward compatibility, you can specify the output file as second argument:

```
fglmkmsg mess01.msg mess01.iem
```

The .iem compiled version of the message file must be distributed on the machine where the programs are executed.

### Related concepts

- **Compiling program code files (.4gl)** on page 2001
  
  The .4gl source files must be compiled to .42m p-code files, in order to be loaded by the runtime system.

- **Compiling form specification files (.per)** on page 1999
  
  The .per form definition files must be compiled to .42f XML files, in order to be loaded by the runtime system.

- **Importing modules** on page 2003
Describes how to define modules interdependence with IMPORT FGL.

**Compiling string resource files**

The `.str` source string files must be compiled to `.42s` binary files, in order to be loaded by the runtime system.

To compile a source string file, use the `fglmkstr` compiler.

```
$ fglmkstr filename.str
```

The `fglmkstr` tool generates a `.42s` file with the `filename` prefix.

**Important:** When compiling a `.str` source string file, you must set the locale (character set) corresponding to the encoding used in the `.str` file.

**Related concepts**

- `fglmkstr` on page 1979
- The `fglmkstr` tool compiles `.str` localized string resource files.
- `Extracting strings from sources` on page 434
- Localized strings can be easily extracted from `.4gl` and `.per` source files.

**Compiling program code files (.4gl)**

The `.4gl` source files must be compiled to `.42m` p-code files, in order to be loaded by the runtime system.

**Understanding .4gl source compilation**

Genero BDL source code modules (with `.4gl` file extension) must be compiled to p-code modules (with `.42m` file extension) by using the `fglcomp` on page 1972 tool.

Compiled p-code modules are independent of the platform and processor architecture. They are interpreted by the Genero runtime system (`fglrun` on page 1968).

The following lines show the compilation of the `prog.4gl` source, in a UNIX™ shell session:

```
$ cat prog.4gl
MAIN
  DISPLAY "hello"
END MAIN

$ fglcomp prog.4gl

$ ls -s prog.42m
  4 prog.42m
```

**Automatic compilation of imported modules**

When compiling a `.4gl` module that imports other modules with the `IMPORT FGL` instruction, `fglcomp` will automatically compile the imported modules, if they are located in the same directory of the current module, and if the `.4gl` source is more recent as the `.42m` file.

For more details, see `Importing modules` on page 2003.

**Handling fglcomp compiler errors**

If an error occurs, the compiler writes by default an error file with the `.err` extension.

```
$ cat prog.4gl
MAIN
  LET x = "hello"
END MAIN
```
$ fglcomp prog.4gl
Compilation was not successful. Errors found: 1.
The file prog.4gl has been written.

$ cat prog.err
MAIN
  LET x = "hello"
  | The symbol 'x' does not represent a defined variable.
  | See error number -4369.
END MAIN

With the -M option, you can force the compiler to display an error message instead of generating an .err error file:

$ fglcomp prog.4gl
xx.4gl:2:8 error:(-4369) The symbol 'x' does not represent a defined variable.

**Produce compiler warnings with -W**

By default, the compiler does not raise any warnings.

To improve code quality, enable compiler warnings with the -W option:

$ cat prog.4gl
MAIN
  DATABASE test1
  SELECT COUNT(*) FROM x, OUTER(y) WHERE x.k = y.k
END MAIN

$ fglcomp -W stdsql prog.4gl
xx.4gl:3: warning: SQL statement or language instruction with specific SQL syntax.

When a warning is raised, you can use the -W error option to force the compiler to stop as if an error was found.

For more details about the -W option, see Arguments for the -W option on page 1974.

**Verbose compilation**

Consider using the --verbose option of the compiler to get detailed information about the source compilation:

$ fglcomp --verbose main.4gl
[parsing main.4gl]
[compiling: fglcomp --import-by=main --verbose mod1]
[parsing mod1.4gl]
[compiling: fglcomp --import-by=main,mod1 --verbose mod2]
[parsing mod2.4gl]
[writing mod2.42m]
[loading mod2.42m]
[writing mod1.42m]
[loading mod1.42m]
[writing main.42m]

**Related concepts**

Importing modules on page 496
Use the IMPORT ... instruction to import BDL, C or Java external modules in the current module.

**Importing modules**

Describes how to define modules interdependence with IMPORT FGL.

With the IMPORT FGL instruction, module symbols such as variables, types and constants can be referenced in the importing module.

The next source example imports the myutils and account modules, and uses the init() and set_account() functions of the imported modules. The first function call is qualified with the module name - this is optional but required to resolve ambiguities when the same function name is used by different modules:

```plaintext
IMPORT FGL myutils
IMPORT FGL account
MAIN
   CALL myutils.init()
   CALL set_account("CFX4559")
   ...
END MAIN
```

**Related concepts**

IMPORT FGL module on page 497

The IMPORT FGL instruction imports module symbols.

**Linking libraries**

Describes how to link .42m modules together to build a .42x library file.

**Grouping .42m modules in .42x libraries**

Compiled .42m modules can be grouped in libraries using the fgllink on page 1975 linker. The library file gets the .42x extension.

The linker can be used to create .42x libraries or .42r program files. If none of the modules provided to the linker defines the MAIN block, the linker creates a library file; if a MAIN block is present, the linker creates a program file. Make sure to use the correct file extension.

**Note:** Linking is supported for backward compatibility, it is recommended that you use IMPORT FGL instead.

Library linking is done with the fgllink tool by using the -l option. The fgllink tool can be used for convenience, it is a simple script calling fglrun -l.

The following lines show a link procedure to create a library in a UNIX™ shell session:

```plaintext
$ fglcomp fileutils.4gl
$ fglcomp userutils.4gl
$ fgllink -o libutils.42x fileutils.42m userutils.42m
```

When you create a library, all functions of the 42m modules used in the link command are registered in the 42x file.

**Important:** The 42x library file does not contain the 42m p-code. When deploying your application, you must provide all compiled 42m modules.

When creating a 42x library, all functions must be uniquely defined; otherwise, error -6203 will be returned by the linker.

**Using libraries when linking programs**

The 42x libraries are typically used to link the final 42r programs:

```plaintext
$ fglcomp mymain.4gl
$ fgllink -o myprog.42r mymain.42m libutils.42x
```
The 42r programs must be re-linked, if the content of the 42x libraries changes.

In this example, if a function of the userutils.4gl source file was removed, you must recompile userutils.4gl, re-link the libutils.42x library and re-link the myprog.42r program.

**Linking libraries with other libraries**

It is possible to create a library by referencing other 42x library files in the link command, as long as 42m modules can be found:

```
$ fglcomp module_1.4gl
$ fglcomp module_2.4gl
$ fgllink -o lib_A.42x module_1.42m
$ fgllink -o lib_B.42x module_2.42m lib_A.42x
$ fgllink -o myprog.42r lib_B.42x
-- will hold functions of module_1 and module_2.
```

**P-Code module find path FGLLDPATH**

If you do not specify an absolute path for a file, the linker searches by default for 42m modules and 42x libraries in the current directory.

If the 42m modules are not in the current directory, you can specify the 42m module search path with the FGLLDPATH environment variable.

**Linking libraries when using C Extensions**

If you are using C-Extensions, you may need to use the -e option to specify the list of extension modules, if the IMPORT keyword is not used:

```
$ fgllink -e extlib,extlib2,extlib3 -o libutils.42x fileutils.42m userutils.42m
```

**Related concepts**

- Compiling program code files (.4gl) on page 2001
  The .4gl source files must be compiled to .42m p-code files, in order to be loaded by the runtime system.

**Linking programs**

Describes how to link .42m modules together to build a .42r program file.

**Purpose of .42r program files**

Traditional Genero programming allows you to call a function without seeing the definition of that function. The goal of linking programs is to resolve function symbols and build a .42r program file.

**Note:** When writing new applications, consider using IMPORT FGL instead of traditional linking. When using IMPORT FGL, the link stage is no longer required, and the 42m module containing the MAIN block can be directly executed.

Genero .42r program files are created by linking several .42m modules and/or .42x libraries together, where one of the modules defines a MAIN block.

By convention, the resulting program file gets the .42r extension.

Program linking is done with the fglrun tool by using the -l option. The fgllink tool can be used for convenience; it is a simple script calling fglrun -l.

The following lines show a link procedure to create a program in a UNIX™ shell session:

```
$ fglcomp main.4gl
$ fglcomp store.4gl
```
$ fgllink -o stores.42r main.42m store.42m

**Important:** If you omit the -o option in the fgllink command, the default output file will get the .42x extension (used for libraries), with the name of the module containing the MAIN block. The .42r file extension is used by convention, to distinguish a program dictionary file from a library dictionary file.

**Symbol resolution with the linker**

The purpose of the linking phase is to check for missing function symbols, and reference all the symbols in the resulting .42r program file. 

**Note:** The IMPORT FGL method is the preferred method for linking. However, you can mix both methods. The job of the linker is to resolve symbols that are not already resolved by the compiler from IMPORT FGL usage.

Any function used in the .42m modules specified in the link line must be provided. Missing symbols will result in a -1338 linker error:

```
$ cat main.4gl
MAIN
    CALL myfunc()
END MAIN

$ fglcomp main.4gl
$ fgllink -o prog.42r main.42m
ERROR(-1338): The function 'myfunc' has not been defined in any module in the program.
```

**Note:** Symbol resolution in only be done when linking programs. When linking a 42x library, there can be references to undefined functions.

When linking a 42r program, global symbols must be unique; otherwise, error -6203 will be returned by the linker. The same error will be returned when linking a 42x library by using modules defining the same functions.

The link process searches recursively for the functions used by the program. For example, if the MAIN block calls function FA in module MA, and FA calls FB in module MB, all functions from module MA and MB will be included in the 42r program definition.

**The linking process steps in detail**

When linking a .42r program (with modules possibly using IMPORT FGL), the linker works as follows:

1. **Loads all modules specified on the command-line. Builds a symbol-table of all public functions. Raises error -6203, if a public function is defined more than once.**

2. **Loads all imported modules (if not specified on the command line). Adds public functions to the symbol-table.**
   - If an imported function is already defined by a linked module, the imported function will be ignored.
   - If an imported function is not defined by a linked module, and is defined more than once, then this function is marked as "ambiguous" (this is legal, no warning or error is produced).

3. **All unresolved symbols on any module (linked modules and imported modules) will be resolved.**
   - If a function is not defined, error -1338 is thrown.
   - If a function is an ambiguous function (2.b), error -8401 is thrown.

**Note:**

Understand the difference in case of error -6203 and -8401:

- Error -6203: A function in a linked module is defined more then once. That's illegal.
- Error -8401: A function in an imported module is define more then once, and used by the linker to resolve a symbol. It's legal to define an imported function more than once, but this function cannot be used by the linker.
Content of a .42r program file

The generated 42r program files do not contain the 42m p-code, it is basically a dictionary of global symbols used by the program.

When deploying an application, both 42m modules and 42r program files must be provided.

Note: Since 42x library files are only used to build programs, you do not have to deploy 42x library files.

When linking a 42r program by using 42x libraries, the modules defined in a library are included only if one of the symbols in the module is used by the program. However, all symbols of 42m modules specified in the command line will always be referenced in the resulting 42r program file.

Note: During the link, when the same function symbols are defined in distinct libraries, the linker will select the function of the first library that was specified in the command line.

All symbols referenced in a module must exist in the final 42r program dictionary file. If a symbol is not found, the runtime system stops with error -1338. This error is fatal and cannot be trapped with an exception handler.

P-Code module find path FGLLDPATH

If you do not specify an absolute path for a file, the linker searches by default for 42m modules and 42x libraries in the current directory.

You can specify the 42m search path with the FGLLDPATH environment variable:

```
$ FGLLDPATH=/usr/dev/lib/maths:/usr/dev/lib/utils
$ export FGLLDPATH
$ ls /usr/dev/lib/maths
mathlib1.42x
mathlib2.42x
mathmodule11.42m
mathmodule12.42m
mathmodule22.42m
$ ls /usr/dev/lib/utils
fileutils.42m
userutils.42m
dbutils.42m
$ fgllink -o myprog.42r mymodule.42m mathlib1.42x fileutils.42m
```

In this example the linker will find the specified files in the /usr/dev/lib/maths and /usr/dev/lib/utils directories defined in FGLLDPATH.

Library versus module function precedence

When creating a .42r program by linking .42m modules with .42x libraries, if the same function is defined in a 42m and in a module of a 42x library, the function of the specified 42m module will be selected by the linker, and the function of the library will be ignored.

However, the linker will raise error -6203, if two 42m modules specified in the link command define the same function.

Exclusion of unused library module

When linking a .42r program by using a .42x library, if none of the functions of a module in the .42x library are used in the program, the complete module is excluded by the linker.

Note: Unused module exclusion may cause undefined function errors at runtime, such as when a function is only used in a dynamic call (an initialization function, for example.)

The following case illustrates this behavior:

```
$ cat module1.4gl
FUNCTION func11()
```
END FUNCTION

$ cat module2.4gl
FUNCTION func21()
END FUNCTION

$ cat main.4gl
MAIN
   CALL func11()
END MAIN

$ fglcomp module1.4gl
$ fglcomp module2.4gl
$ fglcomp main.4gl

$ fgllink -o lib.42x module1.42m module2.42m

$ fgllink -o prog.42r main.42m lib.42x -- Only module1.42m is included in .42r

Here, module x1.42m (with functions fx11 and fx12) will be referenced in the .42r program file, but functions of module x2.42m will not. At runtime, any dynamic call to functions fx21() or fx22() will fail with an untrappable error -1338.

Symbol conflicts with IMPORT FGL and linking

The job of the linker is to resolve symbols that are not already solved by the compiler from IMPORT FGL usage.

If the same function is defined by a linked module and an imported module, and the function is called without the module prefix, the imported function takes precedence over the linked module function.

The following example illustrates this case:

$ cat module1.4gl
FUNCTION func11()
   DISPLAY "module1.func11()"
END FUNCTION

$ cat module2.4gl
IMPORT FGL module1
FUNCTION func21()
   DISPLAY "module2.func21()"
   CALL func11() -- from module1, because it is imported
END FUNCTION

$ cat module3.4gl
FUNCTION func11() -- Same name as in module1.4gl
   DISPLAY "module3.func11()"
END FUNCTION

$ cat main.4gl
MAIN
   CALL func11() -- from module3, because it is linked
       CALL func21()  
END MAIN

$ fglcomp module1.4gl
$ fglcomp module2.4gl
$ fglcomp module3.4gl
$ fglcomp main.4gl
$ fgllink -o prog.42r main.42m module2.42m module3.42m
$ fglrun prog.42r
module3.func11()
Note: To make your code more readable, consider prefixing imported symbols with the module name and thus avoid any ambiguity.

Imported module using linked functions

When linking a program with modules using the IMPORT FGL instruction, the imported modules do not have to be specified in the link line.

However, if the imported module uses functions that come from other modules, which are not imported by this module, these non-imported modules must be specified in the link command line.

For example, if the main module imports module module1 to call the func11(), which in turn calls func21() from module2, but module1 does not import module2, then module2 must be linked to the program:

```
$ cat module1.4gl
FUNCTION func11()
  DISPLAY "module1.func11()"
  CALL func21()
END FUNCTION

$ cat module2.4gl
FUNCTION func21()
  DISPLAY "module2.func21()"
END FUNCTION

$ cat main.4gl
IMPORT FGL module1
MAIN
  CALL module1.func11()
END MAIN

$ fglcomp module1.42m
$ fglcomp module2.42m
$ fglcomp main.4gl

$ fglrun main.42m
module1.func11()
Program stopped at 'module1.4gl', line number 3.
FORMS statement error number -1338.
The function 'func21' has not been defined in any module in the program.

$ fgllink -o prog.42r main.42m module2.42m

$ fglrun prog.42r
module1.func11()
module2.func21()
```

Linking programs with C Extensions

If you are using C-Extensions, you may need to use the -e option to specify the list of extension modules if the IMPORT keyword is not used:

```
$ fgllink -e extlib,extlib2,extlib3 -o stores.42r main.42m store.42m

$ fglrun prog.42r
module1.func11()
module2.func21()
```

Related concepts

Linking programs using C-Extensions on page 2113
When creating a 42r program or 42x library, the linker needs to resolve all function names, including C-Extension functions.

**Using makefiles**

Describes how to define program construction rules in makefiles.

Most UNIX™ platforms provide the make utility program to compile projects. The make program is an interpreter of makefiles. These files contain directives to compile and link programs and/or generate other kind of files.

When developing on Microsoft™ Windows™ platforms, you may use the NMAKE utility provided with Visual C++. However, this tool does not have the same behavior as the UNIX™ make program. To have a compatible make on Windows™, you can install a GNU make or third party UNIX™ tools such as Cygwin.

For more details about the make utility, see the platform-specific documentation.

The follow example shows a typical makefile for Genero applications:

```bash
#------------------------------------------------------
# Generic makefile rules to be included in Makefiles
.SUFFIXES: .42s .42f .42m .42r .str .per .4gl .msg .hlp
FGLFORM=fglform -M
FGLCOMP=fglcomp -M
FGLLINK=fglrun -l
FGLMKMSG=fglmkmsg
FGLMKSTR=fglmkstr
FGLLIB=$$FGLDIR/lib/libfgl4js.42x
all::
  .msg.hlp:
    $(FGLMKMSG) $*.msg $*.hlp
  .str.42s:
    $(FGLMKSTR) $*.str $*.42s
  .per.42f:
    $(FGLFORM) $*.per
  .4gl.42m:
    $(FGLCOMP) $*.4gl
clean::
  rm -f *.hlp *.42? *.out
#-----------------------------
# Makefile example
include Makeincl
FORMS=
  customers.42f\n  orderlist.42f\n  itemlist.42f
MODULES=
  customerInput.42m\n  zoomOrders.42m\n  zoomItems.42m
customer.42x: $(MODULES)
  $(FGLLINK) -o customer.42x $(MODULES)
all:: customer.42x $(FORMS)
```

**42m module information**

Describes how to handle module information in .42m p-code files.

**Compiler and runtime compatibility**

The runtime system (fglrun) used to execute programs must be compatible with the fglcomp compiler version used to build the .42m modules.

To control this compatibility, the compiler writes Genero and p-code version information in the generated 42m files, in the p-code header.
The compiler also writes additional information in the p-code header, such as the source file name used at compilation, a timestamp, or a user-defined string/tag.

The p-code header information of a .42m file can be read with the `fglrun -b module.42m` command. This is useful on production sites, to check the version of the compiler that was used to build the .42m nodules.

It is also possible to get additional information about the p-code module such as the size used in memory with `fglrun --module-size`.

**Identifying the version of the compiler and runtime system**

To check if the version of the compiler or runtime system, use the `-V` option:

```
$ fglcomp -V
fglrun 3.10.12 internal-build-number
Genero virtual machine
Target 164x1212
...

$ fglrun -V
fglrun 3.10.12 internal-build-number
Genero virtual machine
Target 164x1212
...
```

**Extracting p-code header information**

To extract build information from a .42m file, run `fglrun` with the `-b` option:

```
$ fglrun -b mymodule.42m
3.10.12 /home/devel/stores/mymodule.4gl 24
```

The p-code header contains the following fields:

1. An optional timestamp, if the `--timestamp` option was used with `fglcomp`.
2. The Genero product version.
3. The full path of the source file, or the module name, if the `--omit-source-name` option was used with `fglcomp`.
4. The internal identifier of the p-code version.
5. An optional user-defined tag, if the `--tag=string` option was used with `fglcomp`.

**Avoiding the full source file path in the p-code header**

By default, `fglcomp` writes the source file name (full path) in the resulting .42m module:

```
$ fglcomp mymodule.4gl

$ fglrun -b mymodule.42m
3.10.12 /home/devel/stores/mymodule.4gl 24
```

To avoid the source name in the .42m module, use the `--omit-source-name` option of `fglcomp` to write only the module name in the p-code header:

```
$ fglcomp --omit-source-name mymodule.4gl

$ fglrun -b mymodule.42m
3.10.12 mymodule 24
```
Writing a custom string to the p-code header

Use the `--tag="custom-string"` option of `fglcomp`, to add a user-defined string to the p-code header. When reading p-code header information with `fglrun -b`, the user-defined string is printed as `tag="custom-string"`.

The tag field can for example be used to stamp the 42m file with the custom product version:

```
$ fglcomp --tag="OXOGEN 5.23" mymodule.4gl
$ fglrun -b mymodule.42m
3.10.12 /home/devel/stores/mymodule.4gl 24 tag="OXOGEN 5.23"
```

Writing a compilation timestamp to the p-code header

To write timestamp information in the p-code header, use the `--timestamp` option of `fglcomp`:

```
$ fglcomp --timestamp mymodule.4gl
$ fglrun -b mymodule.42m
2008-12-24 11:22:33 3.10.12 /home/devel/stores/mymodule.4gl 24
```

**Important:** When using the `--timestamp` compiler option to write build timestamp information in p-code modules, you will not be able to easily compare 42m files (based on a checksum, for example). Without the timestamp, `fglcomp` generates exactly the same p-code module as if the source file was not modified.

Reading p-code header of older versions

`fglrun` can read the header of p-code modules compiled with older versions of `fglcomp` and display version information for such old modules.

If `fglrun` cannot recognize a p-code module, it returns an execution status that is different from zero.

Reading p-code header of 42x and 42r files

When reading build information of a 42x or 42r file, `fglrun` scans all modules used to build the library or program. You will see different versions in the first column if the modules were compiled with different versions of `fglcomp`. However, it's not recommended that you mix versions on a production site:

```
$ fglrun -b myprogram.42r
3.10.11 /home/devel/stores/mymodule1.4gl 24
3.10.02 /home/devel/stores/mymodule2.4gl 24
3.10.12 /home/devel/stores/mymodule3.4gl 24
```

Computing the p-code size of a module or program

The `fglrun` command provides the `--module-size` option to compute the p-code size of a module:

```
$ fglrun --module-size mymodule.42m
12.34K mymodule
```

This size is defined by the amount of p-code instructions of the module.

**Note:** P-code modules are shared by all `fglrun` instances executing on the same computer. For more details, see Elements shared by multiple programs on page 402.

The `--program-size` option reports the total p-code size of all modules of a program:

```
$ fglrun --module-size myprogram.42r
0.34K module1
2.59K module2
```
Source code edition

Simple helper to better render sources in configurable text editors.

These topics concern source code editing. You are free to use your preferred source code editor to write your programs.

- Choosing the correct locale on page 2012
- Avoid Tab characters in screen layouts on page 2012
- Code completion and syntax highlighting with VIM on page 2012

Choosing the correct locale

Before starting to edit source files, you must identify and configure the editor with the locale (character set) you want to use in your sources.

The language supports single-byte and multibyte character sets. When developing multilingual applications, we recommend that you write .per and .4gl source files in ASCII, and externalize language-dependent messages in string resource files.

Related concepts
Localization on page 405
Localization support allows you to implement programs that follow specific language and cultural rules.

Avoid Tab characters in screen layouts

When editing .per form files, avoid using Tab characters in sources, especially in the LAYOUT or SCREEN sections of forms. Different kinds of text or source code editors can expand Tab characters differently, depending on the configuration settings. As a result, if two programmers are using different Tab expansion settings, the form layout will display in different ways. If used in a grid area, a Tab character will be interpreted as 8 blanks by fgform.

It is legal to use Tab characters in the rest of the .per file or .4gl sources (for example, to indent the code).

Code completion and syntax highlighting with VIM

The VIM editor

VIM is a well-known source code editor for programmers.

Automatic code completion and syntax highlighting is supported by fglcomp and fgform compilers, when using VIM.

Important: In order to use Genero code completion with VIM, you need at least VIM version 7 with the Omni Completion feature.

Configuring VIM for Genero BDL

Perform the following steps to enable code-completion for Genero:

1. Copy Genero VIM plugin files from FGLDIR/vimfiles onto your VIM plugin directory:
   - On Unix platforms, the VIM plugin directory is ~/.vim.
   - On Windows platforms, the VIM plugin directory is %USERPROFILE%\vimfiles.
2. Add the following lines to your VIM resources file
   - On Unix plaforms, the VIM resource file is ~/.vimrc.
• On Windows platforms, the VIM resource file is `%USERPROFILE%\_vimrc`.

```vimscript
au BufNewFile,BufRead *.per setlocal filetype=per
   syntax on
```

Alternatively, if you often switch between different versions of Genero BDL, you can reference the Genero VIM files directly without copying them, by adding the following lines to your VIM resource file:

```vimscript
let generofiles=expand($FGLDIR . "/vimfiles")
if isdirectory(generofiles)
   let &rtp=generofiles.'",.'&rtp
endif
au BufNewFile,BufRead *.per setlocal filetype=per
   syntax on
```

### Using VIM on Microsoft Windows platforms

On Windows platforms, you typically install the GVim (Graphical VIM) software.

**Note:** Some versions of VIM for Windows may use different configuration files and locations (_vimrc or .vimrc?). Refer to the VIM documentation, to make sure that you use the proper files.

When using the command line version VIM, you may want to add:

```bash
color shine
```

### Using code completion with Genero and VIM

First make sure the Genero environment is set (FGLDIR, PATH).

Open a `.4gl` or `.per` file, start to edit the file with VIM.

**Note:** On Windows platforms, if you start GVim from the icon, the Genero environment may not be set. As result fglcomp/fglform cannot be called from VIM. You need to set the Genero BDL environment before starting VIM.

When in insert mode, press `CTRL-X + CTRL-O`, to get a list of language elements to complete the instruction syntax or expression.

For convenience, `TAB` can also be used to get the completion list as with the `CTRL-X + CTRL-O` key combinations. However, `TAB` will only show the completion list, if the edit cursor in after a keyword: At the beginning of the line, `TAB` adds indentation characters.

For more details about VIM, see [http://www.vim.org](http://www.vim.org).

---

### Source documentation

Explains how to automatically generate documentation from your sources.

  - [Commenting a module](#) on page 2019
Understanding source code documentation

This is an introduction to source code documentation.

Documenting sources is an important task in software development, to share the code among applications and achieve better re-usability.

Source documentation must be concise, clear, and complete. However, documenting sources can be boring and subject to mistakes if large repetitive documentation sections have to be written by hand.

Source documentation can be produced automatically with the fglcomp compiler. The compiler can generate source documentation from the .4gl files of your project with minimum effort. The resulting source documentation is generated in simple HTML format and can be published on a web server.

Source documentation is generated with the --build-doc option of fglcomp. To extract documentation from a .4gl source:

```
fglcomp --build-doc filename.4gl
```

You can generate default documentation from the existing sources. For a better description of the code, add special # + comments in your sources to describe code elements such as functions, function parameters, and return values.

By default, only PUBLIC symbols are documented. If you want to include PRIVATE symbols, use the --doc-private option:

```
fglcomp --build-doc --doc-private filename.4gl
```

Prerequisites to produce documentation

This topic lists the requirements to generate source documentation.

To generate the HTML pages, fglcomp first generates .xa files which must be converted to .html files. The conversion from .xa to .html is done with an XSLT processor using the .xsl style sheets files provided in FGLDIR/lib/fgldoc/

You must have an XSLT processor installed on the machine where the documentation is generated.

- On UNIX™, fglcomp runs the FGLDIR/lib/fgldoc/Transform.sh script to convert .xa files to .html files. Therefore you need the xsltproc command line XSLT processor (from the libxml package).
- On Windows®, fglcomp runs the FGLDIR\lib\fgldoc\Transform.js script to convert .xa files to .html files. To run the Transform.js script, you must have cscript.exe installed with the Microsoft™.XMLDOM class (this is the case on recent Windows® versions).

**Note:** If the default result of the transformation does not fit your needs, the style sheets provided in FGLDIR/lib/fgldoc can be adapted to generate different HTML files.

Source documentation structure

The source documentation structure is based on the well-known Java-doc technique.

The generated documentation reflects the structure of your sources; in order to have nicely structured source documentation, you must have a nicely structured source tree.

The source documentation elements are structured as follows (elements in *italic* must be created by hand, others are generated files):

- Top/root directory (the root of your project)
  - overview.4gl (description of the project)
  - overview-summary.html
First create a file named `overview.4gl` in the top directory of the project. This file contains the overall description of the project. In that directory, the documentation generator creates the files `overview-summary.html`, `overview-frame.html`, `allclasses-frame.html`, `index-all.html`, `index.html` and `fgldoc.css`.

The documentation generator can scan sub-directories to build the documentation for a whole project; each source directory defines a package. For each directory (i.e. package), the generator creates a `package-summary.html` and a `package-frame.html` file. If a file with the name `package-info.4gl` exists, it will be scanned to complete the `package-summary.html` file with the package description.

The documentation generator creates a `filename.html` file for each `.4gl` source module, seen as a `class` in the documentation.

Adding comments to sources

Adding relevant information to your source documentation.

Commenting a module constant

The comment body is composed of paragraphs separated by a blank line. The first paragraph of the comment is a short description of the constant. This description will be placed in the constant summary table. The next paragraph is long text describing the constant in detail. Other paragraphs must start with a tag to identify the type of the paragraph; a tag starts with @ (the “at” sign).
Table 408: Supported @ tags

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@code</td>
<td>Indicates that the next lines show a code example using the constant.</td>
</tr>
</tbody>
</table>

Example

```plaintext
#+ This is the constant Pi
#+ To be used in trigo computing
#+ @code
#+ DISPLAY util.Math.cos( Pi / 2 )
#+
PUBLIC CONSTANT Pi = 3.14159
```

Commenting a module variable

To comment a module variable, add some lines starting with `#+`, before the variable definition (i.e., before the `DEFINE` instruction). The comment body is composed of paragraphs separated by a blank line. The first paragraph of the comment is a short description of the variable. This description will be placed in the variable summary table. The next paragraph is long text describing the variable in detail. Other paragraphs must start with a tag to identify the type of the paragraph; a tag starts with the `@` "at" sign.

Table 409: Supported @ tags

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@code</td>
<td>Indicates that the next lines show a code example using the variable.</td>
</tr>
</tbody>
</table>

Example

```plaintext
#+ Customer array
#+
#+ Fill this array with customer records and use it
#+ in DISPLAY ARRAY to control a TABLE
#+
PUBLIC DEFINE cust_list DYNAMIC ARRAY OF RECORD
cust_num INTEGER,
cust_name VARCHAR(50),
cust_addr VARCHAR(100)
END RECORD
```

Commenting a module type

To comment a module type, add some lines starting with `#+`, before the type definition (i.e., before the `TYPE` instruction). The comment body is composed of paragraphs separated by a blank line. The first paragraph of the comment is a short description of the type. This description will be placed in the type summary table. The next paragraph is long text describing the type in detail. Other paragraphs must start with a tag to identify the type of the paragraph; a tag starts with the `@"at"` sign.
Table 410: Supported @ tags

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@code</td>
<td>Indicates that the next lines show a code example using the type.</td>
</tr>
</tbody>
</table>

Example

```lisp
#+ This is the customer type
#+ Define variables with this type to hold customer records.
#+ @code
#+ DEFINE myvar t_cust
#+
PUBLIC TYPE t_cust RECORD
  cust_num INTEGER,
  cust_name VARCHAR(50),
  cust_addr VARCHAR(100)
END RECORD
```

Commenting a function

To comment a function, add some lines starting with `#+`, before the function body. The comment body is composed of paragraphs separated by a blank line. The first paragraph of the comment is a short description of the function. This description will be placed in the function summary table. The next paragraph is long text describing the function in detail. Other paragraphs must start with a tag to identify the type of the paragraph; a tag starts with the `@` "at" sign.

Table 411: Supported @ tags

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@code</td>
<td>Indicates that the next lines show a code example using the function.</td>
</tr>
<tr>
<td>@param name description</td>
<td>Defines a function parameter identified by <code>name</code>, explained by a <code>description</code>.</td>
</tr>
<tr>
<td></td>
<td><code>name</code> must match the parameter name in the function declaration.</td>
</tr>
<tr>
<td>@returnType data-type [, ...]</td>
<td>Defines the data type of the value returned by the function.</td>
</tr>
<tr>
<td>@return description</td>
<td>Describes the values returned by the function.</td>
</tr>
<tr>
<td></td>
<td>Several @return comment lines can be written.</td>
</tr>
</tbody>
</table>

Example using a FUNCTION definition with signature

```lisp
#+ Compute the amount of the orders for a given customer
#+ This function calculates the total amount of all orders for the customer identified by the cust_id number passed as parameter.
```
Example using a FUNCTION definition without signature (needs \texttt{@returnType})

```sql
#+ Compute the amount of the orders for a given customer
#+
#+ This function calculates the total amount of all orders for the
#+ customer identified by the \texttt{cust_id} number passed as parameter.
#+
#+ @code
#+ DEFINE total DECIMAL(10,2)
#+ LET total = ordersTotal(r_customer.cust_id)
#+ @param cid Customer identifier
#+ @returnType DECIMAL(10,2)
#+ @return The total amount as DECIMAL(10,2)
#+
FUNCTION ordersTotal(cid)
DEFINE cid INTEGER
DEFINE ordtot DECIMAL(10,2)
SELECT SUM(ord_amount) INTO ordtot
FROM orders WHERE orders.cust_id = cid
RETURN ordtot
END FUNCTION
```

Commenting a report

To comment a report, add some lines starting with `#+`, before the report body. The comment body is composed of paragraphs separated by a blank line. The first paragraph of the comment is a short description of the report. This description will be placed in the function summary table. The next paragraph is long text describing the report in detail. Other paragraphs must start with a tag to identify the type of the paragraph; a tag starts with the @ "at" sign.

Table 412: Supported @ tags

<table>
<thead>
<tr>
<th>Tag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@code</td>
<td>Indicates that the next lines show a code example using the report.</td>
</tr>
</tbody>
</table>
| @param \texttt{name} \texttt{description} | Defines a report parameter identified by \texttt{name}, explained by a \texttt{description}.  
\texttt{name} must match the parameter name in the report declaration. |
Commenting a module

To comment a .4gl module, you can add `#+` lines at the beginning of the source, before module element declarations such as module variable definitions.

Example

```4gl
#+ This module implements customer information handling
#+ This code uses the 'customer' and 'custdetail' database tables.
#+ Customer input, query and list handling functions are defined here.
#+
DEFINE r_cust RECORD
    cust_id INTEGER,
    cust_name VARCHAR(50),
    cust_address VARCHAR(200)
END RECORD
```

Commenting a package

To describe a complete directory (i.e. package), you must create a `package-info.4gl` file in the directory and add a `#+` comment in the file. The comment will be added to the `package-summary.html` file.

Commenting a project

In the top directory of your sources, you must create a `overview.4gl` file with a `#+` comment describing the project. This file is mandatory in order to generate the tree of HTML pages for an entire project, as it is used as the starting point by fglcomp.

Run the documentation generator

Follow this procedure to produce the source documentation.

1. Go to the top directory of your sources.
2. Create a file named `overview.4gl`, with a `#+` comment describing your project.
3. Go to the subdirectories and create files named `package-info.4gl` with a `#+` comment describing the package.
4. Edit the 4gl modules to add `#+` comments to functions that must be documented.
5. Go back to the top directory of your sources.
6. Run `fglcomp --build-doc overview.4gl`
   - Use the `-W apidoc` compiler option to get warnings for invalid comment tags. For example, when a `@param` tag is missing for a function parameter.
7. To test the result, load the generated `index.html` file in your preferred browser.

Source preprocessor

A typical preprocessor like in the C language.

- Understanding the preprocessor on page 2020
- Compilers command line options on page 2020
- File inclusion on page 2021
- Simple macro definition on page 2023
- Function macro definition on page 2025
- Stringification operator on page 2026
- Concatenation operator on page 2027
- Predefined macros on page 2027
Understanding the preprocessor

This is an introduction to the code preprocessor.

The preprocessor is used to transform your sources before compilation. It allows you to include other files and to define macros that will be expanded when used in the source. It behaves similar to the C preprocessor, with some differences.

Important: It is recommended to avoid using the preprocessor if there is an alternative in the native language. For example, instead of defining program constants with an `#define` macro, use the `CONSTANT` instruction. Other language features such as `IMPORT FGL` increase code readability and modular programming, without the need of a preprocessor. The preprocessor might be desupported in a future version.

The preprocessor transforms files as follows:

- The source file is read and split into lines.
- Continued lines are merged into one long line if it is part of a preprocessor definition.
- Comments are not removed unless they appear in a macro definition.
- Each line is split into a list of lexical tokens.

The preprocessor implements the following features:

1. File inclusion
2. Conditional compilation
3. Macro definition and expansion

There are two kinds of macros:

1. Simple macros
2. Function macros

If a preprocessing directive is invalid, the compilers will generate an `.err` file with the preprocessing error included in the source file at the line position where the problem exists. When using the `-M` option, preprocessor errors will be printed to stderr, like regular compiler errors.

Compilers command line options

Preprocessor options can be used with fglcomp and fglform compilers.

File inclusion path

The `-I` option defines a single path used to search files included by the `#include` directives:

```
-I path
```

Note: To specify multiple include directories, repeat the `-I path` option:

```
fglcomp -I /usr/app1/src/common -I /usr/app1/src/stock ...
```

Macro definition

The `-D` option defines a macro with a default value of 1, so that it can be used in conditional directives like `#ifdef`:

```
-D identifier
```

The `-D` option can also define a macro with a value:

```
-D identifier=value
```
**Note:** If you want to define a macro with a string value containing spaces, you need to provide the identifier and value as a single command line parameter. For example on UNIX®: `-D "VSTR=\"Version 1.32\""`

The `-U` option undefines a macro. The macro will not be defined, even if it is defined with the `-D` option later in the command line, or when it is defined in the code with a `#define` directive:

```bash
-U identifier
```

However, predefined macros such as `__LINE__` cannot be undefined with the `-U` option.

### Preprocessing only

- `E`

By using the `-E` option, only the preprocessing phase is done by the compilers. Result is dumped in standard output.

### Preprocessing options

- `p nopp | noln | fglpp`

When using option `-p nopp`, it disables the preprocessor phase.

By using option `-p noln` with the `-E` preprocessing-only option, you can remove line number information and unnecessary empty lines.

By default, the preprocessor expects an ampersand `&` as preprocessor symbol for macros. The option `-p fglpp` enables the old syntax, using the hash `#` as preprocessor symbol. The hash `#` syntax is not compatible with single-line comments.

### Examples

```bash
fglcomp -E -D DEBUG -I /usr/sources/headers program.4gl
fglcomp -E -p fglpp -I /usr/sources/headers program.4gl
fglcomp -E -p nopp -I /usr/sources/headers program.4gl
```

### Related concepts

- **fglcomp** on page 1972
  The `fglcomp` tool compiles .4gl source files into .42m p-code modules.

- **fglform** on page 1970
  The `fglform` tool compiles form specification files into XML formatted files used by programs.

### File inclusion

The `&include` directive instructs the preprocessor to include a file.

#### Syntax

```bash
&include "filename"
```

1. `filename` is the file to be included during preprocessing.

#### Usage

The file to be included is searched first in the directory containing the current file, then in the directory(s) provided with `-I` option.
filename can be followed by spaces and comments.
The included file will be scanned and processed before continuing with the rest of the current file.

Source: File A

First line
&include "B"
Third line

Source: File B

Second line

Result:

& 1 "A"
First line
& 1 "B"
Second line
& 3 "A"
Third line

These preprocessor directives inform the compiler of its current location with special preprocessor comments, so the compiler can provide the right error message when a syntax error occurs.
The preprocessor-generated comments use the following format:

& number "filename"

where:

- number is the current line in the preprocessed file
- filename is the current file name

**Recursive inclusions**

Recursive inclusions are not allowed. Doing so will fail and output an error message.
The following example is incorrect:

Source: File A

&include "B"

Source: File B

HELLO
&include "A"

fglcomp -M A.4gl output

B.4gl:2:1:2:1:error:(-8029) Multiple inclusion of the source file 'A'.

Including the same file several times is allowed:

Source: File A

&include "B"
&include "B" -- correct
Simple macro definition
A simple macro is identified by its name and body.

Syntax
&define identifier body

1. identifier is the name of the macro. Any valid identifier can be used.
2. body is any sequence of tokens until the end of the line.

After substitution, the macro definition is replaced with blank lines.

Usage
As the preprocessor scans the text, it substitutes the macro body for the name identifier.

The following example show macro substitution with 2 simple macros:

Source: File A

&define MAX_TEST 12
&define HW "Hello world"

MAIN
  DEFINE i INTEGER
  FOR i=1 TO MAX_TEST
    DISPLAY HW
  END FOR
END MAIN

Result:

& 1 "A"
& 1 "B"
HELLO
& 2 "A"
& 1 "B"
HELLO

The macro definition can be continued on multiple lines, but when the macro is expanded, it is joined to a single line as follows:
Source: File A

```plaintext
#define TABLE_VALUES 1, \
 2, \
3
DISPLAY TABLE_VALUES
```

Result:

```plaintext
& 1 "A"
```

```plaintext
DISPLAY 1, 2, 3
```

The source file is processed sequentially, so a macro takes effect at the place it has been written:

Source: File A

```plaintext
DISPLAY X
#define X "Hello"
DISPLAY X
```

Result:

```plaintext
& 1 "A"
```

```plaintext
DISPLAY X
```

```plaintext
DISPLAY "Hello"
```

The macro body is expanded only when the macro is applied:

Source: File A

```plaintext
#define AA BB
#define BB 12
DISPLAY AA
```

Result:

```plaintext
& 1 "A"
```

```plaintext
DISPLAY 12
```

- AA is first expanded to BB.
- The text is re-scanned and BB is expanded to 12.
- When the macro AA is defined, BB is not known yet; but it is known when the macro AA is used.

In order to prevent infinite recursion, a macro cannot be expanded recursively.

Source: File A

```plaintext
#define A B
#define B A
#define C C
A C
```

Result:

```plaintext
& 1 "A"
```
Function macro definition

Function macros are preprocessor macros which can take arguments.

Syntax

\[ \text{\&define identifier( arglist ) body} \]

1. \textit{identifier} is the name of the macro. Any valid identifier can be used.
2. \textit{body} is any sequence of tokens until the end of the line.
3. \textit{arglist} is a list of identifiers separated with commas and optionally white space.
4. There must be no space or comment between the macro name and the opening parenthesis \( ( \). Otherwise the macro is not a function macro, but a simple macro.

Usage

Function macros take arguments that are replaced in the body by the preprocessor.

Source: File A

\[ \text{\&define function_macro(a,b) a + b} \]
\[ \text{\&define simple_macro(a,b) a + b} \]
\[ \text{function_macro( 4 , 5 )} \]
\[ \text{simple_macro( 1,2 )} \]

Result:

\[ \& 1 \ "A" \]

4 + 5
\( (a,b) \ a + b \ (1,2) \)

A function macro can have an empty argument list. In this case, parentheses \( () \) are required for the macro to be expanded. As we can see in the following example, the third line is not expanded because there is no parentheses after \textit{foo}. The function macro cannot be applied even if it has no arguments.

Source: File A

\[ \text{\&define foo() yes} \]
\[ \text{ foo() } \]
\[ \text{foo} \]

Result:

\[ \& 1 \ "A" \]

\textit{yes}
foo

The comma separates arguments. Macro parameters containing a comma can be used with parentheses. In this example, the second line has been substituted, but the third line produced an error, because the number of parameters is incorrect.

Source: File A

```
&define one_parameter(a) a
one_parameter((a,b))
one_parameter(a,b)
```

`fglcomp -M output`

```
source.4gl:3:1:3:1: error:(-8039) Invalid number of parameters for macro one_parameter.
```

Macro arguments are completely expanded and substituted before the function macro expansion.

A macro argument can be left empty.

Source: File A

```
&define two_args(a,b) a b
two_args(,b)
two_args(,)
two_args()
two_args(,,)
```

`fglcomp -M output`

```
source.4gl:4:1:4:1: error:(-8039) Invalid number of parameters for macro two_args.
source.4gl:5:1:5:1: error:(-8039) Invalid number of parameters for macro two_args.
```

Macro arguments appearing inside strings are not expanded.

Source: File A

```
&define foo(x) "x"
foo(toto)
```

Result:

```
& 1 "Å"
"x"
```

**Related concepts**

- Simple macro definition on page 2023
- A simple macro is identified by its name and body.

**Stringification operator**

Transforms a preprocessor macro element to a string.

**Syntax**

```
#param
```
1. *param* is a parameter of the macro

**Usage**

The stringification operator # converts a preprocessor macro parameter to a string.

When a macro parameter is used with a preceding #, it is replaced by a string containing the literal text of the argument.

The argument is not macro expanded before the substitution.

Source: File A

```
#define disp(x) DISPLAY #x
disp(abcdef)
```

Result:

```
& 1 "A"
DISPLAY "abcdef"
```

**Concatenation operator**

Concatenates two parameters of a preprocessor macro.

**Syntax**

```
token1 ## token2
```

1. *token1* is a parameter of the macro or a simple token.
2. *token2* is a parameter of the macro or a simple token.

**Usage**

The double-hash operator ## can be used to merge two tokens while expanding a macro and create a single token.

All tokens can not be merged. Usually these tokens are identifiers, or numbers.

The concatenation result produces an identifier.

Source: File A

```
#define COMMAND(NAME) #NAME, NAME ## _command
COMMAND(quit)
```

Result:

```
& 1 "A"
"quit", quit_command
```

**Predefined macros**

A set of predefined preprocessor macros are available.

The preprocessor predefines 2 macros:

1. **__LINE__** expands to the current line number. Its definition changes with each new line of the code.
2. **__FILE__** expands to the name of the current file as a string constant. For example: "subdir/file.inc"
These macros are often used to generate error messages.

An `#include` directive changes the values of `__FILE__` and `__LINE__` to correspond to the included file.

### Undefining a macro

Undefines a preprocessor macro.

**Syntax**

```c
#undef identifier
```

1. `identifier` is a preprocessor constant.

**Usage**

If a macro is redefined without having been undefined previously, the preprocessor issues a warning and replaces the existing definition with the new one. First undefine a macro with the `#undef` directive.

Source: File A

```c
#define HELLO "hello"
DISPLAY HELLO
#undef HELLO
DISPLAY HELLO
```

**Result:**

```c
 1 "A"
DISPLAY "hello"
DISPLAY HELLO
```

**Note:** It is also possible to undefine a macro with the `-U` command line option of compilers. However, predefined macros cannot be undefined with this option.

### Conditional compilation

Integrate code lines conditionally.

**Syntax 1**

```c
#elif defined identifier ...
  ...
#else ...
  ...
#endif
```

1. `identifier` is a preprocessor constant.

**Syntax 2**

```c
#elif !defined identifier ...
  ...
#else ...
  ...
#endif
```

1. `identifier` is a preprocessor constant.
Usage

The `ifdef` and `ifndef` preprocessor macros can be used to integrate code lines conditionally depending on the existence of a preprocessor constant.

The constant is defined with a `define` or with the `-D` option in the command line.

Even if the condition is evaluated to false, the content of the `ifdef` block is still scanned and tokenized. Therefore, it must be lexically correct.

Sometimes it is useful to use some code if a macro is not defined. You can use `ifndef`, that evaluates to true if the macro is not defined.

Source: File A

```c
#define IS_DEFINED
ifdef IS_DEFINED
DISPLAY "The macro is defined"
endif /* IS_DEFINED */
```

Result:

```c
& 1 "A"
DISPLAY "The macro is defined"
```

Integrated debugger

Describes the command-line debugger you can use to find bugs in your programs.

- Understanding the debugger on page 2029
- Prerequisites to run the debugger on page 2030
- Starting fglrun in debug mode on page 2031
- Attaching to a running program on page 2031
- Debugging on a mobile device on page 2032
- Stack frames in the debugger on page 2034
- Setting a breakpoint programmatically on page 2034
- Expressions in debugger commands on page 2035
- Debugger commands on page 2035

Understanding the debugger

This is an introduction to the integrated debugger.

The debugger is a feature built in the runtime system (`fglrun`) that allows you to control the execution of a program step by step, so that you can find logical and runtime errors.

There are three debug modes possible with the Genero runtime system:

1. Start the `fglrun` program from the command line with the `-d` option. For more details, see Starting fglrun in debug mode on page 2031.
2. Attaching with the `fgldb` tool, to a running fglrun process, for debugging through a TCP socket. For more details, see Attaching to a running program on page 2031.
3. Connect directly with the `fgldb` tool, to the debug TCP port of a runtime system running on a mobile device in standalone mode. For more details, see Debugging on a mobile device on page 2032.

The debugger supports a subset of the standard GNU C/C++ debugger called `gdb`. 
In command line mode, the debugger shows the following prompt

```
(fgldb)
```

A command is a single line of input. It starts with a command name, which may be followed by arguments whose meaning depends on the command name. For example, the command `step` accepts as an argument the number of times to step:

```
(fgldb) step 5
```

You can use command abbreviations. For example, the 'step' command abbreviation is 's':

```
(fgldb) s 5
```

Possible command abbreviations are shown in the command's syntax.

A blank line as input to the debugger (pressing just the RETURN or ENTER keys) usually causes the previous command to repeat. However, commands whose unintentional repetition might cause problems will not repeat in this way.

**Prerequisites to run the debugger**

Some requirements are needed before running the integrated debugger.

**FGLPROFILE configuration option to disable the debugger**

Make sure that the following **FGLPROFILE** entry is not defined, or defined as false:

```
fglrun.ignoreDebuggerEvent = false
```

**Note:** In production environments, the `fglrun.ignoreDebuggerEvent` FGLPROFILE entry should be set for `true`.

**Source file search path (FGLSOURCEPATH)**

Before starting the debugger, make sure you have properly set the **FGLLDPATH** and **FGLSOURCEPATH** environment variable, to let the debugger find the source files.

In order to find source files, the debugger will search in the directories defined by **FGLLDPATH**. If the source file is not found, the search continues in the directories defined by **FGLSOURCEPATH**.

The **FGLSOURCEPATH** environment variable is provided to distinguish execution directories (containing .42m files), from source directories (containing .4gl files), when the sources are not located in the same directory as the pcode files.

**UNIX™ example:**

```
$ FGLSOURCEPATH="/usr/app/source:/home/scott/sources"
$ export FGLSOURCEPATH
```

**Windows® example:**

```
C:\> set FGLSOURCEPATH=C:\app\sources;C:\scott\sources
```
Starting fglrun in debug mode

The runtime system can be started in debug mode with the `-d` option.

To start fglrun in debug mode, use the `-d` option of fglrun, for example:

```
fglrund -d myprog
```

This mode is typically used in development environments when using the command line tools.

The debugger can be used from the command line shell, but can also be called from a graphical debugging tool that understands the debugging commands of `fglrund -d`. The syntax of the commands is similar to the gdb debugger.

The debugger can for example be used alone in command line mode or with a graphical shell compatible with gdb such as ddd:

```
ddd --debugger "fglrund -d myprog"
```

Attaching to a running program

It is possible to remotely start the debugger for a program running on the same computer.

**Basics**

Use the `fgldb` command with the `-p` option to switch the runtime system into debug mode when an application is running on a server.

**Note:** The `fgldb` command must be executed on the machine where the fglrun process executes.

The `fgldb` command line tool takes the fglrun process id as value for the `-p` argument.

**Note:** Before starting a debug session, make sure that you fulfill the prerequisites for debugging.

**Debug a program running on a UNIX server**

First, identify the process id of the fglrun program running on your server.

For example, on a UNIX platform, use the `ps` command:

```
$ ps a | grep fglrun
  10646 pts/0  S+     0:00  /opt/myapp/fgl/lib/fglrund stockinfo.42m
```

**Note:** Inspect the GAS log files to find the id of an fglrun process running behind a GAS application server. Enable full log reports in the GAS to get detailed information about process execution.

You may want to debug processes that use a lot of machine resources (processor, memory or open files). Use a system utility to find a process id by resources used (for example, the `top` command on Linux).

Execute the `fgldb` tool with the process id of the program you want to attach to:

```
$ fgldb -p 10646
108     DISPLAY ARRAY contlist TO sr.*
(fgldb)
```

The `(fgldb)` prompt indicates that you are now connected to the fglrun process, and the program flow is suspended. To continue with the program flow, enter the "continue" debugger command:

```
(fgldb) continue
Continuing.
```
The application will then resume. To suspend the program again and enter debugger commands, press CTRL-C in the debug console. `fgldb` will display the interrupt message and return control to the debugger:

```plaintext
... Continuing. ^C INTERRUPT 108 DISPLAY ARRAY contlist TO sr.* (fgldb)
```

At this point, you can enter debugger commands. For example, set a break point and continue until the break point is reached:

```plaintext
(fgldb) b 427  
Breakpoint 2 at 0x00000000: file contacts.4gl, line 427.  
(fgldb) continue  
Continuing.  
Breakpoint 2, edit_contact() at contacts.4gl:427  
427 IF new THEN  
(fgldb)
```

To finish the debug session, close the connection with the "detach" debugger command:

```plaintext
(fgldb) detach  
Connection closed by foreign host.
```

### Related concepts

- **fgldb** on page 1977

The `fgldb` tool is an interface program for remote debugging.

#### Debugging on a mobile device

It is possible to remotely start the debugger for an app running on a mobile device.

**Basics**

When an app was created with debug mode and is running on a device, it is possible to switch the runtime system in debug mode, by using the `fgldb` command tool with the `-m` option.

**Important:** The app must have been created in debug mode. Apps created in release mode cannot be debugged with the `fgldb` tool. For more details, check out how to build mobile apps with debug mode in the Deploying mobile apps on page 3315 section.

**Important:** On iOS devices, after installing the app, you need to enable the debug port in the app settings, otherwise the app will not listen to the debug port.

The `fgldb` command line tool takes two arguments: The host (or IP address) of the mobile device, and an optional TCP port number to connect to. For mobile devices, the debug TCP port is 6400. Note that this is the same port the mobile front-end is listening to for GUI connection, when working in GUI client/server mode.

**Note:** Before starting a debug session, make sure that you fulfill the prerequisites for debugging.

#### Debugging an app running on a physical device

Considering the mobile device IP address is "192.168.1.23", and the application is running locally on a physical mobile device, you can open a debug session from the development machine as follows:

```plaintext
$ fgldb -m 192.168.1.23:6400  
108 DISPLAY ARRAY contlist TO sr.* (fgldb)
```
The `fgldb` prompt indicates that you are now connected to the fglrun process on mobile device, and the program flow is suspended. To continue with the program flow, enter the "continue" debugger command:

```
(fgldb) continue
Continuing.
```

The application will then resume on the mobile device. To suspend the program again and enter debugger commands, press CTRL-C in the debug console; `fgldb` will show the interrupt message and give you the control back:

```
... Continuing.
^C INTERUPPT
108 DISPLAY ARRAY contlist TO sr.*
(fgldb)
```

At this point, you can for example set a break point and continue until the break point is reached:

```
(fgldb) b 427
Breakpoint 2 at 0x00000000: file contacts.4gl, line 427.
(fgldb) continue
Continuing.
Breakpoint 2, edit_contact() at contacts.4gl:427
427 IF new THEN
(fgldb)
```

To finish the debug session, close the connection with the "detach" debugger command:

```
(fgldb) detach
Connection closed by foreign host.
```

**Debugging an app running on an Android device emulator**

When the mobile application is executing on an Android™ device emulator in the same machine as the development environment, you must first redirect the 6400 TCP port.

First you must connect to the emulator terminal, using the telnet TCP port 5554:

```
$ telnet localhost 5554
Trying ::1...
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
Android Console: type 'help' for a list of commands
OK
help
Android console command help:
    help|h|?         print a list of commands
    crash          crash the emulator instance
    kill           kill the emulator instance
    quit|exit      quit control session
    redir          manage port redirections
    power          power related commands
    event          simulate hardware events
    avd            control virtual device execution
    finger         manage emulator fingerprint
    geo            Geo-location commands
    sms            SMS related commands
    cdma           CDMA related commands
    gsm            GSM related commands
    rotate         rotate the screen by 90 degrees
```

try 'help <command>' for command-specific help
OK

When connected on the device emulator, redirect the port 6400 as follows:

```
$ redir add tcp:6400:6400
```

You may also want to redirect the port 6480, to be able to show GMA service debug information from a browser with the http://localhost:6480 URL:

```
$ redir add tcp:6480:6480
```

Finally, quit the device emulator telnet session with:

```
$ quit
```

**Related concepts**

- **fgldb** on page 1977
  The `fgldb` tool is an interface program for remote debugging.

**Stack frames in the debugger**

The stack frame contains information about function call stack.

Each time your program performs a function call, information about the call is saved in a block of data called a stack frame. Each frame contains the data associated with one call to one function.

The stack frames are allocated in a region of memory called the call stack. When your program is started, the stack has only one frame, that of the function `main`. This is the initial frame, also known as the outermost frame. As the debugger executes your program, a new frame is made each time a function is called. When the function returns, the frame for that function call is eliminated.

The debugger assigns numbers to all existing stack frames, starting with zero for the innermost frame, one for the frame that called it, and so on upward. These numbers do not really exist in your program; they are assigned by the debugger to allow you to designate stack frames in commands.

Each time your program stops, the debugger automatically selects the currently executing frame and describes it briefly. You can use the `frame` command to select a different frame from the current call stack.

**Related concepts**

- **Runtime stack** on page 443
  The runtime stack is used to pass/return values to/from functions.

**Setting a breakpoint programmatically**

Set a breakpoint in the program source code with the `BREAKPOINT` instruction.

If the program flow encounters this instruction, the program stops as if the break point was set by the `break` command:

```
MAIN
  DEFINE i INTEGER
  LET i=123
  BREAKPOINT
  DISPLAY i
END MAIN
```

The `BREAKPOINT` instruction is simply ignored when running in normal mode.
Expressions in debugger commands

A limited expression syntax can be used in debugger commands.

Some debugger commands such as display take an expression as argument. The Genero debugger supports a reduced syntax for command expressions described in this section. For a detailed description of comparison operators, constant values and operands, see Expressions.

Syntax

```
   variable
   | char-const
   | int-const
   | dec-const
   | NULL
   | TRUE
   | FALSE
   | expression IS [NOT] NULL
   | expression = expression
   | expression == expression
   | expression <= expression
   | expression => expression
   | expression < expression
   | expression > expression
   | expression + expression
   | expression - expression
   | expression * expression
   | expression / expression
   | expression OR expression
   | expression AND expression
   | NOT expression
   | - expression
   | ( expression )
```

Note:

1. variable is a program variable name.
2. char-const is character string literal delimited by single or double quotes.
3. int-const is an integer literal.
4. dec-const is a decimal number literal.
5. expression is a combination of one or more listed syntax elements.

Example

```
(fgldb) display a + 1000
1: a = 1140.50
```

Debugger commands

This topic lists all debugger commands.

Table 413: Summary of debugger commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>backtrace /</td>
<td>Print a summary of how your program reached the current state (back trace of all stack frames).</td>
</tr>
<tr>
<td>where</td>
<td></td>
</tr>
<tr>
<td>break</td>
<td>Set a break point at the specified line or function.</td>
</tr>
<tr>
<td>call</td>
<td>Call a function in the program.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>clear</td>
<td>Clear breakpoint at some specified line or function.</td>
</tr>
<tr>
<td>continue</td>
<td>Continue program being debugged.</td>
</tr>
<tr>
<td>delete</td>
<td>Delete some breakpoints or auto-display expressions.</td>
</tr>
<tr>
<td>detach</td>
<td>Closes a remote debug connection.</td>
</tr>
<tr>
<td>disable</td>
<td>Disable some breakpoints.</td>
</tr>
<tr>
<td>display</td>
<td>Print the values of expression $EXP$ each time the program stops.</td>
</tr>
<tr>
<td>down</td>
<td>Select and print the function called by the current function.</td>
</tr>
<tr>
<td>echo</td>
<td>Print the specified text.</td>
</tr>
<tr>
<td>enable</td>
<td>Re-activate breakpoints that have previously been disabled.</td>
</tr>
<tr>
<td>finish</td>
<td>Execute until selected stack frame returns.</td>
</tr>
<tr>
<td>frame</td>
<td>Select and print a stack frame.</td>
</tr>
<tr>
<td>help</td>
<td>Print list of debugger commands.</td>
</tr>
<tr>
<td>ignore</td>
<td>Set ignore-count of a breakpoint number $N$ to $COUNT$.</td>
</tr>
<tr>
<td>info</td>
<td>Provide information about the status of the program.</td>
</tr>
<tr>
<td>list</td>
<td>List specified function or line.</td>
</tr>
<tr>
<td>next</td>
<td>Step program; continue with the next source code line at the same level.</td>
</tr>
<tr>
<td>output</td>
<td>Print the current value of the specified expression; do not include value history and do not print newline.</td>
</tr>
<tr>
<td>print</td>
<td>Print the current value of the specified expression.</td>
</tr>
<tr>
<td>ptype</td>
<td>Print the type of a variable</td>
</tr>
<tr>
<td>quit</td>
<td>Exit the debugger.</td>
</tr>
<tr>
<td>run</td>
<td>Start the debugged program.</td>
</tr>
<tr>
<td>set</td>
<td>Evaluate an expression and assign the result to a variable.</td>
</tr>
<tr>
<td>source</td>
<td>Execute a file of debugger commands.</td>
</tr>
<tr>
<td>signal</td>
<td>Continue program giving it the signal specified by the argument.</td>
</tr>
<tr>
<td>step</td>
<td>Step program until it reaches a different source line.</td>
</tr>
<tr>
<td>tbreak</td>
<td>Set a temporary breakpoint.</td>
</tr>
<tr>
<td>tty</td>
<td>Set terminal for future runs of program being debugged.</td>
</tr>
<tr>
<td>undisplay</td>
<td>Cancel some expressions to be displayed when the program stops.</td>
</tr>
<tr>
<td>until</td>
<td>Continue running until a specified location is reached.</td>
</tr>
<tr>
<td>up</td>
<td>Select and print the function that called the current function.</td>
</tr>
<tr>
<td>watch</td>
<td>Set a watchpoint for an expression. A watchpoint stops the execution of your program whenever the value of an expression changes.</td>
</tr>
<tr>
<td>whatis</td>
<td>Prints the data type of a variable.</td>
</tr>
</tbody>
</table>
**backtrace / where**
The `backtrace` command prints a summary of how your program reached the current state.

**Syntax**

```
backtrace
```

**Usage**
The `backtrace` command prints a summary of your program's entire stack, one line per frame.
Each line in the output shows the frame number and function name.
`bt` and `where` are aliases for the `backtrace` command.

**Example**

```
(fgldb) backtrace
#1 addcount() at mymodule.4gl:6
#2 main() at mymodule.4gl:2
(fgldb)
```

**break**
The `break` command defines a break point to stop the program execution at a given line or function.

**Syntax**

```
break [ \[module.]function
    \[module:]line \]
    \[if condition \]
```

1. `function` is a function name.
2. `module` is the name of a specific source file, without extension.
3. `line` is a source code line.
4. `condition` is an expression evaluated dynamically.

**Usage**
The `break` command sets a break point at a given position in the program.
When the program is running, the debugger stops automatically at breakpoints defined by this command.
If a `condition` is specified, the program stops at the breakpoint only if the `condition` evaluates to TRUE.
If you do not specify any location (function or line number), the breakpoint is created for the current line. For example, if you write "break if var = 1", the debugger adds a conditional breakpoint for the current line, and the program will only stop if the variable is equal to 1 when reaching the current line again.

**Example**

```
(fgldb) break mymodule:5
Breakpoint 2 at 0x00000000: file mymodule.4gl, line 5.
```

**Related concepts**

- **BREAKPOINT** on page 524
  The `BREAKPOINT` instruction sets a program breakpoint when running in debug mode.
- **Setting a breakpoint programmatically** on page 2034
Set a breakpoint in the program source code with the BREAKPOINT instruction.

**call**
The call command calls a function in the program.

**Syntax**

```
call function-name ( [ expression [, ...] ] )
```

1. `function-name` is the name of the function to call.
2. `expression` is a combination of variables, constants and operators.

**Usage**
The call command invokes a function of the program and returns the control to the debugger.
The return values of the function are printed as a comma-separated list delimited by curly brackets.

**Example**

```
MAIN
  DEFINE i INTEGER
  LET i = 1
  DISPLAY i
END MAIN

FUNCTION hello ()
  RETURN "hello", "world"
END FUNCTION

(fgldb) br main
Breakpoint 1 at 0x00000000: file t.4gl, line 4.
(fgldb) run
Breakpoint 1, main() at t.4gl:4
  4         LET i = 1
(fgldb) call hello()
$1 = { "hello", "world" }
(fgldb)
```

**clear**
The clear command clears the breakpoint at a specified line or function.

**Syntax**

```
clear [ function | module: line ]
```

1. `function` is a function name.
2. `module` is a specific source file.
3. `line` is a source code line.

**Usage**

With the clear command, you can delete breakpoints wherever they are in your program.

Use the clear command with no arguments to delete any breakpoints at the next instruction to be executed in the selected stack frame.

Use the delete command to delete individual breakpoints by specifying their breakpoint numbers.
Example

```
(fgldb) clear mymodule:5
Deleted breakpoint 2
(fgldb)
```

**continue**
The `continue` command continues the execution of the program after a breakpoint.

**Syntax**

```
continue [ignore-count]
```

1. `ignore-count` defines the number of times to ignore a breakpoint at this location.

**Usage**
The `continue` command continues the execution of the program until the program completes normally, another breakpoint is reached, or a signal is received.

`c` is an alias for the `continue` command.

**Example**

```
(fgldb) continue
...
(program output)
...
Program exited normally.
```

dump
The `delete` command allows you to remove breakpoints that you have specified in your debugger session.

**Syntax**

```
delete breakpoint
```

1. `breakpoint` is the number assigned to the breakpoint by the debugger.

**Usage**
The `delete` command allows you to remove breakpoints when they are no longer needed in your debugger session.

If you prefer you may disable the breakpoint instead, see the `disable` command.

`d` is an alias for the `delete` command.

**Example**

```
(fgldb) delete 1
(fgldb) run
Program exited normally.
(fgldb)
```
**detach**
The `detach` command closes the TCP connection of a remove debug session.

**Syntax**
```
detach
```

**Usage**
The `detach` command must be used to terminate a remove debug session, by closing the debug TCP connection.

**Example**
```
(fgldb) detach
```

**Related concepts**
- [Attaching to a running program](#) on page 2031
  It is possible to remotely start the debugger for a program running on the same computer.
- [Debugging on a mobile device](#) on page 2032
  It is possible to remotely start the debugger for an app running on a mobile device.

**disable**
The `disable` command disables the specified breakpoint.

**Syntax**
```
disable breakpoint
```

1. `breakpoint` is the number assigned to the breakpoint by the debugger.

**Usage**
The `disable` command instructs the debugger to ignore the specified breakpoint when running the program.

Use the `enable` command to reactivate the breakpoint for the current debugger session.

**Example**
```
(fgldb) disable 1
(fgldb) run
Program exited normally.
(fgldb)
```

**display**
The `display` command displays the specified expression's value each time program execution stops.

**Syntax**
```
display expression
```

1. `expression` is a combination of variables, constants and operators.

**Usage**
The `display` command allows you to add an expression to an automatic display list. The values of the expressions in the list are printed each time program execution stops. Each expression in the list is assigned a number to identify it.
This command is useful in tracking how the values of expressions change during the program’s execution.

**Example**

```
(fgldb) display a
1: a = 6
(fgldb) display i
2: i = 1
(fgldb) step
2: i = 1
1: a = 6
16   for i = 1 to 10
(fgldb) step
2: i = 2
1: a = 6
17   let a = a+1
(fgldb)
```

**down**
The `down` command moves down in the call stack.

**Syntax**

```
down
```

**Usage**
The `down` command moves the focus of the debugger down from the frame currently being examined, to the frame of its callee.

The command selects and prints the function called by the current function.

See [stack frames](#) for a brief description of frames.

```
(fgldb) down
#0 query_cust() at custquery.4gl:22
22   CALL cleanup()
(fgldb)
```

**echo**
The `echo` command prints the specified text as prompt.

**Syntax**

```
echo text
```

1. `text` is the specific text to be output.

**Usage**
The `echo` command allows you to generate exactly the output that you want.

Special characters can be included in text using C escape sequences, such as `\n` to print a newline. No newline is printed unless you specify one. In addition to the standard C escape sequences, a backslash followed by a space stands for a space. A backslash at the end of text can be used to continue the command onto subsequent lines.

**Example**

```
(fgldb) echo hello\n
hello
```
enable
The `enable` command enables breakpoints that have previously been disabled.

Syntax
```
enable breakpoint
```
1. `breakpoint` is the number assigned to the breakpoint by the debugger.

Usage
The `enable` command allows you to reactivate a breakpoint in the current debugger session.
The breakpoint must have been disabled using the `disable` command.

Example
```
(fgldb) disable 1
(fgldb) run
Program exited normally.
(fgldb) enable 1
(fgldb) run
Breakpoint 1, at mymodule.4gl:5
```

finish
The `finish` command continues the execution of a program until the current function returns normally.

Syntax
```
finish
```

Usage
The `finish` command instructs the program to continue running until just after the function in the selected stack frame returns, and then stop.
The returned value, if any, is printed.

Example
```
(fgldb) finish
Run till exit myfunc() at module.4gl:10
Value returned is $1 = 123
(fgldb)
```

frame
The `frame` command selects and prints a stack frame.

Syntax
```
frame [ number ]
```
1. `number` is the stack frame number of the frame that you wish to select.
Usage

The frame command allows you to move from one stack frame to another, and to print the stack frame that you select. Each stack frame is associated with one call to one function within the currently executing program. Without an argument, the current stack frame is printed.

See stack frames for a brief discussion of frames.

Example

```c
(fgldb) frame
#0 func1() at stack.4gl:6
  6  FUNCTION func1(name,id)
(fgldb)
```

Related concepts

Runtime stack on page 443
The runtime stack is used to pass/return values to/from functions.

help

The help command provides information about debugger commands.

Syntax

```
help [command]
```

1. command is the name of the debugger command for which you wish information.

Usage

The help command displays a short explanation of a specified command.

Enter the help command with no arguments to display a list of debugger commands.

Example

```c
(fgldb) help delete
Delete some breakpoints or auto-display expressions
```

ignore

The ignore command defines the number of times a breakpoint must be ignored.

Syntax

```
ignore breakpoint count
```

1. breakpoint is the breakpoint number.
2. count is the number of times the breakpoint will be ignored.

Usage

The ignore command defines the number of times a breakpoint is ignored when the program flow reaches that breakpoint.

The next count times the breakpoint is reached, the program execution will continue, and no breakpoint condition is checked.

You can specify a count of zero to make the breakpoint stop the next time it is reached.

When using the continue command to resume the execution of the program from a breakpoint, you can specify an ignore count directly as an argument.
Example

(fgldb) br main
Breakpoint 1 at 0x00000000: file t.4gl, line 4.
(fgldb) ignore 1 2
Will ignore next 2 crossings of breakpoint 1.
(fgldb) run
1
Program exited normally.
(fgldb) run
1
Program exited normally.
(fgldb) run
Breakpoint 1, main() at t.4gl:4
4   LET i = 1
(fgldb)

info
The info command describes the current state of your program.

Syntax

info {breakpoints | sources | program | variables | locals | files | line {function | module:line}}

1. function is a function name of the program.
2. module:line defines a source code line in a module.

Usage
The info command describes the state of your program.

• info breakpoints lists the breakpoints that you have set.
• info sources prints the names of all the source files in your program.
• info program displays the status of your program.
• info variables displays global variables.
• info locals displays the local variables of the current function.
• info files lists the files from which symbols were loaded.
• info line function prints the program addresses for the first line of the function named function.
• info line module:line prints the starting and ending addresses of the compiled code for the source line specified. See the list command for all the ways that you can specify the source code line.

Example

(fgldb) info sources
Source files for which symbols have been read in:
  mymodule.4gl, fglwinexec.4gl, fglutil.4gl, fgldialog.4gl, fgldummy4js.4gl
(fgldb)
list
The list command prints source code lines of the program being executed.

Syntax

```plaintext
list [ function | {module:line} ]
```

Usage
The list command prints source code lines of your program, by default it begins with the current line.

Example

```plaintext
(fgldb) run
Breakpoint 1, at mymodule.4gl:5
5    CALL addlist()
(fgldb) list
5    CALL add_customer(cust_rec.*)
6    MESSAGE "Customer record was added"
...  
14  END FUNCTION
```

next
The next command continues running the program by executing the next source line in the current stack frame, and then stops.

Syntax

```plaintext
next [ count ]
```

1. `count` defines the number of lines to execute before stopping.

Usage
The next command allows you to execute your program one line of source code at a time. The next command is similar to step, but function calls that appear within the line of code are executed without stepping into the function code.

When the next line of code at the original stack level that was executing when you gave the next command is reached, execution stops.

Using a `count` parameter will repeat the `step` command `count` times.

After reaching a breakpoint, the next command can be used to examine a troublesome section of code more closely.

n is an alias for the next command.

Example

```plaintext
(fgldb) next
5    CALL add_customer(cust_rec.*)
(fgldb) next
6    MESSAGE "Customer record was added"
(fgldb) next 2
8    RETURN TRUE
```
output
The output command prints only the value of the specified expression, suppressing any other output.

Syntax

```
output expression
```

1. **expression** is a **combination** of variables, constants and operators.

Usage
The output command prints the current value of the expression and nothing else, no newline character, no "expr=", etc.

The usual output from the debugger is suppressed, allowing you to print only the value.

Example

```
(fgldb) output cust_rec.cust_id
87324(fgldb)
```

print
The print command displays the current value of the specified expression.

Syntax

```
print expression
```

1. **expression** is a **combination** of variables, constants and operators.

Usage
The print command allows you to examine the data in your program.

It evaluates and prints the value of the specified expression from your program, in a format appropriate to its data type.

*p* is an alias for the print command.

Example

```
(fgldb) print cust_rec.cust_id
$1 = 87324
(fgldb)
```

ptype
The ptype command prints the data type or structure of a variable.

Syntax

```
p type variable-name
```

1. **variable-name** is the name of the variable.

Example

```
(fgldb) ptype cust_rec
type = RECORD
    cust_num INTEGER,
cust_name VARCHAR(10),
```
cust_address VARCHAR(200)
END RECORD

quit
The quit command terminates the debugger session.

Syntax

quit

Usage
The quit command allows you to exit the debugger.
q is an alias for the quit command.

Example

(fgldb) quit

run
The run command starts the program.

Syntax

run _argument [...]

1. argument is an argument to be passed to the program.

Usage
The run command causes your program to execute until a breakpoint is reached or the program terminates normally.

Example

(fgldb) run a b c
Breakpoint 1, at mymodule.4gl:3
  3      CALL add_cust(cust_rec.*)
(fgldb)

set
The set command allows you to configure your debugger session and change program variable values.

Syntax

set | annotate [1|0]
    | environment envname=value
    | prompt ptext
    | set print elements elemcount
    | variable varname=expression
    | verbose _on|off_

1. ptext is the string to which the prompt should be set.
2. varname is the program variable to be set to expression.
3. expression is a combination of variables, constants and operators.
4. envname is the environment variable to be set to value.
5. \textit{elemcount} is the number of elements to define.

\section*{Usage}

The \texttt{set} command allows to change program variables and/or debug environment settings.

\texttt{set variable} sets an program variable, to be taken into account when continuing program execution. The right operand can be an expression.

\texttt{set prompt} changes the prompt text. The text can be set to any string. A space is not automatically added after the prompt string, allowing you to determine whether to add a space at the end of the prompt string.

\texttt{set environment} sets an environment variable, where \texttt{value} may be any string. If the \texttt{value} parameter is omitted, the variable is set to a null value. The variable is set for your program, not for the debugger itself.

\texttt{set verbose on} forces the debugger to display additional messages about its operations, allowing you to observe that it is still working during lengthy internal operations.

\texttt{set annotate 1} switches the output format of the debugger to be more machine readable (this command is used by GUI front-ends like ddd or xxgdb).

\texttt{set print elements elemcount} defines the maximum number of array elements to be printed by the debugger when displaying a program array.

\section*{Example}

\begin{lstlisting}
(fgldb) set prompt ($)
($)
\end{lstlisting}

On UNIX™ systems, if your SHELL variable names a shell that runs an initialization file, any variables you set in that file affect your program. You may wish to move setting of environment variables to files that are only run when you sign on, such as .login or .profile.

\section*{source}

The \texttt{source} command executes a file of debugger commands.

\subsection*{Syntax}

\begin{itemize}
  \item \texttt{source cmdfile}
\end{itemize}

1. \texttt{cmdfile} is the name of the file containing the debugger commands.

\section*{Usage}

The \texttt{source} command allows you to execute a command file of lines that are debugger commands.

The lines in the file are executed sequentially.

The commands are not printed as they are executed, and any messages are not displayed.

Commands are executed without asking for confirmation.

An error in any command terminates execution of the command file.

\section*{Example}

Using the text file \texttt{cmdfile.txt}, which contains the single line with a \texttt{break} command:

\begin{lstlisting}
$ cat cmdfile.txt
break 10
$ fgldr -d myprog
(fgldb) source cmdfile.txt
Breakpoint 2 @ 0x00000000: file mymod.4gl, line 10.
\end{lstlisting}
**signal**
The `signal` command sends an interruption signal to the program.

**Syntax**
```
signal signal
```

**Usage**
The `signal` command resumes execution where your program stopped, but immediately gives it the signal `signal`. `signal` can be the name or the number of a signal.

For example, on many systems signal 2 and signal SIGINT are both ways of sending an interrupt signal. The `signal` `SIGINT` command resumes execution of your program where it has stopped, but immediately sends an interrupt signal. The source line that was current when the signal was received is displayed.

**Note:** The current version only allows the signal `SIGINT`.

**Example**
```
(fgldb) signal SIGINT
Program exited normally.
16  for i = 1 to 10
(fgldb)
```

**step**
The `step` command continues running the program by executing the next line of source code, and then stops.

**Syntax**
```
step [count]
```

1. `count` defines the number of lines to execute before stopping.

**Usage**
The `step` command allows you to "step" through your program, executing one line of source code at a time.

When a function call appears within the line of code, that function is also stepped through.

A common technique is to set a breakpoint prior to the section or function that is causing problems, run the program till it reaches the breakpoint, and then step through it line by line.

Using a `count` parameter will repeat the `step` command `count` times.

`s` is an alias for the `step` command.

**Example**
```
(fgldb) step
4     CALL add_customer(cust_rec.*)
(fgldb) step 2
6     MESSAGE "Customer record was added"
```
**tbreak**
The `tbreak` command sets a temporary breakpoint.

**Syntax**

```
tbreak [ [ function ] | [ module: ] line ] [ if condition ]
```

1. `function` is a function name.
2. `module` is a specific source file.
3. `line` is a source code line.
4. `condition` is an expression evaluated dynamically.

**Usage**
The `tbreak` command sets a breakpoint for one stop only.

The breakpoint is set in the same way as with the `break` command, but the breakpoint is automatically deleted after the first time your program stops there.

If a `condition` is specified, the program stops at the breakpoint only if the `condition` evaluates to true.

If you do not specify any location (function or line number), the breakpoint is created for the current line. For example, if you write "`tbreak if var = 1`", the debugger adds a conditional breakpoint for the current line, and the program will only stop if the variable is equal to 1 when reaching the current line again.

**Example**

```
(fgldb) tbreak 12
Breakpoint 2 at 0x00000000: file custmain.4gl, line 12.
(fgldb)
```

**tty**
The `tty` command resets the default program input and output for future run commands.

**Syntax**

```
tty filename
```

1. `filename` is the file which is to be the default for program input and output.

**Usage**
The `tty` command instructs the debugger to redirect program input and output to the specified file for future run commands.

The redirection is for your program only; your terminal is still used for debugger input and output.

**Example**

```
(fgldb) tty /dev/ttyS0
(fgldb)
```

**undisplay**
The `undisplay` command cancels expressions to be displayed when the program execution stops.

**Syntax**

```
undisplay itemnum
```
1. itemnum is the number of the expressions for which the display is cancelled.

Usage:
When the display command is used, each expression displayed is assigned an item number.
The undisplay command allows you to remove expressions from the list to be displayed, using the item number to specific the expression to be removed.

Example

```
(fgldb) step
2: i = 2
1: a = 20
9 FOR i = 1 TO 10
(fgldb) undisplay 2
(fgldb) step
1: a = 20
10 LET cont = TRUE
(fgldb)
```

until
The until command continues running the program until the specified location is reached.

Syntax
```
until [ function | module: line ]
```

1. function is a function name.
2. module is a specific source file.
3. line is a source code line.

Usage
The until command continues running your program until either the specified location is reached, or the current stack frame returns.
This command can be used to avoid stepping through a loop more than once.

Example

```
(fgldb) until add_customer()
```

up
The up command selects and prints the function that called this one, or the function specified by the frame number in the call stack.

Syntax
```
up [frames]
```

1. frames says how many frames up to go in the stack. The default is 1.

Usage
The up command moves towards the outermost frame, to frames that have existed longer. To print the function that called the current function, use the up command without an argument.
See stack frames for a brief description of frames.
Example

(fgldb) up
#1 main() at customain.4gl:14
14 CALL query_cust()
(fgldb)

watch
The `watch` command sets a watchpoint for an expression.

Syntax

```
watch expression [if boolean-expression]
```

1. `expression` is a combination of variables, constants and operators.
2. `boolean-expression` is an optional boolean expression.

Usage

The `watch` command stops the program execution when the value of the expression changes.

If `boolean-expression` is provided, the `watch` command stops the execution of the program if the expression value has changed and the `boolean-expression` evaluates to true.

The watchpoint cannot be set if the program is not in the context where `expression` can be evaluated. Before using a watchpoint, you typically set a breakpoint in the function where the `expression` makes sense, then you run the program, and then you set the watchpoint. This example illustrates this procedure.

Example

```
MAIN
  DEFINE i INTEGER
  LET i = 1
  DISPLAY i
  LET i = 2
  DISPLAY i
  LET i = 3
  DISPLAY i
END MAIN
```

(fgldb) break main
breakpoint 1 at 0x00000000: file test.4gl, line 4
(fgldb) run
Breakpoint 1, main() at test.4gl:4
  4 LET i = 1
(fgldb) watch i if i >= 3
Watchpoint 1:  i
(fgldb) continue
1
2
Watchpoint 1:  i

Old value = 2
New value = 3
main() at t.4gl:9
  9 DISPLAY i
(fgldb)
**whatis**
The `whatis` command prints the data type of a variable.

**Syntax**

```
whatis variable-name
```

1. `variable-name` is the name of the variable.

**Usage**
The `whatis` command can be used to show the data type of a program variable. The program variable must exist in the current scope.

**Example**

```
(fgldb) run
Breakpoint 1, main() at t.4gl:4
  4    LET i = 1
(fgldb) whatis i
type = INTEGER
(fgldb)
```

---

**Program profiler**

Find out what function is causing the bottleneck in your program.

- Syntax of the program profiler on page 2054
- Understanding the profiler on page 2053
- Profiler output: Flat profile on page 2054
- Profiler output: Call graph on page 2054
- Example on page 2055

**Understanding the profiler**
The profiler is a tool built into the runtime system that allows you to know where your program spends processing time, and which function calls which function.

The profiler can help you to identify parts of your program that are executing slower than expected.

**Important:** The profiler measures CPU times. If the program is waiting (for a user-interaction, or when the program sleeps), then this has no impact on the results. In case of interactive programs, the time spent waiting for user action is ignored.

In order to enable the profiler during the execution of a program, you must start `fglrun` with the `-p` option, for example:

```
fglrun -p myprog
```

When the program ends, the profiler dumps profiling information to the standard error stream.

**Note:** The times reported by the profiler can change from one execution to the other, depending on the available system resources. Consider executing your program several times, to get an average time.
Syntax of the program profiler

The program profiler is enabled by using the –p option of fglrun.

To activate the program profiler, start the fglrun command with the –p option:

```
fglrun -p program[.42r] [argument [...]]
```

1. `program` is the name of the BDL program.
2. `argument` is a command line argument passed to the program.

Profiling statistics are collected during program execution, and printed when the program ends.

Profiler output: Flat profile

The flat profile shows a summary of the functions called during the program execution.

The flat profile contains a list of the functions called while the programs was running.

**Tip:** Runtime system internal function names start with the `rts_` prefix. For example, the `rts_display()` function implements the DISPLAY instruction.

**Table 414: Flat profile columns**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>Counts the number of calls for this function</td>
</tr>
<tr>
<td>$total</td>
<td>Percentage of time spent in this function. Includes time spent in subroutines called from this function.</td>
</tr>
<tr>
<td>$child</td>
<td>Percentage of time spent in functions called from this function.</td>
</tr>
<tr>
<td>$self</td>
<td>Percentage of time spent in this function excluding the time spent in subroutines called from this function.</td>
</tr>
<tr>
<td>name</td>
<td>Function name</td>
</tr>
</tbody>
</table>

**Note:** 100% represents the total processing time. The time spent waiting for user interaction is ignored.

Profiler output: Call graph

The profiler call graph provides detailed function call information.

The section "Call graph" provides the following details for each function:

1. The functions that called it, the number of calls, and an estimation of the percentage of time spent in these functions.
2. The functions called, the number of calls, and an estimation of the time that was spent in the subroutines called from this function.

**Tip:** Runtime system internal function names start with the `rts_` prefix. For example, the `rts_display()` function implements the DISPLAY instruction.

**Table 415: Call graph columns**

<table>
<thead>
<tr>
<th>Column name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>index</td>
<td>Each function has an index which appears at the beginning of its primary line.</td>
</tr>
<tr>
<td>$total</td>
<td>Percentage of time spent in this function. Includes time spent in subroutines called from this function.</td>
</tr>
<tr>
<td>Column name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>%self</td>
<td>Percentage of time spent in this function excluding the time spent in subroutines called from this function.</td>
</tr>
<tr>
<td>%child</td>
<td>Percentage of time spent in the functions called from this function.</td>
</tr>
<tr>
<td>calls/of</td>
<td>Number of calls / Total number of calls</td>
</tr>
<tr>
<td>name</td>
<td>Function name</td>
</tr>
</tbody>
</table>

Output example:

<table>
<thead>
<tr>
<th>index</th>
<th>%total</th>
<th>%self</th>
<th>%child</th>
<th>calls/of</th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1.29</td>
<td>0.10</td>
<td>1.18</td>
<td>1/2</td>
<td></td>
</tr>
<tr>
<td></td>
<td>24.51</td>
<td>1.18</td>
<td>23.33</td>
<td>1/2</td>
<td></td>
</tr>
<tr>
<td>[4]</td>
<td>25.80</td>
<td>1.29</td>
<td>24.51</td>
<td>2</td>
<td>*** fc</td>
</tr>
<tr>
<td></td>
<td>24.51</td>
<td>1.43</td>
<td>23.08</td>
<td>7/8</td>
<td>--&gt; fa</td>
</tr>
</tbody>
</table>

Description:
- The three stars *** indicate the function that is analyzed: fb.
- fc consumed 25.80% of the CPU time, 24.51% was in the called functions, 1.29% in the fc function code.
- fc has been called two times (one time by main and a second time by fb)
- fc has called the fa function 7 times.
- fa has been called 8 times in the program.

Example

Program profiler example.

Sample program

```
MAIN
  DISPLAY "Profiler sample"
  CALL fB()
  CALL fC(2)
END MAIN

FUNCTION fA(s,n_a)
  DEFINE s STRING
  DEFINE n_a,i INTEGER
  FOR i=1 TO n_a
    DISPLAY "fA "||s||" n:"||i
  END FOR
END FUNCTION

FUNCTION fB()
  CALL fA("fB",10)
  CALL fC(5)
END FUNCTION

FUNCTION fC(n_c)
  DEFINE n_c INTEGER
  WHILE n_c > 0
    CALL fA("fC",2)
    LET n_c=n_c-1
  END WHILE
```
Running the profiler

Source code coverage

Collect information about used source lines

- Understanding the coverage tool on page 2057
- Syntax of the coverage tool on page 2057
- Coverage tool usage on page 2057
Understanding the coverage tool
This is an introduction to the code coverage tool.
The coverage tool built in the runtime system allows you to collect information about source code execution.
With the coverage tool, you can:

• Identify dead code that is never executed, or make sure that important code is really executed.
• Find what lines of code are executed many times, to optimize your programs.

For each line of code, the tool reports the number of times it has been executed, if it has never been executed, or if it is not reachable at all.

Important: The output format of code coverage tool is for debug purpose only and can change in next product releases.

Syntax of the coverage tool
The code coverage tool is enabled by setting the FGLCOV environment variable.

Enabling coverage data generation
To collect coverage data while executing programs, you must set the FGLCOV environment variable:

```
$ export FGLCOV=1
```

Merging coverage data files and source files
After producing coverage data files, these must be merged with source files by using the `fglrun --merge-cov` command:

```
fglrun --merge-cov name.4gl [name.42m.cov]
```

Note: Specify the path to the `.42m.cov` file, if this file and the corresponding `.42m` file are not located in the same directory as the `.4gl` source file.

Interpreting coverage indicators and execution counts
In the `.4gl.cov` result file, each source line gets a counting indicator, that must be interpreted as follows:

• num (a number): The line was executed num times.
• - (a dash): The line is not reachable.
• =====: The line is reachable, but has never been executed.

Coverage tool usage
This topic describes how to use the code coverage feature.

Steps to get coverage information
Follow the next steps to collect and interpret coverage data:

1. Delete all existing coverage data files (*.42m.cov)
2. Enable coverage data file generation by setting the FGLCOV environment variable.
3. Execute your program several times (with fglrun): This will produce `module.42m.cov` files.
4. Use the `fglrun --merge-cov` command, to merge `module.42m.cov` coverage data files and `module.4gl` source files, to produce readable coverage information files (`module.4gl.cov`)
5. Inspect the `module.4gl.cov` to find how many times source code lines are executed.
**Cleanup coverage data files**

Before starting a new coverage data collection session, remove existing `.42m.cov` data files.

```bash
$ rm -f *.42m.cov
```

**Enable coverage data generation**

Before starting a program, set the FGLCOV environment variable, to instruct fglrun to produce coverage data files:

```bash
$ export FGLCOV=1
```

In this topic, we will use the following program sample, to show how coverage data is produced:

**Note:** Pay attention to the line containing the `IF FALSE THEN` instruction: This will illustrate how unreachable lines are detected.

```gl
MAIN
    DEFINE i INTEGER
    FOR i=1 TO 10
        IF i MOD 2 == 0 THEN
            CALL func1()
        END IF
    END FOR
END MAIN

FUNCTION func1()
    DISPLAY "Hello"
    IF FALSE THEN
        DISPLAY "... world!"
    END IF
END FUNCTION
```

A coverage data file (`module.42m.cov`) will be created for each module (`module.42m`), when running a program:

```bash
$ fglcomp prog.4gl
$ fglrun prog
Hello
Hello
Hello
Hello
Hello

$ ls prog.*
prog.42m  prog.42m.cov  prog.4gl
```

The coverage data file is created in the directory where the module is found.

**Important:** Coverage information is collected for several program executions: If a `module.42m.cov` file exist for a module, the execution count of source code lines will be summed up.

**Merge coverage data with source files**

The `.42m.cov` coverage data files contain only numbers. In order to interpret coverage data properly, you need to merge the coverage data files with the source file, by using the `fglrun --merge-cov` command:

```bash
$ fglrun --merge-cov prog.4gl
fglcov: prog.4gl.cov created
```
Note: If the .4gl source file and the .42m.cov coverage data file are not located in the same directory as the .42m module, specify the full path the coverage data file as second parameter for the --merge-cov option:

```
fglrun --merge-cov mymodule.4gl ../dist/lib/mymodule.42m.cov
```

After a first time program execution, the resulting prog.4gl.cov file contains:

```
-:    1:MAIN
-:    2:   DEFINE i INTEGER
10:   3:   FOR i=1 TO 10
10:   4:       IF i MOD 2 == 0 THEN
  5:   5:          CALL func1()
-:   6:       END IF
-:   7:   END FOR
  1:   8:END MAIN
-:   9:
-:  10:FUNCTION func1()
5:   11:   DISPLAY "Hello"
5:   12:   IF FALSE THEN
=====:   13:      DISPLAY "... world!"
-:   14:   END IF
5:   15:END FUNCTION
```

In the above output, a couple of code coverage indicators can be interpreted as follows:

- Line #2 shows a - (dash) indicator: The DEFINE statement is not reachable, because it is a declaration statement.
- Line #3 shows the number 10: The FOR (head) instruction has been executed 10 times (10 + 1 = 11, to jump out of the loop)
- Line #4 shows the number 10: The IF statement inside the FOR loop has been executed 10 times.
- Line #13 shows =====: This line is reachable, but is never executed, since the parent IF condition always evaluates to FALSE.

By executing the sample program a second time, the existing coverage data files are completed with additional information:

```
$ fglrun prog
```

Merge again the data files with source files:

```
$ fglrun --merge-cov prog.4gl
fglcov: prog.4gl.cov created
```

And now check the new result file:

```
-:    1:MAIN
-:    2:   DEFINE i INTEGER
22:   3:   FOR i=1 TO 10
20:   4:       IF i MOD 2 == 0 THEN
10:   5:          CALL func1()
-:   6:       END IF
-:   7:   END FOR
  2:   8:END MAIN
-:   9:
-:  10:FUNCTION func1()
10:   11:   DISPLAY "Hello"
10:   12:   IF FALSE THEN
=====:   13:      DISPLAY "... world!"
-:   14:   END IF
10:   15:END FUNCTION
```

You can see that the execution counts of source code lines are summed up across program execution.
Execution trace

Print a function call stack of your program.

**Important:** Sensitive and personal data may be written to the output. Make sure that the log output is written to files that can only be read by application administrators.

- Understanding the program execution trace on page 2060
- Syntax of the program execution trace on page 2060
- Using the program execution trace on page 2061

Understanding the program execution trace

This is an introduction to the program execution trace.

The program execution trace prints all function calls of your program, with the values of parameters passed to and values returned from functions.

**Important:** Sensitive and personal data may be written to the output. Make sure that the log output produced by the runtime trace is written to files that can only be read by application administrators.

This tool can help to understand the code structure of complex programs, and identify bugs in your code.

**Important:** If you plan to use the program execution trace on a production site, pay attention to the amount of data produced by the log: Using the trace can fill up the disk and potentially crash the system in a very short time.

To enable the program execution trace, start fglrun with the `--trace` option, for example:

```
fglrun --trace myprog
```

The function call stack trace will be printed to the stderr stream:

```
Enter prog.main()
   Enter prog.func1(12499,"abcdef") from prog.main at line 8
      Enter prog.func2(12499,1) from prog.func1 at line 16
         Return 12500 from prog.func2 at line 23
   ...
```

**Note:** The output format of FGL trace is for debug purpose only and can change in future product releases.

Additional control is available with FGLTRACE* environment variables, as described in the usage topic.

Syntax of the program execution trace

The execution trace is enable by using the `--trace` option of fglrun.

In order to enable program execution trace, start the `fglr` command with the `--trace` option:

```
fglrun --trace program[.42r] [argument [...]]
```

1. `program` is the name of the BDL program.
2. `argument` is a command line argument passed to the program.

Function calls are printed to stderr during program execution.

By default, the trace starts in **MAIN**.

To define a list of functions to be traced, use the FGLTRACE_FUNCTIONS environment variable.

To exclude a set of functions from the trace, use the FGLTRACE_EXCLUDE environment variable.
Using the program execution trace

The program execution trace is typically used in a development environment, to understand the program flow.

Data produced by the execution trace can be huge

**Important:** The amount of data produced can fill up the disk and potentially crash the system in a very short time. Consider using this feature carefully, especially in production environments.

Starting a program with trace

Take the following code example:

```fortran
MAIN
    DEFINE arr DYNAMIC ARRAY OF INTEGER,
        c INTEGER
    LET arr[1] = 123
    LET arr[2] = 456
    LET c = incr_elems(arr,5)
END MAIN

FUNCTION incr_elems(arr,val)
    DEFINE arr DYNAMIC ARRAY OF INTEGER,
        val INTEGER
    DEFINE i INTEGER
    FOR i=1 TO arr.getLength()
        LET arr[i] = arr[i]+val
    END FOR
    RETURN arr.getLength()
END FUNCTION
```

In order to get a function call stack trace, start your program with the `--trace` option of fglrun:

```bash
fglrun --trace prog.42m
```

The resulting trace printed to the stderr stream will look as follows:

```
Enter prog.main()
    Enter prog.incr elems((123,456),5) from prog.main at line 6
        Enter base.Array.getLength((123,456)) from prog.incr elems at line 13
            Return 2 from base.Array.getLength
        Enter base.Array.getLength((128,456)) from prog.incr elems at line 13
            Return 2 from base.Array.getLength
        Enter base.Array.getLength((128,461)) from prog.incr elems at line 13
            Return 2 from base.Array.getLength
        Enter base.Array.getLength((128,461)) from prog.incr elems at line 16
            Return 2 from base.Array.getLength
    Return 2 from prog.incr elems at line 16
Return from prog.main at line 7
```

Defining the functions to trace

By default, the trace starts with the `MAIN` function and prints all subsequent functions calls of the program.

To define the functions where the trace should start, define the `FGLTRACE_FUNCTIONS` environment variable.

This variable takes a space-separated list of function names.

**Note:** In `FGLTRACE_FUNCTIONS`, the functions can be specified with or without their module prefix.
For example, with the following definition:

```
$ export FGLTRACE_FUNCTIONS="prog.incr_elems otherfunc1 otherfunc2"
```

The new resulting trace will now start at `prog.incr_elems()`:

```
Enter prog.incr_elems((123,456),5) from prog.main at line 6
Enter base.Array.getLength((123,456)) from prog.incr_elems at line 13
Return 2 from base.Array.getLength
Enter base.Array.getLength((128,456)) from prog.incr_elems at line 13
Return 2 from base.Array.getLength
Enter base.Array.getLength((128,461)) from prog.incr_elems at line 13
Return 2 from base.Array.getLength
Enter base.Array.getLength((128,461)) from prog.incr_elems at line 16
Return 2 from base.Array.getLength
Return 2 from prog.incr_elems at line 16
```

Excluding functions from the trace

By default, the trace includes also Genero BDL library APIs, such as `base.Array.getLength()`.

Usually you are not interested in built-in function calls: You want to trace your own functions.

In order to exclude a complete set of methods, class or even a complete package, use the `FGLTRACE_EXCLUDE` environment variable, to define a space-separated list of exclude-patterns, using * and ? wildcards and [a-z] character ranges, as with the MATCHES operator.

**Note:** In `FGLTRACE_EXCLUDE`, user functions must be specified with their module prefix.

In our example, we want to exclude all methods from the build-in dynamic array class, and additionally we can also want to exclude all the calls to the classes of the om.* package (even if these are not used in this code example):

```
$ export FGLTRACE_EXCLUDE="<builtin>.* base.Array.* om.*"
```

**Tip:** To exclude all global built-in functions such as `fgl_getenv()`, use the `<builtin>.*` exclusion pattern.

The new resulting trace will now look as follows, focusing on the user function calls only:

```
Enter prog.incr_elems((123,456),5) from prog.main at line 6
Return 2 from prog.incr_elems at line 16
```

Mixing FGLTRACE_FUNCTIONS and FGLTRACE_EXCLUDE

When both FGLTRACE_FUNCTIONS and FGLTRACE_EXCLUDE are defined, FGLTRACE_FUNCTIONS has a higher priority than FGLTRACE_EXCLUDE:

- Any function listed in FGLTRACE_FUNCTIONS turns trace on
- Any function matching FGLTRACE_EXCLUDE turns trace off

The trace is enabled for a function listed in FGLTRACE_FUNCTIONS, when is it called from a function excluded by FGLTRACE_EXCLUDE. This might cause gaps in the output: an active call path can be disabled and enabled later.

Limited trace output

In order to avoid huge logs when the program creates large string variable or arrays, the output of values is voluntarily limited to a given size. In such case, the trace prints ellipsis (...), to indicate that the actual value is larger.

Try for example to change the MAIN block to fill the array with more elements:

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF INTEGER,
    c INTEGER
```

Package

Packaging web applications

Describes methods of packaging the runtime files and resources of your web applications and services using the fglgar tool.

- Introducing the GAS on page 2063
- Understanding packaging with GAS on page 2064
- Deploying applications on GAS on page 2065
- Packaging war files on page 2069
- Running applications from a war file on page 2069
- Packaging examples on page 2070

Introducing the GAS

The Genero Application Server (GAS) is an engine that plugs into a Web server for the purpose of delivering Genero Web applications and services. A general knowledge of how the GAS operates can be helpful in the planning and deploying of Web applications.

The GAS manages the Genero Browser Client or the Genero Desktop Client application requirements of the Web server. It uses dispatchers and proxies to optimize reliability, performance, and integration in Web servers. The dispatcher handles the GAS configuration and keeps a persistent session table of all proxies for the Dynamic Virtual Machine (DVM) or runtime it starts.

In development environments, it is possible to exclude the Web Server and run applications as standalone on the GAS. The httpdispatch is the standalone dispatcher used to connect to applications from the local machine. From version 3.10 onwards a GAS written in Java (JGAS) can be packaged in a Java Web Archive (war) file and applications can be run as standalone without the need for a separate GAS installation or a Java Enterprise Edition (Java EE) server.

A brief summary of some of GAS features are described:

- Connections between the DVM and the front-end are handled by the GAS in a one-to-one relationship. The GAS manages an application session and provides a debugging and logging mechanism for dispatchers and proxies. Session information is saved in case the Web server fails, which allows for the application to continue when the server restarts.
- The GAS features a command line tool (gasadmin), which allows you to perform several administration tasks including stopping a DVM, if required, without affecting any other applications that are running concurrently on the server.
- The GAS supports a timeout feature called AUTO_LOGOUT which can be configured to log out a user and display a log out page after a specified time of user inactivity on a GUI client.
- The GAS allows for user authorization and authentication to be implemented via delegation and Single sign-on.
- A GAS installation is required if you provide Genero Web Services (GWS) servers because it is designed to manage a pool of connections for clients accessing your Web services.

DEFINE i INTEGER
FOR i=1 TO 100
   LET arr[i] = i
END FOR
LET c = incr_elems(arr,5)
END MAIN

Compile and run again the program: The new trace output will show only the first elements of the array passed as parameter to the incr elems() function:

Enter prog.incr elems((1,2,3,4,5,6,7,8,9,10,11,...more...),...) from prog.main at line 8
Return 100 from prog.incr elems at line 18
• Applications that are deployed to run on a GAS on a Web server can be easily configured based on default application configurations and resources defined in the GAS configuration file as.xcf.

For more information, refer to the Genero Application Server User Guide.

Understanding packaging with GAS

Before deploying applications on a GAS installation, you need to package the required compiled files and resources in a Genero archive file. The fglgar command provides this function and you can find out here what is involved in this process.

Multiple applications may be bundled in a gar file. As a prerequisite, all of the required files and resources must be in a root directory. When you run the fglgar tool with the gar command a Genero archive is created.

```
fglgar gar --application helloWorld.42r --service welcomeService.42m
```

Example gar file

The gar file contains a MANIFEST file, your application modules, form files, configuration files, for example:

- MANIFEST
- helloWorld.42m
- helloWorld.42r
- helloWorld.42f
- welcomeService.42m
- helloWorld.xcf
- welcomeService.xcf

The MANIFEST file

The MANIFEST is an XML file that essentially provides a list of the applications and services in the gar to make available. It can be created automatically by fglgar at the command line for applications specified with the --application and/or --service option.

Or alternatively, if you have many applications to package, you may find it easier to first create the MANIFEST by hand. Running fglgar (without the --application and/or --service option) it checks if a MANIFEST file is present in the directory, and uses it to create the gar. For more information see the MANIFEST file topic in the Genero Application Server User Guide.

Application configuration files

You can provide the application configuration (xcf) files if you wish but they are created automatically for you if you provide the --application and/or --service options with the name of the executable (42r or 42m) files instead of xcf files.

The xcf file is created based on default configurations in the GAS configuration file, as.xcf:

- With option --application, fglgar creates a default xcf based on the "defaultwa" configuration.
- With option --service, fglgar creates a default xcf based on "ws.default" configuration.

In both cases, the generated xcf file is given the name of the 42r or 42m provided at the command line.

Deploy the gar file and enable its applications

You deploy the archive on your GAS installation locally using the gasadmin tool, or the FGL Web services PublishGAR tool that is provided in the Genero BDL installation.

**Note:** If the GAS is on a remote Web server, you can only deploy applications with PublishGAR. You can also use other tools such as curl, etc.

These tools unpack the contents of the archive in the GAS $(res.appdata.path)/deployment path. The applications deployed are identified by the name of the xcf. To make the applications available to end users, enable
the archive using either the gasadmin or the PublishGAR tool. For examples, see Deploying applications on GAS on page 2065.

**Deploying applications on GAS**

Follow these procedures to build archives for deploying applications and services with fglgar.

As a prerequisite, you must have your applications and/or services created, compiled, and tested. Consolidate all the necessary files for your archive under a root directory.

Included in this page are some typical examples of how to build archives and deploy applications:

- **Overview of the main tasks** on page 2065
- **Build a simple archive file** on page 2066
- **Build an archive file with many applications** on page 2066
- **Build an archive with public resources** on page 2067
- **Build an archive with deployment triggers** on page 2067
- **Deploy your application on your machine** on page 2068
- **Enable your application on your machine** on page 2068
- **Run the deployed application** on page 2068

For a full understanding of what Genero archiving offers, please read all archiving topics in the *Genero Application Server User Guide*.

**Overview of the main tasks**

This procedure provides you with a quick overview of the main steps for archiving and deploying an application using fglgar. For more information see fglgar on page 1985.

1. **Create the archive file using the fglgar gar command.**
   
   If you do not have application configuration files created, they are created automatically for you. See Understanding packaging with GAS on page 2064.

   ```
   fglgar gar --application helloWorld.42r --service welcomeService.42m
   ```

   This example shows the same command referencing xcf files you have already created for your application and service.

   ```
   fglgar gar --application helloWorld.xcf --service welcomeService.xcf
   ```

   A gar file is created that has the same name as your current directory. If you wish to specify a name for your archive, use the --output option.

2. **Deploy the archive file.**

   - If you are on the application server, you can deploy the archive with the gasadmin tool or the FGL Web services PublishGAR tool. Examples are shown for each method:

   ```
   gasadmin gar --deploy-archive myApp.gar
   ```

   ```
   fglrun
   $FGLDIR/web_utilities/services/deployment/bin/PublishGAR
   http://localhost:6394 deploy myApp.gar
   ```

   **Note:** This example assumes the standalone dispatcher on your GAS installation is already started on your local machine and you have not changed the default port number.

   - If the GAS is on a remote Web server, you can deploy applications with PublishGAR. In this example, the gar is deployed at the base URL of the GAS (for example http://zeus:8090/gas) on the Web server.

   ```
   fglrun
   ```
$FGLDIR/web_utilities/services/deployment/bin/PublishGAR
http://zeus:8090/gas deploy myApp.gar

The archive is unpacked in the ${res.appdata.path}/deployment directory.

Note: The application deployed is named with the xcf, not the gar file name.

3. Enable the archive.
   This makes applications in the archive available to end users.
   • If you are on the application server, you can enable the archive with the gasadmin tool or the FGL Web services tool, PublishGAR. Examples are shown for each method:

   ```
   gasadmin gar --enable-archive myApp.gar
   ```

   ```
   fglrun
   $FGLDIR/web_utilities/services/deployment/bin/PublishGAR
   http://localhost:6394 enable myApp.gar
   ```

   • If the GAS is on a remote server, you can enable applications with PublishGAR.

   ```
   fglrun
   $FGLDIR/web_utilities/services/deployment/bin/PublishGAR
   http://zeus:8090/gas enable myApp.gar
   ```

   The applications, services, and resources included in the archive are available for your end users.

   **Build a simple archive file**

   The fglgar gar command used with the --application option builds an archive for your application. Using fglgar as shown in this procedure creates this type of archive.

   Create the archive file (gar).
   For example, at the command line type the following:

   ```
   fglgar gar --application myApp.42r
   ```

   A gar file is created that has the same name as your current directory. A MANIFEST file and a configuration file is created automatically and included in the archive.

   **Warning:** If a MANIFEST file already exists when you run the command, errors will be raised. For more information on the use of these options, see fglgar on page 1985.

   **Build an archive file with many applications**

   If you have many applications to package, you may find it easier to create the MANIFEST by hand instead of referencing each application at the command line. The fglgar checks if a MANIFEST file is present in the archive directory and uses it to create the gar.

   1. Create your own MANIFEST file. See the MANIFEST file topic in the Genero Application Server User Guide.
   2. Create your own application configuration files (xcf).
      Make sure to set the PATH element to ${res.deployment.root}. For example, if your compiled files (forms, modules, and so on) were in the /bin directory of your archive, you would specify the PATH element as shown:

      ```
      <PATH>${res.deployment.root}/bin</PATH>
      ```
      For more information, see the Configuring applications on GAS chapter in the Genero Application Server User Guide.
   3. Use the fglgar tool to create a Genero Archive.
If you are in the directory containing your MANIFEST file and your program files:

```
gfglar gar
```

This creates an archive (gar) file with the same name as your current directory.

If you need to specify the directory where the archive content is located, include the `--input-source` option:

```
gfglar gar --input-source ./myArchiveDir
```

This creates an archive file with the same name as the archive directory, drawing its content from the `./myArchiveDir` directory.

If you wish to specify a name for your archive, use the `--output` option:

```
gfglar gar --input-source ./myArchiveDir --output myApp.gar
```

This creates an archive file with the name `myApp.gar`, drawing its content from the `./myArchiveDir` directory.

**Build an archive with public resources**

An archive can contain common or public resources such as images, reports, etc., that all deployed applications on the GAS can use. Using `fglgar` as shown in this procedure creates this type of archive.

1. Put your application's public images in a dedicated directory of your archive directory.
   You can name it, for example, "myAppPublicImages".

2. Create the archive file (gar).
   For example, at the command line type the following command with the `--resource` option specifying the name of the resource directory in the archive directory:

   ```
fglgar gar --resource myAppPublicImages --application myApp.xcf
   ```

   **Note:** A general knowledge of how the Genero Browser Client (GBC) operates can be helpful in the planning and deploying of Web applications. For more information, refer to the *Genero Browser Client User Guide*.

**Build an archive with deployment triggers**

An archive can be defined with deployment parameters. These are commands that execute when deploying and undeploying an application on the GAS. Using `fglgar` as shown in this procedure creates the archive with deployment trigger options.

**Note:** Deployment triggers are typically not required, you can deploy your applications without them.

Create an archive file (gar).

For example:

```
fglgar gar --application myApp.xcf --trigger-component
cpn.gar.execution.local
--deploy-trigger "fglrun mydeploy.42r" --undeploy-trigger "fglrun
myundeploy.42r"
```

Where:

- The `--trigger-component` option references a trigger component in the GAS `as.xcf` that defines the runtime environment where triggers are run. If not set, it defaults to "cpn.gar.execution.local".
- The `--deploy-trigger` specifies your `DEPLOY` command.
- The `--undeploy-trigger` options specifies the `UNDEPLOY` command.
These commands are saved in a MANIFEST file in the gar. See the Triggers page in the Genero Application Server User Guide.

**Warning:** If a MANIFEST file already exists when you run the command, errors will be raised. For more information on the use of these options, see fglgar on page 1985.

**Deploy your application on your machine**

**Before your begin:**

Once you have created an archive for your application, you can now deploy it locally on your machine where the GAS is installed. If the standalone dispatcher on your GAS installation is not already started, run it from the command line using httpdispatch.

Deploy your gar file.

For example, to deploy an archive named myApp.gar using the PublishGar tool, type the following:

```
fglrun
$FGLDIR/web_utilities/services/deployment/bin/PublishGAR
http://localhost:6394 deploy myApp.gar
```

Or if using the gasadmin tool, type the following command:

```
gasadmin gar --deploy-archive myApp.gar
```

The archive is unpacked in the ${{ res.appdata.path }}/deployment directory.

**Note:** The application deployed is named with the xcf, not the gar file name.

**Enable your application on your machine**

Once you have deployed your application, you can now make it available for end users by enabling it on the machine where the GAS is installed. If the standalone dispatcher on your GAS installation is not already started, run it from the command line using httpdispatch.

Enable your application.

For example, using the PublishGAR tool, type the command

```
fglrun
$FGLDIR/web_utilities/services/deployment/bin/PublishGAR
http://localhost:6394 enable myApp.gar
```

Or if using the gasadmin tool, type the command:

```
gasadmin gar --enable-archive myApp.gar
```

**Run the deployed application**

Once the application is enabled, you can now run it. If the standalone dispatcher on your GAS installation is not already started, run it from the command line using httpdispatch.

In a browser enter the address of your deployed application.

```
http://localhost:6394/ua/r/myApp
```

In this example, the URL is looking for a configuration file named myApp.xcf.

If your application is displayed and you can interact with it, you have successfully deployed an application.
Packaging war files

Using the fglgar tool to build a Java Web Archive (war) file allows you to deploy applications that are ready to run.

The fglgar tool run with the war command creates a war file that embeds a Genero Java GAS (JGAS) and the Genero Archive file (gar). The JGAS allows you to run applications and services bundled in your gar file as standalone. This means that you can package applications for deployment and testing without the need to install an additional GAS package on the server side.

Note: The standalone JGAS is for development and testing only, a Java Enterprise Edition (Java EE) server is required for a production environment.

A typical fglgar war command is shown:

```
fglgar war -g MyApp.gar --gbc c:/dev/gbc_custom -o ../MyGeneroJavaApps.war
```

The example uses three of the command's main options:

- The --input-gar (-g) option is mandatory. It allows you to specify the Genero Archive you want to use to create the war file. This means that you need to have a gar file already created to include in the war file. See Deploying applications on GAS on page 2065.
- The --gbc option is optional but it allows you specify a different Genero Browser Client (GBC), for example, one that you have customized specifically for your applications. Otherwise, the default gbc installed with the FGLGWS package is embedded in the war file.
- The --output or -o option specifies the relative or absolute path to the war file to generate.

Running applications from a war file

Applications packaged in a Java Web Archive (war) file can be executed with the fglgar tool's run command.

What is the fglgar run command?

The fglgar run command starts the JGAS that is packaged in the specified .war file.

The command opens the port to listen for incoming requests, to launch GUI applications in a browser or to respond to Web services requests.

Important:

- The FGLGWS needs to be installed on the server to interpret the Genero 4GL applications and services.
- You need a Java Runtime Environment (JRE) version that is at least version 1.8 or greater.

The next example shows fglgar run command using the MyGeneroJavaApps.war package:

```
fglgar run -w MyGeneroJavaApps.war -p 9999 -P 4444 -E log.file.path=`pwd`
```

To understand how to create a .war file, see Packaging war files on page 2069.

fglgar run options

The main fglgar run options are:

- The --war or -w option is mandatory and defines the war file.
- The --http-port or -p option defines the HTTP port. If not set, the default port is 8080.
- The --https-port or -P option defines the HTTPS port. If not set, the default port is 443.
- The --resource-overwrite or -E option defines the GAS resources you want to overwrite, such as the directory of the logs.

See fglgar command reference for more options.
Starting applications from a browser

If, for example, your MyGeneroJavaApps.war file contains two Web application, one called HelloWorld and another called MyApp, the URL requests to launch them then from the browser would look like this:

- http://localhost:9999/MyGeneroJavaApps/HelloWorld/ua/r/HelloWorld
- http://localhost:9999/MyGeneroJavaApps/MyApp/ua/r/MyApp

Tip: The base URL in the context of JGAS is http://server:port/war_file_name. If you type the base URL in a browser, you get an overview page where you can then access all applications and services published in your JGAS.

Getting Web Services WSDLs

To request the Web Services Descriptive Language (WSDL) of a Web service called MyWebService deployed in the MyGeneroJavaApps.war, the URL must look like this:

http://localhost:9999/MyGeneroJavaApps/MyWebService/ws/r/MyWebService?WSDL

Packaging examples

With the fglgar tool you can immediately see the results of a Genero Web Application or Web Service during your development stage without having to install a Web server or a GAS package.

Packaging and running applications with fglgar

If you have a directory named MyFirstApp with a Genero 4GL application and/or a service that you wish to test, then with just three fglgar commands applications are packaged and can be viewed in a browser.

```
$ cd MyFirstApp
$ fglcomp -M HelloWorld.4gl
$ fglcomp -M MyWebService.4gl
$ fglgar gar --application HelloWorld.42m --service MySebService.42m
$ fglgar war --input-gar MyFirstApp.gar
$ fglgar run --war MyFirstApp.war -p 9999
```

Where:

1. The application and service source files (.4gl) are compiled.
2. fglgar is run with the gar command to create an archive file with the compiled applications and services.
3. fglgar is run with the war command to create a war file that embeds the gar file together with the GAS written in Java (JGAS) that allows applications to be run as standalone.
4. fglgar is run with the run command to start the JGAS packaged in the war file. It opens port 9999 to listen for incoming requests to launch applications or Web services. See Running applications from a war file on page 2069.

Adding a customized GBC to the package

If you have customized Genero Browser Client (GBC) in a directory named gbc_customized, then you can include it in the package with the --gbc option.

```
$ cd MyFirstApp
$ fglcomp -M HelloWorld.4gl
$ fglcomp -M MyWebService.4gl
$ fglgar gar --application HelloWorld.42m --service MySebService.42m
$ fglgar war --input-gar MyFirstApp.gar --gbc c:\dev\gbc_customized
$ fglgar run --war MyFirstApp.war -p 9999
```
Packaging multiple applications

If you have multiple applications to deploy in your MyApp directory that you wish to test, you can add them to the fglgar gar with --application options, as shown. The applications are bundled in the gar and run from the war file.

```
$ cd MyApp
$ fglcomp -M HelloWorld.4gl
$ fglcomp -M app1.4gl
$ fglgar gar --application HelloWorld.42m --application app1.42m
$ fglgar war --input-gar MyApp.gar
$ fglgar run --war MyApp.war -p 9999
```

Logging options

Logging solutions allow you to display exchanges between components when a program executes.

Genero provides several build-in options to get debug information, as well as logging features:

- Get the stack trace with `base.Application.getStackTrace()`
- Display the GUI protocol exchange in stderr with `FGLGUIDEBUG`.
- Display the SQL statements execution in stderr with `FGLSQLDEBUG`.
- Display Web Services API calls in stderr with `FGLWSDEBUG`.
- Produce function call stack trace with `fglr --trace` option.
- Produce source code coverage info with `fglr --merge-cov / FGLCOV`.
- Log front-end protocol exchange with `fglr --start-guilog` option.
- Produce application log files in case of runtime error, with `STARTLOG()`.

**Important:** Sensitive and personal data may be written to the output. Make sure that the log output is written to files that can only be read by application administrators.

Extending the language

These topics cover extending Genero Business Development Language with other languages and external components.

- The Java interface on page 2071
- C-Extensions on page 2109
- User-defined front calls on page 2129
- Web Components on page 2149

The Java interface

The Java interface allows you to import Java classes and instantiate Java objects in your programs.

The Java interface gives access to the huge standard Java libraries, as well as commercial libraries for specific purposes.

The methods of Java objects can be called with other Java objects referenced in program, as well as with native language data types such as `INTEGER`, `DECIMAL`, `CHAR`.

The Java interface of Genero has the following limitations:

1. It is not possible to use Java generic types such as `java.util.Vector<E>`, with a type parameter (for example, `Vector<MyClass> v = new Vector<MyClass>()`). However, it is possible to instantiate these classes without a type parameter (for example, `Vector v = new Vector()`).
2. Database connections cannot be shared between Java and Genero programs.
3. Java graphical objects cannot be used in Genero forms.

- Prerequisites and installation on page 2072
- Getting started with the Java interface on page 2075
- Advanced programming on page 2076
- Examples on page 2104

**Prerequisites and installation**

**Learn about Java and OOP**

Before starting with the Java interface, if you are not familiar with Java and Object Oriented Programming, we strongly recommend that you learn more about this language from the different tutorials and courses you can find on the internet.

**Related concepts**

- OOP support on page 460
  Describes Object Oriented Programming basics in the language.

**Java software requirements**

In order to use the Java Interface in your application programs, you need the Java software installed and properly configured.

- Install a Java Development Kit on development sites (if you need to compile your own Java classes)
- Install a Java Runtime Environment on production sites (on the server where your programs are running)

**Note:** Over time, the Java platform has used different versioning systems, to distinguish a "Java developer version", from a "Java product version". For example, the Java developer version (JDK) 1.8 corresponds to the Java product version 8. With recent versions like Java 10, a unique version numbering convention is used.

The Java classes defined by Genero (com.fourjs.fgl.lang.*) are compiled with `javac -source 1.6 -target 1.6` options. Therefore, the minimum theoretical version is Java SE 6. However, depending on the platform, the minimum required Java version may be greater than version 6.

**Note:** As a general rule, always install the current long-term-support (LTS) Java version available on your platform, with JNI support. For example, Java SE 8 (released in March 2014) and Java SE 11 (released in September 2018) are LTS versions.

For a detailed list of supported JVMs, refer to the *Supported platforms and databases* document (available on the Products download page of the Four Js Web site) or contact your support center.

The version of the installed Java software can be shown with the command:

```
java --version
```

In order to execute Java byte code, the Genero runtime system uses the JNI interface. The JVM is loaded as a shared library and its binary format must match the binary format of the Genero runtime system. For example, a 64-bit Genero package requires a 64-bit JVM.

When implementing Java classes for Genero Mobile for Android™ (GMA), check the JDK version required by the Android™ SDK. For more information, see the Android™ Studio web site.

**How to set up Java**

This short procedure describes how to set up a Java environment to be used with Genero.

1. Download the latest JDK from your preferred Java provider. On production sites, you only need a Java Runtime Environment (JRE).
2. Install the package on your platform by following the vendor installation notes.
3. Set the PATH environment variable to the directory containing the Java compiler (javac), and to the Java Virtual Machine (java).

4. Configure your environment for Java Native Interface (JNI) support and to load the JVM shared library:
   - Check Platform-specific notes for the JVM on page 2073.

5. Set the CLASSPATH or pass the --java-option=-Djava.class.path=<pathlist> option to fglrun with the directories of the Java packages you want to use. You must add FGLDIR/lib/fgl.jar to the class path in order to compile Java code with language specific classes such as com.fourjs.fgl.lang.FglDecimal or com.fourjs.fgl.lang.FglRecord.

6. Try your JDK by compiling a small Java sample and executing it.

**Platform-specific notes for the JVM**

**Android™**

The Java Interface can be used in Genero apps build for the Android™ / GMA platform.

On Android™ devices, custom Java classes need to be part of the .apk package and can be used without any further configuration.

**Note:** On Android™ devices, some system functions can only be accessed in the context of a JVM. Use the Java Interface with the com.fourjs.gma.vm.FglRun class to access such system specifics.

For more details, see Executing Java code with GMA on page 2098.

**iOS**

**Important:**

The Java interface cannot be used in apps running on iOS devices: There is no standard free JVM available.

**IBM® AIX®**

Consider the following notes when using the Java Interface with the IBM® Java VM on AIX®:

If you get java.lang.UnsatisfiedLinkError exceptions, set the path to native shared libraries in the LIBPATH environment variable:

```bash
$ LIBPATH=$JAVA_HOME/jre/bin:$JAVA_HOME/jre/bin/j9vm:$JAVA_HOME/jre/lib/ ppc64:$LIBPATH
$ export LIBPATH
```

This is required when using Java code that needs to access native code supplied as part of the JRE. For example, without setting LIBPATH to the appropriate path, the JVM cannot find the shared library libnet.so.

Using the -Djava.library.path=path-to-native-library java VM option does not seem to help.

See also IBM AIX configuration notes on page 45.

**HP-UX®**

Consider the following notes when using the HotSpot JVM on HP/UX:

If you get an error when fglcomp or fglrun try to load the libjvm library, define the LD_PRELOAD environment variable as follows:

```bash
$ LD_PRELOAD=libjvm.sl
$ export LD_PRELOAD
```

Using LD_PRELOAD can make other applications fail. LD_PRELOAD should only be set for the runtime system. If you need to run other applications in the same environment as your application programs, you can set the LD_PRELOAD_ONCE or JAVA_PRELOAD_ONCE variable in the shell scripts found in FGLDIR/bin.
See also HP-UX configuration notes on page 45.

**Microsoft™ Windows®**

On Microsoft™ Windows® platforms, make sure that the PATH environment variable does not contain double quotes around the path to the JVM.DLL dynamic library, otherwise the DLL loader will fail to load the JVM.

See also Microsoft Windows configuration notes on page 47.

**Mac® OS X®**

The JAVA_HOME environment variable must be set to use the Java interface on Mac® OS X.

To find the JAVA_HOME path on Mac® OS X, use the /usr/libexec/java_home tool:

```bash
export JAVA_HOME=`/usr/libexec/java_home`
```

**Note:** On Mac® OS X, the usage of DYLD_LIBRARY_PATH is strongly discouraged, especially since OS X 10.11 this environment variable is no longer exported in sub processes.

The Genero runtime system uses the Java Native Interface (JNI) to interact with the JVM and execute Java code.

By default on Mac® OS X, the JNI feature may not be activated.

To ensure that Java is installed, execute the following command:

```bash
$ /usr/libexec/java_home
```

The output should look like:

```
Library/Java/JavaVirtualMachines/jdk1.8.0_60.jdk/Contents/Home
```

To ensure that JNI is enabled, use the -t JNI option:

```bash
$ /usr/libexec/java_home -t JNI
```

The output should look like:

```
Library/Java/JavaVirtualMachines/jdk1.8.0_60.jdk/Contents/Home
```

If the output is empty or reports an older version, JNI is not enabled for the default java installation.

To enable JNI, edit the Info.plist file:

```bash
$ sudo vi `'/usr/libexec/java_home`/../Info.plist`
```

And add "<string>JNI</string>" in the <array> of the JVMCapabilities key:

```xml
<dict>
  <key>JVMCapabilities</key>
  <array>
    <string>CommandLine</string>
    <string>JNI</string>
  </array>
</dict>
```

See also Mac OS X configuration notes on page 46.
Getting started with the Java interface

Import a Java class

In order to use a Java class in your program code, you must first import the class with the `IMPORT JAVA` instruction:

```
IMPORT JAVA java.util.regex.Pattern
```

This will import the specified Java class into the current program module. Object references can now be defined for this class.

Define an object reference variable

Before creating a Java object in your program, you must declare a program variable to reference the object. The type of the variable must be the name of the Java class, and can be fully qualified if needed:

```
IMPORT JAVA java.util.regex.Pattern
MAIN
    DEFINE p1 Pattern
    DEFINE p2 java.util.regex.Pattern
END MAIN
```

The variables declared with a class are only the handles to reference an object (meaning the object is not yet created).

Instantiate a Java class

To create a new Java object, use `ClassName.create()`, and assign the value returned by the `create()` method to a program variable declared with the Java class name:

```
IMPORT JAVA java.lang.StringBuffer
MAIN
    DEFINE sb StringBuffer
    LET sb = StringBuffer.create()
END MAIN
```

If the Java class constructor uses parameters, pass the parameters to the `create()` method:

```
IMPORT JAVA java.lang.StringBuffer
MAIN
    DEFINE sb1, sb2 StringBuffer
    -- Next code line uses StringBuffer(String str) constructor
    LET sb1 = StringBuffer.create("abcdef")
    -- Next code line uses StringBuffer(int capacity) constructor
    LET sb2 = StringBuffer.create(2048)
END MAIN
```

Calling a method of a class

Class methods (static method in Java) can be called without instantiating an object of the class. Static method invocation must be prefixed with the class name. In the following example, the `compile()` class method of Pattern class returns a new instance of a Pattern object:

```
IMPORT JAVA java.util.regex.Pattern
MAIN
    DEFINE p Pattern
    LET p = Pattern.compile("[,,\s]+")
END MAIN
```
If you define a variable with the same name as a Java class, you must fully qualify the class when calling static methods, as shown in this example:

```java
IMPORT JAVA java.util.regex.Pattern
IMPORT JAVA java.util.regex.Matcher
MAIN
  DEFINE Pattern Pattern
  DEFINE Matcher Matcher
  -- static method, needs full qualifier
  LET Pattern = java.util.regex.Pattern.compile("[a-z]+")
  -- regular instance method, Pattern resolves to variable
  LET Matcher = Pattern.matcher("abcdef")
END MAIN
```

**Note:** In Genero, program variables are case-insensitive (Pattern = pattern).

**Calling a method of an object**

Once the class has been instantiated as an object, and the object reference has been assigned to a variable, you can call a method of the Java object by using the variable as the prefix:

```java
IMPORT JAVA java.util.regex.Pattern
IMPORT JAVA java.util.regex.Matcher
MAIN
  DEFINE p Pattern
  DEFINE m Matcher
  LET p = java.util.regex.Pattern.compile("[a-z]+")
  LET m = p.matcher("abcdef")
  DISPLAY m.matches()
END MAIN
```

In this example, the last line of the MAIN module calls an object method that returns a boolean value that is converted to an INTEGER and displayed.

**Advanced programming**

**Using JVM options**

When using the Java interface, you can instruct `fglrn` or `fglcomp` to pass Java VM specific options during JNI initialization, by using the `--java-option` command line argument.

In the example, `fglrn` passes `-verbose:gc` to the Java Virtual Machine:

```
$ fglrun --java-option=-verbose:gc myprog.42r
```

If you want to pass several options to the JVM, repeat the `--java-option` argument as in this example:

```
$ fglrun --java-option=-verbose:gc --java-option=-esa myprog.42r
```

You may want to pass the Java class path as a command line option to `fglrn` with `-Djava.class.path` option as in this example:

```
$ fglrun --java-option=-Djava.class.path=$FGLDIR/lib/fgl.jar:$MYCLASSPATH myprog.42r
```

Regarding class path specification, the java runtime or javac compiler provide the `-cp` or `-classpath` options but when loading the JVM library from `fglrn` or `fglcomp`, only `-Djava.class.path` option is supported by the JNI interface.
**Case sensitivity with Java**

The Java language is case-sensitive. Therefore, when you write the name of a Java package, class or method in a .4gl source, it must match the exact name as if you were writing a Java program. The fglcomp compiler takes care of this, and writes case-sensitive class and method names in the .42m p-code modules.

```plaintext
IMPORT JAVA java.util.regex.Pattern
MAIN
  DEFINE p java.util.regex.PATTERN -- Note the case error
END MAIN
```

With this code example, fglcomp will raise error -6622 at line 3, because the "java/util/PATTERN" name cannot be found.

**Method overloading in Java**

The Java language allows method overloading: the parameter count and the parameter data types of a method are part of the method identification. Thus, the same method name can be used to implement different versions of the Java method, taking different parameters:

```plaintext
DEFINE int2 SMALLINT, int4 INTEGER, flt FLOAT

-- Next call invokes method display(short) of the Java class
CALL myobj.display(int2)

-- Next call invokes method display(int) of the Java class
CALL myobj.display(int4)

-- Next call invokes method display(double) of the Java class
CALL myobj.display(flt)

-- Next call invokes method display(short,int) of the Java class
CALL myobj.display(int2,int4)
```

**Passing Java objects to functions**

Java objects must be instantiated and referenced by a program variable. The object reference is stored in the variable and can be passed as a parameter or returned from a program function. The Java objects are passed by reference to functions. This means that the called function does not get a clone of the object, but rather a handle to the original object. The function can then manipulate and modify the original object provided by the caller:

```plaintext
IMPORT JAVA java.lang.StringBuffer
MAIN
  DEFINE x java.lang.StringBuffer
  LET x = StringBuffer.create()
  CALL change(x)
  DISPLAY x.toString()
END MAIN

FUNCTION change(sb)
  DEFINE sb java.lang.StringBuffer
  CALL sb.append("abc")
END FUNCTION
```

Similarly, Java object references can be returned from functions:

```plaintext
IMPORT JAVA java.lang.StringBuffer
MAIN
  DEFINE x java.lang.StringBuffer
```

LET x = build()
DISPLAY x.toString()
END MAIN

FUNCTION build()
DEFINE sb java.lang.StringBuffer
LET sb = StringBuffer.create()  -- Creates a new object.
CALL sb.append("abc")
RETURN sb  -- Returns the reference to the object, not a copy/clone.
END FUNCTION

Garbage collection of unused objects

Java objects do not need to be explicitly destroyed; as long as an object is referenced by a variable, on the stack or in an expression, it will remain. When the last reference to an object is removed, the object is destroyed automatically.

The next example shows how a unique object can be referenced twice, using two variables:

FUNCTION test()
-- Declare 2 variables to reference a StringBuffer object
DEFINE sb1, sb2 java.lang.StringBuffer
-- Create object and assign reference to variable
LET sb1 = StringBuffer.create()
-- Same object is now referenced by 2 variables
LET sb2 = sb1
-- Object is modified through first variable
CALL sb1.append("abc")
-- Object is modified through second variable
CALL sb2.append("def")
-- Shows content of StringBuffer object
DISPLAY sb1.toString()
-- Same output as previous line
DISPLAY sb2.toString()
-- Object is only referenced by second variable
LET sb1 = NULL
-- sb2 removed from stack, object is no longer referenced and is destroyed.
END FUNCTION

Using the method return as an object

If a Java method returns an object, you can use the method call directly as an object reference to call another method:

IMPORT JAVA java.util.regex.Pattern
MAIN
DEFINE p Pattern
LET p = Pattern.compile("a*b")
IF p.matcher("aaaab").matches() THEN
DISPLAY "It matches..."
END IF
END MAIN

In this code example, the matcher() method of object p is invoked and returns an object of type java.util.regex.Matcher. The object reference returned by the matcher() method can be directly used to invoke the matches() method of the Matcher class.

Ignorable return of Java methods

Java allows you to ignore the return value of a method (as in C/C++):

StringBuffer sb = new StringBuffer;
sb.append("abc");  -- returns a new StringBuffer object but is ignored
In programs, you can call a Java method and ignore the return value:

```java
IMPORT JAVA java.util.lang.StringBuffer
MAIN
  DEFINE sb StringBuffer
  LET sb = StringBuffer.create()
  LET sb = sb.append("abc")
  CALL sb.append("def") -- typical usage
END MAIN
```

**Static fields of Java classes**

Java classes can have object and class ("static") fields. Java static class fields can be declared as "final" (read-only). It is not possible to change the object or class fields in programs, even if the field is not declared as "static final"; you can however read from it:

```java
IMPORT JAVA java.lang.Integer
MAIN
  DISPLAY Integer.MAX_VALUE
END MAIN
```

**Mapping native and Java data types**

Java and Genero have different built-in data types. Unlike Genero, Java is a strongly typed language: You cannot call a method with a `String` if it was defined to get an `int` parameter. To call a Java method, **Genero native typed values** need to be converted to/from Java types such as `byte`, `int`, `short`, `char` or data objects such as `java.lang.String`. If possible, the fglrun runtime system will do this conversion implicitly.

The `fglcomp` compiler will raise the error `-6606`, if the native data type does not match the Java (primitive) type, using Widening Primitive Conversions. For example, passing a Genero `DECIMAL` when a Java `double` is expected will fail, but passing a `SMALLFLOAT` (equivalent to `float`) when a Java `double` is expected will compile and run.

Genero has advanced native data types such as `DECIMAL`, which do not have an equivalent primitive type or class in Java. For such Genero types, you need to use a specific Java class provided in the FGLDIR/lib/fgl.jar package, like `com.fourjs.fgl.lang.FglDecimal`. You can then manipulate the Genero specific value in the Java code.

Genero also implements structured types with `RECORD` definitions, converted to `com.fourjs.fgl.lang.FglRecord` objects for Java.

The **Genero arrays** cannot be used to call Java methods. You must use a native Java arrays instead.

In some cases you need to explicitly cast with the new `CAST()` operator. See the section about `CAST()` operator for more details.

The following tables show the implicit conversions done by the runtime system when a Java method is called, or when a Java method returns a value or object reference:

**Table 416: Implicit BDL/Java conversions using simple types**

<table>
<thead>
<tr>

<table>
<thead>
<tr>
<th>Genero data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARRAY structures</td>
</tr>
<tr>
<td>Built-in classes</td>
</tr>
</tbody>
</table>

Using the DATE type

When calling a Java method with an expression evaluating to a DATE, the runtime system converts the DATE value to an instance of the com.fourjs.fgl.lang.FglDate class implemented in $FGLDIR/lib/fgl.jar. You can then manipulate the date from within the Java code.

You must add $FGLDIR/lib/fgl.jar to the class path in order to compile Java code with com.fourjs.fgl.lang.FglDate class.

The com.fourjs.fgl.lang.FglDate class implements following:

Table 419: Methods of the com.fourjs.fgl.lang.FglDate class

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.lang.String toString()</td>
<td>Converts the DATE value to a String object representing the date in the format: YYYY-MM-DD</td>
</tr>
<tr>
<td>static FglDate valueOf( java.lang.String val)</td>
<td>Creates a new FglDate object from a String object representing a date in the format YYYY-MM-DD.</td>
</tr>
</tbody>
</table>
In the Java code, you can convert the `com.fourjs.fgl.lang.FglDate` to a `java.util.Calendar` object as in this example:

```java
public static void useDate(FglDate d) throws ParseException {
    SimpleDateFormat sdf = new SimpleDateFormat("yyyy-MM-dd");
    Calendar cal = Calendar.getInstance();
    cal.setTime( sdf.parse(d.toString()) );
    ...
}
```

If you need to create a `com.fourjs.fgl.lang.FglDate` object in your program, you can use the `valueOf()` class method as in this example:

```java
IMPORT JAVA com.fourjs.fgl.lang.FglDate
MAIN
    DEFINE d com.fourjs.fgl.lang.FglDate
    LET d = FglDate.valueOf("2008-12-23")
    DISPLAY d.toString()
END MAIN
```

**Using the DATETIME type**

When calling a Java method with an expression evaluating to a `DATETIME`, the runtime system converts the `DATETIME` value to an instance of the `com.fourjs.fgl.lang.FglDateTime` class implemented in `$FGLDIR/lib/fgl.jar`. You can then manipulate the `DATETIME` from within the Java code.

You must add `$FGLDIR/lib/fgl.jar` to the class path in order to compile Java code with `com.fourjs.fgl.lang.FglDateTime` class.

The `com.fourjs.fgl.lang.FglDateTime` class implements the following:
Table 420: Fields of the com.fourjs.fgl.lang.FglDateTime class

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>final static int YEAR</td>
<td>Time qualifier for year</td>
</tr>
<tr>
<td>final static int MONTH</td>
<td>Time qualifier for month</td>
</tr>
<tr>
<td>final static int DAY</td>
<td>Time qualifier for day</td>
</tr>
<tr>
<td>final static int HOUR</td>
<td>Time qualifier for hour</td>
</tr>
<tr>
<td>final static int MINUTE</td>

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>static int encodeTypeQualifier(&lt;br&gt; int startUnit,&lt;br&gt; int endUnit)</td>
<td>Returns the encoded type qualifier for a datetime with to datetime qualifiers passed:&lt;br&gt; encoded qualifier = (length * 256) + (startUnit * 16) + endUnit&lt;br&gt; Where length defines the total number of significant digits in this time data.&lt;br&gt; For example, with DATETIME YEAR TO MINUTE:&lt;br&gt; startUnit = YEAR&lt;br&gt; length = 12 (YYYYMMDDhhmm)&lt;br&gt; endUnit = MINUTE</td>
</tr>
<tr>
<td>java.lang.String toString()</td>
<td>Converts the DATETIME value to a String object representing a datetime in the format YYYY-MM-DD hh:mm:ss.fff.</td>
</tr>
<tr>
<td>static FglDateTime valueOf(&lt;br&gt; long milliseconds)</td>
<td>Creates a new FglDateTime object representing the specified number of milliseconds since the standard base time known as &quot;the epoch&quot;, namely January 1, 1970, 00:00:00 GMT.</td>
</tr>
<tr>
<td>static FglDateTime valueOf(&lt;br&gt; java.lang.String val)</td>
<td>Creates a new FglDateTime object from a String object representing a datetime value in the format: YYYY-MM-DD hh:mm:ss.fff</td>
</tr>
<tr>
<td>static FglDateTime valueOf(&lt;br&gt; java.lang.String val,&lt;br&gt; int startUnit,&lt;br&gt; int endUnit)</td>
<td>Creates a new FglDateTime object from a String object representing a datetime value in the format YYYY-MM-DD hh:mm:ss.fff, using the qualifiers passed as parameter.</td>
</tr>
</tbody>
</table>

In the Java code, you can convert the com.fourjs.fgl.lang.FglDateTime to a java.util.Calendar object as in this example:

```java
public static void useDatetime(FglDateTime dt) throws ParseException {
    SimpleDateFormat sdf = new SimpleDateFormat("yyyy-MM-dd HH:mm:ss.SSS");
    Calendar cal = Calendar.getInstance();
    cal.setTime( sdf.parse(dt.toString()) );
    ...
}
```

If you need to create a com.fourjs.fgl.lang.FglDateTime object in your program, you can use the valueOf() class method as in this example:

```java
IMPORT JAVA com.fourjs.fgl.lang.FglDateTime
MAIN
    DEFINE dt com.fourjs.fgl.lang.FglDateTime
    LET dt = FglDateTime.valueOf("2008-12-23 11:22:33.123")
    LET dt = FglDateTime.valueOf("11:22:33.123",
        FglDateTime.HOUR, FglDateTime.FRACTION3)
    DISPLAY dt.toString()
END MAIN
```
The `valueOf()` method expects a string representing a complete date-time specification, from year to milliseconds, equivalent to a `DATETIME YEAR TO FRACTION(3)` data type.

### Using the DECIMAL type

When calling a Java method with an expression evaluating to a `DECIMAL`, the runtime system converts the DECIMAL value to an instance of the `com.fourjs.fgl.lang.FglDecimal` class implemented in `$FGLDIR/lib/fgl.jar`. You can then manipulate the DECIMAL from within the Java code.

You must add `$FGLDIR/lib/fgl.jar` to the class path in order to compile Java code with `com.fourjs.fgl.lang.FglDecimal` class.

The `com.fourjs.fgl.lang.FglDecimal` class implements the following methods shown in the table:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>static int encodeTypeQualifier(int precision, int scale)</code></td>
<td>Returns the encoded type qualifier for this decimal based on precision and scale. encoded qualifier = (precision * 256) + scale</td>
</tr>
<tr>
<td><code>java.lang.String toString()</code></td>
<td>Converts the DECIMAL value to a String object.</td>
</tr>
<tr>
<td><code>static FglDecimal valueOf(int val)</code></td>
<td>Creates a new <code>FglDecimal</code> object from an int value.</td>
</tr>
<tr>
<td><code>static FglDecimal valueOf(java.lang.String val)</code></td>
<td>Creates a new <code>FglDecimal</code> object from a String object representing a decimal value.</td>
</tr>
</tbody>
</table>

In the Java code, you can convert the `com.fourjs.fgl.lang.FglDecimal` to a `java.lang.BigDecimal` as in the following example:

```java
public static FglDecimal divide(FglDecimal d1, FglDecimal d2){
    BigDecimal bd1 = new BigDecimal(d1.toString());
    BigDecimal bd2 = new BigDecimal(d2.toString());
    BigDecimal res = bd1.divide(bd2, BigDecimal.ROUND_FLOOR);
    return FglDecimal.valueOf(res.toString());
}
```

If you need to create a `com.fourjs.fgl.lang.FglDecimal` object in your program, you can use the `valueOf()` class method as in this example:

```java
IMPORT JAVA com.fourjs.fgl.lang.FglDecimal
MAIN
    DEFINE jdec com.fourjs.fgl.lang.FglDecimal
    LET jdec = FglDecimal.valueOf("123.45")
    DISPLAY jdec.toString()
END MAIN
```

### Using the TEXT type

When calling a Java method with an expression evaluating to a `TEXT`, the runtime system converts the TEXT handle to an instance of the `com.fourjs.fgl.lang.FglTextBlob` class implemented in `$FGLDIR/lib/fgl.jar`. You can then manipulate the LOB from within the Java code.
You must add $FGLDIR/lib/fgl.jar to the class path in order to compile Java code with com.fourjs.fgl.lang.FglTextBlob class.

The com.fourjs.fgl.lang.FglTextBlob class implements the following:

**Table 423: Methods of the com.fourjs.fgl.lang.FglTextBlob class**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void dispose()</td>
<td>Dereferences the underlying TEXT variable.</td>
</tr>
<tr>
<td>java.lang.String toString()</td>
<td>Converts the large text data to a simple String.</td>
</tr>
<tr>
<td>static FglTextBlob valueOf( java.lang.String val)</td>
<td>Creates a new FglTextBlob object from a String.</td>
</tr>
</tbody>
</table>

In the Java code, you can pass a com.fourjs.fgl.lang.FglTextBlob object as in this example:

```java
public static void useByte(FglTextBlob t) throws ParseException {
    String s = t.toString();
    ...
}
```

If you need to create a com.fourjs.fgl.lang.FglTextBlob object in your program, you can use the `valueOf()` class method as in this example:

```java
IMPORT JAVA com.fourjs.fgl.lang.FglTextBlob
MAIN
    DEFINE jtext com.fourjs.fgl.lang.FglTextBlob
    LET jtext = FglTextBlob.valueOf("abcdef..........")
    DISPLAY jtext.toString()
END MAIN
```

**Using the BYTE type**

When calling a Java method with an expression evaluating to a BYTE, the runtime system converts the BYTE handle to an instance of the com.fourjs.fgl.lang.FglByteBlob class implemented in $FGLDIR/lib/fgl.jar. You can then manipulate the LOB from within the Java code.

You must add $FGLDIR/lib/fgl.jar to the class path in order to compile Java code with com.fourjs.fgl.lang.FglByteBlob class.

The com.fourjs.fgl.lang.FglByteBlob class implements the following:

**Table 424: Methods of the com.fourjs.fgl.lang.FglByteBlob class**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void dispose()</td>
<td>Dereferences the underlying BYTE variable.</td>
</tr>
<tr>
<td>java.lang.String toString()</td>
<td>Returns the HEX string representing the binary data.</td>
</tr>
<tr>
<td>static FglByteBlob valueOf( java.lang.String val)</td>
<td>Creates a new FglByteBlob object from a String object representing the binary data in HEX format.</td>
</tr>
</tbody>
</table>
In the Java code, you can pass a `com.fourjs.fgl.lang.FglByteBlob` object as in this example:

```java
public static void useByte(FglByteBlob b) throws ParseException {
    String s = b.toString();
    ...
}
```

If you need to create a `com.fourjs.fgl.lang.FglByteBlob` object in your program, you can use the `valueOf()` class method as in this example:

```java
IMPORT JAVA com.fourjs.fgl.lang.FglByteBlob
MAIN
    DEFINE jbyte com.fourjs.fgl.lang.FglByteBlob
    LET jbyte = FglByteBlob.valueOf("0FA5617BDE")
    DISPLAY jbyte.toString()
END MAIN
```

**Using the INTERVAL type**

When calling a Java method with an expression evaluating to an `INTERVAL`, the runtime system converts the `INTERVAL` value to an instance of the `com.fourjs.fgl.lang.FglInterval` class implemented in `$FGLDIR/lib/fgl.jar`. You can then manipulate the `INTERVAL` from within the Java code.

You must add `$FGLDIR/lib/fgl.jar` to the class path in order to compile Java code with `com.fourjs.fgl.lang.FglInterval` class.

The `com.fourjs.fgl.lang.FglInterval` class implements the following:
Table 425: Fields of the com.fourjs.fgl.lang.FglInterval class

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>final static int YEAR</td>
<td>Time qualifier for year</td>
</tr>
<tr>
<td>final static int MONTH</td>
<td>Time qualifier for month</td>
</tr>
<tr>
<td>final static int DAY</td>
<td>Time qualifier for day</td>
</tr>
<tr>
<td>final static int HOUR</td>
<td>Time qualifier for hour</td>
</tr>
<tr>
<td>final static int MINUTE</td>
<td>Time qualifier for minute</td>
</tr>
<tr>
<td>final static int SECOND</td>
<td>Time qualifier for second</td>
</tr>
<tr>
<td>final static int FRACTION</td>
<td>Time qualifier for fraction (start qualifier)</td>
</tr>
<tr>
<td>final static int FRACTION1</td>
<td>Time qualifier for fraction(1) (end qualifier)</td>
</tr>
<tr>
<td>final static int FRACTION2</td>
<td>Time qualifier for fraction(2) (end qualifier)</td>
</tr>
<tr>
<td>final static int FRACTION3</td>
<td>Time qualifier for fraction(3) (end qualifier)</td>
</tr>
<tr>
<td>final static int FRACTION4</td>
<td>Time qualifier for fraction(4) (end qualifier)</td>
</tr>
<tr>
<td>final static int FRACTION5</td>
<td>Time qualifier for fraction(5) (end qualifier)</td>
</tr>
</tbody>
</table>
Table 426: Methods of the `com.fourjs.fgl.lang.FglInterval` class

<table>
<thead>
<tr>
<th>Methods</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>static int encodeTypeQualifier(</code></td>
<td>Returns the encoded type qualifier for an interval with to interval qualifiers and length passed:</td>
</tr>
<tr>
<td><code>int startUnit,</code></td>
<td>encoded qualifier = ((length * 256) + (startUnit * 16) + endUnit)</td>
</tr>
<tr>
<td><code>int length,</code></td>
<td>Where (length) defines the total number of significant digits in this time data.</td>
</tr>
<tr>
<td><code>int endUnit)</code></td>
<td>For example, with INTERVAL DAY(5) TO FRACTION3:</td>
</tr>
<tr>
<td></td>
<td>(startUnit = \text{DAY})</td>
</tr>
<tr>
<td></td>
<td>(length = 13 (DDDDhhmmssfff))</td>
</tr>
<tr>
<td></td>
<td>(endUnit = \text{FRACTION3})</td>
</tr>
<tr>
<td><code>java.lang.String toString()</code></td>
<td>Converts the INTERVAL value to a <code>String</code> object representing an interval in default format.</td>
</tr>
<tr>
<td><code>static FglInterval valueOf(</code></td>
<td>Creates a new <code>FglInterval</code> object from a <code>String</code> object representing an interval value in the format:</td>
</tr>
<tr>
<td><code>java.lang.String val)</code></td>
<td>DD hh:mm:ss.fff</td>
</tr>
<tr>
<td><code>static FglInterval valueOf(</code></td>
<td>Creates a new <code>FglDateTime</code> object from a <code>String</code> object representing an interval value in standard format, using the qualifiers and precision passed as parameter.</td>
</tr>
<tr>
<td><code>java.lang.String val,</code></td>
<td></td>
</tr>
<tr>
<td><code>int startUnit,</code></td>
<td></td>
</tr>
<tr>
<td><code>int endUnit)</code></td>
<td></td>
</tr>
</tbody>
</table>

In the Java code, you can pass a `com.fourjs.fgl.lang.FglInterval` object as in this example:

```java
public static void useInterval(FglInterval inv) throws ParseException {
    String s = inv.toString();
    ...
}
```

If you need to create a `com.fourjs.fgl.lang.FglInterval` object in your program, you can use the `valueOf()` class method as in this example:

```java
IMPORT JAVA com.fourjs.fgl.lang.FglInterval
MAIN
    DEFINE inv com.fourjs.fgl.lang.FglInterval
    LET inv = FglInterval.valueOf("-510 12:33:45.123")
    DISPLAY inv.toString()
END MAIN
```

**Identifying Genero data types in Java code**

Java data types and Genero data types are different. To identify Genero types in Java code, you can use the `com.fourjs.fgl.lang.FglTypes` class implemented in `$FGLDIR/lib/fgl.jar`.

You can, for example, identify the data type of a member of an `FglRecord` object.

You must add `$FGLDIR/lib/fgl.jar` to the class path in order to compile Java code with `com.fourjs.fgl.lang.FglType` class.
The `com.fourjs.fgl.lang.FglTypes` class implements the following:
### Table 427: Fields of the com.fourjs.fgl.lang.FglTypes class

<table>
<thead>
<tr>
<th>Field</th>
<th>Corresponding data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>final static int ARRAY</td>
<td>ARRAY object</td>
</tr>
<tr>
<td>final static int BIGINT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>final static int BOOLEAN</td>
<td>BOOLEAN</td>
</tr>
<tr>
<td>final static int BYTE</td>
<td>BYTE</td>
</tr>
<tr>
<td>final static int CHAR</td>
<td>CHAR</td>
</tr>
<tr>
<td>final static int DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>final static int DATETIME</td>
<td>DATETIME</td>

</tr>
<tr>
<td>final static int RECORD</td>
<td>RECORD structure</td>
</tr>
<tr>
<td>final static int SMALLFLOAT</td>
<td>SMALLFLOAT</td>
</tr>
<tr>
<td>final static int SMALLINT</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>final static int STRING</td>
<td>STRING</td>
</tr>
<tr>
<td>final static int TEXT</td>
<td>TEXT</td>
</tr>
<tr>
<td>final static int TINYINT</td>
<td>TINYINT</td>
</tr>
</tbody>
</table>
Using Genero records

When passing a RECORD to a Java method, the runtime system converts the RECORD to an instance of the com.fourjs.fgl.lang.FglRecord class implemented in $FGLDIR/lib/fgl.jar.

The FglRecord object is a copy of the RECORD variable; structure and members of the FglRecord object can be read within the Java code, but cannot be modified.

You must add $FGLDIR/lib/fgl.jar to the class path in order to compile Java code with com.fourjs.fgl.lang.FglRecord class.

The com.fourjs.fgl.lang.FglRecord class implements the following methods:
Table 428: Methods of the com.fourjs.fgl.lang.FglRecord class

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void dispose()</td>
<td>Dereferences the underlaying member variables.</td>
</tr>
<tr>
<td>double getDouble(int p)</td>
<td>Returns the double value of the record member at position p.</td>
</tr>
<tr>
<td>FglByteBlob getFglByteBlob(int p)</td>
<td>Returns the FglByteBlob value of the record member at position p.</td>
</tr>
<tr>
<td>FglDate getFglDate(int p)</td>
<td>Returns the FglDate value of the record member at position p.</td>
</tr>
<tr>
<td>FglDateTime getFglDateTime(int p)</td>
<td>Returns the FglDateTime value of the record member at position p.</td>
</tr>
<tr>
<td>FglDecimal getFglDecimal(int p)</td>
<td>Returns the FglDecimal value of the record member at position p.</td>
</tr>
<tr>
<td>FglInterval getFglInterval(int p)</td>
<td>Returns the FglInterval value of the record member at position p.</td>
</tr>
<tr>
<td>FglTextBlob getFglTextBlob(int p)</td>
<td>Returns the FglTextBlob value of the record member at position p.</td>
</tr>
<tr>
<td>int getFieldCount()</td>
<td>Returns the number of record members.</td>
</tr>
<tr>
<td>java.lang.String getFieldName(int p)</td>
<td>Returns the name of the record member at position p.</td>
</tr>
<tr>
<td>int getInt(int p)</td>
<td>Returns the int value of the record member at position p.</td>
</tr>
<tr>
<td>java.lang.String getString(int p)</td>
<td>Returns the String representation of the value of the record member at position p.</td>
</tr>
<tr>
<td>FglTypes getType(int p)</td>
<td>Returns the FglTypes constant of the record member at position p.</td>
</tr>
<tr>
<td>java.lang.String getTypeName(int p)</td>
<td>Returns the string representation of the data type of the record member at position p.</td>
</tr>
<tr>
<td>int getTypeQualifier(int p)</td>
<td>Returns the encoded type qualifier of the record member at position p.</td>
</tr>
</tbody>
</table>

In the Java code, use the query methods of the com.fourjs.fgl.lang.FglRecord to identify the members of the RECORD:

```java
public static void showMemberTypes(FglRecord rec){
    int i;
    int n = rec.getFieldCount();
    for (i = 1; i <= n; i++)
        System.out.println( String.valueOf(i) + ":" +
            rec.getFieldName(i) + " / " + rec.getTypeName(i) );
```
When assigning a RECORD to a `com.fourjs.fgl.lang.FglRecord`, *widening conversion* applies implicitly. But when assigning a `com.fourjs.fgl.lang.FglRecord` to a RECORD, *narrowing conversion* applies and you must explicitly **CAST** the original object reference to the type of the RECORD. The following example shows how to return an FglRecord object from a Java method:

```java
-- PassRecord.4gl
IMPORT JAVA com.fourjs.fgl.lang.FglRecord
IMPORT JAVA UseRecord
MAIN
  TYPE type1 RECORD
    id INTEGER,
    name VARCHAR(50)
  END RECORD
  DEFINE rec1, rec2 type1
  LET rec1.id = 123
  LET rec1.name = "McFly"
  LET rec2 = CAST(UseRecord.getRecord(rec1) AS type1)
END MAIN

-- UseRecord.java
import com.fourjs.fgl.lang.FglRecord;
public class UseRecord{
  public static FglRecord getRecord(FglRecord rec){
    ...
    return rec;
  }
}
```

**Formatting data in Java code**

To format numeric and date-time data in Java code, use the `com.fourjs.fgl.lang.FglFormat` class implemented in FGLDIR/lib/fgl.jar.

You must add FGLDIR/lib/fgl.jar to the class path in order to compile Java code with `com.fourjs.fgl.lang.FglFormat` class.

The `com.fourjs.fgl.lang.FglFormat` class provides an interface to the data formatting functions of the runtime system. This class is actually an equivalent of the **USING** operator in the language.

The `com.fourjs.fgl.lang.FglFormat` class implements the following:
Table 429: Methods of the com.fourjs.fgl.lang.FglFormat class

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>static String format( int v, String fmt)</td>
<td>Formats the integer value provided as Java int based on fmt. Here fmt must specify a numeric format with [@$*#&amp;&lt;()+-] characters, same as in the USING operator.</td>
</tr>
<tr>
<td>static String format( double v, String fmt)</td>
<td>Formats the FLOAT value provided as Java double based on fmt. Here fmt must specify a numeric format with [ $ @*#&lt;&gt;()+- ,] characters, same as in the USING operator.</td>
</tr>
<tr>
<td>static String format( FglDate v, String fmt)</td>
<td>Formats the DATE value provided as FglDate based on fmt. Here fmt must specify a date format with [mdy] characters, same as in the USING operator.</td>
</tr>
<tr>
<td>static String format( FglDecimal v, String fmt)</td>
<td>Formats the DECIMAL value provided as FglDecimal, by using fmt. Here fmt must specify a numeric format with [ $ @# $&lt;()+- ,] characters, same as in the USING operator.</td>
</tr>
</tbody>
</table>

Example of Java code using the com.fourjs.fgl.lang.FglFormat class:

```java
public static void formatDecimal(FglDecimal dec){
    System.out.println( FglFormat.format(dec,"$#####&.&&" );
}
```

Character set mapping

Application programs use a given locale and character set, while Java uses its own charset internally for the char Java type (16-bit UNICODE).

When passing character strings to/from Java methods or when assigning program strings to java.lang.String, the runtime system handles character set conversion.

Using Java arrays

Java arrays and Genero arrays are different. In order to interface with Java arrays, the Genero language has been extended with a new kind of arrays, called "Java arrays".

Java arrays have to be created with a given length. Like native Java arrays, the length cannot be changed after the array is created.

To create a Java array in Genero, you must define a TYPE in order to call the create() type method of Java arrays. The type of the elements in a Java array must be one of the language types that have a corresponding primitive type in Java (such as INTEGER (int), FLOAT (double)), or it must be a Java class such as java.lang.String.

The Java arrays are passed to Java methods by reference, so the elements of the array can be manipulated in Java. Furthermore, Java arrays can be created in Java code and returned to the Genero program.

This example shows how to create a Java array in Genero, to instantiate a Java Array of INTEGER elements:

```genero
MAIN
    TYPE int_array_type ARRAY[] OF INTEGER
    DEFINE ja int_array_type
    LET ja = int_array_type.create(100)
    LET ja[10] = 123
    DISPLAY ja[10], ja[20]
    DISPLAY ja.getLength()
```
This example shows a program creating a Java array of Java strings:

```
IMPORT JAVA java.lang.String
MAIN
    TYPE string_array_type ARRAY[] OF java.lang.String
    DEFINE names string_array_type
    LET names = string_array_type.create(100)
    LET names[1] = "aaaaaaa"
    DISPLAY names[1]
END MAIN
```

To create a Java array of structured `RECORD` elements, use the `com.fourjs.fgl.lang.FglRecord` class:

```
IMPORT JAVA com.fourjs.fgl.lang.FglRecord
MAIN
    TYPE record_array_type ARRAY[] OF com.fourjs.fgl.lang.FglRecord
    DEFINE ra record_array_type
    TYPE r_t RECORD
        id INTEGER,
        name VARCHAR(100)
    END RECORD
    DEFINE r r_t
    LET ra = record_array_type.create(100)
    LET r.id = 123
    LET r.name = "McFly"
    LET ra[10] = r
    INITIALIZE r TO NULL
    LET r = CAST (ra[10] AS r_t)
    DISPLAY r.*
END MAIN
```

Java arrays of Java classes can be defined. This example introspects the `java.lang.String` class by using Java array of `java.lang.reflect.Method` to query the list of methods from the `java.lang.String` class:

```
IMPORT JAVA java.lang.Class
IMPORT JAVA java.lang.reflect.Method
MAIN
    DEFINE c java.lang.Class
    DEFINE ma ARRAY[] OF java.lang.reflect.Method
    DEFINE i INTEGER
    LET c = Class.forName("java.lang.String")
    LET ma = c.getMethods()
    FOR i = 1 TO ma.getLength()
        DISPLAY ma[i].toString()
    END FOR
END MAIN
```

Java arrays can be created in the Java code, to be returned from a method and assigned to a program variable:

```
public static int [] createIntegerArray(int size) {
    return new int[size];
}
```
Passing variable arguments (varargs)

Java supports variable arguments in method definitions with the ellipsis notation, allowing callers to pass a different number of arguments depending on the need. A typical example is a message print method:

```java
import java.lang.String;

public class MyClass {
    public static void ShowStrings( String... sl ) {
        for ( String s : sl )
            System.out.println(s);
    }
}
```

In order to call such a method from the Genero program, create a Java array of the type of the variable argument, fill the array with objects and call the method with that array:

```java
IMPORT JAVA java.lang.String
IMPORT JAVA MyClass
MAIN
    TYPE sl_t ARRAY[] OF java.lang.String
    DEFINE sl ARRAY[] OF java.lang.String
    LET sl = sl_t.create(2)
    LET sl[1] = "Value 1"
    LET sl[2] = "Value 2"
    CALL MyClass.ShowStrings(sl)
END MAIN
```

Since Java arrays have a static size, you must create the Java array with the exact number of variable arguments to be passed to the method.

If the Java class cannot be modified, consider implementing a function to wrap calls to the Java method, with a varying number of arguments. It can for example take a BDL dynamic array as parameter, to simplify the callers code:

```java
IMPORT JAVA java.lang.String
IMPORT JAVA MyClass
MAIN
    DEFINE a DYNAMIC ARRAY OF STRING
    LET a[1] = "Value 1"
    LET a[2] = "Value 2"
    LET a[3] = "Value 3"
    CALL my_show_strings(a)
    LET a[4] = "Value 1"
    LET a[5] = "Value 2"
    CALL my_show_strings(a)
END MAIN

FUNCTION my_show_strings(sa)
    TYPE sl_t ARRAY[] OF java.lang.String
    DEFINE sa DYNAMIC ARRAY OF STRING
    DEFINE sl ARRAY[] OF java.lang.String
    DEFINE i INTEGER
    LET sl = sl_t.create(sa.getLength())
    FOR i=1 TO sa.getLength()
        LET sl[i] = sa[i]
    END FOR
    CALL MyClass.ShowStrings(sl)
END FUNCTION
```
If the Java class can be modified, a good practice is to write overloaded methods, using a static number of arguments:

```java
public class MyClass {
    private static void _ShowStrings(String... sl) {
        for (String s : sl)
            System.out.println(s);
    }
    public static void ShowStrings(String s1) {
        _ShowStrings(s1);
    }
    public static void ShowStrings(String s1, String s2) {
        _ShowStrings(s1, s2);
    }
    public static void ShowStrings(String s1, String s2, String s3) {
        _ShowStrings(s1, s2, s3);
    }
}
```

#### The CAST operator

Important consideration has to be taken when assigning object references to different target types or classes. A **Widening Reference Conversion** occurs when an object reference is converted to a superclass that can accommodate any possible reference of the original type or class. A **Narrowing Reference Conversion** occurs when an object reference of a superclass is converted to a subtype or subclass of the original object reference. For example, in a vehicle class hierarchy with `Vehicle` and `Car` classes, `Car` is a subclass that inherits from the `Vehicle` superclass. When assigning a `Car` object reference to a `Vehicle` variable, Widening Reference Conversion takes place. When assigning a `Vehicle` object reference to a `Car` variable, Narrowing Reference Conversion occurs.

While widening conversion does not require casts and will not produce compilation or runtime errors, narrowing conversion needs the **CAST operator** to convert to the target type or class:

```
CAST(object_reference AS type_or_class)
```

The next example creates a `java.lang.StringBuffer` object, and assigns the reference to a `java.lang.Object` variable (implying Widening Reference Conversion); then the object reference is assigned back to the `java.lang.StringBuffer` variable (implying Narrowing Reference Conversion and CAST operator usage):

```java
IMPORT JAVA java.lang.Object
IMPORT JAVA java.lang.StringBuffer
MAIN
    DEFINE o java.lang.Object
    DEFINE sb java.lang.StringBuffer
    LET sb = StringBuffer.create()
        -- Widening Reference Conversion
    LET o = sb
        -- Narrowing Reference Conversion needs CAST()
    LET sb = CAST( o AS StringBuffer )
END MAIN
```

#### The INSTANCEOF operator

When manipulating an object reference with a variable defined with a superclass of the real class used to instantiate the object, you sometimes need to identify the real class of the object.

This is possible with the **INSTANCEOF operator**.
This operator checks whether the left operand is an instance of the type or class specified by the right operand:

```
object_reference INSTANCEOF type_or_class
```

This example creates a `java.lang.StringBuffer` object, assigns the reference to a `java.lang.Object` variable, and tests whether the class type of the object reference is a `java.lang.StringBuffer`:

```
IMPORT JAVA java.lang.Object
IMPORT JAVA java.lang.StringBuffer
MAIN
  DEFINE o java.lang.Object
  LET o = StringBuffer.create()
  DISPLAY o INSTANCEOF StringBuffer -- Shows 1 (TRUE)
END MAIN
```

**Java exception handling**

In order to catch Java exceptions within programs, use a **TRY/CATCH** block.

When a Java exception occurs, the runtime system sets the `STATUS` variable to the error code `-8306`. The Java exception details (i.e. the name of the exception) can be found with the `ERR_GET(STATUS)` built-in function.

**Important:** To get the Java exception type with `ERR_GET()`, do not execute other instructions before querying for the error message, otherwise the `STATUS` variable may be reset to zero and the Java exception details would be lost.

To easily identify the type of the Java exceptions in your code, consider writing a library function based on `ERR_GET()`, that recognizes most common Java exceptions, and converts them to integer codes:

```
IMPORT JAVA java.lang.StringBuffer
MAIN
  DEFINE sb java.lang.StringBuffer
  LET sb = StringBuffer.create("abcdef")
  TRY
    CALL sb.deleteCharAt(50) -- out of bounds!
  CATCH
    DISPLAY err_get(STATUS)
    EXIT PROGRAM 1
  END TRY
END MAIN
```

**Note:** As a general pattern, do not use **TRY/CATCH** or **WHENEVER ERROR CONTINUE** exception handlers if no exception is supposed to occur. By default the program will then stop and display the Java exception details.

**Executing Java code with GMA**

On Android™ devices, Genero apps can use the Java interface.

**Note:** The GMA executes a program in a JVM process and therefore does not require more resources to execute Java code.

We distinguish the following use cases where the Java interface of Genero can be used in GMA:

- Use classes from the [standard Java or Android Java library](#).
- Implement and use [user-defined Java classes](#), requiring GMA packaging.
- Implement and execute a [user-defined Android activity](#), requiring GMA packaging.

Java may also be used to extend the GMA front-end with user-defined front calls. For details, see [Implement front call modules for GMA](#) on page 2134.
Standard Java and Android™ library usage
You can use Java classes that are part of the standard Java library and Android Java library.

Using standard Java within the GMA
Java classes provided in the standard Java library and in the Android Java library can be used directly by including the IMPORT JAVA classname keywords in the Genero code:

```genero
IMPORT JAVA java.lang.Runtime
IMPORT JAVA android.os.Build
MAIN
  DEFINE rtm Runtime, msg STRING
  LET rtm = java.lang.Runtime.getRuntime()
  LET msg = SFMT("Device:[%1] %2 - %3 (%4 procs)",
                  android.os.Build.MANUFACTURER,
                  android.os.Build.MODEL,
                  android.os.Build.SERIAL,
                  rtm.availableProcessors() )
  MENU "Test" ATTRIBUTES(STYLE="dialog", COMMENT=msg)
    ON ACTION ok
      EXIT MENU
    END ACTION
  END MENU
END MAIN
```

The Android Java library does not include all the classes of a regular JRE. User interface classes are specific to the Android user interface framework. The list of standard Android Java packages can be found at [http://developer.android.com/reference/packages.html](http://developer.android.com/reference/packages.html).

Only non-interactive classes can be used in this context. To get a graphical user interface, you must implement an Android Activity, as described in Implement Android activities in GMA on page 2101.

Because Android apps are Java-based, the JVM and standard Java library is directly available. There is no need to bundle the Java library with your Genero program files when you deploy your app as .apk package.

When executing the Genero program on a computer in development mode, it is not possible to use classes that are specific to the Android Java library, because the Android Java library is not available in development mode at runtime.

You must compile your app code and deploy it on an Android device for execution. To compile your app code on the development platform, you need to setup the Java SDK environment and the CLASSPATH to the Android SDK library (android.jar).

**Note:** For compilation, JDK_HOME can point to a 32-bit or 64-bit Java Development Kit installation, to match the Genero BDL architecture. However, the Android SDK is only available in 32-bit.

JVM context-dependent Android API calls
On an Android device, the GMA executes a Genero program in a JVM process. Some Android system APIs cannot be directly called from the Genero runtime system context; they must be called from the JVM context.

In order to call such APIs, you must import the `com.fourjs.gma.vm.FglRun` class and get the Android JVM thread context by calling the `getContext()` method of the `FglRun` class.

The `getContext()` method will return an instance of the `android.content.Context` class. For more details, see [http://developer.android.com/reference/android/content/Context.html](http://developer.android.com/reference/android/content/Context.html)

**Note:** To use this Android JVM interface, you must add the `android.jar` library (from the Android SDK) to the class path.
The `com.fourjs.gma.vm.FglRun` class implements the following methods:

Table 430: Methods of the `com.fourjs.gma.vm.FglRun` class

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getContext()</code></td>
<td>Returns the Android JVM context object of the runtime system.</td>
</tr>
</tbody>
</table>

In the program code, use the `getContext()` method to get the JVM context and call specific Android APIs:

```java
IMPORT JAVA android.app.Service
IMPORT JAVA android.content.Context
IMPORT JAVA android.util.DisplayMetrics
IMPORT JAVA android.view.WindowManager
IMPORT JAVA com.fourjs.gma.vm.FglRun

MAIN
    DEFINE w, h, d INT
    MENU "Java"
        ON ACTION test
            CALL android_screen_metrics() RETURNING w, h, d
            MESSAGE "Width: ", w, "\nHeight: ", h, "\nDensity: ", d
        END ACTION
    END MENU
END MAIN

FUNCTION android_screen_metrics()
    DEFINE ctx android.content.Context, dm android.util.DisplayMetrics, wm android.view.WindowManager
    LET ctx = com.fourjs.gma.vm.FglRun.getContext()
    LET dm = android.util.DisplayMetrics.create()
    LET wm = CAST ( ctx.getSystemService("window") AS android.view.WindowManager )
    CALL wm.getDefaultDisplay().getMetrics(dm)
    RETURN dm.widthPixels,
        dm.heightPixels,
        dm.densityDpi
END FUNCTION
```

**Using front calls instead of pure Java**

For maximum portability, consider implementing Android-specific extensions as custom front calls. When using the front call technology, apps can be executed in development (app running on the server) and in deployed mode (app running on the mobile device) with the same Genero code.

For more details about custom front calls with GMA, see Implement front call modules for GMA on page 2134.

**Implement Java user extensions in GMA**

A GMA app can execute custom Java code.

In order to execute Java user code on the mobile device, the compiled Java classes need to be available to the Genero runtime system. They can then be imported with the `IMPORT JAVA classname` instruction.

When executing the Genero program on a computer in development mode, define the CLASSPATH to your .jar files. This allows the JVM loaded by the Genero runtime system find the appropriate Java classes.

When executing the Genero program on a mobile device, the compiled user Java classes must be included in the mobile app Android™ package (.apk), which is created in the Genero Studio deployment procedure.
Related concepts
Packaging custom Java extensions for GMA on page 2102
Custom Java extension must be integrated in the GMA to run on Android™ devices.

Implement Android™ activities in GMA
Android™ activities can be bundled with your GMA app and called from the Genero code.

A Java-based extension that interacts with the end user must be implemented as an Android™ Activity, by using the android.app.Android class.

In order to use your Android™ Activity from the program, it must be integrated in the mobile app Android™ package (.apk), which is created in the Genero Studio deployment procedure.

This code example implements a simple Android™ Activity:

```java
package com.myextension;
import android.app.Activity;
import android.os.Bundle;
import android.widget.TextView;

public class MyActivity extends Activity {
    @Override
    protected void onCreate(Bundle savedInstanceState) {
        super.onCreate(savedInstanceState);
        Button button = new Button(this);
        button.setText("Quit");
        setContentView(button);
        button.setOnClickListener(
            new View.OnClickListener() {
                public void onClick(View v) {
                    int resultCode = RESULT_OK;
                    Intent resultData = new Intent();
                    resultData.putExtra("MyKey", "MyValue");
                    setResult(resultCode, resultData);
                    finish();
                }
            }
        );
    }
}
```

In order to execute this activity from a Genero app, use the `startActivity` front call:

```genero
MAIN
    DEFINE data, extras STRING
    MENU
        ON ACTION activity ATTRIBUTES(TEXT="Call bundled activity")
            CALL ui.Interface.frontCall("android", "startActivityForResult",
                ["android.intent.action.VIEW", NULL, NULL, NULL,
                    "com.myextension.MyActivity"],
                [ data, extras ])
            MESSAGE "data=",data," / extras=",extras
        ON ACTION quit
            EXIT MENU
    END MENU
END MAIN
```

Note: The component name (fifth parameter) of the `startActivity` front call does normally take the APK package name followed by the Java Activity class name (`apk-package-name/java-class-name`). The APK Android™ package name can be defined for the application project in the Genero Studio. When using an user-defined activity that is part of the GMA binary archive, do not specify the APK package in the component parameter, because the Java Activity class will be included in the current APK package. This is true when using the customized GMA
front-end in development mode, and in the final application that is deployed on the device. For more details about the component parameter, see `startActivity (Android)` on page 2564.

Related concepts
Packaging custom Java extensions for GMA on page 2102
Custom Java extension must be integrated in the GMA to run on Android™ devices.

Packaging custom Java extensions for GMA
Custom Java extension must be integrated in the GMA to run on Android™ devices.

Genero Mobile apps for Android are created from Genero Studio, or from the command-line with `gmabuildtool` on page 1989: You need to provide the custom GMA binary archive containing your Java extensions to Genero Studio or to `gmabuildtool`.

- Genero Studio finds the GMA binary archive from the `GMADIR` variable defined in the configuration settings.
- The `gmabuildtool` requires the Android Studio project directory used to build the custom GMA to be specified with the `--build-project` option.

Note: For Genero Mobile 1.30, the minimum version of the JDK installation required is 1.8.

Along with the GMA binary archive, you must provide the `.jar` files of your Java extensions, that will be used to compile Genero application code on the development machine, as well as the `.apk` Android™ packages of GMA, to deploy the front-end part on the device for client/server development (typically with user-defined front calls).

The original GMA binary archive is a zip file containing several `.aar` Android™ libraries. A customized GMA binary archive contains the `.aar` files from the GMA core libraries, the Genero runtime system core libraries, and custom `.aar` files build from your own Java libraries. The custom `.aar` libs are created from Android Studio. The minimum Android Studio version is 0.8.9.

To create a new GMA binary archive, the `extension.jar` file, and the `.apk` packages, including your Java extensions, perform the steps described in `Custom GMA binary archive build` on page 2102.

After completing these steps:
- When compiling application code, Genero Studio can find your `.jar` libraries to resolve Java symbols.
- When deploying the front-end only for client/server development, Genero Studio will find the `.apk` packages to be installed on the device.
- When building an Android™ app in Genero Studio, it will be created from the custom GMA binary archive that includes your Java extensions.
- When building an Android™ app with `gmabuildtool`, it can be created by specifying the custom GMA Android™ project directory with the `--build-project` option.

Related concepts

A GMA app can execute custom Java code.

Custom GMA binary archive build
If you are planning to build Genero Mobile for Android™ extensions for your GMA project, you need to do this using Android™ Studio. Follow this procedure to extend GMA.

Note: When using GMA user extensions, you need to build the Java binaries for the final custom GMA `.apk`, as well as the `user-extension.jar` library, to compile Genero sources using IMPORT JAVA `user-extension`. For a complete overview, see Packaging custom Java extensions for GMA on page 2102.

Important: Android™ Studio must be installed, and minimum Android™ development skills are required to perform this task.

1. Locate the original GMA binary archive on your computer. If using Genero Studio, it is found in the `GMADIR/gma/artifacts` directory. The `GMADIR` variable is set in the Genero Studio configuration settings. If you are not using Genero Studio, the GMA binary archive is provided as a separate package.
The GMA binary archive consists of a file named fjs-gma-<version>-<build>-android-scaffolding.zip. Version 1.30.00 or later is required.

This file contains the original GMA core binary and the sub-project to build custom extensions.

2. Create a project directory, for example extension-example/gma, to where you extract the GMA scaffolding archive.

3. Unzip the fjs-gma-<version>-<build>-android-scaffolding.zip archive into extension-example/gma/project.

4. In Android™ Studio, open the project from extension-example/gma/project.
   
   **Note:** In the Android™ Studio Project view, under the extension library, you can find the TestExtensionActivity.java source file: This is a sample activity to test the extension bundled in the scaffold project. This class is provided for testing purpose and sample. Rename it and change the code for your own purpose, or replace it by your own extension source.

5. Define the extension module package name in the Android™ manifest file.
   
   In the Android™ Studio Project view, under the extension directory, open the AndroidManifest.xml file. Modify the value of the package attribute of the manifest node:

   ```xml
   <manifest xmlns:android="http://schemas.android.com/apk/res/android"
     package="com.gma.extension">
   </manifest>
   
   **Note:** The package name must be a Java-language-style package name, for example, in the format of "com.gma.extension". The package name identifies your extension library, it is not the name used to build a final app in Genero Studio.

6. Add your Java sources to this Android™ Studio project, under the extension library.

7. If required, add external .jar libraries to the project: Copy the additional jar libraries into extension-example/gma/project/extension/libs: These jar libraries will be included when building the project.

8. In Android™ Studio, build the project in release or debug mode.
   
   This creates the custom extensions binaries to build the final .apk and the extension.jar file in extension-example/gma/project/extension/build/libs. The extension.jar file contains Java classes that are callable from Genero BDL. The extension.jar file is required to compile Genero source code using IMPORT JAVA extension.

   **Note:** The project build in Android™ Studio will also create the customized GMA .apk. However, this step is done explicitly later, either from Genero Studio, or by using the gmabuildtool command.

9. Build your custom GMA .apk with your custom extensions.

   If using Genero Studio, perform the following steps:
   a) Modify the CLASSPATH environment variable to include the extension.jar file.
      
      This is required to let the Genero compiler find your Java classes.
   b) Modify the GMADIR configuration variable to point to the extension-example/gma/project directory.
      
      This is required to let Genero Studio use your customized GMA binary to build apps. For more information, see the Configuration for extending Genero Mobile for Android topic in the Genero Studio User Guide.

   If using gmabuildtool to build apps from the command line:
   • Change directory to extension-example and call the gmabuildtool to build and bundle your final .apk file with the required options provided by the tool: gmabuildtool will use by default find GMA binary files and resources in the current working directory. For more details about gmabuildtool usage, see Building Android apps with Genero on page 3317.

10. Deploy the new GMA Android™ application package (.apk) on the device.
   • When using Genero Studio, the apk packages to be installed on the device are referenced from the GMADIR environment variable.
• If not using Genero Studio, you can use the Android™ debug bridge (adb) command-line utility included with Android™ SDK to install the package to your device.

Examples
Java interface usage examples.

Example 1: Using the regex package

```java
IMPORT JAVA java.util.regex.Pattern
IMPORT JAVA java.util.regex.Matcher
MAIN
  DEFINE p Pattern
  DEFINE m Matcher
  LET p = Pattern.compile("[a-z]+,[a-z]+")
  DISPLAY p.pattern()
  LET m = p.matcher("aaa,bbb")
  IF m.matches() THEN
    DISPLAY "The string matches the pattern..."
  ELSE
    DISPLAY "The string does not match the pattern..."
  END IF
END MAIN
```

Example 2: Using the Apache POI framework
This example shows how to create a XLS file, using the Apache POI framework.

Note: This demo requires Apache POI version 4.0.0 or higher.

Download and install the Apache POI package, set CLASSPATH environment variable to point to the POI JAR archives.

After execution, a file named "itemlist.xls" is found in the current directory.

```java
-- Needs Apache POI 4.0.0 +
IMPORT JAVA java.io.FileOutputStream
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFWorkbook
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFSheet
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFRow
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFCell
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFCellStyle
IMPORT JAVA org.apache.poi.hssf.usermodel.HSSFFont
IMPORT JAVA org.apache.poi.ss.usermodel.IndexedColors
IMPORT JAVA org.apache.poi.ss.usermodel.HorizontalAlignment
IMPORT JAVA org.apache.poi.ss.usermodel.FillPatternType
IMPORT JAVA org.apache.poi.ss.usermodel.CellType

MAIN
  DEFINE fo FileOutputStream
  DEFINE workbook HSSFWorkbook
  DEFINE sheet HSSFSheet
  DEFINE row HSSFRow
  DEFINE cell HSSFCell
  DEFINE style HSSFCellStyle
  DEFINE headerFont HSSFFont
  DEFINE i, id INTEGER, s STRING

  LET workbook = HSSFWorkbook.create()

  LET style = workbook.createCellStyle()
  CALL style.setAlignment(HorizontalAlignment.CENTER)
  CALL style.setFillForegroundColor(
```
Example 3: Using Java on Android™

This example shows how to access Android™ components through Java, it includes:

- Access to the JDK API to get the number of cores on your device.
- Access to Android™ APIs to get the screen dimension, the device manufacturer and model (with no need for any additional authorization)
- Access to the Bluetooth stack to list the paired devices.

**Note:** In your GM project, you need to ask for BLUETOOTH authorization.

C-Extensions

With C-Extensions, you can bind your own C libraries in the runtime system, to call C function from the application code.

- Understanding C-Extensions on page 2109
- Header files for ESQL/C typedefs on page 2110
- Creating C-Extensions on page 2110

- Calling program functions from C on page 2124
- Sharing global variables on page 2125
- Simple C-Extension example on page 2126
- Implementing C-Extensions for GMI on page 2127

Understanding C-Extensions

C-Extensions allow you to write custom shared libraries in the C language.

Using C-Extensions, C functions implemented in shared libraries can be called from the Genero application code. This feature allows you to extend the language with custom libraries, or existing standard libraries, by writing some ‘wrapper functions’ to interface with the Genero language.

On regular platforms, C-Extensions are implemented with shared libraries, that are loaded by the fglrun program on demand.

Note: Platforms such as iOS mobile devices do not allow you to load shared libraries. In this case, you must re-link the virtual machine. For more details, see Implementing C-Extensions for GMI on page 2127.

Function parameters and returned values are passed/returned on the runtime stack, using pop/push functions. Be sure to pop and push the exact number of parameters/returns expected by the caller; otherwise, a fatal stack error will be raised at runtime.

In order to use a C-Extension in your program, you typically specify the library name with the IMPORT instruction at the beginning of the module calling the C-Extension functions. The compiler can then check for the existence of the functions and the library will be automatically loaded at runtime.

Note:
- The C code written in C-Extensions is usually platform specific, which does not ease the migration of your application to a different operating system, especially when doing a lot of system calls. Additionally, C data types are defined differently depending on the processor architecture (32 / 64 bits issues). This can also be an issue.
- Make sure that the functions defined in your C-Extensions do not conflict with program functions. In case of conflict, you will get a compiler or a runtime error, depending on the loading technique used.

Related concepts
IMPORT C-Extension on page 496
The IMPORT instruction imports C extension module elements to be used by the current module.

**Header files for ESQL/C typedefs**

C header files (.h) are required to define C structures for complex data types used in a C-Extension.

To compile C-Extensions using data types such as DECIMAL, DATETIME/INTERVAL or BYTE/TEXT, you need IBM® Informix® ESQL/C data type structure definitions such as dec_t, dtime_t, intrvl_t, as well as macros such as TU_ENCODE().

These definitions are not required, if you use standard C types such as short, int or char[].

The definition of the ESQL/C structures like dec_t are provided in individual header files, under the FGLDIR/include/f2c directory: fglDecimal.h, fglDatetime.h, fglLocator.h.

In order to include these data type header files, simply include the fglExt.h header file:

```
#include "f2c/fglExt.h"
```

The other header files are then included automatically.

**Related concepts**

Data types and structures on page 2118

C types are used to write C-Extensions.

**Creating C-Extensions**

Custom C-Extensions must be provided to the runtime system as Shared Objects (.so) on UNIX™, and as Dynamically Loadable Libraries (.DLL) on Windows®.

In order to create a C-Extension, you must:

1. Define the list of user functions in the C interface file, by including the fglExt.h header file.
2. Compile the C interface file with your C compiler.
3. Modify your C source modules by including the fglExt.h header file.
4. Compile the C interface file and the C modules with the position-independent code option.
5. Create the shared library with the compiled C interface file and C modules by linking with the libfgl runtime system library.

Include the fglExt.h header file in the following way:

```
#include "f2c/fglExt.h"
```

When migrating from IBM® Informix® 4GL, it is possible that existing C-Extension sources include Informix® specific headers like sqlhdr.h or decimal.h. You can either remove or keep the original includes, but if you want to keep them, the Informix® specific header files must be included before the fglExt.h header file, in order to let fglExt.h detect that typedefs such as dec_t or dtime_t are already defined by Informix® headers. If you include Informix® headers after fglExt.h, you will get a compilation error.

**Note:** Since fglExt.h defines all Informix-like typedef structures, you can remove the inclusion of Informix® specific header files.

The C functions that are implemented in the C-Extension libraries must be known by the runtime system. To do so, each C-Extension library must publish its functions in a UsrFunction array, which is read by the runtime system when the module is loaded. The UsrFunction array describes the user functions by specifying the name of the function, the C function pointer, the number of parameters and the number of returned values. You typically define the UsrFunction array in the C interface file.

After compiling the C sources, you must link them together with the libfgl runtime system library.

Carefully read the man page of the ld dynamic loader, and any documentation of your operating system related to shared libraries. Some platforms require specific configuration and command line options when linking a shared library, or when linking a program using a shared library (+s option on HP for example).
Extending the language

Linux® command-line example:
```bash
gcc -c -I $FGLDIR/include -fPIC myext.c
gcc -shared -o myext.so myext.o cinterf.o -L$FGLDIR/lib -lfgl
```

Windows™ command-line example using Visual C 8.0 and higher (with SxS manifest for the DLL!):
```bash
c1 /DBUILDDLL /I%FGLDIR%/include /c myext.c
c1 /DBUILDDLL /I%FGLDIR%/include /c cintref.c
link /dll /manifest /out:myext.dll myext.obj cintref.obj %FGLDIR%/lib\libfgl.lib
mt -manifest myext.dll.manifest -outputresource:myext.dll
```

If you build your DLL with a version of Microsoft™ Visual C++ that is different from the version used to build FGLRUN.EXE, the DLL must get private dependencies other than the process default. For example, when the C-Extension DLL needs the Visual C 9.0 runtime library MSVCR90.DLL, while the FGLRUN.EXE was build with VC 10 and needs MSVCR100.DLL. Private dependencies is specified with the resource id ISOLATIONAWARE_MANIFEST_RESOURCE_ID, by adding the ;2 modifier at the end of the -outputresource option, after the filename:
```bash
mt -manifest myext.dll.manifest -outputresource:myext.dll;2
```

To simplify compilation and linking of a C-Extension library, it is also possible to use the fglmkext command line tool:
```bash
fglmkext -o myext.so module_a.c module_b.c
```

Note: The fglmkext command line tool contains platform-specific C compiler and linker options required to build a C Extension library.

fglmkext on page 1976
The fglmkext tool compiles and links a user C Extension.
Header files for ESQL/C typedefs on page 2110
C header files (.h) are required to define C structures for complex data types used in a C-Extension.

Creating Informix® ESQL/C Extensions

C-Extension libraries can be created from ESQL/C sources, as long as you have an Informix® ESQL/C compiler which is compatible with your Genero runtime system.

In order to create a C-Extension from ESQL/C sources, you must:

1. Define the list of user functions in the C interface file, by including the fglExt.h header file.
2. Compile the C interface file with your C compiler.
3. Modify your ESQL/C source modules by including the fglExt.h header file.
4. Compile the ESQL/C modules with the esql compiler, with the position-independent code option.
5. Create the shared library with the compiled C interface file and ESQL/C modules by linking with the libfgl runtime system library, and with the ESQL/C libraries (esql -libs), to resolve the ESQL/C symbols.

Include the fglExt.h header file in the following way:
```c
#include "f2c/fglExt.h"
```

You can compile .ec extensions with the native Informix® esql compiler. This section describes how to use the Informix® esql compiler.

The following example shows how to compile and link an extension library with Informix® esql compiler:
Extending the language

Linux® command-line example:
```
esql -c -I$FGLDIR/include myext.ec
gcc -c -I$FGLDIR/include -fPIC cinterf.c
gcc -shared -o myext.so myext.o cinterf.o -L$FGLDIR/lib -lfgl \
   -L$INFORMIXDIR/lib -L$INFORMIXDIR/lib/esql `esql -libs`
```

Windows® command-line example (using Microsoft™ Visual C++):
```
esql -c myext.ec -I%FGLDIR%/include
cl /DBUILDDLL /I%FGLDIR%/include /c cintref.c
esql -target:dll -o myext.dll myext.obj cinterf.obj %FGLDIR%/lib\libfgl.lib
```

When using Informix® esql, you link the extension library with Informix® client libraries. These libraries will be shared by the extension module and the Informix® database driver loaded by the Genero runtime system. Since both the extension functions and the runtime database driver use the same functions to execute SQL queries, you can share the current SQL connection opened in the Genero program to execute SQL queries in the extension functions. However, mixing connection management instructions (DATABASE, CONNECT TO) as well as database creation can produce unexpected results. For example you cannot do a CREATE DATABASE in your ESQL/C extension, and expect that the main program can use this database to execute SQL statements.

The C interface file

To make your C functions visible to the runtime system, you must define all the functions in the C interface file.

The C interface file is a C source file that defines the usrFunctions array. This array defines C functions that can be called from programs.

The last record of the usrFunctions array must be a line with all the elements set to NULL/0, to define the end of the list.

Each element of the usrFunctions array must include the following members:

1. The first member is the name of the function, provided as a (const char *) character string.
2. The second member is the C function symbol, provided as an (int (*function) (int)) C function pointer.
3. The third member is the number of parameters passed to the function through the runtime stack, provided as an (int); use a negative value like -1 to specify a variable number of arguments.
4. The fourth member is the number of values returned by the function, provided as an (int); use a negative value like -1 to specify a variable number of return values.

Note: The third and fourth member of a UsrFunction element can be defined as a negative value (-1), to indicate a variable number of arguments and/or return values.

You typically do a forward declaration of your C functions, before the usrFunctions array initializer:
```
#include "f2c/fglExt.h"

int c_init(int);
int c_set_trace(int);
int c_get_message(int);
int c_compare(int);
int c_generate(int);

UsrFunction usrFunctions[]={
    { "init",         c_init,         0, 0 },
    { "set_trace",    c_set_trace,    1, 0 },
    { "get_message",  c_get_message,  1, 1 },
    { "compare",      c_compare,     -1, 1 }, /* var. numb. params */
    { "generate",     c_generate,     1,-1 }, /* var. numb. returns */
    { NULL,           NULL,           0, 0 }
};
```
Note that the `UsrFunction` structure contains an additional member, dedicated for internal use. If you experience compiler warnings because of uninitialized structure members, simply complete the C function definitions with a fifth zero value:

```c
/* Avoids C compiler warnings because of un-initialized structure members */
UsrFunction usrFunctions[]={
    { "init",     c_init,         0, 0, 0 },
    /* member for internal use ---^ */
...
```

### Linking programs using C-Extensions

When creating a 42r program or 42x library, the linker needs to resolve all function names, including C-Extension functions.

If extension modules are not specified explicitly in the source files with the `IMPORT` directive, you must give the extension modules with the `-e` option in the command line:

```bash
fgllink -e myext1,myext2,myext3 -o myprog.42r moduleA.42m moduleB.42m ...
```

The `-e` option of `fgllink` does not write C-Extension references into the `.42r` file. If you use the `-e` argument with the `fgllink` command, you must also use the `-e` argument with the `fglrn` command, in order to load the libraries at runtime.

The `-e` option is not needed when using the default `userextension` module, or if C-Extensions are specified with the `IMPORT` directive.

**Related concepts**

* `fgllink` on page 1975

  The `fgllink` tool assembles p-code modules produced with `fglcomp` into a `.42r` program or a `.42x` library.

* `Loading C-Extensions at runtime` on page 2113

  The runtime system can load several C-Extensions libraries, allowing you to properly split your libraries by defining each group of functions in separate C interface files.

* `Compiling source files` on page 1998

  Describes how to build the runtime files from source files.

* `IMPORT C-Extension` on page 496

  The `IMPORT` instruction imports C extension module elements to be used by the current module.

### Loading C-Extensions at runtime

The runtime system can load several C-Extensions libraries, allowing you to properly split your libraries by defining each group of functions in separate C interface files.

**Note:** When running iOS platforms, the C-Extensions are linked statically to the GMI application.

Directories are searched for the C-Extensions libraries based on the `FGLDLPATH` on page 243 environment variable rules.

If the C-Extension library depends on other shared libraries, make sure that the library loader of the operating system can find these shared objects. You may need to set the `LD_LIBRARY_PATH` environment variable on UNIX® or the `PATH` environment variable on Windows® to point to the directory where these other libraries are located.

There are three ways to bind a C-Extension with the runtime system:

1. Using the `IMPORT` instruction in sources.
2. Using the default C-Extension name.
3. Using the `-e` option of `fglrn`. 
**Using the IMPORT instruction**

The IMPORT instruction allows you to declare an external module in a .4gl source file. It must appear at the beginning of the source file.

The name of the module specified after the IMPORT keyword is converted to lowercase by the compiler. Therefore it is recommended to use lowercase file names only.

The compiler and the runtime system automatically know which C-Extensions must be loaded, based on the IMPORT instruction:

```plaintext
IMPORT mylib1
MAIN
    CALL myfunc1("Hello World")  -- C function defined in mylib1
END MAIN
```

When the IMPORT instruction is used, no other action has to be taken at runtime. The module name is stored in the 42m p-code and is automatically loaded when needed.

**Using the default C-Extension name**

It is recommended that all modules using a function from a C-Extension now use the IMPORT instruction. However, this can mean a major change to existing sources.

To simplify migration of existing C-Extensions, the runtime system loads by default a module with the name userextension. Create this shared library with your existing C-Extensions, and the runtime system will load it automatically if found in the directories specified by FGLLDPATH.

**Using the -e fglrun option**

In some cases you need several C-Extension libraries, which are used by different groups of programs, so you cannot use the default userextension solution. However, you don't want to review all your sources in order to use the IMPORT instruction.

You can specify the C-Extensions to be loaded by using the -e option of fglrun. The -e option takes a comma-separated list of module names, and can be specified multiple times in the command line. The following example loads five extension modules:

```plaintext
fglrun -e myext1,myext2,myext3 -e myext4,myext5 myprog.42r
```

By using the -e option, the runtime system loads the modules specified in the command line instead of loading the default userextension module.

**Related concepts**

- [IMPORT C-Extension](#) on page 496
- The IMPORT instruction imports c extension module elements to be used by the current module.

**Runtime stack functions**

To pass values between a C function and a program, the C function and the runtime system use the runtime stack.

**Stack function basics**

The parameters passed to the C function must be popped from the stack at the beginning of the C function, and the return values expected by the Genero BDL call must be pushed on the stack before leaving the C function.

The int parameter of the C function defines the number of input parameters passed on the stack, and the function must return an int value defining the number of values returned on the stack.

**Note:** If you don’t pop / push the specified number of parameters / return values, you corrupt the stack and get a fatal error.
**Pop parameters from the stack**

The runtime system library includes a set of functions to retrieve the values passed as parameters on the stack. This table shows the library functions provided to pop values from the stack into C buffers:

**Table 431: Library functions provided to pop values from the stack into C buffers**

<table>
<thead>
<tr>
<th>Function</th>
<th>Data type</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>void popdate(int4 *dst);</td>
<td>DATE</td>
<td>4-byte integer value corresponding to days since 12/31/1899.</td>
</tr>
<tr>
<td>void popbigint(bigint *dst);</td>
<td>BIGINT</td>
<td>8-byte integer value.</td>
</tr>
<tr>
<td>void popint(mint *dst);</td>
<td>INTEGER</td>
<td>System dependent integer value (int)</td>
</tr>
<tr>
<td>void popshort(int2 *dst);</td>
<td>SMALLINT</td>
<td>2-byte integer value</td>
</tr>
<tr>
<td>void poplong(int4 *dst);</td>
<td>INTEGER</td>
<td>4-byte integer value</td>
</tr>
<tr>
<td>void popflo(float *dst);</td>
<td>SMALLFLOAT</td>
<td>4-byte floating point value</td>
</tr>
<tr>
<td>void popdub(double *dst);</td>
<td>FLOAT</td>
<td>8-byte floating point value</td>
</tr>
<tr>
<td>void popdec(dec_t *dst);</td>
<td>DECIMAL</td>
<td>See structure definition in $FGLDIR/include/f2c headers</td>
</tr>
<tr>
<td>void popquote(char *dst, int size);</td>
<td>CHAR(n)</td>
<td>The size parameter defines the size of the char buffer (with the '0'). The trailing blanks are kept.</td>
</tr>
<tr>
<td>void popvchar(char *dst, int size);</td>
<td>VARCHAR(n)</td>
<td>The size parameter defines the size of the char buffer (with the '0'). The trailing blanks are kept.</td>
</tr>
<tr>
<td>void popstring(char *dst, VARCHAR(n) int size);</td>
<td>VARCHAR(n)</td>
<td>The size parameter defines the size of the char buffer (with the '0'). The trailing blanks are kept.</td>
</tr>
<tr>
<td>void popdtime(dtime_t *dst, int size);</td>
<td>DATETIME</td>
<td>See structure definition in $FGLDIR/include/f2c headers</td>
</tr>
<tr>
<td>void popinv(intrvl_t *dst, int size);</td>
<td>INTERVAL</td>
<td>See structure definition in $FGLDIR/include/f2c headers</td>
</tr>
</tbody>
</table>

```
size = TU_DTENCODE(start, end)
```

```
size = TU_IENCODE(len, start, end)
```
When using a pop function, the value is copied from the stack to the local C variable and the value is removed from the stack.

In a Genero program, strings (CHAR, VARCHAR) are not terminated by '\0'. Therefore, the C variable must have one additional character to store the '\0'. For example, the equivalent of a VARCHAR(100) in Genero BDL programs is a char x[101] in C.

**Stack introspection**

A set of C API functions are provided to query information on the parameters passed on the stack to a C function. Query for the parameter type and the actual size of a character string value, to adapt the buffer receiving the parameter.

**Table 432: Library functions to introspect the runtime stack**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>const char *fglcapi_peekStackType(void)</td>
<td>Returns the type name of the topmost value on the stack as a string. For example, if the value on the stack is a CHAR(100), the function returns the string &quot;CHAR(100)&quot;. <strong>Note:</strong> If the current value on the stack is a string literal, the returned type name is &quot;STRING&quot;.</td>
</tr>
<tr>
<td>int fglcapi_peekStackBufferSize(void)</td>
<td>Returns the size (in bytes) for the topmost value on the stack, to allocate a C char buffer, when using pop* function to get character strings. String pop functions such as popquote() and popvchar() require a C char buffer to be allocated. To allocate the buffer dynamically, use the fglcapi_peekStackBufferSize() function to get the required buffer size. Allocating char buffers with the proposed size avoids truncating values returned from the stack.</td>
</tr>
</tbody>
</table>

Stack introspection example:

```c
int my_function(int n)
{
    int sz;
    char *buf;
    sz = fglcapi_peekStackBufferSize();
    buf = malloc(sz);
    popstring(buf, sz);
    // ...
    free(buf);
    return 0;
}
```
Push returns on the stack

To return a value from the C function, you must use one of the functions provided in the runtime system library.

Table 433: Functions provided in the runtime system library to return a value from a C function

<table>
<thead>
<tr>
<th>Function</th>
<th>Data type</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>void pushdate(int4 val);</td>
<td>DATE</td>
<td>4-byte integer value corresponding to days since 12/31/1899.</td>
</tr>
<tr>
<td>void pushbigint(bigint val);</td>
<td>BIGINT</td>
<td>8-byte integer value.</td>
</tr>
<tr>
<td>void pushdec(const dec_t *val, const unsigned decp);</td>
<td>DECIMAL</td>
<td>See structure definition in $FGLDIR/include/f2c headers</td>
</tr>
<tr>
<td>void pushint(mint val);</td>
<td>INTEGER</td>
<td>System dependent integer value (int)</td>
</tr>
<tr>
<td>void pushlong(int4 val);</td>
<td>INTEGER</td>
<td>4-byte integer value</td>
</tr>
<tr>
<td>void pushshort(int2 val);</td>
<td>SMALLINT</td>
<td>2-byte integer value</td>
</tr>
<tr>
<td>void pushflo(float *val);</td>
<td>SMALLFLOAT</td>
<td>4-byte floating point value.</td>
</tr>
<tr>
<td>void pushdub(double *val);</td>
<td>FLOAT</td>
<td>8-byte floating point value.</td>
</tr>
<tr>
<td>void pushquote(const char *val, int len);</td>
<td>CHAR(n)</td>
<td>len = strlen(val) (without '0')</td>
</tr>
<tr>
<td>void pushvchar(const char *val, int len);</td>
<td>VARCHAR(n)</td>
<td>len = strlen(val) (without '0')</td>
</tr>
<tr>
<td>void pushdtime(const dtime_t *val);</td>
<td>DATETIME</td>
<td>See structure definition in $FGLDIR/include/f2c headers</td>
</tr>
<tr>
<td>void pushinv(const intrvl_t *val);</td>
<td>INTERVAL</td>
<td>See structure definition in $FGLDIR/include/f2c headers</td>
</tr>
</tbody>
</table>

When using a push function, the value of the C variable is copied at the top of the stack; therefore the scope and lifespan of the C variable does not matter.

To simplify migration of IBM I4GL legacy C extensions using ret*() style functions, Genero supports the following synonyms:

Table 434: Return value functions synonyms

<table>
<thead>
<tr>
<th>Function</th>
<th>Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>void retdate(int4 val)</td>
<td>pushdate</td>
</tr>
<tr>
<td>void retdec(const dec_t *val)</td>
<td>pushdec</td>
</tr>
<tr>
<td>Function</td>
<td>Equivalent</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>void retmoney(const dec_t *val)</td>
<td>pushdec</td>
</tr>
<tr>
<td>void retint(int val)</td>
<td>pushint</td>
</tr>
<tr>
<td>void retlong(int4 val)</td>
<td>pushlong</td>
</tr>
<tr>
<td>void retshort(int2 val)</td>
<td>pushshort</td>
</tr>
<tr>
<td>void retflo(float *val)</td>
<td>pushflo</td>
</tr>
<tr>
<td>void retdub(double *val)</td>
<td>pushdub</td>
</tr>
<tr>
<td>void retquote(const char *val)</td>
<td>pushquote</td>
</tr>
<tr>
<td>void retstring(const char *val)</td>
<td>pushquote</td>
</tr>
<tr>
<td>void retrvchar(const char *val)</td>
<td>pushvchar</td>
</tr>
<tr>
<td>void retdtime(const dtime_t *val)</td>
<td>pushdtime</td>
</tr>
<tr>
<td>void retinv(const intrvl_t *val)</td>
<td>pushinv</td>
</tr>
</tbody>
</table>

**Note:** Pay attention to the `retdec()`, `retmoney()`, `retquote()` and `retvchar()` functions. These do not have the same signature as the equivalent `push*()` functions.

**Related concepts**

- **Runtime stack** on page 443
  The runtime stack is used to pass/return values to/from functions.

</tr>
<tr>
<td>dec_t</td>
<td>DECIMAL data type structure</td>
</tr>
<tr>
<td>dtime_t</td>
<td>DATETIME data type structure</td>
</tr>
</tbody>
</table>
Basic data types

Basic data types such as bigint, int 4 and int 2 are provided to define variables that must hold BIGINT (bigint), SMALLINT (int 2), INTEGER (int 4) and DATE (int 4) values. Standard char array can be used to hold CHAR and VARCHAR data.

**DATE**

No specific typedef exists for the DATE type; you can use the int 4 type to store a DATE value.

**DECIMAL/MONEY**

The dec_t structure is provided to hold DECIMAL and MONEY values.

The internals of dec_t structure can be ignored during C-Extension programming, because decimal API functions are provided to manipulate any aspects of a decimal.

**DATETIME**

The dtime_t structure holds a DATETIME value.

Before manipulating a dtime_t, you must initialize its qualifier qt_qual, by using the TU_DTENCODE macro:

```c

dtime_t dt;
dt.dt_qual = TU_DTENCODE(TU_YEAR, TU_SECOND);
dtcvasc( "2004-02-12 12:34:56", &dt );
```

**INTERVAL**

The intrvl_t structure holds an INTERVAL value.

Before manipulating a intrvl_t, you must initialize its qualifier in_qual, by using the TU_IENCODE macro:

```c

intrvl_t in;
in.in_qual = TU_IENCODE(5, TU_YEAR, TU_MONTH);
invcvasc( "65234-02", &in );
```

**TEXT/BYTE Locator**

The ifx_loc_t structure is used to declare host variables for a TEXT/BYTE values (simple large objects). Because the potential size of the data can be quite large, this is a locator structure that contains information about the size and location of the TEXT/BYTE data, rather than containing the actual data.

**Table 436: Fields of the ifx_loc_t structure**

<table>
<thead>
<tr>
<th>Field name</th>
<th>Data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>loc_indicator</td>
<td>int4</td>
<td>Null indicator; a value of -1 indicates a null TEXT/BYTE value. Your program can set the field to indicate the insertion of a null value. Database client libraries set the value for selects and fetches.</td>
</tr>
</tbody>
</table>
### Field name | Data type | Description
--- | --- | ---
loc_type | int4 | data type - SQLTEXT (for TEXT values) or SQLBYTES (for BYTE values).
loc_size | int4 | Size of the TEXT/BYTE value in bytes; your program sets the size of the large object for insertions. Database client libraries set the size for selects and fetches.
loc_loctype | int2 | Location - LOCMEMORY (in memory) or LOCFNAME (in a named file). Set loc_loctype after you declare the locator variable and before this declared variable receives the large object value.
loc_buffer | char * | If loc_loctype is LOCMEMORY, this is the location of the TEXT/BYTE value; your program must allocate space for the buffer and store its address here.
loc_bufsize | int4 | If loc_loctype is LOCMEMORY, this is the size of the buffer loc_buffer; If you set loc_bufsize to -1, database client libraries will allocate the memory buffer for selects and fetches. Otherwise, it is assumed that your program will handle memory allocation and de-allocation.
loc_fname | char * | If loc_loc_type is LOCFNAME, this is the address of the path name string that contains the file.

### Example
C Extension source (ext1.c):

```c
#include <stdio.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <stdlib.h>
#include <unistd.h>
#include <fcntl.h>

#include "f2c/fglExt.h"

int lob_size(int);

int lob_size(int pc)
{
```
ifx_loc_t *pb1;
double ratio;
char *source = NULL;
char *psource = NULL;
int size;

if (pc != 1) exit(1);
poplocator(&pb1);

if (pb1->loc_loctype == LOCMEMORY) {
  psource = pb1->loc_buffer;
  size = pb1->loc_size;
} else if (pb1->loc_loctype == LOCFNAME) {
  int fd;
  struct stat st;
  fd = open(pb1->loc_fname, O_RDONLY);
  fstat(fd, &st);
  size = st.st_size;
  psource = source = (char *) malloc(size);
  read(fd, source, size);
  close(fd);
}
pushint(size);
return 1;

Genero program (main.4gl):

IMPORT libext1
MAIN
DEFINE t TEXT
LOCATE t IN MEMORY
LET t = "aaaaaaaaaaaaaa"
DISPLAY lob_size(t)
END MAIN

Commands to compile and execute (on Linux):

$ gcc -fPIC -c ext1.c -I $FGLDIR/include
$ gcc --shared -o libext1.so ext1.o -L$FGLDIR/lib -lfgl
$ fglcomp main.4gl
$ fglrun main.42m
14

Related concepts
Header files for ESQL/C typedefs on page 2110
C header files (.h) are required to define C structures for complex data types used in a C-Extension.

NULL handing
Handling NULL in C-Extensions.

Variables passed from the BDL code can be checked for NULL depending on the data type.

Define macros as follows to check for NULL values:

#define MY_IS_NULL_SMALLFLOAT(v) (isnan(v))
#define MY_IS_NULL_FLOAT(v) (isnan(v))
#define MY_IS_NULL_INTEGER(v) ((unsigned) v == 0x80000000)
#define MY_IS_NULL_SMALLINT(v) ((unsigned) v == 0x800)
#define MY_IS_NULL_CHAR(v) (v[0] == '\0')
#define MY_IS_NULL_DECIMAL(v) (v.dec_pos < 0)
#define MY_IS_NULL_DATETIME(v) (v.dt_dec.dec_pos < 0)
To return a NULL value from your C extension function, push an empty string on the stack as follows:

```c
pushquote("", 0);
```

**Example**

C Extension source (ext1.c):

```c
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include "f2c/fglExt.h"

int check_null(int pc)
{
    dec_t price;
    const char *answer;
    int len;
    if (pc != 1) exit(1);
    popdec(&price);
    if (MY_IS_NULL_DECIMAL(price)) {
        answer = "This decimal is NULL";
    } else {
        answer = "This decimal is not NULL";
    }
    len = (int) strlen(answer);
    pushquote(answer, len);
    return 1;
}
```

Genero program (main.4gl):

```4gl
IMPORT libext1
MAIN
    DEFINE d DECIMAL(10,2)
    LET d = NULL
    DISPLAY check_null(d)
    LET d = 12.34
    DISPLAY check_null(d)
END MAIN
```

**Commands to compile and execute (on Linux):**

```bash
$ gcc -fPIC -c ext1.c -I $FGLDIR/include
$ gcc --shared -o libext1.so ext1.o -L$FGLDIR/lib -lfgl
$ fglcomp main.4gl
$ fglrun main.42m
```

This decimal is NULL
This decimal is not NULL
Calling C functions from programs

C-Extensions functions can be called from the program in the same way that you call a BDL function.

The C functions that can be called from programs must use the following signature:

```
int function-name( int )
```

Here `function-name` must be written in lowercase letters. The `fglcomp` compiler converts all BDL function names (following a `CALL` keyword) to lowercase.

The C function must be declared in the `usrFunctions` array in the C interface file.

**Important:** Parameters and return values must be pushed/popped on the runtime stack, by using the stack functions. Parameters passed to the C function must be popped in the reverse order of the BDL call list: `CALL c_fct(A, B, C) => pop C, B, A`. However, values returned from the C function must be pushed in the same order as in the BDL returning clause: `push A, B, C => CALL c_fct() RETURNING A, B, C`.

In this code example, the C-Extension module `mycext.c` defines the `c_fct()` function:

```c
#include <stdlib.h>
#include <stdio.h>
#include <string.h>
#include "f2c/fglExt.h"

int c_fct( int n );

UsrFunction usrFunctions[]={
   {"c_fct",c_fct,2,2},
   {0,0,0,0}
};

int c_fct( int n )
{
    int rc;
    float price;
    char name[31];
    if (n != 2) exit(1);
    popflo(&price);
    popvchar(name, sizeof(name));
    printf(">> [%s] price:%f\n", name, price);
    pushint( strlen(name) );
    price = price * 2;
    pushflo(&price);
    return 0;
}
```

The C-Extension library is imported by the BDL module with `IMPORT`:

```c
IMPORT mycext
```

```c
MAIN
   DEFINE len INT, price2 FLOAT
   CALL c_fct("Hand gloves", 120.50)
       RETURNING len, price2
   DISPLAY "len = ", len
   DISPLAY "price2 = ", price2
END MAIN
```

Compilation and execution example on a Linux® system:

```
$ gcc -I $FGLDIR/include -shared -fPIC -o mycext.so mycext.c
```
$ fglcomp myprog.4gl
$ fglrun myprog.42m
>> [Hand gloves] price:120.50000
len =           11
price2 =                 241.0

Functions on page 353
Describes user defined functions.

Calling program functions from C

It is possible to call a BDL function from a C-Extension function.

To call a BDL function from a C-Extension function, use the fgl_call macro:

```c
fgl_call ( function-name, nb-params );
```

In this call, function-name is the name of the program function to call, and nb-params is the number of parameters pushed on the stack for the program function. The function-name must be written in lowercase letters; the fglcomp compiler converts all program function names to lowercase.

The fgl_call() macro is converted to a function that returns the number of values returned on the stack.

**Important:** Parameters and return values must be pushed/popped on the runtime stack, by using the stack functions. Parameters passed to the BDL function must be pushed in the same order as the BDL parameter list: push A, B, C => FUNCTION fct( A, B, C ). However, values returned from the BDL function must be popped in the reverse order of the BDL return clause: RETURN A, B, C => pop C, B, A.

The myprog.4gl BDL module defining the MAIN block and the display_item() function to be called from the C extension:

```c
IMPORT mycext

MAIN
  CALL c_fct()
END MAIN

FUNCTION display_item(name, size)
  DEFINE name VARCHAR(30), size INTEGER
  DISPLAY name, size
  RETURN length(name), (size / 100)
END FUNCTION
```

The mycext.c C extension module calling the BDL function:

```c
#include <stdlib.h>
#include <stdio.h>
#include "f2c/fglExt.h"

int c_fct( int n );

UsrFunction usrFunctions[]={
  {"c_fct",c_fct,0,0},
  {0,0,0,0}
};

int c_fct( int n )
{
```
int rc, len;
float size2;
if (n != 0) exit(1);
pushquote("Hand gloves", 11);
pushint(54);
rc = fgl_call( display_item, 2 );
if (rc != 2) exit(1);
popflo(&size2);
popint(&len);
printf(">> %d %f\n", len, size2);
return 0;
}

Compilation and execution example on a Linux® system:

$ gcc -I $FGLDIR/include -shared -fPIC -o mycext.so mycext.c
$ fglcomp myprog.4gl
$ fglrun myprog.42m
Hand gloves         54
>> 11 0.540000

Sharing global variables

While not recommended, you can share global variables declared in your program with a C module.

In order to share the global variables declared in your program, you must:

1. Generate the .c and .h interface files by using fglcomp -G with the module defining the global variables:

   GLOBALS
   DEFINE g_name CHAR(100)
   END GLOBALS

   fglcomp -G myglobals.4gl

   This will produce two files named myglobals.h and myglobals.c.

2. In the C module, include the generated header file and use the global variables directly:

   #include <string.h>
   #include "f2c/fglExt.h"
   #include "myglobals.h"

   int myfunc1(int c)
   {
       strcpy(g_name, "new name");
       return 0;
   }

3. When creating the C-Extension library, compile and link with the myglobals.c generated file.

   Tip: Using global variables is not recommended. It makes your code difficult to maintain. If you need persistent variables, use module variables and write set/get functions that you can interface with.

   Related concepts
   - **Globals** on page 472
   - **Variables** on page 366
Use the IMPORT ... instruction to import BDL, C or Java external modules in the current module.

Simple C-Extension example

This example shows how to create a C-Extension library on Linux® using gcc.

The command line options to compile and link shared libraries can change depending on the operating system and compiler/linker used.

The "splitext.c" C interface file

```c
#include "f2c/fglExt.h"

int next_token(int);

UsrFunction usrFunctions[] = {
  { "next_token", next_token, 1, 2 },
  { 0, 0, 0, 0 }
};
```

The "split.c" file

```c
#include <string.h>
#include "f2c/fglExt.h"

int next_token( int in_num );

int next_token( int in_num ) {
    char src[513];
    char *p;
    popvchar(src, sizeof(src));
    if (*src == '\0') {
        pushvchar("", 0);
        pushvchar("", 0);
    } else {
        p = strchr(src, ' ');
        if (p == NULL) {
            pushvchar(src, strlen(src));
            pushvchar("", 0);
        } else {
            *p = '\0';
            pushvchar(src, strlen(src));
            p++;
            pushvchar(p, strlen(p));
        }
    }
    return 2;
}
```

Compile the C Module and the interface file

```
$ gcc -c -I $FGLDIR/include -fPIC split.c
$ gcc -c -I $FGLDIR/include -fPIC splitext.c
```

Create the shared library

```
$ gcc -shared -o libsplit.so split.o splitext.o -L$FGLDIR/lib -lfgl
```
The program "split.4gl"

```4gl
IMPORT libsplit
MAIN
  DEFINE t, r VARCHAR(100)
  LET r = "This is my first C Extension"
  WHILE TRUE
    CALL next_token(r) RETURNING t, r
    IF t IS NULL THEN
      EXIT WHILE
    END IF
    DISPLAY "token: ", t
  END WHILE
END MAIN
```

Compile the main module

```
$ fglcomp split.4gl
```

Run the split.42m program

```
$ fglrun split.42m
token: This
token: is
token: my
token: first
token: C
token: Extension
```

Implementing C-Extensions for GMI

This section describes how to program C-Extensions for the GMI VM.

**C-Extensions for GMI**

With C-Extensions for GMI, you can address specific needs on iOS platforms, that are not available by default in the Genero language. For example, implement functions to interface with mobile specific hardware like sensors, card readers, scanners, bluetooth, etc.

The runtime system virtual machine build in the GMI for iOS platforms can be extended with the C-Extension technology. The basics to implement C-Extensions are the same for iOS as for UNIX®/Windows® platforms, but there are some differences, explained in this section.

The main difference is that user libraries cannot be loaded dynamically on iOS and thus require a re-link of the GMI binary with the user-defined C-Extension library.

**Writing C-Extension sources for GMI**

C-Extension source files can be organized in several `.c` or `.m` files, but the final library name must be `userextension`.

For a first test, we recommend that you group all your C-Extension functions in a single source file called `userextension.m`.

In the Objective C source file, add the following lines, to include typical iOS header files:

```c
#include <Foundation/Foundation.h>
#include <UIKit/UIKit.h>
```
The Genero runtime system header file must be included as well:

```c
#include "f2c/fglExt.h"
```

The C-Extension functions must be registered as usual, in a `UsrFunction` array, defining the number of input and output parameters:

```c
UsrFunction usrFunctions[]={
    {"get_user_info",get_user_info,1,1},
    ...
    {NULL,NULL,0,0}
};
```

### Using iOS C-Extensions in your program

The application code needs to be compiled on the development platform before it is deployed on the iOS device or simulator, by using the C-Extension library build for the development platform.

In your Genero program, import the C-Extension module with `IMPORT userextension`. You can also omit this `IMPORT` instruction, because the runtime system tries to find and load the `userextension` library by default. Note also that C-Extension functions have a global scope, so you can omit the prefix of the function name with the `lib/` module name:

```c
IMPORT userextension
MAIN
    DEFINE info STRING
    LET info = get_user_info()
    ...
END MAIN
```

Compiler behavior regarding `IMPORT userextension` usage:

- **With `IMPORT userextension`**: The compiler can check references to functions defined in the extension. The programmer can qualify a function-name as `userextension.function-name`. But in this case, the `userextension.so` shared library must exist on the development platform.
- **Without `IMPORT userextension`**: The compiler cannot check references to those functions. The compiler does not load the `userextension` module implicitly. C-Extension function names cannot be qualified. In this case, the `userextension.so` library is not required for compilation, but it will be needed if the final program is linked, or if you want to execute/test the application in client/server development mode.

### Compiling and linking with C-Extensions on the development platform

On the development machine, if you `link 42r programs`, or if you want the compiler to check for missing symbols (with the `-r` option), the `userextension` library must exist in the development environment.

**Note**: At runtime, on the development machine, the extension library will be loaded at first extension function call. But when the application is deployed on the iOS device, the extension library will be part of the GMI/VM binary (because it is statically linked).

To create the `userextension` library for the development environment, you must build an Objective-C shared library.

If the C-Extension contains iOS API calls, it will not be possible to compile the extension library as is on the development machine: Write conditional pre-processor macros to hide the iOS specific code, and simulate the function behavior for the development platform:

```c
#ifndef EMULATE_IOS
#include <Foundation/Foundation.h>
#include <UIKit/UIKit.h>
#endif
```
... int get_user_info(int pc) {
    char prop[101];
    char value[101];
    int z = (int) sizeof(prop);
    assert(pc==1);
    popvchar(prop, z);
    ifndef EMULATE_IOS
        ... here goes the iOS specific code ...
    else
        value[0] = '\0';
    endif
    pushvchar(value, (int) strlen(value));
    return 1;
}

Command line example to create a shared library with the Xcode® environment (note that we define the NOT_IOS_IMPL constant to compile the code without iOS specific API calls):

$ cc -shared -o userextension.dylib userextension.c \
  -D EMULATE_IOS -I $FGLDIR/include -L $FGLDIR/lib -lfgl

Building the iOS app with C extensions

Genero iOS apps are created with the gmibuildtool command-line tool.

In order to build your iOS app with C extensions, you need to create the static library with the staticlib target of GMIDIR/lib/Makefile-gmi and then pass the static library to the linker with the --extension-libs option of gmibuildtool.

For more details, see Building iOS apps with Genero on page 3332

User-defined front calls

Front-ends can be extended with custom functions to access specific features.

It is possible to implement custom front-end functions to interface with platform-specific features, and use the feature from a Genero program through a front call. For example, you can implement a front-end function module interfacing with a bar code reader, to return bar codes to the Genero program.

This section describes how to implement your own front calls by front-end type. Because each front-end type uses different technologies, you must use native platform APIs to implement front calls.

- Implement front call modules for GDC on page 2129
- Implement front call modules for GMA on page 2134
- Implement front call modules for GMI on page 2139
- Implement front call modules for GBC on page 2146

Implement front call modules for GDC

Custom front call modules for the desktop front-end are implemented by using the API for GDC front calls in C language.

GDC custom front call basics

In order to extend the GDC with your own front calls, you must be familiar with C++ programming, and have a C++ compiler installed on your development platform.
GDC front call modules must be implemented as a Dynamic Linked Library (.DLL) on Windows® platforms, as a shared library (.so) on Linux®, or as a Dynamic Library (.dyLib) under Mac® Os X. This shared library must be deployed on each platform where the GDC front-end executes.

The GDC is able to automatically load the front call module and find the function, based on the module name and function name used in the Genero BDL front call (ui.Interface.frontCall).

The API for GDC front calls is based on the frontEndInterface front call interface structure, that is used to interface with the GDC core, in order to pass/return values to/from a front call.

Follow these steps to implement a custom front call module for the GDC:

1. Create a C source to implement your front call functions.
2. In the front call functions body:
   a. Check the number of parameters passed with the getParamCount () function.
   b. Pop parameter values with one of the pop* () functions.
   c. Perform the function task.
   d. Push the result values with one of the push* () functions.
   e. Return 0 on success, -1 otherwise.
3. Compile and link the shared library.
4. Deploy the shared library to the platform where GDC executes.

The front call interface structure

Information required to execute the front call is transmitted to the extension module through the front call interface structure. This structure contains a list of function pointers to:

- manage the stack (push or pop for each handled data type)
- get information about the function (number of in and out parameters)
- get information about the front-end (front call environment variables)

The following defines the front call interface structure:

```c
struct frontEndInterface
{
    short (* getParamCount) ();
    short (* getReturnCount) ();
    void (* popInteger) (long &, short &);
    void (* pushInteger) (const long, short);
    void (* popString) (char *, short &, short &);
    void (* pushString) (const char *, short, short);
    void (* getFrontEndEnv) (const char *, char *, short &);
    void (* popWString) (wchar_t *, short &, short &);
    void (* pushWString) (const wchar_t*, short, short);
};
```

Important: The front call interface structure is defined for the C++ language.

Prototype of a front call function implementation

The prototype of each front call function must be:

```c
int function_name ( const struct frontEndInterface &fci );
```

1. `function_name` is the name of your function.
2. `fci` is the front call interface structure.

The `fci` structure will be filled in by the GDC and passed to the custom function. You can then use this structure to pop/push values from/to the stack, and get environment information from the core GDC.
The function must return 0 on success, -1 otherwise.

**Front call environment variables**
The front call function can query the GDC for front call environment variables, to get information about the context. The following front call environment variables are supported:

**Table 437: Supported front call environment variables for the GDC**

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>frontEndPath</td>
<td>The path where the GDC front-end is installed.</td>
</tr>
</tbody>
</table>

**Module initialization and finalization**
The front-call module can define initialization and finalization functions. GDC will automatically call these functions as follows:

- `void initialize();`
  
  This function is called when the front call module library is loaded. If needed, perform variable initialization and resource allocation in this function.

- `void finalize();`
  
  This function is called when the GDC front-end stops. If needed, perform resource release in this function.
## The API for custom front call implementation

### Table 438: Front call interface functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>short getParamCount();</code></td>
<td>This function returns the number of parameters given to the function called.</td>
</tr>
<tr>
<td><code>short getReturnCount();</code></td>
<td>This function returns the number of returning values of the function called.</td>
</tr>
<tr>
<td><code>void ( * getFrontEndEnv ) (const char * name, char * value, short &amp; length );</code></td>
<td>This function is used to get context information from the front-end.</td>
</tr>
<tr>
<td>- <code>name</code> is the name of the front call environment variable. - <code>value</code> is the char buffer to hold the value of the variable. - <code>length</code> is the actual length of the value.</td>
<td></td>
</tr>
<tr>
<td><code>void popInteger( long &amp; value, short &amp; isNull );</code></td>
<td>This function is used to get an integer from the stack.</td>
</tr>
<tr>
<td>- <code>value</code> is the reference to where the popped integer will be set. - <code>isNull</code> indicates whether the parameter is null.</td>
<td></td>
</tr>
<tr>
<td><code>void pushInteger( const long value, short isNull );</code></td>
<td>This function is used to push an integer on the stack.</td>
</tr>
<tr>
<td>- <code>value</code> is the value of the integer. - <code>isNull</code> indicates whether the value is null.</td>
<td></td>
</tr>
<tr>
<td><code>void popString( char * value, short &amp; length, short &amp; isNull );</code></td>
<td>This function is used to get a string from the stack.</td>
</tr>
<tr>
<td>- <code>value</code> is the pointer where the popped string will be set. - <code>length</code> is the length of the string. - <code>isNull</code> indicates whether the parameter is null.</td>
<td></td>
</tr>
<tr>
<td><code>void pushString( const char * value, short length, short isNull );</code></td>
<td>This function is used to push a string on the stack.</td>
</tr>
<tr>
<td>- <code>value</code> is the value of the string. - <code>length</code> is the length of the string. A length of -1 indicates that the length is detected based on the content of the string. - <code>isNull</code> indicates whether the parameter is null.</td>
<td></td>
</tr>
<tr>
<td><code>void ( * popWString ) (wchar_t *value, short &amp; length, short &amp; isNull);</code></td>
<td>This function is used to get a WideChar string from the stack.</td>
</tr>
<tr>
<td>- <code>value</code> is the pointer where the popped string will be set. - <code>length</code> is the length of the string. - <code>isNull</code> indicates whether the parameter is null.</td>
<td></td>
</tr>
<tr>
<td><code>void ( * pushWString ) (wchar_t *value, short length, short isNull);</code></td>
<td>This function is used to push a WideChar string on the stack.</td>
</tr>
<tr>
<td>- <code>value</code> is the value of the string. - <code>length</code> is the length of the string. A length of -1 indicates that the length is detected based on the content of the string. - <code>isNull</code> indicates whether the parameter is null.</td>
<td></td>
</tr>
</tbody>
</table>
Calling the custom front call from BDL

In the Genero program, use the `ui.Interface.frontCall()` API to call the front-end function. This method takes the front call module name as the first parameter and the front call function name as second parameter. The front call module name is defined by the name of the dynamic library (`module_name.DLL`, `module_name.so` or `module_name.dylib`).

For example, if you implement a front call module with the name "mymodule.so", the Genero program code must use the name "mymodule" as front call module name:

```
CALL ui.Interface.frontCall("mymodule", "myfunction", ["John DOE"], [msg])
```

Deploying the custom front call module

The shared library implementing the custom front call functions must be deployed on the platform where the GDC executes. Copy your custom front call modules in the bin directory of the GDC installation directory (`%GDCDIR% \bin`).

Example

This example implements a simple front call function that computes the sum of two integer numbers. It takes two parameters and returns two values.

mymodule.h:

```c
struct frontEndInterface
{
    short (* getParamCount) ();
    short (* getReturnCount) ();
    void (* popInteger) (long &, short &);
    void (* pushInteger) (const long, short);
    void (* popString) (char *, short &, short &);
    void (* pushString) (const char *, short, short);
    void (* getFrontEnv) (const char *, char *, short &);
    void (* popWString) (wchar_t *, short &, short &);
    void (* pushWString) (const wchar_t *, short, short);
};
```

```
#ifdef WIN32
#define EXPORT extern "C" __declspec(dllexport)
#else
#define EXPORT extern "C"
#endif

EXPORT void initialize();
EXPORT void finalize();
EXPORT int mysum(const frontEndInterface &fx);
```

mymodule.cpp:

```
#include "mymodule.h"
#include <stdio.h>
#include <string.h>

void initialize() {
}

void finalize() {
}

int mysum(const struct frontEndInterface &fci) {
    long param1, param2;
```
short isNull1, isNull2;
long sum;
char msg[255];

if (fci.getParamCount() != 2 || fci.getReturnCount() != 2) {
    return -1;
}

fci.popInteger(param2, isNull2);
fci.popInteger(param1, isNull1);

sum = param1 + param2;
if (!isNull1 && !isNull2) {
    sum = param1 + param2;
    sprintf(msg, "%d + %d = %d", param1, param2, sum);
} else {
    sum = 0;
    sprintf(msg, "Parameters are NULL");
}

fci.pushInteger(sum, 0);
fci.pushString(msg, strlen(msg), 0);
return 0;

To invoke the sum front-end function, use the ui.Interface.frontCall() method in your Genero program:

```genero
MAIN
DEFINE res INT, msg STRING
MENU
    ON ACTION frontcall ATTRIBUTES(TEXT="Call custom front call")
        CALL ui.Interface.frontCall("mymodule", "mysum",
            [100,250], [res,msg])
        DISPLAY "Result: ", res, "\n", msg
    ON ACTION quit
        EXIT MENU
END MENU
END MAIN
```

- [Genero Desktop Client front calls](#) on page 2516
  This section describes GDC specific front calls.

**Implement front call modules for GMA**

Custom front call modules for the Android™ front-end are implemented by using the API for GMA front calls in Java.

**GMA custom front call basics**

In order to extend the GMA with your own front calls, you must be familiar with Java programming concepts, and if you want to interface with Android™ apps, understand concepts such as Android™ Activity and Intent.

The API for GMA front calls is based on the following Java interfaces:

- com.fourjs.gma.extension.v1.IFunctionCallController
- com.fourjs.gma.extension.v1.IFunctionCall

The front call function controller (IFunctionCallController) is implemented by the GMA, it is used to notify function call results, raise runtime exceptions and invoke activities.

The front call function body (IFunctionCall) implements the actual custom front call code.
The steps to implement an IFunctionCall class are:

1. Create a Java source file with the name of the front call function, for example: "getPhoneId.java", that implements the IFunctionCall interface.
2. Define the Java package name identifying the front call module, for example: "package com.mycompany.utilities;".
3. Define a private IFunctionCallController object reference to handle the function controller.
4. Implement the setFunctionCallController() method for the function controller registration.
5. Implement the invoke() method to perform the actual front call task. In this method, use the controller's returnValues() method to return values from the front call. If needed, you can raise runtime errors with controller's raiseError() method. It is also possible to start an Android™ Activity with the startActivity* controller methods.
6. If an activity is started with controller's startActivityForResult method, implement the onActivityResult() method in the function body class, to handle the end of the activity, and call controller's returnValues() method to return values from the front call.
7. If needed, implement the onSaveInstanceState() and the onRestoreInstanceState() methods, to respectively save and restore information when Android™ has to suspend the application.

**Note:** In any case, the IFunctionCall class must either call the controller's returnValues() or raiseError() methods to give the control back to the Genero program.
**The com.fourjs.gma.extension.v1.IFunctionCall interface**

**Table 439: Methods of the com.fourjs.gma.extension.v1.IFunctionCall interface**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>void setFunctionCallController(IFunctionCallController controller)</code></td>
<td>This method binds the front call function controller object to the function body object. The <code>controller</code> parameter is the <code>IFunctionCallController</code> object to bind with the front call function body object.</td>
</tr>
<tr>
<td><code>abstract void invoke(Object[] args) throws IllegalArgumentException</code></td>
<td>This method performs the front call. It will be called when the front call is executed from the Genero program. The <code>args</code> parameter is a variable list of parameters passed to the front call. This corresponds to the third argument of <code>ui.Interface.frontCall</code> on page 526.</td>
</tr>
<tr>
<td><code>void onSaveInstanceState(Bundle state)</code></td>
<td>Saves the state of an ongoing function call when Android™ needs to suspend the application. The <code>state</code> parameter is the bundle to save the state to.</td>
</tr>
<tr>
<td><code>void onRestoreInstanceState(Bundle state)</code></td>
<td>Restores the state of an ongoing function call, when Android™ needs to restore the application. The <code>state</code> parameter is the bundle to restore the state from.</td>
</tr>
<tr>
<td><code>void onActivityResult(int resultCode, Intent data)</code></td>
<td>Callback invoked when an activity started through <code>IFunctionCallController.startActivityForResult</code> finishes. The <code>resultCode</code> parameter is the integer result code returned by the child activity through its <code>setResult()</code> method. The <code>data</code> parameter is an Intent object, which can return result data to the caller (various data can be attached to Intent “extras”).</td>

## The com.fourjs.gma.extension.v1.IFunctionCallController interface

### Table 440: Methods of the com.fourjs.gma.extension.v1.IFunctionCallController interface

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
</table>
| void returnValues(IFunctionCall functionCall, Object... values) | Notifies the controller that the front call function call has finished successfully. To be called typically at the end of the IFunctionCall.invoke() method.  
  
  The functionCall parameter is the current IFunctionCall object invoked.  
  
  The values parameter defines the variable list of front call function return values. This corresponds to the fourth parameter of ui.Interface.frontCall on page 526. |
| void raiseError(IFunctionCall functionCall, String message) | Notifies the controller of an error in the front call function call. This leads to a BDL runtime exception. To be called if needed within the IFunctionCall.invoke() method.  
  
  The functionCall parameter is the current IFunctionCall object invoked.  
  
  The message parameter holds the error message to be returned to the Genero program in the second part of the error -6333 message (see front call error handling in ui.Interface.frontCall on page 526). |
| void startActivity(IFunctionCall functionCall, Intent intent) | Starts a new activity. The function call won't be notified of the end of the activity. The Genero program will run in parallel of this activity. The behavior is similar to a RUN WITHOUT WAITING.  
  
  The functionCall parameter is the current IFunctionCall object invoked.  
  
  The intent parameter describes the activity to start. |
| void startActivityForResult(IFunctionCall functionCall, Intent intent) | Starts a new activity. The function call won't be notified of the end of the activity. The Genero program will remain blocked as long as the started activity isn't finished. The behavior is similar to a RUN.  
  
  The method IFunctionCall.onActivityResult will be called once the activity finishes.  
  
  The functionCall parameter is the current IFunctionCall object invoked.  
  
  The intent parameter describes the activity to start. |
| IClientHandler getClientHandler() | Returns an IClientHandler object, which is able to interact with Genero applications. A client handler can post action execution, cancel action future execution and check if an action execution is going to be executed. It can also define an application state change listener which triggers callbacks, when the app goes to pause, is resumed or is stopped.  
  
  For more details about the IClientHandler interface, see The com.fourjs.gma.extension.v1.IClientHandler interface on page 2138. |
| Activity getCurrentActivity() | Returns the current Activity object. Provided in case if you need to pass the current activity to an Android API requiring this object.  
  
  Important: Don't use the returned activity to start other activities (don't call Activity.startActivity or Activity.startActivityForResult), use the helpers of the current interface instead. |
The `com.fourjs.gma.extension.v1.IClientHandler` interface

Table 441: Methods of the `com.fourjs.gma.extension.v1.IClientHandler` interface

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void <code>postDialogAction(String action)</code></td>
<td>Post a dialog action to be triggered as soon as a BDL dialog is active and the given action name fits one of the active actions of the current dialog. The <code>action</code> parameter defines the name of the dialog action.</td>
</tr>
<tr>
<td>boolean <code>isDialogActionPending(String action)</code></td>
<td>Checks if a given action is still pending (the action was posted using <code>postDialogAction()</code>, but the action was still not activated by the Genero application and thus was not sent to the runtime). The <code>action</code> parameter defines the name of the dialog action.</td>
</tr>
</tbody>
</table>

**Calling the custom front call from BDL**

In the Genero program, use the `ui.Interface.frontCall()` API to call the front-end function. This method takes the front call module name as first parameter and the front call function name as second parameter. The front call module name is defined by the Java package name of the custom class implementing the `IFunctionCall` interface, and the front call function name is defined by the name of the class.

For example, if you implement the following front call function:

```
package com.mycompany.utilities;
...
public class GetPhoneId implements IFunctionCall {
...
```

The Genero program code must pass the Java package name "com.mycompany.utilities" as front call module name and the class name "GetPhoneId" as front call function name:

```
CALL ui.Interface.frontCall("com.mycompany.utilities", "GetPhoneId", ["John DOE"], [msg])
```

**Deploying the custom front call**

The compiled Java classes implementing the front calls must be included in the mobile application Android™ package (.apk), which is created in the Genero Studio deployment procedure. The same GMA package building rules apply for front calls and for simple Java extensions. See [Packaging custom Java extensions for GMA](#) on page 2102 for more details.

**Example**

The example implements a HelloWorld call as a front call module.

**HelloWorld.java**

```
package com.mycompany.testmodule;

import android.content.Intent;
import android.os.Bundle;
```
import com.fourjs.gma.extension.v1.IFunctionCall;
import com.fourjs.gma.extension.v1.IFunctionCallController;

public class HelloWorld implements IFunctionCall {
    private IFunctionCallController mController;

    @Override
    public void setFunctionCallController(IFunctionCallController controller) {
        mController = controller;
    }

    @Override
    public void invoke(Object[] args) throws IllegalArgumentException {
        if (args.length != 1) {
            throw new IllegalArgumentException("HelloWorld takes one argument");
        }
        mController.returnValue(this, "Hello " + args[0].toString());
    }

    @Override
    public void onSaveInstanceState(Bundle state) {
    }

    @Override
    public void onRestoreInstanceState(Bundle state) {
    }

    @Override
    public void onActivityResult(int returnCode, Intent data) {
    }
}

In order to invoke the HelloWorld front-end function, use the `ui.Interface.frontCall()` API in the Genero program:

```java
MAIN
    DEFINE msg STRING
    MENU
        ON ACTION frontcall ATTRIBUTES(TEXT="Call custom front call")
            CALL ui.Interface.frontCall("com.mycompany.testmodule", "HelloWorld", 
                          ["John DOE"], [msg])
        ON ACTION quit
            EXIT MENU
    END MENU
END MAIN
```

**Implement front call modules for GMI**

Custom front call modules for the iOS front-end are implemented by using the API for GMI front calls in Objective-C.

**GMI custom front call basics**

In order to extend the GMI with your own front calls, you must be familiar with Objective-C programming, and if you want to interface with iOS Apps, have a knowledge of the iOS API.
**Important:** Before starting with GMI front call implementation, you need to get the GMI package and unzip the archive into the FGLDIR directory, as described in the prerequisites sections of *Building iOS apps with Genero* on page 3332.

The API for GMI front calls is based on the `FrontCall` class and the `FrontCallHelper` and `FunctionCall` protocols. You can find these in the file `frontcall.h` in the in the `FGLDIR/include/gmi` directory.

To implement custom front calls, write a class which extends `FrontCall` and implements the “moduleName” and “execute:retCount:params” methods as well as the “initWithFunctionModuleHelper:” initializer.

Follow these steps to implement a custom front call module for the GMI:

1. Import the `frontcall.h` header file in your source.
2. Define an interface (`MyFrontCall`) which extends `FrontCall`.
3. Create the class (`MyFrontCall`) which implements this interface:
   a. Implement the `- (instancetype) initWithFunctionModuleHelper:(id)aHelper` initializer, calling `[super initWithFunctionModuleHelper:aHelper]` to pass the `FrontCallHelper` to the base implementation.
   b. Implement the `- (NSString*) moduleName` method, returning the name of the front call module.
   c. Implement the `- (void)execute:(NSString)name retCount:(int)retCount params:(NSArray)params` method, defining the body of your front calls. See below for details about the `execute` method.

**API to implement custom front calls in GMI**

To get parameters passed from the Genero program to the front call, and return values from the front call to the Genero program, use the following macros and methods of the `FrontCall` class:
<table>
<thead>
<tr>
<th>Macro / Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(void) FC_REQUIRED_PARAMS(count)</td>
<td>Checks that the number of parameters passed by the Genero program equals \textit{count}. This macro will raise an error in the Genero program if not enough parameters were passed.</td>
</tr>
<tr>
<td>(NSString *) FC_PARAM(index)</td>
<td>Get the string parameter passed to the front call, at the given position. If the parameters are of a different type, use the \texttt{doubleValue}, \texttt{floatValue} and \texttt{integerValue} methods on \texttt{NSString} or a \texttt{NSScanner}, to convert the parameter to the expected type.</td>
</tr>
<tr>
<td>(int) FC_PARAM_INT(index)</td>
<td>Get the int parameter passed to the front call, at the given position.</td>
</tr>
<tr>
<td>(void) intResult:(int) intValue</td>
<td>Ends the front call by returning one integer to Genero.</td>
</tr>
<tr>
<td>(void) doubleResult:(double) doubleValue</td>
<td>Ends the front call by returning one double to Genero.</td>
</tr>
<tr>
<td>(void) stringResult:(NSString <em>) stringValue</em></td>
<td>Ends the front call by returning one string to Genero.</td>
</tr>
<tr>
<td>(void) startResult</td>
<td>Initiate setting multiple result values. Must be followed by \texttt{add*} function calls and ended with \texttt{endResult}.</td>
</tr>
<tr>
<td>(void) addIntResult:(int) intValue</td>
<td>Add an integer to the list of results returned. To be used after a \texttt{startResult} call.</td>
</tr>
<tr>
<td>(void) addDoubleResult:(double) doubleValue</td>
<td>Add a double to the list of results returned. To be used after a \texttt{startResult} call.</td>
</tr>
<tr>
<td>(void) addStringResult:(NSString <em>) stringValue</em></td>
<td>Add a string to the list of results returned. To be used after a \texttt{startResult} call.</td>
</tr>
<tr>
<td>(void) endResult</td>
<td>Finalize the setting of multiple result values and return the results to the Genero program, with front call error code zero (indicating success).</td>
</tr>
<tr>
<td>(void) ok</td>
<td>Ends the front call without returning any value to Genero, indicating that the front call execution was successful.</td>
</tr>
<tr>
<td>(void) error(FCErrorCode):error</td>
<td>Ends the front call with a specific front call error code defined in \texttt{FCErrorCode} enum in \texttt{frontcall.h}, to indicate that front call execution failed, typically because of invalid parameters or invalid function name.</td>
</tr>
<tr>
<td>(void) errorWithMessage(NSString <em>) message</em></td>
<td>Ends the front call with front call return code -4 (maps to BDL error -6333), and a user-defined error message, that can be read with \texttt{ERR_GET()} in the Genero program.</td>
</tr>
</tbody>
</table>
Calling the custom front call from BDL

In the Genero program, use the `ui.Interface.frontCall()` API to call the front-end function. This method takes the front call module name as first parameter and the front call function name as second parameter.

The front call module name is defined by the string value returned from the `-(NSString *) moduleName*` method of your front call implementation, and the front call function name is passed to the `execute` method you implemented as first parameter (name).

For example, if you implement the following class:

```objective-c
#import <gmi/frontcall.h>
...
@interface MyFrontCall : FrontCall
...
@end
@class MyFrontCall
-(instancetype) initWithFunctionModuleHelper:(id)aHelper
{
    if (self = [super initWithFunctionModuleHelper:aHelper]) {
        ...
    }
    return self;
}
-(NSString*) moduleName{
    return @"MyModule";
}
-(void)execute:(NSString)name
retCount:(int)retCount
params:(NSArray)params
{
    [super execute:name retCount:retCount params:params];
    if ([[name lowercaseString] isEqualToString:@"myfrontcall"]) {
        ...
}
```

The Genero program code must pass the module name "MyModule" as front call module name and the class name "MyFrontCall" as front call function name:

```objective-c
CALL ui.Interface.frontCall("MyModule", "MyFrontCall", ["John DOE"],[msg])
```

Custom front call implementation details (execute method)

First of all, call the execute method of the parent `FrontCall` class, right at the top of the `execute` method:

```objective-c
[super execute:name retCount:retCount params:params];
```

The `execute` method must check the name of the front call function passed as parameter, to perform the expected code. This is the function name passed to the `ui.Interface.frontCall()` call in the Genero program:

```objective-c
if ([[name lowercaseString] isEqualToString:@"myfunction") {
```

Implement the body of the front call function in the `if()` block as follows:

Add an `assert()` line, to make sure that the number of return values match:

```objective-c
assert(retCount == 2);
```
In order to get the parameters passed from the Genero program, use the FC_* macros in the body of your front call function.

First, check that the number of parameters passed is correct, with the FC_REQUIRED_PARAMS(count) macro:

```
FC_REQUIRED_PARAMS(3);
...
```

Retrieve the parameters passed to the front call with the FC_PARAM(index) or FC_PARAM_INT(index) macros, which return a NSString* and an int respectively. If needed, use the doubleValue, floatValue and integerValue methods on NSString or a NSScanner, to convert the parameter to the expected type:

```
NSString * info = FC_PARAM(0);
int v1 = [FC_PARAM(1) integerValue];
double v2 = [FC_PARAM(2) doubleValue];
```

Implement the actual code of the front call.

To return values to Genero, use one of the helper methods such as intResult:value, if a single value must be returned to the Genero program. If more than one value must be returned, build a return set with the startResult, add*Result and endResult methods:

```
[self startResult];
[self addIntResult:isIpad];
[self addIntResult:canLocate];
[self endResult];
```

If the front call displays a UI (for example, an UIAlertController or displays a customer UIViewController), call the willSetResultLater method of the FrontCall class, to avoid having the control flow returned to the Genero program upon exit of the execute method:

```
[self willSetResultLater];
```

Additionally, if you call the willSetResultLater method, you need to call one of the result methods like stringResult at a later time.

**Deploying the custom front call**

The compiled Objective-C classes must be included in the iOS app build process.

The same app building rules apply for custom front calls as for C extensions.

See Building iOS apps with Genero on page 3332 for more details.

**Example**

In this example, the ExtensionFrontCall class implements two front calls: "isipad" and "logindialog".

We start by defining the interface for the custom front call module:

```
@interface ExtensionFrontCall : FrontCall<UIAlertViewDelegate>
@end
```

The ExtensionFrontCall class extends FrontCall, and implements the UIAlertViewDelegate protocol which is used by the "logindialog" front call.

Next, we start the implementation of the interface:

```
@implementation ExtensionFrontCall
-(instancetype)initWithFunctionModuleHelper:(id)aHelper
```
```objective-c
{
    if (self = [super initWithTitleWithFunctionModuleHelper:aHelper]) {
        return self;
    }

    -(NSString*) moduleName{
        return @"ExtensionFrontCall";
    }

    -(void)execute:(NSString*)name retCount:(int)retCount params:(NSArray*)params {
        [super execute:name retCount:retCount params:params];
        ...
    }

    ...
@end
```

We use the standard initializer which will be called by GMI on start-up and define "ExtensionFrontCall" as module name by returning it from the `moduleName` method.

We also start the implementation of the `execute` method by calling the super method.

Front call modules are compiled with the help of Makefile-gmi to a static IOS library and can be tested instantly on the command line with the help of Makefile-gmi. The static library can be either passed as an command line argument to gmibuildtool or placed in the `gmi` sub directory of a project directory. In both cases GMI detects the extension by enumerating all front call descendant classes upon start-up.

**Note:** When using more than one extension module, take care that class names and object/library file names are distinct.

### The `isipad` front call example

This front call simply returns the information on which device GMI is running. If it is an iPad, the integer 1 will be returned to the Genero program:

```objective-c
if ([[name lowercaseString] isEqualToString:@"isipad"]) {
    assert(retCount == 1);
    BOOL isIpad = UI_USER_INTERFACE_IDIOM() == UIUserInterfaceIdiomPad;
    [self startResult];
    [self addIntResult:isIpad];
    [self endResult];
}
```

After checking that only one return parameter was defined in Genero, the code identifies the platform with the `UI_USER_INTERFACE_IDIOM()` API and stores the result in the `isIpad` variable.

The next three lines return the result value to Genero, by starting a result block with `startResult`, adding an int to the return set with `addIntResult`, and finally calling `endResult` to send the result to the Genero program.

The same behavior can be achieved with a single line: `[self intResult:isIpad];`, since we only return one result value.

The Genero program calls the `isIPad` front call as follows:

```objective-c
DEFINE res INTEGER
CALL ui.Interface.frontCall( "ExtensionFrontCall", "isipad", [ ], [res] )
```
| Extending the language | 2145

The logindialog front call example
This front call displays a log-in dialog to the user. It expects two parameters (the title and the message for the log-in
dialog), and returns the log-in name and the password entered by the end user:
if([[name lowercaseString] isEqualToString:@“logindialog”]) {
assert(retCount == 2);
FC_REQUIRED_PARAMS(2);
NSString *title = FC_PARAM(0);
NSString *message = FC_PARAM(1);
UIAlertView *alert = [[UIAlertView alloc]
initWithTitle:title
message:message
delegate:self
cancelButtonTitle:NSLocalizedString(@"Cancel",@"Cancel")
otherButtonTitles:NSLocalizedString(@"OK",@"OK"),nil];
alert.alertViewStyle = UIAlertViewStyleLoginAndPasswordInput;
[alert show];
[self willSetResultLater];
}
We first check that two result values were set in Genero and that two parameters were supplied to the front call.
Then we use the FC_PARAM macro to fetch the parameters and assign them to NSStrings.
Then we allocate and initialize an UIAlertView with the given message and title and set the alertViewStyle
to "UIAlertViewStyleLoginAndPasswordInput", so that one plain text field and one password field will
be displayed on the alert.
In the initWithTitle call we also set "self" as the delegate of the alert so that we receive callbacks after user
input (we had added the UIAlertViewDelegate protocol to our ExtensionFrontCall interface definition).
Finally, we call willSetResultLater, to keep the control flow in iOS. If we don’t call this function, GMI
concludes the front call was not handled by the execute function (as none of the xxxResult functions was called
inside), and the front call will fail with a “Frontcall not found” error message.
The ExtensionFrontCall class implements the alertView:didDismissWithButtonIndex: method
from the UIAlertViewDelegate protocol:
pragma mark UIAlertViewDelegate(void)
alertView:(UIAlertView *)alertViewdidDismissWithButtonIndex:
(NSInteger)buttonIndex {
[self startResult];
if (buttonIndex != alertView.cancelButtonIndex) {
[self addStringResult:[alertViewtextFieldAtIndex:0].text];
[self addStringResult:[alertViewtextFieldAtIndex:1].text];
} else {
[self addStringResult:nil];
[self addStringResult:nil];
}
[self endResult];
}
This method is called after the user has tapped on one of the buttons and the view has been dismissed. Inside this
method, we first call startResult to enable adding more than one return value.
If the tapped button was not the Cancel button, we add the values of the log-in and password fields as strings to the
results and then call endResult to return the control flow to the Genero program.
The Genero program calls the log-in dialog front call as follows:
DEFINE ul, up STRING
CALL ui.Interface.frontCall( "ExtensionFrontCall", "logindialog",


Extending the language

Note: The file userextension.m of the GMI Extension project contains a complete example on how to write custom front calls.

Genero provides a command-line tool to build applications for iOS devices.

Implement front call modules for GBC
Custom front call modules for the Genero Browser Client (GBC) front-end are implemented by using JavaScript.

GBC custom front call basics
In order to extend the GBC with your own front calls, you must be familiar with JavaScript programming concepts.

Important: Custom front call module and function names must be registered in lowercase for the GBC front-end.

With GBC, front-end calls are JavaScript functions executed locally on the workstation where the browser is running.

Note: Executing front calls in the context of a web browser is limited to the OS functions a web browser can do. For example, it will not be possible to delete a file on the computer where the browser executes.

Customizing the GBC front-end
In order to integrate your custom front calls in the GBC front-end, you need to setup the GBC customization environment.

Basically, you will have to:
1. Setup GBC customization (install Node.js).
2. Extract the GBC front-end archive into a project-dir directory.
3. Copy your custom front calls JavaScript modules in the project-dir/customization.
4. Rebuild the GBC front-end with the grunt utility.
5. Configure the GAS to use the customized GBC front-end.

For more information, see the Genero Browser Client User Guide.

Structure of a custom front call JavaScript module
One JavaScript module will define a front call module implementing several front call functions.
The .js file must be copied into the project-dir/customization directory.

A custom front call JavaScript module must have the following structure:

```javascript
"use strict";

modulum('FrontCallService.modules.module-name', ['FrontCallService'],
/**
 * @param {gbc} context
 * @param {classes} cls
 */
function(context, cls) {
    context.FrontCallService.modules.module-name = {
        function-name: function (param1, ...) {
```
... user code ...

```javascript
\[
\begin{align}
&\downarrow
\text{return } [\text{values } ... ] \\
&\downarrow
\text{this.setReturnValues([values } ... ]); \\
&\downarrow
\}
\]

[...]
/* More functions can be defined for this module */
)
```

Where:

1. `module-name` is the name of the front call module, and corresponds to the first parameter of `ui.Interface.frontCall()`.
2. `function-name` is the name of the front call function, and corresponds to the second parameter of `ui.Interface.frontCall()`.
3. `param1, param2 ...` are the input values provided as third parameter of `ui.Interface.frontCall()`.
4. `values` is a JavaScript array containing the values to be returned in the last parameter of `ui.Interface.frontCall()`.

GBC custom front call API

The following JavaScript functions are provided to implement your custom front calls:

**Table 443: GBC custom front call API**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>this.parametersError( [\ message ] )</code></td>
<td>This function can be invoked when an invalid number of parameters is passed to the front call, in order to raise an exception in the BDL program.</td>
</tr>
<tr>
<td></td>
<td>The <code>message</code> parameter holds the error message to be returned to the Genero program in the second part of the error -6333 message (see front call error handling in <code>ui.Interface.frontCall</code> on page 526).</td>
</tr>
<tr>
<td><code>this.runtimeError( [\ message ] )</code></td>
<td>This function can be used to raise an exception in the BDL program, when the front call needs to warn the program that an error occurred.</td>
</tr>
<tr>
<td></td>
<td>The <code>message</code> parameter holds the error message to be returned to the Genero program in the second part of the error -6333 message (see front call error handling in <code>ui.Interface.frontCall</code> on page 526).</td>
</tr>
<tr>
<td><code>this.setReturnValues( values )</code></td>
<td>This function sets the values to be returned to the BDL program in the case of an asynchronous front call. See Asynchronous custom front calls on page 2148 for more details</td>
</tr>
</tbody>
</table>
Synchronous custom front calls

Synchronous front calls can directly return the front call values with a classic JavaScript `return` instruction, by specifying a JavaScript array.

The code example returns a single value:

```javascript
return ["Hello " + name + " !"];  
```

Following code example returns three values:

```javascript
return ["first", "second", "third"];  
```

Asynchronous custom front calls

JavaScript custom front calls sometimes require asynchronous programming. In such case, the custom front call API provides the `setReturnValues()` function to register values that must be returned to the BDL program.

For example, to return a value after a delay of 5 seconds:

```javascript
window.setTimeout(function () {
    this.setReturnValues(["After 5s, Hello " + name + " !"]);
}.bind(this), 5000);
```

Example

The JavaScript code in this example implements a synchronous and an asynchronous custom front call function:

```javascript
"use strict";

modulum('FrontCallService.modules.mymodule', ['FrontCallService'],
/**
 * @param {gbc} context
 * @param {classes} cls
 */
function(context, cls) {
    context.FrontCallService.modules.mymodule = {
        
        add_hello_sync: function (name) {
            if (name === undefined) {
                this.parametersError();
                return;
            }
            if (name.length === 0) {
                this.runtimeError("name shouldn't be empty");
                return;
            }
            return ["Hello, " + name + " !"];  
        } ,
        
        add_hello_async: function (name) {
            if (name === undefined) {
                this.parametersError();
                return;
            }
            if (name.length === 0) {
                this.runtimeError("name shouldn't be empty");
                return;
            }
            window.setTimeout(function () {
```
```javascript
this.setReturnValue(['"After 5s, Hello, " + name + " !"']);
}.bind(this), 5000);
```

From the Genero BDL program:

```bdbl
DEFINE res INTEGER
CALL ui.Interface.frontcall("mymodule","add_hello_sync", ["world"], [res])
CALL ui.Interface.frontcall("mymodule","add_hello_async", ["world"], [res])
```

## Web Components

Implement specialized form elements with Web Components.

For more details, see [Web components](#) on page 1825.

## Library reference

Reference for classes and functions provided as built-in or extension packages.

- Built-in functions on page 2149
- Utility functions on page 2181
- Built-in packages on page 2244
- Extension packages on page 2574
- Built-in front calls on page 2485
- File extensions on page 2997
- Genero BDL errors on page 2998

## Built-in functions

A *built-in function* is a predefined function that is part of the runtime system, or provided as a library function automatically loaded when a program starts. The built-in functions are part of the language.

Note that some operators such as `FIELD_TOUCHED(field-spec)` look like functions, but these are core language operators that are different in terms of semantics and order of precedence.

- Built-in functions on page 2151
- List of desupported built-in functions on page 2180
- The key code table on page 2181

### Related concepts

Utility functions on page 2181
A utility function is a function provided in a separate library; it is not built in the runtime system.
## Built-in functions

### Table 444: Built-in functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>arg_val(index INTEGER )</code> RETURNS STRING</td>
<td>Returns a command line argument by position.</td>
</tr>
<tr>
<td><code>arr_count()</code> RETURNS INTEGER</td>
<td>Returns the number of rows entered during an INPUT ARRAY statement.</td>
</tr>
<tr>
<td><code>arr_curr()</code> RETURNS INTEGER</td>
<td>Returns the current row in a DISPLAY ARRAY or INPUT ARRAY.</td>
</tr>
<tr>
<td><code>downshift(s STRING )</code> RETURNS STRING</td>
<td>Converts a string to lowercase.</td>
</tr>
<tr>
<td><code>err_get(messageId INTEGER )</code> RETURNS STRING</td>
<td>Returns the text corresponding to an error number.</td>
</tr>
<tr>
<td><code>err_print(messageId INTEGER )</code></td>
<td>Prints in the error line the text corresponding to an error number.</td>
</tr>
<tr>
<td><code>err_quit(messageId INTEGER )</code></td>
<td>Prints in the error line the text corresponding to an error number and terminates the program.</td>
</tr>
<tr>
<td><code>errorlog(message STRING )</code></td>
<td>Copies the string passed as parameter into the error log file.</td>
</tr>
<tr>
<td><code>fgl_buffertouched()</code> RETURNS INTEGER</td>
<td>Returns TRUE if the input buffer was modified in the current field.</td>
</tr>
<tr>
<td><code>fgl_db_driver_type()</code> RETURNS CHAR(3)</td>
<td>Returns the 3-letter identifier/code of the current database driver.</td>
</tr>
<tr>
<td><code>fgl_decimal_truncate(x DECIMAL, scale INTEGER )</code> RETURNS DECIMAL</td>
<td>Returns a decimal truncated to the precision passed as parameter.</td>
</tr>
<tr>
<td><code>fgl_decimal_sqrt(x DECIMAL )</code> RETURNS DECIMAL</td>
<td>Computes the square root of the decimal passed as parameter.</td>
</tr>
<tr>
<td><code>fgl_decimal_exp(x DECIMAL )</code> RETURNS DECIMAL</td>
<td>Returns the value of Euler's constant (e) raised to the power of the decimal passed as parameter.</td>
</tr>
<tr>
<td><code>fgl_decimal_power(x DECIMAL )</code> RETURNS DECIMAL</td>
<td>Returns the natural logarithm of the decimal passed as parameter.</td>
</tr>
</tbody>
</table>
arg_val()
Returns a command line argument by position.

Syntax

```
arg_val(
    index INTEGER )
RETURNS STRING
```

1. `index` is an integer defining the argument position.

Usage

This function provides a mechanism for passing values to the program through the command line that invokes the program. You can design a program to expect or allow arguments after the name of the program in the command line. The `index` parameter defines the argument to be returned. 0 returns the name of the program, 1 returns the first argument.

Like all built-in functions, `arg_val()` can be invoked from any program block. You can use it to pass values to MAIN, which cannot have formal arguments, but you are not restricted to calling `arg_val()` from the MAIN statement.

Use the `arg_val()` function to retrieve individual arguments during program execution. Use the `num_args()` function to determine how many arguments follow the program name on the command line.

If `index` is greater than 0, `arg_val(index)` returns the command-line argument used at a given position. The value of `index` must be between 0 and the value returned by `num_args()`, the number of command-line arguments. The expression `arg_val(0)` returns the name of the application program.

If the argument is negative or greater than `num_args()`, the method returns NULL.

Related concepts

- `num_args()` on page 2154
  Returns the number of program arguments.
- NULL on page 502
  The NULL constant is provided as the "nil" value.

arr_count()
Returns the number of rows entered during an INPUT ARRAY statement.

Syntax

```
arr_count()
RETURNS INTEGER
```

Usage

Use `arr_count()` to determine the number of program records that are currently stored in a static program array used by the INPUT ARRAY instruction.

This function is typically called inside or after INPUT ARRAY or DISPLAY ARRAY statement.

`arr_count()` returns a positive integer, corresponding to the index of the furthest record within the static program array that the user accessed. Not all the rows counted by `arr_count()` necessarily contain data (for example, if the user presses the Down key more times than there are rows of data.

This function is not required when using dynamic arrays. In such case, the total number of rows in defined by the `array.getLength()` method after the dialog, or by the `ui.Dialog.getArrayLength()` method during the dialog execution.
Related concepts
Editable record list (INPUT ARRAY) on page 1425
The INPUT ARRAY instruction provides always-editable record list handling in an application form.

Record list (DISPLAY ARRAY) on page 1394
The DISPLAY ARRAY instruction provides record list navigation in an application form, with optional record modification actions.

arr_curr() on page 2153
Returns the current row in a DISPLAY ARRAY or INPUT ARRAY.

Syntax
```
arr_curr()
RETURNS INTEGER
```

Usage
The arr_curr() function returns an integer value that identifies the current row of a list of rows in an INPUT ARRAY or DISPLAY ARRAY instruction.

The first row is numbered 1.

Important: The row index returned by the arr_curr() function is constant in the context of a dialog block, even when removing rows from the array by program.

The arr_curr() and scr_line() functions can return different values if the program array is larger than the screen array.

The arr_curr() can be used to get the index of the last current row, after the execution of the dialog.

In multiple dialogs implementing several list controllers, consider using the ui.Dialog.getCurrentRow() method instead of arr_curr() to get the current row of a specific list identified by its screen array.

Related concepts
Handling the current row on page 1736
Query and control the current row in a read-only or editable list of records.

downshift()
Converts a string to lowercase.

Syntax
```
downshift(
    s STRING
) RETURNS STRING
```

1. s is the character string to convert to lowercase letters.

Usage
The downshift() function returns a string value in which all uppercase characters in its argument are converted to lowercase.

The character conversion depends on locale settings (the LC_CTYPE environment variable). Non-alphabetic or lowercase characters are not altered.
Related concepts

upshift() on page 2180
Converts a string to uppercase.

scr_line()
Returns the index of the current row in the screen array.

Syntax

```c
scr_line()
RETURNS INTEGER
```

Usage

The `scr_line()` function returns the index of the current row in the screen array. It is typically used inside a `DISPLAY ARRAY` or `INPUT ARRAY` statement.

**Important:** When using new graphical objects such as `TABLE` containers, this function can return an invalid screen array line number, because the current row may not be visible if the user scrolls in the list with scrollbars.

Do not confuse `scr_line()` with `arr_curr()`, the first returns the index of the current row in the form screen array, and the second returns the index of the current row in the program variable.

Related concepts

Screen records / arrays on page 1147
Form fields can be grouped in a `screen record` or `screen array` definition.

`arr_curr()` on page 2153
Returns the current row in a `DISPLAY ARRAY` or `INPUT ARRAY`.

num_args()
Returns the number of program arguments.

Syntax

```c
num_args()
RETURNS INTEGER
```

Usage

Returns the number of arguments passed to the program.

The function returns 0 if no arguments are passed to the program.

Related concepts

`arg_val()` on page 2152
Returns a command line argument by position.

err_get()
Returns the text corresponding to an error number.

Syntax

```c
err_get(
    messageId INTEGER
)
RETURNS STRING
```

1. `messageId` is a runtime error or an Informix® SQL error.
Usage

The `err_get()` function returns the error message corresponding to the number passed as parameter. This can be a Genero BDL error (like -6324), or an IBM® Informix® SQL error message.

**Important:** IBM® Informix® SQL message numbers can only be supported, if the program is connected to an Informix database, and an SQL error occurred just before calling this function. Do not use this function in the context of SQL execution, when using different type of database servers.

**Related reference**

Genero BDL errors on page 2998
System error messages sorted by error number.

`err_print()`

Prints in the error line the text corresponding to an error number.

**Syntax**

```plaintext
err_print( messageId INTEGER )
```

1. `messageId` is a runtime error or an Informix® SQL error.

Usage

The `err_print()` function displays to the screen the error message corresponding to the number passed as parameter. The message will be displayed in the error line defined by the program.

**Important:** IBM® Informix® SQL message numbers can only be supported, if the program is connected to an Informix database, and an SQL error occurred just before calling this function. Do not use this function in the context of SQL execution, when using different type of database servers.

**Related reference**

Genero BDL errors on page 2998
System error messages sorted by error number.

`err_quit()`

Prints in the error line the text corresponding to an error number and terminates the program.

**Syntax**

```plaintext
err_quit( messageId INTEGER )
```

1. `messageId` is a runtime error or an Informix® SQL error.

Usage

The `err_quit()` function prints the error message corresponding to the number passed as parameter. The message will be displayed in standard error stream and the program will terminate.

**Important:** IBM® Informix® SQL message numbers can only be supported, if the program is connected to an Informix database, and an SQL error occurred just before calling this function. Do not use this function in the context of SQL execution, when using different type of database servers.

**Related reference**

Genero BDL errors on page 2998
System error messages sorted by error number.

**errorlog()**
Copies the string passed as parameter into the error log file.

**Syntax**

```plaintext
errorlog(
  message  STRING )
```

1. *message* is the character string to be inserted in the error log file.

**Usage**
The **errorlog()** function writes the passed string in the current error log file. The error log file is defined by a call to the **startlog()** function.

**Important:** Sensitive data may be written to the **startlog()** file. Make sure that the log output produced by **errorlog()** calls is written to files that can only be read by application administrators.

Use this function to identify errors in programs and to customize error handling. The error log functions can also be used to trace the way a program is used in order to improve it, record work habits, or help to detect attempts to breach security.

**Related concepts**
**startlog()** on page 2179
Initializes error logging and opens the error log file passed as the parameter.

**fgl_buffertouched()**
Returns **TRUE** if the input buffer was modified in the current field.

**Syntax**

```plaintext
fgl_buffertouched()
RETURNS INTEGER
```

**Usage**
The function returns **TRUE** if the input buffer has been modified after the current field was selected (i.e. got the focus).

Call this function in **AFTER FIELD, AFTER INPUT, AFTER CONSTRUCT, ON KEY, ON ACTION** blocks.

This function is **not** equivalent to **FIELD_TOUCHED()**: The modification status of **fgl_buffertouched()** is reset when entering a new field, while **FIELD_TOUCHED()** returns **TRUE** when a field was modified during the interactive instruction.

**fgl_db_driver_type()**
Returns the 3-letter identifier/code of the current database driver.

**Syntax**

```plaintext
fgl_db_driver_type()
RETURNS CHAR(3)
```

**Usage**
This function can be called after connecting to a database server with the **CONNECT** or **DATABASE** instructions, in order to identify the type of the target database with the driver type.
Returned value is the 3-letter driver code, in lower case, such as "ifx", "ora", "db2", etc.
See the drivers table for more details about the list of database driver types.

The function returns NULL if there is no current database driver (for example, if database connection is not yet established).

**Related concepts**

**Solution 1: Use database specific serial generators** on page 563

**fgl_decimal_truncate()**

Returns a decimal truncated to the precision passed as parameter.

**Syntax**

```
fgl_decimal_truncate (  
  x DECIMAL,  
  scale INTEGER )  
RETURNS DECIMAL
```

1. \(x\) is the decimal to be converted.
2. \(scale\) defines the number of digits after the decimal point.

**Usage**

This function truncates the decimal to the number of decimal digits specified.

The value is not rounded, it is just truncated. For example, when truncating 12.345 to 2 decimal digits, the result will be 12.34, not 12.35.

**fgl_decimal_sqrt()**

Computes the square root of the decimal passed as parameter.

**Syntax**

```
fgl_decimal_sqrt (  
  x DECIMAL )  
RETURNS DECIMAL
```

1. \(x\) is the decimal to be computed.

**fgl_decimal_exp()**

Returns the value of Euler's constant (\(e\)) raised to the power of the decimal passed as parameter.

**Syntax**

```
fgl_decimal_exp (  
  x DECIMAL )  
RETURNS DECIMAL
```

1. \(x\) is the decimal to be computed.

**fgl_decimal_logn()**

Returns the natural logarithm of the decimal passed as parameter.

**Syntax**

```
fgl_decimal_logn (  
  x DECIMAL )
```
**fgl_decimal_power()**

**Returns** DECIMAL

1. *x* is the decimal to be computed.

**Syntax**

```python
fgl_decimal_power(
    x DECIMAL,
    y DECIMAL
)
RETURNS DECIMAL
```

1. *x* is the decimal to be raise to the power of *exponent*.
2. *y* is the exponent.

**Usage**

Unlike the ** operator, the *fgl_decimal_power()* function supports real numbers for the exponent.

**fgl_dialog_getbuffer()**

**Returns** the text of the input buffer of the current field.

**Syntax**

```python
fgl_dialog_getbuffer()
RETURNS STRING
```

**Usage**

The *fgl_dialog_getbuffer()* function returns the content of the input buffer of the current field. It must be used in INPUT, INPUT ARRAY and CONSTRUCT blocks.

The function is especially useful in a **CONSTRUCT** instruction, because there is no variable associated to fields in this case.

Consider using the *ui.Dialog.getFieldBuffer()* method instead.

**Related concepts**

- **fgl_dialog_setbuffer()** on page 2158
  Sets the input buffer of the current field.
- **GET_FLDBUF()** on page 338
  The GET_FLDBUF() operator returns as character strings the current values of the specified fields.

**fgl_dialog_setbuffer()**

**Sets** the input buffer of the current field.

**Syntax**

```python
fgl_dialog_setbuffer(
    value STRING
)
```

1. *value* is the text to set in the current input buffer.
Usage

In the default buffered input mode, this function modifies the input buffer of the current field; the corresponding input variable is not assigned. It makes no sense to call this function in BEFORE FIELD blocks of INPUT and INPUT ARRAY. However, if the statement is using the UNBUFFERED mode, the function will set both the field buffer and the program variable. If the string set by the function does not represent a valid value that can be stored by the program variable, the buffer and the variable will be set to NULL.

The fgl_dialog_setbuffer() function must be used in INPUT, INPUT ARRAY and CONSTRUCT blocks.

This function sets the modification flag for both FIELD_TOUCHED() and fgl_buffertouched() functions. There is a slight difference between both functions. The modification flag for fgl_buffertouched() is reset to FALSE when entering the field.

The function is especially useful in a CONSTRUCT instruction, because there is no variable associated with fields in this case.

Related concepts

fgl_dialog_getbuffer() on page 2158
Returns the text of the input buffer of the current field.

The buffered and unbuffered modes on page 1618
The buffered and unbuffered mode control the synchronization of program variables and form fields.

fgl_dialog_getfieldname()

Returns the name of the current input field.

Syntax

```plaintext
fgl_dialog_getfieldname()
RETURNS STRING
```

Usage

This function returns the name of the current input field during a dialog execution. It must be use in INPUT, INPUT ARRAY or CONSTRUCT blocks.

Only the column part of the field name is returned (screen record name is omitted).

The fgl_dialog_getfieldname() is similar to the INFIELD() operator and fgl_dialog_infield() function.

fgl_dialog_infield()

This function checks for the current input field.

Syntax

```plaintext
fgl_dialog_infield(
   name STRING )
RETURNS INTEGER
```

1. name is the name if the form field.

Usage

The fgl_dialog_infield() function returns TRUE if the field name passed as the parameter is the current input field.

The function must be called in INPUT, INPUT ARRAY or CONSTRUCT blocks.
This function is the equivalent of the `INFIELD()` operator, except that the function takes a string expression as parameter, while the `INFIELD()` operator expects a hard-coded form field name.

**Related concepts**

*Screen records / arrays* on page 1147
Form fields can be grouped in a *screen record or screen array* definition.

**fgl_dialog_setcursor()**
This function sets the position of the edit cursor in the current field.

**Syntax**

```plaintext
fgl_dialog_setcursor(
    x INTEGER )
```

1. `x` is the edit cursor position in the text.

**Usage**

The `fgl_dialog_setcursor()` moves the edit cursor to the specified position in the current field. The function must be called in interactive instructions control blocks, when staying in the current field.

This function has only an effect when staying in the current field, it is not recommended to call it in an *AFTER FIELD* or *AFTER ROW* event for example.

Note that you can use `FGL_DIALOG_SETSELECTION()` to select a piece of text in a field.

**Important:** When using byte length semantics, the position is expressed in bytes. When using char length semantics, the unit is characters. This matters when using a multibyte locale such as UTF-8.

**Related concepts**

*fgl_dialog_getcursor() / fgl_getcursor()* on page 2162
Returns the position of the edit cursor in the current field.

*fgl_dialog_setselection()* on page 2163
Selects the text in the current field.

**fgl_dialog_setfieldorder()**
This function enables or disables field order constraint.

**Syntax**

```plaintext
fgl_dialog_setfieldorder(
    constrained INTEGER )
```

1. When `constrained` is TRUE, the field order is constrained. When `constrained` is FALSE, the field order is not constrained.

**Usage**

Typical applications control user input with *BEFORE FIELD* and *AFTER FIELD* blocks. In many cases the field order and the sequential execution of *AFTER FIELD* blocks is important in order to validate the data entered by the user. But with graphical front ends you can use the mouse to move to a field. By default the runtime system executes all *BEFORE FIELD* and *AFTER FIELD* blocks of the fields used by the interactive instruction, from the origin field to the target field selected by mouse click. If needed, you can force the runtime system to ignore all intermediate field triggers, by calling this function with a *FALSE* attribute.

This function must be called outside interactive dialog blocks, typically at the beginning of the program.

Consider using the `Dialog.fieldOrder` parameter when all programs are affected. The FGLPROFILE profile entry is the default when the `fgl_dialog_setfieldorder()` function is not used.
Consider using `OPTIONS FIELD ORDER FORM` for new developments with graphical rendering.

**fgl_dialog_setcurrline()**

This function moves to a specific row in a record list.

**Syntax**

```
fgl_dialog_setcurrline(
    screenLine INTEGER,
    row INTEGER )
```

1. `screenLine` is the line number in the form screen array.
2. `row` is the row number in the program array variable.

**Usage**

Moves to the row / screen line specified. See `fgl_set_arr_curr()` for more details.

To be called during a `DISPLAY ARRAY` or `INPUT ARRAY` instruction, inside `BEFORE DISPLAY / BEFORE INPUT` or `ON ACTION / ON KEY` blocks only.

The `screenLine` parameter is ignored in GUI mode.

**Related concepts**

- Screen records / arrays on page 1147
- Form fields can be grouped in a `screen record` or `screen array` definition.

**fgl_dialog_getbufferstart()**

Returns the row offset of the page to feed a paged display array.

**Syntax**

```
fgl_dialog_getbufferstart ()
RETURNS INTEGER
```

**Usage**

The `FGL_DIALOG_GETBUFFERSTART()` function returns the record list offset to be used to fill a page of a `DISPLAY ARRAY` running in `paged mode`.

This function must be called in the context of the `ON FILL BUFFER` trigger. The returned value is undefined if the function is used outside this trigger.

**fgl_dialog_getbufferlength()**

Returns the number of rows to feed a paged `DISPLAY ARRAY`.

**Syntax**

```
fgl_dialog_getbufferlength ()
RETURNS INTEGER
```

**Usage**

The `fgl_dialog_getbufferlength()` function returns the number of rows to be provided by the program to fill a page of a `DISPLAY ARRAY` running in `paged mode`.

This function must be called in the context of the `ON FILL BUFFER` trigger. The returned value is undefined if the function is used outside this trigger.
fgl_dialog_getcursor() / fgl_getcursor()
Returns the position of the edit cursor in the current field.

Syntax

```c
fgl_dialog_getcursor()
RETURNS INTEGER
```

Usage

The `fgl_dialog_getcursor()` function can be used in conjunction with `fgl_dialog_getselectionend()` to get the position of the edit cursor and the piece of text that is selected in the current field.

**Important:** When using byte length semantics, the position is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

Related concepts

- `fgl_dialog_getselectionend()` on page 2162
  Returns the position of the last selected character in the current field.
- `fgl_dialog_setcursor()` on page 2160
  This function sets the position of the edit cursor in the current field.
- `fgl_dialog_setselection()` on page 2163
  Selects the text in the current field.

fgl_dialog_getkeylabel()
Returns the label associated to a key for the current interactive instruction.

Syntax

```c
fgl_dialog_getkeylabel (  
  keyName STRING  
)  
RETURNS STRING
```

1. `keyName` is the logical name of a key such as F11 or DELETE, INSERT, CANCEL.

Usage

The `fgl_dialog_getkeylabel()` function returns the label defined for the function or control key passed as parameter, for the current interactive instruction.

This function returns the key labels defined for the current dialog. There are different levels of key label definitions. This function is provided for backward compatibility, use action defaults to define action view texts.

Related concepts

- Setting action key labels on page 1676
  Labels can be defined to decorate buttons controlled by ON KEY / COMMAND KEY action handlers.
- Configuring actions on page 1646
  Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

fgl_dialog_getselectionend()
Returns the position of the last selected character in the current field.

Syntax

```c
fgl_dialog_getselectionend()
```
Usage

The `fgl_dialog_getselectionend()` function returns the edit cursor position of the last selected character in the text of the current field.

**Important:** When using byte length semantics, the position is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

The function returns zero if the complete text is selected.

The edit cursor position returned by `fgl_dialog_getcursor()` will be lower as the position returned by `fgl_dialog_getselectionend()` if the text has been selected backwards.

**Related concepts**

- `fgl_dialog_getcursor()` / `fgl_getcursor()` on page 2162
  Returns the position of the edit cursor in the current field.
- `fgl_dialog_setselection()` on page 2163
  Selects the text in the current field.

**fgl_dialog_setkeylabel()**

Sets the label associated to a key for the current interactive instruction.

**Syntax**

```c
fgl_dialog_setkeylabel(
    keyName STRING,
    text STRING)
```

1. `keyName` is the logical name of a key such as F11 or DELETE, INSERT, CANCEL.
2. `text` is the text associated to the key.

**Usage**

The `fgl_dialog_setkeylabel()` associates a text description to a function or control key for the current dialog. Default action views (buttons that appears in the action panel of a window) will get the label displayed instead of the function or control key name.

This function defines the key labels for the current dialog. There are different levels of key label definitions.

**Note:** This feature is supported for backward compatibility. Consider using action attributes to define accelerator keys and decorate actions.

**Related concepts**

- Setting action key labels on page 1676
  Labels can be defined to decorate buttons controlled by ON KEY / COMMAND KEY action handlers.
- Configuring actions on page 1646
  Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

**fgl_dialog_setselection()**

Selects the text in the current field.

**Syntax**

```c
fgl_dialog_setselection(
    start INTEGER,
    end INTEGER)
```
1. *start* defines the edit cursor position.
2. *end* defines the selection end position.

Usage

A call to `fgl_dialog_setselection(cursor, end)` sets the text selection in the current form field. The *start* parameter defines the character position of the edit cursor (equivalent to `fgl_dialog_getcursor()` position), while *end* defines the character position of the end of the text selection (equivalent to `fgl_dialog_getselectionend()` position).

**Important:** When using byte length semantics, the positions are expressed in bytes. When using char length semantics, the unit is characters. This matters when using a multibyte locale such as UTF-8.

*start* can be lower, greater or equal to *end*.

This function has only an effect when staying in the current field, it is not recommended to call it in an AFTER FIELD or AFTER ROW event for example.

Related concepts

`fgl_dialog_getcursor() / fgl_getcursor()` on page 2162
Returns the position of the edit cursor in the current field.

`fgl_dialog_getselectionend()` on page 2162
Returns the position of the last selected character in the current field.

`fgl_drawbox()`
Draws a rectangle in the current window.

Syntax

```c
fgl_drawbox(
    height INTEGER,
    width INTEGER,
    posY INTEGER,
    posX INTEGER,
    color INTEGER
)
```

1. *height* is the height of the rectangle.
2. *width* is the width of the rectangle.
3. *posY* is the vertical coordinate (line) of the upper side of the rectangle.
4. *posX* is the horizontal coordinate (column) of the left side of the rectangle.
5. *color* is the color number (ignored).

Usage

The `fgl_drawbox()` function draws a rectangle based on the character terminal coordinates in the current open window.

Dimensions and coordinates are specified in grid cells unit (i.e. characters).

This function is provided for backward compatibility. A call to this function will be ignored if the current window is not SCREEN based. The function is supported to draw rectangles in text mode applications.

Related concepts

`fgl_drawline()` on page 2165
Draws a line in the current window (TUI and traditional mode).

**fgl_drawline()**

Draws a line in the current window (TUI and traditional mode).

**Syntax**

```plaintext
fgl_drawline(
    posY INTEGER,
    posX INTEGER,
    width INTEGER,
    type CHAR(1),
    color INTEGER)
```

1. `posY` is the vertical coordinate (line) of the start of the line.
2. `posX` is the horizontal coordinate (column) of the start of the line.
3. `width` is the width of the line.
4. `type` (ignored).
5. `color` is the color number (ignored).

**Usage**

The `fgl_drawline()` function draws a line based on the character terminal coordinates in the current open window.

Dimensions and coordinates are specified in grid cells unit (i.e. characters).

This function is provided for backward compatibility. A call to this function will be ignored if the current window is not SCREEN based. The function is supported to draw lines in text mode applications.

**Related concepts**

- `fgl_drawbox()` on page 2164
- Draws a rectangle in the current window.

**fgl_eventloop()**

Waits for a user interaction event.

**Syntax**

```plaintext
fgl_eventloop()
RETURNS BOOLEAN
```

**Usage**

The `fgl_eventloop()` function is used to implement the parallel dialog main event loop, in conjunction with `START DIALOG / TERMINATE DIALOG` instructions, used to register and end parallel dialogs.

The function waits until a user interaction event occurs and returns `TRUE` or `FALSE` to indicate if the event loop must continue or stop. It is typically used in a `WHILE / END WHILE` loop:

```plaintext
WHILE fgl_eventloop()
END WHILE
```

Parallel dialogs are registered with the `START DIALOG` instruction. As long as at least one parallel dialog is registered, the `fgl_eventloop()` function returns `TRUE`. When the last parallel dialog is ended with a `TERMINATE DIALOG` instruction, the `fgl_eventloop()` function returns `FALSE` and the even loop is stopped.

**Related concepts**

- `WHILE` on page 352
The **WHILE** statement executes a block of statements until the specified condition becomes false.

**Understanding parallel dialogs** on page 1601

**Parallel dialogs** allow to control several forms simultaneously.

**Parallel dialogs for split views** on page 1804

In order to control the left-hand and right-hand split view content, you must implement two parallel dialogs, each dedicated to a pane.

**fgl_getenv()**

Returns the value of the environment variable.

**Syntax**

```c
fgl_getenv(  
    name  STRING  )  
RETURNS STRING
```

1. *name* is the name of the environment variable.

**Usage**

The argument of `fgl_getenv()` must be the name of an environment variable.

If the requested value exists in the current user environment, the function returns the value of that variable. If the specified environment variable is not defined, the function returns a `NULL` value. If the environment variable is defined but does not have a value assigned to it, the function returns blank spaces.

**Related concepts**

**fgl_setenv()** on page 2175

Sets the value of an environment variable.

**fgl_gethelp()**

Reads the current help file, returning help text based on the help identifier.

**Syntax**

```c
fgl_gethelp(  
    id    INTEGER  )  
RETURNS STRING
```

1. *id* is the help text identifier.

**Usage**

The `fgl_gethelp()` function returns the text corresponding to the help message number passed as parameter. The text is read from the current help file. The current help file is defined by the `OPTIONS HELP_FILE` instruction.

**fgl_getpid()**

Returns the system process identifier.

**Syntax**

```c
fgl_getpid()  
RETURNS INTEGER
```
Usage
The \texttt{fgl_getpid()} function returns the current process identifier. The process identifier is provided by the operating system.

Related concepts
\texttt{fgl_system()} on page 2177
Runs a command on the application server.

\texttt{fgl_getfile()}
Retrieves a file from the front-end context to the virtual machine context.

Syntax
\begin{verbatim}
fgl_getfile(  
    remotePath STRING,  
    localPath STRING )
\end{verbatim}

1. \texttt{remotePath} is the path of the file to retrieve from the front-end context.
2. \texttt{localPath} is the path of the file to write in the virtual machine context.

Usage
The \texttt{fgl_getfile()} function uploads a file from the front-end workstation disk to the application server disk where \texttt{fglrn} is executed.

Important: Using this function can result in a security hole if you allow the end user to specify the file paths without control. There is not limitation on the file content or file paths: If the user executing the application on the server side is allowed to write critical server files, the program could transfer files from the client workstation and overwrite critical server files. On the other hand, critical files can be read from the client workstation and copied on the application server. It is in the hands of the programmer to implement file path and/or file content restrictions in the programs using \texttt{fgl_getfile()}.

When the front-end is located on a mobile device (GMA or GMI), the \texttt{fgl_getfile()} function can take an opaque file path as first argument, to identify a local device resource returned from a front call such as \texttt{choosePhoto} on page 2548, \texttt{takeVideo} on page 2561. This allows you to retrieve the media file into the virtual machine context, for persistent storage, and to share it with applications running on other devices. This \texttt{fgl_getfile()} feature can be used with a standalone app running on the device, or a client/server app executing on a server and displaying on the device. For more details, see Runtime images on page 1052.

Related concepts
\texttt{Types of Genero Mobile apps} on page 3291
Genero supports different types of mobile app architectures: development mode, standalone apps, partially-connected apps, and client-server apps.

\texttt{fgl_putfile()} on page 2172
Transfers a file from the virtual machine context to the front end context.

\texttt{fgl_getkey()}
Waits for a keystroke and returns the key number.

Syntax
\begin{verbatim}
fgl_getkey ()
\end{verbatim}

\texttt{fgl_getkey()} waits for a keystroke and returns the key code corresponding to the pressed physical key.
It is recommended to only use this function in text mode.

Unlike fgl_lastkey(), which can return a value indicating the logical effect of whatever key the user pressed, fgl_getkey() returns an integer representing the key code of the physical key that the user pressed. The fgl_getkey() function recognizes the same codes for keys that the fgl_keyval() function returns. Unlike fgl_keyval(), which can only return keystrokes that are entered during dialogs, fgl_getkey() can be called outside a dialog context.

**Related concepts**

fgl_lastkey() on page 2171
Returns the key code corresponding to the logical key that the user most recently typed in the form.

fgl_getkeylabel()
Returns the default label associated to a key.

**Syntax**

```c
fgl_getkeylabel(
    keyValue STRING )
RETURNS STRING
```

1. keyValue is the logical name of a key such as F11 or DELETE, INSERT, CANCEL.

**Usage**

The fgl_getkeylabel() function returns the default label defined for the function or control key passed as parameter.

This function returns the default key labels defined for all dialogs. There are different levels of key label definitions.

This function is provided for backward compatibility, use action defaults to define action view texts.

**Related concepts**

Setting action key labels on page 1676
Labels can be defined to decorate buttons controlled by ON KEY/COMMAND KEY action handlers.

Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

fgl_getresource()
Returns the value of an FGLPROFILE entry.

**Syntax**

```c
fgl_getresource(
    name STRING )
RETURNS STRING
```

1. name is the FGLPROFILE entry name to be read.

**Usage**

The fgl_getresource() function reads the FGLPROFILE file(s) and returns the value defined for the entry passed as parameter.

If the entry does not exist in the configuration file, the function returns NULL.

Note that FGLPROFILE entry names are not case sensitive.
**fgl_getversion()**

Returns the product version number of Genero.

**Syntax**

```
fgl_getversion()
RETURNS STRING
```

**Usage**

The `fgl_getversion()` function returns the product version number of the Genero Business Development Language runtime system.

**Important:** This function is provided for debugging only; do not write business code dependent on the build number. The format of the returned value is subject of change in future versions.

**fgl_getwin_height()**

Returns the number of rows of the current window.

**Syntax**

```
fgl_getwin_height()
RETURNS INTEGER
```

**Usage**

The `fgl_getwin_height()` function returns the height of the current window, in character units.

This function is provided for text mode applications, in GUI mode, windows are re-sizeable and thus their height is variable.

**Related concepts**

* `fgl_getwin_width()` on page 2169

**fgl_getwin_width()**

Returns the width of the current window as a number of columns.

**Syntax**

```
fgl_getwin_width()
RETURNS INTEGER
```

**Usage**

The `fgl_getwin_width()` function returns the width of the current window, in character units.

This function is provided for text mode applications, in GUI mode, windows are re-sizeable and thus their width is variable.

**Related concepts**

* `fgl_getwin_height()` on page 2169
Returns the number of rows of the current window.

**fgl_getwin_x()**
Returns the horizontal position of the current window.

**Syntax**

```c
fgl_getwin_x()
RETURNS INTEGER
```

**Usage**

The `fgl_getwin_x()` function returns the horizontal coordinate of the top/left corner of the current window. This function is provided for text mode applications, in GUI mode, windows are movable and thus their position is variable.

**Related concepts**

- `fgl_getwin_y()` on page 2170
  Returns the vertical position of the current window.

**fgl_getwin_y()**
Returns the vertical position of the current window.

**Syntax**

```c
fgl_getwin_y()
RETURNS INTEGER
```

**Usage**

The `fgl_getwin_y()` function returns the vertical coordinate of the top/left corner of the current window. This function is provided for text mode applications, in GUI mode, windows are movable and thus their position is variable.

**Related concepts**

- `fgl_getwin_x()` on page 2170
  Returns the horizontal position of the current window.

**fgl_keyval()**
Returns the key code of a logical or physical key.

**Syntax**

```c
fgl_keyval(
    keyName STRING
)
RETURNS INTEGER
```

1. `keyName` can be a single character, a digit, a printable symbol like @, #, $ or a special keyword such as ACCEPT.

**Usage**

`fgl_keyval()` can be used in form-related statements to examine a value returned by the `fgl_lastkey()` and `fgl_getkey()` functions.

Key names recognized by `fgl_keyval()` are: ACCEPT, HELP, NEXT, RETURN, DELETE, INSERT, NEXTPAGE, RIGHT, DOWN, INTERRUPT, PREVIOUS, TAB, ESC, ESCAPE, LEFT, PREVPAGE, UP, F1 through F64, CONTROL-character (where `character` can be any letter except A, D, H, I, J, L, M, R, or X).
The function returns NULL if the parameter does not correspond to a valid key.

If you specify a single character, `fgl_keyval()` considers the case and returns the ASCII value of the character. In all other instances, the function ignores the case of its argument, which can be uppercase or lowercase letters.

To determine whether the user has performed an action, such as inserting a row, specify the logical name of the action (such as INSERT) rather than the name of the physical key (such as F1). For example, the logical name of the Accept action is ACCEPT, while the default physical key is ESCAPE. To test if the key most recently pressed by the user corresponds to the Accept action, specify `fgl_keyval("ACCEPT")` rather than `fgl_keyval("ESCAPE")` or `fgl_keyval("ESC")`. Otherwise, if a key other than ESCAPE is set as the Accept key and the user presses that key, `fgl_lastkey()` does not return a code equal to `fgl_keyval("ESCAPE")`.

This function is provided for backward compatibility especially for TUI mode applications. `fgl_keyval()` is well supported in text mode, but this function can only be emulated in GUI mode, because the front-ends communicate with the runtime system with other events as keystrokes.

**Related concepts**
- `fgl_lastkey()` on page 2171
  Returns the key code corresponding to the logical key that the user most recently typed in the form.
- `fgl_getkey()` on page 2167
  Waits for a keystroke and returns the key number.

**Syntax**

```sql
fgl_lastkey()
RETURNS INTEGER
```

**Usage**

The `fgl_lastkey()` function returns a numeric code corresponding to the user's last keystroke before the function was called. For example, if the last key that the user pressed was a lowercase s, the function returns the code 115 (i.e. the ASCII character set code).

The value of `fgl_lastkey()` is undefined in a `MENU` statement.

The function returns NULL if no key has been pressed.

It is not required to know the specific key codes returned by `fgl_lastkey()`: The `FGL_KEYVAL()` function can be used to compare the key code of the last key pressed. The `FGL_KEYVAL()` function allows you to compare the last key pressed with a logical of physical key. For example, you do not need to know the physical key defined to validate a dialog, you can use the logical name "accept" instead. For a complete list of key codes and logical key names, see the Key code table.

Pay attention to the fact that this function is provided for backward compatibility. The abstract user interface protocol is based on logical events, not only key events. For example, in GUI mode, when selecting a new row with the mouse in a table, there is no key press as when moving in a static screen array in TUI mode. However, the runtime system tries to emulate as much as possible keystrokes from non-keystroke events.

**Related concepts**
- `fgl_keyval()` on page 2170
Returns the key code of a logical or physical key.

**fgl_mblen()**

Returns the number of bytes of the first character in a string.

**Syntax**

```plaintext
fgl_mblen(
    str STRING )
RETURNS INTEGER
```

1. `str` is any valid string expression.

**Usage**

The `fgl_mblen()` function returns the number of bytes used to encode the first character of the specified string, in the current application locale.

When using a multi-byte character set like UTF-8, you can use this function to compute the size in bytes of the first character in the string. Then, you can use this size to identify the position of the next character in the string. This function is mandatory to scan multi-byte strings.

If the parameter is NULL, the function returns zero.

If the parameter starts with an invalid multibyte character, the function returns -1.

**Related concepts**

length() on page 2178

Returns the number of the character string passed as parameter.

`fgl_width()` on page 2177

Returns the number of columns needed to represent the printed version of the expression.

**fgl_putfile()**

Transfers a file from the virtual machine context to the front end context.

**Syntax**

```plaintext
fgl_putfile(
    localPath STRING,
    remotePath STRING)
```

1. `localPath` is the path to the file to transmit from the virtual machine context.
2. `remotePath` is the path to the file to write on the front-end workstation file system. This parameter is ignored when the front-end is GBC in a web browser.

**Usage**

The `fgl_putfile()` function downloads a file from the application server disk where fglrun is executed to the front-end workstation disk.

**Important:** Using this function can result in a security hole if you allow the end user to specify the file paths without control. There is no limitation on the file content or file paths: If the user executing the application on the server side is allowed to read critical server files, the program could transfer these files on the client workstation. On the other hand, critical files can be written on the client workstation. It is in the hands of the programmer to implement file path and/or file content restrictions in the programs using `fgl_putfile()`.

When using the GBC front-end, the `remotePath` parameter is ignored, because browsers cannot directly write to the disk for security reasons. The basename of the filename specified in the `localPath` parameter will be the name of the file to be downloaded.
For example, when performing the following call (with GBC):

```sql
CALL fgl_putfile("/var/myapp/files/myfile.txt", "dummy")
```

The "myfile.txt" basename of the source filename will be used to create the local file, in the browser download directory.

**Related concepts**

fgl_getfile() on page 2167
Retrieves a file from the front-end context to the virtual machine context.

**fgl_report_print_binary_file()**
Prints a file containing binary data during a report.

**Syntax**

```c
fgl_report_print_binary_file(
    path STRING )
```

1. `path` is the name of the binary file.

**Usage**

This function prints a file containing binary data during a report.

This function is provided for backward compatibility and must only be using inside a REPORT routine.

**fgl_report_set_document_handler()**
Redirects the next report to an XML document handler.

**Syntax**

```c
fgl_report_set_document_handler(
    handler om.SaxDocumentHandler )
```

1. `handler` is the document handler variable.

**Usage**

This function attaches the specified XML document handler to the next executed report.

The function must be called before the execution of a START REPORT instruction not using the TO XML HANDLER clause.

**Note:** The fgl_report_set_document_handler() function is provided for backward compatibility. Use the TO XML HANDLER of START REPORT instead. See XML output for reports on page 1926 for more details.

**fgl_setkeylabel()**
Sets the default label associated to a key.

**Syntax**

```c
fgl_setkeylabel(
    keyName STRING,
    text STRING )
```

1. `keyName` is the logical name of a key such as F11 or DELETE, INSERT, CANCEL.
2. `text` is the text associated to the key.
Usage

**fgl_setkeylabel()** associates a text description to a function or control key. Default action views (buttons that appears in the action panel of a window) will get the label displayed instead of the function or control key name.

This function defines the default key labels for all dialogs. There are different levels of key label definitions.

**Note:** This feature is supported for backward compatibility. Consider using action attributes to define accelerator keys and decorate actions.

**Related concepts**

- Setting action key labels on page 1676
- Labels can be defined to decorate buttons controlled by **ON KEY / COMMAND KEY** action handlers.
- Configuring actions on page 1646
- Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

**fgl_scr_size()**

Returns the size of the specified screen array in the current form.

**Syntax**

```plaintext
fgl_scr_size(
    name STRING )
RETURNS INTEGER
```

1. *name* is the name of a screen-array in the current displayed form.

Usage

The **fgl_scr_size()** function takes the name of a screen array as parameter identifying an array in the currently opened form and returns an integer that corresponds to the number of screen records in that screen array.

This function is typically used with traditional text mode forms having screen arrays with a constant size, to display data in screen array rows with the **DISPLAY TO** instruction.

For modern GUI applications, consider using the **UNBUFFERED** mode in dialogs, to get automatic form field synchronization with program variables.

Error -1108 will be raised if the passed screen-array does not exits in the current form, and error -1114 is returned if no form is currently displayed.

**fgl_setsize()**

Sets the size of the main application window.

**Syntax**

```plaintext
fgl_setsize(
    height INTEGER,
    width INTEGER )
```

1. *height* is the number of lines of the window.
2. *width* is the number of columns of the window.

Usage

This function defines the size of the main window when using the **traditional GUI mode**.

**Related concepts**

- **fgl_settitle()** on page 2175
Sets the title of the current application window.

**ui.Interface.setSize** on page 2343
Specify the initial size of the parent container window.

### fgl_settitle()
Sets the title of the current application window.

#### Syntax

```
fgl_settitle(
    newTitle STRING)
```

1. `newTitle` is the text of the title.

#### Usage
The `fgl_settitle()` function defines the title of the current window, as well as the default title for new created windows.

This function is provided for backward compatibility, the title of a window can be defined with the **TEXT** attribute of a LAYOUT section.

**Related concepts**

**ui.Interface.setText** on page 2344
Defines the title for the program.

### fgl_setenv()
Sets the value of an environment variable.

#### Syntax

```
fgl_setenv(
    name STRING,
    value STRING)
```

1. `name` is the name of the environment variable.
2. `value` is the value to be set.

#### Usage
The `fgl_setenv()` function sets or modifies the value of an environment variable.

There is a little difference between Windows™ and UNIX™ platforms when passing a **NULL** as the `value` parameter:
On Windows platforms, the environment variable is removed, while on UNIX, the environment variable gets an empty value (i.e. it is not removed from the environment).

**Important:** You may experience unexpected results if you change environment variables that are already used by the current program - for example, when you are connected to INFORMIX and you change the INFORMIXDIR environment variable.

**Related concepts**

**fgl_getenv()** on page 2166
Returns the value of the environment variable.

**fgl_set_arr_curr()**
Moves to a specific row in a record list.

**Syntax**

```
fgl_set_arr_curr(
    row INTEGER )
```

1.  *row* is the row number is the program array variable.

**Usage**

This function is typically used to control navigation in a **DISPLAY ARRAY** or **INPUT ARRAY**, within an **ON ACTION** or **ON KEY** block. The function can also be used inside **BEFORE DISPLAY** or **BEFORE INPUT** blocks, to jump to a specific row when the dialog starts. It is not recommended to use this function in an other context.

Control blocks like **BEFORE ROW** and field/row validation in **INPUT ARRAY** are performed, as if the user moved to another row, except when the function is called in **BEFORE DISPLAY** or **BEFORE INPUT**.

When a new row is reached by using with this function, the first editable field gets the focus.

An alternative to the **fgl_set_arr_curr()** function is the **ui.Dialog.setCurrentRow()** method; however, the dialog class method will be used in a different programming pattern, as it does not trigger the control blocks like the built-in function.

**Related concepts**

- **Editable record list (INPUT ARRAY)** on page 1425
  The **INPUT ARRAY** instruction provides always-editable record list handling in an application form.
- **Record list (DISPLAY ARRAY)** on page 1394
  The **DISPLAY ARRAY** instruction provides record list navigation in an application form, with optional record modification actions.
- **arr_curr()** on page 2153
  Returns the current row in a **DISPLAY ARRAY** or **INPUT ARRAY**.

**fgl_sqldebug()**
Sets the SQL debug level from program code.

**Syntax**

```
fgl_sqldebug(
    level INTEGER )
```

1.  *level* is the SQL debug level to set. Zero resets the level defined by **FGLSQLDEBUG**.

**Usage**

In order to produce SQL debug messages, one uses normally the **FGLSQLDEBUG** environment variable. However, **FGLSQLDEBUG** will produce SQL debug messages for the whole life time of a program.

The **fgl_sqldebug()** function can be used to force SQL debug log for a particular piece of code:

- When calling **fgl_sqldebug()** with a value different from zero, it has the same effect as setting **FGLSQLDEBUG**.
- When calling **fgl_sqldebug()** with zero, it resets the SQL debug level defined by **FGLSQLDEBUG**.

**Related concepts**

- **Debugging SQL statements** on page 542
Set the FGLSQLDEBUG environment variable to print SQL debug info.

**fgl_system()**
Runs a command on the application server.

**Syntax**

```plaintext
fgl_system(
    program STRING )
```

1. *program* is the command line to be executed on the server.

**Usage**

The `fgl_system()` function suspends the execution of the program and executes the command passed as parameter on the application server where fglrun is executed. The command is executed in a new shell and the program is suspended until the command terminates.

When running the program in TUI mode, the terminal is switched to line mode before executing the command passed to the `fgl_system()` function.

This function is provided for backward compatibility. In older versions, the function could raise a terminal emulator on the front-end to show the command output on the workstation. This feature is no longer supported.

**fgl_width()**
Returns the number of columns needed to represent the printed version of the expression.

**Syntax**

```plaintext
fgl_width(
    str STRING )
RETURNS INTEGER
```

1. *str* is any valid string expression.

**Usage**

The `fgl_width()` function returns the number of columns that will be used if you display *str* on a text terminal.

If the parameter is **NULL**, the function returns zero.

The number of columns used by a character depends on the glyph (i.e. the graphical symbol used to draw the character on the screen). For example, an ASCII character like A uses one column, while one Chinese ideogram uses 2 columns (i.e. on a text terminal, the size of one Chinese ideogram takes the same size as AB).

Trailing blanks are counted in the length of the string.

**Related concepts**

- `length()` on page 2178
  Returns the number of the character string passed as parameter.
- `fgl_mblen()` on page 2172
  Returns the number of bytes of the first character in a string.

**fgl_window_getoption()**
Returns attributes of the current window.

**Syntax**

```plaintext
fgl_window_getoption(
    name STRING )
```
1. `name` is an window attribute name.

**Usage**

The `fgl_window_getoption()` function returns the value of the window attribute passed as parameter.

Possible parameters are: `name`, `x`, `y`, `width`, `height`, `formline`, `messageline`.

This function is provided for backward compatibility, do not use this function in modern GUI applications.

**length()**

Returns the number of the character string passed as parameter.

**Syntax**

```plaintext
length (
    str STRING )
RETURNS INTEGER
```

1. `str` is any valid character string expression supported by the language.

**Usage**

The `length()` function counts the length of a character string.

If the parameter is `NULL`, the function returns zero.

**Important:** When using byte length semantics, the length is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

**Related concepts**

`fgl_width()` on page 2177
Returns the number of columns needed to represent the printed version of the expression.

`fgl_mblen()` on page 2172
Returns the number of bytes of the first character in a string.

**set_count()**

Defines the number of rows containing explicit data in a static array used by the next dialog.

**Syntax**

```plaintext
set_count (
    count INTEGER )
```

1. `count` defines the number of explicit rows in the static array.

**Usage**

When using a static array in an `INPUT ARRAY` (with `WITHOUT DEFAULTS` clause) or a `DISPLAY ARRAY` statement, you must specify the number of rows in the array which contain explicit data. In typical applications, these array elements contain the values fetched from a `SELECT` statement.

`set_count()` must be called before a `DISPLAY ARRAY` or `INPUT ARRAY` statement.

The number of rows can also specified with the `COUNT` attribute of `INPUT ARRAY` and `DISPLAY ARRAY` statements.

When using a dynamic array, the number of rows is implicitly defined by the array.
**Related concepts**

**DYNAMIC ARRAY.getLength** on page 2258
Returns the length of the array.

**arr_curr()** on page 2153
Returns the current row in a DISPLAY ARRAY or INPUT ARRAY.

**fgl_set_arr_curr()** on page 2176
Moves to a specific row in a record list.

**showhelp()**
Displays a runtime help text.

**Syntax**

```
showhelp(  
    number INTEGER  )
```

1. *number* is the help message number in the current help file.

**Usage**

The `showhelp()` function displays a runtime help text, corresponding to its specified argument, from the current help file defined by the `OPTIONS HELP FILE` instruction.

In GUI mode, the help text will be displayed in a new pop-up window. In TUI mode, the help text is displayed in the whole screen.

**Related concepts**

**Message files** on page 1059
Message files centralize strings and larger texts identified by a number, that can be used in programs.

**startlog()**
Initializes error logging and opens the error log file passed as the parameter.

**Syntax**

```
call startlog(  
    path STRING  )
```

1. *path* is the name of the error log file.

**Usage**

Call `startlog()` in the MAIN program block to open or create an error log file. After `startlog()` has been invoked, a record of every subsequent error that occurs during the program execution is written in the error log file.

**Important:** Sensitive and personal data may be written to the output. Make sure that the log output is written to files that can only be read by application administrators.

The format of the error records appended to the error log file after each subsequent error is as follows:

```
Date: 03/06/99 Time: 12:20:20
Program error at "stock_one.4gl", line number 89.
SQL statement error number -239.
Could not insert new row - duplicate value in a UNIQUE INDEX column.
SYSTEM error number -100
ISAM error: duplicate value for a record with unique key.
```

To report specific application errors, use the `errorlog()` function to make an entry in the error log file.
If the argument of `startlog()` is not the name of an existing file, `startlog()` creates a new one. If the file already exists, `startlog()` opens it and positions the file pointer so that subsequent error messages can be appended to this file.

Example

```plaintext
MAIN
   CALL startlog("/tmp/error-" || fgl_getpid() || ".log")
   CALL errorlog("Current user is not allowed to perform this operation")
END MAIN
```

Related concepts

- `errorlog()` on page 2156
  Copies the string passed as parameter into the error log file.

- `Exceptions` on page 451
  Describes exception (error) handling in the programs.

Related reference

- `Genero BDL errors` on page 2998
  System error messages sorted by error number.

`upshift()`

Converts a string to uppercase.

Syntax

```plaintext
upshift ( 
   s STRING )
RETURNS STRING
```

1. `s` is the character string to convert to uppercase letters.

Usage

The `upshift()` function returns a string value in which all lowercase characters in its argument are converted to uppercase.

The character conversion depends on locale settings (the LC_CTYPE environment variable). Non-alphabetic or uppercase characters are not altered.

Related concepts

- `downshift()` on page 2153
  Converts a string to lowercase.

List of desupported built-in functions

</tbody>
</table>

**Utility functions**

A utility function is a function provided in a separate library; it is not built in the runtime system.

To use a utility function, declare the module where the function is defined with the IMPORT FGL instruction:

```
IMPORT FGL fgldialog
...
  CALL fgl_winmessage( ... )
```
For backward compatibility, utility functions are also grouped in a 42x library named libfgl4.js.42x, which can be linked to your programs.

The 42x library file, 42m modules and 42f forms are located in FGLDIR/lib. The sources of the utility functions and form files are provided in the FGLDIR/src directory.

- Database utility functions (IMPORT FGL fgldbutl) on page 2187
- Front-end dialog utility functions (IMPORT FGL fgldwinexec) on page 2191
- fglgallery utility functions (IMPORT FGL fglgallery) on page 2201
- fglsvgcanvas utility functions (IMPORT FGL fglsvgcanvas) on page 2211

### Common dialog utility functions (IMPORT FGL fgldialog)

**Table 447: Common dialog utility functions (fgldialog.4gl)**

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fgl_winbutton</td>
<td>Displays an interactive message box containing multiple choices, in a popup window.</td>
</tr>
<tr>
<td>fgl_winmessage</td>
<td>Displays an interactive message box containing text and OK button.</td>
</tr>
<tr>
<td>fgl_winprompt</td>
<td>Displays a dialog box containing a field that accepts a value.</td>
</tr>
<tr>
<td>fgl_winquestion</td>
<td>Displays an interactive message box with configurable Ok/Yes/No/Cancel/Ignore/Abort/Retry buttons.</td>
</tr>
<tr>
<td>fgl_winwait</td>
<td>Displays an interactive message box and waits for user validation.</td>
</tr>
</tbody>
</table>
fgl_winbutton()
Displays an interactive message box containing multiple choices, in a popup window.

Syntax

fgl_winbutton(  
    title STRING,  
    text STRING,  
    default STRING,  
    buttons STRING,  
    icon STRING,  
    danger SMALLINT )  
RETURNS STRING

1. title defines the title of the message window.
2. text specifies the string displayed in message window.
3. default indicates the default button to be pre-selected.
4. buttons defines a set of button labels separated by "|".
5. icon is the name of the icon to be displayed.
6. danger (for X11 only), number of the warnings item. Otherwise, this parameter is ignored.

Usage

Use the fgl_winbutton() function to open a message box and let the end user select an option in a set of buttons. The function returns the label of the button which has been selected by the user.

Use "\n" in text to separate lines (this does not work in TUI mode).

Supported names for the icon parameter are: information, exclamation, question, stop.

You can define up to 7 buttons that each have 10 characters.

If two buttons start with the same letter, the user will not be able to select one of them in the TUI mode.

The "&" before a letter for a button is displayed in TUI mode, or underlines the next letter in graphical front-ends.

This function is provided for backward compatibility, use a menu with "dialog" style instead.

Example

IMPORT FGL fgldialog
MAIN
    DEFINE answer STRING  
    LET answer = fgl_winbutton( "Media selection", "What is your favorite media?",  
                                "Lynx", "Floppy Disk|CD-ROM|DVD-ROM|Other", "question", 0)  
    DISPLAY "Selected media is: " || answer  
END MAIN

fgl_winmessage()
Displays an interactive message box containing text and OK button.

Syntax

fgl_winmessage(  
    title STRING,  
    text STRING,  
    icon STRING )

1. title defines message box title.
2. text is the text displayed in the message box. Use \n to separate lines.
3. *icon* is the name of the icon to be displayed.

**Usage**

The `fgl_winmessage()` function displays a message box to the end user.

**Important:** With front-ends implementing this function with the system dialog box API creating a modal window, the end user will have to close the modal window first, before continuing within the window of another program. Consider using a menu with "dialog" style instead, to not block other programs.

Supported names for the *icon* parameter are: information, exclamation, question, stop. Note that on some front-ends such as iOS devices, the native message popup window does not display an image.

On front-ends using a system dialog box API, the OK buttons will be automatically localized base on the operating system language settings. On other front-ends, the option buttons will be decorated depending on action default settings.

**Example**

```plaintext
IMPORT FGL fgldialog
MAIN
    CALL fgl_winmessage( "Title", "This is a critical message.", "stop")
END MAIN
```

**Related concepts**

*Configuring actions* on page 1646

Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

**fgl_winprompt()**

Displays a dialog box containing a field that accepts a value.

**Syntax**

```plaintext
fgl_winprompt( 
    x INTEGER,  
y INTEGER,  
text STRING,  
default STRING,  
length INTEGER,  
type INTEGER )
RETURNS STRING
```

1. *x* is the column position in characters.
2. *y* is the line position in characters.
3. *text* is the message shown in the box.
4. *default* is the default value.
5. *length* is the maximum length of the input value.
6. *type* is the data type of the return value.

**Usage**

The `fgl_winprompt()` function allows the end user to enter a value.

This function is provided for backward compatibility, you can also use your own input dialog with a customized form to get a value from the user. Or use the standard PROMPT instruction.

Possible values for the *type* parameter are: 0=CHAR, 1=SMALLINT, 2=INTEGER, 7=DATE, 255=invisible

Avoid passing NULL values.
Example

```plaintext
IMPORT FGL fgldialog
MAIN
  DEFINE answer DATE
  LET answer = fgl_winprompt( 10, 10, "Today", DATE, 10, 7 )
  DISPLAY "Today is " || answer
END MAIN
```

`fgl_winquestion()`
Displays an interactive message box with configurable Ok/Yes/No/Cancel/Ignore/Abort/Retry buttons.

Syntax

```plaintext
fgl_winquestion(
  title STRING,
  text STRING,
  default STRING,
  buttons STRING,
  icon STRING,
  danger SMALLINT )
RETURNS STRING
```

1. `title` is the message box title.
2. `text` is the message displayed in the message box. Use '\n' to separate lines (does not work on ASCII client).
3. `default` defines the default button that is preselected.
4. `buttons` defines the options. Must be a pipe-separated list of 2 or three options: ok, yes, no, cancel, abort, retry, ignore.
5. `icon` is the name of the icon to be displayed.
6. `danger` is supported for backward compatibility. This parameter is ignored.

Usage

The `fgl_winquestion()` function shows a question message box to the end user and waits for an answer.

**Important:** With front-ends implementing this function with the system dialog box API creating a modal window, the end user will have to close the modal window first, before continuing within the window of another program. Consider using a menu with "dialog" style instead, to not block other programs.

The function returns the label of the option which has been selected by the user.

Supported names for the `icon` parameter are: information, exclamation, question, stop. Note that on some front-ends such as iOS devices, the native message popup window does not display an image.

The `buttons` parameter defines the list of options that the user can select. Possible values are: ok, yes, no, cancel, abort, retry, ignore. You must specify a pipe-separated list of options, with a maximum of 3 options. For example: "ok", "yes\|no", "yes\|no\|cancel", "abort\|retry\|ignore".

**Important:** To display the popup window of this API, desktop and mobile front-ends use the platform specific message box API, with a predefined set of buttons. Some non-standard option combinations may not be supported, such as "ok\|yes\|abort". Furthermore, the order of the buttons depends also from platform standards. For example, with "abort\|retry\|ignore", the buttons can appear in the following order: [Retry] [Ignore] [Abort].

On front-ends using a system dialog box API, the option buttons will be automatically localized based on the operating system language settings. On other front-ends, the option buttons will be decorated to action default settings.
Example

```plaintext
IMPORT FGL fgldialog
MAIN
  DEFINE answer STRING
  LET answer = "yes"
  WHILE answer = "yes"
    LET answer = fgl_winquestion(
      "Procedure", "Would you like to continue ? ",
      "cancel", "yes|no|cancel", "question", 0)
  END WHILE
  IF answer = "cancel" THEN
    DISPLAY "Canceled."
  END IF
END MAIN
```

Related concepts

Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

fgl_winwait()
Displays an interactive message box and waits for user validation.

Syntax

```plaintext
fgl_winwait(
  text STRING )
```

1. `text` is the message displayed in the message box. Use `\n` to separate lines (not working on ASCII client).

Usage

The `fgl_winwait()` function displays a message to the end user and waits until the user presses the OK button.

Important: With front-ends implementing this function with the system dialog box API creating a modal window, the end user will have to close the modal window first, before continuing within the window of another program. Consider using a menu with "dialog" style instead, to not block other programs.
Database utility functions (IMPORT FGL fgldbutl)

Table 448: Database utility functions (fgldbutl.4gl)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db_get_database_type()</td>
<td>Returns the database type for the current connection.</td>
</tr>
<tr>
<td>db_get_sequence(id)</td>
<td>Generates a new sequence for a given identifier.</td>
</tr>
<tr>
<td>db_start_transaction()</td>
<td>Starts a nested transaction call.</td>
</tr>
<tr>
<td>db_finish_transaction(commit)</td>
<td>Terminates a nested transaction call.</td>
</tr>
<tr>
<td>db_is_transaction_started()</td>
<td>Indicates whether a nested transaction call is started.</td>
</tr>
</tbody>
</table>

**db_get_database_type()**

Returns the database type for the current connection.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```
db_get_database_type()
RETURNS STRING
```

**Usage**

After connecting to the database, you can get the type of the database server with this function.

**Important:** This function is deprecated, use the `fgl_dbdriver_type()` function instead.

Table 449: Codes returned by `db_get_database_type()` per database type

<table>
<thead>
<tr>
<th>DB Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASE</td>
<td>SAP® ASE</td>
</tr>
<tr>
<td>DB2</td>
<td>IBM® DB2®</td>
</tr>
<tr>
<td>HDB</td>
<td>SAP HANA®</td>
</tr>
<tr>
<td>IFX</td>
<td>IBM® Informix®</td>
</tr>
<tr>
<td>MDB</td>
<td>MariaDB</td>
</tr>
</tbody>
</table>
### db_get_sequence()
Generates a new sequence for a given identifier.

#### Syntax

```sql
db_get_sequence (    id STRING )
RETURNS BIGINT
```

1. *id* is the identifier of the sequence.

#### Usage

This function generates a new sequence from a register table created in the current database.

**Important:**

1. Needs a database table called SEQREG.
2. The function must be called inside a transaction block.

The table must be created as follows:

```sql
CREATE TABLE seqreg (    sr_name VARCHAR(30) NOT NULL,    sr_last BIGINT NOT NULL,    PRIMARY KEY (sr_name) )
```

Each time you call this function, the sequence is incremented in the database table and returned by the function.

It is mandatory to use this function inside a transaction block, in order to generate unique sequences.

#### Example

```plaintext
IMPORT FGL fgldbutl
MAIN
  DEFINE ns BIGINT, s INTEGER
  DATABASE mydb
  BEGIN WORK
    LET ns = db_get_sequence("mytable")
    INSERT INTO mytable VALUES ( ns, 'a new sequence' )
  COMMIT WORK
END MAIN
```

**Related concepts**

[Auto-incremented columns (serials)](page 562)
How to implement automatic record keys.

**db_start_transaction()**
Starts a nested transaction call.

**Syntax**

```plaintext
db_start_transaction()
RETURNS INTEGER
```

**Usage**

On most database engines, you can only have a unique transaction, that is started with `BEGIN WORK` and ended with `COMMIT WORK` or `ROLLBACK WORK`. But in some cases, you may need to do complex nested function calls, executing several SQL instruction that must all be grouped in a single transaction. The nested transaction utility functions help you to implement this.

With this nested transaction technique, you encapsulate transaction start and end within the utility function. Custom functions doing SQL operations can then be reused in different parts of your application: If the caller does not start the transaction, the called function will automatically start and end the transaction.

The `db_start_transaction()` function encapsulates the `BEGIN WORK` instruction to start a transaction, in order to implement nested transactions.

**Note:** These transaction encapsulation functions are provided for special cases, where the function call graph is complex. In general, it is recommended that you simply use the standard `BEGIN WORK / COMMIT WORK / ROLLBACK WORK` instructions to implement transaction blocks.

These transaction management functions execute a real transaction instruction at the boundaries of the subsequent start/finish calls.

**Example**

```plaintext
IMPORT FGL fgldbutl

MAIN
    DEFINE s INTEGER
    DATABASE mydb
    LET s = db_start_transaction() -- real BEGIN WORK
    IF s != 0 THEN DISPLAY "error 1" END IF
    WHENEVER ERROR CONTINUE
    UPDATE customer SET cust_name = 'Undef'
    WHENEVER ERROR STOP
    LET s = SQLCA.SQLCODE
    IF s != 0 THEN
        DISPLAY "error 2"
    ELSE
        LET s = do_update()
        IF s != 0 THEN DISPLAY "error 3" END IF
    END IF
    LET s = db_finish_transaction(s==0) -- real COMMIT or ROLLBACK WORK
    IF s != 0 THEN DISPLAY "error 4" END IF
END MAIN

FUNCTION do_update()
    DEFINE s INTEGER
    LET s = db_start_transaction() -- no SQL command (nested)
    IF s != 0 THEN
        DISPLAY "error 1.1"
    ELSE
        WHENEVER ERROR CONTINUE
        UPDATE customer SET cust_status = 'X'
```

WHENEVER ERROR STOP
LET s = SQLCA.SQLCODE
IF s != 0 THEN
   DISPLAY "error 1.2"
END IF
END IF
LET s = db_finish_transaction(s==0) -- no SQL command (nested)
IF s != 0 THEN DISPLAY "error 1.3" END IF
RETURN s
END FUNCTION

Related concepts

Database transactions on page 631
Database transaction concepts and handling.

db_finish_transaction()
Terminates a nested transaction call.

Syntax

```
db_finish_transaction(
   commit INTEGER )
RETURNS INTEGER
```

1. *commit* is a boolean that indicates whether the transaction must be committed.

Usage

This function encapsulates the COMMIT WORK or ROLLBACK WORK instructions to end a transaction.

When the number of calls to `DB_START_TRANSACTION()` matches, this function executes a COMMIT WORK if the passed parameter is TRUE; if the passed parameter is FALSE, it executes a ROLLBACK WORK.

If the number of start/finish calls does not match, the function does nothing.

Related concepts

Database transactions on page 631
Database transaction concepts and handling.

db_is_transaction_started()
Indicates whether a nested transaction call is started.

Syntax

```
db_is_transaction_started()
RETURNS INTEGER
```

Usage

The function returns TRUE if a transaction was started with `db_start_transaction()`, and was not yet finished with a call to the `db_finish_transaction()` function.

Related concepts

Database transactions on page 631
Database transaction concepts and handling.

</tbody>
</table>
winexec

Executes a program on the workstation where the Windows® front end runs and returns immediately.

Microsoft™ Windows™ only!

Syntax

**winexec**

```
command STRING
RETURNS INTEGER
```

**Usage**

This function executes a program on the workstation where the Windows® front end runs and returns immediately.

**Related concepts**

openDir on page 2507
Displays a file dialog window to get a directory path on the local file system.

winopendir

Opens a dialog window to get a directory path on the front-end workstation.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```
winopendir(dname STRING,
caption STRING )
RETURNS STRING
```

1. **dirname** is the default path to be displayed in the dialog window.
2. **caption** is the label to be displayed.

**Usage**

This function opens a dialog window to let the user select a directory path on the front-end workstation file system. The function returns the directory path on success.

The function returns **NULL** if a problem has occurred or if the user canceled the dialog.

**Important:** This function is provided for backward compatibility and its use is not recommended if running your programs with different front-ends. It must be called after the front-end connection was established.

**Related concepts**

captionDir on page 2507
Displays a file dialog window to get a directory path on the local file system.

winopenfile

Opens a dialog window to get a file to be read on the front-end workstation.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```
winopenfile(dname STRING,
typename STRING,
extlist STRING,
caption STRING )
RETURNS STRING
```

1. **dirname** is the default path to be displayed in the dialog window.
2. **typename** is the name of the file type to be displayed.
3. **extlist** is a blank-separated list of file extensions defining the file type.
4. **caption** is the label to be displayed.
Usage
This function opens a dialog window to let the user select a file path on the front end workstation file system, in order to open the file.

The function returns the file path on success.

The function returns NULL if a problem has occurred or if the user canceled the dialog.

Important: This function is provided for backward compatibility and its use is not recommended if running your programs with different front-ends. It must be called after the front-end connection was established.

Related concepts
openFile on page 2508
Displays a file dialog window to let the user select a single file path on the local file system.

winsavefile()
Opens a dialog window to get a file path to save data on the front-end workstation.

Syntax
Important: This feature is deprecated, and may be removed in a future version.

```
winsavefile (dirname STRING, typename STRING, extlist STRING, caption STRING )
RETURNS STRING
```

1. `dirname` is the default path to be displayed in the dialog window.
2. `typename` is the name of the file type to be saved.
3. `extlist` is a blank separated list of file extensions defining the file type.
4. `caption` is the label to be saved.

Usage
This function opens a dialog window to let the user select a file path on the front end workstation file system, in order to save the file.

The function returns the file path on success.

The function returns NULL if a problem has occurred or if the user canceled the dialog.

Important: This function is provided for backward compatibility and its use is not recommended if running your programs with different front-ends. It must be called after the front-end connection was established.

Related concepts
saveFile on page 2511
Displays a file dialog window to get a path to save a file on the local file system.

winexec() MS Windows® FE Only!
Executes a program on the workstation where the Windows® front end runs and returns immediately.

Syntax
Important: This feature is deprecated, and may be removed in a future version.

```
winexec (command STRING )
RETURNS INTEGER
```
1. *command* is the command to be executed on the front end.

**Usage**

The function executes the program on the Windows® front end and returns the control to the program without waiting.

**Important:** This function is provided for backward compatibility and its use is not recommended if running your programs with different front-ends. It must be called after the front-end connection was established.

**winexecwait() MS Windows® FE Only!**

Executes a program on the workstation where the Windows® front-end runs and waits for termination.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
winexecwait
  ( command STRING )
RETURNS INTEGER
```

1. *command* is the command to be executed on the front end.

**Usage**

The function executes the program on the Windows® front end and waits for its termination.

**Important:** This function is provided for backward compatibility and it is recommended to avoid its use if you intend running your programs with different front-ends. It must be called after the front-end connection is established.

**winshellexec() MS Windows® FE Only!**

Opens a document on the workstation where the Windows® front end runs.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
winshellexec
  ( filename STRING )
RETURNS INTEGER
```

1. *filename* is the file to be opened on the front end.

**Usage**

The function opens a document on the Windows® front end without waiting.

**Important:** This function is provided for backward compatibility and it is recommended to avoid its use if you intend running your programs with different front-ends. It must be called after the front-end connection is established.
vCard utility functions (IMPORT FGL VCard)

Table 451: vCard user defined types (VCard.4gl)

VCAddress type
The VCAddress structured type holds vCard address data.

Syntax

PUBLIC TYPE VCAddress RECORD
    PostOfficeBox,
    ExtendedAddress, -- apartment or suite number
    Street,
    City,
    State,
    ZIP,
    Country STRING
    -- , CountryCode STRING -- X-ABADR:de
END RECORD

Usage
This type defines a record structure to hold vCard address information. It is used for values returned by the scan_address() function.

Example

IMPORT FGL VCard
MAIN
    DEFINE a VCard.VCAddress
    LET a.Street = "Sunset Bld"
**VCName type**
The VCName structured type holds vCard data related to the person name.

**Syntax**

```vcl
PUBLIC TYPE VCName RECORD
  FirstName,
  LastName,
  MiddleName,
  Prefix,
  Suffix STRING
  --, FormattedName STRING
END RECORD
```

**Usage**

This type defines a record structure to hold vCard information related to the person name. It is used for values returned by the `scan_name()` function.

**Example**

```vcl
IMPORT FGL VCard
MAIN
  DEFINE n VCard.VCName
  LET n.FirstName = "Hans"
  LET n.LastName = "Mustermann"
END MAIN
```

**VCPerson type**
The VCPerson structured type holds vCard data.

**Syntax**

```vcl
PUBLIC TYPE VCPerson RECORD
  FirstName STRING, -- N[1]
  LastName STRING, -- N[2]
  MiddleName STRING, -- N[3]
  Prefix STRING, -- N[4]
  Suffix STRING, -- N[5]
  formattedName STRING, -- FN
  nickname STRING, -- NICKNAME
  jobTitle STRING, -- TITLE
  organization STRING, -- ORG.value[1]
  department STRING, -- ORG.value[2]
  birthday STRING, -- BDAY
  note STRING, -- NOTE
  address DYNAMIC ARRAY OF RECORD
    type STRING,
    PostOfficeBox, -- ADR[1]
    ExtendedAddress, -- ADR[2]
    Street, -- ADR[3]
    City, -- ADR[4]
    State, -- ADR[5]
    ZIP, -- ADR[6]
    Country STRING -- ADR[7]
END RECORD,
  phone DYNAMIC ARRAY OF RECORD
    type STRING,
```
Usage
This type defines a record structure to hold vCard information. It is used by VCard functions such as format_person().

Example

```c
IMPORT FGL VCard
MAIN
    DEFINE p VCard.VCPerson
    LET p.FirstName = "Hans"
    LET p.LastName = "Mustermann"
END MAIN
```

format_person()
Converts a VCPerson record to a vCard string representation vCard.

Syntax

```c
format_person(
    person VCPerson
) RETURNS STRING
```

1. `person` is a VCPerson record.

Usage
This function converts a record defined with the VCPerson type, to a string representing a vCard.

The returned value is a version 3.0 vCard formatted string.

Example

```c
IMPORT FGL VCard
MAIN
    DEFINE p VCard.VCPerson
    LET p.FirstName = "Hans"
    LET p.LastName = "Mustermann"
    LET p.email[1].VALUE = "hans@nomail.com"
    LET p.phone[1].TYPE = "HOME"
    LET p.phone[1].number = "+49 123 4567 8901"
    LET p.phone[2].TYPE = "WORK"
    LET p.phone[2].number = "+49 123 9876 5431"
    DISPLAY VCard.format_person(p.*)
END MAIN
```

Output:

```
BEGIN:VCARD
VERSION:3.0
N:Hans;Mustermann;;
FN:Hans Mustermann
TEL;TYPE=HOME:+49 123 4567 8901
TEL;TYPE=WORK:+49 123 9876 5431
EMAIL:hans@nomail.com
```
scan_address()
Extracts an address from a string representing a vCard.

Syntax

```plaintext
scan_address(
    source STRING,
    type STRING
) RETURNS VCAddress
```

1. `source` is the vCard string (version 3.0).
2. `type` is the type of address (HOME, WORK, pref).

Usage

This function parses the vCard string passed as parameter to find address data based on a type, and returns address information in a record defined with the VCAddress type.

The function looks for lines starting with the "ADR" keyword.

The second parameter (`type`) defines is the value of the "TYPE" attribute in an "ADR" line. Values can for example be "HOME", "WORK", "pref". If this parameter is NULL, the address with TYPE=pref will be returned. If no preferred address exists, the first address will be returned.

Example

```plaintext
IMPORT FGL VCard
MAIN
    DEFINE a VCard.VCAddress,
        f TEXT
    LOCATE f IN FILE arg_val(1)
    CALL VCard.scan_address(f, "WORK") RETURNING a.*
    DISPLAY a.*
END MAIN
```

scan_email()
Extracts an email from a string representing a vCard.

Syntax

```plaintext
scan_email(
    source STRING,
    type STRING
) RETURNS STRING
```

1. `source` is the vCard string (version 3.0).
2. `type` is the type of email (HOME, WORK, pref).

Usage

This function parses the vCard string passed as parameter to find "EMAIL" data based on a type, and returns the email address as a string.

The function looks for lines starting with the "EMAIL" keyword.

The second parameter (`type`) defines is the value of the "TYPE" attribute in an "EMAIL" line. Values can for example be "HOME", "WORK", "pref". If this parameter is NULL, the email with TYPE=pref will be returned. If no preferred email exists, the first email will be returned.
Example

```plaintext
IMPORT FGL VCard
MAIN
   DEFINE m STRING,
         f TEXT
   LOCATE f IN FILE arg_val(1)
   CALL VCard.scan_email(f,NULL) RETURNING m
   DISPLAY m
END MAIN
```

**scan_name()**

Extracts name information from a string representing a vCard.

**Syntax**

```plaintext
scan_name(
   source STRING)
RETURNS VCName
```

1. *source* is the vCard string (version 3.0).

**Usage**

This function parses the vCard string passed as parameter to find person name data, and returns name information in a record defined with the VCName type.

**Example**

```plaintext
IMPORT FGL VCard
MAIN
   DEFINE n VCard.VCName,
         f TEXT
   LOCATE f IN FILE arg_val(1)
   CALL VCard.scan_name(f) RETURNING n.*
   DISPLAY n.*
END MAIN
```

**scan_person()**

Extracts person’s data from a string representing a vCard.

**Syntax**

```plaintext
scan_person(
   source STRING)
RETURNS VCPerson
```

1. *source* is the vCard string (version 3.0).

**Usage**

This function parses the vCard string passed as parameter, extracts all information, and returns a record defined with the VCPerson type.

**Example**

```plaintext
IMPORT FGL VCard
MAIN
   DEFINE p VCard.VCPerson,
```
scan_phone()
Extracts a phone number from a string representing a vCard.

Syntax

```plaintext
scan_phone(
  source STRING,
  type STRING )
RETURNS STRING
```

1. `source` is the vCard string (version 3.0).
2. `type` is the type of phone number (HOME, WORK, TEXT, VOICE, FAX, CELL, VIDEO, PAGER, TEXTPHONE, pref).

Usage

This function parses the vCard string passed as parameter to find phone data based on a type, and returns the phone number in a string.

The function looks for lines starting with the "TEL" keyword.

The second parameter (`type`) defines is the value of the "TYPE" attribute in an "TELs" line. Values can for example be "HOME", "WORK", "TEXT", "VOICE", "FAX", "CELL", "VIDEO", "PAGER", "TEXTPHONE", "pref". If this parameter is NULL, the phone number with TYPE=pref will be returned. If no preferred phone number exists, the first phone number will be returned.

Example

```plaintext
IMPORT FGL VCard
MAIN
  DEFINE n STRING,
  f TEXT
  LOCATE f IN FILE arg_val(1)
  CALL VCard.scan_phone(f,NULL) RETURNING n
  DISPLAY n
END MAIN
```

<td>Prepares the fglallery library for use.</td>
</tr>
</tbody>
</table>
**t_struct_value type**
The `t_struct_value` type holds image selection data.

**Syntax**

```
PUBLIC TYPE t_struct_value RECORD
  current INTEGER,
  selected DYNAMIC ARRY OF INTEGER
END RECORD
```

**Usage**

This user-defined type defines a record structure to hold image selection information, to be used in fglgallery web components.

Each picture is identified by its ordinal position in the image gallery.

- The `current` member defines the current picture in the gallery.
- The `selected` member is a dynamic array of integers, defining the selected images. This member is used, when multiple image selection is enabled with `setMultipleSelection()`. The current image can different from a selected image: The current image may not be selected.

Image selection information is stored in the `WEBCOMPONENT` field value, as a JSON formatted string similar to: `{"current":5,"selected":[4,5]}`. The variable bound the fglgallery `WEBCOMPONENT` form field must be defined as `VARCHAR` or `STRING`.

The `t_struct_value` structure is typically used to get the selected image ids, when the image selection action is fired by the fglgallery web component. The web component field value can be parsed with the `util.JSON.parse()` method, to fill a variable defined with the `t_struct_value` type.

The web component field value can also be used to control the image selection from the program code: To select specific images in the gallery, fill the `t_struct_value` variable with image ids, then stringify the structure to JSON with the `util.JSON.stringify()` method, and set the web component field value with this JSON string.

**Example**

In this code example, `rec.gallery_wc` is the name of the fglgallery web component field:

```
DEFINE struct_value fglgallery.t_struct_value
  ...
  ON ACTION image_selection
    CALL util.JSON.parse( rec.gallery_wc, struct_value )
    DISPLAY struct_value.current,
    struct_value.selected.getLength()
  ...
  LET struct_value.current = 3
  LET struct_value.selected.clear()
  LET struct_value.selected[1] = 2
  LET struct_value.selected[2] = 7
  LET struct_value.selected[3] = 15
  LET rec.gallery_wc = util.JSON.stringify(struct_value)
  ...
```

**addImage()**

Adds a picture resource to an fglgallery.

**Syntax**

```
addImage(
  id SMALLINT,
  path STRING,
)```
Usage

This function adds a new image to the fglgallery web component.

The function requires the gallery id, the path to the image file, which can be an URL or a local relative path, and a title/description of the picture.

The id parameter is the fglgallery handler returned by the `create()` function.

The function only registers the image resource for the gallery. In order to display the added images, you must call the `flush()` or the `display()` function.

When displaying regular image resources available from an URL, you can directly specify this URL.

When displaying an application image located on the server, you must use the `ui.Interface.filenameToURI()` method.

Leave `title` NULL, if you don't want to add a description.

Example

Displaying an image from an URL:

```sql
CALL fglgallery.addImage(id,
    "Mountain ridge")
```

Displaying an image resource that is located on the application server:

```sql
CALL fglgallery.addImage(id,
    Interface.filenameToURI("big_smiley.jpg"),
    "The big smiley.")
```

Related concepts

The fglgallery web component on page 1882

The fglallery built-in web component implements a picture gallery, to let the end user select pictures and photos.

`clean()`

Removes all pictures from an fglallery.

Syntax

```sql
clean( id SMALLINT )
```

1. id is the fglallery identifier, as returned by the `create()` function.

Usage

This function removes all pictures from the fglallery.

The id parameter is the fglallery handler returned by the `create()` function.

The cleaned gallery is automatically displayed to the end user.
Example

CALL fglgallery.clean( id )

Related concepts
The fglallery web component on page 1882
The fglallery built-in web component implements a picture gallery, to let the end user select pictures and photos.

create()
Creates a new fglallery handle.

Syntax

create( name STRING )  
RETURNS SMALLINT

1. name is the name of the WEBCOMPONENT form field.

Usage
This function creates a new fglallery handler.

Note: The window/form containing the fglallery web component field must be created before calling this function.
The id returned by this function identifies the web component field in subsequent fglallery API calls.
When the fglallery web component is no longer required, use the destroy() function, to free the resources allocated for this fglallery object.

Example

DEFINE id SMALLINT
LET id = fglallery.create("formonly.gallery")
...
CALL fglallery.destroy(id)

Related concepts
The fglallery web component on page 1882
The fglallery built-in web component implements a picture gallery, to let the end user select pictures and photos.

deleteImages()
Deletes pictures used in an fglallery.

Syntax

deleteImages(   
id SMALLINT,   
indexes DYNAMIC ARRAY OF INTEGER )  
RETURNS STRING

1. id is the fglallery identifier, as returned by the create() function.
2. indexes is the dynamic array of indexes of the pictures to remove from the gallery.

Usage
This function deletes the specified pictures from the fglallery.
The id parameter is the fglallery handler returned by the create() function.
The *indexes* parameter is a `DYNAMIC ARRAY OF INTEGER` that defines a set of picture indexes. Each corresponding picture reference will be removed from the image gallery.

The new gallery is automatically displayed to the end user.

**Example**

```plaintext
DEFINE todel DYNAMIC ARRAY OF INTEGER
LET todel[1] = 3
LET todel[2] = 6
CALL fglgallery.deleteImages(id, todel)
```

**Related concepts**

The `fglgallery` web component on page 1882

The `fglgallery` built-in web component implements a picture gallery, to let the end user select pictures and photos.

**destroy()**

Frees resources allocated for an fglgallery.

**Syntax**

```plaintext
destroy( id SMALLINT )
```

1. *id* is the fglgallery identifier, as returned by the `create()` function.

**Usage**

This function releases the fglgallery identified by the specified handler.

The *id* parameter is the fglgallery handler returned by the `create()` function.

Call this method after closing the window/form displaying the gallery web component.

**Example**

```plaintext
CALL fglgallery.destroy( id )
```

**Related concepts**

The `fglgallery` web component on page 1882

The `fglgallery` built-in web component implements a picture gallery, to let the end user select pictures and photos.

**display()**

Displays an fglgallery to the end user.

**Syntax**

```plaintext
display(
    id SMALLINT,
    type INTEGER,
    size INTEGER )
```

1. *id* is the gallery identifier, as returned by the `create()` function.
2. *type* is the type of rendering to be used for the gallery (`FGLGALLERY_TYPE_*`).
3. *size* is the size hint for the gallery rendering (`FGLGALLERY_SIZE_*`).
**Usage**

This function displays the fglgallery in the corresponding web component field.

The *id* parameter is the fglgallery handler returned by the `create()` function.

The function can be called several times: It is typically used to refresh the image gallery, when the type or the size of the gallery needs to be changed.

The gallery *type* can be one of:

- `FGLGALLERY_TYPE_MOSAIC`
- `FGLGALLERY_TYPE_LIST`
- `FGLGALLERY_TYPE_THUMBNAILS`

The gallery *size* can be one of:

- `FGLGALLERY_SIZE_XSMALL`
- `FGLGALLERY_SIZE_SMALL`
- `FGLGALLERY_SIZE_NORMAL`
- `FGLGALLERY_SIZE_LARGE`
- `FGLGALLERY_SIZE_XLARGE`

**Note:** If you only need to add images to the gallery without changing the gallery type or size, there is no need to redisplay the gallery: Use the `addImage()` and `flush()` functions instead.

**Example**

```
CALL fglgallery.display( id, FGLGALLERY_TYPE_MOSAIC, FGLGALLERY_SIZE_NORMAL )
```

**Related concepts**

- [The fglgallery web component](#) on page 1882
- The fglgallery built-in web component implements a picture gallery, to let the end user select pictures and photos.

- [finalize()](#)
  Releases the fglgallery library.

**Syntax**

```
f finalize( )
```

**Usage**

This function terminates the fglgallery module usage.

It must be performed when the fglgallery library is no longer needed by the caller.

**Related concepts**

- [The fglgallery web component](#) on page 1882
- The fglgallery built-in web component implements a picture gallery, to let the end user select pictures and photos.

- [flush()](#)
  Displays new added images to the end user.

**Syntax**

```
flush( id SMALLINT )
```
1. *id* is the fglgallery identifier, as returned by the `create()` function.

**Usage**

This function flushes the new images to the fglgallery web component.

The `flush()` method is used after adding a set of new images with the `addImage()` function, to show the images when the image gallery is already displayed. A `flush()` call is not required before calling the `display()` method.

The *id* parameter is the fglgallery handler returned by the `create()` function.

**Example**

```plaintext
CALL fglgallery.addImage(id, "http://...", "Picture 1")
CALL fglgallery.addImage(id, "http://...", "Picture 2")
CALL fglgallery.addImage(id, "http://...", "Picture 3")
...
CALL fglgallery.flush()
```

**Related concepts**

The fglgallery web component on page 1882

The fglgallery built-in web component implements a picture gallery, to let the end user select pictures and photos.

**getImageCount()**

Returns the number of pictures in an fglgallery.

**Syntax**

```plaintext
getImageCount( id SMALLINT )
RETURNS INTEGER
```

1. *id* is the fglgallery identifier, as returned by the `create()` function.

**Usage**

This function the number of pictures in the specified fglgallery web component.

The *id* parameter is the fglgallery handler returned by the `create()` function.

In an fglgallery web component, pictures are identified by their ordinal position. This function can be used to loop through the picture indexes.

**Example**

```plaintext
FOR idx = 1 TO fglgallery.getImageCount(id)
    DISPLAY fglgallery.getPath(id, idx)
END FOR
```

**Related concepts**

The fglgallery web component on page 1882

The fglgallery built-in web component implements a picture gallery, to let the end user select pictures and photos.

**getPath()**

Returns the URL of a picture in an fglgallery.

**Syntax**

```plaintext
getPath()
```
1. *id* is the fglgallery identifier, as returned by the `create()` function.
2. *index* is the picture index in the image gallery.

**Usage**

This function returns the path (URL) of a picture in an image gallery. The value returned by this function corresponds to the path provided as second parameter to the `addImage()` function.

The *id* parameter is the fglgallery handler returned by the `create()` function.

The *index* parameter identifies the picture by its ordinal position in the image gallery.

**Example**

```plaintext
DISPLAY fglgallery.getPath( id, 10 )
```

**Related concepts**

The fglgallery web component on page 1882

The `fglgallery` built-in web component implements a picture gallery, to let the end user select pictures and photos.

**getTitle()**

Returns the description of a picture in an fglgallery.

**Syntax**

```plaintext
ggetTitle(
    id SMALLINT,
    index STRING )
RETURNS STRING
```

1. *id* is the fglgallery identifier, as returned by the `create()` function.
2. *index* is the picture index in the image gallery.

**Usage**

This function returns the title of a picture in the fglgallery.

The *id* parameter is the fglgallery handler returned by the `create()` function.

The *index* parameter identifies the picture by its ordinal position in the image gallery.

**Example**

```plaintext
DISPLAY fglgallery.getTitle( id, 10 )
```

**Related concepts**

The fglgallery web component on page 1882
The fglgallery built-in web component implements a picture gallery, to let the end user select pictures and photos.

initialize()
Prepares the fglgallery library for use.

**Syntax**

```plaintext
initialize( )
```

**Usage**
This function initializes the fglgallery module usage. When the fglgallery library is not longer needed, call the finalization function `fglgallery.finalize()`.

**Note:** Initialization and finalization functions can be called several times by different modules using the fglgallery library.

**Example**

```plaintext
IMPORT FGL fglgallery
FUNCTION show_image_gallery()
    ...
    CALL fglgallery.initialize()
    ...
    CALL fglgallery.finalize()
END FUNCTION
```

**Related concepts**
The fglgallery web component on page 1882
The fglgallery built-in web component implements a picture gallery, to let the end user select pictures and photos.

setMultipleSelection()
Enables/disables multiple picture selection in an fglgallery.

**Syntax**

```plaintext
setMultipleSelection( id SMALLINT, 
on BOOLEAN )
```

1. `id` is the fglgallery identifier, as returned by the `create()` function.
2. `on` can be `TRUE` (to enable multi-selection) or `FALSE` (to disable multi-selection).

**Usage**
This function controls multiple picture selection in the specified image gallery.

The `id` parameter is the fglgallery handler returned by the `create()` function.

When multiple selection is enabled, the end user can mark pictures as selected.

Indexes of selected images are provided in the web component field value, using the following JSON notation:

```json
{ "current":5, "selected":[4,5] }
```

Convert this JSON string to a `fglgallery.t_struct_value` record to get the list of picture indexes in the "selected" member.
Example

```
CALL fglgallery.setMultipleSelection( id, TRUE )
```

Related concepts

The fglgallery web component on page 1882
The fglgallery built-in web component implements a picture gallery, to let the end user select pictures and photos.

setAspectRatio()

Displays an fglgallery to the end user.

Syntax

```
setAspectRatio(  
  id SMALLINT,  
  ratio DECIMAL(5,2)  )
```

1. *id* is the gallery identifier, as returned by the `create()` function.
2. *ratio* is the aspect ratio to be used (for example, 1.77 or 16/9).

Usage

In order to align image elements properly when image resources have different sizes, the fglgallery uses the same size for each image.

*Note:* The size of image elements is defined by the `FGLGALLERY_SIZE_*` parameter passed to the `display()` function. This size parameter is relative to the current font size (`em` unit is used in HTML).

The `setAspectRatio()` function defines the aspect ratio for fglgallery image elements.

By default, a square aspect ratio (1:1) is used.

The `id` parameter is the fglgallery handler returned by the `create()` function.

The `display()` function has to used after `setAspectRatio()` to have the changes in the fglgallery take effect.

Example

```
CALL fglgallery.setAspectRatio( id, 16/9 )
```

<td></td>
<td></td>
</tr>
</tbody>
</table>

Selects the SVG canvas handler for subsequent SVG canvas API calls.

Sets the SVG attributes from an attribute set.

Deletes an SVG element from the SVG canvas.

Releases resources allocated for the SVG canvas.

Builds a string with a list of attributes to be used in a canvas API calls.

Converts a string to an SVG string.

Applies a tint factor to an RGB color.

Applies a shade factor to an RGB color.

Creates a new SVG canvas handler.

Releases resources allocated for the SVG canvas.
**t_svg_rect type**
The `t_svg_rect` type defines the position and dimensions of a rectangle.

**Syntax**

```
PUBLIC TYPE t_svg_rect RECORD
  x DECIMAL,
  y DECIMAL,
  width DECIMAL,
  height DECIMAL
END RECORD
```

**Usage**
This user-defined type defines a record structure to the position `(x,y)` and size `(width,height)` of a rectangle.

The structure is for example used with the `getBBox()` function on page 2224.

**SVGATT_constants**
List of predefined SVG attributes.

**Syntax**

```
PUBLIC CONSTANT SVGATT_TRANSFORM = "transform"
PUBLIC CONSTANT SVGATT_CLASS = "class"
PUBLIC CONSTANT SVGATT_STYLE = "style"
PUBLIC CONSTANT SVGATT_ONCLICK = "onclick"
PUBLIC CONSTANT SVGATT_ONMOUSEOVER = "onmouseover"
PUBLIC CONSTANT SVGATT_ONMOUSEOUT = "onmouseout"
PUBLIC CONSTANT SVGVAL_ELEM_CLICKED = "elem_clicked(this)"
PUBLIC CONSTANT SVGVAL_ELEM_MOUSE_OVER = "elem_mouse_over(this)"
PUBLIC CONSTANT SVGVAL_ELEM_MOUSE_OUT = "elem_mouse_out(this)"
PUBLIC CONSTANT SVGATT_FILL = "fill"
PUBLIC CONSTANT SVGATT_FILL_OPACITY = "fill-opacity"
PUBLIC CONSTANT SVGATT_FILL_RULE = "fill-rule"
PUBLIC CONSTANT SVGATT_STROKE = "stroke"
PUBLIC CONSTANT SVGATT_STROKE_WIDTH = "stroke-width"
PUBLIC CONSTANT SVGATT_STROKE_OPACITY = "stroke-opacity"
PUBLIC CONSTANT SVGATT_STROKE_LINECAP = "stroke-linecap"
PUBLIC CONSTANT SVGATT_STROKE_LINEJOIN = "stroke-linejoin"
PUBLIC CONSTANT SVGATT_STROKE_MITERLIMIT = "stroke-miterlimit"
PUBLIC CONSTANT SVGATT_STROKE_DASHARRAY = "stroke-dasharray"
PUBLIC CONSTANT SVGATT_STROKE_DASHOFFSET = "stroke-dashoffset"
PUBLIC CONSTANT SVGATT_FONT_FAMILY = "font-family"
PUBLIC CONSTANT SVGATT_FONT_SIZE = "font-size"
PUBLIC CONSTANT SVGATT_FONT_SIZE_ADJUST = "font-size-adjust"
PUBLIC CONSTANT SVGATT_FONT_STRETCH = "font-stretch"
PUBLIC CONSTANT SVGATT_FONT_STYLE = "font-style"
PUBLIC CONSTANT SVGATT_FONT_VARIANT = "font-variant"
PUBLIC CONSTANT SVGATT_FONT_WEIGHT = "font-weight"
PUBLIC CONSTANT SVGATT_TEXT_ANCHOR = "text-anchor"
PUBLIC CONSTANT SVGATT_MARKER_START = "marker-start"
PUBLIC CONSTANT SVGATT_MARKER_MID = "marker-mid"
PUBLIC CONSTANT SVGATT_MARKER_END = "marker-end"
```
Usage
The SVGATT_predefined constants are available from the fglsvgcanvas module.
Such constants are typically used to build an SVG attribute list for `setAttributes()` or `styleAttributeList()`

animateTransform()
Produces an SVG "animateTransform" element.

Syntax
```plaintext
animateTransform(
    attributeName STRING, attributeType STRING,
    type STRING, from STRING, to STRING,
    by STRING, begin STRING, dur STRING,
    repeatCount STRING )
RETURNS om.DomNode
```

1. The `attributeName`, `attributeType`, `type`, `from`, `to`, `by`, `begin`, `dur`, and `repeatCount` parameters are used to set the corresponding SVG attributes for the `animateTransform` element. See SVG specification for details.

Usage
This function creates an "animateTransform" SVG DOM element from the parameters passed.
For more details about SVG animation, refer to the SVG specification.

Example
```plaintext
DEFINE n om.DomNode
LET n = fglsvgcanvas.animateTransform("transform", "XML",
"rotate", NULL, NULL,
"360", NULL, "12h", "indefinite")
```

Related concepts
The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

circle()
Produces an SVG "circle" element.

Syntax
```plaintext
circle(
    cx DECIMAL,
    cy DECIMAL,
    r DECIMAL )
RETURNS om.DomNode
```

1. `cx` defines the X coordinate of the center point of the circle.
2. `cy` defines the Y coordinate of the center point of the circle.
3. `r` defines the radius of the circle.

Usage
This function creates an "circle" SVG DOM element from the parameters.
Example

```plaintext
DEFINE n om DomNode
LET n = fglsvgcanvas.circle(100,100,50)
CALL n.setAttribute(SVGATT_STYLE,"stroke:#006600;")
```

Related concepts

The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

clean()

Deletes all SVG elements inside the SVG canvas.

Syntax

```plaintext
clean( cid SMALLINT )
```

1. `cid` is the SVG canvas id, as returned by `fglsvgcanvas.create()`.

Usage

This function cleans the SVG canvas.

Note: The `clean()` function will not automatically display the cleaned SVG canvas. To see a visual result, re-display the SVG content with the `display()` function.

Related concepts

The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

clipPath_rect()

Produces an SVG "clipPath" element with a "rect" element.

Syntax

```plaintext
clipPath_rect( id STRING, 
x DECIMAL, 
y DECIMAL, 
width DECIMAL, 
height DECIMAL )
RETURNS om DomNode
```

1. `id` is the SVG object identifier.
2. `x` is the X coordinate of the top-left corner of the clip rectangle.
3. `y` is the Y coordinate of the top-left corner of the clip rectangle.
4. `width` is the width of the clip rectangle.
5. `height` is the height of the clip rectangle.

Usage

This function creates a "clipPath" SVG DOM element using a rectangle as clipping shape.

A clip path can be used in a text or image element, to define the clipping borders.

The clip path element must be added to the `defs` node of the `svg` element.

To use a clip path in an SVG DOM element, set the "clip-path" attribute with the string generate by the `url()` function.
Example

```javascript
DEFINE defs om.DomNode,
    clip_id STRING
...
LET clip_id = "clip_gh_1"
CALL defs.appendChild(
    fglsvgcanvas.clipPath_rect( clip_id, tx, ty, -1, sy )
)
...
LET n = fglsvgcanvas.text( tx + 3, (ty + (sy/2) + 1), "Some text", NULL )
CALL n.setAttribute("clip-path", fglsvgcanvas.url("clip_gh_1") )
```

Related concepts

The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

color_shade()

Applies a shade factor to an RGB color.

Syntax

```javascript
color_shade(
    source STRING,
    factor DECIMAL
) RETURNS STRING
```

1. `source` is the source RGB color.
2. `factor` is the shade factor.

Usage

This function modifies the RGB color specification by applying the shade factor passed as parameter.

Example

```javascript
LET m = fglsvgcanvas.color_shade( "#FFAA34", 0.42 )
```

Related concepts

The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

color_tint()

Applies a tint factor to an RGB color.

Syntax

```javascript
color_tint(
    source STRING,
    factor DECIMAL
) RETURNS STRING
```

1. `source` is the source RGB color.
2. `factor` is the tint factor.

Usage

This function modifies the RGB color specification by applying the tint factor passed as parameter.
Example

LET m = fglsvgcanvas.color_tint( "#FFAA34", 0.42 )

Related concepts
The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

create()
Creates a new SVG canvas handler.

Syntax

```
create( name STRING )
RETURNS SMALLINT
```

1. name is the name of the CSS style.

Usage

This function creates a new SVG canvas handle by using the form field name passed as parameter.

Note: The window/form containing the fglsvgcanvas web component field must be created before calling this function.

The name is used to bind the WEBCOMPONENT form field with the SVG canvas, to display SVG content.

The function returns the id of the new created SVG canvas. This id must be used in subsequent calls to fglsvgcanvas functions.

When the SVG canvas is no longer needed, free the allocated resources with the destroy() function.

Example

Form file:

```
...
ATTRIBUTES
WEBCOMPONENT cv = FORMONLY.canvas,
   COMPONENTTYPE = "fglsvgcanvas",
   PROPERTIES = (selection="item_selection"),
   SIZEPOLICY = FIXED,
   STRETCH = BOTH,
   SCROLLBARS = NONE
;
...
```

Program code:

```
DEFINE cid SMALLINT
LET cid = fglsvgcanvas.create("formonly.canvas")
...
CALL fglsvgcanvas.destroy( cid )
```

Related concepts
The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**createChars()**

Produces a SVG DOM text node.

**Syntax**

```plaintext
createChars( value STRING )
RETURNS om.DomNode
```

1. `value` is the value to be set in the text node.

**Usage**

This function creates a SVG DOM text node from the value passed as parameter.

Use the `createChars()` function when you need to create a SVG text node that cannot be created with one of the fglsvgcanvas functions (such as `title()`).

**Example**

```plaintext
DEFINE t, c om.DomNode
LET t = fglsvgcanvas.createElement( "title", "id1" )
LET c = fglsvgcanvas.createChars( "my value" )
CALL t.appendChild( c )
```

**Related concepts**

The fglsvgcanvas web component on page 1891

createElement() Produces an SVG DOM element with the tag name specified as parameter.

**Syntax**

```plaintext
createElement( 
  tagName STRING,
  id STRING )
RETURNS om.DomNode
```

1. `tagName` is the DOM tag name.
2. `id` is the SVG object identifier.

**Usage**

This function creates an SVG DOM element with the specified tag name.

Use the `createElement()` function when you need to create an SVG element that cannot be created with one of the fglsvgcanvas functions.

**Example**

```plaintext
DEFINE n om.DomNode
LET n = fglsvgcanvas.createElement( "feBlend", "myblend" )
```

**Related concepts**

The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**defs()**

Produces a SVG "defs" element.

**Syntax**

```plaintext
defs(
   id STRING )
RETURNS om.DomNode
```

1. `id` is the SVG object identifier.

**Usage**

This function creates a "defs" SVG DOM element from the parameters.

The `defs` element can be used to centralize SVG drawing elements such as SVG patterns or CSS styles, that can be reused in other SVG elements.

**Example**

Creating a pattern:

```plaintext
DEFINE root_svg, defs, pattern, n om.DomNode
...
LET defs = fglsvgcanvas.defs( NULL )
CALL root_svg.appendChild( defs )

LET pattern = fglsvgcanvas.pattern( "pattern1", 0, 0, 20, 20,
   "userSpaceOnUse",
   NULL, "rotate(45)" ), NULL )
CALL pattern.appendChild( n:=fglsvgcanvas.rect(0,0,1000,10,NULL,NULL) )
CALL n.setAttribute(SVGATT_STYLE, 'stroke:none; fill:blue;' )
CALL pattern.appendChild( n:=fglsvgcanvas.rect(0,10,1000,10,NULL,NULL) )
CALL n.setAttribute(SVGATT_STYLE, 'stroke:none; fill:navy;' )
CALL defs.appendChild( pattern )
```

Creating CSS styles:

```plaintext
CONSTANT STYLE_1 = 1
CONSTANT STYLE_2 = 2
CONSTANT STYLE_3 = 3
DEFINE attr DYNAMIC ARRAY OF om.SaxAttributes
DEFINE root_svg, defs om.DomNode
...
LET defs = fglsvgcanvas.defs( NULL )
CALL defs.appendChild( fglsvgcanvas.styleList(
   fglsvgcanvas.styleDefinition(".style_1",attr[STYLE_1])
   ||
   fglsvgcanvas.styleDefinition(".style_2",attr[STYLE_2])
   ||
   fglsvgcanvas.styleDefinition(".style_3",attr[STYLE_3])
))
CALL root_svg.appendChild( defs )
```

**Related concepts**

The fglsvgcanvas web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

### destroy()
Releases resources allocated for the SVG canvas.

**Syntax**

```
destroy( cid SMALLINT )
```

1. `cid` is the SVG canvas id, as returned by `fglsvgcanvas.create()`.

**Usage**
This function frees resources allocated for the SVG canvas handler that was created with the `create()` function.

**Example**

```
CALL fglsvgcanvas.destroy( cid )
```

**Related concepts**
*The fglsvgcanvas web component* on page 1891
*The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.*

### display()
Displays the SVG canvas.

**Syntax**

```
display( cid SMALLINT )
```

1. `cid` is the SVG canvas id, as returned by `fglsvgcanvas.create()`.

**Usage**
The function sends the SVG content to the front-end for display.

**Example**

```
CALL fglsvgcanvas.display( cid )
```

**Related concepts**
*The fglsvgcanvas web component* on page 1891
*The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.*

### ellipse()
Produces an SVG "ellipse" element.

**Syntax**

```
ellipse(  
    cx DECIMAL,  
    cy DECIMAL,  
    rx DECIMAL,  
    ry DECIMAL )
```

RETURNS `om.DomNode`

1. `cx` defines the X coordinate of the center of the ellipse.
2. `cy` defines the Y coordinate of the center of the ellipse.
3. \(rx\) defines the X radius of the ellipse.
4. \(ry\) defines the Y radius of the ellipse.

**Usage**

This function creates an "ellipse" SVG DOM element from the parameters.

**Example**

```om
DEFINE n om.DomNode
LET n = fglsvgcanvas.ellipse(100,100,50,60)
CALL n.setAttribute(SVGATT_STYLE,"stroke:#006600;")
```

**Related concepts**

- The fglsvgcanvas web component on page 1891
- The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**filter()**

Produces the SVG "filter" element.

**Syntax**

```om
filter(
  id STRING,
  x STRING,
  y STRING,
  width STRING,
  height STRING
)
RETURNS om.DomNode
```

1. \(id\) is the SVG object identifier.
2. \(x\) The X for the filter dimension.
3. \(y\) The Y for the filter dimension.
4. \(width\) The width for the filter dimension.
5. \(height\) The height for the filter dimension.

**Usage**

This function creates a "filter" SVG DOM element from the parameters.

Filters must be defined in a "defs" element, that is created with the \(\text{defs()}\) function.

Create filter effect sub-elements such as "feOffset" or "feGaussianBlur" with the \(\text{createElement()}\) function.

A filter can then be applied to an SVG element, by setting the "filter" attribute with an "url(#filter-name)" reference.

**Example**

```om
DEFINE root_svg, defs, f, fe, fse, n om.DomNode

LET defs = fglsvgcanvas.defs(NULL)
CALL root_svg.appendChild(defs)

CALL defs.appendChild(f:=fglsvgcanvas.filter("blur1", -10, -10, 40, 150))
CALL f.appendChild(fe:=fglsvgcanvas.createElement("feOffset",null))
CALL fe.setAttribute("in","SourceAlpha")
CALL fe.setAttribute("dx","3")
CALL fe.setAttribute("dy","3")
```
CALL fe.setAttribute("result","offset2")
CALL f.appendChild( fe:=fglsvgCanvas.createElement("feGaussianBlur",NULL) )
CALL fe.setAttribute("in","offset2")
CALL fe.setAttribute("stdDeviation","3")
CALL f.appendChild( fe:=fglsvgCanvas.createElement("feMerge",NULL) )
CALL f.appendChild( fse:=fglsvgCanvas.createElement("feMergeNode",NULL) )
CALL fse.setAttribute("in","blur2")
CALL f.appendChild( fse:=fglsvgCanvas.createElement("feMergeNode",NULL) )
CALL fse.setAttribute("in","SourceGraphic")

...  
CALL root_svg.appendChild( n:=fglsvgCanvas.rect(40,50,100,200,5,5) )
CALL n.setAttribute("style", "stroke:gray; fill:blue; filter:url(#blur1);")
...  

Related concepts  
The fglsvgcanvas web component on page 1891  
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

finalize()  
Releases the fglsvgcanvas library.

Syntax  

```
finalize( )
```

Usage  
This function terminates the fglsvgcanvas module usage.
It must be performed when the fglsvgcanvas library is no longer needed by the caller.

Related concepts  
The fglsvgcanvas web component on page 1891  
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

g()  
Produces an SVG "g" element.

Syntax  

```
g(  
    id STRING 
)  
RETURNS om.DomNode
```

1.  
   *id* is the SVG object identifier.

Usage  
This function creates a "g" SVG DOM element from the parameters.
The g element is used to group SVG elements together, apply a transformation, and use common attributes for the group.

For example, you can draw complex shapes inside the "g" element, and rotate the whole object by 180 degrees around point (50,50), by using "rotate(180 50 50)" for the "transform" parameter. For more details about the "transform" SVG attribute, see SVG specification
Example

```plaintext
DEFINE n om.DomNode
LET n = fglsvgcanvas.g( "group1" )
CALL n.setAttribute(SVGATT_TRANSFORM, "rotate(45 50 50)")
```

Related concepts

The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**getBBox()**

Returns the bounding box of an SVG element.

**Syntax**

```plaintext
getBBox( cid SMALLINT, id STRING )
RETURNS t_svg_rect
```

1. `cid` is the SVG canvas id, as returned by `fglsvgcanvas.create()`.
2. `id` identifies the SVG element from which the bounding box is got.

**Usage**

This function returns the bounding box of the SVG element identified by the `id` parameter.

The values returned are x, y, width and height (in the current user space).

The values returned by `getBBox()` can be held in a record variable defined with the `t_svg_rect` type.

If no SVG element is found, the values returned will be `NULL`.

**Example**

```plaintext
DEFINE rect fglsvgcanvas.t_svg_rect
...
ON ACTION get_bbox
  CALL fglsvgcanvas.getBBox(cid, "label_23") RETURNING rect.*
  DISPLAY rect.x, rect.y, rect.width, rect.height
```

Related concepts

The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**getItemid()**

Returns SVG element id after a user action.

**Syntax**

```plaintext
getItemId( cid SMALLINT )
RETURNS STRING
```

1. `cid` is the SVG canvas id, as returned by `fglsvgcanvas.create()`.

**Usage**

This function returns the `id` attribute of the SVG element involved in a user-defined action.

When the `fglsvgcanvas` web component does not have the focus, it is not possible to return the SVG element id in the field value. If user-defined actions are bound to SVG events that can be fired when the field does not have the focus, the only way to identify the SVG element is the `getItemId()` function.
Example

```
DEFINE id STRING
...
ON ACTION mouse_over
  LET id = fglsvgcanvas.getItemId(cid)
```

Related concepts

The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

`image()`

Produces an SVG "image" element.

Syntax

```
image(
  href STRING,
  x DECIMAL,
  y DECIMAL,
  width DECIMAL,
  height DECIMAL,
  preserveAspectRatio STRING )
RETURNS om.DomNode
```

1. `href` defines the xlink:href reference to the image.
2. `x` defines the X coordinate of the image.
3. `y` defines the Y coordinate of the image.
4. `width` defines the width of the image.
5. `height` defines the height of the image.
6. `preserveAspectRatio` defines the aspect ratio to preserve.

Usage

This function creates an "image" SVG DOM element from the parameters.

The `href` parameter defines the image resource or URL.

**Important:** Use the `ui.Interface.filenameToURI()` method to produce an URL for application images.

Example

```
DEFINE n om.DomNode
LET n = fglsvgcanvas.image( ui.Interface.filenameToURI("image02.jpg"),
  100,100,50,50, "xMidYMid meet" )
```

Related concepts

The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

`initialize()`

Prepares the fglsvgcanvas library for use.

Syntax

```
initialize( )
```
Usage
This function initializes the fglsvgcanvas module usage. When the fglsvgcanvas library is not longer needed, call the finalization function `fglsvgcanvas.finalize()`.

Note: Initialization and finalization functions can be called several times by different modules using the fglsvgcanvas library.

Example
```
IMPORT FGL fglsvgcanvas
FUNCTION show_svg_content()
    ...
    CALL fglsvgcanvas.initialize()
    ...
    CALL fglsvgcanvas.finalize()
END FUNCTION
```

Related concepts
The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

line()
Produces an SVG "line" element.

Syntax
```
line(  
    x1 DECIMAL,  
    y1 DECIMAL,  
    x2 DECIMAL,  
    y2 DECIMAL  
)  
RETURNS om.DomNode
```

1. `x1` defines the X coordinate of the start point.
2. `y1` defines the Y coordinate of the start point.
3. `x2` defines the X coordinate of the end point.
4. `y2` defines the Y coordinate of the end point.

Usage
This function creates a "line" SVG DOM element from the parameters.

Example
```
DEFINE n om.DomNode
LET n = fglsvgcanvas.line(10,10,50,30)
CALL n.setAttribute(SVGATT_STYLE,"stroke:#006600;")
```

Related concepts
The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

linearGradient()
Produces an SVG "linearGradient" element.

Syntax
```
linearGradient(  
    id STRING,  
    ...  
)  
RETURNS om.DomNode
```

The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.
### linearGradient

**Parameters**
- `id` STRING,
- `x1` STRING,
- `y1` STRING,
- `x2` STRING,
- `y2` STRING,
- `spreadMethod` STRING,
- `gradientTransform` STRING,
- `gradientUnits` STRING

**Returns** om.Donode

1. `id` is the SVG object identifier.
2. `x1` defines the X coordinate of the linear gradient start point.
3. `y1` defines the Y coordinate of the linear gradient start point.
4. `x2` defines the X coordinate of the linear gradient end point.
5. `y2` defines the Y coordinate of the linear gradient end point.
6. `spreadMethod` defines how the gradient is spread out through the shape.
7. `gradientTransform` defines the gradient transformation.
8. `gradientUnits` defines the coordinate system to be used.

### Usage

This function creates a "linearGradient" SVG DOM element from the parameters.

An SVG "linearGradient" element can be used to define fill colors of shapes.

The element must contain "stop" elements that can be created with the `stop` function.

The resulting gradient definition can be added to a "defs" SVG DOM element.

### Example

```plaintext
DEFINE root_svg, defs, lg om.Donode
...
LET defs = fglsvgcanvas.defs( NULL )
CALL root_svg.appendChild( defs )

LET lg = fglsvgcanvas.linearGradient( "gradient_1",
    "0%", "0%", "0%", "100%",
    "pad", NULL, NULL )
CALL lg.appendChild( fglsvgcanvas.stop( "0%", "gray", 0.8 ) )
CALL lg.appendChild( fglsvgcanvas.stop( "100%", "navy", 0.6 ) )
CALL defs.appendChild( lg )
...
```

### Related concepts

The `fglsvgcanvas` web component on page 1891

The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**marker()**

Produces an SVG "marker" element.

### Syntax

```plaintext
marker(
    id STRING,
    markerUnits STRING,
    refX DECIMAL,
    refY DECIMAL,
    markerWidth DECIMAL,
    markerHeight DECIMAL,
    orient STRING )
```
RETURNS om.DomNode

1. *id* is the SVG object identifier.
2. *markerUnits* defines how the marker scales ("strokeWidth" or "userSpaceOnUse").
3. *refX* defines the X coordinate of the reference point.
4. *refY* defines the Y coordinate of the reference point.
5. *markerWidth* defines the width of the marker.
6. *markerHeight* defines the height of the marker.
7. *orient* defines the orientation of the marker (like "auto").

**Usage**

This function creates a "marker" SVG DOM element from the parameters.

SVG markers define the rendering of start, mid and end of a line or path.

Markers are typically defined in a "defs" SVG element, and then used in a style definition with the *marker-start*, *marker-mid* and *marker-end* attributes, using the *styleList()* and *styleDefinition()* functions (see example below).

**Example**

```om
DEFINE root_svg, defs, m, p, n om.DomNode
DEFINE attr DYNAMIC ARRAY OF om.SaxAttributes
...
LET defs = fglsvgcanvas.defs( NULL )
CALL root_svg.appendChild( defs )

LET m = fglsvgcanvas.marker("m1", NULL, 5,5,10,10, "auto")
CALL defs.appendChild( m )
CALL m.appendChild( n:=fglsvgcanvas.circle(5,5,3) )
CALL n.setAttribute(SVGATT_STYLE,'stroke:gray; fill:blue;')

LET m = fglsvgcanvas.marker("m2", NULL, 2,6,15,15, "auto")
CALL defs.appendChild( m )
CALL m.appendChild( n:=fglsvgcanvas.path("M2,2 L2,11 L10,6 L2,2") )
CALL n.setAttribute(SVGATT_STYLE,'stroke:gray; fill:blue;')

LET attr[1] = om.SaxAttributes.create()
CALL attr[1].addAttribute(SVGATT_STROKE, "blue")
CALL attr[1].addAttribute(SVGATT_STROKE_WIDTH, 1.5 )
CALL attr[1].addAttribute(SVGATT_FILL, "none")
CALL attr[1].addAttribute(SVGATT_MARKER_START, fglsvgcanvas.url("m1") )
CALL attr[1].addAttribute(SVGATT_MARKER_END,   fglsvgcanvas.url("m2") )
CALL defs.appendChild( fglsvgcanvas.styleList(  
       fglsvgcanvas.styleDefinition(".style_1",attr[1])  
     )  )
...
LET p = fglsvgcanvas.path("M100,100 L150,150 L200,150")
CALL p.setAttribute(SVGATT_STYLE,"style_1")
```

**Related concepts**

The *fglsvgcanvas* web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

### mask()

Produces an SVG "mask" element.

#### Syntax

```javascript
mask(
  id STRING,
  x STRING,
  y STRING,
  width STRING,
  height STRING,
  node om.DomNode,
  name STRING )
```

1. `id` is the SVG object identifier.
2. `x` is the X coordinate of the mask.
3. `y` is the Y coordinate of the mask.
4. `width` is the width of the mask.
5. `height` is the height of the mask.
6. `maskUnits` defines the coordinate system for x,y,width,height.
7. `maskContentUnits` defines the coordinate system for the content of the mask.

#### Usage

This function creates a "mask" SVG DOM element from the parameters.

To use a mask in an SVG DOM element, set the "mask" attribute with the string generate by the `url()` function.

#### Related concepts

- The `fglsvgcanvas` web component on page 1891
- The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

### nl_to_tspan()

Converts a string to an SVG "text" element with "tspan" sub-elements.

#### Syntax

```javascript
nl_to_tspan(
  text om.DomNode,
  x STRING,
  y STRING,
  dx STRING,
  dy STRING,
  content STRING )
```

1. `text` is the DOM node to update with tspan elements.
2. `x` is used to set the x attribute of each tspan element.
3. `y` is used to set the y attribute of each tspan element.
4. `dx` is used to set the dx attribute of each tspan element.
5. `dy` is used to set the dy attribute of each tspan element.
6. `content` is the source text with new-line characters.

#### Usage

This function creates "tspan" elements for each line of text.
The `text` DOM element passed as parameter gets "tspan" sub-elements for each new-line character found in the original string.

**Example**

```plaintext
DEFINE root_svg, t, n om.DomNode
...
LET t = fglsvgcanvas.text(NULL,200,NULL)
CALL root_svg.appendChild( t )
CALL fglsvgcanvas.nl_to_tspan(t,120,NULL,NULL,30,"Text using tspan\nLine 2\nLine 3")
```

**Related concepts**
The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**path()**

Produces an SVG "path" element.

**Syntax**

```plaintext
path(
    d STRING )
RETURNS om.DomNode
```

1. `d` is the SVG path specification.

**Usage**

This function creates a "path" SVG DOM element from the parameters.

The path element draws complex SVG shapes combined from lines, arcs, curves, etc.

For more details about path elements, see SVG specification.

**Example**

Displaying an image from an URL:

```plaintext
DEFINE n om.DomNode
LET n = fglsvgcanvas.path("M50,50 A30,30 0 0,1 35,20 ...")
CALL n.setAttribute(SVGATT_STYLE, "stroke:#006600; stroke-width:0.4")
```

**Related concepts**
The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**pattern()**

Produces an SVG "pattern" element.

**Syntax**

```plaintext
pattern(
    id STRING,  
    x DECIMAL, 
    y DECIMAL, 
    width DECIMAL, 
    height DECIMAL, 
    patternUnits STRING, 
    patternContentUnits STRING, 
    patternTransform STRING, 
```
```oml
preserveAspectRatio STRING )
RETURNS om.DomNode

1. id is the SVG object identifier.
2. x defines the X coordinate where the pattern starts.
3. y defines the Y coordinate where the pattern starts.
4. width defines the width of the pattern.
5. height defines the height of the pattern.
6. patternUnits defines the patternUnits attribute.
7. patternContentUnits defines the patternContentUnits attribute.
8. patternTransform defines the patternTransform attribute.
9. preserveAspectRatio is the aspect ratio to preserve.

Usage
This function creates a "pattern" SVG DOM element from the parameters.

The resulting DOM can be used in a "defs" element created with the `defs()` function, to produce pattern definitions.

Example
```
DEFINE pattern, n om.DomNode
... 
LET pattern = fglsvgcanvas.pattern( "pattern1", 0,0,20,20, "userSpaceOnUse", 
   NULL, "rotate(45)" ), NULL )
CALL pattern.appendChild( n:=fglsvgcanvas.rect(0,0,1000,10,NULL,NULL) )
CALL n.setAttribute(SVGATT_STYLE, 'stroke:none; fill:blue;' )
CALL pattern.appendChild( n:=fglsvgcanvas.rect(0,10,1000,10,NULL,NULL) )
CALL n.setAttribute(SVGATT_STYLE, 'stroke:none; fill:navy;' )
```

Related concepts
The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

`polygon()`
Produces an SVG "polygon" element.

Syntax
```
polygon(
   points STRING )
RETURNS om.DomNode
```

1. points is a STRING defining the points of the polygon.

Usage
This function creates a "polygon" SVG DOM element from the parameters.

The points is a string contains a list of X,Y coordinates to draw the shape, in the form "x1,y1 x2,y2 ...".

Example
```
DEFINE n om.DomNode
LET n = fglsvgcanvas.polygon("10,10 10,20 20,20")
CALL n.setAttribute(SVGATT_STYLE, "stroke:#660000; fill:#cc3333;")
```
Related concepts
The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

polyline()
Produces an SVG "polyline" element.

Syntax

```plaintext
polyline(
    points STRING )
RETURNS om.DomNode
```

Usage
This function creates a "polygon" SVG DOM element from the parameters.

Example

```plaintext
DEFINE n om.DomNode
LET n = fglsvgcanvas.polyline("10,10 10,20 20,20")
CALL n.setAttribute(SVGATT_STYLE, "stroke:#660000;")
```

radialGradient()
Produces an SVG "radialGradient" element.

Syntax

```plaintext
radialgradient(
    id STRING,  
    cx STRING,  
    cy STRING,  
    fx STRING,  
    fy STRING,  
    r STRING,  
    spreadMethod STRING,  
    gradientTransform STRING,  
    gradientUnits STRING )
RETURNS om.DomNode
```

1. `id` is the SVG object identifier.
2. `cx` defines the X coordinate of the radial gradient center.
3. `cy` defines the Y coordinate of the radial gradient center.
4. `fx` defines the X coordinate of the radial gradient focal point.
5. `fy` defines the Y coordinate of the radial gradient focal point.
6. `spreadMethod` defines how the gradient is spread out through the shape.
7. `gradientTransform` defines the gradient transformation.
8. `gradientUnits` defines the coordinate system to be used.
Usage
This function creates a "radialGradient" SVG DOM element from the parameters.
An SVG "radialGradient" element can be used to define fill colors of shapes.
The element must contain "stop" elements that can be created with the stop function.
The resulting gradient definition can be added to a "defs" SVG element.

Example

```plaintext
DEFINE root_svg, defs, rg om.DomNode
...
LET defs = fglsvgcanvas.defs( NULL )
CALL root_svg.appendChild( defs )
LET rg = fglsvgcanvas.radialGradient( "gradient_1",
    NULL, NULL, "5%", "5%", "65%",
    "pad", NULL, NULL )
CALL rg.appendChild( fglsvgcanvas.stop( "0%", "gray", 0.4 ) )
CALL rg.appendChild( fglsvgcanvas.stop( "100%", "navy", 0.7 ) )
CALL defs.appendChild( rg )
```

Related concepts
The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

rect()
Produces an SVG "rect" element.

Syntax

```plaintext
rect ( 
    x DECIMAL, 
    y DECIMAL, 
    width DECIMAL, 
    height DECIMAL, 
    rx DECIMAL, 
    ry DECIMAL )
RETURNS om.DomNode
```

1. x defines the X coordinate of the top/left corner.
2. y defines the Y coordinate of the top/left corner.
3. width defines the width of the rectangle.
4. height defines the height of the rectangle.
5. rx defines the X radius for rounded corners.
6. ry defines the Y radius for rounded corners.

Usage
This function creates a "rect" SVG DOM element from the parameters.
One can get rounded borders by setting the rx, ry parameters.

Example

```plaintext
DEFINE n om.DomNode
LET n = fglsvgcanvas.rect(10,10,50,30,1,1)
```
Related concepts
The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

removeElement()
Deletes an SVG element from the SVG canvas.

Syntax

```javascript
removeElement(
    node om.DomNode )
```

1. `node` is the `om.DomNode` to be removed.

Usage
This function deletes an SVG element from the current SVG canvas.
The DOM node to remove is passed as second parameter.
The SVG DOM node object is de-referenced and destroyed.

Example

```javascript
DEFINE root_svg, g om.DomNode
...
LET g = fglsvgcanvas.g( "group1" )
CALL root_svg.appendChild( g )
...
CALL fglsvgcanvas.removeElement( g )
```

Related concepts
The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

setAttributes()
Sets the SVG attributes from an attribute set.

Syntax

```javascript
setAttributes(
    node om.DomNode,
    attrs om.SaxAttributes )
```

1. `node` is the DOM node to be updated.
2. `attrs` is the `om.SaxAttributes` object defining the attributes.

Usage
This function updates the DOM node passed as first parameter with the `om.SaxAttributes` object.

Note: If a SAX attribute value is NULL, the attribute is removed from the node.
The `setAttributes()` function should only be used to set explicitly node-level attributes. Consider using CSS style definitions with the `styleList()` function, or inline styling with the `styleAttributeList()` function.

Steps to define and use an attribute set with `setAttributes()`:
1. Create and fill an `om.SaxAttributes` object,
2. Create the SVG DOM element with one of the fglsvgcanvas functions,
3. Call the `setAttributes()` function with the node and the SAX attributes.

Example

```javascript
CONSTANT COLORS_OCEAN = 1
DEFINE attr DYNAMIC ARRAY OF om.SaxAttributes,
    n om.DomNode
...
LET attr[COLORS_OCEAN] = om.SaxAttributes.create()
CALL attr[COLORS_OCEAN].addAttribute(SVGATT_FILL, "cyan")
CALL attr[COLORS_OCEAN].addAttribute(SVGATT_FILL_OPACITY, "0.3")
CALL attr[COLORS_OCEAN].addAttribute(SVGATT_STROKE, "blue")
...
LET n = fglsvgcanvas.polygon("10,10 10,20 20,20")
CALL fglsvgcanvas.setAttributes( n, attr[COLORS_OCEAN] )
```

Related concepts

The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

`setCurrent()`
Selects the SVG canvas handler for subsequent SVG canvas API calls.

Syntax

```javascript
setCurrent(
    cid SMALLINT )
```

1. `cid` is the SVG canvas id, as returned by `fglsvgcanvas.create()`.

Usage

This function makes the specified SVG canvas current.

Any subsequent calls to a `fglsvgcanvas` function that requires the SVG canvas handler will be done with this identifier.

Example

```javascript
DEFINE cid1, cid2 SMALLINT
LET cid1 = fglsvgcanvas.create("formonly.canvas1") -- current canvas is cid1
LET cid2 = fglsvgcanvas.create("formonly.canvas1") -- current canvas is cid2
CALL fglsvgcanvas.setCurrent( cid1 ) -- current canvas is cid1
```

Related concepts

The `fglsvgcanvas` web component on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

`setRootSVGAttributes()`
Produces the root SVG element.

Syntax

```javascript
setRootSVGAttributes(
    id STRING,
    width STRING,
    height STRING,
    viewBox STRING,
    preserveAspectRatio STRING )
RETURNS om.DomNode
```
1. *id* is the SVG object identifier.
2. *width* and *height* define the SVG viewport.
3. *viewBox* defines the SVG viewbox (the internal coordinate system).
4. *preserveAspectRatio* is the aspect ratio to preserve.

**Usage**

This function sets the attributes of the root "svg" SVG element from the parameters, and returns the SVG DOM element.

**Note:** This method does not create a new DOM node object (it is created when calling the `create()` function):
You can repeat calls to the `setRootSVGAttributes()` function to change/reset the root DOM node SVG attributes.

Create the SVG canvas with the following sequence of calls:

1. Initialize the fglsvgcanvas library with `initialize()`.
2. Create a new SVG canvas handler with `create()` (this creates the DOM node for the root SVG).
3. Set root SVG attributes and get the corresponding DOM node object with `setRootSVGAttributes()`.
4. Use the root DOM node to append child DOM element created from fglsvgcanvas functions.

The *width* and *height* attributes define the SVG viewport, the visible area of the SVG image. You want to leave
the viewport attributes to NULL, to let the SVG image adapt to its container.

The viewBox is specified with the *viewBox* parameter, to define the coordinate system to draw SVG objects. For example "0 0 100 100" defines a viewbox where 0,0 are the coordinates of the top/left corner, and 100,100 are the coordinates of the bottom/right corner. If you draw a rectangle with 25,25,50,50 it will be centered and use the half of the viewbox.

The *preserveAspectRatio* parameter is used in conjunction with the *viewBox* attribute, to control how the SVG content is stretched, whether or not to force uniform scaling. In most case you want to use the "xMidYMin slice" as aspect ratio.

See SVG reference for more details about viewports and viewboxes.

**Example**

Displaying an image from an URL:

```om
DEFINE root_svg om.DomNode
LET root_svg = fglsvgcanvas.setRootSVGAttributes(
    "agenda",
    NULL, NULL,
    "0 0 1000 1000",
    "xMidYMin slice"
)
```

**Related concepts**

The [fglsvgcanvas web component](#) on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**stop()**

Produces an SVG "stop" element for gradients.

**Syntax**

```om
code
stop(  
    offset STRING,  
    color STRING,  
    opacity STRING  )
RETURNS om.DomNode
```
1. *offset* defines the offset SVG attribute.
2. *color* defines the stop-color SVG attribute.
3. *opacity* defines the stop-opacity SVG attribute.

**Usage**

This function creates a "stop" SVG DOM element from the parameters.

An SVG "stop" element defines the ramp of colors to use on a gradient in a "linearGradient" or "radialGradient" element.

For a usage example, see `linearGradient()` on page 2226.

**Related concepts**

The fglsvgcanvas web component on page 1891

The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**styleAttributeList()**

Builds a string with a list of attributes to be used in a style attribute.

**Syntax**

```
styleAttributeList(
    attrs om.SaxAttributes )
RETURNS STRING
```

1. *attrs* is the *om.SaxAttributes* object defining the attributes.

**Usage**

This function builds string containing a list of *name:*value; pairs, from the attribute set defined by an *om.SaxAttributes* object.

The resulting string can then be used to define a CSS style, or it can be defined in an SVG element using `style="attribute-list"`.

Steps to define and use an attribute set with `styleAttributeList()`:

1. Create and fill an *om.SaxAttributes* object,
2. Create the SVG DOM element with one of the fglsvgcanvas functions,
3. Set the "style" attribute with value produced from `styleAttributeList()`.

**Example**

```
CONSTANT COLORS_FIRE = 1
DEFINE attr DYNAMIC ARRAY OF om.SaxAttributes, n om.DomNode
...
LET attr[COLORS_FIRE] = om.SaxAttributes.create()
CALL attr[COLORS_FIRE].setAttribute(SVGATT_STROKE,"red")
...
LET n = fglsvgcanvas.circle(100,100,50)
CALL n.setAttribute(SVGATT_STYLE,
    fglsvgcanvas.styleAttributeList(attr[COLORS_FIRE]) )
...
```

**Related concepts**

The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**styleDefinition()**

Produces a CSS style definition with a selection and list of attributes.

**Syntax**

```plaintext
styleDefinition(
    selector STRING,
    attrs om.SaxAttributes )
RETURNS STRING
```

1. *selector* is the style selector.
2. *attrs* is the *om.SaxAttributes* object defining the attributes.

**Usage**

This function creates a CSS style definition line, from the attribute set defined by an *om.SaxAttributes* object.

The attribute set must be an *om.SaxAttributes* object.

The resulting string can be used in a style list created by the *styleList()* function.

Steps to define and use an attribute set with *styleDefinition()*:

1. Create and fill an *om.SaxAttributes* object,
2. Use the *styleDefinition()* function using the SAX attributes.

**Related concepts**

*The fglsvgcanvas web component* on page 1891

The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**styleList()**

Produces a CSS style list.

**Syntax**

```plaintext
styleList(
    content STRING )
RETURNS om.DomNode
```

1. *content* is the string produced by a set of *styleDefinition()* functions.

**Usage**

This function creates a "style" SVG DOM element with a text sub-node containing a list of style definitions, to create a CSS style. The resulting DOM element can then be used in a "defs" element.

A single CSS style definition can be produced with the *styleDefinition()* function.

**Example**

```plaintext
CONSTANT STYLE_1 = 1
CONSTANT STYLE_2 = 2
CONSTANT STYLE_3 = 3
DEFINE attr DYNAMIC ARRAY OF om.SaxAttributes,
    root_svg, defs om.DomNode
...
LET attr[STYLE_1] = om.SaxAttributes.create()
CALL attr[STYLE_1].setAttribute(SVGATT_STROKE,"red")
...
LET attr[STYLE_2] = om.SaxAttributes.create()
...
LET attr[STYLE_3] = om.SaxAttributes.create()
...
LET defs = fglsvgcanvas.defs(NULL)
CALL defs.appendChild( fglsvgcanvas.styleList(
    fglsvgcanvas.styleDefinition(".style_1", attr[STYLE_1])
    |
    fglsvgcanvas.styleDefinition(".style_2", attr[STYLE_2])
    |
    fglsvgcanvas.styleDefinition(".style_3", attr[STYLE_3])
)
}
CALL root_svg.appendChild(defs)

Related concepts
The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

svg()
Produces an SVG "svg" element.

Syntax

```
svg(
    id STRING,
    x STRING,
    y STRING,
    width STRING,
    height STRING,
    viewBox STRING,
    preserveAspectRatio STRING
RETURNS om.DomNode
```

1. `id` is the SVG object identifier.
2. `x`, `y`, `width`, `height` define the SVG viewport.
3. `viewBox` defines the SVG viewbox.
4. `preserveAspectRatio` is the aspect ratio to preserve.

Usage
This function creates an "svg" SVG DOM element definition from the parameters.
SVG allows to create nested svg sub-elements with their own coordinate system.
Build a tree of svg elements as you need.

Note: The root svg element must be created with the `setRootSVGAttributes()` function.
The viewport is defined by the `x`, `y`, `width` and `height` attributes.
The viewbox is defined by the `viewBox` string for example as "0 0 100 100".
See SVG reference documentation for more details about viewport, viewbox and aspect ratio concepts.

Example

```
DEFINE root_svg, n om.DomNode
...
LET n = fglsvgcanvas.svg("day_1",
    NULL, NULL, NULL, NULL,
    "0 0 500 500",
)
"xMidYMid meet"

... CALL root_svg.appendChild( n )

**Related concepts**
The **fglsvgcanvas web component** on page 1891
The **fglsvgcanvas** built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**text()**
Produces an SVG "text" element.

**Syntax**

```html
text(
    x DECIMAL,
    y DECIMAL,
    content STRING,
    class STRING
) RETURNS om.DomNode
```

1. *x* and *y* define the position of the text.
2. *content* is the actual text.
3. *class* defines a reference to a CSS style.

**Usage**

This function creates a "text" SVG DOM element from the parameters.

To specify the text font attributes, define a CSS style in a **defs()** element with the **styleList()** function, and reference the text style in the *class* parameter of this function.

**Example**

```sql
DEFINE n om.DomNode
LET n = fglsvgcanvas.text(10,10,"Hello!","mystyle_1")
```

**Related concepts**
The **fglsvgcanvas web component** on page 1891
The **fglsvgcanvas** built-in web component implements a drawing canvas for Scalable Vector Graphics content.

**text_path()**
Produces the SVG "text" element with a "textPath" sub-element.

**Syntax**

```html
text_path(
    x DECIMAL,
    y DECIMAL,
    content STRING,
    path STRING
    class STRING
) RETURNS om.DomNode
```

1. *x* and *y* define the position of the text.
2. *content* is the actual text.
3. *path* is the xlink:href reference (without #).
4. *class* defines a reference to a CSS style.
Usage

This function creates a "text" SVG DOM element from the parameters, including a "textPath" sub-element that references a "path" element defined in a "defs" element.

The path parameter is used to build an "xlink:href=#path" reference.

The actual path can be created with the path() function, and included in a "defs" element created with the defs() function.

To specify the text font attributes, define a CSS style in a defs() element with the styleList() function, and reference the text style in the class parameter of this function.

Example

```
DEFINE root_svg, defs, p, n om.DomNode
...
LET defs = fglsvgcanvas.defs(NULL)
CALL root_svg.appendChild(defs)
...
CALL defs.appendChild(p:=fglsvgcanvas.path("M150,400 C175,380 225,320 450,450") )
CALL p.setAttribute("id", "path_1")
LET n = fglsvgcanvas.text_path(NULL,NULL,"This text follows a path...","path_1","style_4")
...
```

Related concepts

The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

text_tref()

Produces the SVG "text" element with a "tref" sub-element.

Syntax

```
text_tref(
 x DECIMAL,
 y DECIMAL,
 tref STRING,
 class STRING )
RETURNS om.DomNode
```

1. x and y define the position of the text.
2. tref is the xlink reference to the tref.
3. class defines a reference to a CSS style.

Usage

This function creates a "text" SVG DOM element from the parameters, including a "tref" sub-element that references a "text" element defined in a "defs" element.

The tref parameter is used to build an "xlink:href=#path" reference.

The "text" element referenced by the "tref" attribute must be defined in a "defs" element, created with the defs() function.

To specify the text font attributes, define a CSS style in a defs() element with the styleList() function, and reference the text style in the class parameter of this function.
Example

```plaintext
DEFINE root_svg, defs, t, n om.DomNode
...
LET defs = fglsvgcanvas.defs( NULL )
CALL root_svg.appendChild( defs )
...
CALL defs.appendChild( t:=fglsvgcanvas.text( NULL, NULL, "The is the referenced text..." ) )
CALL t.setAttribute("id","text_1")
LET n = fglsvgcanvas.text_tref(10,20,"text_1","style_4")
...
```

Related concepts

The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

title()

Produces a SVG "title" element.

Syntax

```plaintext
title( text STRING )
    RETURNS om.DomNode
```

1. `text` defines text for the title element.

Usage

This function creates a "title" SVG DOM element from the text provided as parameter.

In SVG, a title element is usually rendered with a tooltip on desktop platforms.

Note: The title element must be the first child of the parent SVG element. See SVG specification for more details.

Example

```plaintext
DEFINE g om.DomNode
LET g = fglsvgcanvas.g( "g1" )
CALL g.appendChild( fglsvgcanvas.title("This is my text") )
```

Related concepts

The fglsvgcanvas web component on page 1891
The fglsvgcanvas built-in web component implements a drawing canvas for Scalable Vector Graphics content.

tspan()

Produces an SVG "tspan" element.

Syntax

```plaintext
tspan( x DECIMAL, y DECIMAL, dx STRING, dy STRING, style STRING, content STRING )
    RETURNS om.DomNode
```

1. `x` defines the X position of the tspan element.
2. \( y \) defines the Y position of the tspan element.
3. \( dx \) defines the delta-X for horizontal positionning of the tspan element.
4. \( dy \) defines the delta-Y for vertical positionning of the tspan element.
5. \( style \) defines the in-line style to be applied on the tspan element.
6. \( content \) is the actual text.

**Usage**

This function creates a "tspan" SVG DOM element from the parameters.

A tspan element can be used to draw multiple lines of text in SVG.

The DOM nodes created by this function must be added to in a "text" element produced by the `text()` function.

**Example**

```plaintext
DEFINE root_svg, t om.DomNode
... 
LET t = fglsvgcanvas.text(NULL,200,NULL,"style_2")
CALL root_svg.appendChild( t )
CALL t.appendChild( fglsvgcanvas.tspan(120,NULL,NULL,30,NULL,"First line" ) )
CALL t.appendChild( fglsvgcanvas.tspan(120,NULL,NULL,30,NULL,"Second line" ) )
```

**Related concepts**

- The [fglsvgcanvas web component](#) on page 1891
- The [fglsvgcanvas built-in web component](#) implements a drawing canvas for Scalable Vector Graphics content.

**url()**

Produces a "url(#name)" reference for SVG elements.

**Syntax**

```plaintext
url( name STRING )
RETURNS STRING
```

1. \( name \) is the URL name.

**Usage**

This function builds a "url(#name)" SVG attribute with the name passed as parameter.

Such URL attribute is typically used in SVG element to reference a common reusable element defined in the "defs" element, such as SVG patterns.

**Example**

```plaintext
CALL n.setAttribute(SVGATT_STYLE,
    SFMT('stroke:gray; fill:%1;', fglsvgcanvas.url("pattern_1") ) )
```

**Related concepts**

- The [fglsvgcanvas web component](#) on page 1891
The `fglsvgcanvas` built-in web component implements a drawing canvas for Scalable Vector Graphics content.

use()

Produces an SVG "use" element.

Syntax

```plaintext
use (  
  name STRING,  
  x DECIMAL,  
  y DECIMAL  
)  
RETURNS om.DomNode
```

1. `name` is the xlink:href reference (without #).
2. `x` defines the X coordinate to place the shape.
3. `y` defines the Y coordinate to place the shape.

Usage

This function creates a "use" SVG DOM element from the parameters.

The "use" element can reuse an SVG shape from elsewhere in the SVG document, for example to make several copies of shapes defined in the "defs" element.

Example

```plaintext
DEFINE n1, n2 om.DomNode
LET n1 = fglsvgcanvas.use( "myshape1", 100, 100 )
LET n2 = fglsvgcanvas.use( "myshape1", 110, 110 )
```

Related concepts

## Built-in packages

These topics cover the built-in classes provided by the Genero Business Development Language.

- BDL data types package on page 2244
- The base package on page 2268
- The ui package on page 2328
- The om package on page 2429

### BDL data types package

These topics cover the built-in classes of BDL data types

- BYTE data type as class on page 2245
- STRING data type as class on page 2246
- TEXT data type as class on page 2253
- DYNAMIC ARRAY as class on page 2255
- fgl-topics/fgl_ClassDICTIONARY.ditamap
- Java Array type as class on page 2266
BYTE data type as class
The BYTE primitive data type provides a set of utility methods to manipulate BYTE data.

BYTE methods can be invoked with the variable, for example:

```
DEFINE b BYTE
... 
CALL b.writeFile("mydata")
```

Related concepts
BYTE on page 255
The BYTE data type stores any type of binary data, such as images or sounds.

BYTE data type methods

Table 458: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>readFile</strong></td>
<td>Reads a file into a BYTE locator.</td>
</tr>
<tr>
<td>(path STRING)</td>
<td></td>
</tr>
<tr>
<td><strong>writeFile</strong></td>
<td>Writes the content of a BYTE to a file.</td>
</tr>
<tr>
<td>(path STRING)</td>
<td></td>
</tr>
</tbody>
</table>

**BYTE.readFile**
Reads a file into a BYTE locator.

**Syntax**
```
readFile(path STRING )
```

**1.** *path* is the path the file to be loaded.

**Usage**
This method reads a content from the specified file into the BYTE locator.
The bytes are loaded as is, without any conversion.

If the file is not found or if it cannot be read, the error -8087 is raised.

**Example**
```
MAIN
  DEFINE b BYTE
  LOCATE b IN MEMORY
  CALL b.readFile("mydata")
END MAIN
```

**BYTE.writeFile**
Writes the content of a BYTE to a file.

**Syntax**
```
writeFile()
```
1. path is the file to be written to.

Usage

This method writes the content of the current BYTE locator to the specified file. The bytes are written as is, without any conversion. If the file cannot be written, the error -8087 is raised.

Example

```
MAIN
  DEFINE b BYTE
  DATABASE mydb
  LOCATE b IN MEMORY
  SELECT col_byte INTO b FROM tab1
  CALL b.writeFile("mydata")
END MAIN
```

STRING data type as class

The STRING built-in data type provides a set of utility methods to manipulate character strings. STRING methods can be invoked with the variable, for example:

```
DEFINE s STRING
IF s.equalsIgnoreCase("pink") THEN
  ...
END IF
```

Related concepts

STRING on page 269
The STRING data type is a variable-length, dynamically allocated character string data type, without limitation.

**STRING data type methods**

Table 459: Object methods

<table>

<tr>
<td>RETURNS STRING</td>
<td></td>
</tr>
<tr>
<td><code>trimRight()</code></td>
<td>Removes trailing blanc characters.</td>
</tr>
<tr>
<td>RETURNS STRING</td>
<td></td>
</tr>
</tbody>
</table>
**STRING.append**
Concatenates a string.

**Syntax**

```plaintext
append( str STRING )
RETURNS STRING
```

1. `str` is the string to be concatenated.

**Usage**
This method concatenates a string to the current STRING variable and returns the resulting string.
The original STRING variable is not modified.
Appending a NULL will have no effect: the original string is returned.

**Example**

```plaintext
MAIN
    DEFINE s STRING
    LET s = "Some text"
    DISPLAY s.append("... more text")
END MAIN
```

**STRING.equals**
Compares a string to the content of the variable.

**Syntax**

```plaintext
equals( str STRING )
RETURNS BOOLEAN
```

1. `str` is the string to compare with.

**Usage**
This method compares a string to the current STRING variable and returns TRUE if both strings match.
If the original STRING variable or the string passed as parameter is NULL, the result with be FALSE.

**Example**

```plaintext
MAIN
    DEFINE s STRING
    LET s = "white"
    IF s.equals("white") THEN
        DISPLAY "Matches"
    END IF
END MAIN
```

**STRING.equalsIgnoreCase**
Makes a case-insensitive string comparison.

**Syntax**

```plaintext
equalsIgnoreCase( str STRING )
RETURNS BOOLEAN
```
1. *str* is the string to compare with.

**Usage**

This method compares a string to the current STRING variable by ignoring the character case, and returns **TRUE** if both strings match.

If the original STRING variable or the string passed as parameter is **NULL**, the result will be **FALSE**.

**Example**

```plaintext
MAIN
  DEFINE s STRING
  LET s = "white"
  IF s.equalsIgnoreCase("WHITE") THEN
    DISPLAY "Matches"
  END IF
END MAIN
```

**STRING.getCharAt**

Returns the character at the specified position.

**Syntax**

```plaintext
getCharAt ( index INTEGER )
RETURNS CHAR(1)
```

1. *index* is the position of the character in the string.

**Usage**

This method extracts the character at the specified position from the STRING variable.

If the STRING variable is **NULL**, or if the position is out of the bounds of the string, the result will be **NULL**.

**Important:** When using byte length semantics, the position is expressed in bytes, and when using char length semantics, position is specified in characters. In byte length semantics, the method returns **NULL** if the position does not match a valid character-byte index in the current string.

**Example**

```plaintext
MAIN
  DEFINE s STRING
  LET s = "Some text"
  DISPLAY s.getCharAt(4)
END MAIN
```

**Related concepts**

Length semantics settings on page 414

**STRING.getIndexOf**

Returns the position of a sub-string.

**Syntax**

```plaintext
getIndexOf ( str STRING, startIndex INTEGER )
RETURNS INTEGER
```

1. *str* is the sub-string to be searched.
2. `startIndex` is the starting position for the search.

**Usage**

This method scans a `STRING` variable to find the sub-string passed as parameter, and returns the position of the sub-string.

The method starts to search the sub-string at the starting position specified as second parameter.

The method returns zero if:

- The `STRING` variable is `NULL`.
- The `str` sub-string was not found.
- The `str` sub-string is `NULL`.
- The start position is out of bounds.

**Important:** When using byte length semantics, the position is expressed in bytes, and when using char length semantics, it is specified in characters.

**Example**

```plaintext
MAIN
    DEFINE s STRING
    LET s = "Some text"
    DISPLAY s.getIndexOf("text",1)
END MAIN
```

**Related concepts**

- **Length semantics settings** on page 414
  - `STRING.getLength`
    Returns the length of the current string.

**Syntax**

```plaintext
getLength( )
    RETURNS INTEGER
```

**Usage**

This method counts the number of bytes or characters in a `STRING` variable.

**Note:** Unlike the `LENGTH()` function, the `getLength()` method counts the trailing blanks.

If the `STRING` variable is `NULL`, the method returns zero.

**Important:** When using byte length semantics, the length is expressed in bytes, and when using char length semantics, it is expressed in characters.

**Example**

```plaintext
MAIN
    DEFINE s STRING
    LET s = "Some text"
    DISPLAY s.getLength()
END MAIN
```

**Related concepts**

- `length()` on page 2178
  Returns the number of the character string passed as parameter.
  - **Length semantics settings** on page 414
**STRING.subString**

Returns a sub-string from start and end positions in a given string.

**Syntax**

```plaintext
subString(
    startIndex INTEGER,
    endIndex INTEGER )
RETURNS STRING
```

1. `startIndex` is the starting position of the sub-string.
2. `endIndex` is the ending position of the sub-string.

**Usage**

This method returns a sub-string of the current STRING variable based on a start and end positions in the original string.

If the STRING variable is NULL, or when the positions are out of bounds, the method returns NULL.

**Important:** When using byte length semantics, the positions are expressed in bytes, and when using char length semantics, positions are expressed in characters.

**Example**

```plaintext
MAIN
    DEFINE s STRING
    LET s = "Some text"
    DISPLAY s.subString(6,9)
END MAIN
```

**Related concepts**

[Length semantics settings on page 414](#)

**STRING.toLowerCase**

Returns the string converted to lower case.

**Syntax**

```plaintext
toLowerCase( )
RETURNS STRING
```

**Usage**

This method converts the current STRING variable to lower case and returns the resulting string.

If the original STRING variable is NULL, the result is NULL.

**Example**

```plaintext
MAIN
    DEFINE s STRING
    LET s = "Some text"
    DISPLAY s.toLowerCase()
END MAIN
```
**STRING.toUpperCase**
Returns the string converted to upper case.

**Syntax**

```
toUpperCase( )
    RETURNS STRING
```

**Usage**

This method converts the current STRING variable to upper case and returns the resulting string.

If the original STRING variable is NULL, the result is NULL.

**Example**

```
MAIN
    DEFINE s STRING
    LET s = "Some text"
    DISPLAY s.toUpperCase()
END MAIN
```

**STRING.trim**
Removes leading and trailing blank characters.

**Syntax**

```
trim( )
    RETURNS STRING
```

**Usage**

The trim() method removes the leading and trailing blank characters of the current STRING variable and returns a new string.

If the original STRING variable is NULL, the result will be NULL.

**Example**

```
MAIN
    DEFINE s STRING
    LET s = "   Some text   
    DISPLAY s.trim()
END MAIN
```

**STRING.trimLeft**
Removes leading blank characters.

**Syntax**

```
trimLeft( )
    RETURNS STRING
```

**Usage**

The trimLeft() method removes the leading blank characters of the current STRING variable and returns a new string.

If the original STRING variable is NULL, the result will be NULL.
Example

```plaintext
MAIN
    DEFINE s STRING
    LET s = "Some text"
    DISPLAY s.trimLeft()
END MAIN
```

`STRING.trimRight`
Removes trailing blanc characters.

Syntax

```plaintext
trimRight( )
RETURNS STRING
```

Usage

The `trimRight()` method removes the trailing blanc characters of the current `STRING` variable and returns a new string.

If the original `STRING` variable is `NULL`, the result will be `NULL`.

Example

```plaintext
MAIN
    DEFINE s STRING
    LET s = "Some text     
    DISPLAY s.trimRight()
END MAIN
```

`TEXT data type as class`

The `TEXT` primitive data type provides a set of utility methods to manipulate `TEXT` data.

`TEXT` methods can be invoked with a variable, for example:

```plaintext
DEFINE t TEXT
...
CALL t.writeFile("mydata")
```

Related concepts

`TEXT` on page 271
The TEXT data type stores large text data.

**TEXT data type methods**

**Table 460: Object methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getLength()</code></td>
<td>Returns the length of a TEXT content.</td>
</tr>
<tr>
<td><code>readFile(path STRING)</code></td>
<td>Reads a file into a TEXT locator.</td>
</tr>
<tr>
<td><code>writeFile(path STRING)</code></td>
<td>Writes the content of a TEXT to a file.</td>
</tr>
</tbody>
</table>

**TEXT.getLength**

Returns the length of a TEXT content.

**Syntax**

```
GETLENGTH ( )
RETURNS INTEGER
```

**Usage**

This method returns the number of bytes of the TEXT data.

**Important:** This method returns always a number of bytes, even when using character length semantics.

**Example**

```
MAIN
  DEFINE t TEXT
  LOCATE t IN MEMORY
  LET t = "aaaaaaaaaaaaa"
  DISPLAY t.getLength() -- Shows 13
END MAIN
```

**Related concepts**

Length semantics settings on page 414

**TEXT.readFile**

Reads a file into a TEXT locator.

**Syntax**

```
readFile(path STRING)
```

1. `path` is the path the file to be loaded.
Usage
This method reads a content from the specified file into the TEXT locator.

If the file is not found or if it cannot be read, the error -8087 is raised.

Important: The character set used in the file must match the current application locale.

Example

```plaintext
MAIN
   DEFINE t TEXT
   LOCATE t IN MEMORY
   CALL t.readFile("mydata")
END MAIN
```

TEXT.writeFile
Writes the content of a TEXT to a file.

Syntax

```plaintext
writeFile(
    path STRING )
```

1. path is the file to be written to.

Usage
This method writes the content of the current TEXT locator to the specified file.

If the file cannot be written, the error -8087 is raised.

Important: The character set used in the file must match the current application locale.

Example

```plaintext
MAIN
   DEFINE t TEXT
   LOCATE t IN MEMORY
   SELECT col_text INTO t FROM ... 
   CALL t.writeFile("mydata")
END MAIN
```

DYNAMIC ARRAY as class
The DYNAMIC ARRAY (or static ARRAY) type provides a set of utility methods to manipulate the array elements.

DYNAMIC ARRAY methods can be invoked with the variable, for example:

```plaintext
DEFINE a DYNAMIC ARRAY OF STRING
CALL a.appendElement()
DISPLAY a.getLength()
```

Related concepts
Arrays on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

**DYNAMIC ARRAY methods**

**Table 461: Object methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>appendElement()</code></td>
<td>Adds a new element to the end of the array.</td>
</tr>
<tr>
<td><code>clear()</code></td>
<td>Removes all elements of the array.</td>
</tr>
<tr>
<td><code>copyTo(dst dynamic-array-type)</code></td>
<td>Copies a complete array to the destination array passed as parameter.</td>
</tr>
<tr>
<td><code>deleteElement(index INTEGER)</code></td>
<td>Removes an element from the array.</td>
</tr>
<tr>
<td><code>getLength()</code></td>
<td>Returns the length of the array.</td>
</tr>
<tr>
<td><code>insertElement(index INTEGER)</code></td>
<td>Inserts a new element at the given index.</td>
</tr>
<tr>
<td><code>search(key STRING, value STRING)</code></td>
<td>Scans the array to find an element that matches the search parameter.</td>
</tr>
<tr>
<td><code>searchRange(key STRING, value STRING, from INTEGER, to INTEGER)</code></td>
<td>Scans the array to find an element that matches the search parameter.</td>
</tr>
<tr>
<td><code>sort(key STRING, reverse BOOLEAN)</code></td>
<td>Sorts the rows in the array.</td>
</tr>
</tbody>
</table>

**DYNAMIC ARRAY.appendElement**

Adds a new element to the end of the array.

**Syntax**

```
appendElement()
```

**Usage**

This method creates a new element at the end of the array.

The element is initialized to `NULL`.

**Example**

```
MAIN
  DEFINE a DYNAMIC ARRAY OF INTEGER
  DEFINE x INT
```
FOR x=1 TO 5
    CALL a.appendElement()
    LET a[x] = 100+x
END FOR
DISPLAY a.getLength() -- shows 5
DISPLAY a[3] -- shows 103
END MAIN

Since element allocation occurs automatically for dynamic arrays, you can omit the call the `appendElement()` method and assign directly the new element:

MAIN
    DEFINE a DYNAMIC ARRAY OF INTEGER
    LET a[100] = 87234 -- Array gets a length of 100 automatically
    LET a[101] = 98562 -- New element at position 101
END MAIN

However, for better code readability, you might want to use the `appendElement()` method in some cases.

**DYNAMIC ARRAY.clear**
Removes all elements of the array.

**Syntax**

```plaintext
clear( )
```

**Usage**
This method clears the array, by removing all its elements.

For example, if the array is not empty, use the `clear()` method just before filling the array with a new set of elements.

**Example**

MAIN
    DEFINE a1 DYNAMIC ARRAY OF STRING
    CALL fill_array(a1)
    DISPLAY a1.getLength()
    DISPLAY a1[3]
END MAIN

FUNCTION fill_array(arr)
    DEFINE arr DYNAMIC ARRAY OF STRING
    DEFINE i INTEGER
    CALL arr.clear()
    FOR i=1 TO 10
        LET arr[i] = "Item #" || i
    END FOR
END FUNCTION

**DYNAMIC ARRAY.copyTo**
Copies a complete array to the destination array passed as parameter.

**Syntax**

```plaintext
copyTo( dst dynamic-array-type )
```

1. `dst` is the destination dynamic array, with the same type definition as the source array.
2. `dynamic-array-type` is a `DYNAMIC ARRAY OF ...` type that corresponds to the source array.
**Usage**

The `copyTo()` method copies all elements of the source array into the destination array. The method truncates the length of the destination array to the length of the source array.

The `copyTo()` method is equivalent to the following code:

```plaintext
CALL destin.clear()
FOR x=1 TO source.getLength()
    LET destin[x].* = source[x].*
END FOR
```

If the destination array is not of the same type as the source array, error -8112 is thrown.

**Important:** Avoid making a copy of huge arrays, consider using a database temporary table instead.

**Example**

```plaintext
MAIN
    TYPE t_names RECORD
        num INT,
        name STRING
    END RECORD
    DEFINE aa, ab DYNAMIC ARRAY OF t_names
    LET aa[1].num = 101
    LET aa[1].name = "Mike Tormme"
    CALL aa.copyTo(ab)
    DISPLAY ab[1].*
END MAIN
```

**DYNAMIC ARRAY.deleteElement**

Removes an element from the array.

**Syntax**

```plaintext
deleteElement( index INTEGER )
```

1. `index` is the position of the element to be removed.

**Usage**

This method removes the array element at the specified index.

**Note:** No error is raised if the index is out of bounds.

**Example**

```plaintext
MAIN
    DEFINE a DYNAMIC ARRAY OF INTEGER
    LET a[10] = 9
    CALL a.deleteElement(5)
    DISPLAY a.getLength() -- shows 9
    DISPLAY a[9] -- shows 9
END MAIN
```

**DYNAMIC ARRAY.getLength**

Returns the length of the array.

**Syntax**

```plaintext
getLength( )
```
**Usage**

This method returns the number of elements in the array.

**Tip:** To improve performances in `FOR ... END FOR` loops, assign a variable with the array length and use this variable as argument for the `TO` clause.

**Example**

```
MAIN
    DEFINE arr DYNAMIC ARRAY OF STRING,
            i, m INTEGER
    LET arr[1] = "aaa"
    LET arr[2] = "bbbb"
    LET arr[3] = "cccc"
    LET m = arr.getLength()
    FOR i=1 TO m
        DISPLAY arr[i]
    END FOR
END MAIN
```

**DYNAMIC ARRAY.insertElement**

Inserts a new element at the given index.

**Syntax**

```
insertElement ( index INTEGER )
```

1. `index` is the position where a new element must be inserted.

**Usage**

This method inserts a new element in the array, before the specified index.

**Note:** No error is raised if the index is out of bounds.

**Example**

```
MAIN
    DEFINE a DYNAMIC ARRAY OF INTEGER
    LET a[10] = 11
    CALL a.insertElement(10)
    LET a[10] = 10
    DISPLAY a.getLength() -- shows 11
    DISPLAY a[10] -- shows 10
END MAIN
```

**DYNAMIC ARRAY.search**

Scans the array to find an element that matches the search parameter.

**Syntax**

```
search ( key STRING, value STRING )
    RETURNS INTEGER
```

1. `key` is the name of the RECORD member when the array is structured.
2. `value` is the value to look for.
Usage

The `search()` method will scan the whole array, to find a specific element that matches the value passed as second parameter.

The method returns the index of the first occurrence found.

The method returns zero, if no matching element is found.

The `search()` method is equivalent to the following function (same as `arr.search("member", val)`):

```plaintext
FUNCTION search(arr, val)
    DEFINE arr DYNAMIC ARRAY OF ... ,
              val STRING
    DEFINE x INT
    FOR x=1 TO arr.getLength()
        IF arr[x].member = value THEN RETURN x END IF
    END FOR
    RETURN 0
END FUNCTION
```

If the array is structured (`DYNAMIC ARRAY OF RECORD`), the method returns the index of the first occurrence of an element where the record-member specified by `key` is equal to the `value` parameter.

If the array is a flat array (`DYNAMIC ARRAY OF base-type`), the method returns the index of the first occurrence of the element that matches the `value` parameter. The `key` parameter is ignored.

Example

```plaintext
MAIN
    DEFINE a DYNAMIC ARRAY OF RECORD
        name STRING
    END RECORD

    LET a[1].name = "Mike"
    LET a[2].name = "Phil"
    LET a[3].name = "John"

    DISPLAY a.search("name", "Marc")  -- Shows 0
    DISPLAY a.search("name", "John")  -- Shows 3
END MAIN
```

Related concepts

`DYNAMIC ARRAY.searchRange` on page 2260
Scans the array to find an element that matches the search parameter.

`DYNAMIC ARRAY.searchRange` Scans the array to find an element that matches the search parameter.

Syntax

```plaintext
searchRange( key STRING, value STRING,
             from INTEGER, to INTEGER )
       RETURNS INTEGER
```

1. `key` is the name of the RECORD member when the array is structured.
2. `value` is the value to look for.
3. `from` is the start index (inclusive).
4. `to` is the end index (inclusive).
Usage

The searchRange() method is similar to the search() method, except that array rows are scanned from a given index to an ending index.

The method returns the index of the first occurrence found in the specified range.

The method returns zero, if no matching element is found in the specified range.

If the start index is lower than 1, the search starts at index 1.

If the end index is lower than the start index, the method returns zero.

If the end index is greater than the array length, it is ignored and the search is done until the last element of the array.

Example

```main
DEFINE a DYNAMIC ARRAY OF RECORD
    name STRING
END RECORD

LET a[1].name = "Mike"
LET a[2].name = "Phil"
LET a[3].name = "John"
LET a[4].name = "Phil"

DISPLAY a.searchRange("name", "John", 1, 2) -- Shows 0
DISPLAY a.searchRange("name", "Phil", 1, 2) -- Shows 2
DISPLAY a.searchRange("name", "Phil", 3, 4) -- Shows 4
DISPLAY a.searchRange("name", "Phil", 0, 10) -- Shows 2
END MAIN
```

Related concepts

DYNAMIC ARRAY.search on page 2259
Scans the array to find an element that matches the search parameter.

DYNAMIC ARRAY.sort
Sorts the rows in the array.

Syntax

```
sort ( key STRING, reverse BOOLEAN )
```

1. `key` is the name of a member of a structured array (DYNAMIC ARRAY OF RECORD), or NULL if the array is not structured.
2. `reverse` is FALSE for ascending order, TRUE for descending order.

Usage

A dynamic array can be sorted with the sort() method.

- For non-structured dynamic arrays (DYNAMIC ARRAY OF simple-type), the first argument of sort() must be NULL. The array will be sorted by the single-typed elements.
- With structured arrays (DYNAMIC ARRAY OF RECORD), this method sorts the array by the member passed as first parameter.

Use the second parameter to define the sort order as ascending (FALSE) or descending (TRUE).

Note: Character string data is sorted depending on the current application locale. The sort() method is using operating system collation functions. Note that collation rules can slightly differ from platform to platform and therefore produce different ordering.
When doing subsequent calls to the sort() method using different record members of the array, the rows will be ordered by all of the record members specified for the cumulative sorts, with the most recent call defining the main sort field.

Another way to think of this is in terms of the ORDER BY clause of a SQL statement: If your dynamic array contained the variables A, B and C, and you included the following calls to the sort() method:

```
CALL a.sort("C",false)
CALL a.sort("B",false)
CALL a.sort("A",false)
```

This would be equivalent to writing an ORDER BY clause that states:

```
ORDER BY A, B, C
```

**Example**

In the next example, the first call to the sort() method sorts the rows by name in ascending order, and the second call will sort the rows by key in descendant order, then by name within each key. The last sort becomes the main sort field.

```main
DEFINE a DYNAMIC ARRAY OF RECORD
    key INTEGER,
    name VARCHAR(30)
END RECORD
LET a[1].key = 776236    LET a[1].name = "aaaaa"
LET a[2].key = 273434    LET a[2].name = "ccccccc"
LET a[3].key = 934092    LET a[3].name = "bbbb"
CALL a.sort("name",FALSE) -- Sorted by name (asc order)
CALL a.sort("key",TRUE) -- Sorted by key (desc), then by name
END MAIN
```

**DICTIONARY as class**

The DICTIONARY type provides a set of utility methods to manipulate the dictionary elements.

DICTIONARY methods can be invoked with the variable, for example:

```define
DEFINE d DICTIONARY OF STRING
CALL d.clear()
DISPLAY d.getLength()
```

**Related concepts**

Dictionary on page 393
A dictionary holds an unordered collection of elements accessed by a key.

**DICTIONARY methods**

### Table 462: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clear( )</td>
<td>Removes all elements of the dictionary.</td>
</tr>
<tr>
<td>contains( key STRING )</td>
<td>Checks if an element with the given key exists in the dictionary.</td>
</tr>
<tr>
<td>copyTo( dst dictionary-type )</td>
<td>Copies all elements of the dictionary into another dictionary.</td>
</tr>
<tr>
<td>getKeys( )</td>
<td>Returns a dynamic array of all keys of the dictionary.</td>
</tr>
<tr>
<td>getLength( )</td>
<td>Returns the number of elements in the dictionary.</td>
</tr>
<tr>
<td>remove( key STRING )</td>
<td>Removes an element of the dictionary identified by the key.</td>
</tr>
</tbody>
</table>

**DICTIONARY.clear**

Removes all elements of the dictionary.

**Syntax**

```
clear( )
```

**Usage**

The `clear()` method cleans up the dictionary, by removing all its elements.

For example, if the dictionary is not empty, use the `clear()` method just before filling the dictionary with a new set of elements.

**Example**

```
FUNCTION fill_dictionary(dict)
    DEFINE dict DICTIONARY OF STRING
    CALL dict.clear()
    LET dict["abc"] = 111
    LET dict["def"] = 222
    LET dict["xyz"] = 999
END FUNCTION
```

**DICTIONARY.contains**

Checks if an element with the given key exists in the dictionary.

**Syntax**

```
contains( key STRING )
```
1. key is the dictionary key to check.

**Usage**

The `contains()` method scans the dictionary to find if there is an element with the key passed as parameter. The method returns TRUE if the element exists, or FALSE if the element is not found.

**Example**

```plaintext
MAIN
  DEFINE dict DICTIONARY OF STRING
  LET dict["abc"] = 111
  LET dict["def"] = 222
  LET dict["xyz"] = 999
  DISPLAY dict.contains("def") -- shows 1 (TRUE)
  DISPLAY dict.contains("zzz") -- shows 0 (FALSE)
END MAIN
```

**DICTIONARY.copyTo**

Copies all elements of the dictionary into another dictionary.

**Syntax**

```plaintext
copyTo ( dst dictionary-type )
```

1. dst is the destination dictionary, with the same type definition as the source dictionary.
2. dictionary-type is a `DICTIONARY OF ...` type that corresponds to the source dictionary.

**Usage**

The `copyTo()` method clones the complete dictionary into the destination dictionary passed as parameter. The destination dictionary will be cleared before the copy operation starts.

If the destination dictionary is not of the same type as the source dictionary, error -8112 is thrown.

**Important:** Avoid making a copy of huge dictionaries, consider using a database temporary table instead.

**Example**

```plaintext
MAIN
  TYPE t_contact RECORD
    name STRING,
    address STRING,
    birth DATE
  END RECORD
  DEFINE d1, d2 DICTIONARY OF t_contact
  LET d1["Kirk"].name = "James T. Kirk"
  LET d1["Kirk"].address = "Riverside, Iowa"
  LET d1["Spock"].name = "Spock"
  LET d1["Spock"].address = "Shi'Kahr"
  CALL d1.copyTo(d2)
  DISPLAY d2.getLength()
  DISPLAY d2["Spock"].*
END MAIN
```
**DICTIONARY.getLength**

Returns the number of elements in the dictionary.

**Syntax**

```
getLength()  
RETURNS INTEGER
```

**Usage**

The `getLength()` method returns the total number of elements in the dictionary.

**Example**

```
MAIN
    DEFINE dict DICTIONARY OF STRING
    LET dict["abc"] = 111
    LET dict["def"] = 222
    LET dict["xyz"] = 999
    DISPLAY dict.getLength()   -- shows 3
END MAIN
```

**DICTIONARY.getKeys**

Returns a dynamic array of all keys of the dictionary.

**Syntax**

```
getKeys()  
RETURNS DYNAMIC ARRAY OF STRING
```

**Usage**

The `getKeys()` method builds and returns a `DYNAMIC ARRAY OF STRING` with all keys contained in the dictionary.

It is then possible to scan the dictionary with the keys returned by this method.

**Note:** A dictionary is an unordered list of elements. The keys might not be returned in the same order as they have been added to the dictionary.

**Example**

```
MAIN
    DEFINE dict DICTIONARY OF STRING,  
        keys DYNAMIC ARRAY OF STRING,  
        i INTEGER  
    LET dict["first"]  = "abc"  
    LET dict["second"] = "def"  
    LET dict["lasy"]   = "xyz"  
    LET keys = dict.getKeys()  
    FOR i = 1 to keys.getLength()  
        DISPLAY i, dict[keys[i]]  
    END FOR  
END MAIN
```
**DICTIONARY.remove**
Removes an element of the dictionary identified by the key.

**Syntax**

```plaintext
remove( key STRING )
```

1. `key` is the dictionary key of the element to remove.

**Usage**
The `remove()` method deletes and element of the dictionary, identified by the key passed as parameter.

**Example**

```plaintext
MAIN
    DEFINE dict DICTIONARY OF STRING
    LET dict["abc"] = 111
    CALL dict.remove("abc")
    DISPLAY dict.contains("abc") -- shows 0 (FALSE)
END MAIN
```

**Java Array type as class**
The Java Array type provides a set of utility methods for array elements.

Java array methods can be invoked with a type reference or the array variable, for example:

```plaintext
IMPORT JAVA java.lang.String
MAIN
    TYPE string_array_type ARRAY[] OF java.lang.String
    DEFINE names string_array_type
    LET names = string_array_type.create(100)
    LET names[1] = "aaaaaa"
    DISPLAY names.getLength()
END MAIN
```

**Related concepts**
The Java interface on page 2071

The Java interface allows you to import Java classes and instantiate Java objects in your programs.

**ARRAY** on page 387

An array defines a vector variable with a list of elements.

**Java Array type methods**

**Table 463: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>java-array-type.create( size INTEGER )</td>
<td>Creates a new Java array of the given type.</td>
</tr>
</tbody>
</table>
Table 464: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getLength()</code></td>
<td>Returns the length of the Java array.</td>
</tr>
</tbody>
</table>

**java-array-type.create**

Creates a new Java array of the given type.

**Syntax**

```
java-array-type.create(size INTEGER)
RETURNS java-array-type
```

1. `size` defines the actual number of elements of the array.

**Usage**

This class method creates a new instance of the Java array specified by the type used, with the size provided as parameter.

The type must be declared as a user defined type define with the `ARRAY [ ] OF` notation reserved for Java arrays.

**Example**

```
IMPORT JAVA java.lang.String
MAIN
    TYPE string_array_type ARRAY[] OF java.lang.String
    DEFINE names string_array_type
    LET names = string_array_type.create(100)
    LET names[1] = "aaaaaaa"
    DISPLAY names[1]
END MAIN
```

**Related concepts**

**Types** on page 397

Types can be defined by the programmer to centralize the definition of complex/structured variables.

**java-array.getLength**

Returns the length of the Java array.

**Syntax**

```
getLength()
RETURNS INTEGER
```

**Usage**

This method returns the number of elements in the Java array.

**Example**

```
IMPORT JAVA java.lang.String
MAIN
    TYPE string_array_type ARRAY[] OF java.lang.String
    DEFINE names string_array_type
    LET names = string_array_type.create(100)
```
The base package

These topics cover the built-in classes for the base class

- The Application class on page 2268
- The Channel class on page 2273
- The SqlHandle class on page 2292
- The StringBuffer class on page 2307
- The StringTokenizer class on page 2319
- The TypeInfo class on page 2323
- The MessageServer class on page 2326

The Application class

The base.Application class provides a set of utility functions related to the program environment.

Command line arguments, execution directory and FGLPROFILE resource entries are some of the elements you can query with this class.

This class is built-in and can be used directly in the source code.

This class does not have to be instantiated. It provides class methods for the current program.
### base.Application methods

#### Table 465: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>base.Application.getArgument(index INTEGER)</code></td>
<td>Returns the command line argument by position.</td>
</tr>
<tr>
<td><code>base.Application.getArgumentCount()</code></td>
<td>Returns the total number of command line arguments.</td>
</tr>
<tr>
<td><code>base.Application.getProgramDir()</code></td>
<td>Returns the directory path of the current program.</td>
</tr>
<tr>
<td><code>base.Application.getProgramName()</code></td>
<td>Returns the name of the current program.</td>
</tr>
<tr>
<td><code>base.Application.getFglDir()</code></td>
<td>Returns the path to the FGLDIR installation directory.</td>
</tr>
<tr>
<td><code>base.Application.getResourceEntry(name STRING)</code></td>
<td>Returns the value of an fglprofile entry.</td>
</tr>
<tr>
<td><code>base.Application.getStackTrace()</code></td>
<td>Returns the function call stack trace.</td>
</tr>
<tr>
<td><code>base.Application.isMobile()</code></td>
<td>Indicates if the application runs on a mobile device.</td>
</tr>
<tr>
<td><code>base.Application.reloadResources(newResourcePath STRING)</code></td>
<td>Resets FGLRESOURCEPATH and reloads localized string resources.</td>
</tr>
</tbody>
</table>

#### `base.Application.getArgument`

Returns the command line argument by position.

**Syntax**

```java
base.Application.getArgument(
    index INTEGER
) RETURNS STRING
```

1. `index` is the index of the program argument.
Usage
The index is the program argument position. The first program argument is identified by the position 1. Argument number zero is the program name.

Returns NULL if there is no argument provided at the position.

Example

```plaintext
MAIN
  DEFINE i INTEGER
  FOR i=1 TO base.Application.getArgumentCount()
    DISPLAY base.Application.getArgument(i)
  END FOR
END MAIN
```

`base.Application.getArgumentCount`
Returns the total number of command line arguments.

Syntax

```plaintext
base.Application.getArgumentCount ()
RETURNS INTEGER
```

Usage
Returns the total number of command line arguments, can be used to scan the argument values with `base.Application.getArgument()`.

`base.Application.getFglDir`
Returns the path to the FGLDIR installation directory.

Syntax

```plaintext
base.Application.getFglDir ()
RETURNS STRING
```

Usage
The `getFglDir()` method returns the installation directory path defined by the FGLDIR environment variable. The directory path is system-dependent.

`base.Application.getProgramDir`
Returns the directory path of the current program.

Syntax

```plaintext
base.Application.getProgramDir ()
RETURNS STRING
```

Usage
This method returns the directory path where the program file (42r) is located.

The directory path is system-dependent.
**base.Application.getProgramName**

Returns the name of the current program.

**Syntax**

```java
base.Application.getProgramName() 
RETURNS STRING
```

**Usage**

This method returns the name of the current program. This is the name of the 42m or 42r module passed to fglrun, without the file extension.

**base.Application.getResourceEntry**

Returns the value of an fglprofile entry.

**Syntax**

```java
base.Application.getResourceEntry(name STRING) 
RETURNS STRING
```

1. `name` is the name of an fglprofile entry.

**Usage**

This method returns the value of the fglprofile resource entry passed as parameter.

**Example**

```java
MAIN
  DISPLAY base.Application.getResourceEntry("mycompany.params.logmode")
END MAIN
```

**base.Application.getStackTrace**

Returns the function call stack trace.

**Syntax**

```java
base.Application.getStackTrace() 
RETURNS STRING
```

**Usage**

Use the `getStackTrace()` method, to print the stack trace to a log file.

**Important:** Sensitive and personal data may be written to the output. Make sure that the log output is written to files that can only be read by application administrators.

This method returns a string containing a formatted list of the current function stack.

**Note:** The output format of `getStackTrace()` method is for debug purpose only and can change in future product releases.

You typically use this function in a `WHENEVER ERROR CALL` handler.

```java
MAIN
  WHENEVER ANY ERROR CALL my_handler
  CALL func1("abcdef",999)
END MAIN
```
FUNCTION func1(name,id)
    DEFINE name STRING, id INTEGER
    DEFINE r INTEGER
    LET r = div(5,0)
END FUNCTION

FUNCTION div(x,y)
    DEFINE x,y DECIMAL
    RETURN ( x / y )
END FUNCTION

FUNCTION my_handler()
    DISPLAY base.Application.getStackTrace()
END FUNCTION

Example of stack trace output:

#0 my_handler() at x.4gl:17
#1 div() at x.4gl:14
#2 func1() at x.4gl:9
#3 main() at x.4gl:3

base.Application.isMobile
Indicates if the application runs on a mobile device.

Syntax

base.Application.isMobile()
RETURNS BOOLEAN

Usage

This class method can be called to check if the program code is running on a smartphone or tablet device. The method will return TRUE if the program executes in standalone mode (i.e. the runtime system is on the mobile device).

Example

MAIN
    MENU "test"
        COMMAND "check"
            MESSAGE SFMT("isMobile = %1", base.Application.isMobile())
        END COMMAND
    END MENU
END MAIN

base.Application.reloadResources
Resets FGLRESOURCEPATH and reloads localized string resources.

Syntax

base.Application.reloadResources(
    newResourcePath STRING)

Usage

The reloadResources() method overwrites the search path defined by the FGLRESOURCEPATH environment variable, to find program resource files in directories that are only known at runtime.
Warning: The `reloadResources()` method, to reset the FGLRESOURCEPATH environment variable in order to find program resource files in a different directory, must only be used at the beginning of the program execution.

This method is typically used to define a search path for localized string files when a program starts, to let the end user change the current application language. It avoids starting a new application (via `RUN`), after the end user selects a language in a parent program.

The runtime behaves as if FGLRESOURCEPATH had been set to this value from the start.

**Note:** Pay attention to the path separator, which is specific to the operating system. See FGLRESOURCEPATH reference for more details.

The method does the following:

1. Resets the environment variable FGLRESOURCEPATH with the specified value.
2. Reloads already loaded string localization files (.42s)
3. Reloads the default action defaults file (`default.4ad`)

Notes:

- Reloading resources has no effect on displayed forms: only forms displayed after reloading resources will use the new reloaded strings.
- Presentation Styles (.4st) are not reloaded.

  **Note:** The writing direction of a language/script is defined with the `UserInterface.reverse` presentation style attribute:

  ```
  <Style name="UserInterface">
    <StyleAttribute name="reverse" value="yes" />
  </Style>
  ```

  Since presentation styles are not reloaded, it is not possible to switch between scripts having different writing directions. To change the writing direction, the program must be restarted.

- Reloading resources has no effect on .42m modules that are already loaded (any `%"string"` will not be localized again). For this reason, the `reloadResources()` method must be called at a very early stage of the program.

  **Note:** The debugger (fglrun -d) loads all program modules immediately when starting. Therefore, reloading resources has no effect on localized strings in .42m modules when debugging.

Related concepts

**Loading localized strings at runtime** on page 437
Understand the rules for using localized strings at runtime.

The **Channel class**
The `base.Channel` class is a built-in class providing basic input/output functions.

**base.Channel methods**

**Table 466: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>base.Channel.create()</code></td>
<td>Create a new channel object.</td>
</tr>
<tr>
<td>RETURNS <code>base.Channel</code></td>
<td></td>
</tr>
</tbody>
</table>
### Table 467: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataAvailable()</td>
<td>Tests if some data can be read from the channel.</td>
</tr>
<tr>
<td>close()</td>
<td>Closes the channel.</td>
</tr>
<tr>
<td>isEof()</td>
<td>Detect the end of a file.</td>
</tr>
<tr>
<td>openFile(path, mode)</td>
<td>Opening a file channel.</td>
</tr>
<tr>
<td>openPipe(command, mode)</td>
<td>Opening a pipe channel to a sub-process.</td>
</tr>
<tr>
<td>openClientSocket(host, port, mode, timeout)</td>
<td>Open a TCP client socket channel.</td>
</tr>
<tr>
<td>openServerSocket(interface, port, mode)</td>
<td>Open a TCP server socket channel.</td>
</tr>
<tr>
<td>read([variableList])</td>
<td>Reads a list of data delimited by a separator from the channel.</td>
</tr>
<tr>
<td>readLine()</td>
<td>Read a complete line from the channel.</td>
</tr>
<tr>
<td>readOctets(length)</td>
<td>Read a given number of bytes and return it as a character string.</td>
</tr>
<tr>
<td>setDelimiter(delimiter)</td>
<td>Define the value delimiter for a channel.</td>
</tr>
<tr>
<td>write([valueList])</td>
<td>Writes a list of data delimited by a separator to the channel.</td>
</tr>
<tr>
<td>writeLine(value)</td>
<td>Write a complete line to the channel.</td>
</tr>
<tr>
<td>writeNoNL(value)</td>
<td>Writes a string to the channel (without newline character).</td>
</tr>
</tbody>
</table>
*base.Channel.create*
Create a new channel object.

**Syntax**

```
base.Channel.create()
RETURNS base.Channel
```

**Usage**

Use the `base.Channel.create()` class method to create a channel object.

The new created object must be assigned to a program variable defined with the `base.Channel` type.

**Example**

```
DEFINE ch base.Channel
LET ch = base.Channel.create()
```

For a complete example, see Example 1: Reading formatted data from a file on page 2290.

*base.Channel.close*
Closes the channel.

**Syntax**

```
close()
```

**Usage**

Call the `close()` method when you are done with the channel. The channel can be re-opened after it has been closed.

**Note:** A channel is automatically closed, when the channel object is destroyed.

**Example**

```
CALL ch.close()
```

For a complete example, see Example 1: Reading formatted data from a file on page 2290.

*base.Channel.dataAvailable*
Tests if some data can be read from the channel.

**Syntax**

```
dataAvailable()
RETURNS BOOLEAN
```

**Usage**

The `dataAvailable()` method returns `TRUE` if some data can be read from the channel.

This method is only to be used in some rare cases. Use `dataAvailable()` if the protocol allows asynchronous messages from the peer. An example is an asynchronous error message from the peer, to stop sending more data.

`dataAvailable()` checks if at least one byte is available on the stream. A subsequent read will block, if the read operation cannot be completed. This should not happen: the methods `read()` and `readLine()` and their
counterparts \texttt{write()} and \texttt{writeLine()} read and write complete lines (a line is a sequence of characters terminated by the line separator).

The method opens up the possibility to read data asynchronously. One possible use for this method is to stop a data transfer from a local site, after receiving an error message from the remote site.

\textbf{Example}

The local site (\texttt{parent.4gl}) sends a huge amount of data to the remote site (\texttt{child.4gl}) using \texttt{base.Channel.writeLine()}. If an error occurs on the remote side during the processing of data, the remote site writes an error message to the channel, causing the local site to stop the data transmission.

On the local site, the file is \texttt{parent.4gl}.

\begin{verbatim}
MAIN
  DEFINE n INT
  DEFINE c base.Channel

  LET c = base.Channel.create()
  CALL c.openPipe("fglrun child", "u")
  LET n = 0
  WHILE TRUE
    IF c.dataAvailable() THEN
      DISPLAY "message from child: ", c.readLine()
      EXIT WHILE
    END IF
    LET n = n + 1
    DISPLAY "parent: write line ", n
    CALL c.writeLine("line " || n)
  END WHILE
END MAIN
\end{verbatim}

On the remote site, the file is \texttt{child.4gl}:

\begin{verbatim}
MAIN
  DEFINE c base.Channel
  DEFINE s STRING
  DEFINE n INT

  LET c = base.Channel.create()
  CALL c.openFile("", "u")
  LET n = 0
  WHILE NOT c.isEof()
    LET s = c.readLine()
    LET n = n + 1
    IF n == 3 THEN
      CALL c.writeLine("error: something happens")
      CALL readRemainingData(c)
      EXIT WHILE
    END IF
  END WHILE
END MAIN

FUNCTION readRemainingData(c)
  DEFINE c base.Channel
  DEFINE s STRING
  WHILE NOT c.isEof()
    LET s = c.readLine()
  END WHILE
END FUNCTION
\end{verbatim}

\textbf{Note}: Do not add \texttt{DISPLAY} instructions in the child program, as this would corrupt the pipe communication: The parent program opens a pipe channel read from child's stdout and write to child's stdin.
**Related concepts**

`base.Channel.read` on page 2280
Reads a list of data delimited by a separator from the channel.

`base.Channel.readLine` on page 2281
Read a complete line from the channel.

`base.Channel.isEof`
Detect the end of a file.

**Syntax**

```plaintext
isEof()
RETURNS BOOLEAN
```

**Usage**

Use the `isEof()` method to detect the end of a file while reading from a channel.

The end of file is only detected after the last read. In other words, you first read, then check for the end of file and process if not end of file.

**Example**

```plaintext
DEFINE s STRING
WHILE TRUE
    LET s = ch.readLine()
    IF ch.isEof() THEN
        EXIT WHILE
    END IF
    DISPLAY s
END WHILE
```

For a complete example, see Example 3: Reading lines from a file on page 2290.

`base.Channel.openClientSocket`
Open a TCP client socket channel.

**Syntax**

```plaintext
openClientSocket(
    host STRING,
    port INTEGER,
    mode STRING,
    timeout INTEGER )
```

1. `host` is the name of the host machine you want to connect to.
2. `port` is the port number of the service.
3. `mode` is the open mode. Can be "r", "w" or "u" (combined with "b" if needed).
4. `timeout` is the timeout in seconds. -1 indicates no timeout (wait forever)

**Usage**

Use the `openClientSocket()` method to establish a TCP connection to a server.

Pay attention to character set used by the network protocol you want to use by opening a channel with this method:
The protocol must be based on ASCII, or must use the same character set as the application.

The `host` parameter defines the host name of the server.

The `port` parameter defines the TCP port to connect to.
The opening *mode* can be one of the following:

- **r**: For read mode: only to read from the socket
- **w**: For write mode: only to write to the socket
- **u**: For read and write mode: To read and write from/to the socket

Any of these modes can be followed by *b*, to use binary mode and avoid CR/LF translation on Windows platforms.

**Note**: The binary mode is only required in specific cases, and will only take effect when writing data.

If the opening *mode* is not one of the above letters, the method will raise error **-8085**.

When the *timeout* parameter is **-1**, the connection waits forever.

The method raises error **-8084** if the channel cannot be opened.

**Example**

```c
CALL ch.openClientSocket( "localhost", 80, "u", 5 )
```

For a complete example, see Example 4: Communicating with an HTTP server on page 2291.

**Related concepts**

- [Implementing a TCP socket channel](#)
- [base.Channel.openServerSocket](#)

**Syntax**

```c
openFile(
    path STRING,
    mode STRING )
```

1. *path* is the path to the file to open, can be NULL for stdin/stdout.
2. *mode* is the open mode. Can be "r", "w", "a" or "u" (combined with "b" if needed).

**Usage**

The *openFile()* method can be used to open a file for reading, writing, or both.

When passing NULL as file name, the channel can be used to read and/or write to stdout or stdin, depending on the *mode* value.

When passing "$<stderr>" as file name the standard error stream will be used. The application can then print messages to stderr (typically for batch programs). See Example 5: Writing to STDERR on page 2291

The opening *mode* can be one of the following:

- **r**: For read mode: reads from a file (standard input if path is NULL).
- **w**: For write mode: starts with an empty file (standard output if the path is NULL).
- **a**: For append mode: writes at the end of a file (standard output if the path is NULL).
- **u**: For read from standard input and write to standard output (path must be NULL).

Any of these modes can be followed by *b*, to use binary mode and avoid CR/LF translation on Windows platforms.

**Note**: The binary mode is only required in specific cases, and will only take effect when writing data.

If the opening *mode* is not one of the above letters, the method will raise error **-8085**.

When you use the *w* or *a* modes, the file is created if it does not exist.
The method raises error -6340 if the file cannot be opened.

Example

```
CALL ch.openFile( "file.txt", "w" )
```

For a complete example, see Example 1: Reading formatted data from a file on page 2290.

`base.Channel.openPipe`

Opening a pipe channel to a sub-process.

Syntax

```
openPipe(
    command STRING,
    mode STRING )
```

1. `command` is the system command to be executed.
2. `mode` is the open mode. Can be "r", "w", "a" or "u" (combined with "b" if needed).

Usage

With the `openPipe()` method, you can read from the standard output of a subprocess, write to the standard input, or both.

**Important:** This feature is not supported on mobile platforms.

The opening `mode` can be one of the following:

- `r`: For read only from standard output of the command.
- `w`: For write only to standard input of the command.
- `a`: For write only to standard input of the command.
- `u`: For read from standard output and write to standard input of the command.

Any of these modes can be followed by `b`, to use binary mode and avoid CR/LF translation on Windows platforms.

**Note:** The binary mode is only required in specific cases, and will only take effect when writing data.

If the opening `mode` is not one of the above letters, the method will raise error -8085.

Example

```
CALL ch.openPipe( "ls", "r" )
```

For a complete example, see Example 2: Executing the ls UNIX command on page 2290.

`base.Channel.openServerSocket`

Open a TCP server socket channel.

Syntax

```
openServerSocket(
    interface STRING,
    port INTEGER,
    mode STRING )
```

1. `interface` is the name of the network interface to be used.
2. `port` is the port number of the service.
3. `mode` is the open mode. Only "u" is allowed (combined with "b" if needed).
Usage

The `openServerSocket()` method initializes the channel object to listen to a given TCP interface and port.

The server socket accepts multiple client connects: After calling the `openServerSocket()` method, a call to `readLine()` waits until the first client connects and returns after reading a complete line. Only one client connection can be serviced at time: it's not possible to select a specific client connection. A client connection must be closed by writing the EOF character to the channel. The EOF character is ASCII 26. Do not call `base.Channel.close()` to close a client/server connection: This would close the sever socket and reject any pending client connection. The next call to `readLine()` after writing EOF will wait until the next client connects or select the next pending client.

Pay attention to character set used by the network protocol you want to use by opening a channel with this method: The protocol must be based on ASCII, or must use the same character set as the application.

The `interface` parameter defines the network interface to be used, in case if the server uses different network adapters. Use NULL to listen to all network interfaces, or when the server has only one network interface.

The `port` parameter defines the TCP port to listen to.

The opening `mode` must be "u", to read and write from/to the socket. The method will raise error -8085 if the mode is different from "u".

The "u" mode can be combined with the "b" binary mode, to avoid CR/LF translation on Windows platforms.

**Note:** The binary mode is only required in specific cases, and will only take effect when writing data.

The method raises error -8084 if the socket cannot be opened.

Example

```main
DEFINE io base.Channel
DEFINE s STRING
LET io = base.Channel.create()
CALL io.openServerSocket("127.0.0.1", 4711, "u")
WHILE TRUE
  LET s = io.readLine()
  CALL io.readLine(s)
  -- next line closes the current connection
  CALL io.writeLine(ASCII 26) -- EOF
END WHILE
END MAIN
```

Related concepts

Implementing a TCP socket channel on page 2289

`base.Channel.openClientSocket` on page 2277

Open a TCP client socket channel.

`base.Channel.read`

Reads a list of data delimited by a separator from the channel.

Syntax

```plaintext
read(
  [ variableList ]
) RETURNS INTEGER
```

1. `variableList` is a list of program variables separated by a comma, or record.*

Usage

After opening the channel object, use the `read()` method to read a record of data from the channel.
The `read()` method uses the field delimiter defined by `setDelimeter()`.

The `read()` method takes a modifiable list of variables as parameter, by using the `[ ]` square brace notation.

A call to `read()` is blocking until the read operation is complete.

If the `read()` method returns less data than expected, then the remaining variables will be initialized to NULL. If the `read()` method returns more data than expected, the data is silently ignored.

Any target variable must have a primitive type (BOOLEAN, TINYINT, SMALLINT, INT, BIGINT, SMALLFLOAT, FLOAT, DECIMAL, DATE, DATETIME, INTERVAL, BYTE, TEXT, CHAR, VARCHAR, STRING) or be a RECORD that contains only primitive members.

If data is read, the `read()` method returns `TRUE`. Otherwise it returns `FALSE`, indicating the end of the file or stream.

**Example**

```
WHILE ch.read([cust_rec.*])
  ...
END WHILE
```

For a complete example, see Example 1: Reading formatted data from a file on page 2290.

**Related concepts**

- Read and write formatted data on page 2286
- `base.Channel.dataAvailable` on page 2275
  Tests if some data can be read from the channel.

**Syntax**

```
readLine()
RETURNS STRING
```

**Usage**

After opening the channel object, use the `readLine()` method to read a complete line from the channel.

The `readLine()` method returns an empty string if the line is empty.

A call to `readLine()` is blocking until the read operation is complete.

The `readLine()` function returns `NULL` if end of file is reached. To distinguish empty lines from `NULL`, you must use the STRING data type. If you use a CHAR or VARCHAR, you will get `NULL` for empty lines. To detect the end of file, use the `isEof()` method.

**Example**

```
WHILE TRUE
  LET s = ch.readLine()
  IF ch.isEof() THEN EXIT WHILE END IF
  ...
END WHILE
```

For a complete example, see Example 3: Reading lines from a file on page 2290.

**Related concepts**

- Read and write simple lines on page 2287
- `base.Channel.dataAvailable` on page 2275
Tests if some data can be read from the channel.

*base.Channel.readOctets*

Read a given number of bytes and return it as a character string.

**Syntax**

```plaintext
readOctets (  
  length INTEGER)  
RETURNS STRING
```

1. *length* is the number of bytes to read, not the number of characters.

**Usage**

After opening the channel object, call the `readOctets()` method to read a given number of bytes from the channel. The bytes are returned as a character string.

**Important:** The bytes read with `readOctets()` must match the current encoding. In multi-byte encoding (UTF-8), if a sequence of bytes does represent a valid character, the resulting string will get `?` question mark for invalid characters and data will be lost.

A valid use case of the method is the HTTP protocol. Reading HTML content with `readLine()` is not possible: The body consists of multiple lines, and the last line might not be terminated by a line-terminator, and the stream gets not EOF:

```
HTTP/1.0 200 OK
Date: Wed, 16 Apr 2014 18:50:51 GMT
Content-Type: text/html
Content-Length: 1354

<html>
<body>
<h1>My title</h1>
 :
</body>
</html>
```

The `readOctets()` function returns `NULL` if end of file is reached.

**Note:** To distinguish empty lines from `NULL`, you must use the `STRING` data type. If you use a `CHAR` or `VARCHAR`, you will get `NULL` for empty lines. To properly detect end of file, use the `isEof()` method.

If `readOctets()` cannot read as much bytes as specified by the parameter, the method returns `NULL`. Before reading the actual bytes with a `readOctets()` call, find the number of data bytes to read from stream source, as shown in the example below.

**Example**

**Note:** This example uses UTF-8 encoding.

The main program:

```plaintext
MAIN
DEFINE len INTEGER
DEFINE chunk STRING
DEFINE ch base.Channel
LET ch = base.Channel.create()  
CALL ch.openFile("file.txt","r")
WHILE TRUE
  LET len = ch.readOctets(3) -- 3 digits for length
  IF ch.isEof() THEN EXIT WHILE END IF
  LET chunk = ch.readOctets(len)
  DISPLAY len USING "##&"," ", NVL(chunk,"(NULL)")
```
END WHILE
    CALL ch.close()
END MAIN

The data file (contains 3 digits for byte length of following string):

003abc006forêt000001x

Program output (note that forêt needs 3+2+1=6 bytes in UTF-8):

$ fglcomp -M readOctets.4gl  && fglrun readOctets.42m
3 abc
6 forêt
0
1 x

Related concepts
Implementing a TCP socket channel on page 2289

base.Channel.setDelimiter
Define the value delimiter for a channel.

Syntax

```plaintext
setDelimiter(
    delimiter STRING )
```

1. `delimiter` is the value delimiter to be used.

Usage

After creating the channel object, define the field value delimiter with the `setDelimiter()` method.

```plaintext
CALL ch.setDelimiter("^")
```

The default delimiter is defined by the `DBDELIMITER` environment variable, or a pipe (`|`) if `DBDELIMITER` is not defined.

Specify `CSV` as the delimiter to read/write in Comma Separated Value format.

```plaintext
CALL ch.setDelimiter("CSV")
```

**Important**: Setting a `NULL` delimiter is allowed for backward compatibility, but must be avoided: This was a workaround to read/write complete lines. If the delimiter is set to `NULL`, the `read()` and `write()` methods do not use the backslash (`\`) escape character. As a result, data with special characters like backslash, delimiter or line-feed will be written as is, and reading data will ignore escaped characters in the source stream. If you need to read or write non-formatted data, it is recommended that you use the `readLine()`/`writeLine()` methods instead. These methods do not use a delimiter, nor do they use the backslash escape character.

Related concepts
Read and write formatted data on page 2286

base.Channel.write
 Writes a list of data delimited by a separator to the channel.

Syntax

```plaintext
write(
```
1. `valueList` is a list of expressions separated by a comma.

**Usage**

After opening a channel, use the `write()` method to write a record of data to the channel. The `write()` method uses the field delimiter defined by `setDelimiter()`.

The `write()` method takes a modifiable list of variables as the parameter, using the `[ ]` square brace notation.

The method raises error `-6345` if the channel fails to write data.

**Example**

```plaintext
CALL ch.write([cust_rec.*])
```

**Related concepts**

- Read and write formatted data on page 2286
- `base.Channel.writeLine`
  Write a complete line to the channel.

**Syntax**

```plaintext
writeLine(
  value STRING )
```

1. `value` is the string expression to be written to the channel.

**Usage**

After opening a channel, use the `writeLine()` method to write a line of text to the channel.

The `writeLine()` method does not use the field delimiter, it write the text data to the stream, with an ending newline character.

To write a string with no ending newline character, use the `writeNoNL()` method.

The method raises error `-6345` if the channel fails to write data.

**Example**

```plaintext
CALL ch.writeLine("Customer number: "|| custno)
```

For a complete example, see Example 5: Writing to STDERR on page 2291.

**Related concepts**

- Read and write simple lines on page 2287
- `base.Channel.writeNoNL` on page 2284
  Writes a string to the channel (without newline character).

- `base.Channel.writeNoNL`
  Writes a string to the channel (without newline character).

**Syntax**

```plaintext
writeNoNL(
  value STRING )
```
1. *value* is the character string to be written to the channel.

**Usage**

After opening a channel, use the `writeNoNL()` method to write a string to the channel, without a trailing newline character.

**Important:** Do not confuse the `writeNoNL()` method with the `write()` method. The first is provided to write raw character strings to the stream, while the second is designed to write records with formatted data and field delimiters. Note also that the Channel class provides the `writeLine()` method to write a string with a ending newline character.

The method raises error `-6345` if the channel fails to write data.

**Example**

```sql
CALL ch.writeNoNL("Some text ...")
```

**Related concepts**

- `base.Channel.readOctets` on page 2282
  Read a given number of bytes and return it as a character string.

- `base.Channel.writeLine` on page 2284
  Write a complete line to the channel.

- `base.Channel.write` on page 2283
  Writes a list of data delimited by a separator to the channel.

**Usage**

The `base.Channel` class is a built-in class providing basic input/output functionality for:

- text file reading/writing
- subprocess communication (through pipes)
- basic network communication (through TCP sockets)

**Important:** No character set conversion is done when reading or writing data with channel objects. The character set used in the data file must correspond to the locale of the runtime system, for both input and output.

Steps to use a channel object:

- Define a variable with the `base.Channel` type.
- Create a channel object with `base.Channel.create()` and assign it to the variable.
- Open the channel for a file, piped process or socket (as a client).
- Read or write data in formatted mode or in line mode.
- Close the channel.

Channel methods may raise exceptions. Exceptions can be trapped with the `WHENEVER ERROR` or `TRY/CATCH` instructions.

When reading or writing strings, the escape character is the backslash (`\`).

The are three modes to read and write data with Channels:

1. Reading/writing formatted data as a set of fields in a line (i.e. records), with the `read()` and `write()` methods, needing a value separator defined by `setDelimiter()`. This mode follows the same formatting rules as the `LOAD/UNLOAD` instructions, and can also be used to read/write CSV (Comma Separated Value) formatted data.

2. Reading/writing complete lines with the `readLine()` and `writeLine()` methods. This mode is typically used to read/write simple data files.

3. Handling raw character string data by reading/writing pieces of strings, with the `readOctets()` and `writeNoNL()` methods.
**Read and write formatted data**

When the channel is open, use the `read()`/`write()` methods to read and write data records where field values are separated by a delimiter defined by `setDelimiter()`.

**Note:** The `LOAD/UNLOAD` SQL instructions follow the same formatting rules as the `read()`/`write()` channel methods.

The input or output stream is text data where each line contains the string representation of a record. Field values are separated by the delimiter character defined.

For example, a formatted text file looks like this, when using a default pipe (|) delimiter:

```
8712|David|Cosneski|24-12-1978|
3422|Frank|Zapinetti|13-04-1968|
323|Mark|Kelson|03-10-1988|
```

In the serialized data, empty fields (| |) have a length of zero and are considered as `NULL`.

The code in the example reads the above formatted data:

```plaintext
MAIN
  DEFINE ch base.Channel
  DEFINE custinfo RECORD
    cust_num INTEGER,
    cust_fname VARCHAR(40),
    cust_lname VARCHAR(40),
    cust_bdate DATE
  END RECORD
  LET ch = base.Channel.create()
  CALL ch.setDelimiter("|")
  CALL ch.openFile("custinfo.txt","r")
  WHILE ch.read([custinfo.*])
    DISPLAY custinfo.*
  END WHILE
  CALL ch.close()
END MAIN
```

The backslash \ is the escape character: When writing data with `write()`, special characters like the backslash, line-feed or the delimiter character is escaped. When reading data with `read()`, any escaped \char character is converted to char.

The next code example writes a single field value where the character string contains a backslash, the pipe delimiter and a line-feed character. The backslash is also the escape character for string literals, therefore we need to double the backslash to get a backslash in the string, while the line-feed character (<lf>) is represented by backslash-n (\n) in string literals:

```plaintext
CALL ch.setDelimiter("|")
CALL ch.write("aaa\bbb|ccc\n
ddd")   -- [aaa<bs>bbb|ccc<lf>ddd]
```

This code will produce the following text file:

```
aaa\bbb|ccc\n
ddd|
```

When reading such a line back into memory with the `read()` method, all escaped characters are converted back to the single character. In this example, `\ ` becomes \, `\ ` becomes | and `<lf>` becomes `<lf>`.

When using the `read()/write()` methods, the escaped line-feed (LF, \n) characters are written as BS + LF to the output, and when reading with `read()`, BS + LF are detected and interpreted, to be restored as if the value was assigned by a `LET` instruction, with the same string used in the `write()` function.
If you want to write a LF as part of a value, the string must contain the backslash and line-feed as two independent characters. You need to escape the backslash when you write the string constant in the .4gl source file.

```4gl
CALL ch.setDelimiter("|")
CALL ch.write("aaa\nbbb")  -- [aaa<bs><lf>bbb]
CALL ch.write("ccc\nddd")  -- [aaa<lf>bbb]
```

would generate the following output:

```
aaa
bbb
ccc
ddd
```

where the first two lines contain data for the same line, in the meaning of a Channel record.

When you read these lines back with a `read()` call, you get the following strings in memory:

```
Read 1: aaa<bs><lf>bbb
Read 2: ccc
Read 3: ddd
```

These reads would correspond to the following assignments when using string constants:

```
LET s = "aaa\\nbbb"
LET s = "ccc"
LET s = "ddd"
```

Data can also be formatted as CSV (Comma Separated Values), when defining "CSV" as delimiter value:

```4gl
CALL ch.setDelimiter("CSV")
```

This CSV format is similar to the standard channel format, with the following differences:

- Values in the file might be surrounded with double quotes (").
- If a value contains a comma or a NEWLINE, it is not escaped; the value must be quoted in the file.
- Double-quote characters in values are doubled in the output file and the output value must be quoted.
- Backslash characters are not escaped and are read as is; the value must be quoted.
- Leading and trailing blanks are kept (no truncation).
- No ending delimiter is expected at the end of the record line.

**Read and write simple lines**

When the channel is open, use the `readLine()` and `writeLine()` methods to read and write simple lines of data terminated by a line terminator.

When using the `readLine()` and `writeLine()` functions, a LF character represents the end of a line.

For example, a simple text file can look like this:

```
first line
second line
third line
```

Sample code to read the above text file is as follows:

```4gl
MAIN
  DEFINE i INTEGER
  DEFINE s STRING
  DEFINE ch base.Channel
  LET ch = base.Channel.create()
```
CALL ch.openFile("file.txt","r")
LET i = 1
WHILE TRUE
  LET s = ch.readLine()
  IF ch.isEof() THEN EXIT WHILE END IF
  DISPLAY i, " ", s
  LET i = i + 1
END WHILE
CALL ch.close()
END MAIN

LF characters escaped by a backslash are not interpreted as part of the line during a readLine() call.

When a line is written, any LF characters in the string will be written as is to the output. When a line is read, the LF escaped by a backslash is not interpreted as part of the line.

For example, this code:

CALL ch.writeLine("aaa\\nbbb")  -- [aaa<bs><lf>bbb]
CALL ch.writeLine("ccc\nddd")    -- [aaa<lf>bbb]

would generate this output:

aaa\
bbb
ccc
ddd

and the subsequent readLine() will read four different lines, where the first line is ended by a backslash:

Read 1 aaa<bs>
Read 2 bbb
Read 3 ccc
Read 4 ddd

Line terminators on Windows™ and UNIX™

On Windows™ platforms, DOS formatted text files use CR/LF as line terminators. You can manage these type of files with the base.Channel class.

By default, on both Windows™ and UNIX™ platforms, when records are read from a DOS file with the base.Channel class, the CR/LF line terminator is removed. When a record is written to a file on Windows™, the lines are terminated with CR/LF in the file; on UNIX™, the lines are terminated with LF only.

To avoid the automatic translation of CR/LF on Windows™, you can use the b option of the openFile() and openPipe() methods. You can combine the b option with r or w, based on the read or write operations that you want to do.

CALL ch.openFile( "mytext.txt", "rb" )

On Windows™, when lines are read with the b option, only LF is removed from CR/LF line terminators; CR will be copied as a character part of the last field. In contrast, when lines are written with the b option, LF characters will not be converted to CR/LF.

On UNIX™, writing lines with or without the binary mode option does not matter.

Handle channel exceptions

Channel errors can be trapped with the WHENEVER ERROR exception handler:

WHENEVER ERROR CONTINUE
  CALL ch.write([num,label])
  IF STATUS THEN
Error "An error occurred while reading from Channel"
CALL ch.close()
RETURN -1
END IF
WHENEVER ERROR STOP

Or with a **TRY/CATCH** block:

**TRY**
CALL ch.write([num, label])
**CATCH**
  ERROR "An error occurred while reading from Channel"
  CALL ch.close()
  RETURN -1
END TRY

### Implementing a TCP socket channel

The **base.Channel** class provides methods to implement basic TCP client and server programs. Consider character set encodings when designing such programs: No implicit character set conversion is done by the runtime system. Both client and server must use the same character set and length semantics.

The following code example implements a client program connecting to a TCP port, using the **openClientSocket()** method:

**MAIN**
DEFINE ch base.Channel,
  time DATETIME HOUR TO SECOND,
  data STRING
LET ch = base.Channel.create()
CALL ch.openClientSocket("localhost", 99999, "u", 3)
CALL ch.writeLine("get_time")
LET time = ch.readLine()
DISPLAY "client 1: ", time
CALL ch.writeLine("get_string")
LET data = ch.readLine()
DISPLAY "client 2: ", data
CALL ch.writeLine("disconnect")
CALL ch.close()
END MAIN

The next code example implements the server program that can be used with the above client program. The server program uses the **openServerSocket()** and **readLine()** methods to listen to a given TCP interface/port. Note that the connection with a client must be ended by sending an EOF character (ASCII 26) to the client, the next **readLine()** call will wait for a new client connection, or select a pending client connection:

**MAIN**
DEFINE ch base.Channel,
  cmd, data STRING
LET ch = base.Channel.create()
DISPLAY "starting server..."
CALL ch.openServerSocket(null, 99999, "u")
WHILE TRUE
  LET cmd = ch.readLine()
  IF ch.isEof() THEN
    DISPLAY "Connection ended by client..."
    EXIT WHILE
  END IF
  DISPLAY "cmd: ", cmd
  IF cmd == "get_time" THEN
    CALL ch.writeLine(CURRENT HOUR TO SECOND)
  END IF
IF cmd == "get_string" THEN
    LET data = "This is a string..."
    CALL ch.writeLine(data)
END IF
IF cmd == "disconnect" THEN
    CALL ch.writeLine(ASCII 26) -- EOF
END IF
END WHILE
DISPLAY "end of server..."
END MAIN

Related concepts
Application locale on page 405
The application locale defines the language and codeset for your application.

Examples
base.Channel usage examples.

Example 1: Reading formatted data from a file
This program reads data from file.txt, which contains two columns separated by a pipe (|) character. It writes this data to the end of fileout.txt, using a percent sign (%) as the delimiter.

MAIN
DEFINE custinfo RECORD
    cust_num INTEGER,
    cust_name VARCHAR(40)
END RECORD
DEFINE ch_in, ch_out base.Channel
LET ch_in = base.Channel.create()
CALL ch_in.setDelimiter("|")
LET ch_out = base.Channel.create()
CALL ch_out.setDelimiter("%")
CALL ch_in.openFile("file.txt","r")
CALL ch_out.openFile("fileout.txt","w")
WHILE ch_in.read([custinfo.*])
    CALL ch_out.write([custinfo.*])
END WHILE
CALL ch_in.close()
CALL ch_out.close()
END MAIN

Example 2: Executing the ls UNIX" command
This program executes the ls command and displays the filenames and extensions separately.

MAIN
DEFINE fn CHAR(40)
DEFINE ex CHAR(10)
DEFINE ch base.Channel
LET ch = base.Channel.create()
CALL ch.setDelimiter(".")
CALL ch.openPipe("ls -l","r")
WHILE ch.read([fn,ex])
    DISPLAY fn, "   ", ex
END WHILE
CALL ch.close()
END MAIN

Example 3: Reading lines from a file

MAIN
DEFINE i INTEGER
DEFINE s STRING
DEFINE ch base.Channel
LET ch = base.Channel.create()
CALL ch.openFile("file.txt","r")
LET i = 1
WHILE TRUE
    LET s = ch.readLine()
    IF ch.isEof() THEN EXIT WHILE END IF
    DISPLAY i, " ", s
    LET i = i + 1
END WHILE
CALL ch.close()
END MAIN

Example 4: Communicating with an HTTP server

MAIN
    DEFINE ch base.Channel, eof INTEGER
    LET ch = base.Channel.create()
    -- HTTP protocol forces every line to be terminate by \r\n
    WHENEVER ERROR CONTINUE
    CALL ch.openClientSocket("localhost", 80, "ub", 30)
    IF STATUS != 0 THEN
        DISPLAY "Could not open socket: error ", STATUS
        EXIT PROGRAM 1
    END IF
    WHENEVER ERROR STOP
    -- HTTP expects CR+LF: Note that LF is added by writeLine()!
    CALL ch.readLine("GET / HTTP/1.0\r")
    -- No HTTP headers...
    -- Empty line = end of headers
    CALL ch.readLine("\r")
    WHILE NOT eof
        DISPLAY ch.readLine()
        LET eof = ch.isEof()
    END WHILE
    CALL ch.close()
END MAIN

Example 5: Writing to STDERR

The following code implements a simple user function to write messages to the stderr stream:

FUNCTION to_stderr(s)
    DEFINE s STRING
    DEFINE c base.Channel
    LET c = base.Channel.create()
    CALL c.openFile("<stderr>", "w")
    CALL c.writeLine(s)
END FUNCTION
The SqlHandle class
The base.SqlHandle class is a built-in class providing an API to execute parameterized SQL statements, with or without result sets.

</tbody>
</table>
**base.SqlHandle.create**
Create a new base.SqlHandle object.

**Syntax**
```sql
create()
RETURNS base.SqlHandle
```

**Usage**
Use the `create()` method to create a base.SqlHandle object to execute SQL statements.
The value returned by this method must be assigned to a variable defined with the base.SqlHandle type.
As with other built-in classes, the SqlHandle object will be automatically destroyed if no longer referenced.

**Example**
```sql
DEFINE sh base.SqlHandle
LET sh = base.SqlHandle.create()
...
```

For a complete example, see Example 2: SqlHandle with result set SQL on page 2306.

**base.SqlHandle.close**
Closes the SQL handle (cursor).

**Syntax**
```sql
close()
```

**Usage**
Call the `close()` method when you are done with the SQL handle.
The statement can be re-opened after it has been closed.

**Note:** An SqlHandle object is automatically closed when the object is destroyed.
As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

**Example**
```sql
DEFINE sh base.SqlHandle
...
CALL sh.close()
```

For a complete example, see Example 2: SqlHandle with result set SQL on page 2306.

**base.SqlHandle.execute**
Executes a simple SQL statement (without result set).

**Syntax**
```sql
execute()
```
**Usage**

Call the `execute()` method to execute the prepared SQL statement, without producing a result set (INSERT, UPDATE, DELETE, CREATE TABLE, ...).

The SQL statement must have been prepared with a `prepare()` call.

If the SQL statement contains `?` parameter place holders, issue a `setParameter()` call for each parameter before executing the SQL statement.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing `SQLCA.SQLCODE`.

**Example**

```plaintext
DEFINE sh base.SqlHandle
...
CALL sh.execute()
```

For a complete example, see Example 1: `SqlHandle with simple SQL` on page 2305.

`base.SqlHandle.fetch`

Fetches a new row from the SQL result set.

**Syntax**

```plaintext
fetch()
```

**Usage**

Call the `fetch()` method to fetch a new row from the SQL result set.

**Note:** When using a dynamic scroll cursor, the `fetch()` method can be used to fetch to the next row.

The SQL statement must have been opened with a `open()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(index)`, `getResultType(index)` and `getResultValue(index)` methods.

If no row is found (end of result set), `SQLCA.SQLCODE` is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing `SQLCA.SQLCODE`.

**Example**

```plaintext
DEFINE sh base.SqlHandle
...
CALL sh.fetch()
```

For a complete example, see Example 2: `SqlHandle with result set SQL` on page 2306.

`base.SqlHandle.fetchAbsolute`

Fetches to a specified row in a scrollable SQL result set.

**Syntax**

```plaintext
fetchAbsolute(position INTEGER)
```

1. `position` is the absolute row position in the result set (starts at 1).
Usage
Call the `fetchAbsolute()` method to fetch to the specified row in a scrollable SQL result set.

The SQL statement must have been opened with a `openScrollCursor()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(index)`, `getResultType(index)` and `getResultValue(index)` methods.

If no row is found (end of result set), SQLCA.SQLCODE is set to 100 (NOTFOUND).

If the specified position does not correspond to a row position in the result set, SQLCA.SQLCODE is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
DEFINE sh base.SqlHandle
...
CALL sh.fetchAbsolute(10)
```

For a complete example, see Example 4: SqlHandle with scroll cursor on page 2307.

`base.SqlHandle.fetchFirst`
Fetched the first row in a scrollable SQL result set.

Syntax

```
fetchFirst()
```

Usage
Call the `fetchFirst()` method to fetch the first row in a scrollable SQL result set.

The SQL statement must have been opened with a `openScrollCursor()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(index)`, `getResultType(index)` and `getResultValue(index)` methods.

If no row is found (end of result set), SQLCA.SQLCODE is set to 100 (NOTFOUND).

If the result set is empty, SQLCA.SQLCODE is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
DEFINE sh base.SqlHandle
...
CALL sh.fetchFirst()
```

For a complete example, see Example 4: SqlHandle with scroll cursor on page 2307.

`base.SqlHandle.fetchLast`
Fetes the last row in a scrollable SQL result set.

Syntax

```
fetchLast()
```
Usage

Call the `fetchLast()` method to fetch the last row in a scrollable SQL result set.
The SQL statement must have been opened with a `openScrollCursor()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(index)`, `getResultType(index)` and `getResultValue(index)` methods.

If no row is found (end of result set), SQLCA.SQLCODE is set to 100 (NOTFOUND).

If the result set is empty, SQLCA.SQLCODE is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
DEFINE sh base.SqlHandle
...
CALL sh.fetchLast()
```

For a complete example, see Example 4: SqlHandle with scroll cursor on page 2307.

`base.SqlHandle.fetchPrevious`

Fetched the previous row in a scrollable SQL result set.

Syntax

```
fetchPrevious()
```

Usage

Call the `fetchPrevious()` method to fetch to the previous row in a scrollable SQL result set.

The SQL statement must have been opened with a `openScrollCursor()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(index)`, `getResultType(index)` and `getResultValue(index)` methods.

If no row is found (end of result set), SQLCA.SQLCODE is set to 100 (NOTFOUND).

If the result set is empty, or if the current row is already the first row, SQLCA.SQLCODE is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing SQLCA.SQLCODE.

Example

```
DEFINE sh base.SqlHandle
...
CALL sh.fetchPrevious()
```

For a complete example, see Example 4: SqlHandle with scroll cursor on page 2307.

`base.SqlHandle.fetchRelative`

Fetched a row relative to the current row in a scrollable SQL result set.

Syntax

```
fetchedRelative(
    position INTEGER)
```
1. *position* is the row offset in the result set. The offset can be negative, to fetch backwards.

**Usage**

Call the `fetchRelative()` method to fetch the row at the specified offset, relative to the current row in a scrollable SQL result set.

The SQL statement must have been opened with an `openScrollCursor()` call.

After performing the fetch call, you can query for column information with the `getResultCount()`, `getResultName(index)`, `getResultType(index)` and `getResultValue(index)` methods.

If no row is found (end of result set), `SQLCA.SQLCODE` is set to 100 (NOTFOUND).

If the result set is empty, or if no row exists at the specified offset relative to the current row position, `SQLCA.SQLCODE` is set to 100 (NOTFOUND).

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing `SQLCA.SQLCODE`.

**Example**

```sql
DEFINE sh base.SqlHandle
...
CALL sh.fetchRelative(-3)
```

For a complete example, see Example 4: SqlHandle with scroll cursor on page 2307.

**base.SqlHandle.flush**

Flushes the rows from the insert cursor buffer.

**Syntax**

```sql
flush()
```

**Usage**

With an insert cursor, call the `flush()` method to force the buffered rows to the database server.

The SQL statement must have been opened with a `open()` call.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing `SQLCA.SQLCODE`.

**Example**

```sql
DEFINE sh base.SqlHandle
...
CALL sh.flush()
```

For a complete example, see Example 3: SqlHandle with insert cursor on page 2306.

**base.SqlHandle.getResultCount**

Returns the number of result set columns produced by the SQL statement.

**Syntax**

```sql
gergetResultCount()
RETURNS INTEGER```

```sql```
Usage

Call the `getResultCount()` method to query the number of columns in the result set, after executing the SQL statement with the `open()` method and fetching a row with `fetch()`.

Example

```plaintext
DEFINE sh base.SqlHandle, i INT
...
FOR i=1 TO sh.getResultCount()
    DISPLAY sh.getResultName(i)
END FOR
```

For a complete example, see Example 2: SqlHandle with result set SQL on page 2306.

`base.SqlHandle.getResultName`

Returns the name of a column in the result set produced by the SQL statement.

Syntax

```plaintext
getResultName( index INTEGER )
RETURNS STRING
```

1. `index` is the ordinal position of the result set column (starts at 1).

Usage

Call the `getResultName()` method to query the name of a column in the result set, after executing the SQL statement with the `open()` method and fetching a row with `fetch()`.

The method takes the position of the column as the parameter.

Example

```plaintext
DEFINE sh base.SqlHandle, i INT
...
FOR i=1 TO sh.getResultCount()
    DISPLAY sh.getResultName(i)
END FOR
```

For a complete example, see Example 2: SqlHandle with result set SQL on page 2306.

`base.SqlHandle.getResultType`

Returns the Genero type name of a column in the result set produced by the SQL statement.

Syntax

```plaintext
getResultType( index INTEGER )
RETURNS STRING
```

1. `index` is the ordinal position of the result set column (starts at 1).

Usage

Call the `getResultType()` method to query the type of a column in the result set, after executing the SQL statement with the `open()` method and fetching a row with `fetch()`.

The method takes the position of the column as the parameter.

The type name is a string that represents a Genero type. For example, "INTEGER", "DECIMAL(10,2)", "DATE", "DATETIME YEAR TO SECOND".
Important:
The column type returned by the `getResultType()` method can differ, depending on the brand of database server, the character set locale, and the length semantics used:

The native column type is provided by the database client software. This native type is then converted to a Genero type. For example, if you define a column with Oracle's native DATE type, the resulting type returned by `getResultType()` will be a Genero `DATETIME YEAR TO SECOND`, which corresponds to Oracle's DATE `YYYY-MM-DD hh:mm:ss`.

Furthermore, depending on the character set and the length semantics used, the size of `CHAR/VARCHAR` types can differ, in order to get a Genero type that is large enough to hold the maximum character string the query may return. The resulting type can for example be different when using UTF-8 with `CHAR` or with `BYTE` length semantics. When using a single byte character set and `BYTE` length semantics, or when using UTF-8 and `CHAR` length semantics, the `CHAR` size returned by `getResultType()` will always match the size of the database column in character units.

For more details, see Length semantics settings on page 414.

Example

```gen
DEFINE sh base.SqlHandle, i INT
...
FOR i=1 TO sh.getResultCount()
   DISPLAY sh.getResultType(i)
END FOR
```

For a complete example, see Example 2: SqlHandle with result set SQL on page 2306.

Related concepts

Defining the application locale on page 412
This section describes the settings defining the application locale, changing the behavior of the compilers and runtime system.

`base.SqlHandle.getResultValue`

Returns the value of a column in the result set produced by the SQL statement.

Syntax

```gen
getResultValue( index INTEGER )
RETURNS fgl-type
```

1. `index` is the ordinal position of the result set column (starts at 1).

Usage

Call the `getResultValue()` method to get the value of a column in the result set, after executing the SQL statement with the `open()` method and fetching a row with `fetch()`.

The method takes the position of the column as the parameter.

The value returned can be assigned to a program variable of the type corresponding to the type name returned by `getResultType()`.

**Important:** TEXT and BYTE values are returned by reference. In order to get the value of a TEXT or BYTE column, define a variable of this type and assign the `getResultValue()` return. The returned TEXT or BYTE variable is already located in memory, there is no need to LOCATE the variable before calling `getResultValue()`.

```gen
DEFINE p_text TEXT
...
LET p_text = h.getResultValue(3)
...
Example

```sql
DEFINE sh base.SqlHandle, i INT
...
FOR i=1 TO sh.getResultCount()
    DISPLAY sh.getResultValue(i)
END FOR
```

For a complete example, see Example 2: SqlHandle with result set SQL on page 2306.

**base.SqlHandle.open**
Opens the SQL handle (SELECT or INSERT cursor).

**Syntax**

```sql
open ()
```

**Usage**

Call the `open()` method to execute the prepared SQL statement, and open the result set cursor or insert cursor.

The SQL statement must have been prepared with a `prepare()` call.

If the SQL statement contains ? parameters:

- For a statement with a result set (SELECT), values must be provided for each parameter before the `open()` call.
- For an insert cursor, values must be provided after the `open()` call, before each `put()` call.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing `SQLCA.SQLCODE`.

Example

```sql
DEFINE sh base.SqlHandle
...
CALL sh.open()
```

For a complete example, see Example 2: SqlHandle with result set SQL on page 2306.

**base.SqlHandle.openScrollCursor**
Opens the SQL handle (with scrollable option).

**Syntax**

```sql
openScrollCursor ()
```

**Usage**

Call the `openScrollCursor()` method to execute a prepared SQL statement, and open the result set for use with a scrollable SQL cursor.

The SQL statement must have been prepared with a `prepare()` call.

If the SQL statement contains ? parameters, values must be provided for each parameter before the `openScrollCursor()` call.

After opening the scrollable cursor, use methods such as `fetchFirst()`, `fetchPrevious()` and `fetchAbsolute(n)` to move forwards and backwards in the SQL result set.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing `SQLCA.SQLCODE`. 
Example

```gen
DEFINE sh base.SqlHandle
...
CALL sh.openScrollCursor()
```

**base.SqlHandle.prepare**
Prepares an SQL statement for the SQL handle.

**Syntax**

```
prepare(
    sql STRING )
```

1. *sql* is the SQL statement to be prepared.

**Usage**
Call the `prepare()` method to prepare the SQL statement that will be executed with either `execute()` or `open()`.

The SQL statement can contain `?` parameter place holders, to be filled with the `setParameter()` method before executing the statement.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing `SQLCA.SQLCODE`.

**Example**

```gen
DEFINE sh base.SqlHandle
...
CALL sh.prepare("INSERT INTO mytable VALUES (?,?)")
```

For a complete example, see Example 2: SqlHandle with result set SQL on page 2306.

**base.SqlHandle.put**
Put a new row in the insert cursor buffer.

**Syntax**

```
put()
```

**Usage**
Call the `put()` method to create a new row for the insert cursor.

The SQL statement must have been prepared with a `prepare()` call.

All SQL parameter values must be provided before doing the `put()` call.

As with standard Genero SQL instructions, SQL errors can be trapped with `WHENEVER ERROR` or `TRY / CATCH` blocks and by testing `SQLCA.SQLCODE`.

**Example**

```gen
DEFINE sh base.SqlHandle
...
CALL sh.put()
```

For a complete example, see Example 3: SqlHandle with insert cursor on page 2306.
**base.SqlHandle.setParameter**
Sets the value of a SQL parameter for this SQL handle.

**Syntax**

```plaintext
define sh base.SqlHandle
define v_pk int, v_crea datetime year to second
... 
call shsetParameter(1, v_pk)
call shsetParameter(2, v_crea)
```

1. *index* is the ordinal position of the ? SQL parameter (starts at 1).
2. *value* is the variable containing the parameter value.

**Usage**

Call the `setParameter()` method to define the value of a SQL parameter specified with a ? placeholder in the string passed to the `prepare()` method.

The SQL statement must have been prepared with a `prepare()` call.

The method will raise error -8131, if the index passed as parameter is lower as 1 or greater as the number of ? parameter placeholders in the prepared SQL statement.

It is possible to pass numeric and string constants directly to the method, but type conversion cannot be done without a program variable.

**Example**

```plaintext
define sh base.SqlHandle
define v_pk int, v_crea datetime year to second
... 
call sh.setParameter(1, v_pk)
call sh.setParameter(2, v_crea)
```

For a complete example, see Example 2: SqlHandle with result set SQL on page 2306.

**Usage**

The `base.SqlHandle` class is a built-in class providing dynamic SQL support with a 3GL API.

Compared to regular SQL cursor instructions, the main purpose of the `base.SqlHandle` class is to provide column name and SQL data type information with the `getResultName()` and `getResultType()` methods. It is also possible to write generic code for parameterized queries with the `setParameter()` method.

**Important:** A database connection must exist in order to use SqlHandle objects.

Unlike regular Genero cursors, SQL handle objects are created dynamically, and can be passed as parameter or returned from functions:

```plaintext
main
    define h base.SqlHandle
    connect to "mydb"
    let h = base.SqlHandle.create()
    call my_prepare(h)
    call my_execute(h)
end main

function my_prepare(h)
    define h base.SqlHandle
    call h.prepare("INSERT INTO cust VALUES ( ... 
end function

function my_execute(h)
    define h base.SqlHandle
```
CALL h.execute()
END FUNCTION

Executing a simple SQL statement without a result set

Perform the following steps, to execute an SQL statement without a result set:

1. Define the SQL handle variable as base.SqlHandle
2. Create an SQL handle object base.SqlHandle.create()
3. prepare(sql-text)
4. For each SQL parameter:
   a. setParameter(index, value)
5. execute() -- test for SQLCA.SQLCODE
6. Repeat from (5), (4), or (3)

Executing a SQL statement returning a result set

Perform the following steps, to execute an SQL statement with a result set:

1. Define the SQL handle variable as base.SqlHandle
2. Create an SQL handle object base.SqlHandle.create()
3. prepare(sql-text)
4. For each SQL parameter:
   a. setParameter(index, value)
5. open()
6. fetch() -- test for SQLCA.SQLCODE == 100
7. getResultCount() -- for each column index:
   a. getResultName(index)
   b. getResultType(index)
   c. getResultValue(index)
8. close()
9. Repeat from (6), (4), (5), or (3)

Executing a SQL statement returning a result set, as scrollable cursor

Perform the following steps, to execute an SQL statement with a result set and scroll forwards and backwards in the rows:

1. Define the SQL handle variable as base.SqlHandle
2. Create an SQL handle object base.SqlHandle.create()
3. prepare(sql-text)
4. For each SQL parameter:
   a. setParameter(index, value)
5. openScrollCursor()
6. fetch() (next row), fetchLast(), fetchFirst(), fetchPrevious(), fetchRelative(n) or fetchAbsolute(n) -- test for SQLCA.SQLCODE == 100
7. getResultCount() -- for each column index:
   a. getResultName(index)
   b. getResultType(index)
   c. getResultValue(index)
8. close()
9. Repeat from (6), (4), (5), or (3)
Creating rows with an insert cursor

Perform the following steps, to insert many rows with an SQL handle insert cursor:

1. Define the SQL handle variable as base.SqlHandle
2. Create an SQL handle object base.SqlHandle.create()
3. prepare(insert-stmt-with-params)
4. BEGIN WORK
5. open()
6. For each row to insert:
   a. For each SQL parameter:
      i. setParameter(index, value)
   b. put()
7. close()
8. COMMIT WORK
9. Repeat from (4) or (3)

SQL error handling with SqlHandle

Handling SQL error and status information (such as NOTFOUND) can be done with SqlHandle objects as with regular SQL instruction, by testing the SQLCA.SQLCODE register, and by using TRY/CATCH blocks or WHENEVER ERROR.

```main
DEFINE h base.SqlHandle
CONNECT TO "mydb"
LET h = base.SqlHandle.create()
TRY
   CALL h.prepare("SELECT * FROM mytab")
   CALL h.open()
   CALL h.fetch()
   DISPLAY h.getResultValue(1)
   CALL h.close()
CATCH
   DISPLAY "SQL ERROR:", SQLCA.SQLCODE
END TRY
END MAIN
```

If an SQL statement execution fails, error description can be found in the SQLCA.SQLCODE, SQLSTATE, STATUS and SQLERRMESSAGE predefined registers.

Examples

base.SqlHandle usage examples.

Example 1: SqlHandle with simple SQL

The following code executes a simple UPDATE statement with the base.SqlHandle API:

```main
DEFINE h base.SqlHandle
CONNECT TO "mydb"
LET h = base.SqlHandle.create()
```
CALL h.prepare("UPDATE t1 SET name = ? WHERE pk = ?")
CALL h.setParameter(1, "Scott")
CALL h.setParameter(2, "8723")
TRY
  CALL h.execute()
CATCH
  DISPLAY "Error detected: ", SQLCA.SQLCODE
END TRY
END MAIN

Example 2: SqlHandle with result set SQL

The following code executes a simple SELECT statement with the base.SqlHandle API:

```sql
MAIN
  DEFINE h base.SqlHandle,
          v VARCHAR(50),
          i INTEGER
  CONNECT TO ":memory:+driver='dbmsqt'"
  CALL create_table()
  LET h = base.SqlHandle.create()
  CALL h.prepare("SELECT * FROM t1 WHERE name>? ORDER BY pkey")
  LET v = "a"
  CALL h.setParameter(1, v)
  CALL h.open()
  WHILE TRUE
    CALL h.fetch()
    IF SQLCA.SQLCODE==NOTFOUND THEN
      EXIT WHILE
    END IF
    DISPLAY "-------------------"
    FOR i=1 TO h.getResultCount()
      DISPLAY i, ":", h.getResultName(i),
           "/", h.getResultType(i),
           
           " = ", h.getResultValue(i)
    END FOR
  END WHILE
END MAIN

FUNCTION create_table()
  CREATE TABLE t1 ( pkey INTEGER PRIMARY KEY,
                    name VARCHAR(50) )
  INSERT INTO t1 VALUES ( 101, 'aaaaa' )
  INSERT INTO t1 VALUES ( 102, 'bbbbbbbb' )
  INSERT INTO t1 VALUES ( 103, 'cccccc' )
  INSERT INTO t1 VALUES ( 104, 'ddddddd' )
END FUNCTION
```

Example 3: SqlHandle with insert cursor

The following code implements an insert cursor with the base.SqlHandle API:

```sql
MAIN
  DEFINE h base.SqlHandle
  DEFINE i INTEGER
  CONNECT TO ":memory:+driver='dbmsqt'"
  CREATE TABLE t1 ( pkey INTEGER, name VARCHAR(50))
  LET h = base.SqlHandle.create()
  CALL h.prepare("INSERT INTO t1 VALUES (?, ?)"
  BEGIN WORK
    CALL h.open()
```
FOR i=1 TO 10
  CALL h.setParameter(1, i)
  CALL h.setParameter(2, SFMT("item_%1",i))
  CALL h.put()
  IF i MOD 10 == 0 THEN
    CALL h.flush()
  END IF
END FOR
CALL h.close()
COMMIT WORK
SELECT COUNT(*) INTO i FROM t1
DISPLAY i
END MAIN

Example 4: SqlHandle with scroll cursor

The following code implements an insert cursor with the base.SqlHandle API:

MAIN
  DEFINE h base.SqlHandle
  CONNECT TO ":memory:+driver='dbmsqt'"
  CALL create_table()
  LET h = base.SqlHandle.create()
  CALL h.prepare("SELECT * FROM t1 ORDER BY pkey")
  CALL h.openScrollCursor()
  CALL h.fetchFirst()
  DISPLAY h.getResultValue(1), " / ", h.getResultValue(2)
  CALL h.fetchLast()
  DISPLAY h.getResultValue(1), " / ", h.getResultValue(2)
  CALL h.fetchPrevious()
  DISPLAY h.getResultValue(1), " / ", h.getResultValue(2)
  CALL h.fetch()
  DISPLAY h.getResultValue(1), " / ", h.getResultValue(2)
  CALL h.fetchAbsolute(2)
  DISPLAY h.getResultValue(1), " / ", h.getResultValue(2)
  CALL h.fetchRelative(2)
  DISPLAY h.getResultValue(1), " / ", h.getResultValue(2)
  CALL h.close()
END MAIN

FUNCTION create_table()
  CREATE TABLE t1 ( pkey INTEGER PRIMARY KEY,
        name VARCHAR(50) )
  INSERT INTO t1 VALUES ( 101, 'aaaaa' )
  INSERT INTO t1 VALUES ( 102, 'bbbbbbbb' )
  INSERT INTO t1 VALUES ( 103, 'cccccc' )
  INSERT INTO t1 VALUES ( 104, 'ddddddd' )
END FUNCTION

The StringBuffer class

The base.StringBuffer class is a built-in class designed to manipulate character strings.

This class is optimized for string operations such as scanning, replacements, concatenation.

Use the base.StringBuffer class instead of STRING variables to implement heavy string manipulations. When you use a base.StringBuffer object, you work directly on the internal string buffer. When you use the STRING data type and modify a string, the runtime system creates a new buffer. While this does not impact the performance of programs with a user interface or even batch programs doing SQL, it can impact performance when you need to rapidly process large character strings. For example, if you need to process 500 KB of text (such as when you are performing a global search-and-replace of specific words), you get much better performance with a base.StringBuffer object than you would with a STRING variable.
When you pass a `base.StringBuffer` object as a function parameter, the function receives a variable that references the object. Passing the object by reference is much more efficient than using a `STRING` that is passed by value, because `STRING` data is copied on the stack. The function manipulates the original string, not a copy of the string.

**Important:** The methods of this class use character positions and string length. When using byte length semantics, the length is expressed in bytes. When using char length semantics, the unit is characters. This matters when using a multibyte locale such as UTF-8.

### `base.StringBuffer` methods

#### Table 470: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>base.StringBuffer.create()</code></td>
<td>Create a string buffer object.</td>
</tr>

<tr>
<td><code>trimLeft()</code></td>
<td>Removes leading blanc characters.</td>
</tr>
<tr>
<td><code>trimRight()</code></td>
<td>Removes trailing blanc characters.</td>
</tr>
</tbody>
</table>
**base.StringBuffer.create**
Create a string buffer object.

**Syntax**
```
base.StringBuffer.create()
  RETURNS base.StringBuffer
```

**Usage**
Use the `base.StringBuffer.create()` class method to create a string buffer object.
The new created object must be assigned to a program variable defined with the `base.StringBuffer` type.

**Example**
```
DEFINE buf base.StringBuffer
LET buf = base.StringBuffer.create()
...
```
For a complete example, see Example 2: Modify a StringBuffer with a function on page 2319.

**base.StringBuffer.append**
Append a string at the end of the current string.

**Syntax**
```
append(
  str STRING )
```

1. `str` is the string to append to the string buffer.

**Usage**
The `append()` method appends a string to the internal string buffer.

**Example**
```
DEFINE buf base.StringBuffer
LET buf = base.StringBuffer.create()
CALL buf.append("abc")
...
```
For a complete example, see Example 1: Add strings to a StringBuffer on page 2319.

**base.StringBuffer.clear**
Clear the string buffer.

**Syntax**
```
clear()
```

**Usage**
Use the `clear()` method to clear the string buffer.
After clearing, the string buffer is empty and the length is zero.
Example

```plaintext
DEFINE buf base.StringBuffer
CALL buf.clear()
...
```

`base.StringBuffer.equals`

Compare strings (case sensitive).

Syntax

```plaintext
equals(
   str STRING )
RETURNS BOOLEAN
```

1. `str` is the string to compare with.

Usage

Use the `equals()` method to determine whether the value of a `base.StringBuffer` object is identical to a specified string.

This method is case-sensitive.

Since the parameter for the method must be a string, you can use the `toString()` method to convert a `base.StringBuffer` object in order to compare it.

The method returns `TRUE` if the strings are identical, otherwise it returns `FALSE`.

Example

```plaintext
MAIN
   DEFINE buf, buf2 base.StringBuffer,
       mystring STRING

   LET buf = base.StringBuffer.create()
   CALL buf.append("there")

   -- compare to a STRING
   IF buf.equals("there") THEN
       DISPLAY "buf matches there"
   END IF

   -- compare to a STRING variable
   LET mystring = "there"
   IF buf.equals(mystring) THEN
       DISPLAY "buf matches mystring"
   END IF

   -- compare to another StringBuffer object
   LET buf2 = base.StringBuffer.create()
   CALL buf2.append("there")
   IF buf.equals(buf2.toString()) THEN
       DISPLAY "buf matches buf2"
   END IF
END MAIN
```

Output:

```
buf matches there
buf matches mystring
buf matches buf2
```
base.StringBuffer.equalsIgnoreCase
Compare strings (case insensitive)

Syntax

```idl
equalsIgnoreCase(
    str STRING )
RETURNS BOOLEAN
```

1. `str` is the string to compare with.

Usage

The `equalsIgnoreCase()` method compares the current string buffer with the passed string, ignoring the character case.

Since the parameter for the method must be a string, you can use the `toString()` method to convert a `base.StringBuffer` object in order to compare it.

The method returns `TRUE` if the strings are identical, otherwise it returns `FALSE`.

Example

```
MAIN
    DEFINE buf3 base.StringBuffer
    LET buf3 = base.StringBuffer.create()
    CALL buf3.append("there")
    IF buf3.equalsIgnoreCase("There") THEN
        DISPLAY "buf matches There ignoring case"
    END IF
END MAIN
```

Output:

```
buf matches There ignoring case
```

base.StringBuffer.getCharAt
Return the character at a specified position.

Syntax

```idl
getCharAt(
    index INTEGER )
RETURNS STRING
```

1. `index` is the character position in the string.

Usage

The `getCharAt()` method returns the character from the string buffer at the position that you specify.

The first character position is 1.

The method returns `NULL` if the position is lower as 1 or greater as the length of the string.

**Important:** When using byte length semantics, the position is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

Example

```
MAIN
    DEFINE buf base.StringBuffer
```

LET buf = base.StringBuffer.create()
CALL buf.append("abcdef")
DISPLAY buf.getCharAt(3) -- Shows c
END MAIN

*base.StringBuffer.getIndexOf*

Return the position of a substring.

**Syntax**

```plaintext
getIndexOf(
  part STRING,
  start INTEGER )
RETURNS INTEGER
```

1. *part* is the substring to be found.
2. *start* is the starting position.

**Usage**

The `getIndexOf()` method returns the position of a substring in the string buffer. Specify the substring and an integer specifying the position at which the search should begin. Use 1 if you want to start at the beginning of the string buffer.

The method returns zero if the substring is not found.

```plaintext
CALL buf.append("abcdef")
DISPLAY buf.getIndexOf("def",1) -- Shows 4
```

**Important**: When using byte length semantics, the position is expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

**Example**

This example iterates through the complete string to display the position of multiple occurrences of the same substring.

```plaintext
MAIN
  DEFINE buf base.StringBuffer
  DEFINE pos INTEGER
  DEFINE s STRING
  LET buf = base.StringBuffer.create()
  CALL buf.append("---abc-----abc--abc----")
  LET pos = 1
  LET s = "abc"
  WHILE TRUE
    LET pos = buf.getIndexOf(s,pos)
    IF pos == 0 THEN
      EXIT WHILE
    END IF
    DISPLAY "Pos: ", pos
    LET pos = pos + length(s)
  END WHILE
END MAIN
```
`base.StringBuffer.getLength`  
Return the length of a string.

**Syntax**

```
getLength()  
  RETURNS INTEGER
```

**Usage**

Use the `getLength()` method to return the number of characters in the current string buffer, including trailing spaces.

The length of an empty string buffer is 0.

**Important:** When using byte length semantics, the string length is expressed in bytes. When using **char length semantics**, the unit is characters. This matters when using a multibyte locale such as UTF-8.

**Example**

```
MAIN  
  DEFINE buf base.StringBuffer  
  LET buf = base.StringBuffer.create()  
  CALL buf.append("abc")  
  DISPLAY buf.getLength() -- Shows 3  
  -- append three spaces to the end of the string  
  CALL buf.append(" ")  
  DISPLAY buf.getLength() -- Shows 6  
END MAIN
```

`base.StringBuffer.insertAt`  
Insert a string at a given position.

**Syntax**

```
insertAt(  
  index INTEGER,  
  str STRING)
```

1. `index` is the position where the string must be inserted.
2. `str` is the string part to be inserted.

**Usage**

The `insertAt()` method inserts a string before the specified position in the string buffer.

**Important:** When using byte length semantics, the position is expressed in bytes. When using **char length semantics**, the unit is characters. This matters when using a multibyte locale such as UTF-8.

**Example**

```
MAIN  
  DEFINE buf base.StringBuffer  
  LET buf = base.StringBuffer.create()  
  CALL buf.append("abcdef")  
  CALL buf.insertAt(3, "xx")  
  DISPLAY buf.toString() -- Shows abcxxdef
END MAIN
```
**base.StringBuffer.replace**
Replace one string with another.

**Syntax**

```
replace(
    oldStr STRING,
    newStr STRING,
    occurrences INTEGER )
```

1. `oldStr` is the string to be replaced.
2. `newStr` is the new string replacing the old string.
3. `occurrences` is the number of replacements to do (zero for all).

**Usage**
The `replace()` method replaces a string within the current string buffer with a different string. Specify the original string, replacement string, and the number of occurrences to replace. Use 0 to replace all occurrences.

**Example**

```
MAIN
    DEFINE buf base.StringBuffer
    LET buf = base.StringBuffer.create()
    CALL buf.append("aaxxbbxxcc")
    CALL buf.replace("xx", "zz", 1)
    DISPLAY buf.toString() -- Shows aazzbbxxcc
END MAIN
```

**Related concepts**

*base.StringBuffer.replaceAt* on page 2315
Replace part of a string with another string.

*base.StringBuffer.replaceAt*
Replace part of a string with another string.

**Syntax**

```
replaceAt(
    index INTEGER,
    length INTEGER,
    str STRING )
```

1. `index` is position where the replacement starts.
2. `length` is the number of characters to be replaced.
3. `str` is the replacement string.

**Usage**
The `replaceAt()` method replaces part of the current string with another string.

The parameters are integers indicating the position at which the replacement should start, the number of characters to be replaced, and the replacement string.

The first position in the string is 1.

**Important:** When using byte length semantics, the position and length are expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.
Example

```plaintext
MAIN
   DEFINE buf base.StringBuffer
   LET buf = base.StringBuffer.create()
   CALL buf.append("abxxxxef")
   CALL buf.replaceAt(3,4,"cd")
   DISPLAY buf.toString() -- Shows abcdef
END MAIN
```

Related concepts

base.StringBuffer.replace on page 2315
Replace one string with another.

base.StringBuffer.subString
Return the substring at the specified position.

Syntax

```plaintext
subString(
   startIndex INTEGER,
   endIndex INTEGER )
RETURNS STRING
```

1. `startIndex` is the substring to be found.
2. `endIndex` is the ending position.

Usage

The `subString()` method returns the substring defined by the start and end positions passed as parameter.

The first character is at position 1.

Important: When using byte length semantics, the positions are expressed in bytes. When using char length semantics, the unit is characters. This is matters when using a multibyte locale such as UTF-8.

Example

```plaintext
MAIN
   DEFINE buf base.StringBuffer
   LET buf = base.StringBuffer.create()
   CALL buf.append("abcdefg")
   DISPLAY buf.subString(2,5) -- Shows bcde
END MAIN
```

base.StringBuffer.toLowerCase
Converts the string in the buffer to lower case.

Syntax

```plaintext
toLowerCase()
```

Usage

The `toLowerCase()` method converts the current string to lower case.

Example

```plaintext
MAIN
   DEFINE buf base.StringBuffer
   LET buf = base.StringBuffer.create()
   CALL buf.append("abcdefg")
   DISPLAY buf.toLowerCase() -- Shows abcdefg
END MAIN
```
LET buf = base.StringBuffer.create()
CALL buf.append("AbC")
CALL buf.toLowerCase()
DISPLAY buf.toString() -- Shows abc
END MAIN

_base.StringBuffer.toString_
Create a STRING from the string buffer.

**Syntax**

```plaintext
toString()
RETURNS STRING
```

**Usage**
The `toString()` method creates a STRING value from the current string buffer.

Use this method if you need to pass the string to another method or instruction that expects a STRING as parameter.

**Example**

```plaintext
MAIN
  DEFINE buf base.StringBuffer
  LET buf = base.StringBuffer.create()
  CALL buf.append("abc")
  DISPLAY buf.toString() -- Shows abc
END MAIN
```

_base.StringBuffer.toUpperCase_
Converts the string in the buffer to upper case.

**Syntax**

```plaintext
toUpperCase()
```

**Usage**
The `toUpperCase()` method converts the current string to upper case.

**Example**

```plaintext
MAIN
  DEFINE buf base.StringBuffer
  LET buf = base.StringBuffer.create()
  CALL buf.append("AbC")
  CALL buf.toUpperCase()
  DISPLAY buf.toString() -- Shows ABC
END MAIN
```

_base.StringBuffer.trim_
Remove leading and trailing blank characters.

**Syntax**

```plaintext
trim()
```
Usage

The `trim()` method removes the leading and trailing blanc characters in the string buffer.

Example

```main
DEFINE buf base.StringBuffer
LET buf = base.StringBuffer.create()
CALL buf.append(" abc ")
CALL buf.trim()
DISPLAY "["||buf.toString()||"]" -- Shows [abc]
END MAIN
```

`base.StringBuffer.trimLeft`

Removes leading blanc characters.

Syntax

`trimLeft()`

Usage

The `trimLeft()` method removes the leading blanc characters in the string buffer.

Example

```main
DEFINE buf base.StringBuffer
LET buf = base.StringBuffer.create()
CALL buf.append(" abc ")
CALL buf.trimLeft()
DISPLAY "["||buf.toString()||"]" -- Shows [abc ]
END MAIN
```

`base.StringBuffer.trimRight`

Removes trailing blanc characters.

Syntax

`trimRight()`

Usage

The `trimRight()` method removes the trailing blanc characters in the string buffer.

Example

```main
DEFINE buf base.StringBuffer
LET buf = base.StringBuffer.create()
CALL buf.append(" abc ")
CALL buf.trimRight()
DISPLAY "["||buf.toString()||"]" -- Shows [ abc]
END MAIN
```
Examples

**base.StringBuffer usage examples.**

**Example 1: Add strings to a StringBuffer**

```
MAIN
   DEFINE buf base.StringBuffer
   LET buf = base.StringBuffer.create()
   CALL buf.append("abc")
   DISPLAY buf.toString()
   CALL buf.append("def")
   DISPLAY buf.toString()
   CALL buf.append(123456)
   DISPLAY buf.toString()
END MAIN
```

Output:

```
abc
abcdef
abcdef123456
```

**Example 2: Modify a StringBuffer with a function**

```
FUNCTION modify(sb)
   DEFINE sb base.StringBuffer
   CALL sb.append("more")
   DISPLAY "sb is ", sb.toString()
END FUNCTION

MAIN
   DEFINE buf base.StringBuffer
   LET buf = base.StringBuffer.create()
   CALL modify(buf)
   DISPLAY "buf is ", buf.toString()
END MAIN
```

Output:

```
sb is more
buf is more
```

**The StringTokenizer class**

The `base.StringTokenizer` class is designed to parse a string to extract tokens based on delimiters.

The steps to use a string tokenizer are:

1. Define a variable with the `base.StringTokenizer` type.
2. Create the string tokenizer object with one of the create methods, passing the string to be parsed as parameter.
3. Optionally, count the number of tokens with `countTokens()` before processing.
4. Use a `WHILE` loop to process the different tokens, by using `hasMoreTokens()` as loop condition and `nextToken()` inside the loop body to get the next token.
base.StringTokenizer methods

Table 472: Class methods

</tr>
</tbody>
</table>

`base.StringTokenizer.create`
Create a string tokenizer object.

Syntax

```java
base.StringTokenizer.create( 
   str STRING, 
   delimiters STRING ) 
RETURNS base.StringTokenizer
```

1. `str` is the character string to be parsed.
2. `delimiters` defines the delimiters to be used.

Usage

Use the `base.StringTokenizer.create()` class method to create a string tokenizer object.

The created object must be assigned to a program variable defined with the `base.StringTokenizer` type.

The method can take a unique or multiple delimiters into account. A delimiter is always one character long.

The empty tokens are not taken into account, and no escape character is defined for the delimiters. The `nextToken()` method will never return NULL strings.
**Note:** To specify a backslash as a delimiter, you must use double backslashes in both the source string and as the delimiter, as shown in Example 3: Specify a backslash as a delimiter on page 2323

**Example**

```base
DEFINE tok base.StringTokenizer
-- Using a single pipe delimiter
LET tok = base.StringTokenizer.create("aaa|bbb|ccc","|")
-- Using several delimiters
LET tok = base.StringTokenizer.create("aaa|bbb;ccc+ddd","|+;")
```

For a complete example, see Example 1: Split a UNIX directory path on page 2322.

**base.StringTokenizer.createExt**
Create a string tokenizer object with escape char and null handling.

**Syntax**

```base
base.StringTokenizer.createExt(
    str STRING,
    delimiters STRING,
    escapeChar STRING,
    withNulls BOOLEAN)
RETURNS base.StringTokenizer
```

1. *str* is the character string to be parsed.
2. *delimiters* defines the delimiters to be used.
3. *escapeChar* defines the escape character.
4. *withNulls* indicates if empty tokens must be returned.

**Usage**

Use the `base.StringTokenizer.createExt()` class method to create a string tokenizer object, with escape character and null token handling.

The created object must be assigned to a program variable defined with the `base.StringTokenizer` type.

The method can take a unique or multiple delimiters into account. A delimiter is always one character long.

When defining an escape character with the third parameter, the delimiters can be escaped in the source string.

When passing `TRUE` to the last parameter, empty tokens are taken into account. The `nextToken()` method might return NULL strings. In the source string, leading and trailing delimiters or the amount of delimiters between two tokens affects the number of tokens.

**Note:** To specify a backslash as a delimiter, you must use double backslashes in both the source string and as the delimiter, as shown in Example 3: Specify a backslash as a delimiter on page 2323

**Example**

```base
DEFINE tok base.StringTokenizer
LET tok = base.StringTokenizer.createExt("|aaa|b\|bb|ccc","|","\",TRUE)
```

For a complete example, see Example 2: Escaped delimiters and NULL tokens on page 2322.

**base.StringTokenizer.countTokens**

Returns the number of tokens left to be returned.

**Syntax**

```base
countTokens()```
Usage
Use the countTokens() method to count the number of tokens left to be returned by the string tokenizer.

This method can be used to know the number of tokens before processing the source string with the hasMoreTokens() and nextToken() methods.

base.StringTokenizer.hasMoreTokens
Returns TRUE if there are more tokens to return.

Syntax
hasMoreTokens()
RETURNS BOOLEAN

Usage
The hasMoreTokens() method indicates if there are other tokens in the source string that are not yet processed.

Use the hasMoreTokens() method typically as the expression of a WHILE block.

base.StringTokenizer.nextToken
Returns the next token found in the source string.

Syntax
nextToken()
RETURNS STRING

Usage
The nextToken() method parses the source string for tokens, following the creation method used, and returns the next token if found.

The method returns NULL if no token is found, or if an empty token was found and the nulls parameter of the createExt() method was set to TRUE.

Use the hasMoreTokens() method to check if more tokens are to be read.

Examples
base.StringTokenizer usage examples.
Example 1: Split a UNIX™ directory path

```plaintext
MAIN
  DEFINE tok base.StringTokenizer
  LET tok = base.StringTokenizer.create("/home/tomy","/")
  WHILE tok.hasMoreTokens()
    DISPLAY tok.nextToken()
  END WHILE
END MAIN
```

Example 2: Escaped delimiters and NULL tokens

```plaintext
MAIN
  DEFINE tok base.StringTokenizer
  LET tok = base.StringTokenizer.createExt("||\|aaa||bbc|","","\",TRUE)  
  WHILE tok.hasMoreTokens()
    DISPLAY tok.nextToken()
  END WHILE
END MAIN
```
Example 3: Specify a backslash as a delimiter

```
MAIN
  DEFINE tok base.StringTokenizer
  LET tok = base.StringTokenizer.create("C:\My Documents\My Pictures","\")
  WHILE tok.hasMoreTokens()
    DISPLAY tok.nextToken()
  END WHILE
END MAIN
```

The TypeInfo class

The `base.TypeInfo` class creates a DOM node from a structured program variable. You can use this class to do program variables introspection, in order to get the data type names and values in a DOM node, that can be traversed with the XML utility classes, or to be serialized in a file for export purpose. The `base.TypeInfo` class does not have to be instantiated: you can directly use the `create()` method.

A serialized DOM node created by `base.TypeInfo` class looks for example as follows:

```
<?xml version="1.0" encoding="ISO-8859-1">
<Record>
  <Field type="INTEGER" value="234" name="key"/>
  <Field type="CHAR(20)" value="Johnson" name="lastname"/>
  <Field type="DATE" value="12/24/1962" name="birthdate"/>
</Record>
```

Steps to use the class:

- Define a variable with the `om.DomNode` type.
- Create a DOM node with `base.TypeInfo.create(var)` and assign it to the DOM node variable.
- Use the new created DOM node.

For example, to convert a list of database records to XML, fetch rows from a database table in a structured array, specify the array as the input parameter for the `base.TypeInfo.create()` method to create a new `base.DomNode` object, and serialize the resulting DOM node to a file by using the `node.writeXml()` method. You can then pass the resulting file to any application that is able to read XML for input.

**Note:** Consider using the JSON interface to serialize and de-serialize program variables.
base.TypeInfo methods

Table 474: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseTypeInfo.create (</td>
<td>Create a DomNode with the type information and values of a program variable.</td>
</tr>
<tr>
<td>$field$</td>
<td></td>
</tr>
<tr>
<td></td>
<td>RETURNS om.DomNode</td>
</tr>
</tbody>
</table>

**Important:** This feature is deprecated, and may be removed in a future version.

baseTypeInfo.describe (       | Display the type information and values of a program variable.                    |
$field$                      |                                                  |
                              | RETURNS om.DomNode                                |

*baseTypeInfo.create()*
Create a DomNode with the type information and values of a program variable.

**Syntax**

```plaintext
baseTypeInfo.create (      |
$\textit{field}$          |
\textit{base-type}        |
\textit{record-type}      |
\textit{dynamic-array-type} |
\textit{static-array-type} |
\textit{dictionary-type}  |
)                           |
RETURNS om.DomNode          |
```

1. $\textit{field}$ is the program variable to convert to DOM.
2. $\textit{base-type}$ is a base data type of Genero (INTEGER, DATE, VARCHAR)
3. $\textit{record-type}$ is a RECORD ... END RECORD type.
4. $\textit{dynamic-array-type}$ is a DYNAMIC ARRAY OF ... type.
5. $\textit{static-array-type}$ is an ARRAY[n] OF ... type.
6. $\textit{dictionary-type}$ is a DICTIONARY OF ... type.

**Usage**

Use the *baseTypeInfo.create()* class method to create a om.DomNode object from a program variable.

The DOM node contains type information and values of the program variable.

The program variable provided to the method is typically a RECORD, but it can be any sort of structured variable, including arrays.
The data is formatted based on current environment settings (DBDATE, DBFORMAT, and DBMONEY).

The method trims trailing blanks for STRING, CHAR and VARCHAR data, and therefore produce empty strings in the resulting dom elements, when the source variable contains only blanks.

**Example**

```plaintext
MAIN
  DEFINE n om.DomNode
  DEFINE r RECORD
    key INTEGER,
    lastname CHAR(20),
    birthdate DATE,
    comment VARCHAR(200)
  END RECORD
  LET r.key = 234
  LET r.lastname = "Johnson"
  LET r.birthdate = MDY(12, 24, 1962)
  LET r.comment = "   ">
  LET n = base.TypeInfo.create( r )
  DISPLAY n.toString()
END MAIN
```

The generated node contains variable values and data type information:

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
<Record>
  <Field type="INTEGER" value="234" name="key"/>
  <Field type="CHAR(20)" value="Johnson" name="lastname"/>
  <Field type="DATE" value="12/24/1962" name="birthdate"/>
  <Field type="VARCHAR(200)" value="" name="comment"/>
</Record>
```

**Related concepts**

- **The DomNode class** on page 2436
  The `om.DomNode` class provides methods to manipulate a DOM node of a data tree.

- **Records** on page 382
  Records allow structured program variables definitions.

- **Arrays** on page 386
  Arrays (static or dynamic) allow to handle an ordered collection of elements.

*base.TypeInfo.describe()*

Display the type information and values of a program variable.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
base.TypeInfo.describe( field { base-type | record-type | dynamic-array-type | static-array-type | dictionary-type })
```

1. *field* is the program variable to convert to DOM.
2. *base-type* is a base data type of Genero (INTEGER, DATE, VARCHAR)
3. *record-type* is a RECORD ... END RECORD type.
4. **dynamic-array-type** is a **DYNAMIC ARRAY** OF ... type.

5. **static-array-type** is an **ARRAY[n]** OF ... type.

6. **dictionary-type** is a **DICTIONARY** OF ... type.

**Usage**

Use the `base.TypeInfo.describe()` class method to display the type definition and values of the program variable passed as argument. Type information and values is written to the stdout stream.

The method follows the same data formatting rules as `base.TypeInfo.create()` on page 2324.

**Note:** The `base.TypeInfo.describe()` method is deprecated. As replacement, use the `base.TypeInfo.create()` method to create an `om.DomNode` object, and produce the XML string with the `om.DomNode.toString()` method.

**Example**

```plaintext
MAIN
  DEFINE r RECORD
    key INTEGER,
    lastname CHAR(20),
    birthdate DATE,
    comment VARCHAR(200)
  END RECORD
  LET r.key = 234
  LET r.lastname = "Johnson"
  LET r.birthdate = MDY(12,24,1962)
  LET r.comment = "   ">
  CALL base.TypeInfo.describe( r )
END MAIN
```

Output:

```
Field type is :
  RECORD (4 members)
    key:INTEGER
    lastname:CHAR(20)
    birthdate:DATE
    comment:VARCHAR(200)
Field type end.
```

**Related concepts**

`base.TypeInfo.create()` on page 2324

Create a DomNode with the type information and values of a program variable.

**The MessageServer class**

The `base.MessageServer` class allows a program to send a key action over the network to other programs using this service.

This class can be used to join a group of programs to be notified by simple messages (i.e. key events). The programs can run on different machines connected together in a network.

**Important:** This feature is experimental and subject to change.

The `base.MessageServer` uses network API capabilities with Sockets and the UDP protocol. The computers must be configured with a network. The UDP protocol does not guarantee the transmission of datagrams, therefore messages sent with the MessageServer can arrive out of order, duplicated, or go missing without notice.

The UDP port is 6600 and the IP address group is 224.0.1.1. These cannot be changed.

**Important:** This feature is only supported in direct connection with the GDC front-end. It is not supported when using other front-ends or when using the GAS.
**base.MessageServer methods**

**Table 475: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>base.MessageServer.connect()</code></td>
<td>Connects to the group of programs to be notified by a message.</td>
</tr>
<tr>
<td><code>base.MessageServer.send(message STRING)</code></td>
<td>Sends a key event to the group of programs connected together.</td>
</tr>
</tbody>
</table>

**base.MessageServer.connect**

Connects to the group of programs to be notified by a message.

**Syntax**

```plaintext
base.MessageServer.connect()
```

**Usage**

Use the `connect()` method to join the group of programs that can be notified by a key event message.

**base.MessageServer.send**

Sends a key event to the group of programs connected together.

**Syntax**

```plaintext
base.MessageServer.send(
    message STRING
)
```

1. `message` is a string expression defining the key event to be sent over the network.

**Usage**

Once connected to the message server group with `base.MessageServer.connect()`, a program calls the `base.MessageServer.send()` class method to notify other programs registered to the group.

```plaintext
CALL base.MessageServer.send("f1")
```

All programs registered to the message server group are notified, including the program which has sent the message. The messages can be treated by the current dialog with a simple `ON KEY()` interaction block.

**Examples**

*base.MessageServer usage examples.*

**Example 1: Simple MessageServer usage**

```plaintext
MAIN
    CALL base.MessageServer.connect()
    MENU "test"
    COMMAND "Send F1"
        CALL base.MessageServer.send("f1")
    COMMAND KEY (F1)
        ERROR SFMT("Key F1 received at %1",CURRENT HOUR TO SECOND)
    COMMAND "quit"
    EXIT MENU
END MENU
```

<td>Define the parent container for the current program.</td>
</tr>
</tbody>
</table>
ui.Interface.frontCall

ui.Interface.frontCall performs a function call to the current front-end.

Syntax

```plaintext
ui.Interface.frontCall( 
    moduleName STRING,  
    functionName STRING,  
    [ valueList ],  
    [ variableList ] )
```

1. `moduleName` defines the shared library or classpath where the function is implemented.
2. `functionName` defines the name of the function to be called.
3. `valueList` is a list of input parameters.
4. `variableList` is a list of output parameters.

Important: The variables are passed by reference to the `frontCall()` method.

Usage

The `ui.Interface.frontCall()` class method can be used to execute a procedure on the front-end workstation through the front-end software component. You can for example launch a front-end specific application like a browser or a text editor, or manage the clipboard content.

Important: When calling the `ui.Interface.frontCall()` method, the connection to the front-end is initiated, if it is not yet established. Consider avoiding front calls in batch programs and interactive programs using the text mode. This is also important to consider in graphical mode, if no interactive instruction was issued before the front call.

The method takes four parameters:

1. The module, identifying the shared library (.so or .DLL) or the Java class (GMA) implementing the front call function.
2. The function of the module to be executed.
3. The list of input parameters, using the square brace notation.
4. The list of output parameters, using the square brace notation.

Input and output parameters are provided as a variable list of parameters, by using the square brackets notation ([param1,param2,...]):

- Input and output parameters can be of any simple type like INTEGER, a RECORD or a DYNAMIC ARRAY.
- An empty list of input or output parameters is specified with [].
- Input parameters can be an expression such as \(10 \times \text{var}\).
- Output parameters must be variables only, to receive the returning values.
- Output parameters are optional. If the front call returns values, these values will be ignored by the runtime system, if no output parameters are provided to receive these values.

Simple front call example:

```plaintext
FUNCTION call()
    DEFINE info STRING
    CALL ui.Interface.frontCall( "standard", "feInfo", ["feName"], [info] )
END FUNCTION
```

Some front calls need a file path as parameter. File paths must follow the syntax of the front end workstation file system. You may need to escape backslash characters in such parameters. The following example shows how to pass a file path with a space in a directory name to a front-end running on a Microsoft™ Windows® workstation:

```plaintext
FUNCTION call()
    DEFINE path STRING, res INTEGER
```
LET path = "\"c:\work dir\my report.doc\"
-- This is: "c:\work dir\my report.doc"
CALL ui.Interface.frontCall( "standard", "shellExec", [path], [res] )
END FUNCTION

When using RECORD and DYNAMIC ARRAY as front call input or output parameters, the runtime system will use JSON serialization, to pass and return such structured data to/from the front-end. This is important to know when implementing your own custom front calls. Note that one can use the json_null and json_name variable definition attributes to control JSON serialization:

DEFINE optrec RECORD
  mode INTEGER ATTRIBUTES(json_null="null"),
  filter STRING ATTRIBUTES(json_name="Data Filter")
END RECORD
DEFINE flags DYNAMIC ARRAY OF INTEGER ATTRIBUTES(json_null="undefined")
DEFINE result_list DYNAMIC ARRAY OF STRING
LET optrec.mode = 999
LET optrec.filter = "*A*
LET flags[1] = 111
LET flags[3] = 333
CALL ui.Interface.frontCall( "m1", "fc1", [optrec, flags], [result_list] )

Front call cost
A front call is a remote procedure call requiring a full network round trip between the server app and the front end. Depending on the current network speed, this may result in delays in the millisecond to sub second range.

Note: In mobile application development or runOnServer mode, the execution time of a front can be much slower when running the app on the server, compared to embedded apps.

Front call error handling
Exception handling instructions can be used to check the execution status of a front call. Both WHENEVER ERROR directives or TRY/CATCH blocks can surround the front call to avoid program stopping in case of error, and to check the error number returned in the STATUS variable.

Note: There is no need to surround front calls with exception handlers such as TRY/CATCH, if the front call is always supposed to execute without error. For example, the feInfo front call will never produce an exception.

Example of front call error handling with a TRY/CATCH block:

FUNCTION takePhoto()
  DEFINE path STRING
  TRY -- This front call may fail if the front-end is not a mobile device:
    CALL ui.Interface.frontCall( "mobile", "takePhoto", [], [path] )
  CATCH
    MESSAGE "Cannot take photo: ", STATUS, " ", err_get(STATUS)
    LET path = NULL
  END TRY
  RETURN path
END FUNCTION

If the front call module name or the function name is invalid, the errors -6331 or -6332 will be raised, respectively.

If the front call execution fails for some reason, the error -6333 will be raised. The description of the problem can be found in the second part of the error message, returned by a call to the ERR_GET() function.

The error -6334 can be raised in case of input or output parameter mismatch. The control of the number of input and output parameters is in the hands of the front-end. Most of the standard front calls have optional returning parameters and will not raise error -6334, if the output parameter list is left empty. However, front-end specific extensions or user-defined front-end functions may return an invalid execution status in case of input or output parameter mismatch,
raising error -6334. If the front-end sends a call execution status of zero (OK), and the number of returned values does not match the number of program variables, the runtime system will set unmatched program variables to NULL. As a general rule, it is recommended that the program provides the expected input and output parameters as specified in the documentation.

Related concepts

Front calls on page 525
Front call functions execute on the platform where the front-end is installed.

ui.Interface.filenameToURI

Converts a file name to an URI to be used as a web component image resource.

Syntax

```plaintext
ui.Interface.filenameToURI(
    path STRING )
RETURNS STRING
```

1. *path* is the local file name to be converted to a URI.

Usage

The `ui.Interface.filenameToURI()` class method converts a local (VM context / server) file name to an URI that can be accessed by the front ends to get the resource.

This method is typically used to provide application image files in Web Components. It can also be used to provide other resource or media files to the front-end, for specific usage. For example, to display an PDF file with GBC using the "launchUrl" front call. Another use case is to play an audio file with the "playSound" front call.

**Note:** The runtime system uses the same mechanism to provide the front-end with images referenced in form elements: Thus, there is no need to call this method except when using application images in web components.

The `ui.Interface.filenameToURI()` method can be used when executing applications behind a GAS, but it can also be used with direct connection to the front-end (typical GDC desktop connection), or when running apps on a mobile device.

The VM context file name to URI mapping is done as follows:

- If the *path* parameter is already an URI (i.e. has a scheme like http:, https:, file:), the file name is returned as is.
- If the *path* parameter is an absolute, relative file path, or a simple file name:
  - When the program is executing behind a GAS, user agents can access files via HTTP. In this architecture, the method will produce an URI that can be referenced in HTML elements of a web component: The image resource will be available from this location.
  - When using a direct connection to the (GDC) front-end without using the GAS, the method returns the file name as is, and the image resources will be transmitted to the GDC through the FGLIMAGEPATH mechanism.
  - When executing an app on a mobile device, both front-end and runtime system coexist on the same platform and can access the file on the system. In this architecture, the method builds the complete local path to the file from the list of directories defined in the FGLIMAGEPATH environment variable.

**Note:** The URI or file path returned by the `filenameToURI()` method are only valid during the program live time: Do not store URIs returned by `filenameToURI()` in a persistent way.

For more details, see Providing the image resource on page 1049 and Using image resources with the gICAPI web component on page 1855

Example

```plaintext
MAIN
```
DEFINE uri STRING
LET uri = ui.Interface.filenameToURI("myimage.png")
CALL ui.Interface.frontCall("standard", "launchURL", [uri], [])
END MAIN

Related concepts
Web components on page 1825
This section describes how to use web components in your application.

ui.Interface.getChildCount
Get the number of children in a parent container.

Syntax

ui.Interface.getChildCount()
RETURNS INTEGER

Usage

Important: The Window Container Interface is a desktop application feature (for GDC), and is not supported on other front-ends (web and mobile).

The ui.Interface.getChildCount() class method returns the number of child programs attached to the current parent WCI program.

WCI child programs are attached to a given container by using the ui.Interface.setContainer() method. Container and child program identifiers/names are defined by the ui.Interface.setName() method.

Related concepts
Window containers (WCI) on page 1922
WCI containers define window containers to group several programs in a parent multiple document interface presentation.

ui.Interface.getChildInstances
Get the number of child instances for a given program name.

Syntax

ui.Interface.getChildInstances( name STRING )
RETURNS INTEGER

1. name is the name of a child program attached to the container of the current program.

Usage

Important: The Window Container Interface is a desktop application feature (for GDC), and is not supported on other front-ends (web and mobile).

The ui.Interface.getChildInstances() class method returns the number of child instances of a program attached to the current parent WCI program, based on the name of the child program passed as parameter.

The name of a child program is defined by the ui.Interface.setName() method.

The getChildInstances() method is typically used to check if a given child program is already started, to avoid multiple instances of the same program in a given WCI container.

Related concepts
Window containers (WCI) on page 1922
WCI containers define window containers to group several programs in a parent multiple document interface presentation.

*ui.Interface.getContainer*

Get the parent container of the current program.

**Important:** The Window Container Interface is a desktop application feature (for GDC), and is not supported on other front-ends (web and mobile).

**Syntax**

```plaintext
ui.Interface.getContainer()
RETURNS STRING
```

**Usage**

The `ui.Interface.getContainer()` class method returns the name of the parent WCI container defined with `ui.Interface.setContainer()`.

**Related concepts**

- *ui.Interface.setContainer* on page 2342
  Define the parent container for the current program.

- *ui.Interface.getDocument*
  Returns the DOM document of the abstract user interface tree.

**Syntax**

```plaintext
ui.Interface.getDocument()
RETURNS om.DomDocument
```

**Usage**

The `ui.Interface.getDocument()` method returns the DOM document of the abstract user interface tree.

Define a variable with the type `om.DomDocument` to receive the result of this method.

Consider using the `getRootNode()` method instead to get directly the root DOM node of the AUI tree.

**Related concepts**

- *The DomDocument class* on page 2429
  The `om.DomDocument` class provides methods to manipulate a data tree, following the DOM standards.

- *User interface basics* on page 1008
  This section introduces to the foundation of the Genero user interface.

- *ui.Interface.getRootNode* on page 2337
  Get the root DOM node of the abstract user interface.

- *ui.Interface.getFrontEndName*
  Returns the type of the front-end currently in use.

**Syntax**

```plaintext
ui.Interface.getFrontEndName()
RETURNS STRING
```
Usage

The `ui.Interface.getFrontEndName()` class method returns the type of the front end used by the program.

Table 477: Front-end names

<table>
<thead>
<tr>
<th>Front-end name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GDC</td>
<td>Desktop front-end</td>
</tr>
<tr>
<td>GMA</td>
<td>Mobile front-end for Android™</td>
</tr>
<tr>
<td>GMI</td>
<td>Mobile front-end for iOS</td>
</tr>
<tr>
<td>GWC</td>
<td>Web browser front-end</td>
</tr>
<tr>
<td>GBC</td>
<td>Genero Browser Client front-end</td>
</tr>
<tr>
<td>Console</td>
<td>Text front-end (dumb terminal)</td>
</tr>
</tbody>
</table>

**Important:** When calling this method, the user interface module of the runtime system will initialize. As result, in text mode, the terminal will be initialized and get some escape sequences. This may corrupt standard output when executing batch programs. Consider testing the FGLGUI environment variable if you want to check that the batch program executes in text mode, instead of using the `getFrontEndName()` method.

**Related concepts**

Example 1: Get the type and version of the front end on page 2345

`ui.Interface.getFrontEndVersion()` on page 2336

Returns the version of the front-end currently in use.

**Syntax**

```java
ui.Interface.getFrontEndVersion()
```

**Usage**

The `ui.Interface.getFrontEndVersion()` class method returns the version number of the front end used by the program.

**Note:** This method is primarily used for debugging purposes.

**Important:** When calling this method, the user interface module of the runtime system will initialize. As result, in text mode, the terminal will be initialized and get some escape sequences. This may corrupt standard output when executing batch programs. Consider testing the FGLGUI environment variable if you want to check that the batch program executes in text mode, instead of using the `getFrontEndName()` method.

**Related concepts**

Example 1: Get the type and version of the front end on page 2345

`ui.Interface.getFrontEndName()` on page 2335

Returns the type of the front-end currently in use.

**Syntax**

```java
ui.Interface.getImage()
```

**Usage**

The `ui.Interface.getImage()` class method returns the icon image of the program.
Usage
Use the `ui.Interface.getImage()` class method to get the icon image name of the program previously set by `setImage()`.

Related concepts
`ui.Interface.setImage` on page 2342
 Defines the icon image of the program.

`ui.Interface.getName`
Returns the name of the program.

Syntax
```plaintext
ui.Interface.getImage()
RETURNS STRING
```

Usage
The `ui.Interface.getImage()` class method returns the name of the program that was defined with the `setName()` method.

Related concepts
`ui.Interface.setName` on page 2343
Defines the name of the current program for the front-end.

`ui.Interface.getRootNode`
Get the root DOM node of the abstract user interface.

Syntax
```plaintext
ui.Interface.getRootNode()
RETURNS om.DomNode
```

Usage
The `ui.Interface.getRootNode()` method returns the root DOM node of the abstract user interface tree. Define a variable with the type `om.DomNode` to receive the result of this method.

```plaintext
DEFINE rn om.DomNode
LET rn = ui.Interface.getRootNode()
-- use d to inspect/change the AUI tree
```

Example
```plaintext
MAIN
  DEFINE rn om.DomNode
  MENU "Test"
    COMMAND "Display AUI"
      LET rn = ui.Interface.getRootNode()
      DISPLAY rn.toString()
  END MENU
END MAIN
```
The `DomDocument` class provides methods to manipulate a data tree, following the DOM standards.

This section introduces to the foundation of the Genero user interface.

**`ui.Interface.getText`**

Returns the title of the program.

**Syntax**

```plaintext
ui.Interface.getText()
RETURNS STRING
```

**Usage**

Use the `ui.Interface.getText()` class method to get the title of the program previously set by `setText()`.

**Related concepts**

- `ui.Interface.setText` on page 2344
  - Defines the title for the program.

- `ui.Interface.getType`  
  - Returns the type of the program.

**Syntax**

```plaintext
ui.Interface.getType()
RETURNS STRING
```

**Usage**

Use the `ui.Interface.getType()` class method to get the type of the program previously set by `setType()`.

**Related concepts**

- `ui.Interface.setType` on page 2344
  - Defines the type of the program for the front-end.

- `ui.Interface.loadActionDefaults`
  - Load the default action defaults file.

**Syntax**

```plaintext
ui.Interface.loadActionDefaults(
    filename STRING)
```

1. `filename` is the name of action defaults file, without the extension.

**Usage**

Use the `ui.Interface.loadActionDefaults()` class method to load a .4ad file defining action defaults for all program forms.

Specify the file name without the "4ad" extension.

The resource file is searched in several directories in a given order, as described in the `FGLRESOURCEPATH` reference topic.
Example

```
CALL ui.Interface.loadActionDefaults("mydefaults")
```

For a complete example, see Example 4: Loading custom resources on page 2346.

Related concepts

- **FGLRESOURCEPATH** on page 244
  Defines search path for resource files.
- **Configuring actions** on page 1646
  Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

**ui.Interface.loadStartMenu**
Load the start menu file.

**Syntax**

```
ui.Interface.loadStartMenu(
    filename STRING )
```

1. *filename* is the name of a start menu file, without the extension.

**Usage**

Use the `ui.Interface.loadStartMenu()` class method to load a .4sm file defining a start menu.

Specify the file name *without* the "4sm" extension.

The resource file is searched in several directories in a given order, as described in the **FGLRESOURCEPATH** reference topic.

**Example**

```
CALL ui.Interface.loadStartMenu("mystartmenu")
```

Related concepts

- **FGLRESOURCEPATH** on page 244
  Defines search path for resource files.
- **Start menus** on page 1918
  Start menus define a tree of application programs that can be started.

**ui.Interface.loadStyles**
Load the presentation styles file.

**Syntax**

```
ui.Interface.loadStyles(
    filename STRING )
```

1. *filename* is the name of presentation styles file, without the extension.

**Usage**

Use the `ui.Interface.loadStyles()` class method to load a .4st file defining presentation styles for all program forms.

Specify the file name *without* the "4st" extension.
The resource file is searched in several directories in a given order, as described in the FGLRESOURCEPATH reference topic.

Example

CALL ui.Interface.loadStyles("mystyles")

For a complete example, see Example 4: Loading custom resources on page 2346.

Related concepts
FGLRESOURCEPATH on page 244
Defines search path for resource files.

Presentation styles on page 1065
Use presentation styles to specify decoration attributes for window and form elements.

ui.Interface.loadToolBar
Load a default toolbar file.

Syntax

ui.Interface.loadToolBar(
    filename STRING )

1. filename is the name of a toolbar file, without the extension.

Usage

Use the ui.Interface.loadToolBar() class method to load a .4tb file defining a default global toolbar for all forms.

Specify the file name without the "4tb" extension.

The resource file is searched in several directories in a given order, as described in the FGLRESOURCEPATH reference topic.

The default toolbar loaded by this method is also used for the WCI container.

Example

CALL ui.Interface.loadToolBar("mytoolbar")

Related concepts
FGLRESOURCEPATH on page 244
Defines search path for resource files.

Toolbars on page 1327
Toolbars define a bar of buttons that appears at the top of application forms.

Window containers (WCI) on page 1922
WCI containers define window containers to group several programs in a parent multiple document interface presentation.

ui.Interface.loadTopMenu
Load a default topmenu file.

Syntax

ui.Interface.loadTopMenu(
    filename STRING )
1. *filename* is the name of a topmenu file, without the extension.

**Usage**

Use the `ui.Interface.loadTopMenu()` class method to load a .4tm file defining a default topmenu for all forms.

Specify the file name without the "4tm" extension.

The resource file is searched in several directories in a given order, as described in the FGLRESOURCEPATH reference topic.

The default topmenu loaded by this method is also used for the WCI container.

**Example**

```
CALL ui.Interface.loadTopMenu("mytopmenu")
```

**Related concepts**

- Topmenus on page 1334
  Topmenus define typical pull-down menus that appear at the top of application forms.
- Window containers (WCI) on page 1922
  WCI containers define window containers to group several programs in a parent multiple document interface presentation.

**ui.Interface.refresh**

Synchronize the user interface with the front-end.

**Syntax**

```
ui.Interface.refresh()
```

**Usage**

The `ui.Interface.refresh()` class method forces a synchronization of the abstract user interface tree with front-end. This means that the end user will immediately see the recent form modifications done by the program.

By default, during an interactive instruction like `DIALOG`, the AUI tree is refreshed automatically, when the runtime system gets the control back after user code execution. Thus, there is no need to call the refresh method in regular code.

**Important:** Use the `ui.Interface.refresh()` method with care; it is only provided to synchronize with the front-end in specific cases. For example, when you need to display batch processing information to the user. Calling this method too frequently will produce a lot of network traffic.

**Example**

```
MAIN
  DEFINE i INT
  FOR i=1 TO 1000000
    DISPLAY i AT 5,5
    IF (i MOD 100) == 0 THEN
      CALL ui.Interface.refresh()
    END IF
  END FOR
END MAIN
```

**Related concepts**

- The dynamic user interface on page 1009
The dynamic user interface is the base concept of the Genero user interaction components.

`ui.Interface.setContainer`
Define the parent container for the current program.

**Syntax**

```
ui.Interface.setContainer(
    name STRING )
```

1. *name* is the name of the parent container.

**Usage**

The `ui.Interface.setContainer(name)` class method to specify the name of the parent WCI container where the current program windows must be displayed. This creates a WCI relation between two independent programs running with distinct fglrun processes.

Each WCI program must be identified by a name, to be set with the `ui.Interface.setName()` class method.

**Related concepts**

- **Window containers (WCI)** on page 1922
  WCI containers define window containers to group several programs in a parent multiple document interface presentation.

- **Example 3: Using the Window Container Interface** on page 2345

`ui.Interface.setImage`
Defines the icon image of the program.

**Syntax**

```
ui.Interface.setImage(
    image STRING )
```

1. *image* is the image file name to be used as program icon.

**Usage**

Use the `ui.Interface.setImage()` class method to define the icon image for the program to be used by the front-ends. This icon will be used in task bars, for example.

Call the method at the beginning of the program, before any interactive instruction.

**Related concepts**

- **ui.Interface.setName** on page 2343
  Define the name of the current program for the front-end.

- **ui.Interface.setText** on page 2344
  Defines the title for the program.

- **Window containers (WCI)** on page 1922
  WCI containers define window containers to group several programs in a parent multiple document interface presentation.

- **Example 3: Using the Window Container Interface** on page 2345
**ui.Interface.setName**
Define the name of the current program for the front-end.

**Syntax**
```java
ui.Interface.setName(
  name STRING )
```

1. `name` is the identifier of the program.

**Usage**
Use the `ui.Interface.setName()` class method to define the identifier for the program to be used by the front-ends, for example in case of window container usage.

The name passed to this method will be passed to the front-end in order to identify the program.

Call the method at the beginning of the program, before any interactive instruction.

By default, it is the program name (without .42m or .42r extension).

**Related concepts**
- `ui.Interface.setText` on page 2344
  Defines the title for the program.
- `ui.Interface.setImage` on page 2342
  Defines the icon image of the program.
- **Window containers (WCI)** on page 1922
  WCI containers define window containers to group several programs in a parent multiple document interface presentation.
- **Example 3: Using the Window Container Interface** on page 2345

**ui.Interface.setSize**
Specify the initial size of the parent container window.

**Syntax**
```java
ui.Interface.setSize(
  h INTEGER,
  w INTEGER )
```

1. `h` is the initial height of the main window.
2. `w` is the initial width of the main window.

**Usage**
Use the `ui.Interface.setSize()` class method to define the initial size of the parent container window of an window container application. The parameters can be integer or string values.

By default, the unit is the character grid cells, but you can add the `px` unit to specify the height and width in pixels.

The `setSize()` method can also be used to configure the size of the main window when using traditional mode, as a replacement of `fgl_setsize()` built-in function.

Call the method at the beginning of the program, before any interactive instruction.

**Related concepts**
- **Window containers (WCI)** on page 1922
WCI containers define window containers to group several programs in a parent multiple document interface presentation.

Example 3: Using the Window Container Interface on page 2345

`ui.Interface.setText`
Defines the title for the program.

**Syntax**

```
ui.Interface.setText(
    title STRING )
```

1. `title` is the text to be used as program title.

**Usage**

Use the `ui.Interface.setText()` class method to define the title for the program to be used by the front-ends, for example in case of window container usage (as title for the main window), or for the text to be displayed in the task bars.

Call the method at the beginning of the program, before any interactive instruction.

**Related concepts**

`ui.Interface.setName` on page 2343
Define the name of the current program for the front-end.

`ui.Interface.setImage` on page 2342
Defines the icon image of the program.

**Window containers (WCI)** on page 1922
WCI containers define window containers to group several programs in a parent multiple document interface presentation.

Example 3: Using the Window Container Interface on page 2345

`ui.Interface.setType`
Defines the type of the program for the front-end.

**Syntax**

```
ui.Interface.setType(
    type STRING )
```

1. `type` is the identifier of the program.

**Usage**

Use the `ui.Interface.setType()` class method to define the type for the program to be used by the front-ends, for example in case of window container usage.

Possible values are: `normal`, `container`, `child`.

The type passed to this method will be passed to the front-end in order to define the rendering and behavior of the program.

Call the method at the beginning of the program, before any interactive instruction.

**Related concepts**

`ui.Interface.setText` on page 2344
Defines the title for the program.

ui.Interface.setName on page 2342

Defines the icon image of the program.

**Window containers (WCI)** on page 1922

WCI containers define window containers to group several programs in a parent multiple document interface presentation.

**Example 3: Using the Window Container Interface** on page 2345

**Examples**

ui.Interface usage examples.

**Example 1: Get the type and version of the front end**

```plaintext
MAIN
  MENU "Test"
    COMMAND "Get"
      DISPLAY "Name = " || ui.Interface.getFrontEndName()
      DISPLAY "Version = " || ui.Interface.getFrontEndVersion()
    COMMAND "Exit"
      EXIT MENU
  END MENU
END MAIN
```

**Example 2: Get the AUI root node and save it to a file in XML format**

```plaintext
MAIN
  DEFINE n om.DomNode
  MENU "Test"
    COMMAND "SaveUI"
      LET n = ui.Interface.getRootNode()
      CALL n.writeXml("auitree.xml")
    COMMAND "Exit"
      EXIT MENU
  END MENU
END MAIN
```

**Example 3: Using the Window Container Interface**

The WCI parent program:

```plaintext
MAIN
  CALL ui.Interface.setName("main1")
  CALL ui.Interface.setText("This is the parent container")
  CALL ui.Interface.setType("container")
  CALL ui.Interface.setSize("600px","600px")
  CALL ui.Interface.loadStartMenu("appmenu")
  MENU "Main"
    COMMAND "Help" CALL help()
    COMMAND "About" CALL aboutbox()
    COMMAND "Exit"
      IF ui.Interface.getChildCount()>0 THEN
        ERROR "You must first exit the child programs."
      ELSE
        EXIT MENU
      END IF
  END MENU
END MAIN
```

The WCI child program:

```plaintext
MAIN
```
CALL ui.Interface.setName("pro1")
CALL ui.Interface.setText("This is module 1")
CALL ui.Interface.setType("child")
CALL ui.Interface.setContainer("main1")
MENU "Test"
  COMMAND "Exit"
  EXIT MENU
END MENU
END MAIN

Example 4: Loading custom resources

Form file (customer.per):

LAYOUT
GRID
{    Num: [f1]
    Name: [f2]
}  END
END

ATTRIBUTES
EDIT f1 = FORMONLY.cust_id;
EDIT f2 = FORMONLY.cust_name, STYLE="mandatory";
END

Program file:

MAIN
  DEFINE rec RECORD
    cust_id INT,
    cust_name VARCHAR(50)
  END RECORD
  CALL ui.Interface.loadActionDefaults("myactdefs")
  CALL ui.Interface.loadStyles("mystyles")
  OPEN FORM f1 FROM "customer"
  DISPLAY FORM f1
  INPUT BY NAME rec.*
END MAIN

Styles file (mystyles.4st):

<?xml version="1.0" encoding="ANSI_X3.4-1968"?>
<StyleList>
  <Style name="Window">
    <StyleAttribute name="windowType" value="normal" />
  </Style>
  <Style name="Edit.mandatory">
    <StyleAttribute name="backgroundColor" value="lightRed" />
  </Style>
</StyleList>

Action Defaults file (myactdefs.4ad):

<?xml version="1.0" encoding="ANSI_X3.4-1968"?>
<ActionDefaultList>
  <ActionDefault name="accept" text="Accept" acceleratorName="Return"
    acceleratorName2="Enter" />
  <ActionDefault name="cancel" validate="no" text="Cancel"
    acceleratorName="Escape" />
</ActionDefaultList>
The Window class
The `ui.Window` class provides an interface to the window objects created with the `OPEN WINDOW` instruction.

A window is typically created with a form with the `OPEN WINDOW WITH FORM` instruction. If the window contains a form, consider using the `ui.Form` class instead of `ui.Window`.

**ui.Window methods**
Methods of the `ui.Window` class.

**Table 478: Class methods**

<table>
<thead>
<tr>

</tbody>
</table>

**Related concepts**

- **Window titles** on page 1040
  Use the **TEXT** attribute to define a title for a window.

- **`ui.Window.forName`**
  Get a window object by name.

**Syntax**

```javascript
ui.Window.forName(
   name STRING
) RETURNS ui.Window
```

1. *name* defines the name of the window.

**Usage**

The `ui.Window.forName()` class method returns the `ui.Window` object corresponding to an identifier used to create the window with the `OPEN WINDOW` instruction.
Declare a variable of type `ui.Window` to hold the window object reference.

**Example**

```plaintext
DEFINE w ui.Window
OPEN WINDOW w1 WITH FORM "custform"
LET w = ui.Window.forName("w1")
...
```

For a complete example, see Example 1: Get a window by name and change the title on page 2353.

**Related concepts**

- Example 1: Get a window by name and change the title on page 2353
- `ui.Window.getCurrent` on page 2350
- Get the current window object.

**ui.Window.createForm**

Create a new empty form in a window.

**Syntax**

```plaintext
createForm(
    name STRING )
RETURNS ui.Form
```

1. `name` is the name for the form.

**Usage**

The `createForm()` method can be used to create a new empty form in the window object. This is typically used to build forms dynamically, by creating the elements with the OM API.

**Important**: It is mandatory to create a form in a window with the `createForm()` method, otherwise it is not usable.

The method returns a new `ui.Form` instance or `NULL` if the form name passed as the parameter identifies an existing form used by the window.

**Example**

```plaintext
DEFINE w ui.Window,
    f ui.Form,
    n, g om.DomNode
OPEN WINDOW w1 WITH 10 ROWS, 20 COLUMNS
LET w = ui.Window.getCurrent()
LET f = w.createForm("myform")
LET n = f.getNode()
LET g = n.createChild("Grid")
...
```

**Related concepts**

- Create forms dynamically on page 1904
  Dynamic dialogs are typically used with forms that are generated at runtime.
- The DomNode class on page 2436
The `om.DomNode` class provides methods to manipulate a DOM node of a data tree.

**ui.Window.getCurrent**  
Get the current window object.

### Syntax

```plaintext
ui.Window.getCurrent ()  
RETURNS ui.Window
```

### Usage

The `ui.Window.getCurrent()` class method returns the `ui.Window` object corresponding to the current window.

Declare a variable of type `ui.Window` to hold the window object reference.

**Example**

```plaintext
DEFINE w ui.Window
OPEN WINDOW w1 WITH FORM "custform"
LET w = ui.Window.getCurrent()
...
```

For a complete example, see Example 2: Get a the current form and hide a groupbox on page 2353.

**Related concepts**

Example 2: Get a the current form and hide a groupbox on page 2353  
`ui.Window.forName` on page 2348  
Get a window object by name.

**ui.Window.getForm**  
Get the current form of a window.

### Syntax

```plaintext
getForm ()  
RETURNS ui.Form
```

### Usage

The `getForm()` method returns the `ui.Form` object corresponding to the current form used by the window object.

Declare a variable of type `ui.Form` to hold the form object reference.

Consider using the `ui.Dialog.getForm()` method to get the form used by the current dialog.

**Example**

```plaintext
DEFINE f ui.Form
OPEN WINDOW w1 WITH FORM "custform"
LET w = ui.Window.getCurrent()
LET f = w.getForm()
...
```

For a complete example, see Example 2: Get a the current form and hide a groupbox on page 2353.

**Related concepts**

`The Form class` on page 2353
The **ui.Form** class provides an interface to form objects created by an `OPEN WINDOW WITH FORM` or `DISPLAY FORM` instruction.

**ui.Dialog.getForm** on page 2388
Returns the current form used by the dialog.

**ui.Window.getNode**
Get the DOM node of a window.

### Syntax

```plaintext
getNode ()
RETURNS om.DomNode
```

### Usage

The `getNode()` method returns the `om.DomNode` object corresponding to the window object.

Declare a variable of type `om.DomNode` to hold the DOM node object reference.

Consider using the `ui.Dialog.getForm()` method to get the form used by the current dialog.

#### Example

```plaintext
DEFINE w ui.Window, n om.DomNode
OPEN WINDOW w1 WITH FORM "custform"
LET w = ui.Window.getCurrent()
LET n = w.getNode()
...
```

### Related concepts

- **The DomNode class** on page 2436
  The `om.DomNode` class provides methods to manipulate a DOM node of a data tree.

- **ui.Dialog.getForm** on page 2388
  Returns the current form used by the dialog.

- **ui.Window.findNode**
  Search for a specific element in the window.

### Syntax

```plaintext
findNode (  
    type STRING,  
    name STRING )
RETURNS om.DomNode
```

1. *type* defines the type of the node.
2. *name* defines the name of the node.

### Usage

The `findNode()` method allows you to search for a specific DOM node in the abstract representation of the window. You search for a child node by giving its type and the name of the element (i.e. the tagname and the value of the 'name' attribute).

The method returns the first element found matching the specified type (tagname) and node name. Window element names must be unique for the same type of nodes, if you want to distinguish all elements.

The `findNode()` method is provided for `ui.Window` class for specific cases when the window does not contain a form. For windows containing a form, use the `ui.Form.findNode()` method instead.
Example

```
DEFINE w ui.Window, n om.DomNode
OPEN WINDOW w1 WITH FORM "custform"
LET w = ui.Window.getCurrent()
LET n = w.findNode("FormField","customer.cust_name")
...
```

Related concepts

* `ui.Form.findNode` on page 2360
  Search for a child node in the form.

* `ui.Window.getImage`
  Get the window icon.

**Syntax**

```
getImage ()
  RETURNS STRING
```

**Usage**

Use the `getImage()` method to get the current icon of a window.

* `ui.Window.getText`
  Get the window title.

**Syntax**

```
getText ()
  RETURNS STRING
```

**Usage**

Use the `getText()` method to get the current title of a window.

* `ui.Window.setImage`
  Set the window icon.

**Syntax**

```
setImage (image STRING)
```

1. `image` is the image name for the icon of the window.

**Usage**

The `setImage()` method defines the icon of the window.

By default, the icon of a window is defined by the `IMAGE` attribute of the `LAYOUT` definition in form files.

* `ui.Window.setText`
  Set the window title.

**Syntax**

```
setText ()
```
1. *text* is the title of the window.

**Usage**

The `setText()` method defines the title of the window.

By default, the title of a window is defined by the `TEXT` attribute of the `LAYOUT` definition in form files.

**Related concepts**

- **Example 1: Get a window by name and change the title** on page 2353
- **Windows and forms** on page 1032

The section describes the concept of windows and forms in the language.

**Examples**

*ui.Window* usage examples.

**Example 1: Get a window by name and change the title**

```plaintext
MAIN
  DEFINE w ui.Window
  OPEN WINDOW w1 WITH FORM "customer" ATTRIBUTES(TEXT="Unknown")
  LET w = ui.Window.forName("w1")
  IF w IS NULL THEN
    EXIT PROGRAM
  END IF
  CALL w.setText("Customer")
  MENU "Test"
    COMMAND "exit" EXIT MENU
  END MENU
END MAIN
```

**Example 2: Get a the current form and hide a groupbox**

```plaintext
MAIN
  DEFINE w ui.Window
  DEFINE f ui.Form
  OPEN WINDOW w1 WITH FORM "customer"
  LET w = ui.Window.getCurrent()
  IF w IS NULL THEN
    EXIT PROGRAM
  END IF
  LET f = w.getForm()
  MENU "Test"
    COMMAND "hide" CALL f.setElementHidden("gb1",1)
  END MENU
END MAIN
```

**The Form class**

The `ui.Form` class provides an interface to form objects created by an `OPEN WINDOW WITH FORM` or `DISPLAY FORM` instruction.

A form object allows you to manipulate form elements by program. For example, you can hide parts of a form with the `setElementHidden()` method. The runtime system is able to handle hidden fields during a dialog instruction. You can, for example, hide a `GROUP` containing fields and labels.

Outside dialogs, get a `ui.Form` instance of the current form with the `ui.Window.getForm()` method. When executing a dialog, use the `ui.Dialog.getForm()` method.
Note that the **OPEN FORM** instruction does not load a form; it simply declares a handle. The form will be created in the AUI tree when executing the **DISPLAY FORM** instruction. Therefore, the corresponding **ui.Form** object is only available after **DISPLAY FORM** is executed.

**ui.Form methods**
Methods of the **ui.Form** class.

</tr>
<tr>
<td><code>setFieldStyle(name STRING, style STRING)</code></td>
<td>Change the style of a form field.</td>
</tr>
</tbody>
</table>
ui.Form.setDefaultInitializer
Define the default initializer for all forms.

Syntax

```plaintext
ui.Form.setDefaultInitializer(
    initializer STRING
)
```

1. `initializer` is the name of a function in the program.

Usage

Specify a default initialization function with the `ui.Form.setDefaultInitializer()` method, to implement global processing when a form is opened.

The method takes the name of the initialization function as a parameter.

Important:

- The initialization function name is case insensitive.
- The module defining the initialization function must have been loaded when the function is invoked. The error -1338 is raised if the module is not yet loaded, or when the function name mismatches. To make sure that the module is loaded, define other functions in the module, that are invoked with a regular `CALL` instruction.

When a form is loaded with `OPEN FORM / DISPLAY FORM` or with `OPEN WINDOW ... WITH FORM`, the initialization function will be called with a `ui.Form` object as a parameter.

Example

The form file `form1.per`:

```plaintext
LAYOUT
GRID
{
    [f1             ]
}
END
ATTRIBUTES
EDIT f1 = FORMONLY.cust_name;
END
```

The main module:

```plaintext
IMPORT FGL setup

MAIN
    DEFINE cust_name STRING
    CALL setup.init_form_setup(FALSE)
    CALL ui.Form.setDefaultInitializer("form_init")
    OPEN FORM f1 FROM "form1"
    DISPLAY FORM f1 -- initialization function is called
    INPUT BY NAME cust_name
END MAIN
```

The imported module `setup.4gl`:

```plaintext
PRIVATE DEFINE with_toolbar BOOLEAN

PUBLIC FUNCTION init_form_setup(tb)
    DEFINE tb BOOLEAN
    LET with_toolbar = tb
```
PUBLIC FUNCTION form_init(f)
    DEFINE f ui.Form
    IF with_toolbar THEN
        CALL f.loadToolBar("common_toolbar")
    END IF
END FUNCTION

Related concepts
OPEN WINDOW on page 1034
Creates and displays a new window.

OPEN FORM on page 1043
Declares a compiled form in the program.

DISPLAY FORM on page 1044
Displays and associates a form with the current window.

ui.Form.displayTo
Displays values to form fields or screen arrays.

Syntax

```plaintext
displayTo(
    value { base-type | RECORD },
    formFieldName STRING,
    screenLine INTEGER,
    attributes STRING
)
```

1. `value` is the scalar value or RECORD to be displayed, and `base-type` is a base data type of Genero (INTEGER, DATE, VARCHAR)
2. `formFieldName` is a simple form field name, like "customer.cust_name" or the name of a SCREEN RECORD defined in the current form.
3. `screenLine` is a line number in the screen array.
4. `attributes` is a space-separated list of TTY attribute names (like "RED REVERSE").

Usage
The `displayTo()` class method is equivalent to the DISPLAY TO instruction.

Use of this method is only recommended, if the name of the form field, the name of the screen record, and/or the display attributes are not known at compile-time. With regular (static) dialogs, the DISPLAY TO or DISPLAY BY NAME instructions should be used instead.

This method is typically used in the context of dynamic dialog programming.

The `displayTo()` method can be used to:
- display a simple value to a form field,
- display a complete RECORD to all fields of a SCREEN RECORD,
- display a complete RECORD to all cells of a screen array line of a SCREEN RECORD.

Important: When using a RECORD as value parameter, do not use the . notation. However, in the second parameter of the `ui.Form.displayTo()` method, the screen record must be specified with a . notation.

When displaying a complete RECORD to a screen array, you must specify the screen line as third parameter. Otherwise, for simple form fields or flat screen records, the screen line is ignored.
To display a simple value to a form field:

```plaintext
CALL ui.Form.displayTo("foo", "f1", NULL, NULL)
-- is the same as:
DISPLAY "foo" TO f1
```

Assuming that in the next code examples, the `rec` variable is defined as a RECORD, and the "sr" name is used in the definition of the SCREEN RECORD in the current form:

To display all elements of a complete RECORD to all fields grouped in a screen record:

```plaintext
CALL ui.Form.displayTo(rec, "sr.*", NULL, NULL)
-- is the same as:
DISPLAY rec.* TO sr.*
```

To display a complete RECORD to a specific screen array line:

```plaintext
CALL ui.Form.displayTo(rec, "sr.*", 2, "REVERSE, RED")
-- is the same as:
DISPLAY rec.* TO sr[2].* ATTRIBUTES(REVERSE, RED)
```

When passing NULL for the `attributes` parameter, the `displayTo()` method will behave as `DISPLAY TO` without an ATTRIBUTE clause, and the default TTY attributes at dialog, form or window level will apply. If you want to display the value without any TTY attribute, specify the string "normal" in the `attributes` parameter:

```plaintext
CALL ui.Form.displayTo("foo", "f1", NULL, "NORMAL")
-- is the same as:
DISPLAY "foo" TO f1 ATTRIBUTES(NORMAL)
```

**Related concepts**

- **Screen records / arrays** on page 1147
- Form fields can be grouped in a screen record or screen array definition.

- **Form fields** on page 1138
- Form fields are form elements designed for data input and/or data display.

- **DISPLAY TO / BY NAME instruction** on page 1537

- `ui.Form.ensureElementVisible`
  Ensure the visibility of a form element.

**Syntax**

```plaintext
ensureElementVisible(
    name STRING )
```

1. `name` defines the name of the form element.

**Usage**

Use the `ensureElementVisible()` method to make sure that the given form element (not form field) is visible to the user. This method can, for example, be used to show a folder page by passing a field that is located in the folder page, even if the field is not used in a dialog.

This method must be used for static form elements, to make form fields visible, use the `ensureFieldVisible()` method instead.

The form element is identified by its name. If several form elements can have the same name, the first form element found is selected.
Note: The ensureElementVisible() method can only show the specified element, if the focus handling in the current active dialog allows it. For more details, see the ensureFieldVisible() instead.

Related concepts
Giving the focus to a form element on page 1631
How to force the focus to move or stay in a specific form element using program code.

PAGE item type on page 1177
Defines the content of a folder page.

ui.Form.ensureFieldVisible
Ensure visibility of a form field.

Syntax

```plaintext
ensureFieldVisible(
    name STRING
)
```

1. name defines the name of the form field.

Usage

The ensureFieldVisible() method makes the given form field visible to the user. This method can for example be used to show a folder page by passing a field that is located in the folder page, even if the field is not used in a dialog.

The form field is identified by name, with an optional prefix (table.column or column).

This method does not give the focus to the field passed as parameter: The folder page or screen area shown by this method call is temporarily visible and can disappear at the next user interaction, depending on focus management.

For example, consider a folder having two pages. The focus is in a field on the first page. A call to the ensureFieldVisible() method makes the second folder page visible, passing a field located in the second page. When the user presses the TAB key, the focus goes to the next field on the first page, bringing the first page to the top. If you want to show a folder page and give the focus to a specific field in that page, you must explicitly give the focus to a field of the page, with NEXT FIELD.

The ensureFieldVisible() method is used for form fields. To show static form elements such as labels or images, use the ensureElementVisible() method instead.

ui.Form.getNode
Get the DOM node of the form.

Syntax

```plaintext
getNode()
RETURNS om.DomNode
```

Usage

The getNode() method returns the DOM node containing the abstract representation of the window/form.

After loading and displaying a form with OPEN FORM / DISPLAY FORM or with OPEN WINDOW ... WITH FORM, get the form object for example with ui.Dialog.getForm() and use the getNode() method to query the DOM node corresponding to the form.

Example

```plaintext
MAIN
    DEFINE f ui.Form
    DEFINE n om.DomNode
```
DEFINE  rec  RECORD  
  custid  INTEGER,  
  custname  VARCHAR(40)  
END  RECORD  
OPEN  FORM  f1  FROM  "customer"  
DISPLAY  FORM  f1  
INPUT  BY  NAME  rec.*  
BEFORE  INPUT  
  LET  f  =  DIALOG.getForm()  
  LET  n  =  f.getNode()  
  DISPLAY  n.toString()  
END  INPUT  
END  MAIN  

Related concepts

The DomNode class on page 2436
The om.DomNode class provides methods to manipulate a DOM node of a data tree.

OPEN WINDOW on page 1034
Creates and displays a new window.

OPEN FORM on page 1043
Declares a compiled form in the program.

DISPLAY FORM on page 1044
Displays and associates a form with the current window.

ui.Form.findNode
Search for a child node in the form.

Syntax

```plaintext
findFirst(  
  tabName  STRING,  
  name  STRING  )  
RETURNS  om.DomNode
```

1. `tabName` defines the type of the node.
2. `name` defines the name of the node.

Usage

The `findFirst()` method allows you to search for a specific DOM node in the abstract representation of the form. You search for a child node by giving its type and the name of the element (i.e. the tagname and the value of the 'name' attribute).

The method returns the first element found matching the specified type (`tagName`) and node name. Form element names must be unique for the same type of nodes, if you want to distinguish all elements.

Example

```plaintext
MAIN  
  DEFINE  f  ui.Form  
  DEFINE  n,  c  om.DomNode  
  DEFINE  rec  RECORD  
    custid  INTEGER,  
    custname  VARCHAR(40)  
  END  RECORD  
OPEN  FORM  f1  FROM  "customer"  
DISPLAY  FORM  f1  
INPUT  BY  NAME  rec.*  
BEFORE  INPUT
```
LET f = DIALOG.getForm()
LET n = f.findNode("FormField", "formonly.custname")
LET c = n.getFirstChild()
DISPLAY c.getAttribute("shift")
END INPUT
END MAIN

Related concepts
The DomNode class on page 2436
The DomNode class provides methods to manipulate a DOM node of a data tree.

ui.Dialog.getForm on page 2388
Returns the current form used by the dialog.

The abstract user interface tree on page 1010
The abstract user interface tree is the XML representation of the application forms displayed to the end user.

ui.Form.loadActionDefaults
Load form action defaults.

Syntax

```
loadActionDefaults(
    path STRING )
```

1. *path* is the name of the action defaults file without extension.

Usage

Load form specific action defaults at runtime with the `loadActionDefaults()` method.
The `loadActionDefaults()` method is commonly used in the form initialization function.
Specify the file name without the "4ad" extension.
The resource file is searched in several directories in a given order, as described in the FGLRESOURCEPATH reference topic.
If a form contains already action defaults, it will be replaced by the new action defaults loaded by this method.
The `loadActionDefaults()` method of a form object is typically used in a generic form initializer function.

Related concepts
FGLRESOURCEPATH on page 244
Defines search path for resource files.
Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

ui.Form.loadToolBar
Load the form toolbar.

Syntax

```
loadToolBar(
    path STRING )
```

1. *path* is the name of the toolbar file without extension.

Usage

Load a toolbar XML definition file into the form with the `loadToolBar()` method.
The `loadToolBar()` method is commonly used in the form initialization function. Specify the file name without the "4tb" extension.

The resource file is searched in several directories in a given order, as described in the `FGLRESOURCEPATH` reference topic.

If the form already contains a toolbar, it will be replaced by the new toolbar loaded from this method.

**Related concepts**
- **FGLRESOURCEPATH** on page 244
  Defines search path for resource files.
- **Toolbars** on page 1327
  Toolbars define a bar of buttons that appears at the top of application forms.

`ui.Form.loadTopMenu`
Load the form topmenu.

**Syntax**
```
loadTopMenu(
    path STRING
)
```

1. *path* is the name of the topmenu file without extension.

**Usage**
Load a topmenu XML definition file into the form with the `loadTopMenu()` method. The `loadTopMenu()` method is commonly used in the form initialization function. Specify the path without the "4tm" extension.

The resource file is searched in several directories in a given order, as described in the `FGLRESOURCEPATH` reference topic.

If the form already contains a topmenu, it will be replaced by the new topmenu loaded by this method.

**Related concepts**
- **FGLRESOURCEPATH** on page 244
  Defines search path for resource files.
- **Topmenus** on page 1334
  Topmenus define typical pull-down menus that appear at the top of application forms.

`ui.Form.setElementHidden`
Show or hide form elements.

**Syntax**
```
setElementHidden(
    name STRING, 
    hidden INTEGER
)
```

1. *name* defines the name of the node.
2. *hidden* the integer value to show or hide the element.

**Usage**
Change the visibility of a form element with the `setElementHidden()` method. You must pass the identifier of the form element. The identifier is the element name as defined in the form definition.
All elements with this name will be affected. If you want to distinguish all form elements, use unique names in the form definition file.

The `setElementHidden()` method changes the hidden attribute of all form elements identified by the name.

The value passed to hide/show the element can be 0, 1 or 2:

**Table 482: Hidden attribute integer values**

<table>
<thead>
<tr>
<th>Hidden value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Makes the element visible.</td>
</tr>
<tr>
<td>1</td>
<td>The element is hidden and the user cannot make it visible. Typically used to hide information the user is not allowed to see.</td>
</tr>
<tr>
<td>2</td>
<td>The element is hidden and the user can make it visible.</td>
</tr>
</tbody>
</table>

**Note:** Do not hide all fields of a dialog, otherwise the dialog execution stops. At least one field must get the focus during a dialog execution.

**Related concepts**

*Example 2: Hide form elements dynamically* on page 2366

*ui.Form.setElementImage*

Change the image of form elements.

**Syntax**

```
setPositionImage(
   name STRING,
   image STRING )
```

1. `name` defines the name of the node.
2. `image` is the image to be set.

**Usage**

Change the image/icon of a form element with the `setPositionImage()` method. You must pass the identifier of the form element. The identifier is the element name as defined in the form definition.

All elements with this name will be affected. If you want to distinguish all form elements, use unique names in the form definition file.

**Related concepts**

*ui.Form.setElementText* on page 2364

Change the text of form elements.

*ui.Form.setStyle* on page 2363

Change the style of form elements.

*ui.Form.setStyle*

Change the style of form elements.

**Syntax**

```
setPositionStyle(
   name STRING,
   style STRING )
```

1. `name` defines the name of the node.
2. *style* is the style name to be set.

**Usage**

Change the style of a form element with the `setElementStyle()` method. You must pass the identifier of the form element. The identifier is the element name as defined in the form definition.

All elements with this name will be affected. If you want to distinguish all form elements, use unique names in the form definition file.

**Related concepts**
- `ui.Form.setElementImage` on page 2363
  - Change the image of form elements.
- `ui.Form.setElementText` on page 2364
  - Change the text of form elements.
- `ui.Form.setFieldStyle` on page 2365
  - Change the style of a form field.

**Syntax**

```plaintext
setElementText(
    name STRING,
    text STRING )
```

1. *name* defines the name of the node.
2. *text* is the text to be set.

**Usage**

Change the text of a form element with the `setElementText()` method, for example to modify the text of a static label or group box during program execution. You must pass the identifier of the form element. The identifier is the element name as defined in the form definition file (per) or the name attribute for the element as defined in the form file.

All elements with this name will be affected. If you want to distinguish all form elements, use unique names in the form definition file.

**Related concepts**
- Example 3: Change the title of table column headers on page 2366
- `ui.Form.setElementImage` on page 2363
  - Change the image of form elements.
- `ui.Form.setElementStyle` on page 2363
  - Change the style of form elements.

`ui.Form.setFieldHidden`

Show or hide a form field.

**Syntax**

```plaintext
setFieldHidden(
    name STRING,
    hide INTEGER )
```

1. *name* defines the name of the form field.
2. hide the integer value to show or hide the element.

Usage

Change the visibility of a form field with the `setFieldHidden()` method. You must pass the identifier of the form field, as defined in the .per form definition. The form field is identified by column name, with an optional prefix (table.column or column). The form field can be a regular field or a column of a list container such as a TABLE.

The value passed to hide/show the element can be 0, 1 or 2:

**Table 483: Hidden attribute integer values**

<table>
<thead>
<tr>
<th>Hidden value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Makes the field visible.</td>
</tr>
<tr>
<td>1</td>
<td>The field is hidden and the user cannot make it visible. Typically used to hide information the user is not allowed to see.</td>
</tr>
<tr>
<td>2</td>
<td>The element is hidden and the user can make it visible.</td>
</tr>
</tbody>
</table>

Note: Do not hide all fields of a dialog, otherwise the dialog execution stops. At least one field must get the focus during a dialog execution.

Related concepts

- Example 2: Hide form elements dynamically on page 2366
- `ui.Form.setFieldStyle` on page 2365
  Change the style of a form field.
- `ui.Form.setElementStyle` on page 2363
  Change the style of form elements.

`ui.Form.setFieldStyle`

Change the style of a form field.

**Syntax**

```
setFieldStyle(
  name STRING,
  style STRING )
```

1. `name` defines the name of the form field.
2. `style` is the style name to be set.

Usage

Change the style of a form field with the `setFieldStyle()` method. You must pass the identifier of the form field, as defined in the .per form definition. The form field is identified by column name, with an optional prefix (table.column or column). The form field can be a regular field or a column of a list container such as a TABLE.

Related concepts

- `ui.Form.setFieldHidden` on page 2364
  Show or hide a form field.
- `ui.Form.setElementStyle` on page 2363
Change the style of form elements.

Examples
ui.Form usage examples.

Example 1: Implement a global form initialization function

```plaintext
MAIN
   CALL ui.Form.setDefaultInitializer("init")
   OPEN FORM f1 FROM "items"
   DISPLAY FORM f1 -- Form appears in the default SCREEN window
   OPEN WINDOW w1 WITH FORM "customer"
   OPEN WINDOW w2 WITH FORM "orders"
   DISPLAY FORM f1 -- Form appears in w2 window
   MENU "Test"
      COMMAND "exit" EXIT MENU
END MENU
END MAIN

FUNCTION init(f)
   DEFINE f ui.Form
   DEFINE n om.DomNode
   CALL f.loadTopMenu("mymenu")
   LET n = f.getNode()
   DISPLAY "Init: ", n.getAttribute("name")
END FUNCTION
```

Example 2: Hide form elements dynamically

```plaintext
MAIN
   DEFINE w ui.Window
   DEFINE f ui.Form
   DEFINE rec RECORD
      custid INTEGER,
      custname VARCHAR(40)
   END RECORD
   OPEN FORM f1 FROM "customer"
   DISPLAY FORM f1
   LET w = ui.Window.getCurrent()
   LET f = w.getForm()
   INPUT BY NAME rec.*
      ON ACTION hide
         CALL f.setFieldHidden("customer.custid",1)
         CALL f.setElementHidden("label_custid",1)
      ON ACTION show
         CALL f.setFieldHidden("customer.custid",0)
         CALL f.setElementHidden("label_custid",0)
   END INPUT
END MAIN
```

Example 3: Change the title of table column headers

The form file (coltitle.per):

```plaintext
LAYOUT
GRID
{
<TABLE t1 >
  Id    Name
  [c1   c2    ]
  [c1   c2    ]
  [c1   c2    ]
  [c1   c2    ]
}
The program file:

```
MAIN
    DEFINE f ui.Form, i INT
    DEFINE arr DYNAMIC ARRAY OF RECORD
        id INT,
        name VARCHAR(40)
    END RECORD
    OPEN FORM f1 FROM "coltitle"
    DISPLAY FORM f1
    FOR i=1 TO 10
        LET arr[i].id = i
        LET arr[i].name = "aaa"||i
    END FOR
    DISPLAY ARRAY arr TO sr.* ATTRIBUTES(UNBUFFERED)
    BEFORE DISPLAY
        let f = dialog.getForm()
    ON ACTION change_title
        CALL f.setElementText("formonly.col1","ID")
        CALL f.setElementText("formonly.col2","NAME")
    END DISPLAY
END MAIN
```

The Dialog class
The ui.Dialog class provides a set of methods to configure, query and control the current interactive instruction. A ui.Dialog object can for example be used to enable or disable actions and form fields dynamically during the dialog execution.

A dialog object is typically available inside a dialog block, with the predefined DIALOG keyword, and can only be referenced during the execution of that interactive instruction. After the interactive instruction, the dialog object is destroyed and its reference becomes invalid.

Dialog objects can also be created dynamically to handle forms created at runtime. This feature is only provided for specific needs.

Related concepts
The DIALOG control class on page 1611
This topic explains the purpose of the ui.DIALOG class.
Dynamic Dialogs on page 1903
Dialogs can be created at runtime with the `ui.Dialog` class.

### `ui.Dialog` methods
Methods of the `ui.Dialog` class.

#### Table 484: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| `ui.Dialog.createConstructByName` (  
  `fields` DYNAMIC ARRAY OF RECORD  
  name STRING,  
  type STRING  
  END RECORD  
) | Creates a new `ui.Dialog` object to implement a dynamic CONSTRUCT BY NAME. |
| `ui.Dialog.createMultipleDialog` ( ) | Creates a new `ui.Dialog` object to implement a dynamic DIALOG multiple-dialog. |
| `ui.Dialog.createDisplayArrayTo` (  
  `fields` DYNAMIC ARRAY OF RECORD  
  name STRING,  
  type STRING  
  END RECORD,  
  `screenRecord` STRING  
) | Creates a new `ui.Dialog` object to implement a dynamic DISPLAY ARRAY TO. |
| `ui.Dialog.createInputArrayFrom` (  
  `fields` DYNAMIC ARRAY OF RECORD  
  name STRING,  
  type STRING  
  END RECORD,  
  `screenRecord` STRING  
) | Creates an `ui.Dialog` object to implement a dynamic INPUT ARRAY FROM. |
| `ui.Dialog.createInputByName` (  
  `fields` DYNAMIC ARRAY OF RECORD  
  name STRING,  
  type STRING  
  END RECORD  
) | Creates an `ui.Dialog` object to implement a dynamic INPUT BY NAME. |
| `ui.Dialog.getCurrent` () | Returns the current dialog object. |
| `ui.Dialog.setDefaultUnbuffered` (  
  `on` BOOLEAN  
) | Set the default unbuffered mode for all dialogs. |

</tr>
<tr>
<td><code>deleteRow(name STRING, index INTEGER)</code></td>
<td>Deletes a row from the specified list.</td>
</tr>
<tr>
<td><code>getArrayLength(name STRING)</code></td>
<td>Returns the total number of rows in the specified list.</td>
</tr>
<tr>
<td><code>getCurrentItem()</code></td>
<td>Returns the current item having focus.</td>
</tr>
<tr>
<td><code>getCurrentRow(name STRING)</code></td>
<td>Returns the current row of the specified list.</td>
</tr>
<tr>
<td><code>getFieldBuffer(name STRING)</code></td>
<td>Returns the input buffer of the specified field.</td>
</tr>
<tr>
<td><code>getFieldTouched(name STRING)</code></td>
<td>Returns the modification flag for a field.</td>
</tr>
</tbody>
</table>
ui.Dialog.createConstructByName
Creates a new ui.Dialog object to implement a dynamic CONSTRUCT BY NAME.

Syntax

```plaintext
ui.Dialog.createConstructByName(
    fields DYNAMIC ARRAY OF RECORD
        name STRING,
        type STRING
    END RECORD
)
```

1. `fields` is the list of form fields controlled by the dialog. This must be a DYNAMIC ARRAY of RECORD structure, with a `name` and `type` member of type STRING.

Usage

The ui.Dialog.createConstructByName() class method creates a new dialog object to implement the equivalent of a static CONSTRUCT block.

Note: The current form will be attached to the new created dialog.

The method takes a list of field definitions as parameter, as described in Field definition for Dynamic Dialogs on page 2411.

Important: Static CONSTRUCT dialog instructions use the data types of the fields defined in the .per form specification file. Unlike static CONSTRUCT, the dynamic construct uses the data type provided in the dynamic array defining the list of fields.

Example

```plaintext
DEFINE fields DYNAMIC ARRAY OF RECORD
    name STRING,
    type STRING
END RECORD
DEFINE d ui.Dialog
...
LET d = ui.Dialog.createConstructByName(fields)
...```

Related concepts

ui.Dialog.getQueryFromField on page 2388
Returns the SQL condition of a field used in a query by example dialog.

Dynamic Dialogs on page 1903
Dialogs can be created at runtime with the ui.Dialog class.

ui.Dialog.createDisplayArrayTo
Creates a new ui.Dialog object to implement a dynamic DISPLAY ARRAY TO.

Syntax

```plaintext
ui.Dialog.createDisplayArrayTo(
    fields DYNAMIC ARRAY OF RECORD
        name STRING,
        type STRING
    END RECORD,
    screenRecord STRING
)
```

1. `fields` is the list of form fields controlled by the dialog. This must be a DYNAMIC ARRAY of a RECORD structure, with a `name` and `type` member of type STRING.
2. `screenRecord` is the name of the screen array (defined with the `SCREEN RECORD` instruction in form files).

**Usage**

The `ui.Dialog.createDisplayArrayTo()` class method creates a new dialog object to implement the equivalent of a static `DISPLAY ARRAY TO` block.

**Note:** The current form will be attached to the new created dialog.

The method takes a list of field definitions as parameter, as described in Field definition for Dynamic Dialogs on page 2411.

The second parameter passed to the `createDisplayArrayTo()` method is the name of the screen record which groups the fields together, for the list view of the form.

For example, in the next form definition, the screen record name is "sr_custlist":

```plaintext
... INSTRUCTIONS
SCREEN RECORD sr_custlist
  ( customer.cust_id,
    customer.cust_name,
  ... );
END
```

For more details, see Screen records / arrays on page 1147.

**Example**

```plaintext
DEFINE fields DYNAMIC ARRAY OF RECORD
  name STRING,
  type STRING
END RECORD
DEFINE d ui.Dialog
... LET d = ui.Dialog.createDisplayArrayTo(fields, "sr_custlist")
...```

**Related concepts**

Dynamic Dialogs on page 1903

Dialogs can be created at runtime with the `ui.Dialog` class.

`ui.Dialog.createInputArrayFrom`

Creates an `ui.Dialog` object to implement a dynamic `INPUT ARRAY FROM`.

**Syntax**

```plaintext
ui.Dialog.createInputArrayFrom( fields DYNAMIC ARRAY OF RECORD
  name STRING,
  type STRING
END RECORD,
screenRecord STRING )
```

1. `fields` is the list of form fields controlled by the dialog. This must be a DYNAMIC ARRAY of a RECORD structure, with a name and type member of type STRING.
2. `screenRecord` is the name of the screen array (defined with the `SCREEN RECORD` instruction in form files).
Usage

The `ui.Dialog.createInputArrayFrom()` class method creates a dialog object to implement the equivalent of a static `INPUT ARRAY FROM` block.

**Note:** The current form will be attached to the created dialog.

The method takes a list of field definitions as parameter, as described in Field definition for Dynamic Dialogs on page 2411.

A dynamic input array dialog behaves like a static `INPUT ARRAY` using the `WITHOUT DEFAULTS` option: The values set in the internal rows before starting the dialog will be used. However, like with a static `INPUT ARRAY`, when adding a new row, the `DEFAULT` attributes of the form-fields are used.

The second parameter passed to the `createInputArrayFrom()` method is the name of the screen record which groups the fields together, for the list view of the form.

For example, in the following form definition, the screen record name is "sr_custlist":

```plaintext
... 
INSTRUCTIONS
SCREEN RECORD sr_custlist
(  
customer.cust_id, 
customer.cust_name,  
...  
)
END
```

For more details, see Screen records / arrays on page 1147.

Example

```plaintext
DEFINE fields DYNAMIC ARRAY OF RECORD  
    name STRING,  
    type STRING  
END RECORD
DEFINE d ui.Dialog
...
LET d = ui.Dialog.createInputArrayFrom(fields, "sr_custlist")
...
```

Related concepts

Dynamic Dialogs on page 1903
Dialogs can be created at runtime with the `ui.Dialog` class.

`ui.Dialog.createInputByName`
Creates an `ui.Dialog` object to implement a dynamic `INPUT BY NAME`.

Syntax

```plaintext
ui.Dialog.createInputByName(  
    fields DYNAMIC ARRAY OF RECORD  
        name STRING,  
        type STRING  
END RECORD  
    )
```

1. `fields` is the list of form fields controlled by the dialog. This must be a `DYNAMIC ARRAY` of a `RECORD` structure, with a `name` and `type` member of type `STRING`. 
Usage

The `ui.Dialog.createInputByName()` class method creates a dialog object to implement the equivalent of a static `INPUT BY NAME` block.

**Note:** The current form will be attached to the created dialog.

The method takes a list of field definitions as parameter, as described in Field definition for Dynamic Dialogs on page 2411.

A dynamic input dialog behaves like a static `INPUT` dialog using the `WITHOUT DEFAULTS` option: The `DEFAULT` attribute of the form-field is not used.

Example

```plaintext
DEFINE fields DYNAMIC ARRAY OF RECORD
  name STRING,
  type STRING
END RECORD
DEFINE d ui.Dialog
...
LET d = ui.Dialog.createInputByName(fields)
...
```

Related concepts

Dynamic Dialogs on page 1903
Dialogs can be created at runtime with the `ui.Dialog` class.

`ui.Dialog.createMultipleDialog`
Creates a new `ui.Dialog` object to implement a dynamic `DIALOG` multiple-dialog.

Syntax

```plaintext
ui.Dialog.createMultipleDialog()
```

Usage

The `ui.Dialog.createMultipleDialog()` class method creates a new dialog object to implement the equivalent of a static `DIALOG / END DIALOG` block.

**Note:** The current form will be attached to the new created dialog.

The method takes no parameters.

After creating the multiple dialog object, you must add sub-dialogs with the following methods:

- `ui.Dialog.addConstructByName` on page 2375
- `ui.Dialog.addDisplayArrayTo` on page 2376
- `ui.Dialog.addInputArrayFrom` on page 2377
- `ui.Dialog.addInputByName` on page 2378

Use the `addTrigger()` method, to add global or sub-dialog triggers: The scope of the trigger is defined by the `addTrigger()` call order. See `addTrigger()` for more details.

Example

```plaintext
DEFINE fields DYNAMIC ARRAY OF RECORD
  name STRING,
  type STRING
END RECORD
DEFINE d ui.Dialog
...
LET d = ui.Dialog.createMultipleDialog()
```
CALL d.addTrigger("ON ACTION close") -- Adds a global trigger for the dialog
... CALL d.addDisplayArrayTo(fields, "sr_custlist") -- Adds a DISPLAY ARRAY sub-dialog
CALL d.addTrigger("ON ACTION refresh") -- Adds a trigger for the DISPLAY ARRAY sub-dialog
...

Related concepts

Dynamic Dialogs on page 1903
Dialogs can be created at runtime with the ui.Dialog class.

ui.Dialog.getCurrent
Returns the current dialog object.

Syntax

    ui.Dialog.getCurrent ()
    RETURNS ui.Dialog

Usage

To get the current active dialog object, use the ui.Dialog.getCurrent() class method.

The method returns NULL if there is no current active dialog.

Example

    FUNCTION field_disable(name)
        DEFINE name STRING
        DEFINE d ui.Dialog
        LET d = ui.Dialog.getCurrent()
        IF d IS NOT NULL THEN
            CALL d.setFieldActive(name, FALSE)
        END IF
    END FUNCTION

ui.Dialog.setDefaultUnbuffered
Set the default unbuffered mode for all dialogs.

Syntax

    ui.Dialog.setDefaultUnbuffered ( 
        on BOOLEAN )

1.  on is a boolean to enable the unbuffered mode.

Usage

By default, modal dialogs are not sensitive to variable changes. To make a dialog sensitive, use the UNBUFFERED attribute in the dialog instruction definition.

To defined the default for all subsequent dialogs, use the setDefaultUnbuffered() class method:

    CALL ui.Dialog.setDefaultUnbuffered(TRUE)

Note: Only singular and multiple dialogs are sensitive to this API, parallel dialogs are implicitly using the unbuffered mode.
Related concepts

The buffered and unbuffered modes on page 1618
The buffered and unbuffered mode control the synchronization of program variables and form fields.

`ui.Dialog.accept`
Validates and terminates the dialog.

Syntax

```plaintext
accept()
```

Usage

Use the `accept()` method to validate field input and terminate the dialog. This method is equivalent to the `ACCEPT INPUT / ACCEPT DISPLAY / ACCEPT DIALOG` instructions.

The method is provided as a 3GL alternative to the `ACCEPT` control instructions, for example to terminate the dialog in a function, outside the context of a dialog block, where control instructions cannot be used.

Typical dialog validation rules are performed when calling this method. See `ACCEPT DIALOG` for more details.

`ui.Dialog.addConstructByName`
Adds a sub-dialog of type `CONSTRUCT BY NAME` to an existing `ui.Dialog` dynamic dialog.

Syntax

```plaintext
ui.Dialog.addConstructByName(
    fields DYNAMIC ARRAY OF RECORD
        name STRING,
        type STRING
    END RECORD,
    name STRING
)
```

1. `fields` is the list of form fields controlled by the dialog. This must be a `DYNAMIC ARRAY` of `RECORD` structure, with a `name` and `type` member of type `STRING`.
2. `name` is the sub-dialog identifier. This name is used to identify the sub-dialog in dialog events and API calls.

Usage

The `ui.Dialog.addConstructByName()` class method adds a sub-dialog equivalent to a `CONSTRUCT BY NAME` block, to the dynamic multiple dialog created with `ui.Dialog.createMultipleDialog` on page 2373.

The method takes a list of field definitions as parameter, as described in `Field definition for Dynamic Dialogs` on page 2411.

This second parameter will be used to identify the sub-dialog.

**Important:** Static `CONSTRUCT` dialog instructions use the data types of the fields defined in the `.per` form specification file. Unlike static `CONSTRUCT`, the dynamic construct uses the data type provided in the dynamic array defining the list of fields.

Example

```plaintext
DEFINE fields DYNAMIC ARRAY OF RECORD
    name STRING,
    type STRING
END RECORD
DEFINE d ui.Dialog
...
LET d = ui.Dialog.createMultipleDialog()
```
CALL d.addConstructByName(fields,"const1")

Related concepts

ui.Dialog.getQueryFromField on page 2388
Returns the SQL condition of a field used in a query by example dialog.

Dynamic Dialogs on page 1903
Dialogs can be created at runtime with the ui.Dialog class.

ui.Dialog.addDisplayArrayTo
Adds a sub-dialog of type DISPLAY ARRAY TO to an existing ui.Dialog dynamic dialog.

Syntax

ui.Dialog.addDisplayArrayTo(
    fields DYNAMIC ARRAY OF RECORD
    name STRING,
    type STRING
    END RECORD,
    screenRecord STRING )

1. fields is the list of form fields controlled by the dialog. This must be a DYNAMIC ARRAY of a RECORD structure, with a name and type member of type STRING.
2. screenRecord is the name of the screen array (defined with the SCREEN RECORD instruction in form files). This name will also identify the sub-dialog in dialog events and API calls.

Usage

The ui.Dialog.addDisplayArrayTo() classmethod adds a sub-dialog equivalent to a DISPLAY ARRAY TO block, to the dynamic multiple dialog created with ui.Dialog.createMultipleDialog on page 2373.

The method takes a list of field definitions as parameter, as described in Field definition for Dynamic Dialogs on page 2411.

The second parameter passed to the addDisplayArrayTo() method is the name of the screen record which groups the fields together, for the list view of the form. This second parameter will also be used to identify the sub-dialog.

For example, in the next form definition, the screen record name is "sr_custlist":

... INSTRUCTIONS SCREEN RECORD sr_custlist ( customer.cust_id, customer.cust_name, ... )
END

For more details, see Screen records / arrays on page 1147.

Example

DEFINE fields DYNAMIC ARRAY OF RECORD
    name STRING,
    type STRING
    END RECORD
DEFINE d ui.Dialog
... LET d = ui.Dialog.createMultipleDialog()
...
CALL d.addDisplayArrayTo(fields, "sr_custlist")
...

Related concepts
Dynamic Dialogs on page 1903

ui.Dialog.addInputArrayFrom
Adds a sub-dialog of type INPUT ARRAY FROM to an existing ui.Dialog dynamic dialog.

Syntax

```plaintext
ui.Dialog.addInputArrayFrom(
    fields DYNAMIC ARRAY OF RECORD
        name STRING,
        type STRING
    END RECORD,
    screenRecord STRING
)
```

1. `fields` is the list of form fields controlled by the dialog. This must be a DYNAMIC ARRAY of a RECORD structure, with a name and type member of type STRING.
2. `screenRecord` is the name of the screen array (defined with the SCREEN RECORD instruction in form files). This name will also identify the sub-dialog in dialog events and API calls.

Usage
The `ui.Dialog.addInputArrayFrom()` class method adds a sub-dialog equivalent to a INPUT ARRAY FROM block, to the dynamic multiple dialog created with `ui.Dialog.createMultipleDialog` on page 2373.

The method takes a list of field definitions as parameter, as described in Field definition for Dynamic Dialogs on page 2411.

The second parameter passed to the `addInputArrayFrom()` method is the name of the screen record which groups the fields together, for the list view of the form. This second parameter will also be used to identify the sub-dialog.

For example, in the next form definition, the screen record name is "sr_custlist":

```plaintext
... INSTRUCTIONS
SCREEN RECORD sr_custlist
(
    customer.cust_id,
    customer.cust_name,
    ...
);
END
```

For more details, see Screen records / arrays on page 1147.

Example

```plaintext
DEFINE fields DYNAMIC ARRAY OF RECORD
    name STRING,
    type STRING
END RECORD
DEFINE d ui.Dialog
...
LET d = ui.Dialog.createMultipleDialog()
...
CALL d.addInputArrayFrom(fields, "sr_custlist")
...

Related concepts

Dynamic Dialogs on page 1903
Dialogs can be created at runtime with the ui.Dialog class.

ui.Dialog.addInputByName
Adds a sub-dialog of type INPUT BY NAME to an existing ui.Dialog dynamic dialog.

Syntax

```
ui.Dialog.addInputByName(
    fields DYNAMIC ARRAY OF RECORD
        name STRING,
        type STRING
    END RECORD,
    name STRING
)
```

1. `fields` is the list of form fields controlled by the dialog. This must be a DYNAMIC ARRAY of a RECORD structure, with a name and type member of type STRING.
2. `name` is the sub-dialog identifier. This name is used to identify the sub-dialog in dialog events and API calls.

Usage

The ui.Dialog.addInputByName() class method adds a sub-dialog equivalent to an INPUT BY NAME block, to the dynamic multiple dialog created with `ui.Dialog.createMultipleDialog` on page 2373. The method takes a list of field definitions as parameter, as described in Field definition for Dynamic Dialogs on page 2411.

This second parameter will be used to identify the sub-dialog.

Example

```
DEFINE fields DYNAMIC ARRAY OF RECORD
    name STRING,
    type STRING
END RECORD
DEFINE d ui.Dialog
...
LET d = ui.Dialog.createMultipleDialog()
...
CALL d.addInputByName(fields,"input1")
...
```

Related concepts

Dynamic Dialogs on page 1903
Dialogs can be created at runtime with the ui.Dialog class.

ui.Dialog.addTrigger
Adds an event trigger to the dynamic dialog

Syntax

```
addTrigger()
```
trigger STRING )

1. **trigger** is the name of the dialog.

**Usage**

When implementing a dynamic dialog, the `addTrigger()` method must be used to register user-defined triggers:

```sql
CALL d.addTrigger("ON ACTION print")
```

Registered dialog triggers are then typically managed in a **WHILE** loop using the `nextEvent()` method, to wait for dialog events.

Predefined triggers such as "BEFORE ROW", "BEFORE FIELD", "ON CHANGE" are already registered in dynamic dialogs: Such triggers do not have to be added with the `addTrigger()` method. User code can be implemented for predefined triggers when returned from the `nextEvent()` method.

Dynamic multiple dialogs are implemented with `ui.Dialog.createMultipleDialog` on page 2373. When calling the `addTrigger()` method just after `createMultipleDialog()`, it will add a global dialog trigger. When called after methods such as `ui.Dialog.addDisplayArrayTo` on page 2376, it will add a local trigger to the last added sub-dialog.

Sub-dialog actions that are created in the context of a sub-dialog with `addTrigger("ON ACTION action-name")` will be returned as "ON ACTION sub-dialog-name.action-name" from the `nextEvent()` method.

The following triggers are accepted by the `addTrigger()` method:

**Table 486: User-defined triggers for dynamic dialogs**

<table>
<thead>
<tr>
<th>Trigger name</th>
<th>Description</th>
<th>Dialog block equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>ON ACTION action-name</td>
<td>Action handler for the action identified by <code>action-name</code>.</td>
<td>ON ACTION block</td>
</tr>
<tr>
<td>ON APPEND</td>
<td>Row addition action handler for a display array dynamic dialog.</td>
<td>ON APPEND block</td>
</tr>
<tr>
<td>ON DELETE</td>
<td>Row deletion action handler for a display array dynamic dialog.</td>
<td>ON DELETE block</td>
</tr>
<tr>
<td>ON INSERT</td>
<td>Row insertion action handler for a display array dynamic dialog.</td>
<td>ON INSERT block</td>
</tr>
<tr>
<td>ON UPDATE</td>
<td>Row modification action handler for a display array dynamic dialog.</td>
<td>ON UPDATE block</td>
</tr>
</tbody>
</table>

**Related concepts**

`ui.Dialog.nextEvent` on page 2391
Waits for a dialog event.

`Dynamic Dialogs` on page 1903
Dialogs can be created at runtime with the `ui.Dialog` class.

`ui.Dialog.appendRow`
Appends a new row in the specified list.

**Syntax**

```sql
appendRow( name STRING )
```
1. *name* is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.

**Usage**

The `appendRow()` method appends a row to the end of the array controlled by the dialog.

**Important:** This method is designed to be used in an ON ACTION block. It must not be called in control blocks such as BEFORE ROW, AFTER ROW, BEFORE INSERT, AFTER INSERT, BEFORE DELETE, or AFTER DELETE.

The method is similar to appending a new element to the program array, except the internal dialog registers are automatically updated (like the total number of rows returned by `getArrayLength()`). If the list is decorated with cell attributes, the program array defining the attributes will also be synchronized. If multi-row selection is enabled, selection flags of existing rows are kept. The new row is inserted at the end of the list with the selection flag set to zero.

**Note:** The purpose of this method is to implement business logic required to modify the record list in the current dialog. It is typically used in a DISPLAY ARRAY dialog. Avoid using this method in INPUT ARRAY. To allow the end user to append, modify or delete rows in a DISPLAY ARRAY, use list modification interaction blocks.

After the method is called, a new row is created in the program array. You can assign values to the variables before the control goes back to the user. The `getArrayLength()` method will return the new row count.

The method does not set the current row and does not give the focus to the list; you need to call `setCurrentRow()` and execute NEXT FIELD to give the focus.

This method does not execute any BEFORE ROW, BEFORE INSERT, AFTER INSERT or AFTER ROW control blocks.

The `appendRow()` method does not create a temporary row as the implicit append action of INPUT ARRAY; The row is considered permanent once it is added.

**Example**

This example implements a user-defined action to append ten rows at the end of the list.

```plaintext
ON ACTION append_some_rows
    FOR i = 1 TO 10
        CALL DIALOG.appendRow("sa")
        LET r = DIALOG.getArrayLength("sa")
        LET p_items[r].item_quantity = 1.00
    END FOR
END ON ACTION
```

`ui.Dialog.appendNode` Appends a new node in the specified tree-view.

**Syntax**

```plaintext
appendNode(
    name STRING,
    parentIndex INTEGER )
```

1. *name* is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. *parentIndex* is the index of the parent node in the program array (starts at 1).

**Usage**

The `appendNode()` method adds a new node under a given parent, when the dialog controls a tree view.

This method must be used when modifying the array of a tree view during the execution of the dialog, for example when implementing a dynamic tree with ON EXPAND / ON COLLAPSE triggers. Before the execution of the dialog,
you can fill the program array directly. This includes the context of BEFORE DISPLAY or BEFORE DIALOG control blocks.

When adding rows for a tree view, the id of the parent node and new node matters because that information is used to build the internal tree structure. When calling `appendNode()`, you pass the index of the parent node under which the new node will be appended. In the program array, the parent-id member of the new node will automatically be initialized with the value of the id of the parent node identifier by the index passed as parameter, then the internal tree structure is rebuilt.

If the parent index is zero, a new root node will be appended.

The method returns the index of the new inserted node.

In the program array, the parent-id member of the new node will automatically be initialized with the value of the id member of the parent node identified by the index.

```plaintext
DISPLAY ARRAY mytree TO sr.*
... 
  ON EXPAND(id)
    CALL DIALOG.appendNode("sr", id)
  ...
...
```

**Related concepts**

Dynamic filling of very large trees on page 1797
How to optimize the implementation of large tree-views?

`ui.Dialog.arrayToVisualIndex`
Converts the program array index to the visual index for a given screen array.

**Syntax**

```plaintext
arrayToVisualIndex( 
  name STRING, 
  arrayIndex INTEGER )
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. `arrayIndex` is the index of the program array row.

**Usage**

When the end user sorts rows in a table, the program array index may differ from the visual row index.

Use this method to convert a program array row index (`arr_curr()`) to a row index as seen by the end user. For example, if you want to display a typical message with `(current-row / total-rows)`, convert the current program array row to a visual row index before displaying the value:

```plaintext
MESSAGE SFMT( "Row: %1/%2", 
  DIALOG.arrayToVisualIndex( "sr", DIALOG.getCurrentRow("sr") ), 
  DIALOG.getArrayLength( "sr" ) 
)
```

**Related concepts**

Handling the current row on page 1736
Query and control the current row in a read-only or editable list of records.

ON SORT block on page 1414
`ui.Dialog.visualToArrayIndex` on page 2407
Converts the visual index to the program array index for a given screen array.

`ui.Dialog.getCurrentRow` on page 2386
Returns the current row of the specified list.

`ui.Dialog.getRow()` on page 2385

Returns the total number of rows in the specified list.

`ui.Dialog.getArrayLength` on page 2385

Cancels a parent dialog from a sub-dialog.

**Syntax**

```
cancel()
```

**Usage**

The `cancel()` method followed by `CONTINUE INPUT/DISPLAY/CONSTRUCT` is equivalent to the `CANCEL DIALOG` static instruction.

Use the `cancel()` method in the context of a `DIALOG` block using a `SUBDIALOG`, when the `DIALOG` is about to be canceled by the `SUBDIALOG`.

When calling the `cancel()` method, the `INT_FLAG` is set to `TRUE`, and the `AFTER INPUT`, `AFTER DISPLAY`, `AFTER CONSTRUCT` blocks of subdialogs, and the `AFTER DIALOG` block are executed.

**Example**

```
DIALOG mysubinput()
   INPUT BY NAME ...
   ...
   ON ACTION cancel
      CALL DIALOG.cancel()
      CONTINUE INPUT
   END INPUT
END DIALOG
```

`ui.Dialog.close`

Closes a dynamic dialog.

**Syntax**

```
close()
```

**Usage**

Use the `close()` method when the dynamic dialog is finished.

To fully destroy the dialog object, assign `NULL` the to variable referencing it.

**Example**

```
... WHEN "ON ACTION cancel"
   EXIT WHILE
END WHILE
CALL d.close()
LET d = NULL
CLOSE WINDOW w1
```

**Related concepts**

- Ending dynamic dialogs on page 1908
Describes how to terminate dynamic dialogs.

ui.Dialog.deleteAllRows
Deletes all rows from the specified list.

Syntax

```java
deleteAllRows(
    name STRING
)
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.

Usage

The `deleteAllRows()` method removes all the rows of a list driven by a DISPLAY ARRAY or INPUT ARRAY. This is equivalent to a `deleteRow()` call, but instead of deleting one particular row, it removes all rows of the specified list.

This method must not be called in control blocks such as BEFORE ROW, AFTER ROW, BEFORE INSERT, AFTER INSERT, BEFORE DELETE, AFTER DELETE, it is designed to be used in an ON ACTION block.

After the method is called, all rows are deleted from the program array, and the `getArrayLength()` method will return zero.

The method takes the name of the screen-array as parameter.

If the `deleteAllRows()` method is called during an INPUT ARRAY, the dialog will automatically append a new temporary row if the focus is in the list, to let the user enter new data. When using `AUTO APPEND = FALSE` attribute, no temporary row will be created and the current row register will be automatically changed to make sure that it will not be greater than the total number of rows.

If `deleteAllRows()` method is called during an INPUT ARRAY or DISPLAY ARRAY that has the focus, the BEFORE ROW control block will be executed if you delete the current row. This is required to reset the internal state of the dialog.

If the list was decorated with cell attributes, the program array defining the attributes will be cleared. If multi-row selection is enabled, selection flags are cleared.

`ui.Dialog.deleteNode`
Deletes a node from the specified tree-view.

Syntax

```java
deleteNode(
    name STRING,
    index INTEGER
)
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. `index` is the index of the node in the program array that has to be deleted (starts at 1).

Usage

The `deleteNode()` method is similar to `deleteRow()`, except that it has to be used when the dialog controls a tree view.

This method must be used when modifying the array of a tree view during the execution of the dialog, for example when implementing a dynamic tree with ON EXPAND / ON COLLAPSE triggers. Before the execution of the dialog, you can fill the program array directly. This includes the context of BEFORE DISPLAY or BEFORE DIALOG control blocks.
The main difference with `deleteRow()` is that `deleteNode()` will remove recursively all child nodes before removing the node identified by index.

If the index is zero, all root nodes will be deleted from the tree.

**ui.Dialog.deleteRow**

Deletes a row from the specified list.

### Syntax

```plaintext
deleteRow(
    name STRING,
    index INTEGER )
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. `index` is the index of the row to be deleted (starts a 1).

### Usage

The `deleteRow()` method deletes the row in the array controlled by the dialog.

**Important:** This method is designed to be used in an ON ACTION block. It must not be called in control blocks such as BEFORE ROW, AFTER ROW, BEFORE INSERT, AFTER INSERT, BEFORE DELETE, or AFTER DELETE.

The method is similar to deleting an element to the program array, except that internal dialog registers are automatically updated (like the total number of rows returned by `getArrayLength()`). If the list is decorated with cell attributes, the program array defining the attributes will also be synchronized. If multi-row selection is enabled, selection information is synchronized (i.e., selection flags are shifted up) for all rows after the deleted row.

**Note:** The purpose of this method is to implement business logic required to modify the record list in the current dialog. It is typically used in a DISPLAY ARRAY dialog. Avoid using this method in INPUT ARRAY. To allow the end user to append, modify or delete rows in a DISPLAY ARRAY, use list modification interaction blocks.

After the method is called, the row no longer exists in the program array, and the `getArrayLength()` method will return the new row count.

If the `deleteRow()` method is called during an INPUT ARRAY that has the focus, control blocks such as BEFORE ROW and BEFORE FIELD will be executed, if you delete the current row. This is required to reset the internal state of the dialog. However, the method does not execute any BEFORE ROW or AFTER ROW control blocks in a DISPLAY ARRAY dialog.

If the `deleteRow()` method is called during an INPUT ARRAY, and if no more rows are in the list after the call, the dialog will automatically append a new temporary row if the focus is in the list, to let the user enter new data. When using AUTO APPEND = FALSE attribute, no temporary row will be created and the current row register will be automatically changed to make sure that it will not be greater than the total number of rows.

If you pass zero as row index, the method does nothing (if no rows are in the list, `getCurrentRow()` returns zero).

### Example

This example implements a user-defined action to remove rows that have a specific property:

```plaintext
ON ACTION delete_invalid_rows
    FOR r = 1 TO DIALOG.getArrayLength("sa")
        IF NOT s_orders[t].is_valid THEN
            CALL DIALOG.deleteRow("sa",r)
            LET r = r - 1
        END IF
    END FOR
```
ui.Dialog.getArrayLength
Returns the total number of rows in the specified list.

Syntax

```plaintext
getArrayLength(
    name STRING )
RETURNS INTEGER
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.

Usage

The `getArrayLength()` method returns the total number of rows of an INPUT ARRAY or DISPLAY ARRAY list. The name of the screen array is passed as parameter to identify the list.

Example

```plaintext
MAIN
    DEFINE custlist DYNAMIC ARRAY OF RECORD
        pkey INT, name VARCHAR(50)
    END RECORD

    OPEN FORM f1 FROM "form1"
    DISPLAY FORM f1

    DISPLAY ARRAY custlist TO sa_custlist.*
    BEFORE DISPLAY
        MESSAGE "Row count: " || DIALOG.getArrayLength("sa_custlist")
    END DISPLAY

END MAIN
```

ui.Dialog.getCurrentItem
Returns the current item having focus.

Syntax

```plaintext
currentItem()
RETURNS STRING
```

Usage

The `getCurrentItem()` method returns the name of the current form item having the focus.

- If the focus is on an action view (typically, a BUTTON in the form layout), `getCurrentItem()` returns the name of the corresponding action. If several action views a bound to the same action handler with a unique name, there is no way to distinguish which action view has the focus.
- If the focus is in a simple field controlled by an INPUT or CONSTRUCT sub-dialog, `getCurrentItem()` returns the \[tab-name.\]field-name of that current field. The tab-name, prefix is added if a FROM clause is used with an explicit list of fields. No prefix is added if FROM screen-record.* is used or if BY NAME clause is used.
- If the focus is in a list controlled by a DISPLAY ARRAY sub-dialog, `getCurrentItem()` returns the screen-array name identifying the list for a regular DISPLAY ARRAY. If the DISPLAY ARRAY is defined with the FOCUSONFIELD attribute, the method returns screen-array.field-name.
- If the focus is in a field of a list controlled by an INPUT ARRAY sub-dialog, `getCurrentItem()` returns screen-array.field-name, identifying both the list and the current field. In some context, the current field is
undefined. For example when entering the INPUT ARRAY sub-dialog, getCurrentItem() will return the screen-array only when in the BEFORE INPUT control block.

**ui.Dialog.getCurrentRow**

Returns the current row of the specified list.

**Syntax**

```
getCurrentRow(
    name STRING )
RETURNS INTEGER
```

1. *name* is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.

**Usage**

Use the getCurrentRow() method to retrieve the current row of an INPUT ARRAY or DISPLAY ARRAY list. You must pass the name of the screen array to identify the list.

```
DIALOG
    DISPLAY ARRAY custlist TO sa_custlist.*
    BEFORE ROW
        MESSAGE "Current row: " || DIALOG.getCurrentRow("sa_custlist")
    ...
END DISPLAY

INPUT ARRAY ordlist TO sa_ordlist.*
    BEFORE ROW
        MESSAGE "Current row: " || DIALOG.getCurrentRow("sa_ordlist")
    ...
END INPUT
```

**ui.Dialog.getFieldBuffer**

Returns the input buffer of the specified field.

**Syntax**

```
getFieldBuffer(
    name STRING )
RETURNS STRING
```

1. *name* is the form field name, see Identifying fields in dialog methods on page 2409.

**Usage**

The getFieldBuffer() method returns the current input buffer of the specified field. The input buffer is used by the dialog to synchronize form fields and program variables. In some situations, especially when using the buffered mode or in a CONSTRUCT, you may want to access the field input buffer.

**Note:** Use of this method is only recommended in dialogs allowing field input (INPUT, INPUT ARRAY, CONSTRUCT). The behavior is undefined when used in DISPLAY ARRAY.

The parameter is a field specification, a string containing the field qualifier, with an optional prefix ("[table.]column").

```
LET buff = DIALOG.getFieldBuffer("customer.cust_name")
```

The input buffer can be set with:

- A DISPLAY TO or DISPLAY BY NAME instruction
- The `FGL_DIALOG_SETBUFFER()` function (only for the current field)

`ui.Dialog.getFieldTouched`
Returns the modification flag for a field.

**Syntax**

```plaintext
getFieldTouched(
    fields STRING )
RETURNS BOOLEAN
```

1. `fields` is the string with the list of field specification, see Identifying fields in dialog methods on page 2409.

**Usage**

The `getFieldTouched()` method returns TRUE if the modification flag of the specified field(s) is set.

The `fields` parameter is a string containing the field qualifier, with an optional prefix ("[table.]column"), a table prefix followed by a dot and an asterisk ("table.*"), or a simple asterisk ("*").

This code checks if a specific field has been touched:

```plaintext
AFTER FIELD cust_name
    IF DIALOG.getFieldTouched("customer.cust_address") THEN
        ...
```

If the parameter is a screen record following by dot-asterisk, the method checks the touched flags of all the fields that belong to the screen record:

```plaintext
ON ACTION quit
    IF DIALOG.getFieldTouched("customer.*") THEN
        ...
```

When passing a simple asterisk (*) to the method, the runtime system will check all fields used by the dialog:

```plaintext
ON ACTION quit
    IF DIALOG.getFieldTouched("*") THEN
        ...
```

`ui.Dialog.getFieldValue`
Returns the value of a field controlled by a dynamic dialog.

**Syntax**

```plaintext
getFieldValue(
    name STRING )
```

1. `name` is the name of the form field, see Identifying fields in dialog methods on page 2409.

**Usage**

The `getFieldValue()` method can be used when implementing a dynamic dialog, to return the value of a field:

```plaintext
DISPLAY d.getFieldValue( "customer.cust_addr" )
```

In a dynamic dialog controlling a list of records (INPUT ARRAY/DISPLAY ARRAY), this method returns the value for a field in the current row.

**Important:**
• During dialog execution, the `getFieldValue()` method must only be used to get the value of a field for the current row. Calling the `setCurrentRow()` method to change the current row before calling `getFieldValue()` will have no effect.

• In a DISPLAY ARRAY using the paged mode (ON FILL BUFFER), `getFieldValue()` returns NULL, if the current row is not part of the visible page. In a DISPLAY ARRAY using the full list mode, a NULL value is returned, if there is no current row (when the array is empty).

**Related concepts**

ui.Dialog.setFieldValue on page 2404

Sets the value of a field controlled by the dialog object.

Dynamic Dialogs on page 1903

Dialogs can be created at runtime with the `ui.Dialog` class.

**ui.Dialog.getForm**

Returns the current form used by the dialog.

**Syntax**

```java
getForm()  
RETURNS ui.Form
```

**Usage**

The `getForm()` method returns a `ui.Form` object as a handle to the current form used by the dialog.

Use this form object to modify elements of the current form. For example, you can hide some parts of the form with the `ui.Form.setElementHidden()` method.

**ui.Dialog.getQueryFromField**

Returns the SQL condition of a field used in a query by example dialog.

**Syntax**

```java
getQueryFromField ( 
   name STRING )  
RETURNS STRING
```

1. `name` is the name of the form field, see Identifying fields in dialog methods on page 2409.

**Usage**

The `getQueryFromField()` method generates the SQL condition from the value entered in the field specified by the `field-name` parameter.

This method is used in the context of a construct dynamic dialog.

The result of this method can be used to build the `WHERE` part of a SELECT statement to find rows in a database.

Collect and concatenate field conditions returned from `getQueryFromField()`, then add AND or OR boolean operators to create an executable SQL query.

**Note:** The SQL condition is generated based on the current type of database. The SQL syntax may vary depending on the target database. Therefore it is not recommended to reuse the generated SQL conditions. However, the user input of a query by example dialog can be reused for different types of databases (see `ui.Dialog.setFieldValue` on page 2404 and `ui.Dialog.getFieldValue` on page 2387).

**Related concepts**

ui.Dialog.createConstructByName on page 2370
Creates a new `ui.Dialog` object to implement a dynamic `CONSTRUCT BY NAME`.

```
ui.Dialog.getSortKey
```

Returns the name of the sort field selected by the user.

### Syntax

```
getSortKey(
    name STRING
)
RETURNS STRING
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.

### Usage

The `getSortKey()` method returns the form field name selected by the user to sort rows.

This method is used in the context of the `ON SORT` trigger.

**Note:** If the sort is reset, the `getSortKey()` method returns `NULL`.

#### Related concepts

- **ON SORT block** on page 1414
- **Populating a DISPLAY ARRAY** on page 1742
  
The program array must be filled with rows to populate the `DISPLAY ARRAY` dialog.
- **ui.Dialog.isSortReverse** on page 2391
  
Indicates the sort order direction (FALSE=ascending, TRUE=descending)

#### `ui.Dialog.insertNode`

Inserts a new node in the specified tree.

### Syntax

```
insertNode(
    name STRING,
    index INTEGER
)
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. `index` is the index of the next sibling node in the program array (starts at 1).

### Usage

The `insertNode()` method is similar to `insertRow()`, except that it has to be used when the list dialog controls a tree view.

This method must be used when modifying the array of a tree view during the execution of the dialog, for example when implementing a dynamic tree with `ON EXPAND / ON COLLAPSE` triggers. Before the execution of the dialog, you can fill the program array directly. This includes the context of `BEFORE DISPLAY` or `BEFORE DIALOG` control blocks.

When adding rows for a tree view, the id of the parent node and new node matters because that information is used to build the internal tree structure. When calling `insertNode()`, you pass the index of the next sibling node. In the program array, the parent-id member of the new node will automatically be initialized with the value of the parent-id of the next sibling node, then the internal tree structure is rebuilt.
**ui.Dialog.insertRow**

Inserts a new row in the specified list.

### Syntax

```plaintext
insertRow(
    name STRING,
    index INTEGER )
```

1. *name* is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. *index* is the index where the row must be inserted (starts at 1).

### Usage

The `insertRow()` method inserts a row in the list, at a given position.

**Important:** This method is designed to be used in an **ON ACTION** block. It must not be called in control blocks such as **BEFORE ROW**, **AFTER ROW**, **BEFORE INSERT**, **AFTER INSERT**, **BEFORE DELETE**, or **AFTER DELETE**.

The method is similar to inserting a new element in the program array, except the internal dialog registers are automatically updated (like the total number of rows returned by `getArrayLength()`). If the list is decorated with cell attributes, the program array defining the attributes will also be synchronized. If multi-row selection is enabled, selection flags of existing rows are kept. Selection information is synchronized (i.e., flags are shifted down) for all rows after the new inserted row.

**Note:** The purpose of this method is to implement business logic required to modify the record list in the current dialog. It is typically used in a **DISPLAY ARRAY** dialog. Avoid using this method in **INPUT ARRAY**. To allow the end user to append, modify or delete rows in a **DISPLAY ARRAY**, use list modification interaction blocks.

After the method is called, a new row is created in the program array, so you can assign values to the variables before the control goes back to the user. The `getArrayLength()` method will return the new row count.

The method does not set the current row and does not give the focus to the list; you need to call `setCurrentRow()` and execute **NEXT FIELD** to give the focus.

The `insertRow()` method must not be used when controlling a tree view. Use the `insertNode()` method instead.

This method does not execute any **BEFORE ROW**, **BEFORE INSERT**, **AFTER INSERT** or **AFTER ROW** control blocks.

If the index is greater than the number of rows, a new row is appended at the end or the list. This is the equivalent of calling the `appendRow()` method.

If the list is empty, `getCurrentRow()` returns zero. If zero is returned, use 1 to reference the first row, otherwise you can get a `-1326` error when using the program array.

### Example

This example shows a user-defined action to insert ten rows in the list at the current position:

```plaintext
ON ACTION insert_some_rows
    LET r = DIALOG.getCurrentRow("sa")
    IF r == 0 THEN LET r = 1 END IF
    FOR i = 10 TO 1 STEP -1
        CALL DIALOG.insertRow("sa", r)
        LET p_items[r].item_quantity = 1.00
    END FOR
```
**ui.Dialog.isRowSelected**
Queries row selection for a give list and row.

**Syntax**

```java
isRowSelected(
    name STRING,
    row INTEGER
) RETURNS BOOLEAN
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. `row` is a row index.

**Usage**
If multi-row selection is enabled with `setSelectionMode()` , you can check whether a row is selected with the `isRowSelected()` method:

```java
ON ACTION check_current_row_selected
    IF DIALOG.isRowSelected( "sr", DIALOG.getCurrentRow("sr") ) THEN
        MESSAGE "Current row is selected."
    END IF
END IF
```

If multi-row selection is off, the method returns `TRUE` for the current row and `FALSE` for other rows.

**ui.Dialog.isSortReverse**
Indicates the sort order direction (FALSE=ascending, TRUE=descending)

**Syntax**

```java
isSortReverse(
    name STRING
) RETURNS BOOLEAN
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.

**Usage**
The `isSortReverse()` method returns FALSE if the sort order is ascending, and TRUE if the sort is in descending order.

This method is used in the context of the `ON SORT` trigger.

**Related concepts**

- ON SORT block on page 1414
- Populating a DISPLAY ARRAY on page 1742
  The program array must be filled with rows to populate the DISPLAY ARRAY dialog.
- `ui.Dialog.getSortKey` on page 2389
  Returns the name of the sort field selected by the user.
- `ui.Dialog.nextEvent`
  Waits for a dialog event.

**Syntax**

```java
nextEvent()
    RETURNS STRING
```
1. event is the name of the dialog event that raised.

Usage

The `nextEvent()` waits for a dialog event to occur, and returns a string that identifies the dialog event that has raised.

This method is typically used in a **WHILE** loop, to implement a dynamic dialog.

The method can return `NULL`, if a dialog error occurs, or if the dialog terminates (with `ui.Dialog.close()`).

The recommended programming pattern for the event **WHILE** loop is to test for nulls:

```java
DEFINE d ui.Dialog,
    t STRING
...
WHILE (t := d.nextEvent()) IS NOT NULL
    CASE t
        WHEN "BEFORE FIELD cust_name"
            ...
```  

A dialog event can be a user-defined trigger such as "**ON ACTION** print.", or an implicit trigger such as "**BEFORE ROW**", corresponding to the control blocks that can be defined in static dialog instructions such as `DISPLAY ARRAY`.

User-defined triggers are added to the dynamic dialog with the `addTrigger()` method:

**Table 487: User-defined triggers for dynamic dialogs**

<table>
<thead>
<tr>
<th>Trigger name</th>
<th>Description</th>
<th>Dialog block equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ON ACTION</strong> action-name</td>
<td>Action handler for the action identified by <em>action-name</em>.</td>
<td><strong>ON ACTION</strong> block</td>
</tr>
<tr>
<td><strong>ON APPEND</strong></td>
<td>Row addition action handler for a display array dynamic dialog.</td>
<td><strong>ON APPEND</strong> block</td>
</tr>
<tr>
<td><strong>ON DELETE</strong></td>
<td>Row deletion action handler for a display array dynamic dialog.</td>
<td><strong>ON DELETE</strong> block</td>
</tr>
<tr>
<td><strong>ON INSERT</strong></td>
<td>Row insertion action handler for a display array dynamic dialog.</td>
<td><strong>ON INSERT</strong> block</td>
</tr>
<tr>
<td><strong>ON UPDATE</strong></td>
<td>Row modification action handler for a display array dynamic dialog.</td>
<td><strong>ON UPDATE</strong> block</td>
</tr>
</tbody>
</table>

Implicit dialog triggers are predefined and can be detected and handled in the dialog **WHILE** loop if needed:

**Table 488: Implicit triggers for dynamic dialogs**

<table>
<thead>
<tr>
<th>Trigger name</th>
<th>Description</th>
<th>Dialog block equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEFORE DISPLAY</td>
<td>Initialization of the display array dynamic dialog.</td>
<td>BEFORE DISPLAY block</td>
</tr>
<tr>
<td>AFTER DISPLAY</td>
<td>End of the display array dynamic dialog.</td>
<td>AFTER DISPLAY block</td>
</tr>
<tr>
<td>BEFORE INPUT</td>
<td>Initialization of the input by name dynamic dialog.</td>
<td>BEFORE INPUT block</td>
</tr>
<tr>
<td>AFTER INPUT</td>
<td>End of the input by name dynamic dialog.</td>
<td>AFTER INPUT block</td>
</tr>
<tr>
<td>BEFORE CONSTRUCT</td>
<td>Initialization of the query by example dynamic dialog.</td>
<td>BEFORE CONSTRUCT block</td>
</tr>
<tr>
<td>AFTER CONSTRUCT</td>
<td>End of the query by example dynamic dialog.</td>
<td>AFTER CONSTRUCT block</td>
</tr>
<tr>
<td>Trigger name</td>
<td>Description</td>
<td>Dialog block equivalent</td>
</tr>
<tr>
<td>--------------</td>

<td>Leaving the field field-name in an input dynamic dialog.</td>
<td>AFTER FIELD block</td>
</tr>
<tr>
<td></td>
<td>field-name</td>
<td></td>
</tr>
<tr>
<td>ON CHANGE</td>
<td>Value of field field-name changed in an input dynamic dialog.</td>
<td>ON CHANGE block</td>
</tr>
<tr>
<td></td>
<td>field-name</td>
<td></td>
</tr>
</tbody>
</table>

**Related concepts**

*Dynamic Dialogs* on page 1903
Dialogs can be created at runtime with the `ui.Dialog` class.

*ui.Dialog.nextField*
Registering the next field to jump to.

**Syntax**

```plaintext
nextField(
   name STRING )
```

1. `name` is the form field name, see *Identifying fields in dialog methods* on page 2409, or "+NEXT" / "+PREV", "+CURR" to specify respectively the next, previous and current field.

**Usage**

The `nextField()` method registers the name of the next field that must get the focus when control goes back to the dialog.

This method is similar to the *NEXT FIELD instruction*, except that it does not implicitly break the program flow. If you want to get the same behavior as *NEXT FIELD*, the method call must be followed by a *CONTINUE DIALOG* instruction, or an equivalent instruction such as *CONTINUE INPUT*, in case of singular dialog.

When specifying "+NEXT" as parameter, the dialog will register the field next to the current field (like *NEXT FIELD NEXT*). When passing "+PREV", the dialog will register the previous field (like *NEXT FIELD PREVIOUS*). When passing +CURR, it is equivalent to a *NEXT FIELD CURRENT* instruction.

Since this method takes an expression as parameter, you can write generic code, when the name of the target field is not known at compile time. In the next example, the `check_value()` function returns a field name where the value does not satisfy the validation rules.

```plaintext
DEFINE fn STRING
```
ON ACTION save
    IF ( fn:= check_values() ) IS NOT NULL THEN
        CALL DIALOG.nextField(fn)
        CONTINUE DIALOG
    END IF
    CALL save_data()
...

Like NEXT FIELD, the nextField() method is typically used in an editable dialog (INPUT, CONSTRUCT, INPUT ARRAY). However, in a DISPLAY ARRAY using the FOCUSONFIELD attribute, nextField() can be used in conjunction with DIALOG.setCurrentRow(), to set the focus to a specific cell in the list.

Related concepts
Giving the focus to a form element on page 1631
How to force the focus to move or stay in a specific form element using program code.

ui.Dialog.selectionToString
Serializes data of the selected rows.

Syntax

```plaintext
selectionToString(
    name STRING )
RETURNS STRING
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.

Usage

The selectionToString() method can be used to get a tab-separated value list of the selected rows.

When multi-row selection is disabled, the method serializes the current row.

You typically use this method along with drag & drop to fill the buffer, by using a text/plain MIME type, to export data to external applications.

```plaintext
ON ACTION serialize
    LET buff = DIALOG.selectionToString( "sr" )
```

Numeric and date data will be formatted based on current locale settings (DBMONEY, DBDATE).

The visual presentation of data is respected: The dialog will copy the rows in the sort order specified by the user, moved columns will appear in the same positions as in the table and hidden columns will be ignored. Note that phantom columns are not copied.

Items in the tab-separated record will be surrounded by double-quotes if the value contains special characters such as a newline, a double-quote, or controls characters with ASCII code < 0x20. Double-quotes in the value will be doubled.

ui.Dialog.setActionActive
Enabling and disabling dialog actions.

Syntax

```plaintext
setActionActive(
    name STRING,
    active BOOLEAN )
```

1. `name` is the name of the action, see Identifying actions in dialog methods.
2. `active` is a boolean value.
Usage

Use the `setActionActive()` method to enable or disable an action.

```
CALL DIALOG.setActionActive("zoom", FALSE)
```

The second parameter of the method must be a boolean expression that evaluates to 0 (FALSE) or 1 (TRUE).

For more details about action names, see Identifying actions in dialog methods on page 2408.

Related concepts

Enabling and disabling actions on page 1666

By default, dialog actions are enabled. However, it is recommended that an action be disabled when not allowed in the current context.

`ui.Dialog.setActionComment`

Set the comment/hint of a default action view.

Syntax

```
setActionComment(
    name STRING,
    comment STRING
)
```

1. `name` is the name of the action, see Identifying actions in dialog methods.
2. `comment` is the comment to be set.

Usage

Use the `setActionComment()` method to define the comment/hint for the default view of an action.

```
CALL DIALOG.setActionComment( "confirm", "Confirm current order" )
```

The first parameter identifies the action object of the dialog.

**Important:** This method will only affect the rendering of the default view for the specified action. Explicit action views (such as buttons in the form layout) will not get the new attribute value.

Related concepts

Configuring actions on page 1646

Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

`ui.Dialog.setActionHidden`

Showing or hiding a default action view.

Syntax

```
setActionHidden(
    name STRING,
    hidden BOOLEAN
)
```

1. `name` is the name of the action, see Identifying actions in dialog methods.
2. `hidden` is a boolean value.

Usage

Use the `setActionHidden()` method to hide the default view (and context menu option) of an action.

```
CALL DIALOG.setActionHidden( "confirm", TRUE )
```
The first parameter identifies the action object of the dialog.

**Important:** This method will only affect the rendering of the default view for the specified action. Explicit action views (such as buttons in the form layout) will not get the new attribute value.

*ui.Dialog.setActionImage*

Set the image of a default action view.

**Syntax**

```java
setActionImage(
    name STRING,
    image STRING)
```

1. *name* is the name of the action, see Identifying actions in dialog methods.
2. *image* is the image name to be set.

**Usage**

Use the `setActionImage()` method to define the image of the default view of an action.

```java
CALL DIALOG.setActionImage("confirm", "smiley")
```

The first parameter identifies the action object of the dialog.

**Important:** This method will only affect the rendering of the default view for the specified action. Explicit action views (such as buttons in the form layout) will not get the new attribute value.

**Related concepts**

- Configuring actions on page 1646
- Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

*ui.Dialog.setActionText*

Defining the text of a default action view.

**Syntax**

```java
setActionText(
    name STRING,
    text STRING)
```

1. *name* is the name of the action, see Identifying actions in dialog methods.
2. *text* is the text to be set.

**Usage**

Use the `setActionText()` method to define the label of the default view of an action.

```java
CALL DIALOG.setActionText("confirm", "Confirm")
```

The first parameter identifies the action object of the dialog.

**Important:** This method will only affect the rendering of the default view for the specified action. Explicit action views (such as buttons in the form layout) will not get the new attribute value.

**Related concepts**

- Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

**ui.Dialog.setArrayAttributes**
Define cell decoration attributes array for the specified list (singular or multiple dialogs).

**Syntax**

```plaintext
setArrayAttributes(
    name STRING,
    attributes dynamic-array-type )
```

1. *name* is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. *attributes* is a program array defining the cell attributes.
3. *dynamic-array-type* is a DYNAMIC ARRAY OF ... type, which can be:
   • A DYNAMIC ARRAY OF RECORD ... END RECORD (with the same structure as the data array)
   • A DYNAMIC ARRAY WITH DIMENSION 2 OF STRING (to define attributes in dynamic dialog when the row structure is defined at runtime)
   • A DYNAMIC ARRAY OF STRING (to define attributes for complete lines instead of individual cells)

**Usage**

In an INPUT ARRAY or DISPLAY ARRAY dialog, the `setArrayAttributes()` method can be used to specify display attributes for each cell, or for the complete row.

The `setArrayAttributes()` is typically used in a DIALOG block where several screen arrays are defined. The method takes the name of the screen array as first parameter, to identify the list to be decorated with colors. An equivalent method called `setCellAttributes()` can be used, for dialogs where only one screen array is defined.

Possible values for cell attributes are a combination of the following:

- The **bold** attribute
- The **reverse** attribute
- The **blink** attribute
- The **underline** attribute
- One of the supported color names, or an #RRGGBB value.

The cell attributes must be specified in lowercase characters and separated by a blank, for example:

- "lightRed reverse"
- "blue underline"
- "blink"
- "red bold reverse"

The structure of the dynamic array containing the cell attributes can be:

- A DYNAMIC ARRAY OF RECORD, with the same structure as the data array
- A DYNAMIC ARRAY WITH DIMENSION 2 OF STRING, to define a flexible set of cell attributes (for dynamic dialogs)
- A DYNAMIC ARRAY OF STRING, to define attributes for complete lines

The following example defines a dynamic array with the same structure as the data array. Note however that the members of the attributes array use the STRING data type:

```
DEFINE data DYNAMIC ARRAY OF RECORD
  pkey INTEGER,
  name VARCHAR(50)
END RECORD
DEFINE attributes DYNAMIC ARRAY OF RECORD
```
Similarly, the cell attributes array can be defined with a two-dimensional dynamic array of strings:

```plaintext
DEFINE attributes DYNAMIC ARRAY WITH DIMENSION 2 OF STRING
```

The advantage of a two-dimensional array is the flexibility, as it can define an unlimited number of cells for each row. This solution is typically used when implementing a dynamic dialog.

Finally, if you want to decorate complete lines instead of individual cells, use a simple dynamic array of strings:

```plaintext
DEFINE attributes DYNAMIC ARRAY OF STRING
```

Fill the display attributes array with color and video attributes:

```plaintext
FOR i=1 TO data.getLength()  -- length from data array!
    LET attributes[i].name = "blue reverse"
END FOR
```

Then, attach the array to the dialog with the `setArrayAttributes()` method, in a `BEFORE DIALOG`, `BEFORE INPUT` or `BEFORE DISPLAY` block:

```plaintext
BEFORE DIALOG
    CALL DIALOG.setArrayAttributes( "sr", attributes )
```

Like data values, if you change the cell attributes during the dialog, these are not displayed automatically unless the `UNBUFFERED` mode is used.

```plaintext
ON ACTION modify_cell_attribute
    LET attributes[arr_curr()].name = "red reverse"
```

If you set `NULL` to an element, the default TTY attributes will be reset:

```plaintext
ON ACTION clean_cell_attribute
    LET attributes[arr_curr()].name = NULL
```

**Related concepts**

- **Cell color attributes** on page 1751
  List controllers can display every cell in a specific color.

- **ui.Dialog.setCellAttributes** on page 2399
  Define cell decoration attributes array for the specified list (singular dialog only).

- **Example 4: Set display attributes for cells** on page 2413

- **ui.Dialog.setArrayLength**
  Sets the total number of rows in the specified list.

**Syntax**

```plaintext
setArrayLength(
    name STRING,
    length INTEGER )
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. `length` is the new size of the array.
Usage

The `setArrayLength()` method is used to specify the total number of rows when using the `DISPLAY ARRAY` paged mode. The name of the screen array is passed to identify the list, followed by an integer expression defining the number of rows.

When using a regular dynamic array without paged mode (without the `ON FILL BUFFER` clause), you don't need to specify the total number of rows to the `DIALOG` instruction: It is defined by the number of elements in the array. However, when using the paged mode in a `DISPLAY ARRAY`, the total number of rows does not correspond to the elements in the program array, because the program array holds only a page of the whole list. In any other case, a call to this method is just ignored.

**Note:** A call to `setArrayLength()` will not trigger the execution of the `ON FILL BUFFER` clause immediately: This trigger will be executed when the control goes back to the `DIALOG` instruction, after all user code following `setArrayLength()` has been executed.

The `setArrayLength()` method is also used to fix the final number of rows when using `COUNT=-1` attribute. When implementing a paged list without knowing the total number of rows when the dialog starts.

**Note:** In a paged mode `DISPLAY ARRAY` using `COUNT=-1`, before calling `setCurrentRow(screen-array, row-index)`, be sure to provide the actual number of rows with `ui.Dialog.setArrayLength(screen-array, count)` where `count > row-index`. Otherwise, the `setCurrentRow()` call will have no effect, if the dialog has not yet seen `row-index` rows through `ON FILL BUFFER`.

Related concepts

- **Populating a `DISPLAY ARRAY`** on page 1742
  The program array must be filled with rows to populate the `DISPLAY ARRAY` dialog.

- **Paged mode of `DISPLAY ARRAY`** on page 1743
  In order to handle very large result sets, use the paged mode of `DISPLAY ARRAY`.

- **`ON FILL BUFFER block`** on page 1401

  `ui.Dialog.setCellAttributes`

  Define cell decoration attributes array for the specified list (singular dialog only).

Syntax

```plaintext
setCellAttributes(
  attributes dynamic-array-type )
```

1. `attributes` is a program array defining the cell attributes.
2. `dynamic-array-type` is a `DYNAMIC ARRAY OF ...` type, which can be:
   - A `DYNAMIC ARRAY OF RECORD ... END RECORD` (with the same structure as the data array)
   - A `DYNAMIC ARRAY OF STRING` (to define attributes for complete lines instead of individual cells)
   - A `DYNAMIC ARRAY WITH DIMENSION 2 OF STRING` (to define attributes in dynamic dialog when the row structure is defined at runtime)

Usage

In an `INPUT ARRAY` or `DISPLAY ARRAY` dialog, the `setCellAttributes()` method can be used to specify display attributes for each cell, or for the complete row.

The `setCellAttributes()` method is designed for dialog programming, where only one screen array is used (for example, in a singular `DISPLAY ARRAY` dialog). An equivalent method called `setArrayAttributes()` can be used, when several screen arrays are defined in a multiple dialog, to be able to identify the list by the name of the screen array.

Possible values for cell attributes are a combination of the following:

- The **bold** attribute
- The reverse attribute
- The blink attribute
- The underline attribute
- One of the supported color names, or an #RRGGBB value.

The cell attributes must be specified in lowercase characters and separated by a blank, for example:

- "lightRed reverse"
- "blue underline"
- "blink"
- "red bold reverse"

The structure of the dynamic array containing the cell attributes can be:

- A DYNAMIC ARRAY OF RECORD, with the same structure as the data array
- A DYNAMIC ARRAY WITH DIMENSION 2 OF STRING, to define a flexible set of cell attributes (for dynamic dialogs)
- A DYNAMIC ARRAY OF STRING, to define attributes for complete lines

The following example defines a dynamic array with the same structure as the data array. Note however that the members of the attributes array use the STRING data type:

```haskell
DEFINE data DYNAMIC ARRAY OF RECORD
  pkey INTEGER,
  name VARCHAR(50)
END RECORD
DEFINE attributes DYNAMIC ARRAY OF RECORD
  pkey STRING,
  name STRING
END RECORD
```

Similarly, the cell attributes array can be defined with a two-dimensional dynamic array of strings:

```haskell
DEFINE attributes DYNAMIC ARRAY WITH DIMENSION 2 OF STRING
```

The advantage of a two-dimensional array is the flexibility, as it can define an unlimited number of cells for each row. This solution is typically used when implementing a dynamic dialog.

Finally, if you want to decorate complete lines instead of individual cells, use a simple dynamic array of strings:

```haskell
DEFINE attributes DYNAMIC ARRAY OF STRING
```

Fill the display attributes array with color and video attributes:

```haskell
FOR i=1 TO data.getLength()  -- length from data array!
  LET attributes[i].name = "blue reverse"
END FOR
```

Fill the display attributes array with color and video attributes:

```haskell
FOR i=1 TO data.getLength()  -- length from data array!
  LET attributes[i].name = "blue reverse"
END FOR
```

Then, attach the array to the dialog with the setCellAttributes() method, in a BEFORE INPUT or BEFORE DISPLAY block:

```haskell
BEFORE DISPLAY
  CALL DIALOG.setCellAttributes( attributes )
```
Like data values, if you change the cell attributes during the dialog, these are not displayed automatically unless the  
**UNBUFFERED** mode is used.

```
ON ACTION modify_cell_attribute
    LET attributes[arr_curr()].name = "red reverse"
```

If you set **NULL** to an element, the default TTY attributes will be reset:

```
ON ACTION clean_cell_attribute
    LET attributes[arr_curr()].name = NULL
```

**Related concepts**

- **Cell color attributes** on page 1751
  List controllers can display every cell in a specific color.

- **ui.Dialog.setArrayAttributes** on page 2397
  Define cell decoration attributes array for the specified list (singular or multiple dialogs).

- **Example 4: Set display attributes for cells** on page 2413

**ui.Dialog.setCompleterItems**
Define autocompletion items for the a field defined with **COMPLETE** attribute.

**Syntax**

```
setCompleterItems(
    items DYNAMIC ARRAY OF STRING )
```

1. **items** defines the list of completion proposals to be passed to the front-end.

**Usage**

The **setCompleterItems()** dialog method defines the list of completion proposals for the current field, to implement autocompletion.

The field must be defined in the form with the **COMPLETE** attribute.

The list of completion proposal items is passed as a dynamic array of strings:

```
DEFINE items DYNAMIC ARRAY OF STRING
```

To cleanup the completion proposal list for a give field, pass **NULL** as second parameter to the function.

**Important:** The method will raise error **-8114**, if the list of items contains more than 50 elements. Note that this error is not trappable with exception handlers like **TRY/CATCH**, the code must avoid to reach the limit.

See **Enabling autocompletion** on page 1633 for more details.

**Example**

```
DEFINE items DYNAMIC ARRAY OF STRING
...
    ON CHANGE firstname
        -- fill the array with items
        LET items[1] = "Ann"
        LET items[2] = "Anna"
        LET items[3] = "Annabel"
        CALL DIALOG.setCompleterItems(items)
```

**Related concepts**

- **Enabling autocompletion** on page 1633
Autocompletion allows a list of completion proposals to be displayed while the user is typing text into a field.

**Completer attribute** on page 1251

The Completer attribute enables autocompletion for the edit field.

**Ui.Dialog.setCurrentRow**

Sets the current row in the specified list.

**Syntax**

```plaintext
setCurrentRow(
    name STRING,
    row INTEGER
)
```

1. *name* is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. *row* is the new row in the array.

**Usage**

Use the `setCurrentRow()` method to change the current row in an INPUT ARRAY or DISPLAY ARRAY list.

You must pass the name of the screen array to identify the list, and the new row number.

```plaintext
DEFINE x INTEGER
DIALOG
    DISPLAY ARRAY custlist TO sa_custlist.*
    ...
END DISPLAY
ON ACTION goto_x
    CALL DIALOG.setCurrentRow("sa_custlist", x)
    ...
```

Moving to a different row with `setCurrentRow()` will not trigger control blocks such as BEFORE ROW / AFTER ROW, as the `fgl_set_arr_curr()` built-in function does.

The `setCurrentRow()` method will not set the focus; You need to use NEXT FIELD to set the focus to a list.

(This works with DISPLAY ARRAY as well as with INPUT ARRAY.)

If the passed row index is lower than 1, the first row will be selected. If the row index is greater than the total number of rows, the last row will be selected.

If the new current row is not in the current view, the dialog will adapt the list offset to make the new current row visible.

If multi-row selection is enabled, all selection flags of rows are cleared, and the new current row gets automatically selected.

A `setCurrentRow(screen-array, row-index)` in a paged mode DISPLAY ARRAY will subsequently trigger the ON FILL BUFFER code, if the requested row is not in the current page of visible rows.

If DISPLAY ARRAY using ON FILL BUFFER was started with COUNT=-1, and the *row-index* provided by `setCurrentRow()` is greater as the actual number of rows already fetched through ON FILL BUFFER, `setCurrentRow()` will have no effect: The actual number of rows must be provided with `DIALOG.setArrayLength(screen-array, count)` where `count >= row-index`, before calling `setCurrentRow()`:

```plaintext
DISPLAY ARRAY ... ATTRIBUTES(COUNT=-1)
ON FILL BUFFER
...
ON ACTION goto_last_row
    SELECT COUNT(*) INTO cnt FROM ...
    -- Count total rows
    CALL DIALOG.setArrayLength("sr", cnt)
    CALL DIALOG.setCurrentRow("sr", cnt)
```
ui.Dialog.setFieldActive
Enable and disable form fields.

Syntax

```javascript
setFieldActive(
    fields STRING,
    val BOOLEAN )
```

1. `fields` is the string with the list of field specification, see Identifying fields in dialog methods on page 2409.
2. `val` is a boolean value.

Usage

The `setFieldActive()` method can be used to enable / disable form fields.

The `fields` is a string containing the field qualifier, with an optional prefix ("[table.]column"), or a table prefix followed by a dot and an asterisk ("table.*").

```plaintext
CALL DIALOG.setFieldActive( "customer.cust_addr",
    (rec.cust_name IS NOT NULL) )
```

Do not disable all fields of a dialog, otherwise the dialog execution stops (at least one field must get the focus during a dialog execution).

When disabling the current field, the AFTER FIELD block of the current field and the BEFORE FIELD block on the next field in the tabbing order will be executed.

ui.Dialog.setFieldTouched
Sets the modification flag of the specified field.

Syntax

```javascript
setFieldTouched(
    fields STRING,
    val BOOLEAN )
```

1. `fields` is the string with the list of field specification, see Identifying fields in dialog methods on page 2409.
2. `val` is the boolean value to set the modification flag.

Usage

The `setFieldTouched()` method can be used to change the modification flag of the specified field(s).

The `fields` is a string containing the field qualifier, with an optional prefix ("[table.]column"), or a table prefix followed by a dot and an asterisk ("table.*").

You typically use this method to set the touched flag when assigning a variable, to emulate a user input. Remember when using the UNBUFFERED mode, you don't need to display the value to the fields. The `setFieldTouched()` method is provided as a 3GL replacement for the DISPLAY BY NAME / TO instructions to set the modification flags.

```plainsctext
ON ACTION zoom_city
    LET p_cust.cust_city = zoom_city()
    CALL DIALOG.setFieldTouched("customer.cust_city", TRUE)
    ...
```
If the parameter is a screen record following by dot-asterisk, the method checks the modification flags of all the fields that belong to the screen record. You typically use this to reset the touched flags of a group of fields, after modifications have been saved to the database, to get back to the initial state of the dialog:

```plaintext
ON ACTION save
    CALL save_cust_record()
    CALL DIALOG.setFieldTouched("customer.*", FALSE)
...```

The modification flags are reset to false when using an INPUT ARRAY list, every time you leave the modified row.

**ui.Dialog.setFieldValue**
Sets the value of a field controlled by the dialog object.

### Syntax

```plaintext
setFieldValue(
    name STRING,
    value fgl-type
)
```

1. *name* is the name of the field, see Identifying fields in dialog methods on page 2409.
2. *value* is the value to be set.

### Usage

The `setFieldValue()` method can be used when implementing a dynamic dialog, to set the value of a field:

```plaintext
DEFINE default_address STRING,
    default_creadate DATE
...
CALL d.setFieldValue( "customer.cust_addr", default_address )
CALL d.setFieldValue( "customer.cust_creadate", default_creadate )
```

The first parameter defines the field to be set.

In a dynamic dialog controlling a list of records (INPUT ARRAY/DISPLAY ARRAY), this method sets the value for a field in the current row. To fill the list of records before dynamic dialog execution, use `setCurrentRow()` to set the current row, then set field (i.e. cell values) with `setFieldValue()`.

**Important:**
- During dialog execution, the `setFieldValue()` method must only be used to set the value of a field for the current row. Calling the `setCurrentRow()` method to change the current row before calling `setFieldValue()` will have no effect.
- In a DISPLAY ARRAY using the paged mode (ON FILL BUFFER), `setFieldValue()` will produce error -8129, if the current row is not part of the visible page. In a DISPLAY ARRAY using the full list mode, the error -8129 is raised, if there is no current row (when the array is empty).

### Example

The following code example implements a FOR loop to copy values of all fields of the `d_disparr` dialog to the field of the `d_recinp` dialog:

```plaintext
DEFINE row, i INTEGER,
    h base.SqlHandle,
    fields DYNAMIC ARRAY OF RECORD
        name STRING,
        type STRING
    END RECORD,
    d_rec ui.Dialog,
    d_list ui.Dialog
```
CALL h.open()
LET row = 0
WHILE status == 0
   CALL d_list.setCurrentRow("sr_custlist", row:=row+1)
   FOR i = 1 TO h.getResultCount()
      CALL d_list.setFieldValue( h.getResultName(i),
         h.getResultValue(i) )
   END FOR
   CALL h.fetch()
END WHILE
CALL d_list.setCurrentRow("sr_custlist", 1)

CALL d_list.setCurrentRow("sr_custlist", 1)

CALL d_list.setCurrentRow("sr_custlist", 1)

-- Copy field values from d_list to d_rec dialog
FOR i=1 TO fields.getLength()
   CALL d_rec.setFieldValue( fields[i].name,
      d_list.getFieldValue( fields[i].name ) )
END FOR

Related concepts

ui.Dialog.getFieldValue on page 2387
Returns the value of a field controlled by a dynamic dialog.

Dynamic Dialogs on page 1903
Dialogs can be created at runtime with the ui.Dialog class.

ui.Dialog.setSelectionMode
Defines the row selection mode for the specified list.

Syntax

setSelectionMode(  
   name STRING,  
   mode INTEGER  )

1. name is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. mode defines the selection mode (0, 1).

Usage

In DISPLAY ARRAY instructions, the setSelectionMode() method can be used to enable/disable multi-row selection.

Possible values of the mode parameter are 0 (single row selection) or 1 (multi-range selection). Other values are reserved for future use.

If multi-row selection is switched off, selected rows get deselected.

For more details about multi-row selection, see Multiple row selection on page 1752.

ui.Dialog.setSelectionRange
Sets the row selection flags for a range of rows.

Syntax

setSelectionRange(  
   name STRING,  
   start INTEGER,  
   end INTEGER,  
)
value BOOLEAN )

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. `start` is the starting row index.
3. `end` is the ending row index.
4. `value` is the selection flag to set.

Usage

If multi-row selection is enabled with `setSelectionMode()`, you can set the selection flags for a range of rows with the `setSelectionRange()` method.

```
ON ACTION select_all
    CALL DIALOG.setSelectionRange( "sr", 1, -1, TRUE)
```

The start and end index must be in the range of possible row indexes (from 1 to `DIALOG.getArrayLength()`).

If you specify an end index of -1, it will set the flags from start index to the end of the list.

`ui.Dialog.validate`

Check form level validation rules.

Syntax

```
validate(  
    formFieldList  )
RETURNS INTEGER
```

1. `formFieldList` is a [ ] variable list of strings defining the fields to be validated. The [ ] square brackets are optional, if only one element is provided. See also Identifying fields in dialog methods on page 2409.

Usage

Use the `validate()` method in order to execute `NOT NULL`, `REQUIRED` and `INCLUDE` validation rules defined in the form specification files.

The method takes a variable list parameter with the [ ] square brace notation, containing a comma-separated list of fields or screen records. The [ ] square brackets are optional, if only one element is to be validated:

```
DIALOG.validate("customer.cust_name")
DIALOG.validate("cust_rec.*")
DIALOG.validate( [ "cust_rec.*", "ord_rec.*" ] )
```

There are different notations to identify form fields in a dialog. For details, see Identifying fields in dialog methods on page 2409.

The method returns zero if success, or the input error code of the first field which does not satisfy the validation rules.

Note: The current field is always checked, even if it is not part of the validation field list. This is mandatory, otherwise the current field may be left with invalid data.

If an error occurs, the `validate()` method automatically displays the corresponding error message, and registers the next field to jump to when the interactive instruction gets the control back.

The `validate()` method does not stop code execution if an error is detected. You must execute a `CONTINUE DIALOG` or `CONTINUE INPUT` instruction to cancel the code execution.

A typical usage is for a "save" action:

```
ON ACTION save
    IF DIALOG.validate("cust_rec.*") < 0 THEN
```
CONTINUE DIALOG
END IF
CALL customer_save()

ui.Dialog.visualToArrayIndex
Converts the visual index to the program array index for a given screen array.

Syntax

```
visualToArrayIndex(
    name STRING,
    visualIndex INTEGER
)
```

1. `name` is the name of the screen record, see Identifying screen-arrays in dialog methods on page 2410.
2. `visualIndex` is the index of the row as seen by the end user.

Usage

When the end user sorts rows in a table, the visual row index may differ from the program array index.

Use this method to convert a row index as seen by the end user, to the program array index. For example, if
the application implements a feature that allows the user to enter a row index to jump to that row, it will be
entered as a visual row index. You must convert this index to the program array index, for example to make a
setCurrentRow().

```
CALL DIALOG.setCurrentRow("sr", DIALOG.visualToArrayIndex("sr", user_index))
```

Related concepts

Handling the current row on page 1736
Query and control the current row in a read-only or editable list of records.

ui.Dialog.arrayToVisualIndex on page 2381
Converts the program array index to the visual index for a given screen array.

Usage

Referencing the current dialog

In order to reference the current dialog, you can define a variable with the `ui.Dialog` type, and get the current
dialog object with the `ui.Dialog.getCurrent()` method:

```
DEFINE d ui.Dialog

INPUT BY NAME ...
    BEFORE DIALOG
    LET d = ui.Dialog.getCurrent()
    CALL d.setActionActive("zoom", FALSE)

... 
```

As an alternative and to simplify programming, it is recommended that you use the `DIALOG` keyword in the context
of the interactive instruction block. the `DIALOG` keyword is a predefined object variable referencing the current
dialog. The `DIALOG` variable can only be used inside the interactive instruction block:

```
INPUT BY NAME custid, custname
    ON ACTION disable
        CALL DIALOG.setFieldActive("custid", FALSE)
END INPUT
```

Related concepts

Passing a dialog reference to functions on page 2408
Passing a dialog reference to functions

Using the DIALOG keyword outside a dialog instruction block results in a compilation error. However, you can pass the object to a function that defines the dialog parameter with the ui.Dialog type.

The next example passes the DIALOG object reference to the setupDialog() function, which implements action activation rules that must be applied after different events, during the dialog execution:

```
INPUT BY NAME custid, custname, custaddr
BEFORE INPUT
  CALL setupDialog(DIALOG)
...
ON ACTION check_address
  CALL setupDialog(DIALOG)
...
END INPUT

FUNCTION setupDialog(d)
  DEFINE d ui.Dialog
  DEFINE isAdmin BOOLEAN
  LET isAdmin = (global_params.user_group == "admin")
  CALL d.setActionActive("delete", isAdmin)
  CALL d.setActionActive("convert", isAdmin)
  CALL d.setActionActive("check_address", isAdmin AND rec.custaddr IS NOT NULL)
END FUNCTION
```

Related concepts

Referencing the current dialog on page 2407

Identifying actions in dialog methods

In ui.Dialog methods such as setActionActive(), the first parameter identifies the action object to be modified. This parameter can be full-qualified or partly-qualified. If you don't specify a full-qualified name, the action object will be identified based on the focus context.

The action name specification can be any of the following:

- action-name
- dialog-name.action-name
- dialog-name.field-name.action-name
- field-name.action-name (singular dialogs only)

Here action-name identifies the name of the action specified in ON ACTION action-name or COMMAND "action-name" handlers, while dialog-name identifies the singular dialog or sub-dialog and field-name defines the field bound to the action INFIELD clause of ON ACTION.

The action name must be passed in lowercase letters.

The runtime system will raise the error -8089 if the action specified by [dialog-name.]field-name.action-name can not be found within the current dialog.

Note: As a general rule, assign unique action names for each specific dialog action, to avoid the usage of dialog and/ or field identifiers.

In the DIALOG instruction, actions can be prefixed with the sub-dialog identifier. However, if methods like setActionActive() are called in the context of the sub-dialog, the prefix can be omitted. When using a field-specific action defined with the INFIELD clause of ON ACTION, you can identify the action with the full-qualified name dialog-name.field-name.action-name. Like sub-dialog actions, if you specify only action-name, the runtime system will search for the action object based on the focus context.
Note that an INPUT or CONSTRUCT sub-dialogs have no identifier by default. The dialog name can be defined with the NAME attribute. For more details, see Identifying sub-dialogs in procedural DIALOG on page 1490.

When using a singular dialog like INPUT, you can identify field-specific actions by field-name.action-name, if the dialog was defined without a NAME attribute.

Example

```
MAIN
  DEFINE cust_rec RECORD
    num INT,
    name VARCHAR(50),
    city INT
  END RECORD
DEFINE orders DYNAMIC ARRAY OF RECORD
    ord_num INT,
    cust_num INT,
    ord_date DATE
END RECORD
OPEN FORM f1 FROM "cust_ord"
DISPLAY FORM f1
DIALOG ATTRIBUTES(UNBUFFERED)
  INPUT BY NAME cust_rec.* ATTRIBUTES(NAME="cust")
    ON ACTION compare
      CALL compare()
    ON ACTION check INFIELD cust_city
      CALL check_city(cust_rec.city)
  END INPUT
  DISPLAY ARRAY orders TO sr_ord.*
    ON ACTION archive
      CALL archive()
  END DISPLAY
  ON ACTION print
    CALL print()
  ON ACTION disable_all
    CALL DIALOG.setActionActive("cust.compare", FALSE)
    CALL DIALOG.setActionActive("cust.cust_city.check", FALSE)
    CALL DIALOG.setActionActive("sr_ord.archive", FALSE)
    CALL DIALOG.setActionActive("print", FALSE)
  END DIALOG
END MAIN
```

Related concepts

Enabling and disabling actions on page 1666
By default, dialog actions are enabled. However, it is recommended that an action be disabled when not allowed in the current context.

Binding action views to action handlers on page 1664
How are action views of the forms bound to action handlers in the program code?

Identifying fields in dialog methods

In ui.Dialog methods such as setFieldActive(), the first parameter identifies the form field (or, for some methods, a list of fields) to be modified. The form field names can be fully-qualified or partly-qualified.

Fields are identified by the form field name specification, not the program variable name used by the dialog. Remember form fields are bound to program variables with the binding clause of dialog instruction (INPUT variable-list FROM field-list,INPUT BY NAME variable-list,CONSTRUCT BY NAME sql ON column-list,CONSTRUCT sql ON column-list FROM field-list,INPUT ARRAY array-name FROM screen-array.*).

The field name specification can be any of the following:
• field-name
• table-name.field-name
• screen-record-name.field-name
• FORMONLY.field-name

Here are some examples:

• "cust_name",
• "customer.cust_name",
• "cust_screen_record.cust_name",
• "item_screen_array.item_label",
• "formonly.total",
• "customer.*" (only some methods accept the "dot asterisk" notation)

When no field name prefix is used, the first form field matching that field name will be used. If the field specification is invalid (i.e. no field in the current dialog matches the field specification), the method will throw the error -1373.

When using a prefix in the field name specification, it must be equal to the field prefix used in the variable for the field binding clause of the dialog.

• When no screen-record was specified in the field binding clause (for example, when using INPUT BY NAME variable-list), the field prefix must be the database table name (or FORMONLY) used in the form file, or any valid screen-record using that field.
• When the FROM clause of the dialog specifies an explicit screen-record (for example, in INPUT variable-list FROM screen-record.* / field-list-with-screen-record-prefix or INPUT ARRAY array-name FROM screen-array.*) the field prefix must be the screen-record name used in the FROM clause.

The methods validate(), setFieldActive(), setFieldTouched(), getFieldTouched() can take a list of fields as parameter, by using the "dot-asterisk" notation (screen-record.*). This way you can check, query or change a complete list of fields in one method call:

```
ON ACTION save
    CALL save_cust_record()
    CALL DIALOG.setFieldTouched("customer.*", FALSE)
    ...
```

Identifying screen-arrays in dialog methods

In ui.Dialog methods such as setCurrentRow(), the first parameter is the name of the screen array to identify the list container in the form.

Important: The screen-array passed to ui.Dialog methods must be provided in lowercase letters.

Screen arrays are defined in form specification files with the SCREEN RECORD clause, and used in DISPLAY ARRAY and INPUT ARRAY instructions to bind program array variables to the list container.

In the form file:

```
LAYOUT
...
INSTRUCTIONS
SCREEN RECORD custlist ( ... );
END
```

In the program code:

```
DISPLAY ARRAY custarr TO custlist.*
    ...
    ON ACTION set_row
        CALL DIALOG.setCurrentRow("custlist", row_index)
```
Related concepts

Variable binding in INPUT ARRAY on page 1429

Field definition for Dynamic Dialogs
Dynamic dialog creation methods require field definitions in a dynamic array with a predefined structure.

Dynamic dialog creation methods such as `ui.Dialog.createInputByName()` require a dynamic array as parameter, to define the list of fields that the dialog will control.

This parameter must be defined as a `DYNAMIC ARRAY OF RECORD`, with name and type members declared as `STRING`:

```
DEFINE fields DYNAMIC ARRAY OF RECORD
  name STRING,
  type STRING
END RECORD
```

The names provided in the field definition list must identify form fields of the current form.

For example, if the current form file defines the following fields:

```
LAYOUT
  ...
END
TABLES
  customer
END
ATTRIBUTES
  EDIT f1 = customer.cust_id;
  EDIT f2 = customer.cust_name;
  ...
END
```

The field names provided in the dynamic array must be:

```
LET fields[1].name = "customer.cust_id"
LET fields[2].name = "customer.cust_name"
...
```

The types provided in the field definition list will identify the data type to be used for data input and display.

Possible values for types are the string equivalents of the Genero BDL built-in types, for example:

- "INTEGER"
- "VARCHAR(50)"
- "DATE"
- "DECIMAL(10,2)"
- "DATETIME YEAR TO FRACTION(5)"

Note: The type used to define form fields can be the returning value of a `base.SqlHandle.getResultType()` method.

For example:

```
DEFINE fields DYNAMIC ARRAY OF RECORD
  name STRING,
  type STRING
END RECORD
```
type STRING
END RECORD
DEFINE d ui.Dialog

OPEN FORM f1 FROM "custform"
DISPLAY FORM f1

LET fields[1].name = "customer.cust_id"
LET fields[1].type = "INTEGER"

LET fields[2].name = "customer.cust_name"
LET fields[2].type = "VARCHAR(50)"
...

LET d = ui.Dialog.createInputByName(fields)
...

Related concepts
Dynamic Dialogs on page 1903
Dialogs can be created at runtime with the ui.Dialog class.

Examples
ui.Dialog usage examples.
Example 1: Disable fields dynamically

FUNCTION input_customer()
  DEFINE custid INTEGER
  DEFINE custname CHAR(10)
  INPUT BY NAME custid, custname
  ON ACTION enable
    CALL DIALOG.setFieldActive("custid",1)
  ON ACTION disable
    CALL DIALOG.setFieldActive("custid",0)
  END INPUT
END FUNCTION

Example 2: Get the form and hide fields

FUNCTION input_customer()
  DEFINE f ui.Form
  DEFINE custid INTEGER
  DEFINE custname CHAR(10)
  INPUT BY NAME custid, custname
  BEFORE INPUT
    LET f = DIALOG.getForm()
    CALL f.setElementHidden("customer.custid",1)
  END INPUT
END FUNCTION

Example 3: Pass a dialog object to a function

DEFINE r_user RECORD
  can_print BOOLEAN,
  can_query BOOLEAN
END RECORD

FUNCTION input_customer()
  DEFINE custid INTEGER
  DEFINE custname CHAR(10)
  INPUT BY NAME custid, custname
  BEFORE INPUT
    CALL setup_dialog(DIALOG)
  END INPUT
FUNCTION setup_dialog(d)
  DEFINE d ui.Dialog
  CALL d.setActionActive("print",r_user.can_print)
  CALL d.setActionActive("query",r_user.can_query)
END FUNCTION

Example 4: Set display attributes for cells

Note: This code example uses a DYNAMIC ARRAY with the same RECORD structure as the data array. You could also use a two-dimensional dynamic array or a simple flat array of strings. For more details, see `ui.Dialog.setArrayAttributes` on page 2397

FUNCTION display_items()
  DEFINE i INTEGER
  DEFINE items DYNAMIC ARRAY OF RECORD
    key INTEGER,
    name CHAR(10)
  END RECORD
  DEFINE attributes DYNAMIC ARRAY OF RECORD
    key STRING,
    name STRING
  END RECORD
  FOR i=1 TO 10
    CALL items.appendElement()
    LET items[i].key = i
    LET items[i].name = "name " || i
    CALL attributes.appendElement()
    IF i MOD 2 = 0 THEN
      LET attributes[i].key = "red"
      LET attributes[i].name = "blue reverse"
    ELSE
      LET attributes[i].key = "green"
      LET attributes[i].name = "magenta reverse"
    END IF
  END FOR
  DISPLAY ARRAY items TO sr.* ATTRIBUTES(UNBUFFERED)
  BEFORE DISPLAY
    CALL DIALOG.setCellAttributes(attributes)
  ON ACTION att_modify_cell
    LET attributes[2].key = "red reverse"
  ON ACTION att_clear_cell
    LET attributes[2].key = NULL
  END DISPLAY
END FUNCTION

The ComboBox class

The `ui.ComboBox` class provides an interface to the COMBOBOX form field view in the abstract user interface tree. In .per form specification files, a COMBOBOX form field defines both a form field and a view for that model. The `ui.ComboBox` class is an interface to the view of a COMBOBOX form field. It is typically used to configure the widget dynamically in programs, for example to create the list of items shown in the drop down box.

Related concepts

</tbody>
</table>

**ui.ComboBox.setDefaultInitializer**
Define the default initializer for combobox form items.

**Syntax**

```
ui.ComboBox.setDefaultInitializer(
```
**initializer** STRING )

1. **initializer** is the name of the initialization function.

**Usage**

The `ui.ComboBox.setDefaultInitializer()` class method defines the default initialization function to be called each time a COMBOBOX form field is created when loading forms.

Use this method if you want to define a global/default initialization function for all comboboxes of the program. For individual comboboxes, consider using the `INITIALIZER` form field attribute instead.

**Important:**

- The initialization function name is case insensitive.
- The module defining the initialization function must have been loaded when the function is invoked. The error `-1338` is raised if the module is not yet loaded, or when the function name mismatches. To make sure that the module is loaded, define other functions in the module, that are invoked with a regular CALL instruction.

The function is called with the `ui.ComboBox` object as the parameter.

The combobox initialization functions are typically used to fill the drop down list with items.

**Example**

The form file `form1.per`:

```plaintext
LAYOUT
GRID
{
  [cb1]
}
END
END
ATTRIBUTES
COMBOBOX cb1 = FORMONLY.city;
END
```

The main module:

```plaintext
IMPORT FGL setup
MAIN
  DEFINE city STRING
  CALL setup.init_combo_setup(TRUE)
  CALL ui.ComboBox.setDefaultInitializer("cb_init")
  OPEN FORM f1 FROM "form1"
  DISPLAY FORM f1 -- initialization function is called
  INPUT BY NAME city
END MAIN
```

The imported module `setup.4gl`:

```plaintext
PRIVATE DEFINE with_undef BOOLEAN
PUBLIC FUNCTION init_combo_setup(wu)
  DEFINE wu BOOLEAN
  LET with_undef = wu
END FUNCTION
PUBLIC FUNCTION cb_init(cb)
  DEFINE cb ui.ComboBox
  CALL cb.clear()
  IF with_undef THEN
```
CALL cb.addItem(0,"Undefined")
END IF
CALL cb.addItem(0,"Paris")
CALL cb.addItem(0,"London")
CALL cb.addItem(0,"Rome")
...
END FUNCTION

**ui.ComboBox.forName**
Search for a combobox in the current form.

**Syntax**

```plaintext
type ui.ComboBox.forName(
    name STRING
) RETURNS ui.ComboBox
```

1. *name* is the name of COMBOBOX form item.

**Usage**

The **ui.ComboBox.forName()** class method searches for a ui.ComboBox object by form field name in the current form.

**Important:** The form field name must be in lowercase letters: The language syntax allows case-insensitive form field names, and the runtime system must reference fields in lowercase letters internally. Since the form compiler converts field names to lowercase in the 42f file, the name must be lowercase in this method call.

After loading a form with **OPEN WINDOW WITH FORM**, use the class method to retrieve a ui.ComboBox object into a variable defined as a ui.ComboBox.

```plaintext
DEFINE cb ui.ComboBox
LET cb = ui.ComboBox.forName("formonly.airport")
```

Verify the function has returned an object, as the form field may not exist.

```plaintext
IF cb IS NULL THEN
    ERROR "Form field not found in current form"
    EXIT PROGRAM
END IF
```

Once instantiated, the ui.ComboBox object can be used, for example to fill the items of the drop down list.

```plaintext
CALL cb.clear()
CALL cb.addItem(1,"Paris")
CALL cb.addItem(2,"London")
CALL cb.addItem(3,"Madrid")
```

**ui.ComboBox.addItem**
Add an element to the item list.

**Syntax**

```plaintext
addItem(
    code STRING,
    text STRING
)
```

1. *code* is the unique key that identifies the item.
2. *text* is the text to be displayed in the drop down list.
Usage

The `addItem()` method adds an item to the end of the drop down list of the COMBOBOX.

The first parameter is the value that can be set in the form field. The second parameter is the label to be displayed in the drop down list. If the second parameter is `NULL`, the runtime system automatically uses the first parameter as the display value.

Uniqueness is not checked by the runtime system. Make sure that the items created are unique, regarding the value key and the display label.

Trailing spaces are not recommended when populating the first parameter because values get truncated when field validation occurs, and the resulting value (without trailing spaces) will no longer match the COMBOBOX item name. Additionally, trailing spaces in the second parameter may cause the COMBOBOX to be much wider than expected. To avoid such problems, use VARCHAR or STRING variables, or use the CLIPPED operator with CHAR variables.

`ui.ComboBox.clear`

Clear the item list of a combobox.

Syntax

```
clear()
```

Usage

The `clear()` method clears the item list of the combobox.

If the item list is empty, the COMBOBOX drop-down button shows an empty list on the client side.

`ui.ComboBox.getColumnName`

Get the column name of the form field.

Syntax

```
getColumnName()
```

Usage

The `getColumnName()` method returns the form field column name. The form field column name can be `NULL` if not defined at the form field level.

Use the `getTableName()` and `getColumnName()` methods together in order to identify the form field associated with the COMBOBOX. This allows to identify the combobox field in your program, for example to fill the drop down list with the appropriate items.

```
IF cb.getTableName() || "." || cb.getColumnName() == "customer.cust_city" THEN
   CALL cb.clear()
   CALL cb.addItem(1, "Paris")
   CALL cb.addItem(2, "London")
   CALL cb.addItem(3, "Madrid")
END IF
```

Related concepts

`ui.ComboBox.getTableName` on page 2420
Get the table prefix of the form field.

`ui.ComboBox.getItemsOf`  
Get an item position by name.

**Syntax**

```plaintext
getIndexOf(
    code STRING
) RETURNS INTEGER
```

1. `code` is the name of a combobox item.

**Usage**

The `getIndexOf()` method takes an item name as parameter and returns the position of the item in the drop down list.

The first item is at position 1. The method returns 0 (zero) if the item name does not exist.

The next example checks for item existence, before adding the item.

```plaintext
IF cb.getIndexOf("SFO") == 0 THEN
    CALL cb.addItem("SFO", "San Francisco International Airport, CA")
END IF
```

`ui.ComboBox.getItemsCount`

Get the number of items.

**Syntax**

```plaintext
getItemCount()
RETURNS INTEGER
```

**Usage**

The `getItemCount()` method returns the current number of items defined for the `COMBOBOX` form field.

The method returns 0 (zero) if no items are defined.

`ui.ComboBox.getItemsName`

Get an item name by position.

**Syntax**

```plaintext
getItemName(
    index INTEGER
) RETURNS STRING
```

1. `index` is the index of the combobox item.

**Usage**

The `getItemName()` method returns the name of an item at the give position.

The first item starts at position 1.
ui.ComboBox.getItemText
Get the item text by position.

Syntax

```java
getItemText(
    index INTEGER 
) 
RETURNS STRING
```

1. `index` is the index of the combobox item.

Usage
The `getItemText()` method returns the display label of an item at the give position. The first item starts at position 1.

ui.ComboBox.getTableName
Get the table prefix of the form field.

Syntax

```java
getTableName() 
RETURNS STRING
```

Usage
The `getTableName()` method returns the name of the form field table prefix. The form field table prefix can be `NULL` if not defined at the form field level.

This allows to identify a COMBOBOX field in your program, for example to fill the drop down list with the appropriate items.

Related concepts
ui.ComboBox.getColumnName on page 2418
Get the column name of the form field.

ui.ComboBox.getTag
Get the combobox tag value.

Syntax

```java
getTag() 
RETURNS STRING
```

Usage
The `getTag()` method returns the value define by the `TAG` attribute.

Use the tag to mark COMBOBOX form items with your own flags, in order to adapt the configuration of the combobox dynamically by program. For example, if `TAG` contains the token "short", fill the drop down list with short names, otherwise fill with long names. The same code can then be used for different COMBOBOX form fields.

ui.ComboBox.getTextOf
Get the item text by name.

Syntax

```java
getTextOf(
```
**Usage**

The `getTextOf()` method returns the display label of the item identified by the name passed as parameter.

The method returns `NULL` if the item name does not exist.

`ui.ComboBox.getTextOf(code)`

Remove an item by name.

**Syntax**

```
removeItem(
    code STRING )
```

**Usage**

The `removeItem()` method deletes an item from the list. The item to be removed is identified by the name passed as a parameter. If the item does not exist, the method returns without error.

The following example fills a combobox with a few items, and then removes one by using the item name:

```plaintext
DEFINE cb ui.ComboBox
...
LET cb = ui.ComboBox.forName("formonly.airport")
CALL cb.addItem("CDG", "Paris-Charles de Gaulle, France")
CALL cb.addItem("LCY", "London-City Airport, UK")
CALL cb.addItem("LHR", "London-Heathrow, UK")
...
CALL cb.removeItem("CDG")
```

**Related concepts**

Example Get a ComboBox form field view and fill the item list on page 2421

**Examples**

`ui.ComboBox` usage examples.

*Example Get a ComboBox form field view and fill the item list*

**Form Specification File:**

```
DATABASE FORMONLY
LAYOUT GRID
{    
   Airport: [cb01 ]
 }
END
END
ATTRIBUTES COMBOBOX cb01 = FORMONLY.airport TYPE CHAR;
END
```

**Program File:**

```
MAIN
```
DEFINE cb ui.ComboBox
DEFINE airport CHAR(3)
OPEN FORM f1 FROM "combobox"
DISPLAY FORM f1
LET cb = ui.ComboBox.forName("formonly.airport")
IF cb IS NULL THEN
   ERROR "Form field not found in current form"
   EXIT PROGRAM
END IF
CALL cb.clear()
CALL cb.addItem("CDG", "Paris-Charles de Gaulle, France")
CALL cb.addItem("LCY", "London-City Airport, UK")
CALL cb.addItem("LHR", "London-Heathrow, UK")
CALL cb.addItem("FRA", "Frankfurt Airport, Germany")
IF cb.getIndexOf("SFO") == 0 THEN
   CALL cb.addItem("SFO", "San Francisco International Airport, CA"
END IF
INPUT BY NAME airport
END MAIN

Example Using the INITIALIZER attribute in the form file

Form Specification File:

DATABASE FORMONLY
LAYOUT
GRID
{
   Airport: [cb01 ]
}
END
END
ATTRIBUTES
COMBOBOX cb01 = FORMONLY.airport TYPE CHAR, INITIALIZER=initcombobox;
END

Initialization function:

FUNCTION initcombobox(cb)
DEFINE cb ui.ComboBox
CALL cb.clear()
CALL cb.addItem("CDG", "Paris-Charles de Gaulle, France")
CALL cb.addItem("LCY", "London-City Airport, UK")
CALL cb.addItem("LHR", "London-Heathrow, UK")
CALL cb.addItem("FRA", "Frankfurt Airport, Germany")
CALL cb.addItem("SFO", "San Francisco International Airport, CA"
END FUNCTION

The DragDrop class
The ui.DragDrop class is used to control the events related to drag & drop events.

When implementing drag & drop in a dialog, the ON DRAG*/ON DROP dialog control blocks take a ui.DragDrop variable as a parameter to let you configure and control the drag & drop events. The ui.DragDrop variable must be declared in the scope of the dialog implementing drag & drop.

Related concepts
Drag & drop on page 1819

<tr>
<td><code>setOperation</code></td>
<td>Define the type of Drag &amp; Drop operation.</td>
</tr>
</tbody>
</table>
ui.DragDrop.addPossibleOperation
Add a possible operation.

Syntax

```java
addPossibleOperation(
    operation STRING )
```

| 1. operation is the name of a drag & drop operation. |

Usage

Drag & drop actions can be of different kinds; you can do a copy of the dragged object, or move the dragged object from the source to the destination.

The default drag & drop operation is defined by a call to setOperation() method in ON DRAG_START. Use the addPossibleOperation() method to define additional operations that are allowed.

See setOperation() for possible values.

ui.DragDrop.dropInternal
Perform built-in row drop in trees.

Syntax

```java
dropInternal()
```

Usage

In order to simplify drag & drop programming in the same list, the ui.DragDrop class provides the dropInternal() utility method, to be called in the ON DROP block. This method will perform all the row changes in the array and move row selection as well as cell attributes.

When implementing drag & drop on a tree-view, dropping an element on the tree requires complex code in order to handle parent-child relationships. Nodes can be inserted under a parent between two children, appended at the end of the children list, and at different levels in the tree hierarchy. However, the dropInternal() method can also be used simple lists displayed in a regular TABLE.

A call to dropInternal() will silently be ignored, if the drag source is not the drop target, or if the method is called in a different context as ON DROP.

For more details about dropping elements in tree-views, see Drag & drop on page 1819.

ui.DragDrop.getBuffer
Get drag & drop data from the buffer.

Syntax

```java
getBuffer()
    RETURNS STRING
```

Usage

After identifying the MIME type of a dropped object with getSelectedMimeType(), you can call the getBuffer() method to get text data from the drag & drop buffer.

Drag & drop data is only available at ON DROP time, therefore, the getBuffer() method must be called in ON DROP only.
Note: When using URI MIME types (for file paths for example), the string returned from the `getBuffer()` method can contain URL-encoded characters such as %5E, which represents the ^ caret. Therefore, you must URL-decode strings returned from `getBuffer()` with `util.Strings.urlDecode()`. When setting the drag & drop buffer content, if required by the front-end platform, the string can be URL-encoded using `util.Strings.urlEncode()` for `setBuffer()`. However, URL-encoding file paths for `setBuffer()` is usually not required.

Related concepts
`ui.DragDrop.getSelectedMimeType` on page 2426
Get the previously selected MIME type.

`ui.DragDrop.getLocationParent`
Get the index of the parent node where the object was dropped.

Syntax

```java
getLocationParent()
RETURNS INTEGER
```

Usage
When using a tree view, a node can be dropped as a sibling or as a child node to another node. In order to distinguish between the cases, you must use the `getLocationParent()` method, which returns the index of the parent node of the drop target node returned by `getLocationRow()`.

If both methods return the same row index, you must append the dropped row as a child of the target node. Otherwise, `getLocationParent()` identifies the parent node where the dropped row has to be added as a child, and `getLocationRow()` is the index of a sibling node. In the last case the dropped node must be inserted before the node identified by `getLocationRow()`.

These methods are typically used in the `ON DROP` block, but can also be used in `ON DRAG_OVER` to deny the drop depending on the indexes returned; for example, the program might only allow the drop of objects as new children for a given parent node.

Related concepts
`ui.DragDrop.getLocationRow` on page 2425
Get the index of the target row where the object was dropped.

`ui.DragDrop.getLocationRow`
Get the index of the target row where the object was dropped.

Syntax

```java
getLocationRow()
RETURNS INTEGER
```

Usage
The `getLocationRow()` method returns the index of the row in the drop target list pointed to by the mouse cursor.

This method is typically used in the `ON DROP` block to get the index of the target row to be modified or replaced by the dragged object.

In order to deny the drop, the `getLocationRow()` can be used in conjunction with `setOperation(NULL)` in the `ON DRAG_ENTER` or `ON DRAG_OVER`, if the current target row returned by `getLocationRow()` is not valid for a drop operation.
Related concepts

`ui.DragDrop.getLocationParent` on page 2425
Get the index of the parent node where the object was dropped.

`ui.DragDrop.getSelectedMimeType`  
Get the previously selected MIME type.

**Syntax**

```plaintext
getSelectedMimeType()  
RETURNS STRING
```

**Usage**

Before retrieving data from the drag & drop buffer with `getBuffer()`, first call the `getSelectedMimeType()` method to identify the data format that was previously selected by a `selectMimeType()` call.

The `getSelectedMimeType()` method is typically called in `ON DROP` to identify the format of the dropped object.

Related concepts

`ui.DragDrop.getBuffer` on page 2424
Get drag & drop data from the buffer.

`ui.DragDrop.selectMimeType` on page 2427
Select the MIME type before getting the data.

`ui.DragDrop.setMimeType` on page 2428
Define the MIME type of the dragged object.

`ui.DragDrop.getOperation`  
Identify the type of operation on drop.

**Syntax**

```plaintext
getOperation()  
RETURNS STRING
```

**Usage**

The `getOperation()` method returns the type of the current drag & drop operation ("copy", "move", or "none").

Depending on the value returned by this method, the program can make the appropriate changes in the data model. For example, after a row has been dropped into another list, the source list can remove the original row if the operation was a "move", but keeps the original row if the operation was a "copy".

The `getOperation()` method is typically called in the `ON DRAG_FINISHED` block.

Related concepts

`ui.DragDrop.setOperation` on page 2429
Define the type of Drag & Drop operation.

`ui.DragDrop.addPossibleOperation` on page 2424
Add a possible operation.

*ui.DragDrop.selectMimeType*

Select the MIME type before getting the data.

**Syntax**

```
selectMimeType (mimeType STRING )
```

1. *mimeType* defines the MIME type for dragged objects.

**Usage**

Call the `selectMimeType()` method to check that data is available in a format identified by the MIME type passed as parameter.

If this type of data is available in the buffer, the method returns `TRUE` and you can later get the data with `getBuffer()`.

The `selectMimeType()` method is typically used in `ON DRAG_ENTER`, `ON DRAG_OVER` to deny the drag & drop operation if none of the supported MIME types is available in the buffer.

**Related concepts**

- *ui.DragDrop.getSelectedMimeType* on page 2426
  Get the previously selected MIME type.
- *ui.DragDrop.setBuffer*  
  Set the text data of the dragged object.

**Syntax**

```
setBuffer (buffer STRING )
```

1. *buffer* is a string expression containing drag & drop data.

**Usage**

Use the `setBuffer()` method to provide the text data of objects dragged from the program to an external application.

The `setBuffer()` method is typically used in an `ON DRAG_START` block together with `setMimeType()`.

By default, the dialog will serialize the data of the selected rows as a tab-separated list of values.

The text/plain MIME type is the default.

**Note:** When using URI MIME types (for file paths for example), the string returned from the `getBuffer()` method can contain URL-encoded characters such as `%5E`, which represents the `^` caret. Therefore, you must URL-decode strings returned from `getBuffer()` with `util.Strings.urlDecode()`. When setting the drag & drop buffer content, if required by the front-end platform, the string can be URL-encoded using `util.Strings.urlEncode()` for `setBuffer()`. However, URL-encoding file paths for `setBuffer()` is usually not required.

**Related concepts**

- *ui.DragDrop.setMimeType* on page 2428
Define the MIME type of the dragged object.

\textit{ui.DragDrop.setMimeType}

Define the appearance of the target during Drag & Drop.

Syntax

\begin{verbatim}
setFeedback(
    feedback STRING
)
\end{verbatim}

1. \textit{feedback} is the type of feedback to display during the drag & drop operation.

Usage

The \textit{setFeedback()} method defines the appearance the target object must have during the drag & drop process.

For example, in a table or tree view, when the mouse is flying over rows in the drop target, a different visual indicator will appear depending on the value that was passed to \textit{setFeedback()}.

Possible values for the \textit{setFeedback()} method are:

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
Parameter & Values & Description \\
\hline
\textit{all} & Dragged object will be dropped somewhere on the target widget, the exact location does not matter. \\
\textit{insert} & In lists, dragged object will be inserted in between existing rows. \\
\textit{select} & In lists, dragged object will replace the current row under the mouse. \\
\hline
\end{tabular}
\caption{Table 492: Values for the \textit{setFeedback()} method}
\end{table}

\textit{ui.DragDrop.setMimeType}

Define the MIME type of the dragged object.

Syntax

\begin{verbatim}
setMimeType(
    mimeType STRING
)
\end{verbatim}

1. \textit{mimeType} defines the MIME type for the drag & drop buffer.

Usage

Objects dragged from the program to an external application need to be identified with a MIME type and the program must provide the data. The MIME type can be specified with the \textit{setMimeType()} method.

The \textit{setMimeType()} method is typically used in an ON DRAG_START block along with \textit{setBuffer()}.

By default, the source target will use the text/plain MIME type and copy the data of the selected rows into the Drag & Drop buffer.

Related concepts

\textit{ui.DragDrop.setBuffer} on page 2427
Set the text data of the dragged object.

**ui.DragDrop.setOperation**

Define the type of Drag & Drop operation.

**Syntax**

```
setOperation(
  operation STRING )
```

1. *operation* is the name of a drag & drop operation.

**Usage**

Drag & drop actions can be of different kinds; you can do a copy of the dragged object, or move the dragged object from the source to the destination.

Use the `setOperation()` method to define/force the type of drag & drop operation or to deny/cancel the drag & drop process.

**Table 493: Parameters for the `setOperation()` method**

<table>
<thead>
<tr>
<th>Parameter Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>To deny/cancel the drag &amp; drop process.</td>
</tr>
<tr>
<td>copy</td>
<td>To allow drag &amp; drop as a copy of the source object.</td>
</tr>
<tr>
<td>move</td>
<td>To allow drag &amp; drop as a move of the source object.</td>
</tr>
</tbody>
</table>

The `setOperation()` method can be called in different drag & drop triggers.

A common usage is to deny drag & drop by passing `NULL` in the `ON DRAG_ENTER` and/or `ON DRAG_OVER` blocks because the dragged object does not correspond to the type of objects the target can receive.

This method is also used in `ON DRAG_START` to force a specific type of drag & drop operation (copy or move), or to deny drag start if the context does not allow a drag & drop action.

When called in the `ON DRAG_ENTER` block, the method forces a specific drag & drop operation.

**Related concepts**

- `ui.DragDrop.addPossibleOperation` on page 2424
  Add a possible operation.

**The om package**

These topics cover the built-in classes for the om class

<tr>
<td><code>removeElement( oldChild om.DomNode )</code></td>
<td>Remove a DomNode object and all its descendants.</td>
</tr>
</tbody>
</table>
om.DomDocument.create
Create a new empty om.DomDocument object.

Syntax

```javascript
om.DomDocument.create(
    tagName STRING
)
RETURNS om.DomDocument
```

1. `tagName` defines the tag name of the root element.

Usage

Use the class method om.DomDocument.create() to instantiate a new, empty DOM document object.

To hold the reference to a DOM document object, define a variable with the om.DomDocument type.

Example

```javascript
DEFINE d om.DomDocument
LET d = om.DomDocument.create("Vehicles")
...
```

Related concepts

- om.DomDocument.createFromXmlFile on page 2432
- om.DomDocument.createFromFromString on page 2431
  Create a new om.DomDocument object from an XML string.

om.DomDocument.createFromFromString
Create a new om.DomDocument object from an XML string.

Syntax

```javascript
om.DomDocument.createFromFromString(
    s STRING
)
RETURNS om.DomDocument
```

1. `s` is the string expression containing XML data.

Usage

Use the class method om.DomDocument.createFromFromString() to instantiate a new DomDocument object that is filled with the content of the specified XML formatted string.

To hold the reference to a DOM document object, define a variable with the om.DomDocument type.

Example

```javascript
DEFINE d om.DomDocument
LET d = om.DomDocument.createFromFromString("<Vehicles/>")
...
```

Related concepts

- om.DomDocument.create on page 2431
  Create a new empty om.DomDocument object.
- om.DomDocument.createFromXmlFile on page 2432

**om.DomDocument.createFromXmlFile**

Syntax

```plaintext
om.DomDocument.createFromXmlFile(
    path STRING )
RETURNS om.DomDocument
```

1. *path* is the path to the file containing XML data.

Usage

Use the class method `om.DomDocument.createFromXmlFile()` to instantiate a new DomDocument object that is filled with the content of the specified XML file.

To hold the reference to a DOM document object, define a variable with the `om.DomDocument` type.

Example

```plaintext
DEFINE d om.DomDocument
LET d = om.DomDocument.createFromXmlFile("vehicles.xml")
...
```

**Related concepts**

- `om.DomDocument.create` on page 2431
  - Create a new empty `om.DomDocument` object.
- `om.DomDocument.createFromXmlFile` on page 2431
  - Create a new `om.DomDocument` object from an XML string.
- `om.DomDocument.getDocumentElement` on page 2431
  - Returns the root node element of the DOM document.

Syntax

```plaintext
getDocumentElement ()
RETURNS om.DomNode
```

Usage

To hold the reference to the root node, define a variable with the `om.DomNode` type.

Example

```plaintext
MAIN
    DEFINE mydoc om.DomDocument
    DEFINE n om.DomNode
    LET mydoc = om.DomDocument.create("Test")
    LET n = mydoc.getDocumentElement()
END MAIN
```

**Related concepts**

- The DomNode class on page 2436
The `om.DomNode` class provides methods to manipulate a DOM node of a data tree.

**om.DomDocument.getElementById**

Returns a node element ID based on the internal AUI tree id.

### Syntax

```javascript
getDocumentById(
  id INTEGER )
RETURNS om.DomNode
```

### Usage

The method `getElementById()` returns the `om.DomNode` element of the DOM document based on the internal id number passed as parameter.

Each DOM node gets an internal integer id when it is created in the abstract user interface tree. It can be referenced by this unique id. The node id is typically used in other nodes, to reference a node in the DOM document.

To hold the reference to the root node, define a variable with the `om.DomNode` type.

### Example

```plaintext
MAIN
  DEFINE uid om.DomDocument
  DEFINE n om.DomNode
  LET uid = ui.Interface.getDocument()
  MENU "test"
    COMMAND "Get UI node by ID"
      LET n = uid.getElementById(1)
      IF n IS NOT NULL THEN
        DISPLAY n.toString()
      END IF
    COMMAND "Exit"
    EXIT MENU
  END MENU
END MAIN
```

### Related concepts

- **The DomNode class** on page 2436
- **om.DomNode.getId** on page 2447

### Syntax

```javascript
createChars(
  value STRING )
RETURNS om.DomNode
```

1. `value` defines the content of the text node.

### Usage

Use the method `createChars()` to create a new `om.DomNode` text node. The content of the text node must be passed as parameter.
The created node will have the reserved tagName "@chars", and a single attribute named "@chars" storing the character data.

To hold the reference to the new node, define a variable with the om.DomNode type.

**Example**

```
MAIN
  DEFINE mydoc  om.DomDocument
  DEFINE root, text om.DomNode
  LET mydoc = om.DomDocument.create("Test")
  LET root = mydoc.getDocumentElement()
  LET text = mydoc.createChars("Hello, world!")
  DISPLAY text.getAttribute("@chars")
  CALL root.appendChild(text)
  CALL root.writeXML("output.xml")
END MAIN
```

**Related concepts**

- The DomNode class on page 2436
- The om.DomNode class provides methods to manipulate a DOM node of a data tree.

```
createElement ( 
  tagName STRING ) 
RETURNS om.DomNode
```

1. *tagName* defines the tag name of the node.

**Usage**

Use the method `createElement()` to create a new om.DomNode element node. The tag name of the element must be passed as parameter.

To hold the reference to the new node, define a variable with the om.DomNode type.

**Example**

```
MAIN
  DEFINE mydoc om.DomDocument
  DEFINE n om.DomNode
  LET mydoc = om.DomDocument.create("Test")
  LET n = mydoc.createElement("Car")
END MAIN
```

**Related concepts**

- The DomNode class on page 2436
- The om.DomNode class provides methods to manipulate a DOM node of a data tree.

```
createEntity ( 
  name STRING )
```

Create a new entity node in the DOM document.
RETURNS `om.DomNode`

1. *name* defines the name of the entity node.

**Usage**

Use the method `createEntity()` to create a new `om.DomNode` entity node. The entity name must be passed as parameter.

The text representation of a entity node is `&name;`.

The created node will have the reserved `tagName` "@entity", with a single attribute named "@entity" containing the text of the entity.

To hold the reference to the new node, define a variable with the `om.DomNode` type.

**Example**

```plaintext
MAIN
  DEFINE mydoc om.DomDocument
  DEFINE n om.DomNode
  LET mydoc = om.DomDocument.create("Test")
  LET n = mydoc.createEntity("quote")
END MAIN
```

**Related concepts**

The DomNode class on page 2436

The `om.DomNode` class provides methods to manipulate a DOM node of a data tree.

`om.DomDocument.copy`

Create a new element node by copying an existing node.

**Syntax**

```plaintext
copy(
  old om.DomNode,
  deep INTEGER
)
RETURNS om.DomNode
```

1. *old* references the source node to copy.
2. *deep* is a boolean to control the recursive node copy.

**Usage**

Use the method `copy()` to create a new `om.DomNode` element node from an existing node.

Pass `TRUE` as second parameter to clone a complete tree of nodes.

To hold the reference to the new node, define a variable with the `om.DomNode` type.

**Example**

```plaintext
MAIN
  DEFINE mydoc om.DomDocument
  DEFINE n, s om.DomNode
  LET s = mydoc.createElement("Car")
  LET n = mydoc.copy(s, TRUE)
END MAIN
```

**Related concepts**

The DomNode class on page 2436
The `om.DomNode` class provides methods to manipulate a DOM node of a data tree.

*om.DomDocument.removeElement*
Remove a DomNode object and all its descendants.

**Syntax**

```javascript
removeElement(
    oldChild om.DomNode)
```

1. `oldChild` is the DOM node to be removed.

**Usage**

Use the `removeElement()` method to remove an element and all its descendants from DOM document. Any reference to the removed `om.DomNode` objects becomes invalid.

**Examples**

*om.DomDocument usage examples.*

*Example 1: Creating a DOM document*

```javascript
MAIN
    DEFINE d om.DomDocument
    DEFINE r om.DomNode
    LET d = om.DomDocument.create("MyDocument")
    LET r = d.getDocumentElement()
END MAIN
```

---

**The DomNode class**

The `om.DomNode` class provides methods to manipulate a DOM node of a data tree.

This class follows the DOM standards.

A DomNode object is a node (or element) of a `DomDocument`.

Tag and attribute names of DOM nodes are case sensitive; "Wheel" is not the same as "wheel".

Text nodes cannot have attributes, but they have plain text. In text nodes, the characters can be accessed with the `@chars` attribute name. In XML representation, a text node is the text itself. Do not confuse it with the parent node. For example, `<Item id="32">Red shoes</Item>` represents 2 nodes: The parent 'Item' node and a text node with string 'Red shoes'.

If you need to identify an element, use a common attribute like "name". If you need to label an element, use a common attribute like "text".
### om.DomNode methods
Methods of the om.DomNode class.

#### Table 496: Object methods: Node creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>

</table>
### Table 498: Object methods: Node identification

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| `getId()`     | RETURNS INTEGER
|               | Returns the internal AUI tree id of a DOM node.                             |
| `getTagName()`| RETURNS STRING
|               | Returns the XML tag name of a DOM node.                                     |

### Table 499: Object methods: Attributes management

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| `getAttribute(name STRING)`               | RETURNS STRING
|                                           | Returns the value of a DOM node attribute.                                  |
| `getAttributesCount()`                    | RETURNS INTEGER
|                                           | Returns the number of attributes in the DOM node.                           |
| `getAttributeInteger(name STRING, defaultValue STRING)` | RETURNS INTEGER
|                                           | Returns the value of a DOM node attribute, with default integer value.      |
| `getAttributeString(name STRING, defaultValue STRING)` | RETURNS STRING
|                                           | Returns the value of a DOM node attribute, with default string value.       |
| `getAttributeName(index INTEGER)`         | RETURNS STRING
|                                           | Returns the name of a DOM node attribute by position.                       |
| `getAttributeValue(index INTEGER)`        | RETURNS STRING
|                                           | Returns the value of a DOM node attribute by position.                      |
| `setAttribute(name STRING, value STRING)` | Sets the value of a DOM node attribute.                                     |
| `removeAttribute(name STRING)`            | RETURNS STRING
|                                           | Delete the specified attribute from the DOM node.                          |
Table 500: Object methods: Tree navigation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getChildByIndex(index)</td>
<td>Returns a child DOM node by position.</td>
</tr>
<tr>
<td>getFirstChild()</td>
<td>Returns the first child DOM node.</td>
</tr>
<tr>
<td>getLastChild()</td>
<td>Returns the last child DOM node.</td>
</tr>
<tr>
<td>getNext()</td>
<td>Returns the next sibling DOM node of this node.</td>
</tr>
<tr>
<td>getParent()</td>
<td>Returns the parent DOM node.</td>
</tr>
<tr>
<td>getPrevious()</td>
<td>Returns previous sibling DOM node of this node.</td>
</tr>
<tr>
<td>selectByPath(path)</td>
<td>Finds descendant DOM nodes from an XPath-like pattern.</td>
</tr>
<tr>
<td>selectByTagName(tagName)</td>
<td>Finds descendant DOM nodes based on a tag name.</td>
</tr>
</tbody>
</table>

**omDOMNode.appendChild**

Adds an existing node at the end of the list of children in the current node.

**Syntax**

```plaintext
appendChild(newChild omDOMNode)
```

1. `newChild` is a reference to a node.

**Usage**

The `appendChild()` method takes an existing `omDOMNode` element node and adds it at the end of the children of the object node calling the method.
The child node passed to the `appendChild()` method must have been created from the same DOM document object, for example with the `om.DOMDocument.createElement()` method.

If the node passed to the `appendChild()` method is already attached to another parent node, it will be detached from that parent node before being attached to the new parent node.

**Example**

```plaintext
DEFINE parent, child om.DomNode
...
LET child = parent.appendChild("Item")
```

For a complete example, see Example 1: Creating a DOM tree on page 2456.

**Related concepts**
- `om.DOMDocument.replaceChild` on page 2451
  Replaces a node by another in the child nodes of the current node.
- `om.DOMDocument.removeChild` on page 2450
  Deletes the specified child node from the current node.
- `om.DOMDocument.createElement` on page 2434
  Create a new element node in the DOM document.
- `om.DomNode.createChild`
  Creates and adds a node at the end of the list of children in the current node.

**Syntax**

```plaintext
createChild (tagName STRING )
RETURNS om.DomNode
```

1. `tagName` is the tag name of the new node.

**Usage**
The `createChild()` method creates a new `om.DomNode` element with the tag name passed as parameter, and adds it at the end of the children of the object node calling the method.

The method returns the reference to the created object.

**Example**

```plaintext
DEFINE parent, child om.DomNode
...
LET child = parent.createChild("Item")
```

For a complete example, see Example 1: Creating a DOM tree on page 2456.

**Related concepts**
- `om.DOMNode.appendChild` on page 2439
  Adds an existing node at the end of the list of children in the current node.
- `om.DOMNode.insertBefore`
  Inserts an existing node before the existing node specified.

**Syntax**

```plaintext
insertBefore (newChild om.DomNode,
```

oldChild om.DomNode)

1. *newChild* is a reference to a new created node.
2. *oldChild* is a reference to a child node existing in the current node.

**Usage**

The `insertBefore()` method takes an existing `om.DomNode` element node and inserts it before the child node passed as second parameter, in the list of nodes of the object node calling the method.

The child node passed to the `insertBefore()` method must have been created from the same DOM document object, for example with the `om.DomDocument.createElement()` method.

**Important:** When using the `om` API to update the AUI tree, it is not possible to insert nodes, if the parent node has already been synchronized with the front-end. Child nodes can be inserted, only if the parent node is not yet synchronized with the front-end. For more details, see [Manipulating the abstract user interface tree](#) on page 1010.

**Example**

```
DEFINE parent, other, child om.DomNode
...
LET child = mydoc.createElement("Item")
CALL parent.insertBefore(child, other)
```

**Related concepts**

- `om.DomDocument.createElement` on page 2434
  Create a new element node in the DOM document.

- `om.DomNode.loadXml`
  Load an XML file into the current node.

**Syntax**

```
loadXml(
    path STRING )
RETURNS om.DomNode
```

1. *path* is the path to the XML file.

**Usage**

The `loadXml()` method takes a file path as parameter and loads the XML content into the current node, by creating a new DOM structure in memory. The method then returns the created child DOM node.

To hold the reference to the new node, define a variable with the `om.DomNode` type.

**Example**

```
DEFINE parent, new om.DomNode
...
LET new = parent.loadXml("myfile.xml")
```

**Related concepts**

- `om.DomNode.writeXml` on page 2456
Creates an XML file from the current DOM node.

*om.DomNode.parse*

Parses an XML formatted string and creates the DOM structure in the current node.

**Syntax**

```
parse(
  s STRING
) RETURNS om.DomNode
```

1. *s* is an XML formatted string.

**Usage**

The `parse()` method scans the XML formatted string passed as parameter and creates the corresponding DOM nodes in the current node. The method then returns the created child DOM node.

The node must be created before it is passed as parameter to this method, typically, with `om.DomDocument.createElement()`.

**Example**

```
DEFINE parent, child om.DomNode
...
LET child = parent.parse("<Item/>")
```

**Related concepts**

*om.DomNode.toString* on page 2455
Serializes the current node into an XML formatted string.

*om.DomNode.getAttribute*

Returns the value of a DOM node attribute.

**Syntax**

```
getAttribute(
  name STRING
) RETURNS STRING
```

1. *name* is the name of the attribute.

**Usage**

The `getAttribute()` method returns the value of the attribute passed as parameter, as defined in the current node.

DOM node attribute names are case-sensitive.

If the attribute does not exist for this node type, or if the attribute is not set, the method returns NULL.

For character nodes (created for example with the `createChars()` of a `DomDocument` object), you can get the text value by passing the @chars attribute name to the method.

**Example**

```
DEFINE node om.DomNode
...
DISPLAY node.getAttribute("color")
```
Related concepts

**om.DomNode.getAttributeString** on page 2444
Returns the value of a DOM node attribute, with default string value.

**om.DomNode.getAttributeInteger** on page 2443
Returns the value of a DOM node attribute, with default integer value.

**om.DomNode.setAttribute** on page 2454
Sets the value of a DOM node attribute.

**om.DomDocument.createChars** on page 2433
Create a new text node in the DOM document.

**om.DomNode.getAttributeInteger**
Returns the value of a DOM node attribute, with default integer value.

### Syntax

```plaintext
getAttributeInteger(
    name STRING,
    defaultValue STRING)
RETURNS INTEGER
```

1. `name` is the name of the attribute.
2. `defaultValue` is the default value.

### Usage

The `getAttributeInteger()` method returns the value of the attribute passed as parameter, as defined in the current node.

DOM node attribute names are case-sensitive.

If the attribute is not defined, the method returns the default value passed as second parameter.

**Related concepts**

**om.DomNode.getAttribute** on page 2442
Returns the value of a DOM node attribute.

**om.DomNode.setAttribute** on page 2454
Sets the value of a DOM node attribute.

**om.DomNode.getAttributesCount**
Returns the number of attributes in the DOM node.

### Syntax

```plaintext
getAttributesCount()
RETURNS INTEGER
```

### Usage

The `getAttributesCount()` method returns the number of attributes defined in the current node.

This method is typically used to scan all the attributes of a node by position, with the `getAttributeName()` and `getAttributeValue()` methods.

**Example**

```plaintext
FUNCTION display_attribute_names(node om.DomNode)
    DEFINE index, count INTEGER
```
LET count = node.getAttributeCount()
FOR index = 1 TO count
    DISPLAY node.getAttributeName(index)
END FOR
END FUNCTION

Related concepts

`om.DomNode.getAttributeName` on page 2444
Returns the name of a DOM node attribute by position.

`om.DomNode.getAttributeValue` on page 2445
Returns the value of a DOM node attribute by position.

`om.DomNode.getAttributeString`
Returns the value of a DOM node attribute, with default string value.

Syntax

```plaintext
getAttributeString(
    name STRING,
    defaultValue STRING )
RETURNS STRING
```

1. `name` is the name of the attribute.
2. `defaultValue` is the default value.

Usage

The `getAttributeString()` method returns the value of the attribute passed as parameter, as defined in the current node.

DOM node attribute names are case-sensitive.

If the attribute is not defined, the method returns the default value passed as second parameter.

Related concepts

`om.DomNode.getAttribute` on page 2442
Returns the value of a DOM node attribute.

`om.DomNode.setAttribute` on page 2454
Sets the value of a DOM node attribute.

`om.DomNode.getAttributeName`
Returns the name of a DOM node attribute by position.

Syntax

```plaintext
getAttributeName(
    index INTEGER )
RETURNS STRING
```

1. `index` is the index of the attribute, starts at 1.

Usage

The `getAttributeName()` method returns the name of an attribute by position in the current node.

DOM node attribute names are case-sensitive.

If the attribute does not exist at the given position, the method returns `NULL`.
Example

```om
DEFINE node om.DomNode
...
DISPLAY node.getAttributeName(12)
```

For a complete example, see Example 2: Displaying a DOM tree recursively on page 2457.

Related concepts

- `om.DomNode.getAttributeValue` on page 2445
  Returns the value of a DOM node attribute by position.
- `om.DomNode.getAttributesCount` on page 2443
  Returns the number of attributes in the DOM node.

`om.DomNode.getAttributeValue`
Returns the value of a DOM node attribute by position.

Syntax

```om
getAttributeValue(
    index INTEGER
) RETURNS STRING
```

1. `index` is the index of the attribute, starts at 1.

Usage

The `getAttributeValue()` method returns the value of an attribute by position in the current node.

DOM node attribute names are case-sensitive.

If the attribute does not exist at the given position, the method returns `NULL`.

Example

```om
DEFINE node om.DomNode
...
DISPLAY node.getAttributeValue(12)
```

For a complete example, see Example 2: Displaying a DOM tree recursively on page 2457.

Related concepts

- `om.DomNode.getAttributeName` on page 2444
  Returns the name of a DOM node attribute by position.
- `om.DomNode.getAttributesCount` on page 2443
  Returns the number of attributes in the DOM node.

`om.DomNode.getChildByIndex`
Returns a child DOM node by position.

Syntax

```om
getChildByIndex(
    index INTEGER
) RETURNS om.DomNode
```

1. `index` is the index of the child node, starts at 1.
Usage

The `get_childByIndex()` method returns the child DOM node by position in the current node. If there is no child node at the given position, the method returns `NULL`.

Related concepts

`om.DomNode.getChildCount` on page 2446
Returns the number of children nodes.

`om.DomNode.getChildCount`
Returns the number of children nodes.

Syntax

```plaintext
get_childCount()
RETURNS INTEGER
```

Usage

The `get_childCount()` method returns the number of child nodes in the current node. This method is typically used to scan the child nodes of a DOM node, with the `get_childByIndex()` method.

Example

```plaintext
FUNCTION display_children(node om.DomNode)
    DEFINE index, count INTEGER
    DEFINE child om.DomNode
    LET count = node.get_childCount()
    FOR index = 1 TO count
        LET child = node.get_childByIndex(index)
        DISPLAY child.toString()
    END FOR
END FUNCTION
```

Related concepts

`om.DomNode.get_childByIndex` on page 2445
Returns a child DOM node by position.

`om.DomNode.getFirstChild`
Returns the first child DOM node.

Syntax

```plaintext
get_firstChild()
RETURNS om.DomNode
```

Usage

The `get_firstChild()` method returns the first child DOM node in the current node. This method is typically used to scan child nodes with the `getNext()` method, until `getNext()` returns `NULL`.

Example

```plaintext
FUNCTION display_children(node om.DomNode)
    DEFINE child om.DomNode
    LET child = node.get_firstChild()
    WHILE child IS NOT NULL
        LET child = child.getNext()
```
Related concepts

- `om.DomNode.getNext` on page 2448
  Returns the next sibling DOM node of this node.

- `om.DomNode.getPrevious` on page 2449
  Returns previous sibling DOM node of this node.

- `om.DomNode.getItemId`
  Returns the internal AUI tree id of a DOM node.

Syntax

```plaintext
getId()
RETURNS INTEGER
```

Usage

The `getId()` method returns an internal integer identifier generated automatically for any `om.DomNode` object created in the abstract user interface tree.

The internal id is typically used to reference a DOM node in an attribute of another node, to link nodes logically together.

If the DOM node does not belong to the AUI tree, the method returns zero.

Related concepts

- `om.DomDocument.getElementById` on page 2433
  Returns a node element ID based on the internal AUI tree id.

- `om.DomNode.getLastChild`
  Returns the last child DOM node.

Syntax

```plaintext
getLastChild()
RETURNS om.DomNode
```

Usage

The `getLastChild()` method returns the last child DOM node in the current node.

This method is typically used to scan child nodes with the `getPrevious()` method, until `getPrevious()` returns `NULL`.

Example

```plaintext
FUNCTION display_children(node om.DomNode)
    DEFINE child om.DomNode
    LET child = node.getLastChild()
    WHILE child IS NOT NULL
        DISPLAY child.toString()
        LET child = child.getPrevious()
    END WHILE
END FUNCTION
```
Related concepts

*om.DomNode.getPrevious* on page 2449
Returns previous sibling DOM node of this node.

*om.DomNode.getNext* on page 2448
Returns the next sibling DOM node of this node.

Syntax

```javascript
getNext ()
RETURNS om.DomNode
```

Usage

The `getNext()` method returns the next sibling DOM node following the current node, within the children list of the parent node.

Related concepts

*om.DomNode.getFirstChild* on page 2446
Returns the first child DOM node.

*om.DomNode.getPrevious* on page 2449
Returns previous sibling DOM node of this node.

*om.DomNode.getParent*
Returns the parent DOM node.

Syntax

```javascript
getParent ()
RETURNS om.DomNode
```

Usage

The `getParent()` method returns the parent DOM node of the current node.

If the current node is the root node, the method returns `NULL`.

Example

```javascript
DEFINE parent, current om.DomNode
...
LET parent = current.getParent()
```

Related concepts

*om.DomNode.getFirstChild* on page 2446
Returns the first child DOM node.

*om.DomNode.getLastChild* on page 2447
Returns the last child DOM node.
Returns the last child DOM node.

*om.DonNode.getLastChild*  
Returns the last child DOM node.

**Syntax**

```
getPrevious()
RETURNS om.DomNode
```

**Usage**

The `getPrevious()` method returns the previous sibling DOM node preceding the current node, within the children list of the parent node.

**Related concepts**

*om.DonNode.getLastChild* on page 2447  
Returns the last child DOM node.

*om.DonNode getNext* on page 2448  
Returns the next sibling DOM node of this node.

*om.DonNode.getTagNode*  
Returns the XML tag name of a DOM node.

**Syntax**

```
tagName()
RETURNS STRING
```

**Usage**

The `getTagName()` method returns the XML tag name of the node.  
Use this method to identify the type of the node.

*om.DonNode.removeAttribute*  
Delete the specified attribute from the DOM node.

**Syntax**

```
removeAttribute(
    name STRING )
RETURNS STRING
```

1. `name` is the name of the attribute.

**Usage**

The `removeAttribute()` method deletes the attribute identified by the name passed as parameter.  
DOM node attribute names are case-sensitive.  
If the attribute does not exist for this node the method returns silently.

**Example**

```
DEFINE node om.DomNode
...
```
CALL node.removeAttribute("comments")

Related concepts

om.DomNode.setAttribute on page 2454
Sets the value of a DOM node attribute.

om.DomNode.removeChild
Deletesthe specified child node from the current node.

Syntax

```javascript
removeChild(
  node om.DomNode
)
```

1. `node` is a reference to a node.

Usage

The `removeChild()` method detaches an `om.DomNode` element node from the current node. The removed node is not destroyed, if it is still referenced by a variable. The `removeChild()` method will only break the link between the parent node and the child node. The child node still exists in the DOM document, but it is an orphan node, that can be attached to another parent node in the document.

Example

```javascript
MAIN
  DEFINE doc om.DomDocument,
      r om.DomNode,
      p om.DomNode,
      c om.DomNode

  LET doc = om.DomDocument.create("Items")

  LET r = doc.createElement("Zoo")
  CALL r.appendChild(p)

  LET c = doc.createElement("Dodo")
  CALL c.setAttribute("name", "momo")
  CALL c.setAttribute("gender", "male")
  CALL p.appendChild(c)

  CALL r.writeXml("file1.xml")

  CALL p.removeChild(c)

  -- c is orphan but still exists
  CALL c.writeXml("file2.xml")
  LET c = NULL -- unref/destroy the node

  CALL r.writeXml("file3.xml")
END MAIN
```

The above program will produce the following files:

**file1.xml**

```xml
<?xml version='1.0' encoding='ASCII'?>
<Zoo>
 <DodoList>
```

Related concepts

- `om.DomNode.appendChild` on page 2439
  Adds an existing node at the end of the list of children in the current node.

- `om.DomNode.replaceChild` on page 2451
  Replaces a node by another in the child nodes of the current node.

**Syntax**

```
replaceChild(
    new om.DomNode,
    old om.DomNode)
```

1. `new` is a reference to the new node.
2. `old` is the node to be replaced.

**Usage**

The `replaceChild()` method puts the `om.DomNode` element passed as first parameter at the place of the node referenced by the second parameter, in the children list of the object node calling the method.

The new child node passed to the `replaceChild()` method must have been created from the same DOM document object, for example with the `om.DomDocument.createElement()` method.

The old node is not destroyed, if it is still referenced by a variable. The old node still exists in the DOM document, but it is an orphan node, that can be attached to another parent node in the document.

**Example**

```
MAIN
    DEFINE doc om.DomDocument,
           r om.DomNode,
           p om.DomNode,
           o om.DomNode,
           n om.DomNode

    LET doc = om.DomDocument.create("Items")

    LET r = doc.createElement("Zoo")
    LET p = doc.createElement("DodoList")
    CALL r.appendChild(p)
```
LET o = doc.createElement("Dodo")
CALL o.setAttribute("name", "momo")
CALL o.setAttribute("gender", "male")
CALL p.appendChild(o)

CALL r.writeXml("file1.xml")

LET n = doc.createElement("Dodo")
CALL n.setAttribute("name", "kiki")
CALL n.setAttribute("gender", "female")

CALL p.replaceChild(n, o)

-- o is orphan but still exists
CALL o.writeXml("file2.xml")
LET o = NULL -- unref/destroy the node

CALL r.writeXml("file3.xml")
END MAIN

The above program will produce following files:

file1.xml

<?xml version='1.0' encoding='ASCII'?>
<Zoo>
  <DodoList>
    <Dodo name="momo" gender="male"/>
  </DodoList>
</Zoo>

file2.xml

<?xml version='1.0' encoding='ASCII'?>
<Dodo name="momo" gender="male"/>

file3.xml

<?xml version='1.0' encoding='ASCII'?>
<Zoo>
  <DodoList>
    <Dodo name="kiki" gender="female"/>
  </DodoList>
</Zoo>

Related concepts

*om.DomNode.appendChild* on page 2439
Adds an existing node at the end of the list of children in the current node.

*om.DomNode.removeChild* on page 2450
Deletes the specified child node from the current node.

*om.DomDocument.createElement* on page 2434
Create a new element node in the DOM document.

*om.DomNode.selectByPath*
Finds descendant DOM nodes from an XPath-like pattern.

**Syntax**

```javascript
selectByPath()
```

library reference 2453

<table>
<thead>
<tr>
<th>path STRING</th>
</tr>
</thead>
<tbody>
<tr>
<td>RETURNS om.NodeList</td>
</tr>
</tbody>
</table>

1. *path* is an XPath-like pattern.

**Usage**

The `selectByPath()` method scans the DOM tree for descendant nodes from the specified XPath-like pattern.

**Important:** The `selectByPath()` method supports a limited XPath syntax.

The search pattern must always start with `/` or `//`, must contain at least on tag name, and the attributes expression allows only equality comparison.

The pattern supported by `selectByPath()` is limited to the following syntax:

```markdown
{ | / | // } TagName [ [@AttributeName="Value"] ] [...]
```

DOM node tag names and attributes names are case-sensitive.

The method creates a list of nodes as an `om.NodeList` object. This list object is then used to process the nodes found.

**Table 501: XPath examples**

<table>
<thead>
<tr>
<th>XPath expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/Vehicle</code></td>
<td>The document element <code>&lt;Vehicle/&gt;</code> of this document.</td>
</tr>
<tr>
<td><code>//Vehicle</code></td>
<td>All <code>&lt;Vehicle/&gt;</code> elements in the document.</td>
</tr>
<tr>
<td><code>//Transport/Vehicle</code></td>
<td>All <code>&lt;Vehicle/&gt;</code> elements that are children of <code>&lt;Transport/&gt;</code> elements.</td>
</tr>
<tr>
<td><code>//Transport//Engine</code></td>
<td>All <code>&lt;Engine/&gt;</code> elements that are arbitrary descendants of <code>&lt;Transport/&gt;</code> elements.</td>
</tr>
<tr>
<td><code>//Transport/*/Engine</code></td>
<td>All <code>&lt;Engine/&gt;</code> elements that are grandchildren of <code>&lt;Transport/&gt;</code> elements.</td>
</tr>
<tr>
<td><code>//Transport/*</code></td>
<td>All elements that are children of <code>&lt;Transport/&gt;</code> elements.</td>
</tr>
<tr>
<td><code>//Engine[@power=&quot;185&quot;]</code></td>
<td>All <code>&lt;Engine/&gt;</code> elements where the <code>power</code> attribute equals 185.</td>
</tr>
<tr>
<td><code>//Vehicle[@type=&quot;car&quot;]/Engine[@power=&quot;185&quot;]</code></td>
<td>All <code>&lt;Engine/&gt;</code> elements where the <code>power</code> attribute equals 185, children of <code>&lt;Vehicle/&gt;</code> elements where the <code>type</code> attribute is &quot;car&quot;.</td>
</tr>
</tbody>
</table>

**Example**

```javascript
DEFINE node om.DomNode,
     nodelist om.NodeList
...
LET nodelist = node.selectByPath("//Grid/Table[@tabName="t1"]")
```
For a complete example, see Example 2: Search nodes by XPath on page 2460.

**Related concepts**

The NodeList class on page 2458
A om.NodeList object hold a list of DOM nodes.

*om.DomNode.selectByTagName*

Finds descendant DOM nodes based on a tag name.

**Syntax**

```
selectByTagName(
    tagName STRING
)RETURNS om.NodeList
```

1. `tagName` is a tag name for the search.

**Usage**

The `selectByTagName()` method scans the DOM tree for descendant nodes defined with the tag name specified as parameter.

DOM node tag names are case-sensitive.

The method creates a list of nodes as a `om.NodeList` object. This list object is then used to process the nodes found.

**Example**

```
DEFINE node om.DomNode,
    nodelist om.NodeList
...
LET nodelist = node.selectByTagName("Car")
```

For a complete example, see Example 1: Search nodes by tag name on page 2459.

**Related concepts**

The NodeList class on page 2458
A om.NodeList object hold a list of DOM nodes.

*om.DomNode.setAttribute*

Sets the value of a DOM node attribute.

**Syntax**

```
setAttribute(
    name STRING, 
    value STRING 
)
```

1. `name` is the name of the attribute.
2. `value` is the attribute value.

**Usage**

The `setAttribute()` method sets the value of an attribute in the current node.

DOM node attribute names are case-sensitive.

**Note:** Make sure that the strings passed to the method do not contain illegal XML characters. Illegal XML characters will be silently ignored. Illegal XML characters are any character below space (ASCII 32), except \r (ASCII 13), \n (ASCII 10) and \t (ASCII 9).
Example

```oml
DEFINE node om.DomNode...
CALL node.setAttribute("name", "tiger")
```

For a complete example, see Example 1: Creating a DOM tree on page 2456.

**Related concepts**

- `om.DomNode.getAttribute` on page 2442
  Returns the value of a DOM node attribute.
- `om.DomNode.getAttributeString` on page 2444
  Returns the value of a DOM node attribute, with default string value.
- `om.DomNode.getAttributeInteger` on page 2443
  Returns the value of a DOM node attribute, with default integer value.

**om.DomNode.toString**

Serializes the current node into an XML formatted string.

**Syntax**

```oml
toString()
RETURNS STRING
```

**Usage**

The `toString()` method builds an XML formatted string with the DOM structure of the current node and returns the string.

Example

```oml
DEFINE node om.DomNode, s STRING...
LET s = node.toString()
```

**Related concepts**

- `om.DomNode.parse` on page 2442
  Parses an XML formatted string and creates the DOM structure in the current node.

- `om.DomNode.write`
  Processes a DOM document with a SAX document handler.

**Syntax**

```oml
write(
    sdh om.SaxDocumentHandler)
```

1. `sdh` references a SAX document handler.

**Usage**

The `write()` method processes the current DOM node content with the SAX document handler passed as parameter.

See the SAX document handler class for more details.

**Related concepts**

- The SaxDocumentHandler class on page 2467
The `om.SaxDocumentHandler` class provides an interface to write an XML filter with events.

**om.DonNode.writeXml**

Creates an XML file from the current DOM node.

**Syntax**

```plaintext
writeXml(
    path STRING )
```

1. `path` is the path to the XML file.

**Usage**

The `writeXml()` method writes the content of the current DOM node to the file passed as parameter.

**Example**

```plaintext
DEFINE node om.DonNode
...
CALL noe.writeXml("output.xml")
```

**Related concepts**

`om.DonNode.loadXml` on page 2441
Load an XML file into the current node.

**Examples**

`om.DonNode` usage examples.

**Example 1: Creating a DOM tree**

To create a DOM tree with the following structure (represented in XML format):

```xml
<Vehicles>
  <Car name="Corolla" color="Blue" weight="1546">Nice car!</Car>
  <Bus name="Maxibus" color="Yellow" weight="5278">
    <Wheel width="315" diameter="925" />
    <Wheel width="315" diameter="925" />
    <Wheel width="315" diameter="925" />
    <Wheel width="315" diameter="925" />
  </Bus>
</Vehicles>
```

You write the following:

```plaintext
MAIN
  DEFINE d om.DonDocument
  DEFINE r, n, t, w om.DonNode
  DEFINE i INTEGER
  LET d = om.DonDocument.create("Vehicles")
  LET r = d.getDocumentElement()
  LET n = r.createElement("Car")
  CALL n.setAttribute("name","Corolla")
  CALL n.setAttribute("color","Blue")
  CALL n.setAttribute("weight","1546")
  LET t = d.createChars("Nice car!")
  CALL n.appendChild(t)
  CALL n.appendChild(t)
```
LET t = d.createChars("Yes, very nice!")
CALL n.appendChild(t)

LET n = r.createChild("Bus")
CALL n.setAttribute("name","Maxibus")
CALL n.setAttribute("color","yellow")
CALL n.setAttribute("weight","5278")
FOR i=1 TO 4
  LET w = n.createChild("Wheel")
  CALL w.setAttribute("width","315")
  CALL w.setAttribute("diameter","925")
END FOR

CALL r.writeXml("Vehicles.xml")
END MAIN

Example 2: Displaying a DOM tree recursively

The following example displays a DOM tree content recursively:

FUNCTION displayDomNode(n,e)
  DEFINE n om.DomNode
  DEFINE e, i, s INTEGER

  LET s = e*2
  DISPLAY s SPACES || "Tag: " || n.getTagName()

  DISPLAY s SPACES || "Attributes:
  FOR i=1 TO n.getAttributesCount()
    DISPLAY s SPACES || "  " || n.getAttributeName(i) || ":" || n.getAttributeValue(i) || ""
  END FOR
  LET n = n.getFirstChild()

  DISPLAY s SPACES || "Child Nodes:
  WHILE n IS NOT NULL
    CALL displayDomNode(n,e+1)
    LET n = n.getNext()
  END WHILE

END FUNCTION

Example 3: Writing a DOM tree to a SAX handler

The following example outputs a DOM tree without indentation.

MAIN
  DEFINE d  om.DomDocument
  DEFINE r, n, t, w om.DomNode
  DEFINE dh om.SaxDocumentHandler
  DEFINE i INTEGER

  LET dh = om.XmlWriter.createPipeWriter("cat")
  CALL dh.setIndent(FALSE)

  LET d = om.DomDocument.create("Vehicles")
  LET r = d.getDocumentElement()

  LET n = r.createChild("Car")
  CALL n.setAttribute("name","Corolla")
  CALL n.setAttribute("color","Blue")
CALL n.setAttribute("weight","1546")

LET t = d.createChars("Nice car!")
CALL n.appendChild(t)

LET n = r.createChild("Bus")
CALL n.setAttribute("name","Maxibus")
CALL n.setAttribute("color","yellow")
CALL n.setAttribute("weight","5278")
FOR i=1 TO 4
  LET w = n.createChild("Wheel")
  CALL w.setAttribute("width","315")
  CALL w.setAttribute("diameter","925")
END FOR

CALL r.write(dh)
END MAIN

The NodeList class
A om.NodeList object holds a list of DOM nodes.

The list is created from an om.DomNode.selectByTagName() or om.DomNode.selectByPath() method.

After creating the node list, you can process the nodes with the getLength() and item() methods of the om.NodeList object.

om.NodeList methods
Methods of the om.NodeList class.

Table 502: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getLength()</td>
<td>Returns the number of elements in the node list.</td>
</tr>
<tr>
<td>item( index INTEGER )</td>
<td>Returns a DOM node element by position in the node list.</td>
</tr>
</tbody>
</table>

om.NodeList.getLength
Returns the number of elements in the node list.

Syntax

getLength()
RETURNS INTEGER

1. node is a reference to a node.

Usage

The getLength() method returns the size of the node list.

Query the node list for elements with the item() method, in the range 1 to getLength().

Example

DEFINE list om.NodeList
... 
DISPLAY list.getLength() 

For a complete example, see Example 1: Search nodes by tag name on page 2459.

Related concepts

**om.DomNode.selectByTagName** on page 2454  
Finds descendant DOM nodes based on a tag name.

**om.DomNode.selectByPath** on page 2452  
Finds descendant DOM nodes from an XPath-like pattern.

**om.NodeList.item**  
Returns a DOM node element by position in the node list.

**Syntax**

```plaintext
item( index INTEGER )
RETURNS om.DomNode
```

1. `index` is the ordinal position of the node in the list.

**Usage**

The `item()` method returns the `om.DomNode` object at the position specified.

First element is at position 1.

If there is no element at the specified index, the method returns NULL.

**Example**

```plaintext
DEFINE list om.NodeList, 
    node om.DomNode 
...
LET node = list.item(12) 
```

For a complete example, see Example 1: Search nodes by tag name on page 2459.

Related concepts

**om.DomNode.selectByTagName** on page 2454  
Finds descendant DOM nodes based on a tag name.

**om.DomNode.selectByPath** on page 2452  
Finds descendant DOM nodes from an XPath-like pattern.

**Examples**

om.NodeList usage examples.

**Example 1: Search nodes by tag name**

```plaintext
MAIN 
DEFINE nl om.NodeList 
DEFINE r, n om.DomNode 
DEFINE i INTEGER 

LET r = ui.Interface.getRootNode() 
LET nl = r.selectByTagName("Form") 

FOR i=1 to nl.getLength() 
    LET n = nl.item(i) 
    DISPLAY n.getAttribute("name") 
END FOR
```
**Related concepts**

*om.DomNode.selectByTagName* on page 2454
Finds descendant DOM nodes based on a tag name.

**Example 2: Search nodes by XPath**

```
MAIN
  DEFINE nl om.NodeList
  DEFINE r, n om.DomNode
  DEFINE i INTEGER

  LET r = ui.Interface.getRootNode()
  LET nl = r.selectByPath("//Window[@name="screen"]")

  FOR i=1 to nl.getLength()
    LET n = nl.item(i)
    DISPLAY n.getAttribute("name")
  END FOR
END MAIN
```

**Related concepts**

*om.DomNode.selectByPath* on page 2452
Finds descendant DOM nodes from an XPath-like pattern.

**The SaxAttributes class**
The *om.SaxAttributes* class holds a set of attributes to process with a SAX reader or writer.

To process SAX attributes, create a *om.SaxAttributes* object with a **SAX reader** or **SAX writer** object.

Get an instance of SaxAttributes with the *om.XmlReader.getAttributes()* method.

**om.SaxAttributes methods**
Methods of the *om.SaxAttributes* class.

**Table 503: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>copy(attr om.SaxAttributes)</code></td>
<td>Clones an existing SAX attributes object.</td>
</tr>
<tr>
<td><code>create()</code></td>
<td>Create a new SAX attributes object.</td>
</tr>
<tr>
<td>RETURNS om.SaxAttributes</td>
<td></td>
</tr>
</tbody>
</table>
Table 504: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>addAttribute(name STRING, value STRING)</td>
<td>Appends a new attribute to the end of the list.</td>
</tr>

<tr>
<td>setAttributes(attr om.SaxAttributes)</td>
<td>Clears the list and copies the attributes passed.</td>
</tr>
</tbody>
</table>

**om.SaxAttributes.addAttribute**

Appends a new attribute to the end of the list.

**Syntax**

```
addAttribute(
    name STRING,
    value STRING )
```

1. `name` is the name of the attribute.
2. `value` is the value of the attribute.

**Usage**

The `addAttribute()` method appends a new attribute with name and value at the end of the list. Attribute names are case-sensitive.
Note: Make sure that the strings passed to the method do not contain illegal XML characters. Illegal XML characters will be silently ignored. Illegal XML characters are any character below space (ASCII 32), except \r (ASCII 13), \n (ASCII 10) and \t (ASCII 9).

Example

```plaintext
DEFINE attrs om.SaxAttributes
...
CALL attrs.addAttribute("name","jo")
```

For a complete example, see Example 2: Creating a SAX attributes object on page 2466.

Related concepts

`om.SaxAttributes.setAttributes` on page 2466
Clears the list and copies the attributes passed.

`om.SaxAttributes.copy`
Clones an existing SAX attributes object.

Syntax

```plaintext
copy (attr om.SaxAttributes) RETURNS om.SaxAttributes
```

1. `attr` is a set of SAX attributes to clone.

Usage

The `om.SaxAttributes.copy()` class method makes a clone of the `om.SaxAttributes` object passed as reference and returns the created object.

Example

```plaintext
DEFINE copy, orig om.SaxAttributes
...
LET copy = om.SaxAttributes.copy(orig)
```

For a complete example, see Example 2: Creating a SAX attributes object on page 2466.

Related concepts

`om.SaxAttributes.create` on page 2462
Create a new SAX attributes object.

`om.SaxAttributes.create`
Create a new SAX attributes object.

Syntax

```plaintext
create ()
RETURNS om.SaxAttributes
```

Usage

The `om.SaxAttributes.create()` class method creates a new `om.SaxAttributes` object and returns it.

To hold the reference to a SAX attributes object, define a variable with the type `om.SaxAttributes` type.
Example

```define attrs om.SaxAttributes
.../
let attrs = om.SaxAttributes.create()
```n
For a complete example, see Example 2: Creating a SAX attributes object on page 2466.

Related concepts

`om.SaxAttributes.copy` on page 2462
Clones an existing SAX attributes object.

`om.SaxAttributes.clear`
Clears the SAX attribute list.

Syntax

```clear()
```n
Usage

Use the `clear()` method to clean the SAX attribute list.

Related concepts

`om.SaxAttributes.addAttribute` on page 2461
Appends a new attribute to the end of the list.

`om.SaxAttributes.getLength`
Returns the number of attributes in the list.

Syntax

```getLength()
returns integer
```n
Usage

The `getLength()` method returns the number of attributes in the current SAX attribute list.
Use this method with `getName()` and `getValueByIndex()` to retrieve attributes by position.

Example

```define attrs om.SaxAttributes,
index integer
.../
for index = 1 to attrs.getLength()
  display attrs.getName(index), " = ", attrs.getValueByIndex(index)
end for
```n
Related concepts

`om.SaxAttributes.getName` on page 2464
Returns the name of an attribute by position.

`om.SaxAttributes.getValueByIndex` on page 2465
Returns an attribute value by position.

`om.SaxAttributes.getName`

Returns the name of an attribute by position.

**Syntax**

```plaintext
getName(
    index INTEGER )
RETURNS STRING
```

1. `index` is the position of the attribute in the list.

**Usage**

The `getName()` method returns the name of the attribute at the specified ordinal position in the list.

If the attribute does not exist at the given position, the method returns `NULL`.

**Example**

```plaintext
DEFINE attrs om.SaxAttributes
...
DISPLAY attrs.getName(3)
```

For a complete example, see Example 2: Creating a SAX attributes object on page 2466.

**Related concepts**

- `om.SaxAttributes.getLength` on page 2463
  - Returns the number of attributes in the list.
- `om.SaxAttributes.getValueByIndex` on page 2465
  - Returns an attribute value by position.

`om.SaxAttributes.getValue`

Returns the value of an attribute by name.

**Syntax**

```plaintext
getValue(
    name STRING )
RETURNS STRING
```

1. `name` is the name of an attribute.

**Usage**

The `getValue()` method returns the value of the attribute identified by the name passed as parameter.

If the attribute does not exist, the method returns `NULL`.

**Example**

```plaintext
DEFINE attrs om.SaxAttributes
...
DISPLAY attrs.getValue("name")
```

For a complete example, see Example 2: Creating a SAX attributes object on page 2466.

**Related concepts**

- `om.SaxAttributes.getValueByIndex` on page 2465
Returns an attribute value by position.

`om.SaxAttributes.getValueByIndex`  
Returns an attribute value by position.

**Syntax**

```
getValueByIndex(
   index INTEGER 
) RETURNS STRING
```

1. *index* is the position of the attribute in the list.

**Usage**

The `getValueByIndex()` method returns the value of the attribute at the specified ordinal position in the list.

If the attribute does not exist at the given position, the method returns `NULL`.

**Example**

```
DEFINE attrs om.SaxAttributes
...
DISPLAY attrs.getValueByIndex(3)
```

For a complete example, see Example 2: Creating a SAX attributes object on page 2466.

**Related concepts**

- `om.SaxAttributes.getLength` on page 2463  
  Returns the number of attributes in the list.
- `om.SaxAttributes.getName` on page 2464  
  Returns the name of an attribute by position.

`om.SaxAttributes.removeAttribute`  
Delete an attribute by position.

**Syntax**

```
removeAttribute(
   index INTEGER 
)
```

1. *index* is the position of the attribute in the list.

**Usage**

The `removeAttribute()` method removes the attribute at the given ordinal position.

If the attribute does not exist at the given position, the method returns silently.

**Example**

```
DEFINE attrs om.SaxAttributes
...
CALL attrs.removeAttribute( attrs.getLength() )
```

For a complete example, see Example 2: Creating a SAX attributes object on page 2466.

**Related concepts**

- `om.SaxAttributes.add Attribute` on page 2461
Appends a new attribute to the end of the list.

**om.SaxAttributes.setAttributes**
Clears the list and copies the attributes passed.

### Syntax

```java
setAttributes(
    attr om.SaxAttributes )
```

1. *attr* is a reference to a list of attributes.

### Usage

The `setAttributes()` method takes an existing `om.SaxAttributes` object reference and makes a copy of all attributes into the current attribute list.

### Example

```java
DEFINE curr, orig om.SaxAttributes
...
CALL curr.setAttributes(orig)
```

For a complete example, see Example 2: Creating a SAX attributes object on page 2466.

### Related concepts

- **om.SaxAttributes.addAttribute** on page 2461
  Appends a new attribute to the end of the list.

### Examples

- **om.SaxAttributes usage examples.**
  - **Example 1: Displaying SAX attributes of an XML node**
    ```java
    FUNCTION displayAttributes( a )
        DEFINE a om.SaxAttributes
        DEFINE i, m INTEGER
        LET m = a.getLength()
        FOR i=1 to m
            DISPLAY a.getName(i) || "=" || a.getValueByIndex(i) || ""
        END FOR
    END FUNCTION
    ```
  - **Example 2: Creating a SAX attributes object**
    ```java
    MAIN
        DEFINE a, c om.SaxAttributes,
            i, m INTEGER
        LET a = om.SaxAttributes.create()
        CALL a.addAttribute("name","Jo")
        CALL a.addAttribute("birth","2008-12-20")
        DISPLAY a.getValue("birth")
        LET c = om.SaxAttributes.copy( a )
        LET m = a.getLength()
        DISPLAY "Len = ", m
        FOR i=1 TO m
            DISPLAY i, ": ", a.getName(i),
                " = ", a.getValueByIndex(i)
        END FOR
        CALL a.removeAttribute("birth")
        CALL c.setAttributes(a)
        CALL a.clear()
    ```
The SaxDocumentHandler class
The `om.SaxDocumentHandler` class provides an interface to write an XML filter with events.

This class follows the `SAX` standards.

A `om.SaxDocumentHandler` object can be used in two different ways:

1. To implement an XML SAX filter, based of functions defined in a `.4gl` module, by using the `createForName()` class method.
2. To write an XML document to a file, process or socket output, by using `om.XmlWriter` creation methods, and the `om.SaxDocumentHandler` processing methods.

The `om.SaxDocumentHandler` class also provides methods to process all SAX events by hand. This is useful if you want to chain SAX filters.

**om.SaxDocumentHandler methods**
Methods of the `om.SaxDocumentHandler` class.

</tbody>
</table>

---

**om.SaxDocumentHandler.createForName**

Creates a new SAX document handler object for the given .4gl module.

**Syntax**

```java
om.SaxDocumentHandler.createForName(
    moduleName STRING)
RETURNS om.SaxDocumentHandler
```

1. `moduleName` is the name of the .4gl module defining the document handler events.

**Usage**

The `om.SaxDocumentHandler.createForName()` method creates a `om.SaxDocumentHandler` instance and binds the .42m module passed as argument to the object.

To hold the reference to a SAX document handler object, define a variable with the type `om.SaxDocumentHandler` type.
The module must be available as a compiled .42m file, which is loadable based on the environment settings (FGLLDPATH).

The module must implement the following functions to process the SAX filter events:

### Table 507: Functions of the SAX document handler module

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startDocument()</td>
<td>Called once at the beginning of the document processing.</td>
</tr>
<tr>
<td>endDocument()</td>
<td>Called once at the end of the document processing.</td>
</tr>
<tr>
<td>startElement( tagname STRING, attrs om.SaxAttributes )</td>
<td>Called when an XML element is reached. Use the om.SaxAttributes methods to handle the attributes of the processed element.</td>
</tr>
<tr>
<td></td>
<td>1. <em>tagname</em> is the tag name of element.</td>
</tr>
<tr>
<td></td>
<td>2. <em>attrs</em> is list of attributes.</td>
</tr>
<tr>
<td>endElement( tagname STRING )</td>
<td>Called when the end of an XML element is reached.</td>
</tr>
<tr>
<td></td>
<td>1. <em>tagname</em> is the tag name of element.</td>
</tr>
<tr>
<td>processingInstruction( piname STRING, data STRING )</td>
<td>Called when a processing instruction is reached.</td>
</tr>
<tr>
<td></td>
<td>1. <em>piname</em> is the name of the processing instruction.</td>
</tr>
<tr>
<td></td>
<td>2. <em>data</em> is the content of the processing instruction.</td>
</tr>

<td>Called when a text node is reached.</td>
</tr>
<tr>
<td></td>
<td>1. <em>data</em> is the text data.</td>
</tr>
<tr>
<td>skippedEntity( name STRING )</td>
<td>Called when an unknown entity node is reached (like &amp;xxx; for example).</td>
</tr>
<tr>
<td></td>
<td>1. <em>name</em> is the name of the unknown entity.</td>
</tr>
</tbody>
</table>

**Example**

```plaintext
DEFINE f om.SaxDocumentHandler
LET f = om.SaxDocumentHandler.createForName("mysaxmod")
...
```

For a complete example, see Example 1: Extracting phone numbers from a directory on page 2473.

**Related concepts**

- The SaxAttributes class on page 2460
- The om.SaxAttributes class holds a set of attributes to process with a SAX reader or writer.
- FGLLDPATH on page 243
Defines the search paths to load program modules.

*om.SaxDocumentHandler.characters*

Processes a text node.

**Syntax**

```java
characters(
    chars STRING )
```

1. *chars* is the content of the text node.

**Usage**

The `characters()` method processes a text node with the SAX interface.

**Note:** Make sure that the strings passed to the method do not contain illegal XML characters. Illegal XML characters will be silently ignored. Illegal XML characters are any character below space (ASCII 32), except \r (ASCII 13), \n (ASCII 10) and \t (ASCII 9).

**Related concepts**

*om.SaxDocumentHandler.skippedEntity* on page 2473

Processes an unresolved entity.

*om.SaxDocumentHandler.endDocument*

Processes the end of the document.

**Syntax**

```java
endDocument() 
```

**Usage**

The `endDocument()` method ends the document processing with the SAX interface.

**Related concepts**

*om.SaxDocumentHandler.startDocument* on page 2472

Processes the beginning of the document.

*om.SaxDocumentHandler.endElement*

Processes the end of an element.

**Syntax**

```java
endElement(
    name STRING )
```

1. *name* is the tag name of the element.

**Usage**

The `endElement()` method processes the end of an element with the SAX interface.

**Related concepts**

*om.SaxDocumentHandler.startElement* on page 2472
Processes the beginning of an element.

`om.SaxDocumentHandler.processingInstruction`

Processes a processing instruction.

**Syntax**

```
processingInstruction(
  name STRING,
  data STRING )
```

1. `name` is the name of the processing instruction (token after `<?`).
2. `data` is the string in the processing instruction tag.

**Usage**

The `processingInstruction()` method processes a processing instruction with the SAX interface.

A processing instruction appears in an XML formatted text as:

```
<?name data ?>
```

**Related concepts**

The `SaxAttributes` class on page 2460

The `om.SaxAttributes` class holds a set of attributes to process with a SAX reader or writer.

`om.SaxDocumentHandler.readXmlFile`

Reads and processes an XML file with the SAX document handler.

**Syntax**

```
readXmlFile(
  path STRING )
```

1. `path` is the path to an XML formatted file.

**Usage**

Use the `readXmlFile()` method after creating the `om.SaxDocumentHandler` object, to process the XML data from a file input stream.

**Example**

```
DEFINE f om.SaxDocumentHandler
LET f = om.SaxDocumentHandler.createForName("mysaxmod")
CALL f.readXmlFile("cars.xml")
...
```

For a complete example, see Example 1: Extracting phone numbers from a directory on page 2473.

**Related concepts**

The `SaxAttributes` class on page 2460

The `om.SaxAttributes` class holds a set of attributes to process with a SAX reader or writer.

`FGLLDPATH` on page 243
Defines the search paths to load program modules.

*om.SaxDocumentHandler.setIndent*
Controls indentation in XML output.

### Syntax

```java
setIndent ( indenting BOOLEAN )
```

1. *indenting*: TRUE enables indentation; FALSE disables indentation.

### Usage

By default, the *om.SaxDocumentHandler* object outputs XML with indentation.

In order to disable indentation, use the `setIndent(FALSE)` method.

*om.SaxDocumentHandler.startDocument*
Processes the beginning of the document.

### Syntax

```java
startDocument ()
```

### Usage

The `startDocument()` method begins the document processing with the SAX interface.

#### Related concepts

*om.SaxDocumentHandler.endDocument* on page 2470
Processes the end of the document.

*om.SaxDocumentHandler.startElement*
Processes the beginning of an element.

### Syntax

```java
startElement ( name STRING, atts om.SaxAttributes )
```

1. *name* is the tag name of the element.
2. *atts* is the list of attributes of the element.

### Usage

The `startElement()` method processes the beginning of an element with the SAX interface. Use the *om.SaxAttributes* methods to handle the attributes of an element.

#### Example

```java
DEFINE out om.SaxDocumentHandler
node om.DomNode,
    attrs om.SaxAttributes,
    x, c INTEGER
...
CALL attrs.clear()
LET c = node.getChildCount()
```
FOR x=1 TO c
    CALL attrs.addAttribute( node.getAttributeName(x),
                          node.getAttributeValue(x) )
END FOR
CALL out.startElement( node.getTagname(), attrs )

Related concepts
om.SaxDocumentHandler.endElement on page 2470
Processes the end of an element.

The SaxAttributes class on page 2460
The om.SaxAttributes class holds a set of attributes to process with a SAX reader or writer.

om.SaxDocumentHandler.skippedEntity
Processes an unresolved entity.

Syntax

skippedEntity(
    name STRING )

1. name is the name of the unknown entity.

Usage

The skippedEntity() method processes an entity that is not known by the XML parser.

Related concepts
om.SaxDocumentHandler.characters on page 2470
Processes a text node.

Examples
om.SaxDocumentHandler usage examples.
Example 1: Extracting phone numbers from a directory
This example shows how to write a SAX filter to extract phone numbers from a directory file written in XML.

MAIN
    DEFINE f om.SaxDocumentHandler
    LET f = om.SaxDocumentHandler.createForName("module1")
    CALL f.readXmlFile("customers.xml")
END MAIN

Note: The parameter of the createForName() method specifies the name of a source file that has been compiled into a .42m file ("module1.42m" in our example).

The module module1.4gl:

FUNCTION startDocument()
END FUNCTION

FUNCTION processingInstruction(name,data)
    DEFINE name,data STRING
END FUNCTION

FUNCTION startElement(name,attr)
    DEFINE name STRING
    DEFINE attr om.SaxAttributes
    DEFINE i INTEGER
    CASE name
        WHEN "Customer"
            CALL attrs.addElement("description" + i, ""
        END WHEN
    END CASE
END FUNCTION
The XML file `customers.xml`:

```
<Customers>
  <Customer customer_num="101" fname="Ludwig" lname="Pauli"
      company="All Sports Supplies" address1="213 Erstwild Court"
      address2="" city="Sunnyvale" state="CA" zip-code="94086">
    <CellPhone number="408-789-8075" />
    <WorkPhone number="873-123-4543" />
  </Customer>
  <Customer customer_num="102" fname="Carole" lname="Sadler"
      company="Sports Spot" address1="785 Geary St"
      address2="" city="San Francisco" state="CA" zip-code="94117">
    <CellPhone number="415-822-1289" />
    <WorkPhone number="834-842-8373" />
  </Customer>
  <Customer customer_num="103" fname="Philip" lname="Currie"
      company="Phil's Sports" address1="654 Poplar"
      address2="P. O. Box 3498" city="Palo Alto" state="CA"
      zip-code="94303">
    <CellPhone number="415-328-4543" />
    <WorkPhone number="932-118-4824" />
  </Customer>
</Customers>
```

Output:

```
Pauli Ludwig
   Cell phone: 408-789-8075
   Work phone: 873-123-4543
Sadler Carole
   Cell phone: 415-822-1289
   Work phone: 834-842-8373
Currie Philip
   Cell phone: 415-328-4543
   Work phone: 932-118-4824
```
Example 2: Producing an XML file with om.SaxDocumentHandler

This example shows how to write an XML file by using a SAX document handler object created from the om.XmlWriter.createFileWriter() method:

```
MAIN
  DEFINE w om.SaxDocumentHandler
  DEFINE a om.SaxAttributes

  LET a = om.SaxAttributes.create()

  LET w = om.XmlWriter.createFileWriter("output.xml")
  CALL w.startDocument()
  CALL w.startElement("Foo", NULL)
  CALL w.processingInstruction("PI2", "val")

  CALL w.startElement("Foo1", NULL)
  CALL w.characters("foo bar")
  CALL w.skippedEntity("nbsp")
  CALL w.EndElement("Foo1")

  CALL w.endElement("Foo")
  CALL w.endDocument()
END MAIN
```

The XmlReader class

The om.XmlReader class provides methods to read and process a file written in XML format.

The processing of the XML file is streamed-data based; the file is loaded and processed sequentially with events. To process XML element attributes, an om.XmlReader object must cooperate with a om.SaxAttributes object. The XmlReader class can only read from a file. To write to a file, use the om.XmlWriter class.

Steps to use a XML reader:

1. Declare a variable with the om.XmlReader type.
2. Create the reader object with the createFileReader() method and assign the reference to the variable.
3. Process SAX events in a WHILE loop, by reading document fragments with the read() method.
4. Inside the loop, depending on the SAX event, process element attributes with getAttributes() or get the element data with the getCharacters() methods.

om.XmlReader methods

Methods of the om.XmlReader class.

</table>

*om.XmlReader.createFileReader*

Creates an XML reader object from a file.

**Syntax**

```plaintext
createFileReader(
   path STRING )
RETURNS om.XmlReader
```

1. *path* is the path to an XML formatted file.

**Usage**

Use the `om.XmlReader.createFileReader()` method to create a new `om.XmlReader` object, to process the XML data from a file input stream.

To hold the reference to an XmlReader object, define a variable with the type `om.XmlReader` type.

**Example**

```plaintext
DEFINE r om.XmlReader
LET r = om.XmlReader.createFileReader("cars.xml")
...
```

For a complete example, see Example 1: Parsing an XML file on page 2480.

**Related concepts**

- `om.XmlReader.read` on page 2478
Reads the next SAX event to process.

*om.XmlReader.getAttributes*

Builds an attribute list for the current processed element.

### Syntax

```plaintext
getAttributes()
RETURNS om.SaxAttributes
```

### Usage

Use the `getAttributes()` method to create a list of attributes as an `om.SaxAttributes` object, from the current processed element, in the `StartElement` or `EndElement` event context.

Declare a variable with the `om.SaxAttributes` type to reference the attribute list.

Note that once created with the `getAttributes()` method, the `om.SaxAttributes` object is automatically updated based on the element currently processed by the `om.XmlReader`.

### Example

```plaintext
DEFINE r om.XmlReader,
    e STRING, i INT
    a om.SaxAttributes
...
LET e = r.read()
WHILE e IS NOT NULL
    CASE e
        ...
        WHEN "StartElement"
            LET a = r.getAttributes()
            FOR i=1 to a.getLength()
                ...
    ...
```

For a complete example, see [Example 1: Parsing an XML file](#) on page 2480.

**Related concepts**

- The `SaxAttributes` class on page 2460
  The `om.SaxAttributes` class holds a set of attributes to process with a SAX reader or writer.

*om.XmlReader.getCharacters*

Returns the character data of the current processed element.

### Syntax

```plaintext
getCharacters()
RETURNS STRING
```

### Usage

Use the `getCharacters()` method to get the character data of the current processed element, in the `Characters` event context.

### Example

```plaintext
DEFINE r om.XmlReader,
    e STRING
    ...
LET e = r.read()
```
WHILE e IS NOT NULL
CASE e
...
WHEN "Characters"
  DISPLAY "Characters:'",r.getCharacters(),'"
...

For a complete example, see Example 1: Parsing an XML file on page 2480.

`om.XmlReader.getTagName`
Returns the tag name of the current processed element.

**Syntax**

```plaintext```
getTagName()
RETURNS STRING
```

**Usage**
Use the `readXmlFile()` method to get the tag name of the current processed element, in the `StartElement` or `EndElement` event context.

**Example**

```plaintext```
DEFINE r om.XmlReader,
  e STRING
  ...
  LET e = r.read()
  WHILE e IS NOT NULL
    CASE e
      ...
      WHEN "StartElement"
        DISPLAY "TagName = ", r.getTagName()
      ...
```

For a complete example, see Example 1: Parsing an XML file on page 2480.

`om.XmlReader.read`
Reads the next SAX event to process.

**Syntax**

```plaintext```
read()
RETURNS STRING
```

**Usage**
The `read()` method reads the next XML fragment and returns the name of the SAX event to process.
### Table 510: Events that can be returned by the `read()` method

<table>
<thead>
<tr>
<th>Event name</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>StartDocument</td>
<td>Beginning of the document</td>
<td>Prepare processing (allocate resources)</td>
</tr>
<tr>
<td>StartElement</td>
<td>Beginning of a node</td>
<td>Get current element's tag name or attributes with <code>getTagName()</code> and <code>getAttributes()</code></td>
</tr>
<tr>
<td>Characters</td>
<td>Value of the current element</td>
<td>Get current text element's value with <code>getCharacters()</code></td>
</tr>
<tr>
<td>SkippedEntity</td>
<td>Reached skipped entity</td>
<td>Get current skipped entity element's value with <code>skippedEntity()</code></td>
</tr>
<tr>
<td>EndElement</td>
<td>Ending of a node</td>
<td>Get current element's tagname with <code>getTagName()</code></td>
</tr>
<tr>
<td>EndDocument</td>
<td>Ending of the document</td>
<td>Finish processing (release resources)</td>
</tr>
</tbody>
</table>

### Example

```
DEFINE r om.XmlReader,
   e STRING
...
LET e = r.read()
WHILE e IS NOT NULL
  CASE e
    ...
  END CASE
LET e = r.read()
END WHILE
```

For a complete example, see [Example 1: Parsing an XML file](on page 2480).

*om.XmlReader.skippedEntity*

Returns the name of an unresolved entity.

### Syntax

```
skippedEntity() 
  RETURNS STRING
```

### Usage

The `skippedEntity()` method returns the name of the unresolved entity, in the SkippedEntity event context. The parser identifies well know character entities such as `&amp;`/`&apos;`/`&lt;`/`&gt;`/`&quot;`, other character entities are treated as skipped entities and can be processed in the SkippedEntity event.

### Example

```
DEFINE r om.XmlReader,
   e STRING
...
LET e = r.read()
WHILE e IS NOT NULL
```
CASE e
   ...
   WHEN "SkippedEntity"
      DISPLAY "Entity:'", r.skippedEntity(),"
   ...

For a complete example, see Example 1: Parsing an XML file on page 2480.

Related concepts

Examples
om.XmlReader usage examples.
Example 1: Parsing an XML file

MAIN
   DEFINE i, l INTEGER
   DEFINE r om.XmlReader
   DEFINE e String
   DEFINE a om.SaxAttributes
   LET r = om.XmlReader.createFileReader("myfile.xml")
   LET l = 0
   LET e = r.read()
   WHILE e IS NOT NULL
      CASE e
         WHEN "StartDocument"
            DISPLAY "StartDocument:
         WHEN "StartElement"
            LET l = l+1
            DISPLAY l SPACES, "StartElement:", r.getTagName()
            LET a = r.getAttributes()
            FOR i=1 to a.getLength()
               DISPLAY l SPACES, "  ",
               a.getName(i)," = ",
               a.getValueByIndex(i)
            END FOR
         WHEN "Characters"
            DISPLAY l SPACES, "  Characters:'", r.getCharacters(),"
         WHEN "SkippedEntity"
            DISPLAY "Entity:'", r.skippedEntity(),"
         WHEN "EndElement"
            DISPLAY l SPACES, "EndElement:", r.getTagName()
            LET l = l-1
         WHEN "EndDocument"
            DISPLAY "EndDocument:"
         OTHERWISE
            DISPLAY "Invalid event: ", e
      END CASE
      LET e = r.read()
   END WHILE
END MAIN

The XmlWriter class
The om.XmlWriter class implements methods to write XML to a stream.

The om.XmlWriter class implements methods to create a om.SaxDocumentHandler object.

Steps to use a XML writer:
1. Declare a variable with the `om.SaxDocumentHandler` type.

2. Create the writer object with one of the class methods of `om.XmlWriter` and assign the reference to the variable.
   - `om.XmlWriter.createFileWriter(filename)` creates an object writing to a file.
   - `om.XmlWriter.createPipeWriter(command)` creates an object writing to a pipe opened by a subprocess.
   - `om.XmlWriter.createSocketWriter(hostname, portnum)` creates an object writing to the TCP socket.

3. Output XML data with the methods of the `om.SaxDocumentHandler` object:
   - a. Use the method `startDocument()` to start writing to the output.
   - b. From this point, the order of method calls defines the structure of the XML document. To write an element, fill an `om.SaxAttributes` object with attributes.
   - c. Then, initiate the element output with the method `startElement()`.
   - d. Write element data with the `characters()` method.
   - e. Entity nodes are created with the `skippedEntity()` method.
   - f. Finish element output with a call to the `endElement()` method.
   - g. Repeat these steps as many times as you have elements to write.
   - h. Instead of using the `startElement()` method, you can generate processing instruction elements with `processingInstruction()`.
   - i. Finally, you must finish the document output with a `endDocument()` call.

### om.XmlWriter methods

Methods of the `om.XmlWriter` class.

#### Table 511: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>om.XmlWriter.createChannelWriter(channel base.Channel)</code></td>
<td>Creates an <code>om.SaxDocumentHandler</code> object writing to a channel object.</td>
</tr>
<tr>
<td><code>om.XmlWriter.createPipeWriter(command STRING)</code></td>
<td>Creates an <code>om.SaxDocumentHandler</code> object writing to a pipe created for a process.</td>
</tr>
<tr>
<td><code>om.XmlWriter.createSocketWriter(host STRING, port INTEGER)</code></td>
<td>Creates an <code>om.SaxDocumentHandler</code> object writing to a socket.</td>
</tr>
</tbody>
</table>

**om.XmlWriter.createChannelWriter**

Creates an `om.SaxDocumentHandler` object writing to a channel object.

**Syntax**

```java
om.XmlWriter.createChannelWriter()
```
1. *channel* is a `base.Channel` object reference.

### Usage

The `om.XmlWriter.createChannelWriter()` class method creates an `om.SaxDocumentHandler` object that will write to the specified channel object, when using the `om.SaxDocumentHandler` methods.

The `base.Channel` object must exist and be open to receive data from the SAX document handler.

### Example

The next example uses the channel to write to stdout, passing `NULL` as file name to the `base.Channel.openFile()` method:

```oml
DEFINE w om.SaxDocumentHandler
DEFINE ch base.Channel
...
LET ch = base.Channel.create()
CALL ch.openFile(NULL,"w")
LET w = om.XmlWriter.createChannelWriter(ch)
...
```

### Related concepts

- **The Channel class** on page 2273
  The `base.Channel` class is a built-in class providing basic input/output functions.

- **The SaxDocumentHandler class** on page 2467
  The `om.SaxDocumentHandler` class provides an interface to write an XML filter with events.

- **`om.XmlWriter.createFileWriter`**
  Creates an `om.SaxDocumentHandler` object writing to a file.

### Syntax

```
`om.XmlWriter.createFileWriter`
( `path` STRING )
RETURNS `om.SaxDocumentHandler`
```

1. *path* is the path to the file.

### Usage

The `om.XmlWriter.createFileWriter()` class method creates an `om.SaxDocumentHandler` object that will write to the specified file when using the `om.SaxDocumentHandler` methods.

The file is created if it does not exist. If the file cannot be created, the method returns `NULL`.

When passing `NULL` as file name, the XmlWriter can be used to write to stdout.

### Example

```oml
DEFINE w om.SaxDocumentHandler
...
LET w = om.XmlWriter.createFileWriter("mydata.xml")
IF w IS NULL THEN
   ERROR "Could not create file."
   EXIT PROGRAM 1
END IF
...
```
-- Create an XmlWriter object to write to stdout:
LET w = om.XmlWriter.createFileWriter(NULL)
...

Related concepts
The SaxDocumentHandler class on page 2467
The om.SaxDocumentHandler class provides an interface to write an XML filter with events.

**om.XmlWriter.createPipeWriter**
Creates an om.SaxDocumentHandler object writing to a pipe created for a process.

Syntax

```
om.XmlWriter.createPipeWriter(
    command STRING
) RETURNS om.SaxDocumentHandler
```

1. **command** is the command to be executed.

Usage

The om.XmlWriter.createPipeWriter() class method creates an om.SaxDocumentHandler object that will write to a pipe created for the specified command. XML data will be send through the pipe when using the om.SaxDocumentHandler methods.

If the process or pipe cannot be created, the method returns NULL.

Example

```
DEFINE w om.SaxDocumentHandler
...
LET w = om.XmlWriter.createPipeWriter("sort -u")
IF w IS NULL THEN
    ERROR "Could not create process."
    EXIT PROGRAM 1
END IF
...
```

Related concepts
The SaxDocumentHandler class on page 2467
The om.SaxDocumentHandler class provides an interface to write an XML filter with events.

**om.XmlWriter.createSocketWriter**
Creates an om.SaxDocumentHandler object writing to a socket.

Syntax

```
om.XmlWriter.createSocketWriter(
    host STRING,
    port INTEGER
) RETURNS om.SaxDocumentHandler
```

1. **host** is the name of the host computer listening to the TCP port.
2. **port** is the port number to connect to.
Usage
The om.XmlWriter.createSocketWriter() class method creates an om.SaxDocumentHandler object that will write to a socket identified by the host and port number passed as parameters. XML data will be send through the socket when using the om.SaxDocumentHandler methods.

If the socket cannot be opened, the method returns NULL. No timeout is used.

Example

```om
DEFINE w om.SaxDocumentHandler
...
LET w = om.XmlWriter.createSocketWriter("myhost",8012)
IF w IS NULL THEN
   ERROR "Could not open socket."
   EXIT PROGRAM 1
END IF
...
```

Related concepts

### Table 517: WinMail front-end functions: General

<table>
<thead>
<tr>
<th>Function name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Important:</strong> This feature is deprecated, and may be removed in a future version.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>CALL</th>
</tr>
</thead>
</table>
| ui.Interface.frontCall("WinMail","Init",
  [], [id ] ) |

- `ret` is the identifier of the message initialized.
- For each Init function, a `Close` must be called.

**Important:** This feature is deprecated, and may be removed in a future version.

<table>
<thead>
<tr>
<th>CALL</th>
</tr>
</thead>
</table>
| ui.Interface.frontCall("WinMail","Close",
  [id], [ result ] ) |

The `Close` function clears all information corresponding to a message, and frees the memory occupied by the message.

**Important:** This feature is deprecated, and may be removed in a future version.

<table>
<thead>
<tr>
<th>CALL</th>
</tr>
</thead>
</table>
| ui.Interface.frontCall("WinMail","SetBody",
  [ id, body ], [ result ] ) |

The `SetBody` function sets the body of the mail.

**Important:** This feature is deprecated, and may be removed in a future version.

<table>
<thead>
<tr>
<th>CALL</th>
</tr>
</thead>
</table>
| ui.Interface.frontCall("WinMail","SetSubject",
  [ id, subject ], [ result ] ) |

The `SetSubject` function sets the subject of the mail.

**Important:** This feature is deprecated, and may be removed in a future version.

<table>
<thead>
<tr>
<th>CALL</th>
</tr>
</thead>
</table>
| ui.Interface.frontCall("WinMail","AddTo",
  [ id, name, address ], [ result ] ) |

The `AddTo` function adds a "To" addressee to the mail.

**Important:** This feature is deprecated, and may be removed in a future version.

<table>
<thead>
<tr>
<th>CALL</th>
</tr>
</thead>
</table>
| ui.Interface.frontCall("WinMail","AddCC",
  [ id, name, address ], [ result ] ) |

The `AddCC` function adds a "CC" addressee to the mail.

</table>

### Standard front calls

Standard front call functions provide common utility APIs to control the front-end.

This table shows the functions implemented by the front-ends in the "standard" module, available on all front-ends.
### Table 525: Standard front-end functions

<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;standard&quot;, &quot;hardCopy&quot;, [pgsize], [result])</td>
<td>Prints a screen shot of the current window</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;standard&quot;, &quot;launchURL&quot;, [url], [mode], [result])</td>
<td>Opens an URL with the default URL handler of the front end.</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;standard&quot;, &quot;mdClose&quot;, [name], [result])</td>
<td>Unloads a DLL or shared library front call module.</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;standard&quot;, &quot;openDir&quot;, [path], [caption], [result])</td>
<td>Displays a file dialog window to get a directory path on the local file system.</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;standard&quot;, &quot;openFile&quot;, [path], [name], [wildcards], [caption], [result])</td>
<td>Displays a file dialog window to let the user select a single file path on the local file system.</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;standard&quot;, &quot;openFiles&quot;, [path], [name], [wildcards], [caption], [result])</td>
<td>Displays a file dialog window to let the user select a list of file paths on the local file system.</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;standard&quot;, &quot;playSound&quot;, [resource], [])</td>
<td>Plays the sound file passed as parameter on the front-end platform.</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;standard&quot;, &quot;saveFile&quot;, [path], [name], [filetype], [caption], [result])</td>
<td>Displays a file dialog window to get a path to save a file on the local file system.</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;standard&quot;, &quot;setReportFont&quot;, [font], [result])</td>
<td>Override the font used for report generation for the current application.</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;standard&quot;, &quot;setReportPrinter&quot;, [printer], [result])</td>
<td>Override the printer configuration used for report generation for the current application.</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
**Important:** This feature is deprecated, and may be removed in a future version.

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>GDC</td>
<td>Defines the base path where web components are located.</td>
<td>Yes</td>
<td>N/A</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>GBC</td>
<td>OPENs a file on the front-end platform with the program associated to the file extension.</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>GMA</td>
<td><em>cbAdd</em> Adds to the content of the clipboard.</td>

<td></td>
<td></td>
</tr>
<tr>
<td><em>cbGet</em></td>
<td><em>cbGet</em> Gets the content of the clipboard.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Syntax**

```javascript
ui.Interface.frontCall("standard", "cbAdd", [text], [result])
```

1. **text** - The text to be added.
2. **result** - The execution status (TRUE=success, FALSE=error).

**Usage**

The "cbAdd" front call adds the text passed as parameter to the content of the clipboard of the front-end platform.

```javascript
ui.Interface.frontCall("standard", "cbClear", [], [result])
```

1. **result** - The execution status (TRUE=success, FALSE=error).

**Usage**

The "cbClear" front call clears the content of the clipboard. This front call takes no input parameters.

```javascript
ui.Interface.frontCall("standard", "cbGet", [], [text])
```

1. **text** - The text found in the clipboard.
Usage
The "cbGet" front call returns the current content of the clipboard.
This front call takes no input parameters.

**cbPaste**
Pastes the content of the clipboard to the current field.

**Syntax**

```javascript
ui.Interface.frontCall("standard", "cbPaste", [], [result])
```

1. **result** - The execution status (TRUE=success, FALSE=error).

**Usage**
The "cbPaste" front call pastes the content of the clipboard to the current field.
This front call takes no input parameters.

**cbSet**
Set the content of the clipboard.

**Syntax**

```javascript
ui.Interface.frontCall("standard", "cbSet", [text], [result])
```

1. **text** - The text to be set.
2. **result** - The execution status (TRUE=success, FALSE=error).

**Usage**
The "cbSet" front call sets the content of the clipboard with the text passed as parameter.

**Note:** GBC specific: Due to browsers security policies, GBC cannot paste content in the clipboard without user permissions. When using the **cbSet** call, GBC will present data in a text box, that you can copy and paste elsewhere.

**execute**
Executes a command on the front-end platform, with or without waiting.

**Syntax**

```javascript
ui.Interface.frontCall("standard", "execute", [command, wait], [result])
```

1. **command** - The command to be executed.
2. **wait** - The wait option (TRUE=wait, FALSE=do not wait).
3. **result** - The execution status (TRUE=success, FALSE=error).

**Usage**
The "execute" front call runs a command on the front-end platform, with or without waiting option.

**Tip:** When specifying a file path, pay attention to platform specific rules regarding directory separators and space characters in file names. When the front-end executes on a recent Microsoft® Windows™ system, you can use the / slash character as directory separator, like on Unix systems. A directory or file name can contain spaces, and there is
no need to surround the path with double quotes in such case. When using backslash directory separators, make sure to escape backslash characters in string literals with `\`.

If the second parameter is set to `TRUE`, the runtime system will wait until the front-end gives the control back after the local command was executed.

**Example**

For Microsoft™ Windows™ system:

```
-- Using backslash as directory separator:
CALL ui.Interface.frontCall("standard", "execute",
    ["C:\\Program Files\\FourJS\\gdc\\3.10\\bin\\gdc.exe --help",FALSE],
    [res] )

-- Using slash as directory separator:
CALL ui.Interface.frontCall("standard", "execute",
    ["C:/Program Files/FourJS/gdc/3.10/bin/gdc.exe --help",FALSE], [res] )
```

**Related concepts**

- **startActivity (Android)** on page 2564
  Starts an external Android™ application (activity), and returns to the GMA application immediately.

- **startActivityForResult (Android)** on page 2565
  Starts an external application (Android activity) and waits until the activity is closed.

**feInfo**

Queries general front-end properties.

**Syntax**

```
ui.Interface.frontCall("standard", "feInfo",
    [name], [result])
```

1. `name` - The name of the property.
2. `result` - The value of the property.

**Usage**

The `feInfo` front call returns a front-end property value depending on the property name passed in as the parameter. Some `feInfo` options take an optional parameter, such as `screenResolution`:

```
CALL ui.Interface.frontCall("standard", "feInfo", ["screenResolution", 2],
    [resolution])
```

**Table 526: Property names and descriptions for the standard.feInfo front call**

feInfo property values
<table>
<thead>
<tr>
<th>Property name</th>
<th>Description</th>
</tr>
</thead>
</table>
| dataDirectory | Returns the directory name that can be used for temporary files on the front-end side. This directory is cleaned at front-end start-up and end, and is common to all front-end instances, except for the Genero Browser Client (GBC).

The possible values returned are:

- With Genero Browser Client, this is not applicable.
- With Genero Desktop Client, the local cache directory. For example, "/home/username/.cache/Four Js/Genero Desktop".
- With Genero Mobile for Android™, this is the GMA application cache directory. Content may be erased, once the app is closed.
- With Genero Mobile for iOS, this is the temporary directory in the application sandbox (iOS NSTemporaryDirectory() system call). Content may be erased, once the app is closed.

<table>
<thead>
<tr>
<th>dictionariesDirectory</th>
<th>Returns the directory name where spell checking dictionary files are located. This parameter is only supported by GDC, for the spellCheck style attribute of TextEdit elements. A program can query the dictionariesDirectory info in order to send dictionary files to the GDC with an fgl_putfile() call.</th>
</tr>
</thead>
<tbody>
<tr>
<td>deviceModel</td>
<td>Returns the name of the device, e.g. &quot;iPad4,5&quot;.</td>
</tr>
</tbody>
</table>
| deviceId | • With Genero Mobile for iOS, returns the identifierForVendor.
• With Genero Mobile for Android™, returns this IMEI, otherwise the Android™ id (but may change after device reinstallation)

**Important:** For GMA / Android™, accessing this device information requires the android.permission.READ_PHONE_STATE Dangerous Permission. See Android permissions on page 3321.
<table>
<thead>
<tr>
<th>Property name</th>
<th>Description</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
</table>
| feName        | The code identifying the type of front-end component. **Note:** Consider using `ui.Interface.getFrontEndName()` instead, to save a network roundtrip. The possible values returned are:  
• "Genero Desktop Client" for Genero Desktop Client.  
• "GBC" for Genero Browser Client.  
• "GMA" for Genero Mobile for Android™.  
• "GMI" for Genero Mobile for iOS. | Yes | Yes | Yes | Yes |
| fePath        | The installation directory of the front-end executable.  
• With Genero Desktop Client, it returns the path to the installation directory of the GDC.  
• With Genero Browser Client, it returns the path to the installation directory of the GAS.  
• With Genero Mobile for Android™, it returns the installation directory. For example, "/data/data/com.fourjs.gma/fgl".  
• With Genero Mobile for iOS, it returns the installation directory. For example: "/private/var/mobile/Applications/B3E6-C48A-ED4EFA". Below the installation directory are the "Documents" (which is by default `pwd`), "GMI.app" (deployed p-code resides in `GMI.app/app/`) and "tmp" directories.  
**Important:** The installation path returned by this front call may change in future versions, do not base application code on this. On mobile devices, consider using the `os.Path.pwd` on page 2653 utility function to get the application working directory when executing programs. | Yes | No | Yes | Yes |
| freeStorageSpace | Returns the number of bytes available on the device. | Yes | No | Yes | Yes |
| iccid         |  
• With Genero Mobile for iOS, returns an error (not allowed).  
• With Genero Mobile for Android™, returns the ICCID if available, otherwise raise an error.  
**Important:** For GMA / Android™, accessing this device information requires the `android.permission.READ_PHONE_STATE` Dangerous Permission. See Android permissions on page 3321. | N/A | N/A | Yes | Yes |

| imei         | • With Genero Mobile for iOS, returns an error (not allowed).  
               • With Genero Mobile for Android™, returns the IMEI if available, otherwise raises an error.  
               **Important:** For GMA / Android™, accessing this device information requires the android.permission.READ_PHONE_STATE Dangerous Permission. See Android permissions on page 3321.  
               Returns the IP address of the network interface used for the GUI connection.  
               For mobile platforms, this is the preferred IP address of the device. If there is WIFI, either the IPv4 address is returned (for example: 192.168.0.12) or if there is no IPv4 address, the IPv6 address is returned (for example: 2a02:810a:82c0:478:d462:e334:6a1d:fb78).  
               If there is no WIFI, either the cellular IPv4 or IPv6 address is returned. If there is no network, NULL is returned. | Yes | No | Yes | Yes |
| ip           | Returns "1" if the front-end runs in Active X mode (GDC specific). | Yes | No | Yes | Yes |
| isActiveX   | For Genero Mobile clients, the return value will always be "0" | No | | No | Yes |
| numScreens  | Number of screens available on the front-end platform. | Yes | No | No | No |
| osType       | The operating system type where the front-end is running. | Yes | Yes | Yes | Yes |
| osVersion    | The version of the operating system. | Yes | No | Yes | Yes |
| ppi          | Returns the screen pixel density of the front-end platform (Pixels Per Inch). This front call takes an optional screen number as parameter (1 is the default).  
               • With Genero Mobile for iOS, it returns the PixelsPerInch of an iOS device.  
               • With Genero Mobile for Android™, it returns the DPI (ppi == dpi) | Yes | No | Yes | Yes |
Property name | Description | GDC | GBC | GMA | GMI
--- | --- | --- | --- | --- | ---
screenResolution | Returns the screen resolution of the front-end platform. This front call takes an optional screen number as parameter (1 is the default).
| Example of returned values: "1200x1824", "1920x1104".
| Note: For mobile devices, the value can change depending on the device orientation.
| | Yes | Yes | Yes | Yes |
target | Returns the build platform target code name, identifying the operating system the front-end binary was compiled. This front call is provided for debugging purpose, do not base code on the returned value, it can change if the target OS version is upgraded for example. Use the ostype property instead.
| Example of returned values:
| • "w32v100" = Windows® 32 bits, Visual C++ 10.
| • "w64v110" = Windows® 64 bits, Visual C++ 11.
| • "d32a040" = Android™ 4.0 ARM 32 bits.
| • "d32x040" = Android™ 4.0 x86 32 bits.
| • "i32a070" = iOS 7.0 ARM 32 bits.
| • "i32x070" = iOS 7.0 x86 32 bits.
| Note: For GBC, it returns the same value as osType.
| | Yes | Yes | Yes | Yes |
windowSize | Returns the current size of the front-end view-port.
| • For mobile front-ends, this is the size of the mobile screen.
| • For Genero Desktop Client, this is the size of the current window.
| • For Genero Browser Client, this is the size of the browser webview.
| Example of returned values: "1200x1824", "1920x1104".
| | Yes | Yes | Yes | Yes |
userPreferredLang | Returns the language and territory of the locale defined on the front-end platform, in the language_territory format.
| • For Genero Desktop Client and mobile front-ends, the front-end locale is defined by the operating system.
| • For Genero Browser Client, the front-end locale is defined in the web browser preferences.

getEnv
Returns an environment variable set in the user session on the front end platform.

Syntax

```plaintext
ui.Interface.frontCall("standard", "getEnv", "variable")
```
[name], [value])

1. name - The name of the environment variable.
2. value - The value of the environment variable.

Usage
The "getEnv" front call returns an environment variable set in the user session on the front-end platform.

Related concepts
Environment variables on page 226
Genero BDL related environment variables.

ggetWindowId
Returns the local window manager identifier of the window corresponding to the AUI window id passed as parameter.

Syntax
```
ui.Interface.frontCall("standard", "getWindowId", [aui-win-id], [loc-win-id])
```

1. aui-win-id - The id of the window node in the AUI tree.
2. loc-win-id - The id of the window in the window manager where the front-end is running.

Usage
Returns the local identifier that corresponds to the AUI window id passed as parameter, in the window manager where the front-end is displaying the application forms.

The node id must reference a Window node, otherwise "0" is returned. In traditional mode, window widgets are simple frames. Use "0" as aui-win-id parameter to get the top level window id in the local window system.

hardCopy
Prints a screen shot of the current window

Syntax
```
ui.Interface.frontCall("standard", "hardCopy", [pgsize], [result])
```

1. pgsie - Pass "1" to adapt the screenshot to the page size.
2. result - The execution status (TRUE=success, FALSE=error).

Usage
The "hardCopy" front call allows you to print a screenshot of the current window.

The pgsie parameter is optional; either leave out, or enter "1" to indicate that the screenshot must be adapted to the page size.

launchURL
Opens an URL with the default URL handler of the front-end.

Syntax
```
ui.Interface.frontCall("standard", "launchURL", [url], [mode])
```

Usage
The "launchURL" front call allows you to open a URL in the default URL handler of the front-end.
1. url - The URL / URI to invoke.
2. mode (optional) - This parameter is ignored by GMA/GMI/GDC. With GBC, by default, a new browser window/tab is opened. Use "replace" mode, to reuse the current web browser window/tab for the specified URL.

Usage

The "launchURL" front call opens an URL with the default URL handler available on the front-end platform. This is typically the web browser for "HTTP:" URLs, or the mailer for "mailto:" URLs, but the corresponding application may also be dedicated to the type of object specified by the URL (for example, a mapping service or to initiate a phone call).

Important: Some types of URLs are not supported by all front-end platforms. Make sure that you test all target front-ends when using a launchURL front call. For example, when the GBC front-end is running from HTTP/HTTPS (through the GAS), the web browser will block file://host/path URIs from opening, as this would create a security hole.

This front call is a powerful feature: front-end applications can register themselves as URL handlers, so you can start applications on the front-end through the launchURL front call.

Supported schemes depend on your system configuration.

Tip: It is possible to produce an URI with the ui.Interface.filenameToURI() method, from the file located on the application server. This URI can then be used with the launchURL front call for example, to show PDF files.

The mode parameter is optional and is interpreted differently depending on the front-end type:

• With the Genero Browser Client (GBC), use "replace" for the mode parameter, if you want the current application in the browser window or tab to be replaced with the new URL, instead of launching a new browser window or tab. If it is not present, or if a value other than "replace" is specified, the Genero Browser Client behaves like the Genero Desktop Client, opening the URL in a new browser window.
• With Genero Mobile for Android (GMA), Genero Mobile for iOS (GMI), and Genero Desktop Client (GDC) front-ends, the mode parameter is ignored if specified.

Example

To invoke Google Play Store:

CALL ui.Interface.frontCall("standard", "launchURL", 
["market://details?id=com.google.android.apps.currents"], [])

CALL ui.Interface.frontCall("standard", "launchURL", 
["market://details?id=com.google.zxing.client.android"], [])

To open Google Maps:

CALL ui.Interface.frontCall("standard", "launchURL", 
["geo:48.613363,7.711083?z=17"], [])

To open Google Street View:

CALL ui.Interface.frontCall("standard", "launchURL", 
["google.streetview:cbll=48.613363,7.711083&cbp=1,0,,0,1.0&mz=17"], [])

To initiate a phone call:

CALL ui.Interface.frontCall("standard", "launchURL", ["tel:+336717623"], [])
mdClose
Unloads a DLL or shared library front call module.

Syntax

```plaintext
ui.Interface.frontCall("standard", "mdClose", [name], [result])
```

1. name - The name of the module to be closed.
2. result - The result status (0 = success, -1 = module not found, -2 = cannot unload (busy)).

Usage

Front call modules are loaded on demand. After calling a function of a specific module, you can use the "mdClose" front call to unload the shared library and save resources.

openDir
Displays a file dialog window to get a directory path on the local file system.

Syntax

```plaintext
ui.Interface.frontCall("standard", "openDir", [path, caption], [result])
```

1. path - The default path of the directory like "/tmp".
2. caption - The caption to be displayed.
3. result - The name of the selected directory (or NULL if canceled).

Usage

When invoking the "openDir" front call, the front-end displays the file dialog window using the local file system, to let the end user enter a directory path.

Note: The file dialog window rendering and features depend on the type of front end and the type of the front end platform (desktop OS, web browser).

If the user cancels the dialog, the front call returns NULL in the result variable.

Tip: When specifying a file path, pay attention to platform specific rules regarding directory separators and space characters in file names. When the front-end executes on a recent Microsoft Windows® system, you can use the / slash character as directory separator, like on Unix systems. A directory or file name can contain spaces, and there is no need to surround the path with double quotes in such case. When using backslash directory separators, make sure to escape backslash characters in string literals with \.

Example

```plaintext
MAIN
DEFINE rec RECORD
    path STRING,
    caption STRING
END RECORD
DEFINE result STRING
LET rec.path = "/tmp"
LET rec.caption = "Select directory"
CALL ui.Interface.frontCall("standard","openDir",[rec.*],[result])
IF result IS NULL THEN
    DISPLAY "No directory was selected."
ELSE
```
Related concepts

openFile on page 2508
Displays a file dialog window to let the user select a single file path on the local file system.

openFiles on page 2509
Displays a file dialog window to let the user select a list of file paths on the local file system.

saveFile on page 2511
Displays a file dialog window to get a path to save a file on the local file system.

openFile
Displays a file dialog window to let the user select a single file path on the local file system.

Syntax

```
ui.Interface.frontCall("standard", "openFile",
    [path, name, wildcards, caption],
    [result])
```

1. **path** - The default path to the file like "/tmp/document.txt".
2. **name** - The label to be displayed for the file types / wildcards.
3. **wildcards** - A space-separated list of wildcards (for example: "*.pdf" or "README* test*.txt")
4. **caption** - The caption to be displayed.
5. **result** - The name of the selected file (or NULL if canceled).

Usage

When invoking the "openFile" front call, the front-end displays a file dialog window using the local file system, to let the end user select an existing file.

**Note:** The file dialog window rendering and features depend on the type of front end and the type of the front end platform (desktop OS, web browser).

If the user cancels the dialog, the front call returns NULL in the result variable.

**Important:** With the GBC front-end in a web browser, the path parameter is ignored, and wildcards can only hold one type of file extension.

**Tip:** When specifying a file path, pay attention to platform specific rules regarding directory separators and space characters in file names. When the front-end executes on a recent Microsoft Windows system, you can use the / slash character as directory separator, like on Unix systems. A directory or file name can contain spaces, and there is no need to surround the path with double quotes in such case. When using backlash directory separators, make sure to escape backlash characters in string literals with \\.

Example

```
MAIN
    DEFINE rec RECORD
        path STRING,
        name STRING,
        wildcards STRING,
        caption STRING
    END RECORD
    DEFINE result STRING
    LET rec.path = "/tmp/bird.jpg"
```
LET rec.name = "Image files"
LET rec.wildcards = "*.jpg *.png"
LET rec.caption = "Open file"
CALL ui.Interface.frontCall("standard","openFile",[rec.*],[result])

IF result IS NULL THEN
   DISPLAY "No file was selected."
ELSE
   DISPLAY "File :", result
END IF

END MAIN

Related concepts

openFiles on page 2509
Displays a file dialog window to let the user select a list of file paths on the local file system.

openDir on page 2507
Displays a file dialog window to get a directory path on the local file system.

saveFile on page 2511
Displays a file dialog window to get a path to save a file on the local file system.

openFiles
Displays a file dialog window to let the user select a list of file paths on the local file system.

Syntax

ui.Interface.frontCall("standard", "openFiles", [path, name, wildcards, caption], [result])

1. path - The default path of a directory like "/tmp".
2. name - The label to be displayed for the file types / wildcards.
3. wildcards - A space-separated list of wildcards (for example: ".*pdf" or "README* test*.txt")
4. caption - The caption to be displayed.
5. result - The list of selected file paths as a JSON array (or NULL if canceled).

Usage

When invoking the "openFiles" front call, the front-end displays a file dialog window, to let the end user select several file paths from the local file system.

Note: The file dialog window rendering and features depend on the type of front end and the type of the front end platform (desktop OS, web browser).

This front call is typically used to let the end user select several files that will be processed by the application.

Important: With the GBC front-end in a web browser, the path parameter is ignored, and wildcards can only hold one type of file extension.

When the file dialog is validated, the result variable contains a JSON formatted string representing an array of file paths:

["/my/first/path", "/my/second/path", "/my/third/path"]

The resulting string can then be converted to a DYNAMIC ARRAY OF STRING with the util.JSON.parse() method.

Note: The order of the paths in the result variable can differ from the selection order of the user.

If the user cancels the dialog, the front call returns an empty JSON array ([]) in the result variable.
Tip: When specifying a file path, pay attention to platform specific rules regarding directory separators and space characters in file names. When the front-end executes on a recent Microsoft™ Windows™ system, you can use the / slash character as directory separator, like on Unix systems. A directory or file name can contain spaces, and there is no need to surround the path with double quotes in such case. When using backslash directory separators, make sure to escape backslash characters in string literals with \\.

Example

```csharp
IMPORT util
MAIN
  DEFINE rec RECORD
    path STRING,
    name STRING,
    wildcards STRING,
    caption STRING
  END RECORD
DEFINE result STRING
DEFINE files DYNAMIC ARRAY OF STRING
DEFINE x INTEGER

  LET rec.path = "/tmp"
  LET rec.name = "Image files"
  LET rec.wildcards = "*.jpg *.png"
  LET rec.caption = "Select files"
  CALL ui.Interface.frontCall("standard","openFiles",[rec.*],[result])

  CALL util.JSON.parse( result, files )

  FOR x=1 TO files.getLength()
    DISPLAY SFMT("File %1: %2 ", x, files[x])
  END FOR

END MAIN
```

Related concepts

- openDir on page 2507
  Displays a file dialog window to get a directory path on the local file system.

- openFile on page 2508
  Displays a file dialog window to let the user select a single file path on the local file system.

- saveFile on page 2511
  Displays a file dialog window to get a path to save a file on the local file system.

- playSound
  Plays the sound file passed as parameter on the front-end platform.

Syntax

```
ui.Interface.frontCall("standard", "playSound", [resource], [])
```

1. `resource` - The sound file to play.

Usage

The "playSound" front call opens the sound file/resource passed as parameter and plays the sound on the front-end. Supported sound file format depends on the front-end infrastructure (platform, technology, web browser, etc.)

The sound file must be located on the front-end platform, or be an URI that can be loaded by the front-end.
Tip: It is possible to produce an URI with the `ui.Interface.filenameToURI()` method, from the file located on the application server. This URI can then be used with the `playSound` front call.

When using a file name, it can be an absolute or relative path. In a client/server front-end configuration, if the sound file is located on the application server, it is in charge of the program to transfer the file on the front-end platform.

When executing an app on a mobile device, if it is not an absolute path, the sound file path is relative to the `appdir`.

Tip: When specifying a file path, pay attention to platform specific rules regarding directory separators and space characters in file names. When the front-end executes on a recent Microsoft™ Windows™ system, you can use the `/` slash character as directory separator, like on Unix systems. A directory or file name can contain spaces, and there is no need to surround the path with double quotes in such case. When using backslash directory separators, make sure to escape backslash characters in string literals with `\`.

Example

```ini
CALL ui.Interface.frontCall("standard", "playSound", ["beep.mp3"], [])
```

Related concepts

  Platform-specific rules need to be considered when deploying on Android™ devices (GMA).

- **Directory structure for GMI apps** on page 3330
  Platform-specific rules need to be considered when deploying on iOS devices (GMI).

**saveFile**

Displays a file dialog window to get a path to save a file on the local file system.

**Syntax**

```ini
ui.Interface.frontCall("standard", "saveFile", 
    [path, name, filetype, caption], 
    [result])
```

1. **path** - The default path to the file like "/tmp/document.txt".
2. **name** - The label to be displayed for the file types / wildcards.
3. **filetype** - The file types (as a blank space-separated list of extensions).
4. **caption** - The caption to be displayed.
5. **result** - The name of the selected file (or NULL if canceled).

**Usage**

When invoking the "saveFile" front call, the front-end displays the file dialog window using the local file system, to let the end user enter a file path.

**Note:** The file dialog window rendering and features depend on the type of front end and the type of the front end platform (desktop OS, web browser).

If the user cancels the dialog, the front call returns NULL in the result variable.

Tip: When specifying a file path, pay attention to platform specific rules regarding directory separators and space characters in file names. When the front-end executes on a recent Microsoft™ Windows™ system, you can use the `/` slash character as directory separator, like on Unix systems. A directory or file name can contain spaces, and there is no need to surround the path with double quotes in such case. When using backslash directory separators, make sure to escape backslash characters in string literals with `\`.

Example

```ini
MAIN
    DEFINE rec RECORD
        path STRING,
```
name STRING,
wildcards STRING,
caption STRING
END RECORD

DEFINE result STRING

LET rec.path = "/tmp/new_file.jpg"
LET rec.name = "Image files"
LET rec.wildcards = "*.jpg *.png"
LET rec.caption = "Save file"
CALL ui.Interface.frontCall("standard","saveFile", [rec.*], [result])

IF result IS NULL THEN
  DISPLAY "No file name was entered."
ELSE
  DISPLAY "File ": result
END IF

END MAIN

Related concepts

openDir on page 2507
Displays a file dialog window to get a directory path on the local file system.

openFile on page 2508

openFiles on page 2509
Displays a file dialog window to let the user select a list of file paths on the local file system.

setReportFont
Override the font used for report generation for the current application.

Syntax

descide="ui.Interface.frontCall("standard", "setReportFont", [font], [result])"

1. font - A string describing the font to use for report generation (see Usage for details).
2. result - The execution status (TRUE=success, FALSE=error).

Usage

The "setReportFont" front call allows you to override the default font used for report generation for the current application. You can simply copy/paste the font string from the "Report To Printer" font panel from GDC Monitor. An empty or null string resets it to the default behavior.

The font parameter is a string that describe the font to use for report generation. For example: "Helvetica, Bold, Italic, 13". Alternatively, you can specify "<ASK_ONCE>" , "<ASK_ALWAYS>" , "<USER_DEFINED>" or "<USE_DEFAULT>" which will perform the corresponding actions.

setReportPrinter
Override the printer configuration used for report generation for the current application.

Syntax

descide="ui.Interface.frontCall("standard", "setReportPrinter", [printer], [result])"

1. printer - A string describing the printer to use for report generation (see Usage for details).
2. **result** - The execution status (TRUE=success, FALSE=error).

**Usage**

The "setReportPrinter" front call allows you to override the printer configuration used for report generation for the current application. You can simply copy/paste the printer string from the "Report To Printer" printer panel from GDC Monitor. An empty or null string resets it to the default behavior.

The *printer* parameter is a string that describes the printer to use for report generation. For example: "moliere, Portrait, A4, 96 dpi, 1 copy, Ascendent, Color, Auto". Alternatively, you can specify "<ASK_ONCE>"", "<ASK_ALWAYS>"", "<USER_DEFINED>" or "<USE_DEFAULT>" which will perform the corresponding actions.

**setWebComponentPath**

Defines the base path where web components are located.

**Syntax**

Important: This feature is deprecated, and may be removed in a future version.

```
ui.Interface.frontCall("standard", "setWebComponentPath", [path], [])
```

1. **path** - The base URL. For example, "http://myserver/components" or "file:///c:/components".

**Usage**

This front call defines the base path to find gICAPI web components files.

Important: The `standard.setWebComponentPath` front call is deprecated. Consider using deployment solutions described in Deploying the gICAPI web component files on page 1850.

For the Genero Desktop Client, it defines the base path where web components are located, when GDC is directly connected to the runtime system. This is ignored when GDC is connected to the GAS.

For Genero Mobile, it sets the main web component lookup path. An URI is expected. For example, "file:///data/data/com.fourjs.gma/cache/appdata/mywebcomponents" or "http://mygas/mywebcomponents/".

**shellExec**

Opens a file on the front-end platform with the program associated to the file extension.

**Syntax**

```
ui.Interface.frontCall("standard", "shellExec", [document, action], [result])
```

1. **document** - The document file to be opened.
2. **action** - (optional, Windows® Only!) The action to perform, related to the way the file type is registered in Windows® Registry.
3. **result** - The execution status (TRUE=success, FALSE=error).

**Usage**

The "shellExec" front call opens a file on the front-end platform with the program associated to the file extension. This front call is mainly designed for the Genero Desktop Client on Windows® platforms.
**Important:** Under X11 Systems, this uses `xdg-open`, which needs to be installed and configured on your system. `Kfmclient` will be used as a workaround when `xdg-open` is not available.

**Tip:** In order to view a document (like a PDF for example), if that document can be displayed by web browsers, use the `launchURL` on page 2505 front call instead, especially if you want to use both the Genero Desktop Client (GDC) and the Genero Browser Client (GBC) front-ends.

**Tip:** When specifying a file path, pay attention to platform specific rules regarding directory separators and space characters in file names. When the front-end executes on a recent Microsoft™ Windows™ system, you can use the `/` slash character as directory separator, like on Unix systems. A directory or file name can contain spaces, and there is no need to surround the path with double quotes in such case. When using backslash directory separators, make sure to escape backslash characters in string literals with `\`.

**Web component front calls**

This section describes web component specific front calls.

This table shows the functions provided by the "webcomponent" module on the front-ends supporting URL-based web components.

**Table 527: Webcomponent module front-end functions**

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ui.Interface.frontCall(&quot;webcomponent&quot;, &quot;call&quot;, [aui-name, function-name, \ param1, param2, ... \], [result] )</code></td>
<td>Calls a JavaScript function through the web component.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;webcomponent&quot;, &quot;frontCallAPIVersion&quot;, [],[result])</code></td>
<td>Returns the API version of web component front-end calls.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;webcomponent&quot;, &quot;getTitle&quot;, [aui-name], [result] )</code></td>
<td>Returns the title of the HTML doc rendered by a web component.</td>
</tr>
</tbody>
</table>

**Related tasks**

**Using a URL-based web component** on page 1832

This section describes how to add a *URL-based web component* to your application.

**call**

Calls a JavaScript function through the web component.

**Syntax**

```
ui.Interface.frontCall("webcomponent", "call", [aui-name, function-name, [param1, param2, ...]], [result] )
```

1. *aui-name* - This is the name of the web component name in the AUI tree.
2. *function-name* - This is the name of the web component JavaScript function to be called.
3. *param1, param2, ...* - Optional parameters to be passed to the web component JavaScript function.
4. *result* - Holds the JavaScript function return value.
**Usage**

This front call executes a JavaScript function of the `WEBCOMPONENT` form field identified by `aui-name`.

The JavaScript function identified by `function-name` must be implemented in the HTML content pointed by the URL-based web component, or in the user-defined JavaScript of a gICAPI-based web component.

The arguments following the `function-name` argument will be passed to the JavaScript function.

The `result` variable will contain the value returned by the JavaScript function.

When using simple data types in arguments, values are passed as is to the JavaScript function of the web component. When using `RECORD` or `DYNAMIC ARRAY` types, the runtime system converts the structured data to a JSON string. Similarly, if the JavaScript function returns a complex data structure in JSON notation, it must be used to assign a `RECORD` or `DYNAMIC ARRAY`.

For more details about JSON notation usage for complex data types, see the `ui.Interface.frontCall()` method.

**Example 1: Using a simple string parameter and return value:**

```
DEFINE result STRING
CALL ui.Interface.frontCall("webcomponent","call",

    ["formonly.mywebcomp","echoString","abcdef"],

    [result])
```

**Example 2: Using structured variables to be converted to JSON for the JavaScript code:**

```
DEFINE options RECORD
    filter STRING,
    creation DATE
END RECORD,
    items DYNAMIC ARRAY OF STRING
LET options.filter = "abc*"
LET options.creation = TODAY
CALL ui.Interface.frontCall("webcomponent","call",

    ["formonly.mywebcomp","getItems", options ],

    [ items ])
```

For a complete example, see Example 1: Calling a JavaScript function on page 1857.

**frontCallAPIVersion**

Returns the API version of web component front-end calls.

**Syntax**

```
ui.Interface.frontCall("webcomponent", "frontCallAPIVersion",

    [],

    [result])
```

1. `result` - Holds the API version for web component front calls.

**Usage**

This front call can be used to check the API version for the web component front calls.

If the API version changes, you must adapt the code to the expected front call API implemented for the web components.

The value returned by this front call is a typicaly version number such as 1.0, 1.1, etc.

**Example**

```
FUNCTION wc_api_version()

    DEFINE vers STRING
```
TRY
    CALL ui.Interface.frontCall("webcomponent","frontCallAPIVersion",[],[vers])
    -- we can safely call "webcomponent" "call" in the code
    RETURN vers
CATCH
    -- we cannot call the "webcomponent" functions...
    RETURN 0
END TRY
END FUNCTION

getTitle
Returns the title of the HTML doc rendered by a web component.

Syntax
ui.Interface.frontCall("webcomponent", "getTitle", [aui-name], [result] )

1. aui-name - This is the name of the web component in the AUI tree.
2. result - Holds the title of the HTML document.

Usage
This front call can be used to get the title of the HTML document that is rendered by the web component identified by the aui-name. For more details refer to http://www.w3schools.com/tags/tag_title.asp.

A typical usage of this front call is when implementing a web component based on the O-Auth mechanism to identify the current user. For example, with the Google accounts authentication service, after the login and password have been validated by Google, the authentication token is returned in the title of the HTML document. This token is typically used by the application to identify the user in remote API calls.

Genero Desktop Client front calls
This section describes GDC specific front calls.

The GDC front-end implements the following front call modules:
- GDC Monitor Front Calls on page 2516
- Windows DDE Support on page 2517
- Windows COM Support on page 2523
- Windows Mail extension on page 2531

Important: These front call modules are only available on Windows® platforms.

GDC Monitor Front Calls
This section describes front calls specific to the GDC monitor.

The GDC monitor is the administration component of the Genero Desktop Front-End. This component allows you to configure the GDC and do setup tasks.

The following table shows the functions implemented by all front-ends in the "monitor" module.
Table 528: monitor module front-end functions

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ui.Interface.frontCall(&quot;monitor&quot;, &quot;update&quot;, [path_to_update_file], [result])</code></td>
<td>Starts the GDC update.</td>
</tr>
</tbody>
</table>

**update**

Starts the GDC update.

**Syntax**

```plaintext
ui.Interface.frontCall("monitor", "update", [path_to_update_file], [result])
```

1. *path_to_update_file* - Defines the path to the zip archive containing the update material.
2. *result* - The execution status (TRUE=success, FALSE=error).

**Usage**

The "update" front call will start the update process based on the specified file. This file is expected to have been pushed previously on the GDC (generally using the `fgl_putfile()` built-in function).

For more details about this feature, see the *Genero Desktop Client User Guide*, in the Auto-Update section.

  Transfers a file from the virtual machine context to the front end context.

**Windows™ DDE Support**

Description of Windows™ DDE support.

**Important:** This feature is deprecated, and may be removed in a future version.

Dynamic Data Exchange (DDE) is a form of inter-process communication implemented by Microsoft™ for Windows™ platforms. DDE uses shared memory to exchange data between applications. Applications can use DDE for one-time data transfers and for ongoing exchanges in applications that send updates to one another as new data becomes available.

Please refer to your Microsoft™ documentation for DDE compatibility between existing versions. As an example, DDE commands were changed between Office 97 and Office 98.

We provide a DDE interface as a Front-End Extension: WinDDE.DLL

- **Using the WinDDE API** on page 2517
- **WINDDDE API front calls** on page 2518
- **WinDDE example** on page 2522

**Using the WinDDE API**

With WinDDE Support, you can invoke a Windows® application and send or receive data to or from it. To use this functionality, the program must use the Windows® front-end.

Before using the DDE functions, the TCP communication channel between the application and the front-end must be established with a display (OPEN WINDOW, MENU, DISPLAY TO).
Figure 113: The four-part procedure of the DDE API

The DDE API is used in a four-part procedure, as described in the following steps:

1. The application sends to the Front End the DDE order using the TCP/IP channel.
2. The Front End executes the DDE order and sends the data to the Windows® application through the DDE API.
3. The Windows® application executes the command and sends the result, which can be data or an error code, to the Front End.
4. The Windows® Front End sends back the result to the application using the TCP/IP channel.

A DDE connection is uniquely identified by two values: the name of the DDE Application, and the document. Most DDE functions require these two values to identify the DDE source or target.

**WINDDE API front calls**

The DDE API is based on the front call technique.

The DDE API is based on the front call technology. All DDE functions are grouped in the WINDDE front end function module.

**Table 529: Windows® DDE front-end functions**

<table>

**DDEConnect**

DDEConnect opens a DDE connection.

**Syntax**

Important: This feature is deprecated, and may be removed in a future version.

```lisp
call ui.Interface.frontCall("WINDE", "DDEConnect", [ program, document, encoding ], [ result ])
```

- `program` is the name of the DDE application.
- `document` is the document that is to be opened.
- `encoding` is an optional parameter. It allows to force the encoding to use between ASCII and wide char/unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are:
• UNICODE
• ASCII
• result is an integer variable receiving the status.
• result is TRUE if the function succeeded, FALSE otherwise.
• If the function fails, use DDEError to get the description of the error.

Warnings
• If the function fails with DMLERR_NO_CONV_ESTABLISHED, then the DDE application was probably not running. Use the execute or shellexecute front call to start the DDE application.
• In Microsoft™ Office 2010, the use of DDE is disabled by default. You need to uncheck Ignore other applications that use Dynamic Data Exchange(DDE) in advanced options, otherwise DDEConnect will fail.

DDEExecute
DDEExecute executes a DDE command.

Syntax
Important: This feature is deprecated, and may be removed in a future version.

CALL ui.Interface.frontCall("WINDDE","DDEExecute",
[ program, document, command, encoding ], [result] )

• program is the name of the DDE application.
• document is the document that is to be used.
• command is the command that needs to be executed.
• encoding is an optional parameter. It allows to force the encoding to use between ASCII and wide char/unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are: "UNICODE", "ASCII"
• Refer to the program documentation to know the syntax of command.
• result is an integer variable receiving the status.
• result is TRUE if the function succeeded, FALSE otherwise.
• If the function fails, use DDEError to get the description of the error.

Warnings
• The DDE connection must be opened see DDEConnect.

DDEFinish
DDEFinish closes a DDE connection.

Syntax
Important: This feature is deprecated, and may be removed in a future version.

CALL ui.Interface.frontCall("WINDDE","DDEFinish",
[ program, document ], [result] )

• program is the name of the DDE application.
• document is the document that is to be closed.
• result is an integer variable receiving the status.
• result is TRUE if the function succeeded, FALSE otherwise.
• If the function fails, use DDEError to get the description of the error.
**Warnings**

- The DDE connection must be opened, see [DDEConnect](#).

**DDEFinishAll**

DDEFinishAll closes all DDE connections.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WINDE", "DDEFinishAll", [], [result] )
```

- `result` is TRUE if the function succeeded, FALSE otherwise.

**Usage**

This function closes all DDE connections, as well as the DDE server program.

**DDEError**

DDEError returns error information about the last DDE operation.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WINDE", "DDEError", [], [errmsg] )
```

- `errmsg` is the error message. It is set to NULL if no error occurred.

**DDEPeek**

DDEPeek retrieves data from the specified program and document using the DDE channel.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WINDE", "DDEPeek", [program, container, cells, encoding], [result, value] )
```

- `program` is the name of the DDE application.
- `container` is the document or sub-document that is to be used. A sub-document can, for example, be a sheet in Microsoft™ Excel.
- `cells` represents the working items; see the `program` documentation to know the format of `cells`.
- `encoding` is an optional parameter. It allows to force the encoding to use between ASCII and wide char/unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are: "UNICODE", "ASCII"
- `value` represents the data to be retrieved; see the `program` documentation to know the format of `values`.
- `result` is an integer variable receiving the status.
- `result` is TRUE if the function succeeded, FALSE otherwise.
- If the function fails, use [DDEError](#) to get the description of the error.
- `value` is a variable receiving the cells values.

**Warnings**

- The DDE connection must be opened; see [DDEConnect](#).
- [DDEError](#) can only be called once to check if an error occurred.
**DDEPoke**

DDEPoke sends data to the specified program and document using the DDE channel.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```
CALL ui.Interface.frontCall("WINDE", "DDEPoke", [program, container, cells, values, encoding], [result])
```

- `program` is the name of the DDE application.
- `container` is the document or sub-document that is to be used. A sub-document can, for example, be a sheet in Microsoft™ Excel.
- `cells` represents the working items; see the `program` documentation to know the format of `cells`.
- `values` represents the data to be sent; see the `program` documentation to know the format of `values`.
- `encoding` is an optional parameter. It allows to force the encoding to use between ASCII and wide char/unicode. When not specified, WinDDE will try to retrieve the correct encoding by itself. Possible values are: "UNICODE", "ASCII"
- `result` is an integer variable receiving the status.
- `result` is TRUE if the function succeeded, FALSE otherwise.
- If the function fails, use `DDEError` to get the description of the error.

**Warnings**

- The DDE connection must be opened; see `DDEConnect`.
- An error may occur if you try to set many (thousands of) cells in a single operation.

**WinDDE example**

This section provides a WinDDE example.

dde_example.per

```
DATABASE formonly

SCREEN
{
    Value to be given to top-left corner:
    [f00]
    Value found on top-left corner:

DISPLAY "Exit with DDE Error."
EXIT PROGRAM (-1)
END FUNCTION

Windows™ COM Support
"COM" stands for Component Object Model. It allows anyone to directly access Windows™ Applications Objects.
You can create instances of those objects, call methods on them, and get or set their properties.

Important: This feature is deprecated, and may be removed in a future version.

- Using the WinCOM API on page 2523
- WINCOM API front calls on page 2524
- WinCOM examples on page 2526

Using the WinCOM API
With WinCOM Support, you can invoke a Windows™ application and send or receive data to or from it.

Prerequisites
To use this functionality, the program must use the Windows™ Front End.

Supported syntax
COM language syntax is very flexible and allows lots of notation. Genero WinCOM API is slightly more strict:

- := notation is allowed in version 2.00.1e (or later) only; for instance: myFunction(SourceType:=3)
- "no parenthesis" notation is not allowed; for instance: myFunction 3 must be written myFunction(3)
- numeric constants are allowed in version 2.00.1e (or later) only. The constant list depends on the application used via WinCOM, therefore the list is configurable: a file named etc/WinCOM.cst gathers all the constants provided today by Microsoft™ for Office XP. It can be modified to add user-defined constants. Example with Word: CALL ui.Interface.frontCall("WINCOM","SetProperty", [wdapp,"Selection.Font.Bold","9999998"],[wddoc]) Here, "9999998" stands for the constant wdToggle (see etc/WinCOM.cst).
- There is no way to handle an array as a method argument. This is also due to BDL limitation: you can't pass BDL Arrays to frontcalls.
**WINCOM API front calls**
The WinCOM API is based on the front call technique as described in Front End Functions. All WinCOM functions are grouped in the WinCOM front end function module.

**Table 530: Windows® COM front-end functions**

</tbody>
</table>
CreateInstance
The `CreateInstance` function creates an instance of a registered COM object.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WINCOM","CreateInstance", [program], [handle] )
```

- `program` is the classname of the registered COM object.
- `handle` is an integer variable receiving the status.
- `handle` is -1 if there as an error, otherwise an integer value that can be used for a later call to the API.
- If the function fails, use `GetError` to get the description of the error.

CallMethod
The `CallMethod` function calls a method on a specified object.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WINCOM","CallMethod", [ handle, method, arg1, ... ], [result] )
```

- `handle` is the handle returned by another front call (`CreateInstance`, `CallMethod`, `GetProperty`).
- `method` is the WINCOM method to call.
- `arg1 (and ...)` are the arguments to pass to the method call.
- `result` is either a handle or a value of a predefined type. -1 in case of error.

**Usage**

Depending on the syntax allowed by the version of the program you're interacting with, arguments might be used inside brackets or outside.

The best way for Microsoft™ applications is to initially test your code with a macro of the manipulation you're expecting to do. Depending on the method used, arguments may or may not be optional.

In case of error, `result` is set to -1. Use `GetError` to get the description of the error.

GetProperty
The `GetProperty` function gets a property of an object.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WINCOM","GetProperty", [ handle, member ], [result] )
```

- `handle` is the handle returned by another front call (`CreateInstance`, `CallMethod`, `GetProperty`).
- `member` is the member property name to get.
- `result` is either a handle or a value of a predefined type.
- `result` is -1 in case of error (use `GetError` to get the description of the error).
**SetProperty**
The `SetProperty` function sets a property of an object.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WINCOM","SetProperty",
                     [ handle, member, value ], [result] )
```

- `handle` is the handle returned by another front call (`CreateInstance, CallMethod, GetProperty`).
- `member` is the member property name to set.
- `value` is the value to which the property will be set.
- `result` is -1 in case of error (use `GetError` to get the description of the error), otherwise it is 0.

**GetError**
The `GetError` function gets a description of the last error which occurred.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WINCOM","GetError",
                      [ ], [result] )
```

- `result` is the description of the last error.
- the returned value is NULL if there was no error.

**ReleaseInstance**
The `ReleaseInstance` function releases an Instance of a COM object.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WINCOM","ReleaseInstance",
                     [handle], [result] )
```

- `handle` is the handle returned by another front call (`CreateInstance, CallMethod, GetProperty`).
- `result` is -1 in case of error (use `GetError` to get the description of the error), otherwise it is 0.

Windows™ Mail extension
Description of the Windows™ Mail extension.

**Important:** This feature is deprecated, and may be removed in a future version.

Send mail using MAPI
MAPI is an acronym for Messaging Application Programming Interface. The MAPI extension will create a new mail in the default mailer software, which needs to be "MAPI" compatible, and ask the user to send the mail. The mail sent using MAPI will be stored by the default mailer software in the same way as any other mail created by the user.

Send mail using an SMTP server
Another method of sending mail is to connect directly to an SMTP server (Simple Mail Transfer Protocol is the de facto standard for email transmission across the Internet). The extension will connect to a given SMTP server and send the mail through this server. The mail is not kept on the client side.

Binary format of GDC and WinMAIN DLL
**Important:** Since GDC and WinMAIN DLL binary format must match, the 32-bit WinAPI can only be used with a 32-bit GDC.

- WinMail API front calls on page 2531
- WinMail examples on page 2537

WinMail API front calls
The WinMail API is based on the front call technique as described in Front End Functions. All WinMail functions are grouped in the WinMail front end function module.

**Table 531: WinMail front-end functions: General**

<table>
<thead>

</table>
## Function name | Description
---|---
**Important:** This feature is deprecated, and may be removed in a future version.

```
CALL ui.Interface.frontCall("WinMail","AddAttachment", [ id, fileName], [ result ] )
```

The `AddAttachment` function adds a file as an attachment to the mail.

*Important:* This feature is deprecated, and may be removed in a future version.

```
CALL ui.Interface.frontCall("WinMail","SendMailSMTP", [ id ], [ result ] )
```

The `SendMailSMTP` function sends the mail with the SMTP protocol.

*Important:* This feature is deprecated, and may be removed in a future version.

```
CALL ui.Interface.frontCall("WinMail","SendMailMAPI", [ id ], [ result ] )
```

The `SendMailMAPI` function sends the mail with the MAPI protocol.

*Important:* This feature is deprecated, and may be removed in a future version.

```
CALL ui.Interface.frontCall("WinMail","GetError", [ id ], [ result ] )
```

The `GetError` function gets a description of the last error that occurred.

The following functions are needed when you use SMTP server connections:

### Table 532: WinMail front-end functions: SMTP-specific

## Function name | Description
---|---
**Important:** This feature is deprecated, and may be removed in a future version.

```
CALL ui.Interface.frontCall("WinMail","SetSmtp", [ id, smtp:port ], [ result ] )
```

The `SetSmtp` function sets the SMTP server to be used.

*Important:* This feature is deprecated, and may be removed in a future version.

```
CALL ui.Interface.frontCall("WinMail","SetFrom", [ id, name, address ], [ result ] )
```

The `SetFrom` function sets sender information.
**Init**
The Init function initializes the module.

**Syntax**
**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WinMail", "Init", [], [id] )
```

- `ret` is the identifier of the message initialized.
- For each Init function, a `Close` must be called.

**Usage**
This function initializes the module. It returns the identifier for the message, which will be used in other functions.

**Close**
The Close function clears all information corresponding to a message, and frees the memory occupied by the message.

**Syntax**
**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WinMail", "Close", [id], [result] )
```

- `id` is the message identifier.
- `result` is the status of the function.

**SetBody**
The SetBody function sets the body of the mail.

**Syntax**
**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WinMail", "SetBody", [id, body], [result] )
```

- `id` is the message identifier.
- `body` is the string text containing the body of the mail.
- `result` is the status of the function.

**SetSubject**
The SetSubject function sets the subject of the mail.

**Syntax**
**Important:** This feature is deprecated, and may be removed in a future version.

```plaintext
CALL ui.Interface.frontCall("WinMail", "SetSubject", [id, subject], [result] )
```

- `id` is the message identifier.
- `subject` is the string text containing the subject of the mail.
- `result` is the status of the function.
AddTo
The AddTo function adds a "To" addressee to the mail.

Syntax
Important: This feature is deprecated, and may be removed in a future version.

```javascript
CALL ui.Interface.frontCall("WinMail","AddTo",
    [ id, name, address ], [ result ] )
```

- `id` is the message identifier.
- `name` is the name to be displayed in the mail.
- `address` is the mail address to be used for this addressee.
- `result` is the status of the function.

Usage
This function adds a "To" Addresssee to the mail. The Addresssee has a name and a mail address.

AddCC
The AddCC function adds a "CC" addressee to the mail.

Syntax
Important: This feature is deprecated, and may be removed in a future version.

```javascript
CALL ui.Interface.frontCall("WinMail","AddCC",
    [ id, name, address ], [ result ] )
```

- `id` is the message identifier.
- `name` is the name to be displayed in the mail.
- `address` is the mail address to be used for this addressee.
- `result` is the status of the function.

Usage
This function adds a "CC" Addresssee to the mail. The Addresssee has a name and a mail address.

AddBCC
The AddBCC function adds a "BCC" addressee to the mail.

Syntax
Important: This feature is deprecated, and may be removed in a future version.

```javascript
CALL ui.Interface.frontCall("WinMail","AddBCC",
    [ id, name, address ], [ result ] )
```

- `id` is the message identifier.
- `name` is the name to be displayed in the mail.
- `address` is the mail address to be used for this addressee.
- `result` is the status of the function.

Usage
This function adds a "BCC" Addresssee to the mail. The Addresssee has a name and a mail address.
AddAttachment
The AddAttachment function adds a file as an attachment to the mail.

Syntax
Important: This feature is deprecated, and may be removed in a future version.

CALL ui.Interface.frontCall("WinMail","AddAttachment", [ id, fileName], [ result ])

- id is the message identifier.
- fileName is the path of the attachment; the path can be relative to the directory from which GDC is run, or absolute.
- result is the status of the function.

Usage
This function adds a file as an attachment to the mail. The file must be located on the front-end.

SendMailSMTP
The SendMailSMTP function sends the mail with the SMTP protocol.

Syntax
Important: This feature is deprecated, and may be removed in a future version.

CALL ui.Interface.frontCall("WinMail","SendMailSMTP", [ id ], [ result ])

- id is the message identifier.
- result is TRUE in case of success; use GetLastError to get the description of the error when needed.

Usage
This function sends the mail by using the SMTP protocol. default mailer software is called to create the mail. The user must press the "send" button to send the mail.

SendMailMAPI
The SendMailMAPI function sends the mail with the MAPI protocol.

Syntax
Important: This feature is deprecated, and may be removed in a future version.

CALL ui.Interface.frontCall("WinMail","SendMailMAPI", [ id ], [ result ])

- id is the message identifier.
- result is TRUE in case of success; use GetLastError to get the description of the error when needed.

Important:
- MAPI needs to log in to the mailer software. The first login can take time, depending on the mailer software. Your Genero application will be blocked until MAPI returns.
- MAPI depends on the mailer software for error management. For instance, Mozilla Thunderbird returns "success" when the mail is created, but Outlook 2002 only returns "success" when the mail is sent.
Usage

This function sends the mail by using the MAPI protocol. With MAPI, the default mailer software is called to create the mail. The user must press the "send" button to send the mail.

GetError

The GetError function gets a description of the last error that occurred.

Syntax

Important: This feature is deprecated, and may be removed in a future version.

CALL ui.Interface.frontCall("WinMail","GetError",
[ id ], [ result ] )

• id is the message identifier.
• result is the description of the last error.
• the returned value is NULL if there was no error.

SetSmtp

The SetSmtp function sets the SMTP server to be used.

Syntax

Important: This feature is deprecated, and may be removed in a future version.

CALL ui.Interface.frontCall("WinMail","SetSmtp",
[ id, smtp:port ], [ result ] )

• id is the message identifier.
• smtp is the string text containing the SMTP server to be used.
• port is optional. It allows to specify a port for your SMTP server. When not specified, the default port remains 25.
• result is the status of the function.

SetFrom

The SetFrom function sets sender information.

Syntax

Important: This feature is deprecated, and may be removed in a future version.

CALL ui.Interface.frontCall("WinMail","SetFrom",
[ id, name, address ], [ result ] )

• id is the message identifier.
• name is the name to be displayed in the mail.
• address is the mail address to be used for this addressee.
• result is the status of the function.

Mail using SMTP server

This topic provides an example of sending mail using an SMTP server.

```plaintext
MAIN
DEFINE result, id INTEGER
DEFINE str STRING
-- first, we initialize the module
CALL ui.Interface.frontCall("WinMail", "Init", [], [id])

-- Set the body of the mail
CALL ui.interface.frontCall("WinMail", "SetBody", [id, "This is a text mail using WinMail API - MAPI"], [result])

-- Set the subject of the mail
CALL ui.interface.frontCall("WinMail", "SetSubject", [id, "test mail - ignore it"], [result])

-- Add an Addressee as "TO"
CALL ui.Interface.frontCall("WinMail", "AddTo", [id, "myBoss", "boss@mycompany.com"], [result])

-- Add another Addressee as "BCC"
CALL ui.Interface.frontCall("WinMail", "AddBCC", [id, "my friend", "friend@mycompany.com"], [result])

-- Add Two attachments
CALL ui.Interface.frontCall("WinMail", "AddAttachment", [id, "c:\mydocs\report.doc"], [result])
CALL ui.Interface.frontCall("WinMail", "AddAttachment", [id, "c:\mydocs\demo.png"], [result])

-- Send the mail via the default mailer
CALL ui.Interface.frontCall("WinMail", "SendMailMAPI", [id], [result])
IF result == TRUE THEN
  DISPLAY "Message sent successfully"
ELSE
  CALL ui.Interface.frontCall("WinMail", "GetError", [id], [str])
  DISPLAY str
END IF
CALL ui.Interface.frontCall("WinMail", "Close", [id], [result])
END MAIN
```
CALL ui.Interface.frontCall("WinMail", "SetSmtp", [id, "smtp.mycompany.com"], [result])

-- Add an Addressee as "TO"
CALL ui.Interface.frontCall("WinMail", "AddTo", [id, "myBoss", "boss@mycompany.com"], [result])

-- Add another Addressee as "BCC"
CALL ui.Interface.frontCall("WinMail", "AddBCC", [id, "my friend", "friend@mycompany.com"], [result])

-- Add Two attachments
CALL ui.Interface.frontCall("WinMail", "AddAttachment", [id, "c:\mydocs\report.doc"], [result])
CALL ui.Interface.frontCall("WinMail", "AddAttachment", [id, "c:\mydocs\demo.png"], [result])

-- Send the mail via smtp
CALL ui.Interface.frontCall("WinMail", "SendMailSMTP", [id], [result])
IF result == TRUE THEN
    DISPLAY "Message sent successfully"
ELSE
    CALL ui.Interface.frontCall("WinMail", "GetError", [id], [str])
    DISPLAY str
END IF
CALL ui.Interface.frontCall("WinMail", "Close", [id], [result])
END MAIN

**Theme front calls**

This section describes Genero Browser Client (GBC)-specific front calls.

This table shows the functions implemented by the GBC in the "theme" module. These front calls were made available starting with GBC 1.00.47

**Table 533: theme module front-end functions**

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ui.Interface.frontCall(&quot;theme&quot;, &quot;setTheme&quot;, [name], [])</td>
<td>Activates a specific GBC theme.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;theme&quot;, &quot;getCurrentTheme&quot;, [], [result])</td>
<td>Gets the active GBC theme.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;theme&quot;, &quot;listThemes&quot;, [], [result])</td>
<td>Lists all available GBC themes.</td>
</tr>
</tbody>
</table>

**Related concepts**

Front calls on page 525
Front call functions execute on the platform where the front-end is installed.

**setTheme**
Activates a specific GBC theme.

**Syntax**

```plaintext
ui.Interface.frontCall("theme", "setTheme", [name], [])
```

- *name* - The theme to be activated.

**Usage**
The `setTheme` function allows the application to specify the theme to use for the application.

**Example**

```plaintext
main.4gl

IMPORT util

MAIN

DEFINE themes DYNAMIC ARRAY OF RECORD
    name STRING,
    title STRING
    -- conditions DYNAMIC ARRAY OF STRING
END RECORD

DEFINE result string

OPEN WINDOW w WITH FORM "myform"

CALL ui.Interface.frontCall("theme", "setTheme", ["highcontrast"], []
DISPLAY "highcontrast" to formonly.setTheme

CALL ui.Interface.frontCall("theme", "getCurrentTheme", [], [result])
DISPLAY result to formonly.getCurrentTheme

CALL ui.Interface.frontCall("theme", "listThemes", [], [result])
DISPLAY result to formonly.listThemes
CALL util.JSON.parse(result, themes)
DISPLAY ARRAY themes TO themes.*

MENU
    ON ACTION CANCEL
        EXIT MENU
    ON ACTION CLOSE
        EXIT MENU
END MENU

END MAIN
```

myform.per

```plaintext
LAYOUT
GRID
{
    setTheme                 [setTheme                  ]
    getCurrentTheme          [getCurrentTheme           ]
    listThemes               [listThemes                ]
}
**getCurrentTheme**

Gets the active GBC theme.

**Syntax**

```
ui.Interface.frontCall("theme", "getCurrentTheme", [], [result])
```

- `result` - The name of the active theme.

**Usage**

The `getCurrentTheme` function allows the application to ask for and receive the theme that, by default, will be used when displaying the application.

**Example**

main.4gl

```4gl
IMPORT util
MAIN

    DEFINE themes DYNAMIC ARRAY OF RECORD
        name STRING,
        title STRING
    -- conditions DYNAMIC ARRAY OF STRING
    END RECORD

    DEFINE result string

    OPEN WINDOW w WITH FORM "myform"

    CALL ui.Interface.frontCall("theme", "setTheme", ["highcontrast"], [])
    DISPLAY "highcontrast" to formonly.setTheme

    CALL ui.Interface.frontCall("theme", "getCurrentTheme", [], [result])
    DISPLAY result to formonly.getCurrentTheme

    CALL ui.Interface.frontCall("theme", "listThemes", [], [result])
    DISPLAY result to formonly.listThemes
    CALL util.JSON.parse(result, themes)
    DISPLAY ARRAY themes TO themes.*
```
myform.per

LAYOUT

INSTRUCTIONS
SCREEN RECORD themes(name, title)

listThemes
Lists all available GBC themes.

Syntax

```
ui.Interface.frontCall("theme", "listThemes",
  [], [result])
```

- **result** - A string containing a JSON array of the available themes. For each theme, the name, title, and conditions are listed. The conditions are contained within a second JSON array.

Usage

The `listThemes` function returns a JSON array of the themes available to the running application. The array consists of the name, title and conditions of each available theme. For example, the function returns the following when run against the out-of-the-box runtime installation on a desktop machine (line breaks added for readability):

```
[{
  "name": "default",
  "title": "Default",
  "conditions": ["isDesktop"]
}, {
  "name": "highcontrast",
  "title": "High contrast",
  "conditions": ["isDesktop"]
}]
```

Example

```
main.4gl

IMPORT util
```
MAIN

DEFINE themes DYNAMIC ARRAY OF RECORD
   name STRING,
   title STRING
-- conditions DYNAMIC ARRAY OF STRING
END RECORD

DEFINE result string

OPEN WINDOW w WITH FORM "myform"

CALL ui.Interface.frontcall("theme", "setTheme", ["highcontrast"], [])
DISPLAY "highcontrast" to formonly.setTheme

CALL ui.Interface.frontcall("theme", "getCurrentTheme", [], [result])
DISPLAY result to formonly.getCurrentTheme

CALL ui.Interface.frontcall("theme", "listThemes", [], [result])
DISPLAY result to formonly.listThemes
CALL util.JSON.parse(result, themes)

Local storage front calls

This section describes front calls to store data on the front-end platform.

Key/Value pairs can be stored locally on the front-end side with the localStorage front calls.
Local storage is supported by all front-ends.
The data is stored on the platform where the front-end executes, and is persistent across application sessions.
This feature can for example be used to keep a trace of the authenticated users, if the authentication mechanism is written in Genero.

The table shows the functions implemented by all front-ends in the "localStorage" module.

### Table 534: localStorage module front-end functions

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ui.Interface.frontCall(&quot;localStorage&quot;, &quot;clear&quot;, [&quot;, [&quot;]</code></td>
<td>Removes all local storage key/value pairs.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;localStorage&quot;, &quot;getItem&quot;, [key], [value])</code></td>
<td>Returns the current value of local storage key.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;localStorage&quot;, &quot;keys&quot;, [&quot;, [key-list]</code>)</td>
<td>Returns the list of defined local storage keys.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;localStorage&quot;, &quot;removeItem&quot;, [key], [])</code></td>
<td>Deletes the specified local storage key.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;localStorage&quot;, &quot;setItem&quot;, [key, value], [])</code></td>
<td>Sets a value for local storage key.</td>
</tr>
</tbody>
</table>

### setItem
Sets a value for local storage key.

**Syntax**

```plaintext
ui.Interface.frontCall("localStorage", "setItem", [key, value], [])
```

- `key` is the name of the local storage key.
- `value` is the value to set for the named key.

**Usage**
The `setItem` function sets the specified local storage key with the value passed as parameter.

### getItem
Returns the current value of local storage key.

**Syntax**

```plaintext
ui.Interface.frontCall("localStorage", "getItem", [key], [value])
```

- `key` is the name of the local storage key.
- `value` is the current value of the named key.
Usage

The `getItem` function returns the value of the specified local storage key.

**removeItem**

Deletes the specified local storage key.

**Syntax**

```plaintext
ui.Interface.frontCall("localStorage", "removeItem", [key], [])
```

- `key` is the name of the local storage key.

**Usage**

The `removeItem` function deletes the specified local storage key.

**keys**

Returns the list of defined local storage keys.

**Syntax**

```plaintext
ui.Interface.frontCall("localStorage", "keys", [], [key-list])
```

- `key-list` list of key names as a JSON array of strings.

**Usage**

The `keys` function returns the current local storage keys defined on the front-end platform.

The list of keys is returned in a string variable, as a JSON array of strings.

Convert the JSON array to a BDL dynamic array with `util.JSON.parse` on page 2616:

```plaintext
IMPORT util ...

DEFINE key_list STRING,
                   key_array DYNAMIC ARRAY OF STRINGS

CALL ui.Interface.frontCall("localStorage", "keys", [], [key_list])
CALL util.JSON.parse( key_list, key_array )
```

**clear**

Removes all local storage key/value pairs.

**Syntax**

```plaintext
ui.Interface.frontCall("localStorage", "clear", [], [])
```

**Usage**

The `clear` function removes all local storage keys currently saved on the front-end side.
Genero Mobile common front calls

This section describes common front calls provided by all mobile front-ends.

This table shows the functions implemented by all mobile front-ends in the "mobile" module.
<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;chooseContact&quot;, [], [result])</td>
<td>Lets the user choose a contact from the mobile device contact list and returns the vCard.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;choosePhoto&quot;, [], [path])</td>
<td>Lets the user select a picture from the mobile device's photo gallery and returns a picture identifier.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;chooseVideo&quot;, [], [path])</td>
<td>Lets the user select a video from the mobile device's video gallery and returns a video identifier.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;composeMail&quot;, [to, subject, content, cc, [result]])</td>
<td>Invokes the user's default mail application for a new mail to send.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;composeSMS&quot;, [recipients, content, [result]])</td>
<td>Sends an SMS text to one or more phone numbers.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;connectivity&quot;, [], [result])</td>
<td>Returns the type of network available for the mobile device.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;getGeolocation&quot;, [], [status, latitude, longitude])</td>
<td>Returns the Global Positioning System (GPS) location of a mobile device.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;getRemoteNotifications&quot;, [], [data])</td>
<td>This front call retrieves push notification messages.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;importContact&quot;, [vcard], [result])</td>
<td>Creates a new contact, or merges to an existing entry, the contact details passed in a vCard string.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;isForeground&quot;, [], [result])</td>
<td>Indicates if the mobile app is in foreground mode.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;registerForRemoteNotifications&quot;, [], [registration-token])</td>
<td>This front call registers a mobile device for push notifications.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;runOnServer&quot;, [appurl, timeout], [])</td>
<td>Run an application from the Genero Application Server using the specified URL.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;scanBarCode&quot;, [], [code, type])</td>
<td>Allow the user to scan a barcode with a mobile device.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;takePhoto&quot;, [], [path])</td>
<td>Lets the user take a picture with the mobile device and returns the corresponding picture identifier.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;takeVideo&quot;, [], [path])</td>
<td>Lets the user take a video with the mobile device and returns the corresponding video identifier.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;mobile&quot;, &quot;unregisterFromRemoteNotifications&quot;, [], [])</td>
<td>This front call unregisters the mobile device from push notifications.</td>
</tr>
</tbody>
</table>
chooseContact

Lets the user choose a contact from the mobile device contact list and returns the vCard.

Syntax

```
ui.Interface.frontCall("mobile", "chooseContact", [], [result])
```

- `result` - The vCard string from the device's contacts database.

Usage

The "chooseContact" front call opens the mobile device contact chooser, allows the user to select a contact and returns the contact as a vCard string.

**Important:** For GMA / Android™, using the chooseContact front call needs the `android.permission.READ_CONTACTS` Dangerous Permission to be specified when building the APK. See Android permissions on page 3321 for more details. On Android™ 5.1 and lower (< API 23), use the `android.permission.GET_ACCOUNTS` permission.

If the user cancels the contact chooser, NULL is returned.

Example

```
DEFINE vcard STRING
CALL ui.Interface.frontCall("mobile", "chooseContact", [], [vcard])
```

choosePhoto

Lets the user select a picture from the mobile device's photo gallery and returns a picture identifier.

Syntax

```
ui.Interface.frontCall("mobile", "choosePhoto", [], [path])
```

1. `path` - Holds the device opaque path to the chosen photo.

Usage

The "choosePhoto" front call starts the system's photo chooser (the device's photo gallery), allows the user to choose a photo, and returns the path/URL on the mobile device of the chosen photo.

If the user cancels the photo chooser, NULL is returned.

**Important:** For GMA / Android™, using the choosePhoto front call needs the `android.permission.READ_EXTERNAL_STORAGE` Dangerous Permission to be specified when building the APK. See Android permissions on page 3321 for more details.

The value returned in the `path` variable contains a reference to the system location of the picture on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the picture.

For more details about mobile image handling, see images handling on mobile devices.
Related concepts

Describes how to use pictures in the forms of your application.

fgl_getfile() on page 2167
Retrieves a file from the front-end context to the virtual machine context.

takePhoto on page 2560
Lets the user take a picture with the mobile device and returns the corresponding picture identifier.

chooseVideo
Lets the user select a video from the mobile device's video gallery and returns a video identifier.

Syntax

```javascript
ui.Interface.frontCall("mobile", "chooseVideo", [], [path])
```

1. **path** - Holds the device opaque path to the selected video.

Usage

The "chooseVideo" front call starts the system's video chooser (the device's video gallery), allows the user to choose a video, and returns the path/URL on the mobile device of the selected video.

If the user cancels the video chooser, NULL is returned.

**Important:** For GMA / Android™, using the chooseVideo front call needs the android.permission.READ_EXTERNAL_STORAGE Dangerous Permission to be specified when building the APK. See Android permissions on page 3321 for more details.

The value returned in the path variable contains a reference to the system location of the video on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the video.

Once the video identifier/path is known, it is possible to fetch the video file from the device to the program context with the fgl_getfile() API. The procedure is similar to fetching photos from the device. For more details, see the section about video handling on mobile devices.

To play the video, you can perform a "launchURL" front call, with the opaque path returned by this front call.

Retrieves a file from the front-end context to the virtual machine context.

takeVideo on page 2561
Lets the user take a video with the mobile device and returns the corresponding video identifier.

composeMail
Invokes the user's default mail application for a new mail to send.

Syntax

```javascript
ui.Interface.frontCall("mobile", "composeMail", [to, subject, content, cc, bcc, attachments ...], [result])
```

- **to** - A list of recipients, separated by commas. While the list uses commas to separate the recipients in the list, the list itself is enclosed in a single set of quotes.
• **subject** - The subject of the email.
• **content** - The body of the email.
• **cc** - (optional) A list of recipients for the carbon-copy email field, separated by commas. While the list uses commas to separate the recipients in the list, the list itself is enclosed in a single set of quotes.
• **bcc** - (optional) A list of recipients for the blind carbon-copy email field, separated by commas. While the list uses commas to separate the recipients in the list, the list itself is enclosed in a single set of quotes.
• **attachments** ... - (optional) All remaining arguments are treated as paths to attachment files. Each attachment file name is enclosed in its own set of quotes. The comma is used to separate the attachments in the list.
• **result** - Holds a status message.

**Usage**

The "composeMail" front call invokes the user's default mail application and sets up a new mail to send.

The returned result string takes one of the following values:
• "ok": The email was sent.
• "cancel": The email was canceled.
• "saved": The email was saved.
• "failed: reason": The email was not sent.

This example opens an email and populates the To, CC, and BCC fields, the Subject line, the message body, and it specifies two attachments..

```
DEFINE result STRING
CALL ui.Interface.frontCall("mobile", "composeMail",
    ["john.doe@4js.com,jane.doe@4js.com", "Hello world",
     "This is the hello world text", "john.doe@4js.com,jane.doe@4js.com",
     "hidden@4js.com",
     "/sdcard/Pictures/photo1.jpg", "/sdcard/Pictures/photo2.jpg" ], [result])
```

The next example opens an email and populates the To field, the Subject line, and the message body. No CC or BCC recipients and no attachments are specified.

```
DEFINE result STRING
CALL ui.Interface.frontCall("mobile","composeMail",
    ["huhu@haha.com","test mail","sent from my device"],[result])
```

**composeSMS**

Sends an SMS text to one or more phone numbers.

**Syntax**

```
ui.Interface.frontCall("mobile", "composeSMS",
    [ recipients, content ],
    [ result ] )
```

• **recipients** - A list of phone numbers, separated by commas. While the list uses commas to separate the phone numbers in the list, the list itself is enclosed in a single set of quotes.
• **content** - The SMS message.
• **result** - Holds a status message.

**Usage**

The "composeSMS" front call sends an SMS text to one or more phone numbers.

Consider using global phone numbers with a + plus sign, as described in [RFC3966].

The returned result string can take one of the following values:
• "ok": The SMS was sent.
• "cancel": The SMS was canceled.
• "failed": The SMS could not be sent.

Error -6333 is raised, if there is no permission to compose an SMS on the mobile phone.

Example

```
DEFINE result STRING
CALL ui.Interface.frontCall("mobile", "composeSMS",

["+332781211,+339956789", "This is the SMS text"],

[result])
```

**connectivity**

Returns the type of network available for the mobile device.

**Syntax**

```
ui.Interface.frontCall("mobile", "connectivity",

[], [result] )
```

- **result** - Holds the type of network available.

**Usage**

The "connectivity" front call checks for the best available mobile network connectivity to the internet.

The returned result string can take one of the following values:

- "NONE": No connectivity is available to the internet or the specified host.
- "MobileNetwork": Connectivity is available via the mobile network (Edge, 3G, 4G).
- "WIFI": Connectivity is available via a WIFI connection.

Example

```
DEFINE network STRING
CALL ui.Interface.frontCall("mobile", "connectivity", 

[], [network] )
IF network == "WIFI" THEN
    ...
END IF
```

**Related concepts**

- [Front calls](on page 525)

Front call functions execute on the platform where the front-end is installed.

**getGeolocation**

Returns the Global Positioning System (GPS) location of a mobile device.

**Syntax**

```
ui.Interface.frontCall("mobile", "getGeolocation",

[], [status, latitude, longitude] )
```

1. **status** - Holds the status of the front call execution.
2. **latitude** - Holds the current latitude.
3. **longitude** - Holds the current longitude.
Usage

The "getGeolocation" front call returns the current location of the mobile device, based on the current GPS information.

Important: For GMA / Android™, using the getGeolocation front call needs the android.permission.ACCESS_FINE_LOCATION and android.permission.ACCESS_COARSE_LOCATION Dangerous Permissions to be specified when building the APK. See Android permissions on page 3321 for more details.

The possible values returned in the status parameter are:

• "ok": The mobile device location was found.
• In case of failure, the status variable contains the error description, for example, "location services not enabled".

It is recommended that the returned coordinates are stored in FLOAT variables.

If the device's location cannot be found within a given period, the front call returns an error status.

Example

```plaintext
DEFINE status STRING, latitude, longitude FLOAT
CALL ui.Interface.frontCall("mobile", "getGeolocation", [], [status, latitude, longitude] )
MESSAGE SFMT("Geo location: (status=%1) Latitude=%2 Longitude=%3", status, latitude, longitude )
```

getRemoteNotifications

This front call retrieves push notification messages.

Syntax

```plaintext
ui.Interface.frontCall("mobile","getRemoteNotifications", [], [data] )
```

1. data - STRING containing a JSON array of notifications.

Usage

After registering for push notifications with the registerForRemoteNotifications on page 2556 front call, the getRemoteNotifications front call can be called in the context of an ON ACTION notificationpushed action handler.

The GMI or GMA front-end will send the notificationpushed special action, when it receives notifications from the push notification server. When this action is fired, use the getRemoteNotifications front call to get notification data.

Important:

When an app restarts, if notifications are pending and the app has already registered for push notification in a previous execution, the notificationpushed action will be raised as soon as a dialog with the corresponding ON ACTION handler activates. The app then performs a getRemoteNotifications on page 2552 front call as in the usual way, to get the pending notifications pushed to the device while the app was off.

However, special consideration needs to be given to iOS devices. When push notification arrives for an iOS app that has not started, there is no mechanism to wake up the app and get the push data. Therefore, when the user starts the app from the springboard, there will never be any push data available. Depending on the context, implement the following programming patterns to solve this problem:

1. If the push notification contains a badge number, the app can verify if the badge is greater than 0 (with the getBadgeNumber front call) in order to perform a getRemoteNotifications front call. Even if there
is no data available with the front call, it is recommended that the app sends a request directly to the server push provider to get last push data.

2. If the push notification does not contain badge numbers, it is still recommended that the app performs a `getRemoteNotification` front call when it starts. If there is no push data available from the front call, the recommendation is that the app sends a request to the server push provider to see if there is push data available. This is by the way also recommended when receiving a `notificationpushed` action during application life time.

3. If the user starts the app from the Notification Center, the app is launched with push data transmitted from the system, and the `notificationpushed` action is sent. It is recommended that the app perform a `getRemoteNotifications` front call and get the push data.

The "getRemoteNotifications" front call returns a list of notification records as a JSON array string. Use the `util.JSONArray` or `util.JSON` class to extract notification data from the returned string. The structure of a push notification is platform specific. See below for details.

**Important:** When an iOS app is in background, silent push notifications can occur, but notification message data (i.e. the payload) may not be available. In such case, GMI is able to detect that a notification arrived (i.e. when the app badge number is greater than zero) and raise the `notificationpushed` action, but the `getRemoteNotifications` front call will return no message data (`data` return param is `NULL`). If such case, implement a fallback mechanism (based on RESTful web services for example), to contact the push notification provider and retrieve the message information.

**Push notification records with GMA / Android™**

The returned JSON string from a FCM notification server contains an array of notification records.

A notification record contains the following JSON keys:

- "type" - can be "message" or "token".
- "data" - Contains notification data.
  - When "type":"message", the notification record is a FCM application message, and the data attribute contains custom notification information. An element of "data" can be a "genero_notification" record, that will produce an Android™ graphical notification. This record must define the following attributes:
    - "title" - title of the graphical notification
    - "content" - text content of the graphical notification
    - "icon" - icon of the graphical notification
  
  The "genero_notification" record can be followed by custom notification data.
  - When "type":"token", the notification record is a registration token update, and the "data" attribute contains the new registration token, that is required to be re-sent to the push notification server.
  - "from" - Contains the FCM project id.

JSON push notification data example for GMA:

```
[
  {
    "type": "message",
    "data": { custom-attributes ... },
    "from": "project-id"
  },
  {
    "type": "token",
    "data": "new-registration-token",
    "from": "project-id"
  },
  ...
]```
Note that the JSON push notification data can contain a "data" attribute with a "genero_notification" record, that will produce an Android™ graphical notification:

```json
[
  {
    "type": "message",
    "data": {
      "genero_notification": {
        "title": "Game Request!",
        "content": "Bob wants to play poker...",
        "icon": "smiley"
      },
      custom-attributes ...
    },
    "from": "project-id"
  },
  ...
]
```

**Push notification records with GMI / iOS**

The returned JSON string from an Apple® Push Notification contains an array of notification records.

A push notification record contains the following JSON attributes:

- "aps" (required) - key to be recognized by devices as an Apple® Push Notification
  - "alert" (required) - key of the push notification content. If not specified as a single value, the alert key can hold:
    - "title" - title of the alert.
    - "body" - the message to be displayed.
  - "badge" (optional) - the number to display as the badge of the app icon. If this property is absent, the badge is not changed. You need to manage it through your push notification provider.
  - "sound" (optional) - the sound played by the alert (aiff, wav, or caf format) default value: "default". To use a custom file you will need to use the GMI extension project and be familiar with Objective-C. The file must bundled with the app.
  - "content-available" (required) - The content-available property with a value of 1 allows the remote notification to act as a “silent” notification. The recommendation is that notifications received in background mode are stored for delivery when the app enters foreground mode.

JSON push notification data example for GMI:

```json
[
  {"aps": {
    "alert": "My first push",
    "badge": 1,
    "sound": "default",
    "content-available": 1
  }},
  {"aps": {
    "alert": {
      "title": "Push",
      "body": "My second push"
    }
  }}
]```
In the last record, custom information is provided in the "new_ids" and "updated_ids" attributes, as a JSON array of identifiers.

For more details, see Apple Push Notification Service.

Example

```
IMPORT util -- JSON API
DEFINe notif_list STRING
DIALOG ...
...
ON ACTION notificationpushed
   CALL ui.Interface.frontCall(
      "mobile", "getRemoteNotifications",
      [ ], [ notif_list ] )
   -- Analyse content of notiflist
   DISPLAY util.JSON.format(notif_list)
...
```

Related concepts

registerForRemoteNotifications on page 2556
This front call registers a mobile device for push notifications.

importContact
Creates a new contact, or merges to an existing entry, the contact details passed in a vCard string.

Syntax

```
ui.Interface.frontCall("mobile", "importContact",
   [vcard], [result] )
```

1. `vcard` - Holds a vCard string to be imported into the device's contacts database.
2. `result` - Holds the completed vCard string.

Usage
The "importContact" front call sends the vCard definition passed as parameter to the mobile device.

If the contact import is canceled, the front-end returns NULL. Otherwise, it returns the vCard data.

On iOS devices, the user has the choice to create a new contact, or complete an existing contact entry. When creating a new entry, the contact input form is opened on the mobile device, to let the user complete the default values passed as parameter. When merging contact information to an existing entry, the user selects an entry from the contact list. If the contact import is validated, the front call returns the completed vCard string.
On Android™ devices, this front call creates a new contact entry directly in the mobile contact list, depending on the VCard definition passed as parameter, no intermediate input form is presented to the end user. If the contact import is validated, the front call returns the original vCard string passed as parameter.

**Important:** For GMA / Android™, using the importContact front call needs the android.permission.WRITE_EXTERNAL_STORAGE Dangerous Permission to be specified when building the APK. See Android permissions on page 3321 for more details.

**Example**

```
DEFINE vcard, result STRING
LET vcard="BEGIN:VCARD
"||"VERSION:3.0\n"||"N:Willi;;;;\n"||"TEL;type=HOME;type=VOICE;type=pref:03812225610\n"||"END:VCARD\n"
CALL ui.interface.frontcall("mobile","importContact",[vcard],[result])
```

**Related concepts**

newContact (iOS) on page 2568

Lets the user input contact information to create a new entry in the contact database of the mobile device.

**isForeground**

Indicates if the mobile app is in foreground mode.

**Syntax**

```
ui.Interface.frontCall("mobile", "isForeground", [], [result])
```

- **result** - Is set to **TRUE** if the app is in foreground mode, or **FALSE** if in background mode.

**Usage**

The "isForeground" front call checks if the mobile app is currently in foreground or background mode.

```
DEFINE fg BOOLEAN
CALL ui.Interface.frontCall("mobile", "isForeground", [], [fg])
IF fg THEN
  ...
END IF
```

Use the isForeground front call in conjunction with the enterforeground and enterbackground predefined actions.

**registerForRemoteNotifications**

This front call registers a mobile device for push notifications.

**Syntax**

```
ui.Interface.frontCall("mobile","registerForRemoteNotifications", [], [registration-token])
```

1. **registration-token** - Registration token to be sent to the push notification provider. For GMA/Android, this is the "registration token" obtained from Firebase Cloud Messaging (FCM), for GMI/iOS, this is the "device token" obtained from Apple Push Notification services (APNs).
Usage

The "registerForRemoteNotifications" front call registers the mobile device for push notifications. Once the registration procedure is done (see below for platform specifics), it is possible to get notification events through the notificationpushed predefined action, and retrieve notification data with the getRemoteNotifications on page 2552 front call.

Note: The app does not need to register for notification each time it is restarted. Even if the app is closed, the registration is still active until the unregisterFromRemoteNotifications front call is performed. At first execution, an app will typically ask if the user wants to get push notifications and register to the push service if needed. To disable push notification, apps usually implement an option that can be disabled (to unregister) and re-enabled (to register again) by the user. On Android™, the app must register for notification each time it is upgraded.

Registering with FCM on Android

On Android™ the registration-token is the registration token returned by FCM. Once registered with the FCM service, the app must also send this registration token to the FCM application server. Registration tokens are typically sent to the FCM application server using a RESTful HTTP POST.

Note: Android™ apps using push notification services need specific permissions to be defined in the manifest, such as android.permission.GET_ACCOUNTS, com.google.android.c2dm.permission.RECEIVE, and especially application-package-name.permission.C2D_MESSAGE. These Android permissions will be automatically set by the gmabuildtool, depending on the package name specified with the --build-app-package-name option.

For more details, see FCM documentation and About FCM Connection Server.

Registering with APNs on iOS

On iOS when using APNs, the registration-token is the device token returned by the Apple Push Notification service. Once registered with the Apple Push Notification service, the app must also send this device token to the push notification provider, typically using a RESTful HTTP POST.

For more details about Apple Push Notification Provider, see the Apple Push Notification Service web site.

Example

The following code example registers with Firebase Cloud Messaging or Apple Push Notification service. It then sends the registration token to the push notification provider:

```java
IMPORT com  -- For RESTful post
IMPORT util -- JSON API
DEFINE registration_token STRING
DEFINE req com.HTTPRequest,
    obj util.JSONObject,
    resp com.HTTPResponse

-- First get the registration token
CALL ui.Interface.frontCall(
    "mobile", "registerForRemoteNotifications",
    [], [ registration_token ] )

-- Then send registration token to push notification provider
TRY
    LET req = com.HTTPRequest.create("http://SERVER_IP:4930")
    CALL req.setHeader("Content-Type", "application/json")
    CALL req.setMethod("POST")
    CALL req.setTimeOut(5)
    LET obj = util.JSONObject.create()
    CALL obj.put("registration_token", registration_token)
    CALL req.doTextRequest(obj.toString())
    LET resp = req.getResponse()
```
IF resp.getStatusCode() != 200 THEN
    MESSAGE SFMT("HTTP Error (%1) %2",
                   resp.getStatusCode(),
                   resp.getStatusDescription())
ELSE
    MESSAGE "Registration token sent."
END IF
CATCH
    MESSAGE SFMT("Could not post registration token to server: %1", STATUS)
END TRY

Related concepts

unregisterFromRemoteNotifications on page 2561
This front call unregisters the mobile device from push notifications.

The APNS class on page 2766
The com.APNS class implements Apple® Push Notification Service APIs.

runOnServer
Run an application from the Genero Application Server using the specified URL.

Syntax

ui.Interface.frontCall("mobile", "runOnServer",
                     [ appurl, timeout ], [ ] )

• appurl - The GAS URL to the Genero application (this must be a ua/r URL).
• timeout - The timeout (in seconds) to wait for the remote application.

Usage

The runOnServer front call allows you to start an application in the Genero Application Server (GAS), from an embedded/local application running on the mobile device. The remote application's graphical user interface displays on the mobile device.

The front call returns when the called application ends, and the control goes back to the initial application executing on the mobile device.

The applications executed on the GAS server must use the UTF-8 encoding. Mobile front-ends will reject any attempt to display forms of an application using an encoding other than UTF-8.

The remote application cannot use RUN WITHOUT WAITING to start child programs. Only RUN is supported.

The first parameter (appurl) identifies the remote application to be started and must contain an "ua/r" URL syntax (the UA protocol introduced with the GAS 3.00).

For example: http://myappserver:6394/ua/r/myapp.

This URL may contain a query string, with parameters for the application to be executed by the GAS.

The timeout parameter is optional. It can be used to give the control back to the local app, if the remote app takes too long to respond. If not specified, or when zero is passed, the timeout is infinite.

In case of failure (such as application not found, or timeout expired), the front call raises the runtime error -6333 and the HTTP status code of the request can be found in the error message details.

Note: The application running on the GAS can only access the data-directory directory, in the sandbox of the embedded application that executes the runOnServer front call. File handling APIs like fgl_getfile() and fgl_putfile() can only access this directory on the mobile device. If no absolute path is specified in the file path for the mobile device, the data-directory is used.
**Example**

```plaintext
TRY
    CALL ui.interface.frontcall("mobile","runOnServer","["http://santana:6394/ua/r/orders"],[])
CATCH
    ERROR err_get(STATUS)
END TRY
```

**Related concepts**

- **Running mobile apps on an application server** on page 3342

From the mobile device, programs can be started remotely on an application server, and displayed on the device.

**scanBarCode**

Allow the user to scan a barcode with a mobile device

**Syntax**

```plaintext
ui.Interface.frontCall("mobile", "scanBarCode", [], [code, type])
```

1. `code` - Holds a string representation of the barcode.
2. `type` - Holds the name of the barcode type.

**Usage**

The "scanBarCode" front call starts the barcode scanner to let the user scan a barcode with the device.

After reading the barcode, the front call returns the string representation of the barcode and the barcode type (i.e. symbology).

The `code` return parameter contains the barcode string.

The `type` return parameter indicates the type of barcode that was scanned.

- If the barcode scan was canceled, the `code` return parameter is set to `NULL` and `type` is set to "canceled".

- On iOS devices, the barcode reader used by GMI is "ZBar". For more details, see ZBar barcode reader.
- On Android™ devices, the barcode reader used by GMA is "zxing". The zxing barcode reader must be installed as a separate app. For more details, see Barcode Scanner.

**takePhoto**

Lets the user take a picture with the mobile device and returns the corresponding picture identifier.

**Syntax**

```java
ui.Interface.frontCall("mobile", "takePhoto",
    [], [path] )
```

1. *path* - Holds the device opaque path to the picture that has been taken.

**Usage**

The "takePhoto" front call invokes the mobile device's camera to let the user take a picture and returns the local path/URL on the mobile device to the picture.

If the photo is canceled by the user, the front call returns **NULL**.

**Important:** For GMA / Android™, using the `takePhoto` front call needs the `android.permission.WRITE_EXTERNAL_STORAGE` Dangerous Permission to be specified when building the APK. See [Android permissions](#) on page 3321 for more details.

The value returned in the *path* variable contains a reference to the system location of the picture on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the picture.

For more details about mobile image handling, see [images handling on mobile devices](#).

**Related concepts**

- [Using images](#) on page 1046
  Describes how to use pictures in the forms of your application.

- [fgl_getfile()](#) on page 2167
  Retrieves a file from the front-end context to the virtual machine context.

- [choosePhoto](#) on page 2548
Lets the user select a picture from the mobile device's photo gallery and returns a picture identifier.

**takeVideo**
Lets the user take a video with the mobile device and returns the corresponding video identifier.

**Syntax**

```java
ui.Interface.frontCall("mobile", "takeVideo", [], [path])
```

1. **path** - Holds the device opaque path to the video.

**Usage**

The "takeVideo" front call invokes the mobile device's camera to let the user take a video and returns the local path/URL to the video on the mobile device.

If the photo is canceled by the user, the front call returns NULL.

**Important:** For GMA / Android™, using the `takeVideo` front call needs the `android.permission.WRITE_EXTERNAL_STORAGE` Dangerous Permission to be specified when building the APK. See Android permissions on page 3321 for more details.

The value returned in the `path` variable contains a reference to the system location of the video on the mobile device. This path is platform dependent, and may change in future versions. Consider the path returned by this front call as an opaque local file identifier, and do not use this path as a persistent file name for the video.

Once the video identifier/path is known, it is possible to fetch the video file from the device to the program context with the `fgl_getfile()` API. The procedure is similar to fetching photos from the device. For more details, see the section about video handling on mobile devices.

To play the video, you can perform a "launchURL" front call, with the opaque path returned by this front call.

**Related concepts**

- Using images on page 1046
- `fgl_getfile()` on page 2167
- chooseVideo on page 2549
- unregisterFromRemoteNotifications

This front call unregisters the mobile device from push notifications.

**Syntax**

```java
ui.Interface.frontCall("mobile", "unregisterFromRemoteNotifications", [], [])
```

**Usage**

The "unregisterFromRemoteNotifications" front call unregisters the device from push notifications after it has been registered with the `registerForRemoteNotifications` on page 2556 front call.

**Example**

```java
CALL ui.Interface.frontCall(
    "mobile", "unregisterFromRemoteNotifications", [
        [], []
    ]
)
Related concepts
registerForRemoteNotifications on page 2556
This front call registers a mobile device for push notifications.

Genero Mobile Android™ front calls
This section describes front calls specific to the Android™ platform.

This table shows the functions implemented by the Android™ front-end in the "android" module.

Table 537: Android™ module front-end functions

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ui.Interface.frontCall(&quot;android&quot;, &quot;askForPermission&quot;, [permission], [result])</td>
<td>Ask the user to enable a dangerous feature on the Android device.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;android&quot;, &quot;showAbout&quot;, [])</td>
<td>Shows the GMA about box displaying version information.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;android&quot;, &quot;showSettings&quot;, [])</td>
<td>Shows the GMA settings box controlling debug options.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;android&quot;, &quot;startActivity&quot;, [action, data, category, type, component, extras], [])</td>
<td>Starts an external Android™ application (activity), and returns to the GMA application immediately.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;android&quot;, &quot;startActivityForResult&quot;, [action, data, category, type, component, extras], [outdata, outextras])</td>
<td>Starts an external application (Android activity) and waits until the activity is closed.</td>
</tr>
</tbody>
</table>

Related concepts
Genero Mobile common front calls on page 2546
This section describes common front calls provided by all mobile front-ends.

askForPermission (Android™)
Ask the user to enable a dangerous feature on the Android device.

Syntax

ui.Interface.frontCall("android", "askForPermission", [permission], [result])

1. permission - Identifies the Android™ permission to enable.
2. result - Holds the execution status of the front call:
   • "ok": the user accepted the permission.
   • "rejected": the user refused the permission.
Usage
The "askForPermission" front call opens a message box, to let the end user confirm the access to a "Dangerous Permission" on Android™, to enable a risky feature of the mobile device.

**Important:** The askForPermission front call has been introduced for Android™ 6: Since this version of Android, permissions to access dangerous mobile functions are no longer asked during app installation: The app code must explicitly ask the user for dangerous permissions when needed, with an askForPermission front call.

The permissions parameter defines the Android™ permission to be asked. It must be a string representing one of the permission constants, as defined in Android's Manifest permissions, prefixed by the "android.permission." string. For example, the "android.permission.WRITE_EXTERNAL_STORAGE" string can be used to identify the permission to access the SDCARD storage unit.

**Important:** Android™ Dangerous Permissions required by the app also need to be specified when building the app. For more details, see Android permissions on page 3321.

The front call will raise a runtime exception if the permission identifier is not valid.

Example
The following code example asks the user to access the SDCARD, and handles the user choice:

```plaintext
DEFINE result STRING
CALL ui.Interface.frontCall(
   "android", "askForPermission",
   ["android.permission.WRITE_EXTERNAL_STORAGE"],
   [result] )
CASE result
   WHEN "ok"
      CALL os.Path.mkDir("/sdcard/myfiles")
   WHEN "rejected"
      ERROR "SDCARD access was denied by user"
END CASE
```

Related concepts
Building Android apps with Genero on page 3317
Genero provides a command-line tool to create applications for Android™ devices.

**showAbout (Android™)**
Shows the GMA about box displaying version information.

Syntax
```plaintext
ui.Interface.frontCall("android", "showAbout", [],[])
```

Usage
This front call simply shows a typical about box, indicating GMA version information.

**Important:** This front call is only available for an application running on an Android™ device.

No input parameters are required, and no parameters are returned.

**showSettings (Android™)**
Shows the GMA settings box controlling debug options.

Syntax
```plaintext
ui.Interface.frontCall("android", "showSettings", [],[])
```
Usage

This front call opens the settings box to enable or disable GMA programming options.

**Important:** This front call is only available for an application running on an Android™ device.

No input parameters are required, and no parameters are returned.

The following features can be controlled with the GMA settings box:

- HTTP debug server on port 6480 (to inspect the AUI tree and show app logs)
- GUI display (FGLSERVER on page 245) and remote debug with fgldb on port 6400
- Android™ logcat recording
- Managing allowed certificates (SSH connections)
- Cookies cleanup (for SSO authentication tokens)

**Related concepts**

[Debugging a mobile app](#) on page 3313

Different solutions are available to debug a mobile app.

**startActivity (Android™)**

Starts an external Android™ application (activity), and returns to the GMA application immediately.

**Syntax**

```javascript
ui.Interface.frontCall("android","startActivity",
    [action, data, category, type, component, extras],
    []
)
```

1. **action** - Identifies the activity to be started on the Android™ device.
2. **data** - (optional) The data to operate on in the activity (URL, etc).
3. **category** - (optional) A comma separated list of categories.
4. **type** - (optional) Specifies the type of the data passed to the activity.
5. **component** - (optional) Specifies a component class to use for the intent.
6. **extras** - (optional) This is a JSON string containing parameters to pass to the activity.

**Usage**

The "startActivity" front call starts an external application (Android™ activity), and returns to the GMA application immediately after invoking the activity.

**Important:** This front call is only available for an application running on an Android™ device.

This front call is similar to the **RUN WITHOUT WAITING** statement: It allows the user to switch between the GMA and the launched application.

The parameters passed to this front call are used to build an Android "intent" object to start an "activity". For more details about Android intent object, refer to the [Android "Intent" definition](#).

The **action** parameter defines the Android™ activity to perform, such as "android.intent.action.MAIN", "android.intent.action.VIEW", and so on.

The **data** (optional) parameter contains the data to operate on. This is the main parameter to transmit data to the activity. It can for example be an URL.

The **category** (optional) parameter contains a comma separated list of categories, where a category gives additional information about the action to execute. For example, "android.intent.category.LAUNCHER" means it appears in the Launcher as a top-level application. See the Android™ documentation for details about possible categories for a given activity.

The **type** (optional) parameter defines the type (in fact, a MIME type) of the activity data. Normally the type is inferred from the data itself. By setting this attribute, you disable that evaluation and force an explicit type.
The \textit{component} (optional) parameter defines the name of a component class to use for the intent. Normally this is determined by looking at the other information in the intent. The component name typically specified as "apk-package-name/java-class-name" or "java-class-name" (the APK package name is optional). If the APK package is not specified, GMA considers that the Java class is included in the current APK.

The \textit{extras} (optional) parameter specifies a JSON string containing parameters to pass to the activity. This can be used to provide extended information to the component. For example, with an action sending an e-mail message, the extra data can include data to supply a subject, body, for the e-mail.

\textbf{Example}

The following code example starts the VIEW Android™ activity to show an image. The Genero program flow will continue after this call, but the started activity will be shown. Note that such action is better performed with a \texttt{launchurl} front call.

\begin{verbatim}
CALL ui.Interface.frontCall("android", "startActivity",
    [ "android.intent.action.VIEW",
      "file:///storage/path_to_image_file",
      NULL, "image/*" ],
    [ ] )
\end{verbatim}

\textbf{Related concepts}

\texttt{startActivityForResult (Android)} on page 2565

Starts an external application (Android activity) and waits until the activity is closed.

\texttt{startActivityForResult (Android™)}

Starts an external application (Android activity) and waits until the activity is closed.

\textbf{Syntax}

\begin{verbatim}
ui.Interface.frontCall("android", "startActivityForResult",
    [action, data, category, type, component, extras],
    [outdata, outextras])
\end{verbatim}

1. \textit{action} - Identifies the activity to be started on the Android™ device.
2. \textit{data} - (optional) The data to operate on in the activity (URL, etc).
3. \textit{category} - (optional) A comma separated list of categories.
4. \textit{type} - (optional) Specifies the type of the data passed to the activity.
5. \textit{component} - (optional) Specifies a component class to use for the intent.
6. \textit{extras} - (optional) This is a JSON string containing parameters to pass to the activity.

Return values include:

1. \textit{outdata} - holds the flat value returned by the invoked activity.
2. \textit{outextras} - holds the JSON data of structured value returned by the invoked activity.

The return values depend entirely on the invoked activity.

\textbf{Usage}

The "\texttt{startActivityForResult}" front call starts an external application (Android activity), then waits for the user to exit the external application prior to returning the GMA application.

\textbf{Important}: This front call is only available for an application running on an Android™ device.

This front call is similar to the \texttt{RUN} statement: The user cannot return to the GMA application while the activity is executing.

The parameters passed to this front call are used to build an Android "intent" object to start an "activity". For more details about Android intent object, refer to the \texttt{Android "Intent" definition}. 

The *action* parameter defines the Android™ activity to perform, such as "android.intent.action.MAIN", "android.intent.action.VIEW", and so on.

The *data* (optional) parameter contains the data to operate on. This is the main parameter to transmit data to the activity. It can for example be an URL.

The *category* (optional) parameter contains a comma separated list of categories, where a category gives additional information about the action to execute. For example, "android.intent.category.LAUNCHER" means it appears in the Launcher as a top-level application. See the Android™ documentation for details about possible categories for a given activity.

The *type* (optional) parameter defines the type (in fact, a MIME type) of the activity data. Normally the type is inferred from the data itself. By setting this attribute, you disable that evaluation and force an explicit type.

The *component* (optional) parameter defines the name of a component class to use for the intent. Normally this is determined by looking at the other information in the intent. The component name typically specified as "apk-package-name/java-class-name" or "java-class-name" (the APK package name is optional). If the APK package is not specified, GMA considers that the Java class is included in the current APK.

The *extras* (optional) parameter specifies a JSON string containing parameters to pass to the activity. This can be used to provide extended information to the component. For example, with an action sending an e-mail message, the extra data can include data to supply a subject, body, for the e-mail.

The *outdata* returning argument will contain the flag value returned from the activity, typically when the data is simple and not structured.

The *outextras* returning argument can hold JSON data of any structured value returned by the invoked activity, or NULL in case of error (for example, when the application corresponding to the activity is not installed)

**Example**

This example invokes the barcode scanner application, and returns the scanned barcode.

```java
IMPORT util ...
DEFINE data, extras STRING,
    json_object util.JSONObject,
    scanned_value STRING ...
CALL ui.Interface.frontCall(
    "android", "startActivityForResult",
    [ "com.google.zxing.client.android.SCAN",
      NULL, "android.intent.category.DEFAULT" ],
    [ data, extras ])
IF extras IS NULL THEN
    -- If the application isn't installed invoke
    -- the Play Store to give the user a chance to install it
    CALL ui.Interface.frontCall("standard", "launchurl",
        ["market://details?id=com.google.zxing.client.android"], [])
ELSE
    LET json_object = util.JSONObject.parse(extras)
    -- Fetch the scanned value
    LET scanned_value = json_object.get("SCAN_RESULT")
END IF
```

**Related concepts**

[**startActivity (Android)**](#) on page 2564

Starts an external Android™ application (activity), and returns to the GMA application immediately.

**Genero Mobile iOS front calls**

This section describes front calls specific to the iOS platform.

This table shows the functions implemented by the iOS front-end in the "ios" module.
Table 538: iOS module front-end functions

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ui.Interface.frontCall(&quot;ios&quot;, &quot;getBadgeNumber&quot;, [, [value]])</code></td>
<td>Returns the current badge number associated to the app.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;ios&quot;, &quot;newContact&quot;, [defaults], [vcard])</code></td>
<td>Lets the user input contact information to create a new entry in the</td>
</tr>
<tr>
<td></td>
<td>contact database of the mobile device.</td>
</tr>
<tr>
<td><code>ui.Interface.frontCall(&quot;ios&quot;, &quot;setBadgeNumber&quot;, [value], [])</code></td>
<td>Sets the current badge number associated to the app.</td>
</tr>
</tbody>
</table>

Related concepts

Genero Mobile common front calls on page 2546
This section describes common front calls provided by all mobile front-ends.

**getBadgeNumber (iOS)**

Returns the current badge number associated to the app.

Syntax

```plaintext
ui.Interface.frontCall("ios", "getBadgeNumber", [, [value]])
```

- `value` - Holds the current badge number.

Usage

The iOS "getBadgeNumber" front call returns the current badge number associated to the app.

**Important**: This front call is only available for an application running on an iOS device.

The badge number appears on the app icon and is typically used for Push notifications on page 3345.

**Important**: In order to query or set the badge number, the app program must have executed a `registerForRemoteNotifications` front call before (in the current or prior execution instance). This registration is required in order to set the appropriate app permissions to access badge number data.

Example

```plaintext
DEFINE value INTEGER
CALL ui.interface.frontcall("ios","getBadgeNumber",[],[value])
```

Related concepts

Deploying mobile apps on iOS devices on page 3330
This section contains information to create a mobile application to be deployed on iOS devices.

**setBadgeNumber (iOS)** on page 2568
Sets the current badge number associated to the app.

**newContact (iOS)**

Lets the user input contact information to create a new entry in the contact database of the mobile device.

**Syntax**

```
ui.Interface.frontCall("ios", "newContact",
[defaults], [vcard])
```

- **defaults** - A vCard string with default values for the new contact input.
- **vcard** - Holds the vCard string of the new created contact.

**Usage**

The iOS "newContact" front call opens the contact input form on the mobile device, with default values passed in the vCard structure of the first parameter, allows the user to enter contact information.

**Important:** This front call is only available for an application running on an iOS device.

If the contact creation is validated, the front call returns the completed vCard string. If the contact import is canceled, the front-end returns NULL.

**Example**

```
DEFINE defaults, vcard STRING
LET defaults="BEGIN:VCARD
"||"VERSION:3.0\n"
||"N:Willi;;;;\n"
||"TEL;type=HOME;type=VOICE;type=pref:03812225610\n"
||"END:VCARD\n"
CALL ui.interface.frontcall("ios","newContact",[defaults],[vcard])
```

**Related concepts**

**importContact** on page 2555

Creates a new contact, or merges to an existing entry, the contact details passed in a vCard string.

**setBadgeNumber (iOS)**

Sets the current badge number associated to the app.

**Syntax**

```
ui.Interface.frontCall("ios", "setBadgeNumber",
[value], [])
```

- **value** - Holds the badge number to be set.

**Usage**

The iOS "setBadgeNumber" front call sets the badge number associated to the app.

**Important:** This front call is only available for an application running on an iOS device.

The badge number appears on the app icon and is typically used for **Push notifications** on page 3345.

**Important:** In order to query or set the badge number, the app program must have executed a **registerForRemoteNotifications** front call before (in the current or prior execution instance). This registration is required in order to set the appropriate app permissions to access badge number data.
Example

```
DEFINE value INTEGER
LET value = 2
CALL ui.interface.frontcall("ios","setBadgeNumber",[value],[])
```

Related concepts

  Returns the current badge number associated to the app.

Cordova plugin front calls

Genero provides a set of Cordova plugin front calls that make use of the Cordova plugins.

This table shows the functions implemented by the Android™ and iOS front-end in the "cordova" module.

### Table 539: Cordova front-end functions

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ui.Interface.frontCall(&quot;cordova&quot;, &quot;call&quot;,</td>
<td>Calls a function in a cordova plugin and returns a result.</td>
</tr>
<tr>
<td>[plugin-name, function-name [, param1, param2, ... [, [result] ] ] ]</td>
<td></td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;cordova&quot;, &quot;callWithoutWaiting&quot;,</td>
<td>Calls a function asynchronously in a Cordova plugin, without waiting</td>
</tr>
<tr>
<td>[plugin-name, function-name [, param1, param2, ... [, [callback-id]] ] ]</td>
<td>for a result.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;cordova&quot;, &quot;getCallbackDataCount&quot;,</td>
<td>Returns the number of pending Cordova plugin results.</td>
</tr>
<tr>
<td>[], [count]</td>
<td></td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;cordova&quot;, &quot;getFirstCallbackData&quot;,</td>
<td>Returns the first Cordova plugin result from the result queue of all</td>
</tr>
<tr>
<td>[], [result, callback-id]</td>
<td>asynchronous Cordova plugin front calls, and removes it from the queue.</td>
</tr>
<tr>
<td>ui.Interface.frontCall(&quot;cordova&quot;, &quot;getAllCallbackData&quot;,</td>
<td>Returns all results for asynchronous Cordova plugin front calls, based</td>
</tr>
<tr>
<td>[callback-id-filter], [results] )</td>
<td>on a callback ID filter.</td>
</tr>
</tbody>
</table>

Related concepts

- Cordova plugins on page 3370
This section describes how to use Cordova plugins.

**call**
Calls a function in a cordova plugin and returns a result.

**Syntax**
```lua
ui.Interface.frontCall("cordova", "call", 
    [plugin-name, function-name [, param1, param2, ... ]], 
    [result]
)
```

1. **plugin-name** - This is the name of the Cordova plugin.
2. **function-name** - This is the name of plugin function to be called.
3. **param1, param2, ...** - Optional parameters to be passed to the Cordova function.
4. **result** - Holds the Cordova function return value.

**Usage**
The `call` front call executes synchronously the Cordova plugin function identified by the `plugin-name` and the `function-name`.

The other arguments (`param1, param2, ...`) are arguments for the Cordova plugin function. Each argument may have a different type like `FLOAT`, `INTEGER`, `STRING`, `RECORD` or `DYNAMIC ARRAY` (for `RECORD` and `DYNAMIC ARRAY`, the runtime system will do the BDL to JSON conversion automatically).

The front call returns one `result` variable of type `FLOAT`, `INTEGER`, `STRING`, `RECORD` or `DYNAMIC ARRAY`, that matches the JSON equivalent of the plugin function result (for `RECORD` and `DYNAMIC ARRAY`, the runtime system will do the JSON to BDL conversion automatically).

The `call` Cordova front call is synchronous: This means that the call will not return until the plugin returns a result. Some functions may not return a result at all (such as start/stop functions) and therefore would cause the front call to wait forever. Those functions need to be called asynchronously with the `callWithoutWaiting` front call.

In case of an error, the front call raises a runtime error -6333 that can be caught with `TRY/CATCH` or `WHENEVER ERROR`.

**Note:** Use the `err_get()` function, to identify the reason of the error. For more details about front call error handling, see `ui.Interface.frontCall()`.

**Example**
```lua
DEFINE calendars DYNAMIC ARRAY OF STRING
CALL ui.interface.frontcall( "cordova", "call", 
    ["Calendar", "listCalendars"], [calendars] )
```

**callWithoutWaiting**
Calls a function asynchronously in a Cordova plugin, without waiting for a result.

**Syntax**
```lua
ui.Interface.frontCall("cordova", "callWithoutWaiting", 
    [plugin-name, function-name [, param1, param2, ... ]], 
    [callback-id])
```

1. **plugin-name** - This is the name of the Cordova plugin.
2. **function-name** - This is the name of plugin function to be called.
3. **param1, param2, ...** - Optional parameters to be passed to the Cordova function.
4. **callback-id** - Holds the callback identifier for this Cordova asynchronous front call.
**Usage**

The `callWithoutWaiting` front call executes asynchronously the Cordova plugin function identified by the `plugin-name` and the `function-name`.

The other arguments (`param1`, `param2`, ...) are arguments for the Cordova plugin function. Each argument may have a different type like `FLOAT`, `INTEGER`, `STRING`, `RECORD` or `DYNAMIC ARRAY` (for `RECORD` and `DYNAMIC ARRAY`, the runtime system will do the BDL to JSON conversion automatically).

The `callWithoutWaiting` front call behaves the same as the `call` front call, but does not wait for a result from the plugin. Instead it returns directly a unique callback ID, to be able to identify the call later on. The program execution can continue, while the plugin processes the result asynchronously.

When the plugin produces the result, it is stored internally by GMI/GMA in a result queue. Then result data can be retrieved with `getCallbackData/getAllCallbackData` front calls in conjunction with the "cordovaCallback" action.

When the current dialog contains an `ON ACTION` handler for the `cordovaCallback` predefined action, this action is triggered by the front end to notify the Genero program that there is plugin data to fetch.

The `cordovaCallback` action is triggered:

1. If the result queue is empty, and a result is added to the queue.
2. If a new dialog that contains this action is entered or re-entered, and the result queue is non empty.

**Important:** Some plugin functions may return results repeatedly in a short time intervals with one and the same `callback-id`, examples are for delivering motion/audio/bluetooth data.

In case of an error, the front call raises a runtime error -6333 that can be caught with `TRY/CATCH` or `WHENEVER ERROR`.

**Note:** Use the `err_get()` function, to identify the reason of the error. For more details about front call error handling, see `ui.Interface.frontCall()`.

**Example**

```plaintext
DEFINE id, song STRING
CALL ui.interface.frontcall( "cordova", "callWithoutWaiting", 
      ["Media", "play", song], [id] )
...
ON ACTION cordovaCallback ATTRIBUTE(DEFAULTVIEW=NO)
   -- Process results
   ...
```

**getCallbackDataCount**

Returns the number of pending Cordova plugin results.

**Syntax**

```plaintext
ui.Interface.frontCall("cordova", "getCallbackDataCount", 
       [], [count])
```

1. `count` - Holds the number of pending results.

**Usage**

When initiating an asynchronous Cordova plugin front call with `callWithoutWaiting`, results are stored in the result queue when the Cordova function terminates, and a `cordovaCallback` action is fired if the current dialog defines a corresponding `ON ACTION` handler.

The `getCallbackDataCount` front call returns the number of results currently in the result queue, for all asynchronous Cordova plugin front calls initiated by a `callWithoutWaiting`. 
It is then possible to implement a FOR loop to retrieve all results with the `getCallbackData` front call.

In case of an error, the front call raises a runtime error -6333 that can be caught with TRY/CATCH or WHENEVER ERROR.

**Note:** Use the `err_get()` function, to identify the reason of the error. For more details about front call error handling, see `ui.Interface.frontCall()`.

**Example**

```boinc
DEFINE cnt SMALLINT
CALL ui.Interface.frontCall("cordova", "getCallbackDataCount", [], [cnt])
```

### getCallbackData

Returns the first Cordova plugin result from the result queue of all asynchronous Cordova plugin front calls, and removes it from the queue.

#### Syntax

```boinc
ui.Interface.frontCall("cordova", "getCallbackData", [], [result, callback-id])
```

1. **result** - Holds the result returned from the result queue.
2. **callback-id** - Holds the callback identifier of the Cordova asynchronous front call.

#### Usage

When initiating an asynchronous Cordova plugin front call with `callWithoutWaiting`, results are stored in the result queue when the Cordova function terminates, and a `cordovaCallback` action is fired if the current dialog defines a corresponding `ON ACTION` handler.

The `getCallbackData` front call returns the first Cordova plugin result from the result queue, and removes it from the queue. A subsequent `getCallbackData` front call gives back the next result and so on.

The first value returned by the front call (result) is the actual result. This can be a variable of type `FLOAT`, `INTEGER`, `STRING`, `RECORD` or `DYNAMIC ARRAY`, that matches the JSON equivalent of the plugin function result (for `RECORD` and `DYNAMIC ARRAY`, the runtime system will do the JSON to BDL conversion automatically).

The second returned value is `callback-id`, the identifier returned by the `callWithoutWaiting` front call that is causing this result. For example, for a Media plugin front call, the `callback-id` can look like:

```boinc
Media-messageChannel:0
```

If the result queue is empty, both `result` and `callback-id` are NULL.

In case of an error, the front call raises a runtime error -6333 that can be caught with TRY/CATCH or WHENEVER ERROR.

**Note:** Use the `err_get()` function, to identify the reason of the error. For more details about front call error handling, see `ui.Interface.frontCall()`.

**Example**

```boinc
DEFINE res, id STRING
CALL ui.Interface.frontCall("cordova", "getCallbackData", [], [res, id])
```

### Related concepts

- `getCallbackDataCount` on page 2571
Returns the number of pending Cordova plugin results.

**getAllCallbackData**
Returns all results for asynchronous Cordova plugin front calls, based on a callback ID filter.

**Syntax**

```
ui.Interface.frontCall("cordova", "getAllCallbackData",
[callback-id-filter], [results])
```

1. **callback-id-filter** - Provides the callback ID filter for Cordova asynchronous front calls.
2. **results** - The array of results returned by the Cordova asynchronous front call identified by `callback-id`.

**Usage**

When initiating an asynchronous Cordova plugin front call with `callWithoutWaiting`, results are stored in the result queue when the Cordova function terminates, and a `cordovaCallback` action is fired if the current dialog defines a corresponding `ON ACTION` handler.

The purpose of the `getAllCallbackData` front call is to retrieve high traffic data in bloc (such as motion sensor data) to avoid too many front calls in a short time frame.

The `getAllCallbackData` front call returns all results produced by Cordova asynchronous front calls, that match the `callback-id-filter` provided as parameter. For example, if you specify "Media-" as filter, all results related to callback ids starting with "Media-" will be retrieved.

All results in the queue matching the filter are retrieved into the array, and are removed from the result queue.

The results are returned into a DYNAMIC ARRAY OF STRING or a DYNAMIC ARRAY OF RECORD, a structured record to be defined as the JSON equivalent of the plugin function result (when using a DYNAMIC ARRAY OF RECORD, the runtime system can do the JSON to BDL conversion automatically).

In case of an error, the front call raises a runtime error -6333 that can be caught with TRY/CATCH or WHENEVER ERROR.

**Note:** Use the `err_get()` function, to identify the reason of the error. For more details about front call error handling, see `ui.Interface.frontCall()`.

**Example**

```
DEFINE events DYNAMIC ARRAY OF RECORD
  x FLOAT,
  y FLOAT,
  z FLOAT,
  timestamp DECIMAL
END RECORD
DEFINE id STRING
DEFINE x INTEGER
...
CALL ui.interface.frontcall("cordova", "callWithoutWaiting",
  ["Accelerometer","start"], [id])
...
ON IDLE 2
  CALL ui.interface.frontcall("cordova", "getAllCallbackData",
    [id], [events])
  FOR x=1 TO events.getLength()
    CALL process_motion_event( events[x].* )
  END FOR
```

**Related concepts**

`getCallbackDataCount` on page 2571
Returns the number of pending Cordova plugin results.

**Extension packages**

Several utility classes and functions are provided in additional packages to be included with the `IMPORT` instruction.

- The util package on page 2574
- The os package on page 2640
- The com package on page 2658
- The xml package on page 2774
- The security package on page 2971

**Related concepts**

Importing modules on page 496

Use the `IMPORT ...` instruction to import BDL, C or Java external modules in the current module.

**The util package**

These topics cover the classes for the `util` package.

**The util.Date class**

The `util.Date` class provides DATE data-type related utility methods.

This class is provided in the `util` C-Extension library; To use the `util.Date` class, you must import the `util` package in your program:

```c
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

**Related concepts**

IMPORT C-Extension on page 496

The `IMPORT` instruction imports c extension module elements to be used by the current module.

**util.Date methods**

Methods for the `util.Date` class.

**Table 540: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>`util.Date.isLeapYear(</td>
<td>Checks is the year passed as parameter is a leap year.</td>
</tr>
<tr>
<td>year INTEGER )</td>
<td></td>
</tr>
<tr>
<td>RETURNS BOOLEAN</td>
<td></td>
</tr>
<tr>
<td>`util.Date.parse(</td>
<td>Converts a string to a DATE value based on a format specification.</td>
</tr>
<tr>
<td>s STRING,</td>
<td></td>
</tr>
<tr>
<td>format STRING )</td>
<td></td>
</tr>
<tr>
<td>RETURNS DATE</td>
<td></td>
</tr>
</tbody>
</table>
**util.Date.parse**

Converts a string to a DATE value based on a format specification.

**Syntax**

```plaintext
util.Date.parse(s STRING,
              format STRING)
  RETURNS DATE
```

1. `s` is the source string to be parsed.
2. `format` is the format specification (see Formatting DATE values on page 284).

**Usage**

The `util.Date.parse()` method parses a string based on a format specification, to produce a DATE value.

The format specification must be a combination of `dd`, `mm`, `yyyy` place holders as used in the `USING` operator.

The method returns `NULL`, if the source string cannot be converted to a DATE value depending on the format specification.

For more details about the supported formats, see Formatting DATE values on page 284.

**Example**

```plaintext
IMPORT util
MAIN
  DISPLAY util.Date.parse( "2014-03-15", "yyyy-mm-dd" )
END MAIN
```

**Related concepts**

**USING** on page 320

The USING operator converts date and numeric values to a string based on a formatting mask.

**util.Date.isLeapYear**

Checks if the year passed as parameter is a leap year.

**Syntax**

```plaintext
util.Date.isLeapYear(year INTEGER)
  RETURNS BOOLEAN
```

1. `year` is an INTEGER representing a year.

**Usage**

The `util.Date.isLeapYear()` method returns `TRUE` if the year passed in parameter is a leap year.

**Example**

```plaintext
IMPORT util
MAIN
  DISPLAY util.Date.isLeapYear( 2003 )
  DISPLAY util.Date.isLeapYear( 2004 )
END MAIN
```
The util.Datetime class

The util.Datetime class provides DATETIME data-type related utility methods.

This class is provided in the util C-Extension library. To use the util.Datetime class, you must import the util package in your program:

```
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

Related concepts

IMPORT C-Extension on page 496
The IMPORT instruction imports C extension module elements to be used by the current module.

**util.Datetime methods**

Methods for the util.Datetime class.

<table>

| **util.Datetime.toUTC** | Converts a datetime value to the UTC datetime. |
| \[ \text{util.Datetime.toUTC}(  
| \[ t \text{ DATETIME q1 TO q2}  
| \] )  
| \] RETURNS DATETIME q1 TO q2 |  |

**util.Datetime.format**

Formats a datetime value based on a specified format.

**Syntax**

\[
\text{util.Datetime.format}(  
\text{t DATETIME q1 TO q2,}  
\text{format STRING}  
) 
\]
**RETURNS STRING**

1. \( t \) is the datetime value to be formatted.
2. \( \text{format} \) is the format string, as described in Formatting DATETIME values on page 285.

**Usage**

The `util.Datetime.format()` method formats a DATETIME value based on the format specification.

The format string must be a combination of place holders such as `%Y`, `%m`, `%d`, as described in Formatting DATETIME values on page 285.

If the source value is NULL the result will be NULL.

**Example**

```plaintext
IMPORT util
MAIN
    DISPLAY util.Datetime.format( CURRENT, "%Y-%m-%d %H:%M" )
END MAIN
```

**Related concepts**

* `util.Datetime.parse` on page 2579
  Converts a string to a DATETIME value based on a specified format.

* `util.Datetime.fromSecondsSinceEpoch`
  Converts a number of seconds since Epoch to a datetime.

**Syntax**

```plaintext
util.Datetime.fromSecondsSinceEpoch( 
    t FLOAT
) 
RETURNS DATETIME q1 TO q2
```

1. \( t \) is the number of seconds since Epoch. This can be a whole integer or a decimal, if the target datetime

**Usage**

The `util.Datetime.fromSecondsSinceEpoch()` method converts the number of seconds since the Unix Epoch (1970-01-01 00:00:00 GMT) passed as parameter, to a DATETIME value, in the local time.

**Important**: If the number of seconds passed as parameter is a floating point number including a fraction of seconds, the result will be a DATETIME YEAR TO FRACTION(N), otherwise it is DATETIME YEAR TO SECOND.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE dt DATETIME YEAR TO SECOND
    LET dt = util.Datetime.fromSecondsSinceEpoch( 9876234 )
    DISPLAY dt
END MAIN
```

**Related concepts**

* `util.Datetime.toSecondsSinceEpoch` on page 2580
Converts a datetime to a number of seconds since Epoch.

`util.Datetime.getCurrentAsUTC`  
Returns the current date/time in UTC.

**Syntax**

```plaintext
util.Datetime.getCurrentAsUTC( )  
RETURNS DATETIME YEAR TO FRACTION(5)
```

**Usage**

The `util.Datetime.getCurrentAsUTC()` method returns the current system date/time in UTC (Universal Time).

This method is provided to solve the daylight saving time transition issue of the `util.Datetime.toUTC()` method.

**Note:** The precision of the value returned by this method is a DATETIME YEAR TO FRACTION(5). Note that this precision is different from the default CURRENT precision when no qualifiers are specified.

**Example**

```plaintext
IMPORT util
MAIN  
  DEFINE utc DATETIME YEAR TO FRACTION(5)
  LET utc = util.Datetime.getCurrentAsUTC( )
  DISPLAY "Current UTC: ", utc
END MAIN
```

**Related concepts**

- `util.Datetime.toLocalTime` on page 2580  
  Converts a UTC datetime to the local time.

- `util.Datetime.parse`  
  Converts a string to a DATETIME value based on a specified format.

**Syntax**

```plaintext
util.Datetime.parse(  
  s STRING,  
  format STRING  
)  
RETURNS DATETIME q1 TO q2
```

1. `s` is the source string to be parsed.
2. `format` is the format specification (see Formatting DATETIME values on page 285).

**Usage**

The `util.Datetime.parse()` method parses a string based on a format specification, to produce a DATETIME value.

The format specification must be a combination of place holders such as %Y, %m, %d, etc.

The precision of the resulting DATETIME value depends on the format specification. For example, when using "%Y-%m-%d %H:%M", the resulting value will be a DATETIME YEAR TO MINUTE.

The method returns NULL, if the source string cannot be converted to a DATETIME value depending on to the format specification.
For more details about the supported formats, see Formatting DATETIME values on page 285.

Example

```
IMPORT util
MAIN
  DEFINE dt DATETIME YEAR TO MINUTE
  LET dt = util.Datetime.parse( "2014-12-24 23:45", "%Y-%m-%d %H:%M" )
  DISPLAY dt
END MAIN
```

Related concepts

util.Datetime.format on page 2577
Formats a datetime value based on a specified format.

`util.Datetime.toLocalTime`
Converts a UTC datetime to the local time.

Syntax

```
util.Datetime.toLocalTime(
    t DATETIME q1 TO q2
) RETURNS DATETIME q1 TO q2
```
1. `t` is the datetime value in UTC.

Usage

The `util.Datetime.toLocalTime()` method converts a DATETIME value from "Coordinated Universal Time" (UTC), also known as "Greenwich Mean Time" (GMT), to the local timezone datetime.

Example

```
IMPORT util
MAIN
  DEFINE loc DATETIME YEAR TO SECOND
  LET loc = util.Datetime.toLocalTime( DATETIME(2015-08-22 15:34:56) YEAR TO SECOND )
  DISPLAY "LOC: ", loc
END MAIN
```

Related concepts

util.Datetime.toUTC on page 2581
Converts a datetime value to the UTC datetime.

`util.Datetime.getCurrentAsUTC` on page 2579
Returns the current date/time in UTC.

`util.Datetime.toSecondsSinceEpoch`
Converts a datetime to a number of seconds since Epoch.

Syntax

```
util.Datetime.toSecondsSinceEpoch(
    t DATETIME q1 TO q2
) RETURNS FLOAT
```
1. `t` is the local datetime value.
**Usage**

The `util.Datetime.toSecondsSinceEpoch()` method converts the `DATETIME` value passed as parameter to a number of seconds since the Unix Epoch (1970-01-01 00:00:00 GMT)

**Important:** The result is a whole number when the source is a `DATETIME YEAR TO SECOND`, but will be a floating point number when the source is a `DATETIME YEAR TO FRACTION(N)`, to include the fractional part.

**Example**

```plaintext
IMPORT util

MAIN
  DEFINE sec INTEGER, loc DATETIME YEAR TO SECOND
  LET loc = CURRENT YEAR TO SECOND
  LET sec = util.Datetime.toSecondsSinceEpoch( loc )
  DISPLAY sec
END MAIN
```

**Related concepts**

- `util.Datetime.fromSecondsSinceEpoch` on page 2578
  Converts a number of seconds since Epoch to a datetime.

- `util.Datetime.toUTC`
  Converts a datetime value to the UTC datetime.

**Syntax**

```plaintext
util.Datetime.toUTC(
  t DATETIME q1 TO q2
)
RETURNS DATETIME q1 TO q2
```

1. `t` is the local timezone datetime value.

**Usage**

The `util.Datetime.toUTC()` method converts the local timezone `DATETIME` value passed as parameter to the "Coordinated Universal Time" (UTC), also known as "Greenwich Mean Time" (GMT).

The `toUTC()` method on local timezone information settings.

**Fall/Autumn daylight saving time transition period**

**Important:** The `toUTC()` function cannot determine if the local datetime value represents a time before or after the daylight saving time change, when the value is in the hour of the daylight saving time transition period in the fall (this is for example, the hour 02:00 PM to 03:00 PM on the last Sunday of October in Europe and first Sunday of November in the USA). Depending on the operating system, the `toUTC()` method can interpret the local time as summer time or as winter time. In order to get the current system time in UTC, use the `util.Datetime.getCurrentAsUTC()` method.

The `DATETIME` value passed as parameter to the `toUTC()` method is the datetime in the local timezone. However, this value does not contain the GMT offset indicator or daylight saving time information.

When passing local datetime values in the hour of the daylight saving time transition period in the fall (when clocks roll back one hour), the `toUTC()` function cannot determine if the local datetime value represents a point in time before or after the daylight saving time transition occurred. Depending on the operating system, the `toUTC()` method can interpret the local time as summer time or as a winter time. As a result, the conversion to the UTC time can be mis-interpreted.

For example, in Europe, the fall daylight saving time changes on the 25 of October, at 3:00 PM. The ambiguous period is between 2:00 PM and 3:00 PM (local time). If you pass, for example, the datetime value 2015-10-25
02:34:11 to the `toUTC()` method, there is no way for the method to know if this local time is the time before (CEST / UTC+2h) or after (CET / UTC+1h) the daylight saving time change.

This behavior can be illustrated with the following code example:

```c
IMPORT util

MAIN
    DISPLAY "Original UTC         Local time (Paris)   toUTC(local-time)
( toUTC() - Orig UCT )"
    CALL test( "2015-10-24 23:59:59" )
    CALL test( "2015-10-25 00:59:59" )
    CALL test( "2015-10-25 01:59:59" )
    CALL test( "2015-10-25 02:59:59" )
END MAIN

FUNCTION test(utc)
    DEFINE utc, loc, utc2 DATETIME YEAR TO SECOND
    LET loc = util.Datetime.toLocalTime(utc)
    LET utc2 = util.Datetime.toUTC(loc)
    DISPLAY SFMT("%1  %2  %3  %4", utc,loc,utc2,utc2-utc)
END FUNCTION
```

The above code will produce the following output on Linux®, with `TZ='Europe/Paris'`:

<table>
<thead>
<tr>
<th>Original UTC</th>
<th>Local time (Paris)</th>
<th>toUTC(local-time)</th>
<th>( toUTC() - Orig UCT )</th>
</tr>
</thead>
<tbody>
<tr>
<td>2015-10-25 00:59:59</td>
<td>2015-10-25 02:59:59</td>
<td>2015-10-25 00:59:59</td>
<td>00:00:00</td>
</tr>
<tr>
<td>2015-10-25 01:59:59</td>
<td>2015-10-25 02:59:59</td>
<td>2015-10-25 00:59:59</td>
<td>-00:01:00</td>
</tr>
<tr>
<td>2015-10-25 02:59:59</td>
<td>2015-10-25 03:59:59</td>
<td>2015-10-25 02:59:59</td>
<td>00:00:00</td>
</tr>
</tbody>
</table>

As you can see, the local time 2015-10-25 02:59:59 is always converted to UTC 2015-10-25 00:59:59.

**Example**

```c
IMPORT util

MAIN
    DEFINE utc DATETIME YEAR TO SECOND
    LET utc = util.Datetime.toUTC( DATETIME(2015-08-22 15:34:56) YEAR TO SECOND )
    DISPLAY "UTC: ", utc
END MAIN
```

**Related concepts**

- `util.Datetime.toLocalTime` on page 2580
  Converts a UTC datetime to the local time.

**The `util.Integer` class**

The `util.Integer` class provides INTEGER data-type related utility methods.

This class is provided in the `util C-Extension` library. To use the `util.Integer` class, you must import the `util` package in your program:

```c
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.
Related concepts
IMPORT C-Extension on page 496
The `IMPORT` instruction imports C extension module elements to be used by the current module.

**util.Integer methods**

Methods for the `util.Integer` class.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>util.Integer.abs(i INTEGER)</code></td>
<td>Returns the absolute value of an integer.</td>
</tr>
<tr>
<td><code>util.Integer.and(x INTEGER, y INTEGER)</code></td>
<td>Returns the result of a bitwise AND on two INTEGER values.</td>
</tr>
<tr>
<td><code>util.Integer.andNot(x INTEGER, y INTEGER)</code></td>
<td>Returns the result of a bitwise AND of the 1st INTEGER and the inverted 2nd INTEGER.</td>
</tr>
<tr>
<td><code>util.Integer.clearBit(i INTEGER, n SMALLINT)</code></td>
<td>Returns the INTEGER parameter with the bit at the designated position set to 0.</td>
</tr>
<tr>
<td><code>util.Integer.not(i INTEGER)</code></td>
<td>Returns the INTEGER value with all bits inverted.</td>
</tr>
<tr>
<td><code>util.Integer.or(x INTEGER, y INTEGER)</code></td>
<td>Returns the result of a bitwise OR on two INTEGER values.</td>
</tr>
<tr>
<td><code>util.Integer.parseBinaryString(s STRING)</code></td>
<td>Returns an INTEGER from its binary (base 2) string representation.</td>
</tr>
<tr>
<td><code>util.Integer.parseHexString(s STRING)</code></td>
<td>Returns an INTEGER from its hexadecimal (base 16) string representation.</td>
</tr>
<tr>
<td><code>util.Integer.setBit(i INTEGER, n INTEGER)</code></td>
<td>Returns the INTEGER parameter with the bit at the designated position set to 1.</td>
</tr>
<tr>
<td><code>util.Integer.shiftLeft(i INTEGER, n SMALLINT)</code></td>
<td>Returns the INTEGER value left-shifted by the given bit places.</td>
</tr>
</tbody>
</table>
**util.Integer.abs**

Returns the absolute value of an integer.

**Syntax**

```plaintext
util.Integer.abs(
    i INTEGER
)
RETURNS INTEGER
```

1. *i* is the integer value to convert.

**Usage**

The `util.Integer.abs()` method converts the value passed as parameter to a positive integer when it is negative.

**Example**

```plaintext
IMPORT util
MAIN
    DISPLAY util.Integer.abs( -234 ) -- displays 234
END MAIN
```

**util.Integer.and**

Returns the result of a bitwise AND on two INTEGER values.

**Syntax**

```plaintext
util.Integer.and(
    x INTEGER,
    y INTEGER
)
RETURNS INTEGER
```

1. *x* is an integer value.
2. *y* is an integer value.

**Usage**

The `util.Integer.and()` method makes a bitwise AND operation with the integer values passed as parameter:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
<td>210 (00000000 00000000 00000000 11010010)</td>
</tr>
<tr>
<td>y</td>
<td>135 (00000000 00000000 00000000 10000111)</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td>result</td>
<td>130 (00000000 00000000 00000000 10000010)</td>
</tr>
</tbody>
</table>

**Note:** Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value -1 (11111111 11111111 11111111 11111111).
2. The NULL value for the INTEGER type is represented internally with the value 0x80000000 (10000000 00000000 00000000 00000000). When NULL is used with the `util.Integer` bitwise methods, it will be interpreted as 0x80000000 instead of a null value. However, if the result of the bitwise operation produces the value 0x80000000, it will be interpreted as NULL when used in an expression.
Example

```plaintext
IMPORT util
MAIN
  DISPLAY util.Integer.and( 3, 1 ) -- displays 2
  DISPLAY util.Integer.and( util.Integer.parseBinaryString("111"),
                           util.Integer.parseBinaryString("010") ) --
                     displays 2
END MAIN
```

Related concepts

**util.Integer.andNot** on page 2587
Returns the result of a bitwise AND of the 1st INTEGER and the inverted 2nd INTEGER.

**util.Integer.not** on page 2589
Returns the INTEGER value with all bits inverted.

**util.Integer.or** on page 2590
Returns the result of a bitwise OR on two INTEGER values.

**util.Integer.xor** on page 2597
Returns the result of a bitwise XOR on two INTEGER values.

**util.Integer.andNot**
Returns the result of a bitwise AND of the 1st INTEGER and the inverted 2nd INTEGER.

Syntax

```plaintext
util.Integer.andNot(
  x INTEGER,
  y INTEGER
)
RETURNS INTEGER
```

1. `x` is an integer value.
2. `y` is an integer value.

Usage

The `util.Integer.andNot()` method makes a bitwise AND operation with the first integer value and the second inverted integer:

```
x : 210 (00000000 00000000 00000000 11010010)
y : 135 (00000000 00000000 00000000 10000111)
~y : (11111111 11111111 11111111 01111000)
-----------------------
result :  80 (00000000 00000000 00000000 01010000)
```

This method simplifies mask operations.

**Note:** Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value -1 (11111111 11111111 11111111 11111111).
2. The NULL value for the INTEGER type is represented internally with the value 0x80000000 (10000000 00000000 00000000 00000000). When NULL is used with the `util.Integer` bitwise methods, it will be interpreted as 0x80000000 instead of a null value. However, if the result of the bitwise operation produces the value 0x80000000, it will be interpreted as NULL when used in an expression.
Example

```
IMPORT util
MAIN
  DISPLAY util.Integer.andNot( 3, 2 ) -- displays 1
END MAIN
```

Related concepts

- `util.Integer.and` on page 2586
  Returns the result of a bitwise AND on two INTEGER values.
- `util.Integer.not` on page 2589
  Returns the INTEGER value with all bits inverted.
- `util.Integer.or` on page 2590
  Returns the result of a bitwise OR on two INTEGER values.
- `util.Integer.xor` on page 2597
  Returns the result of a bitwise XOR on two INTEGER values.
- `util.Integer.clearBit`
  Returns the INTEGER parameter with the bit at the designated position set to 0.

Syntax

```
util.Integer.clearBit(
  i INTEGER,
  n SMALLINT
)
RETURNS INTEGER
```

1. `i` is the integer value to modify.
2. `n` is the bit position (LSB is at position zero).

Usage

The `util.Integer.clearBit()` method modifies the integer value by clearing the bit at the position passed as second parameter.

**Note:** The position of the least significant bit (LSB) is the position zero:

- In `00000001` (integer 1), the bit set to 1 is at position 0.
- In `00100010` (integer 34), the bits set to 1 are at position 1 and 5.

**Note:** Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value `-1 (11111111 11111111 11111111 11111111)`.
2. The NULL value for the INTEGER type is represented internally with the value `0x80000000 (10000000 00000000 00000000 00000000)`. When NULL is used with the `util.Integer` bitwise methods, it will be interpreted as `0x80000000` instead of a null value. However, if the result of the bitwise operation produces the value `0x80000000`, it will be interpreted as NULL when used in an expression.

Example

```
IMPORT util
MAIN
  DISPLAY util.Integer.clearBit( 34, 5 ) -- displays 2
END MAIN
```
Related concepts
util.Integer.setBit on page 2592
Returns the INTEGER parameter with the bit at the designated position set to 1.

util.Integer.testBit on page 2595
Returns TRUE, if in the INTEGER value, the bit at the designed position is set.

util.Integer.not
Returns the INTEGER value with all bits inverted.

Syntax

```java
util.Integer.not (i INTEGER)
RETURNS INTEGER
```

1. \(i\) is the integer value to convert.

Usage
The `util.Integer.not()` method inverts all bits of the integer values passed as parameter:

<table>
<thead>
<tr>
<th>i</th>
<th>210 (00000000 00000000 00000000 11010010)</th>
</tr>
</thead>
<tbody>
<tr>
<td>result</td>
<td>-211 (11111111 11111111 11111111 00101101)</td>
</tr>
</tbody>
</table>

Note: Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value \(-1\) (11111111 11111111 11111111 11111111).
2. The NULL value for the INTEGER type is represented internally with the value 0x80000000 (10000000 00000000 00000000 00000000). When NULL is used with the `util.Integer` bitwise methods, it will be interpreted as 0x80000000 instead of a null value. However, if the result of the bitwise operation produces the value 0x80000000, it will be interpreted as NULL when used in an expression.

Example

```java
IMPORT util
MAIN
    DISPLAY util.Integer.not(
        util.Integer.parseBinaryString("11111111111111111111111111111110")
    ) -- displays 1
END MAIN
```

Related concepts
util.Integer.and on page 2586
Returns the result of a bitwise AND on two INTEGER values.

util.Integer.andNot on page 2587
Returns the result of a bitwise AND of the 1st INTEGER and the inverted 2nd INTEGER.

util.Integer.or on page 2590
Returns the result of a bitwise OR on two INTEGER values.

util.Integer.xor on page 2597
Returns the result of a bitwise XOR on two INTEGER values.

util.Integer.or
Returns the result of a bitwise OR on two INTEGER values.

Syntax

```java
util.Integer.or(
    x INTEGER,
    y INTEGER
)
RETURNS INTEGER
```

1. `x` is an integer value.
2. `y` is an integer value.

Usage

The `util.Integer.or()` method makes a bitwise OR operation with the integer values passed as parameter:

```
x     : 210 (00000000 00000000 00000000 11010010)
y     : 135 (00000000 00000000 00000000 10000111)
--------------------------------------------------
result : 215 (00000000 00000000 00000000 11010111)
```

Note: Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value -1 (11111111 11111111 11111111 11111111).
2. The NULL value for the INTEGER type is represented internally with the value 0x80000000 (10000000 00000000 00000000 00000000). When NULL is used with the `util.Integer` bitwise methods, it will be interpreted as NULL instead of a null value. However, if the result of the bitwise operation produces the value 0x80000000, it will be interpreted as NULL when used in an expression.

Example

```java
IMPORT util
MAIN
    DISPLAY util.Integer.or( 3, 1 ) -- displays 1
END MAIN
```

Related concepts

util.Integer.and on page 2586
Returns the result of a bitwise AND on two INTEGER values.

util.Integer.andNot on page 2587
Returns the result of a bitwise AND of the 1st INTEGER and the inverted 2nd INTEGER.

util.Integer.not on page 2589
Returns the INTEGER value with all bits inverted.
Returns the result of a bitwise XOR on two INTEGER values.

`util.Integer.parseHexString`
Returns an INTEGER from its hexadecimal (base 16) string representation.

**Syntax**

```
util.Integer.parseHexString(
    s STRING
)
RETURNS INTEGER
```

1. `s` is the string in hexadecimal.

**Usage**

The `util.Integer.parseHexString()` method scans the hexadecimal string and converts it to an integer value.

**Note:** Regarding A-F hexadecimal letters, the `parseHexString()` method is case-insensitive. The hexadecimal strings "ae3f", "aE3f" and "AE3F" are equivalent.

If the hexadecimal string does not fit in an INTEGER or if it contains an invalid hexadecimal representation, the method raises the numeric conversion error -1213, that can be trapped with a TRY/CATCH or WHENEVER ANY ERROR.

**Note:** Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value -1 (11111111 11111111 11111111 11111111).

2. The NULL value for the INTEGER type is represented internally with the value 0x80000000 (10000000 00000000 00000000 00000000). When NULL is used with the `util.Integer` bitwise methods, it will be interpreted as 0x80000000 instead of a null value. However, if the result of the bitwise operation produces the value 0x80000000, it will be interpreted as NULL when used in an expression.

**Example**

```
IMPORT util
MAIN
    DISPLAY util.Integer.parseHexString("6F12") -- displays 28434
END MAIN
```

**Related concepts**

- `util.Integer.toHexString` on page 2595
  Returns the string representation of an INTEGER, as an unsigned integer in base 16.

- `util.Integer.parseBinaryString`
  Returns an INTEGER from its binary (base 2) string representation

**Syntax**

```
util.Integer.parseBinaryString(
    s STRING
)
RETURNS INTEGER
```

1. `s` is the string in binary format (0 and 1).
Usage

The `util.Integer.parseBinaryString()` method scans the string as a set of 0 and 1 digits, and converts it to an integer value.

If the binary representation does not fit in an INTEGER or if it contains an invalid binary representation, the method raises the numeric conversion error -1213, that can be trapped with a `TRY/CATCH` or `WHENEVER ANY ERROR`.

**Note:** Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value -1 (11111111 11111111 11111111 11111111).

2. The NULL value for the INTEGER type is represented internally with the value 0x80000000 (10000000 00000000 00000000 00000000). When NULL is used with the `util.Integer` bitwise methods, it will be interpreted as 0x80000000 instead of a null value. However, if the result of the bitwise operation produces the value 0x80000000, it will be interpreted as NULL when used in an expression.

Example

```import util
main
    display util.integer.parseBinaryString( "0010" ) -- displays 2
end main```

Related concepts

`util.Integer.toBinaryString` on page 2596
Returns the string representation of an INTEGER, as an unsigned integer in base 2.

`util.Integer.setBit`
Returns the INTEGER parameter with the bit at the designated position set to 1.

Syntax

```util.integer.setBit( 
    i INTEGER, 
    n INTEGER 
) 
returns INTEGER```

1. `i` is the integer value to modify.
2. `n` is the bit position (LSB is at position zero).

Usage

The `util.Integer.setBit()` method modifies the integer value by setting the bit at the position passed as second parameter.

**Note:** The position of the least significant bit (LSB) is the position zero:

- In 00000001 (integer 1), the bit set to 1 is at position 0.
- In 00100010 (integer 34), the bits set to 1 are at position 1 and 5.

**Note:** Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value -1 (11111111 11111111 11111111 11111111).
2. The NULL value for the INTEGER type is represented internally with the value 0x80000000 (10000000 00000000 00000000 00000000). When NULL is used with the util.Integer bitwise methods, it will be interpreted as 0x80000000 instead of a null value. However, if the result of the bitwise operation produces the value 0x80000000, it will be interpreted as NULL when used in an expression.

Example

```plaintext
IMPORT util
MAIN
    DISPLAY util.Integer.setBit( 0, 0 ) -- displays 1 (00000001)
    DISPLAY util.Integer.setBit( 1, 0 ) -- displays 1 (00000001)
    DISPLAY util.Integer.setBit( 16, 2 ) -- displays 20 (00010100)
END MAIN
```

Related concepts

util.Integer.clearBit on page 2588
Returns the INTEGER parameter with the bit at the designated position set to 0.

util.Integer.testBit on page 2595
Returns TRUE, if in the INTEGER value, the bit at the designed position is set.

util.Integer.shiftLeft
Returns the INTEGER value left-shifted by the given bit places.

Syntax

```plaintext
util.Integer.shiftLeft(  
    i INTEGER,  
    n SMALLINT  
)  
RETURNS INTEGER
```

1. i is the integer value to shift.
2. n is the left-shift distance in bits.

Usage

The util.Integer.shiftLeft() method shifts the bits to the left in the integer value passed in the first parameter by the number places specified by the second parameter.

```plaintext
i  : 210 (00000000 11010010)
n  : 3
--------------------------------
result :1680 (00000110 10010000)
```

Bits shifted out from the left end are lost.

Bits shifted in from the right end are set to 0.

Note: Bitwise methods provided by the util.Integer class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, util.Integer.not(0) produces the INTEGER value -1 (11111111 11111111 11111111 11111111).
2. The NULL value for the INTEGER type is represented internally with the value 0x80000000 (10000000 00000000 00000000 00000000). When NULL is used with the util.Integer bitwise methods, it will be interpreted as 0x80000000 instead of a null value. However, if the result of the bitwise operation produces the value 0x80000000, it will be interpreted as NULL when used in an expression.
**Example**

```plaintext
IMPORT util
MAIN
    DISPLAY util.Integer.shiftLeft(
        util.Integer.parseIntBinaryString("11"),
        3 ) -- displays 24
END MAIN
```

`util.Integer.shiftRight`

Returns the INTEGER value right-shifted by the given bit places.

**Syntax**

```plaintext
util.Integer.shiftRight(
    i INTEGER,
    n SMALLINT
) RETURNS INTEGER
```

1. `i` is the integer value to shift.
2. `n` is the right-shift distance in bits.

**Usage**

The `util.Integer.shiftRight()` method shifts the bits to the right in the integer value passed in the first parameter by the number of places specified by the second parameter.

<table>
<thead>
<tr>
<th>i</th>
<th>210 (00000000 11010010)</th>
</tr>
</thead>
<tbody>
<tr>
<td>n</td>
<td>3</td>
</tr>
<tr>
<td>result</td>
<td>26 (00000000 00011010)</td>
</tr>
</tbody>
</table>

Bits shifted out from the right end are lost.

Bits shifted in from the left end are set to 0.

**Note:** Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value -1 (11111111 11111111 11111111 11111111).
2. The NULL value for the INTEGER type is represented internally with the value 0x80000000 (10000000 00000000 00000000 00000000). When NULL is used with the `util.Integer` bitwise methods, it will be interpreted as 0x80000000 instead of a null value. However, if the result of the bitwise operation produces the value 0x80000000, it will be interpreted as NULL when used in an expression.

**Example**

```plaintext
IMPORT util
MAIN
    DISPLAY util.Integer.shiftRight(
        util.Integer.parseIntBinaryString("1100"),
        2 ) -- displays 3
END MAIN
```
**util.Integer.testBit**

Returns **TRUE**, if in the **INTEGER** value, the bit at the designed position is set.

**Syntax**

```java
util.Integer.testBit(
    i INTEGER
    n INTEGER
)
RETURNS BOOLEAN
```

1. `i` is an integer value to check.
2. `n` is the bit position (LSB is at position zero).

**Usage**

The `util.Integer.clearBit()` method returns **TRUE** if the passed integer value has the bit set to **1** at the specified position.

**Note:** The position of the least significant bit (LSB) is the position zero:

- In `00000001` (integer 1), the bit set to **1** is at position **0**.
- In `00100010` (integer 34), the bits set to **1** are at position **1** and **5**.

**Note:** Bitwise methods provided by the `util.Integer` class are based on the **INTEGER** type. Consider the following facts when using these methods:

1. The **INTEGER** type is a four-byte signed integer: If the bit at position 31 is set to **1**, the corresponding **INTEGER** value will be negative. Thus, `util.Integer.not(0)` produces the **INTEGER** value `-1` (`11111111 11111111 11111111 11111111`).

2. The **NULL** value for the **INTEGER** type is represented internally with the value `0x80000000` (`10000000 00000000 00000000 00000000`). When **NULL** is used with the `util.Integer` bitwise methods, it will be interpreted as `0x80000000` instead of a null value. However, if the result of the bitwise operation produces the value `0x80000000`, it will be interpreted as **NULL** when used in an expression.

**Example**

```java
IMPORT util
MAIN
    DISPLAY util.Integer.testBit( 3, 1 ) -- displays 1 (TRUE)
END MAIN
```

**Related concepts**

- `util.Integer.clearBit` on page 2588
  Returns the **INTEGER** parameter with the bit at the designated position set to **0**.

- `util.Integer.setBit` on page 2592
  Returns the **INTEGER** parameter with the bit at the designated position set to **1**.

- `util.Integer.toHexString`
  Returns the string representation of an **INTEGER**, as an unsigned integer in base **16**.

**Syntax**

```java
util.Integer.toHexString(
    i INTEGER
)
RETURNS STRING
```

1. `i` is the source integer value to convert.
Usage

The `util.Integer.toHexString()` method generates the hexadecimal representation of the integer passed as parameter.

The resulting hexadecimal string represents the unsigned integer, in base 16.

**Note:** The result has no leading zeros.

**Note:** Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value \(-1\) (11111111 11111111 11111111 11111111).

2. The NULL value for the INTEGER type is represented internally with the value `0x80000000` (10000000 00000000 00000000 00000000). When NULL is used with the `util.Integer` bitwise methods, it will be interpreted as `0x80000000` instead of a null value. However, if the result of the bitwise operation produces the value `0x80000000`, it will be interpreted as NULL when used in an expression.

Example

```java
IMPORT util
MAIN
    DISPLAY util.Integer.toHexString(234) -- displays "ea"
END MAIN
```

Related concepts

`util.Integer.parseHexString` on page 2591
Returns an INTEGER from its hexadecimal (base 16) string representation.

`util.Integer.toBinaryString`
Returns the string representation of an INTEGER, as an unsigned integer in base 2.

Syntax

```java
util.Integer.toBinaryString(
    i INTEGER
) RETURNS STRING
```

1. `i` is the source integer value to convert.

Usage

The `util.Integer.toBinaryString()` method generates the binary representation of the integer passed as parameter.

The resulting binary string represents the unsigned integer, in base 2.

**Note:** The result has no leading zeros.

**Note:** Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value \(-1\) (11111111 11111111 11111111 11111111).

2. The NULL value for the INTEGER type is represented internally with the value `0x80000000` (10000000 00000000 00000000 00000000). When NULL is used with the `util.Integer` bitwise methods, it will be interpreted as `0x80000000` instead of a null value. However, if the result of the bitwise operation produces the value `0x80000000`, it will be interpreted as NULL when used in an expression.
Example

```
IMPORT util
MAIN
    DISPLAY util.Integer.toBinaryString( 24 ) -- displays "11000"
END MAIN
```

Related concepts

`util.Integer.parseBinaryString` on page 2591
Returns an INTEGER from its binary (base 2) string representation

`util.Integer.xor`
Returns the result of a bitwise XOR on two INTEGER values.

Syntax

```
util.Integer.xor(
    x INTEGER,
    y INTEGER
)
RETURNS INTEGER
```

1. `x` is an integer value.
2. `y` is an integer value.

Usage

The `util.Integer.xor()` method makes a bitwise XOR operation with the integer values passed as parameter:

```
x     : 210 (00000000 00000000 00000000 11010010)
y     : 135 (00000000 00000000 00000000 10000111)
--------------------------------------------------
result :  85 (00000000 00000000 00000000 01010101)
```

Note: Bitwise methods provided by the `util.Integer` class are based on the INTEGER type. Consider the following facts when using these methods:

1. The INTEGER type is a four-byte signed integer: If the bit at position 31 is set to 1, the corresponding INTEGER value will be negative. Thus, `util.Integer.not(0)` produces the INTEGER value `-1 (11111111 11111111 11111111 11111111).
2. The NULL value for the INTEGER type is represented internally with the value `0x80000000 (10000000 00000000 00000000 00000000)`. When NULL is used with the `util.Integer` bitwise methods, it will be interpreted as `0x80000000` instead of a null value. However, if the result of the bitwise operation produces the value `0x80000000`, it will be interpreted as NULL when used in an expression.

Example

```
IMPORT util
MAIN
    DISPLAY util.Integer.xor( 6, 2 ) -- displays 4
END MAIN
```

Related concepts

`util.Integer.and` on page 2586
Returns the result of a bitwise AND on two INTEGER values.

`util.Integer.andNot` on page 2587
Returns the result of a bitwise AND of the 1st INTEGER and the inverted 2nd INTEGER.

`util.Integer.not` on page 2589
Returns the INTEGER value with all bits inverted.

util.Integer.or on page 2590
Returns the result of a bitwise OR on two INTEGER values.

The util.Interval class
The util.Interval class provides INTERVAL data-type related utility methods.

This class is provided in the util C-Extension library. To use the util.Interval class, you must import the util package in your program:

```
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

Related concepts
IMPORT C-Extension on page 496
The IMPORT instruction imports c extension module elements to be used by the current module.

util.Interval methods
Methods for the util.Interval class.

Table 543: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>util.Interval.format(t INTERVAL q1 TO q2, format STRING)</code></td>
<td>Formats an interval value based on a specified format.</td>
</tr>
<tr>
<td><code>util.Interval.parse(s STRING, format STRING)</code></td>
<td>Converts a string to a DATETIME value based on a specified format.</td>
</tr>
</tbody>
</table>

`util.Interval.format`
Formats an interval value based on a specified format.

Syntax

```
util.Interval.format(
    t INTERVAL q1 TO q2,
    format STRING
)
RETURNS STRING
```

1. `t` is the interval value to be formatted.
2. `format` is the format string, as described in Formatting INTERVAL values on page 287.

Usage

The `util.Interval.format()` method formats an INTERVAL value based on the format specification.

The format string must be a combination of place holders such as `%Y`, `%m`, `%d`, as described in Formatting INTERVAL values on page 287.
If the source value is NULL the result will be NULL.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE iv INTERVAL DAY(6) TO MINUTE
    LET iv = "-157 11:23"
    DISPLAY util.Interval.format(iv, "%d %H:%M")
END MAIN
```

**Related concepts**

*util.Interval.parse* on page 2599

Converts a string to a DATETIME value based on a specified format.

*util.Interval.parse*

Converts a string to a DATETIME value based on a specified format.

**Syntax**

```plaintext
util.Interval.parse(
    s STRING,
    format STRING
) RETURNS DATETIME q1 TO q2
```

1. `s` is the source string to be parsed.
2. `format` is the format specification (see Formatting INTERVAL values on page 287).

**Usage**

The *util.Interval.parse()* method parses a string based on a format specification, to produce an INTERVAL value.

The format specification must be a combination of place holders such as `%Y`, `%m`, `%d`, etc.

The precision of the resulting INTERVAL value depends on the format specification. For example, when using "%Y-%m", the resulting value will be an INTERVAL YEAR TO MONTH.

The method returns NULL, if the source string cannot be converted to an INTERVAL value based on the format specification.

For more details about the supported formats, see Formatting INTERVAL values on page 287.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE iv INTERVAL DAY(6) TO FRACTION(5)
    LET iv = util.Interval.parse("-37467 + 23:45:34.12345", "%d + %H:%M:%S %F5")
END MAIN
```

**Related concepts**

*util.Interval.format* on page 2598
Formats an interval value based on a specified format.

**The util.Strings class**  
The *util.Strings* class provides STRING data-type related utility methods.

This class is provided in the *util C-Extension* library. To use the *util.Strings* class, you must import the *util* package in your program:

```plaintext
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

**Related concepts**  
IMPORT *C-Extension* on page 496
The `IMPORT` instruction imports C extension module elements to be used by the current module.

**util.Strings methods**
Methods for the `util.Strings` class.

**Table 544: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>util.Strings.base64Decode</code> (</td>
<td><code>base64 STRING,</code></td>
</tr>
<tr>
<td><code>filename STRING</code> )</td>
<td>Decodes a Base64 encoded string and writes the bytes to a file.</td>
</tr>
<tr>
<td><code>util.Strings.base64Encode</code> (</td>
<td><code>filename STRING</code> )</td>
</tr>
<tr>
<td><code>util.Strings.base64DecodeToHexString</code> (</td>
<td><code>base64 STRING</code> )</td>

<td><code>s STRING</code> )</td>
</tr>
<tr>
<td><code>util.Strings.urlEncode</code> (</td>
<td><code>source STRING</code> )</td>
</tr>
</tbody>
</table>
**util.Strings.base64Decode**  
Decodes a Base64 encoded string and writes the bytes to a file.

**Syntax**

```
util.Strings.base64Decode(
    base64 STRING,
    filename STRING
)
```

1. `base64` is the Base64 encoded string.
2. `filename` is the name of the file to write to.

**Usage**

The `util.Strings.base64Decode()` method converts the Base64 encoded string passed as first parameter, and writes the bytes to file specified as second parameter.

**Example**

```
IMPORT util
MAIN
   DEFINE base64 STRING
   LET base64 = util.Strings.base64Encode( "picture1.png" )
   DISPLAY base64
   CALL util.Strings.base64Decode( base64, "picture2.png" )
END MAIN
```

**Related concepts**

- `util.Strings.base64Encode` on page 2602  
  Converts the content of a file to a Base64 encoded string.

**util.Strings.base64Encode**  
Converts the content of a file to a Base64 encoded string.

**Syntax**

```
util.Strings.base64Encode(
    filename STRING
)
```

1. `filename` is the name of the file to read from.

**Usage**

The `util.Strings.base64Encode()` method reads the content of the file passed as parameter, and converts the bytes to a Base64 encoded string.

**Example**

```
IMPORT util
MAIN
   DISPLAY util.Strings.base64Encode( "picture.png" )
END MAIN
```

**Related concepts**

- `util.Strings.base64Decode` on page 2602
Decodes a Base64 encoded string and writes the bytes to a file.

`util.Strings.base64DecodeToHexString`
Decodes a base64 encoded string and returns the corresponding hexadecimal string.

**Syntax**

```java
util.Strings.base64DecodeToHexString(
    base64 STRING
)  
RETURNS STRING
```

1. `base64` is the Base64 encoded string.

**Usage**

The `util.Strings.base64DecodeToHexString()` method converts the Base64 encoded string passed as parameter to an array of bytes, then it converts the byte array to the hexadecimal representation of this array of bytes, and returns that string.

**Tip:** After converting the Base64 string to an hexadecimal string, use the `util.parseHexString()` method to convert bytes of the hexadecimal string to integers.

**Example**

```java
IMPORT util
MAIN
DEFINE hexa VARCHAR(50)
DISPLAY util.Strings.base64DecodeToHexString( "AA==" )
DISPLAY util.Strings.base64DecodeToHexString( "AAAAAA==" )
DISPLAY util.Strings.base64DecodeToHexString( "AQ==" )
DISPLAY util.Strings.base64DecodeToHexString( "//8=" )
DISPLAY util.Strings.base64DecodeToHexString( "QUJDRA==" )
LET hexa = util.Strings.base64DecodeToHexString( "QUJDRA==" )
DISPLAY util.Integer.parseHexString( hexa[1,2] )
DISPLAY util.Integer.parseHexString( hexa[3,4] )
DISPLAY util.Integer.parseHexString( hexa[5,6] )
DISPLAY util.Integer.parseHexString( hexa[7,8] )
END MAIN
```

**Output:**

```
00
00000000
01
ffff
41424344
  65
  66
  67
  68
```

**Related concepts**

`util.Strings.base64EncodeFromHexString` on page 2604
Converts the hexadecimal string passed as parameter to a Base64 encoded string.

**util.Strings.base64DecodeToString**

Decodes a base64 encoded string and returns the corresponding string.

**Syntax**

```plaintext
util.Strings.base64DecodeToString(
  base64 STRING
)
RETURNS STRING
```

1. `base64` is the Base64 encoded string.

**Usage**

The `util.Strings.base64DecodeToString()` method converts the Base64 encoded string passed as parameter to an array of bytes, then it converts the byte array to a string representation in the current locale, and returns that string.

If the Base64 source string contains a sequence of bytes that does not represent a valid character in the current application locale, the function returns `NULL`.

**Note:** In contrast to `util.Strings.urlDecode()`, the original string is not converted from UTF-8 to the application character encoding: The Base64 source string must represent valid characters in the current application locale.

**Example**

(Character encoding is UTF-8)

```plaintext
IMPORT util
MAIN
  DEFINE base64 STRING
  LET base64 = util.Strings.base64EncodeFromString( "Forêt" )
  DISPLAY base64
  DISPLAY util.Strings.base64DecodeToString( base64 )
END MAIN
```

**Output:**

```
Rm9yw6p0
Forêt
```

**Related concepts**

- `util.Strings.base64EncodeFromString` on page 2605
  > Converts the string passed as parameter to a Base64 encoded string.

- `util.Strings.base64EncodeFromHexString`
  > Converts the hexadecimal string passed as parameter to a Base64 encoded string.

**Syntax**

```plaintext
util.Strings.base64EncodeFromHexString(
  s STRING
)
RETURNS STRING
```

1. `s` is the source hexadecimal string to convert in Base64.
Usage

The `util.Strings.base64EncodeFromHexString()` method first converts the hexadecimal string passed as parameter to an array of bytes, then it converts the array of bytes to a Base64 representation, and returns the resulting Base64 encoded string.

**Tip:** Use the `util.Integer.toHexString()` method to build an hexadecimal string from a set of integer/byte values, then convert the hexadecimal string to a Base64 representation.

Example

```util
IMPORT util
MAIN
  DEFINE hexa VARCHAR(50)
  DISPLAY util.Strings.base64EncodeFromHexString( "00" )
  DISPLAY util.Strings.base64EncodeFromHexString( "0000" )
  DISPLAY util.Strings.base64EncodeFromHexString( "FFFF" )
  DISPLAY util.Strings.base64EncodeFromHexString( "42EFB3E5" )
  LET hexa = util.Integer.toHexString(65)
  || util.Integer.toHexString(66)
  || util.Integer.toHexString(67)
  DISPLAY hexa
  DISPLAY util.Strings.base64EncodeFromHexString( hexa )
END MAIN
```

Output:

```
AA==
AAA=
//8=
Qu+z5Q==
414243
QUJD
```

Related concepts

- `util.Strings.base64DecodeToHexString` on page 2603
  Decodes a base64 encoded string and returns the corresponding hexadecimal string.

- `util.Strings.base64EncodeFromString`
  Converts the string passed as parameter to a Base64 encoded string.

Syntax

```c
util.Strings.base64EncodeFromString( 
  s STRING 
) 
RETURNS STRING
```

1. `s` is the source string to convert in Base64.

Usage

The `util.Strings.base64EncodeFromString()` method first converts the string passed as parameter (in the current character encoding of the application) to an array of bytes, then it converts the array of bytes to a Base64 representation, and returns the resulting Base64 encoded string.

**Note:** In contrast to `util.Strings.urlEncode()`, the original string is not converted from the application locale to UTF-8, before performing the encoding to Base64: The resulting Base64 encoded string will contain byte sequences representing characters in the current application locale.
Example

(Character encoding is UTF-8)

```plaintext
IMPORT util
MAIN
  DISPLAY util.Strings.base64EncodeFromString( "Forêt" )
END MAIN
```

Output:

```
Rm9yw6p0
```

Related concepts

util.Strings.base64DecodeToString on page 2604
Decodes a base64 encoded string and returns the corresponding string.

util.Strings.urlDecode
Converts the URL-encoded string to a string in the current application locale.

Syntax

```plaintext
util.Strings.urlDecode(
  s STRING
)
RETURNS STRING
```

1. `s` is the URL-encoded source string (UTF-8 bytes).

Usage

The `util.Strings.urlDecode()` method converts the URL-encoded string passed as parameter to a character string.

The source string must contain ASCII characters and/or %xx hexadecimal representation of UTF-8 encoding bytes.

The decoder is error tolerant:

- Alphabetical characters of a %xx element can be uppercase or lowercase (%b2 = %B2).
- If the source string contains a set of %xx elements that represent a UTF-8 encoded character which is not existing in the current application locale, it will be converted to a ? question mark.
- If the percent character is not followed by two hexadecimal digits, then a "%" is copied to the result string and the decoder continues at the next character.

Example

```plaintext
IMPORT util
MAIN
  DISPLAY util.Strings.urlDecode("abc%C3%84%E2%82%AC")
END MAIN
```

Output:

```
abcĀ€
```

Related concepts

Defining the application locale on page 412
This section describes the settings defining the application locale, changing the behavior of the compilers and runtime system.

util.Strings.urlEncode on page 2607
Converts a string from the current codeset to a URL-encoded string.

**util.Strings.urlEncode**

Converts a string from the current codeset to a URL-encoded string.

**Syntax**

```plaintext
util.Strings.urlEncode(
  source STRING
)
RETURNS STRING
```

1. *source* is the source string to url-encode.

**Usage**

The `util.Strings.urlEncode()` method converts the character string passed as parameter to a URL-encoded string.

All characters not matching `[-_.~a-zA-Z0-9]` are "percent encoded": Percent-encoding involves converting those characters to UTF-8 and representing its corresponding byte values by a percent sign ("%") and a pair of hexadecimal digits.

**Example**

```plaintext
IMPORT util
MAIN
  DISPLAY util.Strings.urlEncode("abc€")
END MAIN
```

Output:
abc%C3%84%E2%82%AC

**Related concepts**

- **util.Strings.urlDecode** on page 2606
  Converts the URL-encoded string to a string in the current application locale.

**The util.Math class**

The `util.Math` class provides basic mathematical functions based on floating point numbers (`FLOAT`).

This class does not have to be instantiated; it provides class methods for the current program.

This class is provided in the `util C-Extension` library. To use the `util.Math` class, you must import the `util` package in your program:

```plaintext
IMPORT util
```

**Related concepts**

- **IMPORT C-Extension** on page 496
The `IMPORT` instruction imports C extension module elements to be used by the current module.

**util.Math methods**
Methods for the `util.Math` class.
### Table 545: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>util.Math.acos (x FLOAT )</code></td>
<td>Computes the arc cosine of the passed value, measured in radians.</td>

<tr>
<td><code>util.Math.pow (x FLOAT, y FLOAT )</code></td>
<td>Computes the value of $x$ raised to the power $y$.</td>
</tr>
<tr>
<td><code>util.Math.rand (max INTEGER )</code></td>
<td>Returns a positive pseudo-random number.</td>
</tr>
<tr>
<td><code>util.Math.sin (x FLOAT )</code></td>
<td>Computes the sine of the passed value, measured in radians.</td>
</tr>
<tr>
<td><code>util.Math.sqrt (x FLOAT )</code></td>
<td>Returns the square root of the argument provided.</td>
</tr>
<tr>
<td><code>util.Math.srand ()</code></td>
<td>Initializes the pseudo-random numbers generator.</td>
</tr>
<tr>
<td><code>util.Math.tan (x FLOAT )</code></td>
<td>Computes the tangent of the passed value, measured in radians.</td>
</tr>
<tr>
<td><code>util.Math.toDegrees (x FLOAT )</code></td>
<td>Converts an angle measured in radians to an approximately equivalent angle measured in degrees.</td>
</tr>
<tr>
<td><code>util.Math.toRadians (x FLOAT )</code></td>
<td>Converts an angle measured in degrees to an approximately equivalent angle measured in radians.</td>
</tr>
</tbody>
</table>
util.Math.acos
Computes the arc cosine of the passed value, measured in radians.

Syntax
```
util.Math.acos(
    x FLOAT )
RETURNS FLOAT
```

1. $x$ is a floating point value.

Usage
Returns NULL if the argument provided is invalid.

util.Math.asin
Computes the arc sine of the passed value, measured in radians.

Syntax
```
util.Math.asin(
    x FLOAT )
RETURNS FLOAT
```

1. $x$ is a floating point value.

Usage
Returns NULL if the argument provided is invalid.

util.Math.atan
Computes the arc tangent of the passed value, measured in radians.

Syntax
```
util.Math.atan(
    x FLOAT )
RETURNS FLOAT
```

1. $x$ is a floating point value.

Usage
Returns NULL if the argument provided is invalid.

util.Math.cos
Computes the cosine of the passed value, measured in radians.

Syntax
```
util.Math.cos(
    x FLOAT )
RETURNS FLOAT
```

1. $x$ is a floating point value.

Usage:
Returns NULL if the argument provided is invalid.
util.Math.exp
Computes the base-e exponential of the value passed as parameter.

Syntax

```java
util.Math.exp(
    x FLOAT )
RETURNS FLOAT
```

1. \( x \) is a floating point value.

Usage

Returns NULL if the argument provided on error.

util.Math.pi
Returns the FLOAT value of PI.

Syntax

```java
util.Math.pi()
RETURNS FLOAT
```

util.Math.pow
Computes the value of \( x \) raised to the power \( y \).

Syntax

```java
util.Math.pow(
    x FLOAT, 
    y FLOAT )
RETURNS FLOAT
```

1. \( x \) is the value to be raised.
2. \( y \) is the power operand.

Usage

The function returns NULL if one of the argument provided is invalid.

If \( x \) is negative, the caller must ensure that \( y \) is an integer value.

util.Math.rand
Returns a positive pseudo-random number.

Syntax

```java
util.Math.rand(
    max INTEGER )
RETURNS INTEGER
```

1. \( max \) is the maximum random number that can be generated.

Usage

The \( \text{rand}() \) function returns a pseudo-random integer number between zero and \( max \).

Important:
The `srand()` function initializes the pseudo-random numbers generator. It must be called before subsequent calls to the `rand()` function. If you do not call the `srand()` function, the `rand()` function will generate the same sequence of numbers for every program execution. The numbers generated by `rand()` can vary depending on the operating system.

The maximum random number returned by the `rand()` function is 2,147,483,646.

The `rand()` function returns zero if the argument is lower or equal to 0.

**Example**

```plaintext
IMPORT util

MAIN
    DEFINE i SMALLINT
    DISPLAY "Before srand() call:"
    FOR i=1 TO 3
        DISPLAY util.Math.rand(100)
    END FOR
    CALL util.Math.srand()
    DISPLAY "After srand() call:"
    FOR i=1 TO 3
        DISPLAY util.Math.rand(100)
    END FOR
END MAIN
```

(run this example several times)

`util.Math.sin`

Computes the sine of the passed value, measured in radians.

**Syntax**

```plaintext
util.Math.sin(
    x FLOAT )
RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage**

Returns NULL if the argument provided is invalid.

`util.Math.sqrt`

Returns the square root of the argument provided.

**Syntax**

```plaintext
util.Math.sqrt(
    x FLOAT )
RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage**

The function returns NULL if the argument provided is invalid.
**util.Math.srand**
Initializes the pseudo-random numbers generator.

**Syntax**

```java
util.Math.srand()
```

**Usage**
The `srand()` function initializes the pseudo-random numbers generator. It must be called before subsequent calls to the `rand()` function. If you do not call the `srand()` function, the `rand()` function will generate the same sequence of numbers for every program execution. The numbers generated by `rand()` can vary depending on the operating system.

**util.Math.tan**
Computes the tangent of the passed value, measured in radians.

**Syntax**

```java
util.Math.tan(
    x FLOAT )
RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage**
Returns NULL if the argument provided is invalid.

**util.Math.log**
Computes the natural logarithm of the passed value.

**Syntax**

```java
util.Math.log(
    x FLOAT )
RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage**
Returns NULL if the argument provided is invalid.

**util.Math.toDegrees**
Converts an angle measured in radians to an approximately equivalent angle measured in degrees.

**Syntax**

```java
util.Math.toDegrees(
    x FLOAT )
RETURNS FLOAT
```

1. `x` is a floating point value to be converted to degrees.
**util.Math.toRadians**  
Converts an angle measured in degrees to an approximately equivalent angle measured in radians.

**Syntax**

```plaintext
util.Math.toRadians(
    x FLOAT )
RETURNS FLOAT
```

1. `x` is a floating point value to be converted to radians.

**The util.JSON class**  
The `util.JSON` class provides a basic interface to convert program variable values to/from JSON data.

The `util.JSON` class is provided in the `util C-Extension` library. To use the `util.JSON` class, you must import the `util` package in your program:

```
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

The purpose of the `util.JSON` class is to convert a JSON string from/to a BDL variable, to interface with other software based on the JSON format.

The BDL variable can be:

- a simple variable (defined with a primitive type such as `DATE`, `INTEGER`, `VARCHAR(20)`)  
- a structured variable (`RECORD ... END RECORD`)  
- a dynamic array (`DYNAMIC ARRAY OF ...`)  
- a dictionary (`DICTIONARY OF ...`)  

It is not possible to modify JSON elements with this class. In order to manipulate JSON objects, use the `util.JSONObject` and `util.JSONArray` classes.

**Related concepts**  
[JSON support](#) on page 465  
Genero BDL supports JSON data manipulation.

```
IMPORT C-Extension on page 496
```
The IMPORT instruction imports C extension module elements to be used by the current module.

**util.JSON methods**
Methods for the `util.JSON` class.

**Table 546: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>util.JSON.format</code> (\n  <code>s</code> STRING ) \n RETURNS STRING</td>
<td>Formats a JSON string with indentation.</td>
</tr>
<tr>
<td><code>util.JSON.parse</code> (\n  <code>s</code> STRING, \n  variableRef \n  \n  <code>base-type</code> \n  <code>record-type</code> \n  <code>dynamic-array-type</code> \n  \n  <code>dictionary-type</code> )</td>
<td>Parses a JSON string and fills program variables with the values.</td>
</tr>
<tr>
<td><code>util.JSON.proposeType</code> (\n  <code>s</code> STRING ) \n RETURNS STRING</td>
<td>Describes the record structure that can hold a given JSON data string.</td>
</tr>
<tr>
<td><code>util.JSON.stringify</code> (\n  <code>value</code> \n  <code>base-type</code> \n  <code>record-type</code> \n  <code>dynamic-array-type</code> \n  \n  <code>dictionary-type</code> ) \n RETURNS STRING</td>
<td>Transforms a record variable to a flat JSON formatted string, by including empty records and empty arrays.</td>
</tr>
<tr>
<td><code>util.JSON.stringifyOmitNulls</code> (\n  <code>value</code> \n  <code>RECORD</code> \n  <code>DYNAMIC ARRAY</code> ) \n RETURNS STRING</td>
<td>Transforms a record variable to a flat JSON formatted string, by excluding empty records and empty arrays.</td>
</tr>
</tbody>
</table>

**util.JSON.format**
Formats a JSON string with indentation.

**Syntax**

```plaintext
util.JSON.format (\n  `s` STRING ) \n RETURNS STRING
```

1. `s` is a string value that contains JSON formatted data.
Usage

The `util.JSON.format()` class method takes a JSON string as parameter and reorganizes the JSON data for better readability.

If the provided string is not valid JSON, the `format()` method will raise error `-8109`. Consider enclosing the `format()` method call in a `TRY/CATCH` block, if the source string can be malformed JSON.

The main purpose of this method is to beautify a JSON data string that is on a single line, by adding line breaks and indentation.

Example

```plaintext
IMPORT util

MAIN
   DISPLAY "1: ", util.JSON.format('{}')
   DISPLAY "2: ", util.JSON.format('{"pkey":8374,"name":"John"}"
   DISPLAY "3: ", util.JSON.format('{"ids":[234,3452,9845]}"
   DISPLAY "4: ", util.JSON.format('{"pkey":8374,"orders":[]}"
END MAIN
```

Output:

```
1: {}
2: {
   "pkey": 8374,
   "name": "John"
}
3: {
   "ids": [
   234,
   3452,
   9845
   ]
}
4: {
   "pkey": 8374,
   "orders": []
}
```

Related concepts

Records on page 382
Records allow structured program variables definitions.

`util.JSON.parse`
Parses a JSON string and fills program variables with the values.

Syntax

```plaintext
util.JSON.parse(
   s STRING,
   variableRef \[ base-type
   record-type
   dynamic-array-type
   dictionary-type
   ]
)
```

1. `s` is a string value that contains JSON formatted data.
2. `variableRef` is the variable to be initialized with values of the JSON string.

   **Important:** The `variableRef` parameter is passed by reference to the method.
3. *base-type* is a base data type of Genero (INTEGER, DATE, VARCHAR)
4. *record-type* is a RECORD ... END RECORD type.
5. *dynamic-array-type* is a DYNAMIC ARRAY OF ... type.
6. *dictionary-type* is a DICTIONARY OF ... type.

**Usage**

The `util.JSON.parse()` class method scans the JSON source string passed as parameter and fills the destination variable members by name.

If the provided string is not valid JSON, the `parse()` method will raise error -8109. Consider enclosing the `parse()` method call in a TRY/CATCH block, if the source string can be malformed JSON.

The destination variable is expected to have the same structure as the JSON source data, it can be a RECORD, DYNAMIC ARRAY or a DICTIONARY.

The `parse()` method initializes the target variable to NULL before the parsing starts.

See JSON support on page 465 for details on how the destination variable is populated when the structures are not identical.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE cust_rec RECORD
        cust_num INTEGER,
        cust_name VARCHAR(30),
        order_ids DYNAMIC ARRAY OF INTEGER
    END RECORD
    DEFINE js STRING
    LET js='{ "cust_num":2735, "cust_name":"McCarlson",
              "order_ids":[234,3456,24656,34561] }'
    TRY
        CALL util.JSON.parse( js, cust_rec )
        DISPLAY cust_rec.cust_name
        DISPLAY cust_rec.order_ids[4]
    CATCH
        DISPLAY "ERROR:", STATUS
    END TRY
END MAIN
```

**Related concepts**

*Records* on page 382

Records allow structured program variables definitions.

*util.JSON.proposeType*

Describes the record structure that can hold a given JSON data string.

**Syntax**

```plaintext
util.JSON.proposeType(  
    s STRING  
)  
RETURNS STRING
```

1. *s* is a string value that contains JSON formatted data.

**Usage**

The `util.JSON.proposeType()` class method takes a JSON formatted string as parameter and generates the RECORD definition that can be used as base record definition hold the source JSON string.
If the provided string is not valid JSON, the `proposeType()` method will raise error -8109. Consider enclosing the `proposeType()` method call in a TRY/CATCH block, if the source string can be malformed JSON.

In order to respect the BDL syntax, and match exactly the JSON source structure, the type generated by `proposeType()` may need to be reviewed.

For example, if the JSON property name contains characters not allowed in a BDL identifiers, use the `json_name` variable definition attribute to map the JSON property name to the RECORD element. Furthermore, the type `DICTIONARY` will not be proposed. As result, a source JSON string like ("Fist Name":"John","LastName":"Piper") will produce:

```
RECORD
  First Name STRING,
  Last Name STRING
END RECORD
```

That needs to be adapted to use `json_name` attributes:

```
RECORD
  first_name STRING ATTRIBUTES(json_name="First Name"),
  last_name STRING ATTRIBUTES(json_name="Last Name")
END RECORD
```

Or to a `DICTIONARY` type:

```
DICTIONARY OF STRING
```

**Example**

```
IMPORT util
MAIN
  DEFINE js STRING
  LET js='{ "cust_num":2735, "cust_name":"McCarlson",
  "orderids":[234,3456,24656,34561] }'
  DISPLAY util.JSON.proposeType( js )
END MAIN
```

Displays:

```
RECORD
  cust_num FLOAT,
  cust_name STRING,
  orderids DYNAMIC ARRAY OF FLOAT
END RECORD
```

**Related concepts**

- [Records](#) on page 382
  Records allow structured program variables definitions.

- **`util.JSON.stringify`**
  Transforms a record variable to a flat JSON formatted string, by including empty records and empty arrays.

**Syntax**

```
util.JSON.stringify(
  value _ base-type
  | record-type
  | dynamic-array-type
  | dictionary-type
)
```
1. value is the program variable to be converted to a JSON string.
2. base-type is a base data type of Genero (INTEGER, DATE, VARCHAR)
3. record-type is a RECORD ... END RECORD type.
4. dynamic-array-type is a DYNAMIC ARRAY OF ... type.
5. dictionary-type is a DICTIONARY OF ... type.

Usage

The util.JSON.stringify() class method takes a RECORD, DYNAMIC ARRAY or DICTIONARY variable as parameter, and generates the corresponding data string in JSON format, as defined in the [RFC4627] specification.

Important: Unlike util.JSON.stringifyOmitNulls(), empty records (where all members are NULL), and empty arrays will be written in the JSON string. For detailed control on null and empty variables when serializing to JSON elements, use the json_null variable definition attribute.

The method raises error -8110 if the JSON string cannot be generated.

For more details about FGL to JSON conversion, see JSON support on page 465.

Example

```groovy
IMPORT util
MAIN
   DEFINE rec RECORD
      field1 INTEGER,
      field2 CHAR(1),
      subrec1 RECORD
         field11 INTEGER,
         field12 VARCHAR(30)
      END RECORD,
      subarr1 DYNAMIC ARRAY OF INTEGER
   END RECORD
   INITIALIZE rec.* TO NULL
   LET rec.field1 = 999
   LET rec.subarr1[3] = 888
   DISPLAY "stringify() : ", util.JSON.stringify(rec)
END MAIN
```

Output:

```
stringify() : {"field1":999,"subrec1":{},"subarr1":[null,null,888]}
```

Related concepts

util.JSON.stringifyOmitNulls on page 2619
Transforms a record variable to a flat JSON formatted string, by excluding empty records and empty arrays.

Records on page 382
Records allow structured program variables definitions.

util.JSON.stringifyOmitNulls
Transforms a record variable to a flat JSON formatted string, by excluding empty records and empty arrays.

Syntax

```
util.JSON.stringifyOmitNulls(
   value \ RECORD \ DYNAMIC ARRAY \)
RETURNS STRING
```
1. *value* is the program variable to be converted to a JSON string.

**Usage**

The `util.JSON.stringifyOmitNulls()` class method takes a RECORD or DYNAMIC ARRAY variable as parameter, and generates the corresponding data string in JSON format, as defined in the [RFC4627] specification.

**Important:** Unlike `util.JSON.stringify()`, empty records (where all members are NULL), and empty arrays will NOT be written in the JSON string. For detailed control on null and empty variables when serializing to JSON elements, use the `json_null` variable definition attribute and the `stringify()` method. The method `stringifyOmitNulls()` behaves like `stringify()`, when all variable elements are defined with the `json_null="undefined"` attribute.

The method raises error -8110 if the JSON string cannot be generated.

For more details about FGL to JSON conversion, see JSON support on page 465.

**Example**

```pascal
IMPORT util
MAIN
    DEFINE rec RECORD
        field1 INTEGER,
        field2 CHAR(1),
        subrec1 RECORD
            field11 INTEGER,
            field12 VARCHAR(30)
        END RECORD,
        subarr1 DYNAMIC ARRAY OF INTEGER
    END RECORD
    INITIALIZE rec.* TO NULL
    LET rec.field1 = 999
    DISPLAY "stringify()         : ", util.JSON.stringify(rec)
    DISPLAY "stringifyOmitNulls(): ", util.JSON.stringifyOmitNulls(rec)
END MAIN
```

Output:

```
stringify()         : {"field1":999,"subrec1":{},"subarr1":[]}
stringifyOmitNulls(): {"field1":999}
```

**Related concepts**

`util.JSON.stringify` on page 2618
Transforms a record variable to a flat JSON formatted string, by including empty records and empty arrays.

`Records` on page 382
Records allow structured program variables definitions.

**Examples**

`util.JSON` usage examples.

**Example 1: Reading a JSON file**

This program reads JSON data from `customers.json`, then parses the file content to fill the program array `custlist`, converts the array back to a JSON string and writes a formatted JSON string to the standard output.

**Note:** The `parse()` method is enclosed in a TRY/CATCH block, to detect potential JSON format errors in the source file.

```pascal
IMPORT util
MAIN
    DEFINE jsondata TEXT,
        custlist DYNAMIC ARRAY OF RECORD
    num INTEGER,
```
name VARCHAR(40)
END RECORD,
tmp STRING
LOCATE jsndata IN FILE "customers.json"
TRY
   CALL util.JSON.parse( jsndata, custlist )
   DISPLAY "Array length = ", custlist.getLength()
   LET tmp = util.JSON.stringify(custlist)
   DISPLAY util.JSON.format( tmp )
CATCH
   DISPLAY "ERROR:", STATUS
END TRY
END MAIN

The file customers.json:

[ {
   "num": 823,
   "name": "Mark Renbing"
},
   {
   "num": 234,
   "name": "Clark Gambler"
} ]

Note that the JSON file does not contain the name of the dynamic array (custlist), but starts directly with the JSON array in [ ] square brackets.

The util.JSONObject class
The util.JSONObject class provides methods to handle an structured data object following the JSON string syntax.

The util.JSONObject class is provided in the util C-Extension library. To use the util.JSONObject class, you must import the util package in your program:

IMPORT util

A JSONObject is an unordered collection of name/value pairs. The format of a JSON object string is a comma-separated "name":value pairs, wrapped in curly brackets. The value can be simple numeric or string value, but it can also be an array of values enclosed in square brackets, or a sub-element enclosed in curly brackets:

{ 
   "cust_num":2735,  
   "cust_name":"McCarlson",  
   "order_ids":[234,3456,24656,34561],  
   "address": {  
      "street":"34, Sunset Bld",  
      "city":"Los Angeles",  
      "state":"CA"
   }
}

A JSONObject object must be created before usage with one of the class methods like util.JSONObject.create().

The JSONObject class provides methods for accessing, adding/replacing or deleting the values by name with the get(), put() and remove() methods.

The get() method can return a simple value, a util.JSONObject or a util.JSONArray object reference.
The `put()` method can take a simple value, a `RECORD`, or an `ARRAY` as parameter.

If the structure of the JSON object is not known at compile time, you can introspect the elements of the object with the `getLength()`, `getType()` and `name()` methods.

**Related concepts**

- **JSON support** on page 465
  Genero BDL supports JSON data manipulation.

- **IMPORT C-Extension** on page 496
  The `IMPORT` instruction imports C extension module elements to be used by the current module.

**util.JSONObject methods**

Methods for the `util.JSONObject` class.

**Table 547: Class methods**

<td><code>util.JSONObject.toFGL(recordRef record-type)</code></td>
<td>Fills a record variable with the entries contained in the JSON object.</td>
</tr>
<tr>
<td><code>util.JSONObject.toString()</code></td>
<td>Builds a JSON string from the values contained in the JSON object.</td>
</tr>
</tbody>
</table>

**util.JSONObject.create**

Creates a new JSON object.

**Syntax**

```
util.JSONObject.create()
RETURNS util.JSONObject
```

**Usage**

The `util.JSONObject.create()` method creates a new JSON object.

The new created object must be assigned to a program variable defined with the `util.JSONObject` type.
Example

```plaintext
IMPORT util
MAIN
  DEFINE obj util.JSONObject
  LET obj = util.JSONObject.create()
  ...
END MAIN
```

Related concepts

**util.JSONObject.fromFGL** on page 2624
Creates a new JSON object from a RECORD.

**util.JSONObject.parse** on page 2625
Parses a JSON string and creates a JSON object from it.

**util.JSONObject.fromFGL**
Creates a new JSON object from a RECORD.

Syntax

```plaintext
util.JSONObject.fromFGL(
  record record-type
)
RETURNS util.JSONObject
```

1. `record` is the record variable used to create the JSON object.
2. `record-type` is a RECORD ... END RECORD type.

Usage

The `util.JSONObject.fromFGL()` method creates a new JSON object from the RECORD variable passed as parameter.

The new created object must be assigned to a program variable defined with the `util.JSONObject` type.

The members of the RECORD are converted to name/value pairs in the JSON object.

For more details about FGL to JSON conversion, see **JSON support** on page 465.

Example

```plaintext
IMPORT util
MAIN
  DEFINE cust_rec RECORD
    cust_num INTEGER,
    cust_name VARCHAR(30),
    order_ids DYNAMIC ARRAY OF INTEGER
  END RECORD
  DEFINE obj util.JSONObject
  LET cust_rec.cust_num = 345
  LET cust_rec.cust_name = "McMaclum"
  LET cust_rec.order_ids[1] = 4732
  LET cust_rec.order_ids[2] = 9834
  LET cust_rec.order_ids[3] = 2194
  LET obj = util.JSONObject.fromFGL(cust_rec)
  DISPLAY obj.toString()
END MAIN
```

Related concepts

**Records** on page 382
Records allow structured program variables definitions.

`util.JSONObject.create` on page 2623
Creates a new JSON object.

`util.JSONObject.parse` on page 2625
Parses a JSON string and creates a JSON object from it.

**`util.JSONObject.parse`**
Parses a JSON string and creates a JSON object from it.

**Syntax**

```plaintext
util.JSONObject.parse(
    s STRING
) RETURNS util.JSONObject
```

1. `s` is a string value that contains JSON formatted data.

**Usage**
The `util.JSONObject.parse()` method scans the JSON source string passed as parameter and creates a JSON object from it.

The created object must be assigned to a program variable defined with the `util.JSONObject` type.

The source string must follow the JSON format specification. It can contain multi-level structured data, but it must start with a curly brace.

The method raises error `-8109` if the JSON source string is not properly formatted. Consider enclosing the `parse()` method call in a `TRY/CATCH` block, if the source string can be malformed JSON.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE js STRING
    DEFINE obj util.JSONObject
    LET js='{ "cust_num":2735, "cust_name":"McCarlson", 
        "orderids":[234,3456,24656,34561] }'
    LET obj = util.JSONObject.parse( js )
    DISPLAY obj.get("cust_name")
END MAIN
```

**Related concepts**

`util.JSONObject.create` on page 2623
Creates a new JSON object.

`util.JSONObject.fromFGL` on page 2624
Creates a new JSON object from a `RECORD`.

`util.JSONObject.get`
Returns the value corresponding to the specified entry name.

**Syntax**

```plaintext
util.JSONObject.get(
    name STRING
) RETURNS result-type
```

1. `name` is the string identifying the JSON object property.
2. *result-type* can be a simple type, a `util.JSONObject` or a `util.JSONArray` object reference.

**Usage**

The `get()` method returns the value or JSON object corresponding to the element name passed as parameter.

If the element identified by the name is a simple value, the method returns a string. If the element is structured, the method returns a `util.JSONObject` instance and the returned object must be assigned to a program variable defined with the `util.JSONObject` type. If the element is a list of values, the method a `util.JSONArray` instance and the returned object must be assigned to a program variable defined with the `util.JSONArray` type.

A name/value pair can be set with the `put()` method.

**Example**

```java
IMPORT util

MAIN
    DEFINE obj, sub util.JSONObject
    DEFINE jarr util.JSONArray
    DEFINE rec RECORD
        id INTEGER,
        name STRING
    END RECORD
    DEFINE arr DYNAMIC ARRAY OF INTEGER
    DEFINE x INT
    LET obj = util.JSONObject.create()
    -- Simple value
    CALL obj.put("simple", 234)
    LET x = obj.get("simple")
    -- Sub-element
    LET rec.id = 234
    LET rec.name = "Barton"
    CALL obj.put("record", rec)
    LET sub = obj.get("record")
    -- Array
    LET arr[1] = 234
    LET arr[2] = 2837
    CALL obj.put("array", arr)
    LET jarr = obj.get("array")

END MAIN
```

**Related concepts**

`util.JSONObject.put` on page 2629
Sets a name-value pair in the JSON object.

`util.JSONObject.getLength`
Returns the number of name-value pairs in the JSON object.

**Syntax**

```
util.JSONObject.getLength()
RETURNS INTEGER
```

**Usage**

The `getLength()` method returns the number of name-value pairs in the JSON object.

This method can be used along with the `name()` and `getType()` methods to read the entries of a JSON object.

**Example**

```java
IMPORT util
```

```java
```
DEFINE obj util.JSONObject
DEFINE i INTEGER
LET obj = util.JSONObject.parse('{"id":123,"name":"Scott"}')
FOR i=1 TO obj.getLength()
    DISPLAY i, ": ", obj.name(i), ": ", obj.get(obj.name(i))
END FOR
END MAIN

Related concepts
util.JSONObject.name on page 2628
Returns the name of a JSON object entry by position.

util.JSONObject.getType on page 2627
Returns the type of a JSON object element.

Syntax

util.JSONObject.getType(
    name STRING
) RETURNS STRING

1. name is the name of the element.

Usage
The getType() method returns the JSON data type name corresponding to the element name passed as parameter.

This method can be used along with the name() and getLength() methods, to read the entries of a JSON object.

Possible values returned by this method are:

- NUMBER: A numeric value.
- STRING: A string value delimited by double quotes.
- BOOLEAN: A boolean value (true/false)
- NULL: A un-existing element.
- OBJECT: A structured object.
- ARRAY: An ordered list of elements.

Example

IMPORT util
MAIN
    DEFINE obj util.JSONObject
    LET obj = util.JSONObject.create()
    CALL obj.put("id", 8723)
    DISPLAY obj.getType("id") -- NUMBER
    CALL obj.put("name", "Brando")
    DISPLAY obj.getType("name") -- STRING
    DISPLAY obj.getType("undef") -- NULL
END MAIN

Related concepts
util.JSONObject.getLength on page 2626
Returns the number of name-value pairs in the JSON object.

util.JSONObject.name on page 2628
Returns the name of a JSON object entry by position.

*util.JSONObject.has*

Checks if the JSON object contains a specific entry name.

**Syntax**

```plaintext
util.JSONObject.has(
    name STRING )
RETURNS BOOLEAN
```

1. *name* is a string identifying a JSON object property.

**Usage**

The `has()` method determines if the JSON object holds a property identified by the element name passed as parameter.

The method returns `TRUE` if the name/value pair exists in the JSON object.

A name/value pair can be set with the `put()` method.

**Related concepts**

*util.JSONObject.put* on page 2629

Sets a name-value pair in the JSON object.

*util.JSONObject.name*

Returns the name of a JSON object entry by position.

**Syntax**

```plaintext
util.JSONObject.name(
    index INTEGER )
RETURNS STRING
```

1. *index* is the index of the name-value pair in the JSON object.

**Usage**

The `name()` method returns the entry name in the JSON object at the given position.

The index corresponding to the first name-value pair is 1.

If no entry exists at the given index, the method returns `NULL`.

This method can be used along with the `getLength()` and `getType()` methods to read the entries of a JSON object.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    DEFINE i INTEGER
    LET obj = util.JSONObject.parse('"id":123,"name":"Scott"')
    FOR i=1 TO obj.getLength()
        DISPLAY i, ": ", obj.name(i)
    END FOR
END MAIN
```
Related concepts
util.JSONObject.getLength on page 2626
Returns the number of name-value pairs in the JSON object.

util.JSONObject.getType on page 2627
Returns the type of a JSON object element.

util.JSONObject.put
Sets a name-value pair in the JSON object.

Syntax
util.JSONObject.put(
    name STRING,
    value value-type )

1. name is a string defining the entry name.
2. value is the value to be associated to the name.
3. value-type can be a simple string or numeric type, a RECORD or a DYNAMIC ARRAY.

Usage
The put() method adds a name-value pair to the JSON object.
The first parameter is the name of the element. The second parameter can be a simple string or numeric value, or a complex variable defined as RECORD or DYNAMIC ARRAY.
If the element exists, the existing value is replaced.

Example
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    DEFINE rec RECORD
        id INTEGER,
        name STRING
    END RECORD
    DEFINE arr DYNAMIC ARRAY OF INTEGER
    LET obj = util.JSONObject.create()
    CALL obj.put("simple", 234)
    LET rec.id = 234
    LET rec.name = "Barton"
    CALL obj.put("record", rec)
    LET arr[1] = 234
    LET arr[2] = 2837
    CALL obj.put("array", arr)
    DISPLAY obj.toString()
END MAIN

Related concepts
util.JSONObject.get on page 2625
Returns the value corresponding to the specified entry name.

util.JSONObject.remove
Removes the specified element in the JSON object.

Syntax
util.JSONObject.remove(

1. *name* is the string identifying the JSON object property.

**Usage**

The `remove()` method deletes a name-value pair identified by the name passed as parameter.

**Example**

```
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    LET obj = util.JSONObject.create()
    CALL obj.put("address", "5 Brando Street")
    CALL obj.remove("address")
    DISPLAY obj.get("address")
END MAIN
```

**Related concepts**

- *util.JSONObject.put* on page 2629
  Sets a name-value pair in the JSON object.
- *util.JSONObject.get* on page 2625
  Returns the value corresponding to the specified entry name.
- *util.JSONObject.toFGL*
  Fills a record variable with the entries contained in the JSON object.

**Syntax**

```
util.JSONObject.toFGL(
    recordRef record-type
)
```

1. *recordRef* is the variable to be set with values of the JSON string.

   **Important:** The *recordRef* is a RECORD variable is passed by reference to the method.

2. *record-type* is a RECORD ... END RECORD type.

**Usage**

The `toFGL()` method fills the RECORD variable passed as parameter with the corresponding values defined in the JSON object.

The destination record must have the same structure as the JSON source data. For more details see JSON support on page 465.

**Example**

```
IMPORT util
MAIN
    DEFINE cust_rec RECORD
        cust_num INTEGER,
        cust_name VARCHAR(30),
        order_ids DYNAMIC ARRAY OF INTEGER
    END RECORD
    DEFINE js STRING
    DEFINE obj util.JSONObject
    LET js='{"cust_num":2735, "cust_name":"McCarlson",
                 "order_ids":[234,3456,24656,34561]}'
    LET obj = util.JSONObject.parse( js )
    CALL obj.toFGL( cust_rec )
```
Related concepts

util.JSONObject.toString on page 2631
Builds a JSON string from the values contained in the JSON object.

Syntax

```javascript
util.JSONObject.toString()
RETURNS STRING
```

Usage

The toString() method produces a JSON formatted string from the name-value pairs contained in the JSON object.

Example

```javascript
IMPORT util
MAIN
DEFINE obj util.JSONObject
LET obj = util.JSONObject.create()
CALL obj.put("num", "75263")
CALL obj.put("name", "Ferguson")
CALL obj.put("address", "12 Marylon Street")
DISPLAY obj.toString()
END MAIN
```

Related concepts

util.JSONObject.toFGL on page 2630
Fills a record variable with the entries contained in the JSON object.

The util.JSONArray class

The util.JSONArray class provides methods to handle an array of values, following the JSON string syntax.

The util.JSONArray class is provided in the util C-Extension library. To use the util.JSONArray class, you must import the util package in your program:

```javascript
IMPORT util
```

A JSONArray is an sequence of unnamed values. The format of a JSON array string is a list of values wrapped in square brackets with commas between the values:

```
[123,546,"abc","def","xyz"]
```

A JSONArray object must be created before usage with one of the class methods like util.JSONArray.create().

The JSONArray class provides methods for accessing, adding/replacing or deleting the array values by index with the get(), put() and remove() methods.

If the structure of the JSON array is not known at compile time, you can introspect the elements of the array with the getLength() and getType() methods.
**Related concepts**

### util.JSONArray.create

Creates a new JSON array object.

### Syntax

```plaintext
util.JSONArray.create() RETURNS util.JSONArray
```

### Usage

The `util.JSONArray.create()` method create a new JSON array object.

The new created object must be assigned to a program variable defined with the `util.JSONArray` type.

### Example

```plaintext
IMPORT util
MAIN
    DEFINE arr util.JSONArray
    LET arr = utilJSONArray.create()
    ...
END MAIN
```
Related concepts
util.JSONArray.fromFGL on page 2634
Creates a new JSON array object from a DYNAMIC ARRAY.

util.JSONArray.parse on page 2634
Parses a JSON string and creates a JSON array object from it.

util.JSONArray.fromFGL
Creates a new JSON array object from a DYNAMIC ARRAY.

Syntax

```fgl
utilJSONArray.fromFGL(
    array dynamic-array-type )
RETURNS util.JSONArray
```

1. `array` is the dynamic array variable used to create the JSON array object.
2. `dynamic-array-type` is a DYNAMIC ARRAY OF ... type.

Usage

The `util.JSONArray.fromFGL()` method creates a new JSON array from the DYNAMIC ARRAY variable passed as parameter.

The new created object must be assigned to a program variable defined with the `util.JSONArray` type.

The members of the DYNAMIC ARRAY are converted to a list of name / value pairs in the JSON array object.

The dynamic array can be structured with a RECORD definition: the elements of the array will be converted individually.

For more details about FGL to JSON conversion, see JSON support on page 465.

Example

```fgl
IMPORT util
MAIN
    DEFINE da DYNAMIC ARRAY OF INTEGER
    DEFINE arr util.JSONArray
    LET da[1] = 123
    LET da[2] = 972
    LET arr = util.JSONArray.fromFGL(da)
    DISPLAY arr.toString()
END MAIN
```

Related concepts

Arrays on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

util.JSONArray.parse
Parses a JSON string and creates a JSON array object from it.

Syntax

```fgl
util JSONArray.parse(
    s STRING )
RETURNS util JSONArray
```

1. `s` is a string value that contains JSON formatted data as a list of elements delimited by square brackets.
Usage

The `util.JSONArray.parse()` method scans the JSON source string passed as parameter and creates a new JSON array object from it.

The created object must be assigned to a program variable defined with the `util.JSONArray` type.

The source string must follow the JSON format specification. Elements of the list can contain multi-level structured data, but the string must follow the JSON array string syntax `'[ element, ... ]'` with square brackets.

The method raises error `-8109` if the JSON source string is not properly formatted. Consider enclosing the `parse()` method call in a `TRY/CATCH` block, if the source string can be malformed JSON.

Example

```plaintext
IMPORT util
MAIN
    DEFINE da DYNAMIC ARRAY OF INTEGER
    DEFINE arr util.JSONArray
    LET arr = util.JSONArray.parse("[1,2,3,4,5]")
    DISPLAY arr.toString()
END MAIN
```

Related concepts

- `util JSONArray.fromFGL` on page 2634
  Creates a new JSON array object from a `DYNAMIC ARRAY`.
- `util JSONArray.create` on page 2633
  Creates a new JSON array object.

`util.JSONArray.get`

Returns the value of a JSON array element.

Syntax

```plaintext
util.JSONArray.get(
    index INTEGER
) RETURNS result-type
```

1. `index` is the index of the element in the JSON array object.
2. `result-type` can be a simple type, a `util.JSONObject` or a `util.JSONArray` object reference.

Usage

The `get()` method returns the value or JSON object corresponding to the element at the given position. The index corresponding to the first element is 1.

If no element exists at the given index, the method returns `NULL`.

If the element identified by the name is a simple value, the method returns a string. If the element is structured, the method returns a `util.JSONObject` instance and the returned object must be assigned to a program variable defined with the `util.JSONObject` type. If the element is a list of values, the method a `util.JSONArray` instance and the returned object must be assigned to a program variable defined with the `util.JSONArray` type.

A name/value pair can be set with the `put()` method.

Example

```plaintext
IMPORT util
MAIN
    DEFINE arr util.JSONArray
    LET arr = util.JSONArray.parse('[123,"abc",null]')
```
Related concepts

util.JSONArray.put on page 2637
Sets an element by position in the JSON array object.

util.JSONArray.getLength
Returns the number of elements in the JSON array object.

Syntax

```plaintext
util.JSONArray.getLength()
RETURNS INTEGER
```

Usage

The `getLength()` method returns the number of elements in the JSON array object.

This method can be used along with the `get()` and `getType()` method to read elements of a JSON array object.

Example

```plaintext
IMPORT util
MAIN
  DEFINE arr util.JSONArray
  DEFINE i INTEGER
  LET arr = util.JSONArray.parse('[123,8723,9232]')
  FOR i=1 TO arr.getLength()
    DISPLAY i, ": ", arr.get(i)
  END FOR
END MAIN
```

Related concepts

util.JSONArray.getType on page 2636
Returns the type of a JSON array element.

util.JSONArray.getType
Returns the type of a JSON array element.

Syntax

```plaintext
util.JSONArray.getType(
    index INTEGER)
RETURNS STRING
```

1. `index` is the ordinal position of the element.

Usage

The `getType()` method returns the data type name corresponding to the JSON array element at the given position.

The index corresponding to the first element is 1.

This method can be used along with the `getLength()` method to read the entries of a JSON array object.

Possible values returned by this method are:

- NUMBER: A numeric value.
- STRING: A string value delimited by double quotes.
- **BOOLEAN**: A boolean value (true/false)
- **NULL**: A non-existing element.
- **OBJECT**: A structured object.
- **ARRAY**: An ordered list of elements.

**Example**

```plaintext
IMPORT util
MAIN
  DEFINE arr util.JSONArray
  LET arr = util.JSONArray.parse('[123,"abc",null]')
  DISPLAY arr.getType(1) -- NUMBER
  DISPLAY arr.getType(2) -- STRING
  DISPLAY arr.getType(3) -- NULL
END MAIN
```

**Related concepts**

*util.JSONArray.getLength* on page 2636

Returns the number of elements in the JSON array object.

*util.JSONArray.put*

Sets an element by position in the JSON array object.

**Syntax**

```plaintext
util.JSONArray.put(
  index INTEGER,
  value value-type )
```

1. `index` is the index of the element in the JSON array object.
2. `value` is the value to be associated to the index.
3. `value-type` can be a simple string or numeric type, a RECORD or a DYNAMIC ARRAY.

**Usage**

The `put()` method sets an element value by position in the JSON array object.

The first parameter is the index of the element. The second parameter can be a simple string or numeric value, or a complex variable defined as RECORD or DYNAMIC ARRAY.

The index corresponding to the first element is 1.

If the element exists, the existing value is replaced.

**Example**

```plaintext
IMPORT util
MAIN
  DEFINE ja util.JSONArray
  DEFINE rec RECORD
    id INTEGER,
    name STRING
  END RECORD
  DEFINE arr DYNAMIC ARRAY OF INTEGER
  LET ja = util.JSONArray.create()
  CALL ja.put(1, 234)
  LET rec.id = 234
  LET rec.name = "Barton"
  CALL ja.put(2, rec)
  LET arr[1] = 234
  LET arr[2] = 2837
```
CALL ja.put(3, arr)
DISPLAY ja.toString()
END MAIN

Related concepts
util.JSONArray.get on page 2635
Returns the value of a JSON array element.

util.JSONArray.remove
Removes the specified entry in the JSON array object.

Syntax
util.JSONArray.remove(
index INTEGER )

1. index is the index of the element in the JSON array object.

Usage
The remove() method deletes an element in the JSON array object at the given position.
The index corresponding to the first element is 1.
If no element exists at the specified index, the method returns silently.

Example
IMPORT util
MAIN
DEFINE arr util.JSONArray
LET arr = util.JSONArray.parse('["aa","bb","cc"]')
CALL arr.remove(2)
DISPLAY arr.get(2) -- cc
END MAIN

Related concepts
util JSONArray.put on page 2637
Sets an element by position in the JSON array object.

util.JSONArray.toFGL
Fills a dynamic array variable with the elements contained in the JSON array object.

Syntax
util.JSONArray.toFGL(
arrayRef dynamic-array-type )

1. arrayRef is the array variable to be set with values of the JSON string.

   Important: The arrayRef is a dynamic array passed by reference to the method.

2. dynamic-array-type is a DYNAMIC ARRAY OF ... type.

Usage
The toFGL() method fills the DYNAMIC ARRAY passed as parameter with the corresponding values defined in the JSON array object.
The destination array must have the same structure as the JSON source data. For more details see JSON support on page 465.
Example

```plaintext
IMPORT util
MAIN
  DEFINE ja util.JSONArray
  DEFINE arr DYNAMIC ARRAY OF STRING
  LET ja = util.JSONArray.parse('["aa","bb","cc"]')
  CALL ja.toFGL(arr)
  DISPLAY arr[2] -- bb
END MAIN
```

Related concepts

- **Arrays** on page 386
  Arrays (static or dynamic) allow to handle an ordered collection of elements.

- **Records** on page 382
  Records allow structured program variables definitions.

- **util.JSONArray.toString** on page 2639
  Builds a JSON string from the elements contained in the JSON array object.

**util.JSONArray.toString**
Builds a JSON string from the elements contained in the JSON array object.

Syntax

```plaintext
util.JSONArray.toString()
RETURNS STRING
```

Usage

The `toString()` method produces a JSON formatted string from the elements contained in the JSON array object.

Example

```plaintext
IMPORT util
MAIN
  DEFINE ja util.JSONArray
  LET ja = util.JSONArray.create()
  CALL ja.put(1,"aa")
  CALL ja.put(2,"bb")
  CALL ja.put(3,"cc")
  DISPLAY ja.toString() -- ["aa","bb","cc"]
END MAIN
```

Related concepts

- **util JSONArray.toFGL** on page 2638
Fills a dynamic array variable with the elements contained in the JSON array object.

**The os package**

These topics cover the classes for the `os` package.

**The os.Path class**

The `os.Path` class provides functions to manipulate files and directories on the machine where the program executes.

This class is provided in the `util C-Extension` library. To use the `os.Path` extension, you must import the `os` package in your program:

```
IMPORT os
```

In order to manipulate files, this API give you access to low-level system functions. Pay attention to operating system specific conventions like path separators.

**Important:** Some methods are OS specific, like `os.Path.rwx()` which works only on UNIX™ systems. Other methods may behave differently, depending on the OS. For example, the `os.Path.rename()` method cannot rename a file across file systems on a UNIX platform.

**Related concepts**

IMPORT `C-Extension` on page 496
The `IMPORT` instruction imports C extension module elements to be used by the current module.
# os.Path methods

## Table 551: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>os.Path.atime(path STRING) RETURNS STRING</td>
<td>Returns the time of the last file access.</td>
</tr>
<tr>
<td>os.Path.baseName(path STRING) RETURNS STRING</td>
<td>Returns the last element of a path.</td>
</tr>
<tr>
<td>os.Path.chDir(path STRING) RETURNS INTEGER</td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td>os.Path.chOwn(path STRING, uid INTEGER, gui INTEGER) RETURNS INTEGER</td>
<td>Changes the UNIX™ owner and group of a file.</td>
</tr>
<tr>
<td>os.Path.chRwx(path STRING, mode INTEGER) RETURNS INTEGER</td>
<td>Changes the UNIX™ permissions of a file.</td>
</tr>
<tr>
<td>os.Path.chVolume(volume STRING) RETURNS INTEGER</td>
<td>Changes the current working volume.</td>
</tr>
<tr>
<td>os.Path.copy(fromPath STRING, toPath STRING) RETURNS INTEGER</td>
<td>Creates a new file by copying an existing file.</td>
</tr>
<tr>
<td>os.Path.delete(path STRING) RETURNS INTEGER</td>
<td>Deletes a file or a directory.</td>
</tr>
<tr>
<td>os.Path.dirClose(dirHandle INTEGER)</td>
<td>Closes the directory referenced by the directory opened by os.Path.diropen().</td>
</tr>
<tr>
<td>os.Path.dirFMask(mask INTEGER)</td>
<td>Defines a filter mask for os.Path.dirOpen().</td>
</tr>
<tr>
<td>os.Path.dirFName(path STRING) RETURNS STRING</td>
<td>Returns all components of a path excluding the last one.</td>
</tr>
<tr>
<td>os.Path.dirNext(dirHandle INTEGER)</td>
<td>Reads the next entry in the directory opened with os.Path.dirOpen().</td>
</tr>
</tbody>
</table>
**os.Path.atime**
Returns the time of the last file access.

**Syntax**
```
os.Path.atime(
    path STRING
) RETURNS STRING
```

1. `path` is the path to a file.

**Usage**
The function returns a string containing the last access time for the specified file, in the standard format 'YYYY-MM-DD HH:MM:SS'.
If the function fails, it returns NULL.

**os.Path.basename**
Returns the last element of a path.

**Syntax**
```
os.Path.basename(
    path STRING
) RETURNS STRING
```

1. `path` is the name of the file.

**Usage**
This method extracts the last component of a path provided as argument.
For example, if you pass "/root/dir1/file.ext" as the parameter, it will return "file.ext".
See Example 1: Extracting the parts of a file name on page 2656 for more examples.

**os.Path.copy**
Creates a new file by copying an existing file.

**Syntax**
```
os.Path.copy(
    fromPath STRING,
    toPath STRING
) RETURNS INTEGER
```

1. `fromPath` is the name of the file to copy.
2. `toPath` is the destination name of the copied file.

**Usage**
The function returns TRUE if the file has been successfully copied, FALSE otherwise.

**os.Path.chDir**
Changes the current working directory.

**Syntax**
```
os.Path.chDir()
```
1. *path* is the path to the directory to select.

**Usage**

Use this function to change the current working directory.

The function returns **TRUE** if the current directory is successfully selected, **FALSE** otherwise.

*os.Path.chRwx*

Changes the UNIX™ permissions of a file.

**Syntax**

```
os.Path.chRwx(
    path STRING,
    mode INTEGER
) RETURNS INTEGER
```

1. *path* is the name of the file.
2. *mode* is the UNIX™ permission combination in decimal (not octal!).

**Usage**

This method can only be used on UNIX™!

Function returns **TRUE** on success, **FALSE** otherwise.

The *mode* must be a decimal value which is the combination of read, write and execution bits for the user, group and other part of the UNIX™ file permission. Make sure to pass the *mode* as the decimal version of permissions, not as octal (the chrwx UNIX™ command takes an octal value as parameter). For example, to set `-rw-r--r--` permissions, you must pass `(((4+2)*64) + (4*8) + 4) = 420` to this method.

*os.Path.chOwn*

Changes the UNIX™ owner and group of a file.

**Syntax**

```
os.Path.chOwn(
    path STRING,
    uid INTEGER,
    gui INTEGER
) RETURNS INTEGER
```

1. *path* is the name of the file.
2. *uid* is the user id.
3. *gui* is the group id.

**Usage**

This method can only be used on UNIX™!

Function returns **TRUE** on success, **FALSE** otherwise.
**os.Path.chVolume**
Changes the current working volume.

**Syntax**

```plaintext
os.Path.chVolume(
    volume STRING)
RETURNS INTEGER
```

1. `volume` is the name of the volume to select as the new current working volume.

**Usage**

To change the current volume to C:

```plaintext
LET result = os.Path.chVolume("C:\")
```

The function returns TRUE if the current working volume is successfully changed, FALSE otherwise.

**os.Path.delete**
Deletes a file or a directory.

**Syntax**

```plaintext
os.Path.delete(
    path STRING)
RETURNS INTEGER
```

1. `path` is the path to the file or directory to delete.

**Usage**

A directory can only be deleted if it is empty. The function returns TRUE if the file has been successfully deleted, FALSE otherwise.

**os.Path.dirClose**
Closes the directory referenced by the directory opened by `os.Path.dirOpen()`.

**Syntax**

```plaintext
os.Path.dirClose(
    dirHandle INTEGER)
```

1. `dirHandle` is the directory handle of the directory to close.

**Usage**

This function closes the directory search handle opened with `os.Path.dirOpen()`.

**os.Path.dirFMask**
Defines a filter mask for `os.Path.dirOpen()`.

**Syntax**

```plaintext
os.Path.dirFMask(
    mask INTEGER)
```

1. `mask` defines the filter mask.
Usage
When you call this function, you define the filter mask for any subsequent `os.Path.dirOpen()` call.

By default, all kinds of directory entries are selected by the `dirOpen()` function. You can restrict the number of entries by using a filter mask.

The parameter of the `os.Path.dirFMask()` function must be a combination of the following bits:

- 0x01 = Exclude hidden files (.*)
- 0x02 = Exclude directories
- 0x04 = Exclude symbolic links
- 0x08 = Exclude regular files

For example, to retrieve only regular files, you must call:

```sql
CALL os.Path.dirFMask( 1 + 2 + 4 )
```

`os.Path.dirName`
Returns all components of a path excluding the last one.

Syntax
```
os.Path.dirName(
    path STRING)
RETURNS STRING
```

1. `path` is the path to a file or directory.

Usage
This method removes the last component of a path provided as argument.

For example, if you pass "/root/dir1/file.ext" as the parameter, it will return "/root/dir1".

See Example 1: Extracting the parts of a file name on page 2656 for more examples.

`os.Path.dirNext`
Reads the next entry in the directory opened with `os.Path.dirOpen()`.

Syntax
```
os.Path.dirNext(
    dirHandle INTEGER)
RETURNS STRING
```

1. `dirHandle` is the directory handle of the directory to read.

Usage
This function returns the next entry of the directory opened with `os.Path.dirOpen()`.

Returns NULL if all entries have been read.

Related concepts
`os.Path.dirOpen` on page 2647
Opens a directory and returns an integer handle to this directory.

**os.Path.dirOpen**

Opens a directory and returns an integer handle to this directory.

**Syntax**

```
os.Path.dirOpen(
    path STRING)
RETURNS INTEGER
```

1. *path* is the name of the directory.
2. *handle* is the directory handle.

**Usage**

This function creates a handle to scan the elements of a directory.

The function returns a value of 0 if it fails to open the directory.

Before calling the `dirOpen()` method, you can define a filter with `os.Path.dirFMask()`, and a sort order with `os.Path.dirSort()`.

**os.Path.dirSort**

Defines the sort criteria and sort order for `os.Path.dirOpen()`.

**Syntax**

```
os.Path.dirSort(
    criteria STRING,
    order INTEGER )
```

1. *criteria* is the sort criteria.
2. *order* defines ascending (1) or descending (-1) order.

**Usage**

When you call this function, you define the sort criteria and sort order for any subsequent `os.Path.dirOpen()` call.

The *criteria* parameter must be one of the following strings:

- "undefined" = No sort. This is the default. Entries are read as returned by the OS functions.
- "name" = Sort by file name.
- "size" = Sort by file size.
- "type" = Sort by file type (directory, link, regular file).
- "atime" = Sort by access time.
- "mtime" = Sort by modification time.
- "extension" = Sort by file extension.

When sorting by name, directory entries will be ordered base on the current locale.

When sorting by any criteria other than the file name, entries having the same value for the given criteria are ordered by name following the value of the *order* parameter.
**os.Path.executable**
Checks if a file is executable.

**Syntax**

```python
os.Path.executable(
    path STRING)
RETURNS INTEGER
```

1. `path` is the path to a file.

**Usage**

The function returns `TRUE` if the file is executable, `FALSE` otherwise.

**os.Path.exists**
Checks if a file exists.

**Syntax**

```python
os.Path.exists(
    path STRING)
RETURNS INTEGER
```

1. `path` is the path to a file.

**Usage**

The function returns `TRUE` if the file exists, `FALSE` otherwise.

**os.Path.extension**
Returns the file extension.

**Syntax**

```python
os.Path.extension(
    path STRING)
RETURNS STRING
```

1. `path` is the path to a file.

**Usage**

The function returns the string following the last dot found in `path`. If `path` does not have an extension, the function returns `NULL`.

**os.Path.fullPath**
Returns the canonical equivalent of a path.

**Syntax**

```python
os.Path.fullPath(
    path STRING)
RETURNS STRING
```

1. `path` is the path to complete.
Usage

The `os.path.fullPath()` class method takes a path as parameter and resolves extra path separator characters (/ on UNIX™, \ on Windows™), as well as references to current (.) and parent directory (..). The result is called a canonical path.

On UNIX™, symbolic links are not followed. Use the `os.Path.isLink()` method to identify symbolic links.

Example

```python
DISPLAY os.Path.fullPath("/home/usr//scott/tmp/../images")
```

Resolves to:

```
/home/usr/scott/images
```

`os.Path.gid`

Returns the UNIX™ group id of a file.

Syntax

```python
os.Path.gid(
    path STRING
) RETURNS INTEGER
```

1. `path` is the path to a file.

Usage

This function returns the group id of the file.

This method can only be used on UNIX™!

Function returns -1 if it fails to get the user id.

`os.Path.homeDir`

Returns the path to the HOME directory of the current user.

Syntax

```python
os.Path.homeDir()
```

RETURNS STRING

Usage

This function returns the home directory of the current user.

`os.Path.isDirectory`

Checks if a file is a directory.

Syntax

```python
os.Path.isDirectory(
    path STRING
) RETURNS BOOLEAN
```

1. `path` is the path to the directory.
Usage
The function returns TRUE if the file is a directory, FALSE otherwise.

`os.Path.isFile`
Checks if a file is a regular file.

Syntax

```
os.Path.isFile (path STRING)
RETURNS BOOLEAN
```

1. `path` is the path to a file.

Usage
The function returns TRUE if the file is a regular file, FALSE otherwise.

`os.Path.isHidden`
Checks if a file is hidden.

Syntax

```
os.Path.isHidden (path STRING)
RETURNS BOOLEAN
```

1. `path` is the file or directory path.

Usage
The function returns TRUE if the file is hidden, FALSE otherwise.

For example, on UNIX™, files starting with a dot in the file name are considered as hidden when using the ls command.

`os.Path.isLink`
Checks if a file is UNIX™ symbolic link.

Syntax

```
os.Path.isLink (path STRING)
RETURNS BOOLEAN
```

1. `path` is the file or directory path.

Usage
The function returns TRUE if the files is a symbolic link, FALSE otherwise.

This method can only be used on UNIX™!

`os.Path.isRoot`
Checks if a file path is a root path.

Syntax

```
os.Path.isRoot (path STRING)
```
x

1. *path* is the path to check.

**Usage**

The function returns **TRUE** if the path is a root path, **FALSE** otherwise.

On UNIX™ the root path is `'/`. On Windows™ the root path matches `'[a-zA-Z]:\`.

**os.Path.join**

Joins two path segments adding the platform-dependent separator.

**Syntax**

```javascript
os.Path.join(
  begin STRING,
  end STRING )
RETURNS STRING
```

1. *begin* is the beginning path segment.
2. *end* is the ending path segment.

**Usage**

Use this method to construct a path with no system-specific code to use the correct path separator:

```javascript
LET path = os.Path.join(os.Path.homedir(), name)
```

This method returns the ending path segment if it is an absolute path.

If one of the arguments is **NULL**, the function returns **NULL**.

**os.Path.makeTempName**

Generates a temporary file name.

**Syntax**

```javascript
os.Path.makeTempName()
RETURNS STRING
```

**Usage**

This method creates a new temporary file path, with the unique file name, in the temporary directory of the process.

**Note:** The method just returns a new temporary file name. A file created with this name must be deleted by the programmer. It will not be deleted automatically when exiting the program.

The temporary directory can be defined with the DBTEMP environment variable. If the DBTEMP variable is not defined, the runtime system uses the temporary directory as defined by the operating system. For more details, see the **DBTEMP environment variable**.
**os.Path.mtime**
Returns the time of the last file modification.

**Syntax**

```plaintext
os.Path.mtime(path STRING) RETURNS STRING
```

1. *path* is the path to a file.

**Usage**
The function returns a string containing the last modification time for the specified file, in the standard format 'YYYY-MM-DD HH:MM:SS'.
If the function fails, it returns NULL.

**os.Path.mkDir**
Creates a new directory.

**Syntax**

```plaintext
os.Path.mkDir(path STRING) RETURNS INTEGER
```

1. *path* is the path of the directory to create.

**Usage**
The function returns TRUE if the directory has been successfully created, FALSE otherwise.

**os.Path.pathSeparator**
Returns the character used in environment variables to separate path elements.

**Syntax**

```plaintext
os.Path.pathSeparator() RETURNS STRING
```

**Usage**
You typically use this method to build a path from two components.
On UNIX™, the path separator is ':'.
On Windows™, the path separator is ';'.

**os.Path.pathType**
Checks if a path is a relative path or an absolute path.

**Syntax**

```plaintext
os.Path.pathType(path STRING) RETURNS STRING
```

1. *path* is the path to check.
Usage
The function returns "absolute" if the path is an absolute path, or "relative" if the path is a relative path.

Note: On Unix-style platforms, an absolute path starts with a ( / ) slash. On Windows® platforms, an absolute path starts with a backslash ( \ ), a slash ( / ), or starts with a drive letter followed by a colon ( C: )

If the path is NULL, the function returns NULL.

*os.Path.pwd*
Returns the current working directory.

Syntax

```
os.Path.pwd()    
RETURNS STRING
```

Usage
This function returns the path of the current working directory.

On a mobile device, this front call returns the current application working directory:

- On Android™, it returns the directory where the program executes.
- On iOS, it returns the "Documents" directory under the application directory.

*os.Path.readable*
Checks if a file is readable.

Syntax

```
os.Path.readable(
    path STRING)
RETURNS INTEGER
```

1. *path* is the path to a file or directory.

Usage
The function returns TRUE if the file is readable, FALSE otherwise.

*os.Path.rename*
Renames a file or a directory.

Syntax

```
os.Path.rename(
    oldPath STRING,
    newPath STRING)
RETURNS INTEGER
```

1. *oldPath* is the current name of the file or directory to be renamed.
2. *newPath* is the new name to assign to the file or directory.

Usage
The function returns TRUE if the file or directory has been successfully renamed, FALSE otherwise.

On UNIX™ platforms, you can rename/move files and directories located on the same file system.
On Microsoft™ Windows™ platforms only files can be renamed/moved. However, on Windows™ you can move files across disks and directories.

**os.Path.separator**

Returns the character used to separate path segments.

**Syntax**

```
{code:python}
os.Path.separator()

RETURNS STRING
```

**Usage**

Use this method to build a path from two components.

On UNIX™, the directory separator is '/'.

On Windows™, the directory separator is '\'.

**os.Path.size**

Returns the size of a file.

**Syntax**

```
{code:python}
os.Path.size(path STRING)

RETURNS INTEGER
```

1. *path* is the path to a file.

**Usage**

The function returns the size in bytes for the specified file.

**os.Path.rootDir**

Returns the root directory of the current working path.

**Syntax**

```
{code:python}
os.Path.rootDir()

RETURNS STRING
```

**Usage**

This function returns the root directory of the current working path.

On UNIX™, it always returns ""/".

On Windows™, it returns the current working drive as "[a-zA-Z]:"/

**os.Path.rootName**

Returns the file path without the file extension of the last element of the file path.

**Syntax**

```
{code:python}
os.Path.rootName(path STRING)

RETURNS STRING
```

1. *path* is the path to a file or directory.
**Usage**

This method removes the file extension from the path provided as parameter. For example, if you pass "/root/dir1/file.ext" as the parameter it will return "/root/dir1/file".

See Example 1: Extracting the parts of a file name on page 2656 for more examples.

**os.Path.rwx**

Returns the UNIX™ file permissions of a file.

**Syntax**

```python
os.Path.rwx(
    path STRING)
RETURNS INTEGER
```

1. `path` is the path to a file or directory.

**Usage**

This function returns the combination of permissions for user, group and other.

This method can only be used on UNIX™!

Function returns -1 if it fails to get the permissions.

The `mode` is returned as a decimal value which is the combination of read, write and execution bits for the user, group and other part of the UNIX™ file permission. For example, if a file has the `rwxr-xr-x` permissions, the method returns `((4+2+1) * 64 + (4+1) * 8) + (4+1) ) = 493`.

**os.Path.type**

Returns the file type as a string.

**Syntax**

```python
os.Path.type(
    path STRING)
RETURNS STRING
```

1. `path` is the path to file.

**Usage**

On UNIX™, this method follows symbolic links. Use the `os.Path.islink()` method to identify symbolic links.

The possible values returned by this method are:

1. `file`: the file is a regular file
2. `directory`: the file is a directory
3. `socket`: the file is a socket
4. `fifo`: the file is a fifo
5. `block`: the file is a block device
6. `char`: the file is a character device

**os.Path.uid**

Returns the UNIX™ user id of a file.

**Syntax**

```python
os.Path.uid(
    path STRING)
```
1. *path* is the path to a file or directory.

**Usage**

This method can only be used on UNIX™!

Function returns -1 if it fails to get the user id.

*os.Path.volumes*

Returns the available volumes.

**Syntax**

```python
os.Path.volumes()
RETURNS STRING
```

**Usage**

The function returns the list of all available volumes separated by "|".

To display the list of available volumes, a volume is identified by its letter, followed by a colon and a backslash (:\).

```python
DISPLAY os.Path.volumes()
```

Output example:

```
C:\|E:\|F:\
```

*os.Path.writable*

Checks if a file is writable.

**Syntax**

```python
os.Path.writable(path STRING)
RETURNS INTEGER
```

1. *path* is the path to a file or directory.

**Usage**

The function returns TRUE if the file is writable, FALSE otherwise.

**Examples**

*os.Path usage examples.*

*Example 1: Extracting the parts of a file name*

This program uses the file functions to extract the directory name, the base name, the root name, and the file extension:

```python
IMPORT os
MAIN
    DISPLAY "Dir name = ", os.Path.dirName(arg_val(1))
    DISPLAY "Base name = ", os.Path.baseName(arg_val(1))
    DISPLAY "Root name = ", os.Path.rootName(arg_val(1))
    DISPLAY "Extension = ", os.Path.extension(arg_val(1))
END MAIN
```
Example results:

**Table 552: Example results**

<table>
<thead>
<tr>
<th>Path</th>
<th>os.Path.dirname</th>
<th>os.Path.basename</th>
<th>os.Path.rootname</th>
<th>os.Path.extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>.</td>
<td>.</td>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>..</td>
<td>.</td>
<td>..</td>
<td>.</td>
<td>NULL</td>
</tr>
<tr>
<td>/</td>
<td>/</td>
<td>/</td>
<td>/</td>
<td>NULL</td>
</tr>
<tr>
<td>/usr/lib</td>
<td>/usr</td>
<td>lib</td>
<td>/usr/lib</td>
<td>NULL</td>
</tr>
<tr>
<td>/usr/</td>
<td>/</td>
<td>usr</td>
<td>/usr/</td>
<td>NULL</td>
</tr>
<tr>
<td>usr</td>
<td>.</td>
<td>usr</td>
<td>usr</td>
<td>NULL</td>
</tr>
<tr>
<td>file.xx</td>
<td>.</td>
<td>file.xx</td>
<td>file</td>
<td>xx</td>
</tr>
<tr>
<td>/tmp.yy/ file.xx</td>
<td>/tmp.yy</td>
<td>file.xx</td>
<td>/tmp.yy/file.xx</td>
<td>xx</td>
</tr>
<tr>
<td>/tmp.yy/ file.xx.yy</td>
<td>/tmp.yy</td>
<td>file.xx.yy</td>
<td>/tmp.yy/file.xx</td>
<td>YY</td>
</tr>
<tr>
<td>/tmp.yy/</td>
<td>/</td>
<td>tmp.yy</td>
<td>/tmp.yy/</td>
<td>NULL</td>
</tr>
<tr>
<td>/tmp.yy/ .</td>
<td>/tmp.yy</td>
<td>.</td>
<td>/tmp.yy/</td>
<td>NULL</td>
</tr>
</tbody>
</table>

These examples use UNIX™ file names. On Windows™ the result would be different, as the file name separator is a backslash (`\`).

**Example 2: Browsing directories**

This program takes a directory path as an argument and scans the content recursively:

```plaintext
IMPORT os

MAIN
    CALL showDir(arg_val(1))
END MAIN

FUNCTION showDir(path)
    DEFINE path STRING
    DEFINE child STRING
    DEFINE h INTEGER

    IF NOT os.Path.exists(path) THEN
```
RETURN
END IF

IF NOT os.Path.isDirectory(path) THEN
  DISPLAY " ", os.Path.baseName(path)
  RETURN
END IF

DISPLAY "[", path, "]"
CALL os.Path.dirSort("name", 1)
LET h = os.Path.dirOpen(path)
WHILE h > 0
  LET child = os.Path.dirNext(h)
  IF child IS NULL THEN EXIT WHILE END IF
  IF child == "." OR child == ".." THEN CONTINUE WHILE END IF
  CALL showDir( os.Path.join( path, child ) )
END WHILE
CALL os.Path.dirClose(h)
END FUNCTION

The com package

The Genero Web Services com package provides classes and methods that allow you to perform tasks associated with creating Services and Clients, and managing the services.

Use the IMPORT statement at the top of the module using this library:

IMPORT com

Related concepts

Web services on page 3102
Create a Web service client or server with Genero BDL.

Web services classes

The Web services classes manage Web Services servers.

</tr>
<tr>
<td><code>setFeature(feature STRING, value STRING)</code></td>
<td>Defines a feature for the current Web Service object.</td>
</tr>
</tbody>
</table>
Creates a new object to implement a Web Service.

**Syntax**

```java
createFault(
    fault RECORD,
    encoded INTEGER
)
```

1. *fault* defines the Web Service fault.
2. *encoded* defines an integer value specifying the encoding mechanism.

**Usage**

The `createFault()` method creates a global fault for this Web Service object.

The *fault* parameter can be of any type that defines the SOAP fault in a SOAP response. In case of SOAP fault, the client for this Web Service will receive a variable with the same structure.

When the parameter *encoded* is true (1), the SOAP Section 5 encoding mechanism is used, False (0) indicates the XML Schema mechanism.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Example**

```java
com.WebService.createHeader
```

Defines the header for the Web Service object.

**Syntax**

```java
createHeader(
    header RECORD,
    encoded INTEGER
)
```

1. *header* defines the header for the Web Service object.
2. *encoded* defines an integer value specifying the encoding mechanism.

**Usage**

The `createHeader()` method creates a global header for the current Web Service object.

The Web Service header is defined by the first parameter. This will define SOAP headers exchanged by the client and server.

When the parameter *encoded* is true (1), the SOAP Section 5 encoding mechanism is used, False (0) indicates the XML Schema mechanism.

**Important:** Since Web Services headers are generally in Document Style, we recommend to set the *encoded* parameter to 0.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Example**

```java
com.WebService.CreateWebService
```

Creates a new object to implement a Web Service.
ns STRING } 
RETURNS com.WebService

1. *name* defines the Web Service identifier.
2. *ns* defines the namespace for the Web Service.

**Usage**

The *name* and *ns* parameters must uniquely identify the Web Service across the entire application, when multiple Web Service programs run on the same server. In theory, the value of *ns*+*name* must be unique on the internet.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

`com.WebService.CreateStatefulWebService`  
Creates a new object to implement a stateful Web Service.

**Syntax**

```java
com.WebService.CreateStatefulWebService(
    name STRING,
    ns STRING,
    state RECORD
) 
RETURNS com.WebService
```

1. *name* defines the Web Service identifier.
2. *ns* defines the namespace for the Web Service.
3. *state* defines the state between the client and server.

**Usage**

The *name* and *ns* parameters must uniquely identify the Web Service across the entire application, when multiple Web Service programs run on the same server. In theory, the value of *ns*+*name* must be unique on the internet.

The *state* variable is used to identify the state between the client and the server:

- For a WS-Addressing stateful service, the *state* variable must be a RECORD with the following structure, with the `W3CEndpointReference` variable attribute:

  ```java
  RECORD ATTRIBUTES(W3CEndpointReference)
  address STRING, -- The location of the Web Service (for ex: URL)
  ref RECORD
  ... (other members defining the state)
  END RECORD
  END RECORD
  ```

- For a stateful service based on HTTP cookies, the *state* variable must be a simple variable defined with a basic data type.

It is up to the programmer to manage the *state* variable and to restore the service state from a database.

When creating a stateful Web Service, all published Web Operations require a session in the client request excepted those defined as 'initiateSession'.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts
Stateful web services on page 3110

com.WebService.generateWSDL
Creates an xml.DomDocument object with the WSDL corresponding to the Web Service object.

Syntax

```java
generateWSDL(  
    location STRING  
)  
RETURNS xml.DomDocument
```

1. **location** defines the URL where the Web Service will be deployed.

Usage

The `generateWSDL()` method creates a new xml.DomDocument object containing the WSDL data of the Web Service object.

The URL where the Web Service will be deployed must be specified.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts
com.WebService.setComment on page 2667
Defines the comment for the Web Service object.

com.WebService.publishOperation
Publishes a Web Operation.

Syntax

```java
publishOperation(  
    op com.WebOperation,  
    role STRING  
)
```

1. **op** defines the Web Operation object.
2. **role** identifies uniquely the Web Operation.

Usage

The `publishOperation()` method publishes the Web Operation specified by the `com.WebOperation` object passed as parameter.

The **role** identifies the operation, if several operations have the same name, by setting the SOAPAction HTTP header. Usually this parameter is set to NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts
The WebOperation class on page 2668
The `com.WebOperation` class provides an interface to create and manage the operations of a Genero Web Service.

`com.WebService.registerInputHTTPVariable`

Registers the record variable for HTTP input.

**Syntax**

```plaintext
registerInputHTTPVariable ( headers RECORD )
```

1. `headers` defines the HTTP input record variable with the following structure:

```plaintext
RECORD
  verb  STRING,
  url   STRING,
  headers DYNAMIC ARRAY OF RECORD
    name  STRING,
    value  STRING
END RECORD
END RECORD
```

**Usage**

The `registerInputHTTPVariable()` method registers a program variable with a specific structure, that will be filled with the HTTP request headers when a Web Operation arrives.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

- `com.WebService.registerOutputHTTPVariable` on page 2665
  Registers the record variable for HTTP output.

**com.WebService.registerInputRequestHandler**

Registers the function to be executed on incoming SOAP requests.

**Syntax**

```plaintext
registerInputRequestHandler ( function STRING )
```

1. `function` has the name of a program function.

**Usage**

The `registerInputRequestHandler()` method registers a function to be called when an incoming SOAP request is received and before the SOAP engine has processed it.

The callback function must be defined with a unique parameter of type `xml.DomDocument`, and must return the reference to this object, or `NULL`:

```plaintext
FUNCTION myRequestInputHandler ( in )
  DEFINE in xml.DomDocument
  ...
  RETURN in
END FUNCTION
```
The input callback function typically modifies the content of the SOAP input request DOM document object passed as parameter.

When returning `NULL` from the input callback function, the output callback function will be called with the default SOAP fault node, which can then be modified.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

*Server handlers* on page 3165

`com.WebService.registerOutputRequestHandler` on page 2665

Registers the function to be executed just before the SOAP response is forwarded to the client.

`com.WebService.registerOutputHTTPVariable`

Registers the record variable for HTTP output.

**Syntax**

```
registerOutputHTTPVariable(
 headers RECORD )
```

1. `headers` defines the HTTP input record variable with the following structure:

```
RECORD
    code INTEGER,
    desc STRING,
    headers DYNAMIC ARRAY OF RECORD
        name STRING,
        value STRING
END RECORD
END RECORD
```

**Usage**

The `registerOutputHTTPVariable()` method registers a program variable with a specific structure, that will be used to fill the HTTP response headers when a Web Operation is completed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

`com.WebService.registerInputHTTPVariable` on page 2664

Registers the record variable for HTTP input.

`com.WebService.registerOutputRequestHandler`

Registers the function to be executed just before the SOAP response is forwarded to the client.

**Syntax**

```
registerOutputRequestHandler(
    function STRING )
```

1. `function` has the name of a program function.
**Usage**

The `registerOutputRequestHandler()` method registers a function to be called just after the SOAP engine has processed the request and before the SOAP response is forwarded to the client.

The output callback function must be defined with a unique parameter of type `xml.DomDocument`, and must return the reference to this object:

```FUNCTION myRequestOutputHandler( out )
   DEFINE out xml.DomDocument
   ...
   RETURN out
END FUNCTION```

The output callback function typically modifies the content of the SOAP output request DOM document object passed as parameter.

If `NULL` was returned from the input callback function, the output callback function will be called with the default SOAP fault node.

When WS-Addressing is enabled, and the server side callback is triggered, the SOAP engine has already created the SOAP:Header node with the correct WS-Addressing entries. If other headers need to be added (for WS-Security for instance), it is recommended to add them as child nodes of the existing SOAP header node, instead of creating a new header node. Otherwise, you may get two SOAP headers in a same response, which is not allowed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**Related concepts**

- Server handlers on page 3165
- `com.WebService.registerInputRequestHandler` on page 2664
  Registers the function to be executed on incoming SOAP requests.

**Syntax**

```
registerWSDLHandler(
   function STRING )
```

1. `function` has the name of a program function.

**Usage**

The `registerWSDLHandler()` method registers a function to be called when the WSDL of the current Web Service object is generated.

The callback function must be defined with a unique parameter of type `xml.DomDocument`, and must return the reference to this object:

```FUNCTION myWSDLHandler( wsdl )
   DEFINE wsdl xml.DomDocument
   ...
   RETURN wsdl
END FUNCTION```

The callback function typically modifies the content of the WSDL DOM document object passed as parameter.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**
- Server handlers on page 3165
- com.WebService.saveWSDL
  - Writes to a file the WSDL corresponding to the Web Service object.

**Syntax**

```java
saveWSDL(
    location STRING
) RETURNS INTEGER
```

1. *location* defines the URL where the Web Service will be deployed.

**Usage**
The `saveWSDL()` method writes the WSDL data corresponding to the Web Service object.

The URL where the Web Service will be deployed must be specified.

The name of the file will be the name of the Web Service defined by the *name* parameter passed to the `createWebService()` or `createStatefulWebService()` methods.

The method returns 0 if the file was saved, -1 in case of error.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**
- com.WebService.setComment on page 2667
  - Defines the comment for the Web Service object.

**Syntax**

```java
setComment(
    comment STRING
)
```

1. *comment* defines the comment to be set.

**Usage**
The `setComment()` method defines the comment associated with a `com.WebService` object.

The comment will be used when generating the WSDL file, as defined by the standard.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**
- com.WebService.setFeature
Defines a feature for the current Web Service object.

**Syntax**

```java
setFeature(
    feature STRING,
    value STRING )
```

1. `feature` defines the name of the Web Service feature.
2. `value` defines the value of the feature.

**Usage**

The `setFeature()` method defines a feature for the current Web Service object by specifying a feature name and a value.

The features names are predefined. The second parameter must have a valid value for the specified feature.

**Table 555: Support Web Service features for the setFeature() method**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Soap1.1</td>
<td>Defines whether the Web Service supports the SOAP 1.1 protocol. Default value is FALSE.</td>
</tr>
<tr>
<td>Soap1.2</td>
<td>Defines whether the Web Service supports the SOAP 1.2 protocol. Default value is FALSE.</td>
</tr>
</tbody>
</table>
| WS-Addressing1.0   | Defines whether the Web Service supports WS-Addressing 1.0. Valid values include:  
                         • TRUE - The service supports WS-Addressing 1.0 and accepts requests without WS-Addressing.  
                         • REQUIRED - The service supports WS-Addressing 1.0 and accepts only requests with WS-Addressing.  
                         • FALSE - WS-Addressing 1.0 is disabled (Default). |

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**The WebOperation class**

The `com.WebOperation` class provides an interface to create and manage the operations of a Genero Web Service.

**Important:** This Web Services class is not supported on GMI mobile devices.

The Web Operation can be created as RPC Style or Document Style. Both RPC/Literal and Doc/Literal Styles are WS-I compliant (standards set by the Web Services Interoperability organization).

RPC Style Service (RPC/Literal) is generally used to execute a function, such as a service that returns a stock option. Document Style Service (Doc/Literal) is generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document; this is the MS.Net default. The input or output `RECORD` cannot have `XMLNamespace` attributes set on their members.

Calling the appropriate function to create the desired style is the only difference in your Genero code that creates the service. The remainder of the code that describes the service is the same, regardless of whether you want to create an RPC or Document style of service.

Do not use the `setInputEncoded()` and `setOutputEncoded()` methods, as they will specify the RPC/Encoded Style, which is not recommended (see Choosing a Web Service Style).
Since release 2.0 GWS allows you to create RPC Style and Document Style operations in the same Web Service. However, we do not recommend this, as it is not WS-I compliant.

**com.WebOperation methods**
Methods for the com.WebOperation class.

### Table 557: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| **addFault**<br/>  
  *fault RECORD, wsaaction STRING* | Adds a fault to the current Web Operation definition. |
| **addInputHeader**<br/>  
  *header RECORD* | Adds an input header for the current Web Operation definition. |
| **addOutputHeader**<br/>  
  *header RECORD* | Adds an output header for the current Web Operation definition. |
| **initiateSession**<br/>  
  *ok INTEGER* | Defines the Web Operation as session initiator. |
| **setComment**<br/>  
  *comment STRING* | Sets the comment for the Web Operation object. |
| **setInputAction**<br/>  
  *action STRING* | Sets the WS-Addressing action identifier of the input operation. |
| **setInputEncoded**<br/>  
  *val INTEGER* | Defines the encoding mechanism for Web Operation input parameters. |
| **setOutputAction**<br/>  
  *action STRING* | Sets the WS-Addressing action identifier of the output operation. |
| **setOutputEncoded**<br/>  
  *val INTEGER* | Defines the encoding mechanism for Web Operation output parameters. |

*com.WebOperation.addFault*<br/>  
Adds a fault to the current Web Operation definition.

### Syntax

```plaintext
addFault(
  fault RECORD ,
  wsaaction STRING )
```

1. *fault* defines the program variable defining the fault.
2. *wsaaction* defines the type of action.

### Usage

Adds a fault the Web Operation can throw during operation processing, where *fault* is any variable previously created as fault of the *com.WebService* object, and *wsaaction* the WS-Addressing action identifier if WS-Addressing is supported. If WS-Addressing is not supported, pass NULL as second parameter.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**com.WebOperation.addInputHeader**

Adds an input header for the current Web Operation definition.

**Syntax**

```java
addInputHeader ( 
    header RECORD 
)
```

1. `header` defines the program variable defining the header.

**Usage**

This method adds a header to the Web Operation object for input parameters.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**com.WebOperation.addOutputHeader**

Adds an output header for the current Web Operation definition.

**Syntax**

```java
addOutputHeader ( 
    header RECORD 
)
```

1. `header` defines the program variable defining the header.

**Usage**

This method adds a header to the Web Operation object for input parameters.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**com.WebOperation.CreateDOCStyle**

Creates a new Web Operation object with Document style.

**Syntax**

```java
com.WebOperation.CreateDOCStyle ( 
    function STRING, 
    operation STRING, 
    inputVar RECORD , 
    outputVar RECORD ) 
RETURNS com.WebOperation
```

1. `function` defines the program function to be called to process the XML operation.
2. `operation` defines the XML operation.
3. `inputVar` defines the variable defining the input parameters of the operation (or NULL if there is none).
4. `outputVar` defines the variable defining the output parameters of the operation (or NULL if there is none).
Usage

This method creates a Request-Response Document style `com.WebOperation` object, where `function` is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`com.WebOperation.CreateRPCStyle`

Creates a new Web Operation object with RPC style.

Syntax

```java
com.WebOperation.CreateRPCStyle(  
    function STRING,  
    operation STRING,  
    inputVar RECORD,  
    outputVar RECORD )  
RETURNS com.WebOperation
```

1. `function` defines the program function to be called to process the XML operation.
2. `operation` defines the XML operation.
3. `inputVar` defines the variable defining the input parameters of the operation (or NULL if there is none).
4. `outputVar` defines the variable defining the output parameters of the operation (or NULL if there is none).

Usage

This method creates a Request-Response RPC style `com.WebOperation` object, where `function` is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`com.WebOperation.CreateOneWayDOCStyle`

Creates a new Web Operation object with One-Way Document style.

Syntax

```java
com.WebOperation.CreateOneWayDOCStyle(  
    function STRING,  
    operation STRING,  
    inputVar RECORD )  
RETURNS com.WebOperation
```

1. `function` defines the program function to be called to process the XML operation.
2. `operation` defines the XML operation.
3. `inputVar` defines the variable defining the input parameters of the operation (or NULL if there is none).

Usage

This method creates a One-Way DOC style `com.WebOperation` object, where `function` is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.
There is no output parameter to be returned to the client.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.WebOperation.CreateOneWayRPCStyle

Creates a new Web Operation object with One-Way RPC style.

**Syntax**

```java
com.WebOperation.CreateOneWayRPCStyle(
    function STRING,
    operation STRING,
    inputVar RECORD
) RETURNS com.WebOperation
```

1. `function` defines the program function to be called to process the XML operation.
2. `operation` defines the XML operation.
3. `inputVar` defines the variable defining the input parameters of the operation (or NULL if there is none).

**Usage**

This method creates a One-Way RPC Style `com.WebOperation` object, where `function` is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

There is no output parameter to be returned to the client.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.WebOperation.initiateSession

Defines the Web Operation as session initiator.

**Syntax**

```java
initiateSession(
    ok INTEGER
)
```

1. `ok` must have an integer value of 1 to define a session initiator.

**Usage**

Pass the parameter with the value of 1 to `initiateSession()` in order to define the current Web Operation as a session initiator.

A new session must be instantiated in this operation, and must be returned to the client via the `state` variable defined at service creation.

This method works only for stateful web services.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.WebOperation.setComment
Sets the comment for the Web Operation object.

**Syntax**

```java
setComment(
    comment STRING )
```

1. *comment* defines the comment to be set.

**Usage**

The `setComment()` method defines a comment to the current Web Operation object.

The comment will appear in the WSDL of the service.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

---

**com.WebOperation.setInputAction**

Sets the WS-Addressing action identifier of the input operation.

**Syntax**

```java
setInputAction(
    action STRING )
```

1. *action* defines the WSA action identifier.

**Usage**

When WS-Addressing is enabled, this method defines the WS-Addressing action identifier of the input operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

---

**com.WebOperation.setInputEncoded**

Defines the encoding mechanism for Web Operation input parameters.

**Syntax**

```java
setInputEncoded(
    val INTEGER )
```

1. *val* defines an integer value defining the encoding mechanism to be used.

**Usage**

When the parameter `encoded` is true (1), the SOAP Section 5 encoding mechanism is used, False (0) indicates the XML Schema mechanism.

The XML Schema mechanism (FALSE) is not recommended.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

---

**com.WebOperation.setOutputAction**
Sets the WS-Addressing action identifier of the output operation.

**Syntax**

```java
setOutputAction(
    action STRING )
```

1. `action` defines the WSA action identifier.

**Usage**

When WS-Addressing is enabled, this method defines the WS-Addressing action identifier of the output operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

com.WebOperation.setOutputEncoded

Defines the encoding mechanism for Web Operation output parameters.

**Syntax**

```java
setOutputEncoded(
    val INTEGER  )
```

1. `val` defines an integer value defining the encoding mechanism to be used.

**Usage**

When the parameter `encoded` is true (1), the SOAP Section 5 encoding mechanism is used, False (0) indicates the XML Schema mechanism.

The XML Schema mechanism (FALSE) is not recommended.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**The WebServiceEngine class**

The `com.WebServiceEngine` class provides an interface to manage the Web Services engine.

**Important:** This Web Services class is not supported on GMI mobile devices.
**com.WebServiceEngine methods**
Methods for the `com.WebServiceEngine` class.

**Table 558: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| `com.WebServiceEngine.Flush()`  
RETURNS INTEGER | Forces the Web Service engine to immediately flush the response of the web service operation. |
| `com.WebServiceEngine.GetHTTPServiceRequest (timeout INTEGER)`  
RETURNS `com.HTTPServiceRequest` | Get a handle for an incoming HTTP service request. |
| `com.WebServiceEngine.GetOption (option STRING)`  
RETURNS STRING | Returns the value of a Web Service engine option. |
| `com.WebServiceEngine.HandleRequest (timeout INTEGER, status RECORD)`  
RETURNS `com.HTTPServiceRequest` | Get a handle for an incoming HTTP service request. |
RETURNS INTEGER | Specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services. |
| `com.WebServiceEngine.SetFaultCode (code STRING, ns STRING)` | Get a handle for an incoming HTTP service request. |
| `com.WebServiceEngine.SetOption (optionName STRING, optionValue STRING)` | Sets an option for the Web Service engine. |

`com.WebServiceEngine.Flush`
Forces the Web Service engine to immediately flush the response of the web service operation.

**Syntax**

```java
com.WebServiceEngine.Flush()
RETURNS INTEGER
```

**Usage**

The `com.WebServiceEngine.flush()` class method allows for the return of the response inside a high-level web service operation, before the end of the web service function.

When this method is used, any other web operation output parameter changes are ignored.

The `status` returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of `com.WebServicesEngine` on page 2686

**Note:** The return status of the `com.WebServiceEngine.flush()` method has the same meaning as a status returned by `com.WebServiceEngine.ProcessServices()`, with the additional status code -32, meaning that the flush method was called outside of a web operation execution context.

**Note:** `com.WebServiceEngine.ProcessServices()` and `com.WebServiceEngine.HandleRequest()` can return the status code of -31, meaning that the flush function has been called in the last executed web operation.

**Example**

In this code example, the `flush()` method is used to force the response of the web service operation.

```qBasic
DEFINE echoBoolean_in, echoBoolean_out RECORD
   a_boolean  BOOLEAN ATTRIBUTES(XMLName="Boolean")
END RECORD

MAIN
DEFINE ret INTEGER
...
WHILE true
   LET ret = com.WebServiceEngine.ProcessServices(-1)
   CASE ret
      WHEN 0
         DISPLAY "Request automatically processed."
      WHEN -31
         DISPLAY "Operation has been flushed."
      ...
   END WHILE
...
END MAIN

FUNCTION echoBoolean()
   DEFINE ret INTEGER
   --- Assign output parameter with input parameter
   LET echoBoolean_out.a_boolean = echoBoolean_in.a_boolean
   --- Immediate flush of web operation
   LET ret = com.WebServiceEngine.flush()
   IF ret != 0 THEN
      DISPLAY "ERROR Code : ",ret
      EXIT PROGRAM (1)
   END IF
   --- Changing the output parameters after flush() would have no effect.
END FUNCTION
```
**Related concepts**

`com.WebServiceEngine.HandleRequest` on page 2679  
Get a handle for an incoming HTTP service request.

`com.WebServiceEngine.ProcessServices` on page 2680  
Specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

`com.WebServiceEngine.GetHTTPServiceRequest`  
Get a handle for an incoming HTTP service request.

**Syntax**

```plaintext
com.WebServiceEngine.GetHTTPServiceRequest (
    timeout INTEGER)
RETURNS com.HTTPServiceRequest
```

1. `timeout` defines the timeout in seconds.

**Usage**

The `com.WebServiceEngine.GetHTTPServiceRequest()` class method returns a `com.HTTPServiceRequest` object to handle an incoming HTTP request, or NULL if there was no request during the given period of time.

The `timeout` parameter defines the time in seconds to wait for an incoming request. A value of -1 means infinite wait. When the timeout occurs, the method returns NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

Any new call to this function will raise an error until the previous HTTP request was handled by sending a response back to the client, or destroyed.

The error -15575 can be thrown if the GAS disconnects the Web Services program.

URLs are sent in UTF-8 on the network, if the web services server is not able to convert UTF-8 URLs back to fglrun locale charset, error -15552 will be thrown. As a general advice, run you WS server program in UTF-8.

**Example**

```plaintext
DEFINE req com.HTTPServiceRequest
...
TRY
    WHILE TRUE
        LET req = com.WebServiceEngine.getHTTPServiceRequest(-1)
        IF req IS NULL THEN
            DISPLAY "HTTP request timeout...: ", CURRENT YEAR TO FRACTION
        ELSE
            CALL req.sendTextResponse(200,NULL,"It works")
        END IF
    END WHILE
CATCH
    IF status == -15575 THEN
        DISPLAY "Disconnected : ",SQLCA.SQLERRM
    ELSE
        DISPLAY "ERROR : ",status,SQLCA.SQLERRM
    END IF
END TRY
...
Related concepts

**com.WebServiceEngine.ProcessServices** on page 2680
Specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

**com.WebServiceEngine.HandleRequest** on page 2679
Get a handle for an incoming HTTP service request.

**com.WebServiceEngine.GetOption**
Returns the value of a Web Service engine option.

### Syntax

```java
com.WebServiceEngine.GetOption(
    option STRING
) 
RETURNS STRING
```

1. `option` defines the option to be queried.

### Usage

The `com.WebServiceEngine.GetOption()` class method returns the current value of the given Web Services engine option.

See [WebServiceEngine options](#) on page 2684 for the supported options.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls](#) (STATUS) on page 3280.

**com.WebServiceEngine.HandleRequest**
Get a handle for an incoming HTTP service request.

### Syntax

```java
com.WebServiceEngine.HandleRequest(
    timeout INTEGER,
    status RECORD
) 
RETURNS com.HTTPServiceRequest
```

1. `timeout` defines the timeout in seconds.
2. `status` defines the variable receiving the method execution status.

### Usage

The `com.WebServiceEngine.HandleRequest()` class method returns a `com.HTTPServiceRequest` object to handle an incoming HTTP request, or `NULL` if there was no request during the given period of time.

The `timeout` parameter defines the time in seconds to wait for an incoming request. A value of -1 means infinite wait.

- If there is no request in the given period of time, or if there is an error, the status code is updated by reference, and a `NULL` object is returned.
- If the request is intended for a registered web service, it is processed automatically. The status code is updated by reference and a `NULL` object is returned.
- If the request isn't dedicated to a registered web service, a status code of value 1 is returned by reference, and a valid instance of an `com.HTTPServiceRequest` object, immediately usable to handle the incoming request, is returned.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls](#) (STATUS) on page 3280.
Any new call to this function will raise an error until the previous HTTP request was handled by sending a response back to the client, or destroyed.

The status returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of com.WebServicesEngine on page 2686

**Note:** If the com.WebServiceEngine.Flush() method is used, the return status handling must be done in the web operation function, while com.WebServiceEngine.HandleRequest() will return the code -31, to indicate that a flush was done.

The error -15575 can be thrown if the GAS disconnects the Web Services program.

URLs are sent in UTF-8 on the network, if the web services server is not able to convert UTF-8 URLs back to fglrun locale charset, error -15552 will be thrown. As a general advice, run you WS server program in UTF-8.

**Related concepts**

com.WebServiceEngine.ProcessServices on page 2680
Specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

com.WebServiceEngine.GetHTTPServiceRequest on page 2678
Get a handle for an incoming HTTP service request.

---

### Syntax

```plaintext
  timeout INTEGER
) RETURNS INTEGER
```

1. timeout defines the timeout in seconds.

### Usage

The com.WebServiceEngine.ProcessServices() class method specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

The timeout parameter defines the wait period for an HTTP input request, to process an operation of one of the registered Web Services. The value -1 specifies an infinite waiting time.

The status returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of com.WebServicesEngine on page 2686

The execution status is typically handled in a CASE / END CASE block, to treat all possible execution cases. For a complete example of execution status handling, see Process the requests on page 3171.

**Note:** If the com.WebServiceEngine.Flush() method is used, the return status handling must be done in the web operation function, while com.WebServiceEngine.ProcessServices() will return the code -31, to indicate that a flush was done.

**Related concepts**

com.WebServiceEngine.HandleRequest on page 2679
Get a handle for an incoming HTTP service request.

com.WebServiceEngine.GetHTTPServiceRequest on page 2678
Get a handle for an incoming HTTP service request.
Get a handle for an incoming HTTP service request.

**Syntax**

```java
com.WebServiceEngine.SetFaultCode(
    code STRING,
    ns STRING )
```

1. `code` defines the fault code.
2. `ns` defines the namespace of the fault code.

**Usage**

The `com.WebServiceEngine.SetFaultCode()` class method defines a user SOAP Fault code to be returned to the client, where `code` is the mandatory SOAP Fault code and `ns` is the mandatory code namespace.

This method must be called inside a Web Service operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**com.WebServiceEngine.SetFaultDetail**

Defines the published SOAP Fault.

**Syntax**

```java
com.WebServiceEngine.SetFaultDetail(
    fault RECORD )
```

1. `fault` defines the published fault.

**Usage**

The `com.WebServiceEngine.SetFaultDetail()` class method defines the published SOAP Fault to be returned to the client when operation has finished, where `fault` is one of the published variables defined as Fault for that operation.

This method must be called inside a Web Service operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**com.WebServiceEngine.SetFaultString**

Defines the description of a SOAP Fault.

**Syntax**

```java
com.WebServiceEngine.SetFaultString(
    str STRING )
```

1. `str` defines the description of the fault.

**Usage**

The `com.WebServiceEngine.SetFaultString()` class method defines a user SOAP Fault description to be returned to the client, where `desc` contains the description of the fault.

This method must be called inside a Web Service operation.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**com.WebServiceEngine.SetOption**  
Sets an option for the Web Service engine.

**Syntax**

```java
com.WebServiceEngine.SetOption(
    optionName STRING,
    optionValue STRING)
```

1. `optionName` defines the option to set.  
2. `optionValue` defines the value of the option to set.

**Usage**

The `com.WebServiceEngine.SetOption()` class method configures the Web Services engine with options. See WebServiceEngine options on page 2684 for the supported options. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**com.WebServiceEngine.RegisterService**  
Registers a service in the engine.

**Syntax**

```java
com.WebServiceEngine.RegisterService(
    ws com.WebService)
```

1. `ws` defines the name of the service object to register.

**Usage**

The `com.WebServiceEngine.RegisterService()` class method registers the `com.WebService` object passed as parameter. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**com.WebServiceEngine.Start**  
Starts the Web Service engine.

**Syntax**

```java
com.WebServiceEngine.Start()
```

**Usage**

The `com.WebServiceEngine.Start()` class method starts the engine for all registered Web Services. If you run the Web Services server program in standalone mode, port 80 is used unless FGLAPPSERVER is set. We recommend that you set FGLAPPSERVER, as port 80 may already be in use by other Web servers. If you run the Web Services server program through the Genero Application Server, the FGLAPPSERVER variable is automatically set by the Genero Application Server. Do NOT manually set FGLAPPSERVER in this case.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

FGLAPPSERVER on page 239

Defines the listening TCP port of the Web service in development context.

**WSDL generation options notes**

If you are planning to work with WSDL generation, you are advised to review these notes.

1. For the DECIMAL(5,2) data type, when wsdl_decimalsize is TRUE, the generated WSDL file contains the total size and the size of the fractional part of the decimal:

```xml
<types>
  <schema xmlns="http://www.w3.org/2001/XMLSchema"
          targetNamespace="http://www.mycompany.com/types/">
    <simpleType name="echoDecimal5_2_a_dec5_2_out_FGLDecimal">
      <restriction base="decimal">
        <totalDigits value="5" />
        <fractionDigits value="2" />
      </restriction>
    </simpleType>
  </schema>
</types>
```

When wsdl_decimalsize is FALSE, the total size and the size of the fractional part are not mentioned:

```xml
<message name="echoDecimal5_2">
  <part name="dec5_2" type="xsd:decimal" />
</message>
```

2. If the WSDL file does not contain the size, the client application has no way of knowing the size. In this case, a default value for the size is generated. For example, the exported server type DECIMAL(5,2) becomes a DECIMAL(32) on the client side.

3. It is better to keep the options wsdl_arraysize, wsdl_stringsize and wsdl_decimalsize set to TRUE so that the client program can do exact type mapping. The default for all three options is TRUE.

4. When setting a facet constraint attribute on a simple data type, the generation of the WSDL will take this attribute into account even if an option has been set to perform the opposite.

5. When setting one facet constraint attribute, all of the default constraint attributes won’t be generated anymore unless you specify them as facet constraint attributes.
**WebServiceEngine options**

**Table 559: Options for the com.WebServiceEngine**

<table>
<thead>
<tr>
<th>Flag</th>
<th>Client or Server</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>autocookiesmanagement</td>
<td>Client</td>
<td>If set to TRUE, it activates the automatic cookies management for any HTTPRequest. It is the same as calling <code>req.setAutoCookies(TRUE)</code> for all HTTPRequest to a single instance of fglrun. By setting to TRUE, the program does not need to call <code>req.setAutoCookies(true)</code> on any HTTPRequest in its code. The global option is called once at the start of the program, and all cookies received from a server are automatically sent back according to the cookie definition (path, expiration date, domain). Default value is FALSE.</td>
</tr>
<tr>
<td>connectiontimeout</td>
<td>Client</td>
<td>Defines the default maximum time in seconds a client, an HTTPRequest and a TCPRequest have to wait for the establishment of a connection with a server. A value of -1 means infinite wait. The default is 30 seconds for non-Windows, 5 seconds for Windows®.</td>
</tr>
<tr>
<td>http_invoketimeout</td>
<td>Client</td>
<td>Defines the default maximum time in seconds a client has to wait before the client connection raises an error because the server is not responding. A value of -1 means that it has to wait until the server responds. The default is -1. <strong>Important:</strong> Deprecated - use readwritetimeout instead.</td>
</tr>
<tr>
<td>maximumpersistentcookies</td>
<td>Client</td>
<td>Specify the maximum number of persistent cookies that can be handled by a single fglrun process. If the limit is reached, the older cookies will be deleted to create room for the newer cookies. This option applies to the client side only. Default value is 50.</td>
</tr>
<tr>
<td>maximumresponselength</td>
<td>Both</td>
<td>Defines the maximum authorized size in KBytes for a client, server, HTTP or TCP response, before a break (when it stops and returns from the function because the amount of data surpassed the maximumresponselength.) A value of -1 means no limit. The default is -1.</td>
</tr>
<tr>
<td>readwritetimeout</td>
<td>Client</td>
<td>Defines the default maximum time in seconds a client, a HTTP request/response and a TCP request/response have to wait before raising an error that the server doesn't return or accept data. A value of -1 means infinite wait. The default is -1.</td>
</tr>
<tr>
<td>Flag</td>
<td>Client or Server</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>server_readwritetimeout</td>
<td>Server</td>
<td>Defines how long a socket read or write operation can wait before raising an error. The default value is 5 seconds.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> Before this option was introduced, the default value was -1 (infinite) and was configurable with the accept timeout parameter via ProcessServices() method.</td>
</tr>
<tr>
<td>SoapModuleURI</td>
<td>Both</td>
<td>Defines the SOAP role of a Genero application with an URI to identify it along a SOAP message path. The default value is NULL.</td>
</tr>
<tr>
<td>tcp_connectiontimeout</td>
<td>Client</td>
<td>Defines the default maximum time in seconds a client has to wait for the establishment of a TCP connection with a server. A value of -1 means infinite wait. The default is 30 seconds for non-Windows, 5 seconds for Windows®.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Important:</strong> Deprecated - use connectiontimeout instead.</td>
</tr>
<tr>
<td>wsdl_arraysize</td>
<td>Server</td>
<td>Defines whether the size of a BDL array will be taken into account during the WSDL generation. See WSDL generation options notes on page 2683. A value of zero means FALSE. The default is TRUE.</td>
</tr>
<tr>
<td>wsdl_decimalsize</td>
<td>Server</td>
<td>Defines whether the precision and scale of a DECIMAL variable will be taken into account during the WSDL generation. See WSDL generation options notes on page 2683. A value of zero means FALSE. The default is TRUE.</td>
</tr>
<tr>
<td>wsdl_stringsize</td>
<td>Server</td>
<td>Defines whether the size of a CHAR or VARCHAR variable will be taken into account during the WSDL generation. See WSDL generation options notes on page 2683. A value of zero means FALSE. The default is TRUE.</td>
</tr>
</tbody>
</table>

**Related concepts**

com.WebServiceEngine.GetOption on page 2679
Returns the value of a Web Service engine option.

com.WebServiceEngine.SetOption on page 2682
Sets an option for the Web Service engine.

**Error codes of com.WebServicesEngine**
Error codes returned by com.WebServiceEngine methods.

**Table 560: com.WebServiceEngine error codes**

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1     | Timeout  
com.WebServiceEngine.ProcessServices(x) timeout is reached. No requests to process during x seconds. |
| -2     | AsCloseCommand  
GAS tells the DVM to shutdown. You must exit your application. |
| -3     | ConnectionBroken  
Client has closed the connection in standalone GWS (without GAS). |
| -4     | ConnectionInterrupted  
Ctrl-C received. Interruption received by DVM. You must exit your application. |
| -5     | BadHTTPHeader  
Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |
| -6     | MalformedSOAPEnvelope  
Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |
| -7     | MalformedXMLDocument  
Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |
| -8     | InternalHTTPError  
Communication issue with application server or client. |
| -9     | Unsupported operation  
The URL of the operation requested is unknown. Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |
| -10    | UnknownError  
This is an internal error, contact the support team. You must exit your application. |
| -11    | WSDL generation failed  
You need to debug your application. |
| -12    | WSDL Service not found  
Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |
| -13    | Reserved  
No need to exit the application. A new request might not have the issue. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -14    | Incoming request overflow  
You exceed the data maximum length allowed by `com.WebServiceEngine.SetOption(maximumresponseLength)`. |
| -15    | Server was not started  
Call to `com.WebServiceEngine.Start()` failed. You must exit your application. |
| -16    | Request still in progress  
With RESTful service, you are currently processing a request and have not yet send the response and try to process another request. You need to debug your application. It depends, you might not need to stop your application. |
| -17    | Stax response error  
You need to debug your application. Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |
| -18    | Input request handler error  
You need to debug your application. Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |
| -19    | Output request handler error  
You need to debug your application. Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |
| -20    | WSDL handler error  
You need to debug your application. Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |
| -21    | SOAP Version mismatch  
Your client SOAP version does not match your server SOAP version, amend either your client or your server code. |
| -22    | SOAP header not understood  
Modify your server code to handled the mustUnderstand attribute. Use the incoming request handler. |
| -23    | Deserialization error  
Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |
| -24    | Reserved error code -24  
This error code is reserved for future use. |
| -25    | Web Services Addressing action is mandatory  
Check that the WSA action is specified in the SOAP message. |
| -26    | Web Services Addressing message header is invalid  
Check that the WSA header is correct in the SOAP message. |
| -27    | Web Services Addressing message header is mandatory  
Check that the WSA header is specified in the SOAP message. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -28    | Web Services Addressing message protocol does not match  
        Check that the WSA message uses the protocol version of the client matches the version expected by the server. |
| -29    | Cookie error  
        Check that the HTTP request contains a valid cookie. |
| -30    | No active web operation  
        The method was called outside the context of a web operation processing. |
| -31    | Web Operation was flushed  
        This code is returned by the ProcessServices() or the HandlerRequest() method, to indicated that the Flush() method was called during the last web operation execution. |
| -32    | Serialization error  
        Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |

The HTTPServiceRequest class
The com.HTTPServiceRequest class provides an interface to process incoming XML and TEXT requests over HTTP on the server side, with an access to the HTTP layer and additional XML streaming possibilities.

Important: This Web Services class is not supported on GMI mobile devices.

com.HTTPServiceRequest methods
Methods of the com.HTTPServiceRequest class.

Table 561: Object methods: Request URLs

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| getURL()     | RETURNS STRING  
        Returns the URL of the HTTP service request. The URL may consists of a host name, a port number, a path, and a query. |
| getURLHost() | RETURNS STRING  
        Returns the host name contained in the URL of a HTTP service request. |
| getURLPath()  | RETURNS STRING  
        Returns the path contained in the URL of a HTTP service request. |
| getURLPort()  | RETURNS INTEGER  
        Returns the port number contained in the URL of a HTTP service request. |
| getURLQuery()  | query RECORD  
        Takes a dynamic array of RECORD of two strings and fills that array with the decoded query string of a HTTP service request. |
Table 562: Object methods: Request headers

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>get_request_header(name STRING)</code></td>
<td>Returns the value of an HTTP header.</td>
</tr>
<tr>
<td><code>get_request_header_count()</code></td>
<td>Returns number of request headers.</td>
</tr>
<tr>
<td><code>get_request_header_name(ind INTEGER)</code></td>
<td>Returns a request header name by position.</td>
</tr>
<tr>
<td><code>get_request_header_value(ind INTEGER)</code></td>
<td>Returns a request header value by position.</td>
</tr>
<tr>
<td><code>get_request_version()</code></td>
<td>Returns the HTTP version of the service request.</td>
</tr>
</tbody>
</table>
Table 563: Object methods: Request body

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>beginXmlRequest()</code></td>
<td>Starts an HTTP streaming request.</td>
</tr>
<tr>
<td><code>endXmlRequest(stax xml.StaxReader)</code></td>
<td>Terminates an HTTP streaming request.</td>
</tr>
<tr>
<td><code>getMethod()</code></td>
<td>Returns the HTTP method of the service request.</td>
</tr>
<tr>
<td><code>hasRequestKeepConnection()</code></td>
<td>Returns TRUE if the connection remains after sending a response.</td>
</tr>
<tr>
<td><code>readDataRequest(b BYTE)</code></td>
<td>Returns the body of a request into a BYTE.</td>
</tr>
<tr>
<td><code>readFileRequest()</code></td>
<td>Returns the body of a request into a file.</td>
</tr>
<tr>
<td><code>readFormEncodedRequest(utf8 INTEGER)</code></td>
<td>Returns the string of a GET request with UTF-8 conversion option.</td>
</tr>
<tr>
<td><code>readTextRequest()</code></td>
<td>Returns the request body as a plain string.</td>
</tr>
<tr>
<td><code>readXmlRequest()</code></td>
<td>Returns the request body as an XML document.</td>
</tr>
</tbody>
</table>
### Table 564: Object methods: Request multipart

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getRequestMultipartType()</code></td>
<td>Returns the multipart type of an incoming request.</td>
</tr>
<tr>
<td><code>getRequestPart(pos INTEGER)</code></td>
<td>Returns the HTTPPart object at the specified index position.</td>
</tr>
<tr>
<td><code>getRequestPartCount()</code></td>
<td>Returns the number of additional multipart elements.</td>
</tr>
<tr>
<td><code>getRequestPartFromID(id STRING)</code></td>
<td>Returns the HTTPPart object of the given Content-ID value.</td>
</tr>
</tbody>
</table>

### Table 565: Object methods: Response header

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>setResponseCharset(charset STRING)</code></td>
<td>Defines the HTTP response character set.</td>
</tr>
<tr>
<td><code>setResponseHeader(name STRING, value STRING)</code></td>
<td>Defines a header for the HTTP response.</td>
</tr>
<tr>
<td><code>setResponseVersion(version STRING)</code></td>
<td>Defines the HTTP response version.</td>
</tr>
</tbody>
</table>
### Table 566: Object methods: Response body

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| `beginXmlResponse` (  
  `code` INTEGER,  
  `description` STRING  )  
  RETURNS xml.StaxWriter | Starts an HTTP streaming response. |
| `endXmlResponse` (  
  `stax` xml.StaxWriter  ) | Terminates an HTTP streaming response. |
| `sendResponse` (  
  `code` INTEGER,  
  `description` STRING  ) | Sends HTTP response without body. |
| `sendDataResponse` (  
  `code` INTEGER,  
  `description` STRING,  
  `b` BYTE  ) | Sends an HTTP response with data of a BYTE variable. |
| `sendFileResponse` (  
  `code` INTEGER,  
  `description` STRING,  
  `filename` STRING  ) | Sends an HTTP response with the data contained in a file. |
| `sendTextResponse` (  
  `code` INTEGER,  
  `description` STRING,  
  `txt` STRING  ) | Sends and HTTP response with data from a plain string. |
| `sendXmlResponse` (  
  `code` INTEGER,  
  `desc` STRING,  

### Table 567: Object methods: Response multipart

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| `addResponsePart` (  
  `part` com.HTTPPart  ) | Adds a new part to the HTTP root part response. |
| `setResponseMultipartType` (  
  `type` STRING,  
  `start` STRING,  
  `boundary` STRING  ) | Sets HTTP response in multipart mode of given type. |
### Table 568: Object methods: Cookie management

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>findRequestCookie</strong> ( &lt;br&gt;name STRING)  &lt;br&gt;RETURNS STRING</td>
<td>Enables the server to retrieve a cookie sent by the client by name.</td>
</tr>
<tr>
<td><strong>setResponseCookies</strong> ( &lt;br&gt;cookies RECORD  )</td>
<td>Allows the server to return cookies to be set on client application sending the request.</td>
</tr>
</tbody>
</table>

**com.HTTPServiceRequest.addResponsePart**  <br>Adds a new part to the HTTP root part response.

**Syntax**

```java
addResponsePart(<br>part com.HTTPPart)
```

1. *part* defines *com.HTTPPart* used to manage the HTTP attachment.

**Usage**

Adds a new part to the HTTP root part response. It will be sent after root part has been processed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

- Examples using *com.HTTPServiceRequest* methods on page 2713  <br>These examples use methods of the *com.HTTPServiceRequest* class.
- Examples: Using the *com.HTTPPart* class on page 2753  <br>Examples using methods of the *com.HTTPPart* class.

**com.HTTPServiceRequest.beginXmlRequest**  <br>Starts an HTTP streaming request.

**Syntax**

```java
beginXmlRequest()<br>RETURNS xml.StaxReader
```

**Usage**

The `beginXmlRequest()` method starts the streaming of HTTP request and returns an *xml.StaxReader* object ready to read the XML from the client.

Supported methods are PUT and POST.

The request Content-Type header must be of the form */xml* or */+xml*. For example: `application/xhtml+xml`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280

Related concepts

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.beginXmlResponse
Starts an HTTP streaming response.

Syntax

```
beginXmlResponse(
    code INTEGER,
    description STRING
)
RETURNS xml.StaxWriter
```

1. `code` defines the status code of the response.
2. `description` defines the description of the response.

Usage

The beginXmlResponse() method starts a HTTP streaming response by sending the a status (`code`) and description (`desc`), followed by the headers previously set, and returns a `xml.StaxWriter` object ready to send XML as the HTTP body.

If the request fails to be read, its content will be discarded; for example, when a request is not well formatted.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `*/+xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is `NULL`, a default description based on the status code is sent.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280

Related concepts

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.endXmlRequest
Terminates an HTTP streaming request.

Syntax

```
endXmlRequest(
    stax xml.StaxReader
)
```

1. `stax` defines the `xml.StaxReader` object used for streaming.
**Usage**

The `endXmlRequest()` method ends the streaming HTTP request by closing the `xml.StaxReader` object passed as parameter.

The `stax` object must be created with the `beginXmlRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**Related concepts**

Examples using `com.HTTPServiceRequest` methods on page 2713
These examples use methods of the `com.HTTPServiceRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753
Examples using methods of the `com.HTTPPart` class.

---

**Syntax**

```java
endXmlRequest()
```

1. `stax` defines `xml.StaxReader` used to write the HTTP body.

**Usage**

The `endXmlResponse()` method terminates the HTTP streaming response by closing the `xml.StaxWriter` object created by `beginXmlResponse`.

The body of the request is discarded.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**Related concepts**

Examples using `com.HTTPServiceRequest` methods on page 2713
These examples use methods of the `com.HTTPServiceRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753
Examples using methods of the `com.HTTPPart` class.

---

**Syntax**

```java
endXmlResponse(
    stax xml.StaxWriter
)
```

**Usage**

The `endXmlResponse()` method terminates the HTTP streaming response by closing the `xml.StaxWriter` object passed as parameter.

The body of the request is discarded.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**Related concepts**

Examples using `com.HTTPServiceRequest` methods on page 2713
These examples use methods of the `com.HTTPServiceRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753
Examples using methods of the `com.HTTPPart` class.

---

**Syntax**

```java
findRequestCookie(
    name STRING
)
```

**Usage**

Enables the server to retrieve a cookie sent by the client by name.
1. *name* defines the cookie to retrieve.

**Usage**

Enables the server to retrieve a cookie sent by the client by name.

The method returns the value of the cookie, or *NULL* if the named cookie does not exist.

In case of error, the method throws an exception and sets the *STATUS* variable. Depending on the error, a human-readable description of the problem is available in the *SQLCA.SQLERRM* register. See Error handling in GWS calls (*STATUS*) on page 3280.

**Related concepts**

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the *com.HTTPServiceRequest* class.

Examples: Using the *com.HTTPPart* class on page 2753
Examples using methods of the *com.HTTPPart* class.

com.HTTPServiceRequest.getMethod

Returns the HTTP method of the service request.

**Syntax**

```
getMethod()
RETURNS STRING
```

**Usage**

The *getMethod()* method returns the HTTP method of the request (GET, POST, PUT, HEAD, DELETE).

In case of error, the method throws an exception and sets the *STATUS* variable. Depending on the error, a human-readable description of the problem is available in the *SQLCA.SQLERRM* register. See Error handling in GWS calls (*STATUS*) on page 3280.

**Related concepts**

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the *com.HTTPServiceRequest* class.

Examples: Using the *com.HTTPPart* class on page 2753
Examples using methods of the *com.HTTPPart* class.

com.HTTPServiceRequest.getRequestVersion

Returns the HTTP version of the service request.

**Syntax**

```
getRequestVersion()
RETURNS STRING
```

**Usage**

The *getRequestVersion()* method returns the HTTP version of the request (1.0 or 1.1).

In case of error, the method throws an exception and sets the *STATUS* variable. Depending on the error, a human-readable description of the problem is available in the *SQLCA.SQLERRM* register. See Error handling in GWS calls (*STATUS*) on page 3280.
Related concepts

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.getRequestHeader
Returns the value of an HTTP header.

Syntax

```java
getRequestHeader (name STRING )
RETURNS STRING
```

1. `name` defines an HTTP header.

Usage

The `getRequestHeader()` method returns the value of the HTTP header specified by the `name` parameter, or NULL if there is not found.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.getRequestHeaderCount
Returns number of request headers.

Syntax

```java
getRequestHeaderCount ()
RETURNS INTEGER
```

Usage

The `getRequestHeaderCount()` method returns the entire URL request containing the host, port, document and query string.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.getRequestHeaderName
Returns a request header name by position.

**Syntax**

```
getRequestHeaderName (ind INTEGER )
RETURNS STRING
```

1. *ind* defines the ordinal position of the header.

**Usage**

The `getRequestHeaderName()` method returns the name of the header at the given position.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

---

Com. HTTPServiceRequest.getRequestHeaderValue

Returns a request header value by position.

**Syntax**

```
getRequestHeaderValue (ind INTEGER )
RETURNS STRING
```

1. *ind* defines the ordinal position of the header.

**Usage**

The `getRequestHeaderValue()` method returns the value of the header at the given position.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

---

Com. HTTPServiceRequest.getRequestMultipartType

Returns the multipart type of an incoming request.

**Syntax**

```
getRequestMultipartType ()
RETURNS STRING
```
Usage
Returns the multipart type of an incoming request, returns NULL if not a multipart request.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts
Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

Usage
Returns the multipart type of an incoming request, returns NULL if not a multipart request.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Can raise error -15554 (Index is out of bounds).

Related concepts
Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

Syntax

```java
getRequestPart(
    pos INTEGER
) RETURNS com.HTTPPart
```

1. pos defines the index position.

Usage
Returns the multipart type of an incoming request, returns NULL if not a multipart request.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Can raise error -15554 (Index is out of bounds).

Related concepts
Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

Usage
The root multipart is handled via standard readTextRequest(), readXmlRequest(), readDataRequest() and beginXmlRequest().

The number of parts is only available when the entire request has been read.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
com.HTTPServiceRequest.getRequestPartFromID
Returns the HTTPPart object of the given Content-ID value.

Syntax

```java
getRequestPartFromID (id STRING)
RETURNS com.HTTPPart
```

1. `id` defines the Content-ID value.

Usage

Returns the HTTPPart object of the given Content-ID value, returns NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.getURL
Returns the URL of the HTTP service request. The URL may consists of a host name, a port number, a path, and a query.

Syntax

```java
getURL ()
RETURNS STRING
```

Usage

The `getURL()` method returns the entire URL request containing the host, port, document and query string.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

URLs are sent in UTF-8 on the network. If the query part of the URL cannot be converted from UTF-8 to the fglrun locale charset, STATUS will be set to -15552. In this case, the document part of the URL is available, but the query string must be retrieved through HTTPServiceRequest.readFormEncodedRequest(). As a general advice, run your WS server program in UTF-8.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the `com.HTTPPart` class.

`com.HTTPServiceRequest.getURLHost`

Returns the host name contained in the URL of a HTTP service request.

**Syntax**

```java
getURLHost ()
RETURNS STRING
```

**Usage**

Returns the host name contained in the URL of a HTTP service request.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

- Examples using `com.HTTPServiceRequest` methods on page 2713
  These examples use methods of the `com.HTTPServiceRequest` class.

- Examples: Using the `com.HTTPPart` class on page 2753
  Examples using methods of the `com.HTTPPart` class.

`com.HTTPServiceRequest.getURLPath`

Returns the path contained in the URL of a HTTP service request.

**Syntax**

```java
getURLPath ()
RETURNS STRING
```

**Usage**

Returns the path contained in the URL of a HTTP service request.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

  These examples use methods of the `com.HTTPServiceRequest` class.

- Examples: Using the `com.HTTPPart` class on page 2753
  Examples using methods of the `com.HTTPPart` class.

`com.HTTPServiceRequest.getURLPort`

Returns the port number contained in the URL of a HTTP service request.

**Syntax**

```java
getURLPort ()
RETURNS INTEGER
```

**Usage**

Returns the port number contained in the URL of a HTTP service request.
The method returns NULL if there is no port.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

- Examples using com.HTTPServiceRequest methods on page 2713
  These examples use methods of the com.HTTPServiceRequest class.

- Examples: Using the com.HTTPPart class on page 2753
  Examples using methods of the com.HTTPPart class.

**com.HTTPServiceRequest.getURLQuery**

Takes a dynamic array of RECORD of two strings and fills that array with the decoded query string of a HTTP service request.

**Syntax**

```plaintext
getURLQuery (
    query RECORD)
```

1. `query` defines a record with the following structure:

   ```plaintext
   DEFINE query DYNAMIC ARRAY OF RECORD
   name STRING,
   value STRING
   END RECORD
   ```

   The WSHelper library provides the WSHelper.WSQueryType variable for your use. See WSHelper variables and records on page 3246.

**Usage**

Takes a dynamic array of RECORD of two strings and fills that array with the decoded query string of a HTTP service request. If there is no query string, the dynamic array size will be zero (0).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

If the given array is not of the expected type, it raises exception -15535.

If there is an encoding issue, the STATUS is set to -15552. No exception is raised. You can process the query parts that do not have any UTF-8 conversion issues.

**Related concepts**

- Examples using com.HTTPServiceRequest methods on page 2713
  These examples use methods of the com.HTTPServiceRequest class.

- Examples: Using the com.HTTPPart class on page 2753
  Examples using methods of the com.HTTPPart class.

**com.HTTPServiceRequest.hasRequestKeepConnection**

Returns TRUE if the connection remains after sending a response.

**Syntax**

```plaintext
hasRequestKeepConnection ()
RETURNS INTEGER
```
Usage

The `hasRequestKeepConnection()` method returns if the request expects the connection to stay open after sending the response.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.readDataRequest

Returns the body of a request into a `BYTE`.

Syntax

```java
readDataRequest (  
  b BYTE) 
```

1. `b` defines a variable of type `BYTE` that will be filled with the request body.

Usage

The `readDataRequest()` method returns the body of the request in a `BYTE`.

Supported methods are PUT and POST.

The `BYTE` variable must be located in memory, and will be filled with the request body. The existing content of the `BYTE` will be discarded.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280

Related concepts

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.readFileRequest

Returns the body of a request into a file.

Syntax

```java
readFileRequest ( ) 
```

RETURNS STRING

Usage

The `readFileRequest()` method returns the body of the request into a file on the disk.
The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file is the basename found in the HTTP Content-Disposition Header. If this basename is not specified, the filename is created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form: `/tmp/ABC/filename_index.ext`, where `index` represents the number of files with the same name on disk.

Supported methods are PUT and POST.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**Related concepts**

- Examples using `com.HTTPServiceRequest` methods on page 2713
  These examples use methods of the `com.HTTPServiceRequest` class.
- Examples: Using the `com.HTTPPart` class on page 2753
  Examples using methods of the `com.HTTPPart` class.

**com.HTTPServiceRequest.readFormEncodedRequest**

Returns the string of a GET request with UTF-8 conversion option.

**Syntax**

```java
readFormEncodedRequest (utf8 INTEGER )
RETURNS STRING
```

- `utf8` specifies if the string must be decoded to the current charset.

**Usage**

The `readFormEncodedRequest()` method returns the query of a POST "application/x-www-form-urlencoded" request or the query string of a GET request, decoded depending on HTML4 or XFORM if `utf8` is TRUE.

**Note:** If the result string contains `&` or `=` XForms special characters, these are doubled as follows:

`na&me=va=lu`.e

If the `utf8` parameter is TRUE, the decoded query string is translated from UTF-8 to the current character set. This may lead to a conversion error.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**Related concepts**

  These examples use methods of the `com.HTTPServiceRequest` class.
- Examples: Using the `com.HTTPPart` class on page 2753
  Examples using methods of the `com.HTTPPart` class.

**com.HTTPServiceRequest.readTextRequest**
Returns the request body as a plain string.

**Syntax**

```java
readTextRequest ()
RETURNS STRING
```

**Usage**

The `readTextRequest()` method returns the body of the request as a string.

Supported methods are PUT and POST.

The request Content-Type header can be of any form */*. For example: `application/json`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 3280).

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see [Interruption handling in GWS calls (INT_FLAG)](page 3280)

Examples using methods of the `com.HTTPPart` class.

---

Returns the request body as an XML document.

**Syntax**

```java
readXmlRequest ()
RETURNS xml.DomDocument
```

**Usage**

The `readXmlRequest()` method returns the request as an entire XML document, contained in a `xml.DomDocument` object.

Supported methods are PUT and POST.

The request Content-Type header must be of the form */xml or */+xml. For example: `application/xhtml+xml`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 3280).

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see [Interruption handling in GWS calls (INT_FLAG)](page 3280)

**Related concepts**

- [Examples using com.HTTPServiceRequest methods](page 2713)
- [Examples: Using the com.HTTPPart class](page 2753)

**Examples using com.HTTPServiceRequest methods**

These examples use methods of the `com.HTTPServiceRequest` class.

**Examples: Using the com.HTTPPart class**

Examples using methods of the `com.HTTPPart` class.
Sends an HTTP response with data of a BYTE variable.

**Syntax**

```java
sendDataResponse(
    code INTEGER,
    description STRING,
    b BYTE
)
```

1. `code` specifies the status code of the response.
2. `description` specifies the description of the response.
3. `b` defines a BYTE type containing the data to be sent.

**Usage**

The `sendDataResponse()` method performs the HTTP response by sending the status (`code`) and description (`description`), followed by the headers previously set and binary data contained in the `b` program variable as body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server is expected to send an HTTP response with the code of 400 (Bad Request). See HTTP status codes (wikipedia) for more details about common HTTP response codes.

The `b` parameter is defined as a BYTE and must be located in memory and not NULL, otherwise the operation fails.

The default Content-Type header is `application/octet-stream`, but it can be changed to any other mime type. For example: `image/jpeg`.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is NULL, a default description according to the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**Related concepts**

Examples using `com.HTTPServiceRequest` methods on page 2713

These examples use methods of the `com.HTTPServiceRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753

Examples using methods of the `com.HTTPPart` class.

**Examples using `com.HTTPServiceRequest.sendFileResponse`**

Sends an HTTP response with the data contained in a file.

**Syntax**

```java
sendFileResponse(
    code INTEGER,
    description STRING,
    filename STRING
)
```

1. `code` specifies the status code of the response.
2. `description` specifies the description of the response.
3. *filename* specifies the path of the file containing the data to be send.

Usage

The `sendFileResponse()` method performs the HTTP response by sending the status (*code*) and description (*description*), followed by the headers previously set and the data contained in the specified file as body.

It is important for the server to return a correct status *code*, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server is expected to send an HTTP response with the code of 400 (Bad Request). See [HTTP status codes (wikipedia)](http://example.com) for more details about common HTTP response codes.

If not defined by the programmer, the HTTP headers are automatically set as follows:

- **Content-Type** is defined based on the file name extension. If the file extension is not recognized, **Content-Type** defaults to **application/octet-stream**.

  **Note:** File extensions to **Content-Type** mapping can be customized in the file FGLDIR/lib/wse/mime.cfg.

- **Content-Disposition** is set with the base name of the given *filename* as follows: attachment; filename="basename".

For example, when calling the method as follows:

```java
CALL server.sendFileResponse( 200, NULL, "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP headers of the response will look like:

```plaintext
Content-Type: image/jpeg
Content-Disposition: attachment; filename="logo.jpg"
```

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the *description* is **NULL**, a default description according to the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See [Error handling in GWS calls (STATUS)](http://example.com) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see [Interruption handling in GWS calls (INT_FLAG)](http://example.com) on page 3280.

`com.HTTPServiceRequest.sendResponse`

Sends and HTTP response without body.

**Syntax**

```java
sendResponse(
    code INTEGER,
    description STRING )
```

1. *code* specifies the status code of the response.
2. *description* specifies the description of the response.

**Usage**

The `sendResponse()` method performs the HTTP response by sending a status (`code`) and description (`description`), followed by the headers previously set, without a body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server is expected to send an HTTP response with the code of 400 (Bad Request). See [HTTP status codes](https://en.wikipedia.org/wiki/List_of_HTTP_status_codes) for more details about common HTTP response codes.

If the description is `NULL`, a default description based on the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 3280).

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see [Interruption handling in GWS calls (INT_FLAG)](page 3280).

`com.HTTPServiceRequest.sendTextResponse`

Sends and HTTP response with data from a plain string.

**Syntax**

```java
sendTextResponse(
    code INTEGER,
    description STRING,
    txt STRING)
```

1. *code* specifies the status code of the response.
2. *description* specifies the description of the response.
3. *txt* defines the string containing the data to be sent.

**Usage**

The `sendTextResponse()` method performs the HTTP response by sending the a status (`code`) and description (`description`), followed by the headers previously set, and text data contained in the string as body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server is expected to send an HTTP response with the code of 400 (Bad Request). See [HTTP status codes](https://en.wikipedia.org/wiki/List_of_HTTP_status_codes) for more details about common HTTP response codes.

The default Content-Type header is `text/plain`, but it can be changed if of the form `/*/*`. For example: `application/json`.

Automatic conversion from locale to user-defined charset is performed when possible, otherwise throws an exception.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is `NULL`, a default description based on the status code is sent.
New incoming requests can be retrieved again with the

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.HTTPServiceRequest.sendXmlResponse
Sends an HTTP response with data from a XML document object.

**Syntax**

```java
sendXmlResponse(
    code INTEGER,
    desc STRING,
    doc xml.DomDocument )
```

1. `code` specifies the status code of the response.
2. `description` specifies the description of the response.
3. `doc` specifies the XML document containing the data to be sent.

**Usage**
The sendXmlResponse() method performs the HTTP response by sending the a status (`code`) and description (`description`), followed by the headers previously set, and the XML data contained in the passed `xml.DomDocument` object as body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server is expected to send an HTTP response with the code of 400 (Bad Request). See HTTP status codes (wikipedia) for more details about common HTTP response codes.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `*/+xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is `NULL`, a default description based on the status code is sent.

New incoming requests can be retrieved again with the

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.HTTPServiceRequest.setResponseCharset
Defines the HTTP response character set.

Syntax

```
setResponseCharset (  
    charset STRING  )
```

1. `charset` defines the HTTP response character set.

Usage

The setResponseCharset() method defines the character set to use when sending an HTTP response.

The server must send a response in a character set that the client understands.

If the response character set is not defined by setResponseCharset(), the same character set as the client request is used, or the implicit ISO-8859-1 charset is used if the character is not defined by the client request.

The method must be called before sending the response with one of sendResponse, sendTextResponse, sendXmlResponse, or beginXmlResponse and endXmlResponse methods.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts

Localization support allows you to implement programs that follow specific language and cultural rules.

Examples using com.HTTPServiceRequest methods on page 2713
These examples use methods of the com.HTTPServiceRequest class.

com.HTTPServiceRequest.setResponseCookies
Allows the server to return cookies to be set on client application sending the request.

Syntax

```
setResponseCookies (  
    cookies RECORD  )
```

1. `cookies` defines a dynamic array for the cookies to be set. See WSHelper variables and records on page 3246 for more information regarding WSServerCookiesType.

Usage

Allows the server to return cookies to be set on client application sending the request.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Setting cookies example

```
IMPORT FGL WSHelper

DEFINE cookies WSHelper.WSServerCookiesType
```
# Set first cookie named 'CookieName'
LET cookies[1].name = "CookieName"
LET cookies[1].value = "AnyValue"
LET cookies[1].expires = now + INTERVAL (5) MINUTE TO MINUTRE

# Set second cookie named 'SecondCookie'
LET cookies[2].name = "SecondCookie"
LET cookies[2].value = "AnotherValue"

# Set all cookies defined in the cookie array
CALL req.setResponseCookies(cookies)
CALL req.sendTextResponse(200, NULL, "Hello world")

Related concepts

Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.setResponseHeader
Defines a header for the HTTP response.

Syntax

```
setResponseHeader (
    name STRING,
    value STRING )
```

1. name specifies the name of a header.
2. value defines the value of a header.

Usage
The setResponseVersion() method sets (or replaces) the name and value of a HTTP response header.
The Content-Length header cannot be set, because it is computed internally according to the body size.
The method must be called before sending the response with one of sendResponse, sendTextResponse, sendXmlResponse, or beginXmlResponse and endXmlResponse methods.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.setResponseMultipartType
Sets HTTP response in multipart mode of given type.

Syntax

```
setResponseMultipartType ( 
    type STRING,
    start STRING,
    )
```

setResponseMultipartType
**boundary** STRING

1. *type* defines one of the following:
   - form-data: Browser Xform with attachment
   - mixed: Parts are independent
   - related: Parts are dependent (Required for SOAP)
   - alternative: Parts are different type of a same document
   - or any other type
   - NULL: switch multipart mode off
2. *start* specifies the Content-ID value of root multipart document. Must be ASCII. (optional)
3. *boundary* specifies the string used as multipart boundary. Must be ASCII. (optional)

**Usage**

Sets HTTP response in multipart mode of given type. Calling one of the standard request method will send the HTTP response as given multipart type, even if no other part has been set.

The root HTTP part must be handled via the standard HTTPServiceRequest methods such as `sendTextRequest()`, `sendXmlRequest()`, `sendDataRequest()` and `BeginXmlResponse()`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

Examples using methods of the com.HTTPPart class.

---

**com.HTTPServiceRequest.setResponseVersion**

Defines the HTTP response version.

**Syntax**

```java
setResponseVersion(
    version STRING
)
```

1. *version* specifies the HTTP response version.

**Usage**

The `setResponseVersion()` method defines the HTML response version (1.0 or 1.1).

If not set, the same version as the request is used.

The method must be called before sending the response with one of `sendResponse`, `sendTextResponse`, `sendXmlResponse`, or `beginXmlResponse` and `endXmlResponse` methods.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

<td>Define the login and password to use for proxy authentication.</td>
</tr>
</tbody>
</table>

com.HTTPRequest.addPart
Add a new part to the HTTP root part request.

Syntax

```java
addPart(part com.HTTPPart)
```

1. `part` defines the HTTPPart object.

Usage

Add a new part to the HTTP root part request. This part is sent after root part has been processed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts

Examples using com.HTTPRequest methods on page 2734
These examples use methods of the `com.HTTPRequest` class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the `com.HTTPPart` class.

**com.HTTPRequest.beginXmlRequest**

Starts a streaming HTTP request.

**Syntax**

```java
beginXmlRequest ()
RETURNS xml.StaxWriter
```

**Usage**

The `beginXmlRequest()` starts a streaming HTTP request and returns an `xml.StaxWriter` object ready to send XML to the server.

Supported methods are PUT and POST.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `*/*+xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**Related concepts**

- Examples using com.HTTPRequest methods on page 2734
- Examples: Using the com.HTTPPart class on page 2753
- Examples using methods of the com.HTTPPart class.

**com.HTTPRequest.clearAuthentication**

Removes user-defined authentication.

**Syntax**

```java
clearAuthentication()
```

**Usage**

Removes user-defined authentication.

If an `authenticate` entry exists in the FGLPROFILE file, it will be used for authentication, even if the user-defined authentication was removed.

**Important:** The iOS HTTP stack doesn't provide a simple way to handle authentication. The GMI front-end uses the global iOS credential management system, that keeps credential value of previous request based on host and realm, until the keep-alive session is closed. Therefore, doing a `clearAuthentication()` on iOS devices is not working immediately.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

Examples using com.HTTPRequest methods on page 2734
These examples use methods of the `com.HTTPRequest` class.

**Examples: Using the `com.HTTPPart` class** on page 2753
Examples using methods of the `com.HTTPPart` class.

`com.HTTPRequest.clearHeaders`
Removes all user-defined HTTP request headers.

**Syntax**

```
clearHeaders()
```

**Usage**
Removes all user-defined HTTP request headers defined with the `setHeader()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**Related concepts**

Examples using `com.HTTPRequest` methods on page 2734
These examples use methods of the `com.HTTPRequest` class.

**Examples: Using the `com.HTTPPart` class** on page 2753
Examples using methods of the `com.HTTPPart` class.

`com.HTTPRequest.Create`
Creates a new `HTTPRequest` object from a URL.

**Syntax**

```
com.HTTPRequest.Create (  
  url STRING  
)  
RETURNS com.HTTPRequest
```

1. `url` defines the URL for the HTTP request.

**Usage**
Creates a `HTTPRequest` object by providing a mandatory URL with HTTP or HTTPS as protocol.

The `url` parameter can be an identifier of an URL mapping with an optional `alias://` prefix. See FGLPROFILE Configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**Related concepts**

Examples using `com.HTTPRequest` methods on page 2734
These examples use methods of the `com.HTTPRequest` class.

**Examples: Using the `com.HTTPPart` class** on page 2753
Examples using methods of the `com.HTTPPart` class.

`com.HTTPRequest.doDataRequest`
Performs the request by sending binary data.

**Syntax**

```java
doDataRequest (  
  b BYTE )
```

1. `b` defines the binary data.

**Usage**

Performs the request by sending binary data contained in the `b` variable.

Supported methods are PUT and POST.

The `b` must be located in memory and not NULL otherwise operation fails.

The default Content-Type header is `application/octet-stream`, but it can be changed to any other mime type. For example: `image/jpeg`.

In HTTP 1.1, if the body size is greater than 32k, the request will be sent in several chunks of the same size.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2725 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse` on page 2724 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**Related concepts**

- Examples using `com.HTTPRequest` methods on page 2734
  These examples use methods of the `com.HTTPRequest` class.

- Examples: Using the `com.HTTPPart` class on page 2753
  Examples using methods of the `com.HTTPPart` class.

**Examples using `com.HTTPRequest`**

```java
com.HTTPRequest.doFileRequest
```

Performs the request by sending data contained in a file.

**Syntax**

```java
doFileRequest (  
  filename STRING )
```

1. `filename` defines the file containing the data to be send.

**Usage**

Performs the request by sending data contained in the file passed as parameter. The data is sent as is without any further conversion.

Supported methods are PUT and POST.

If not defined by programmer, the HTTP headers are automatically set as follows:

- `Content-Type` is defined based on the file name extension. If the file extension is not recognized, `Content-Type` defaults to `application/octet-stream`.
Note: File extensions to Content-Type mapping can be customized in the file FGLDIR/lib/wse/mime.cfg.  

- Content-Disposition is set with the base name of the given filename as follows: attachment; filename="basename".

For example, when calling the method as follows:

```java
CALL request.doFileRequest( "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP headers of the POST or PUT will look like:

```plain
Content-Type: image/jpeg
Content-Disposition: attachment; filename="logo.jpg"
```

In HTTP 1.1, if the body size is greater than 32k, the request will be sent in several chunks of the same size.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2725 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.GetAsyncResponse` on page 2724 method, to check if a response is available.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**Related concepts**
- Examples using com.HTTPRequest methods on page 2734
  These examples use methods of the com.HTTPRequest class.
- Examples: Using the com.HTTPPart class on page 2753
  Examples using methods of the com.HTTPPart class.

**com.HTTPRequest.doFormEncodedRequest**
Performs an "application/x-www-form-urlencoded forms" encoded query.

**Syntax**

```java
doFormEncodedRequest ( 
    query STRING, 
    utf8 INTEGER )
```

1. `query` defines a list of name/value pairs separated by an `&`.
2. `utf8` defines if the query string is UTF-8 encoded.

**Usage**

The `doFormEncodedRequest()` method performs request with an "application/x-www-form-urlencoded forms" encoded query.

Supported methods are GET and POST.

The `query` string is a list of name/value pairs separated by an ampersand (`&`). For example:

```java
name1=value1&name2=value2&name3=value3
```

**Note:** If you need to URL-encode the separator characters `&` and `=`, double them as following: `na&me=va==lue`. 

```java
na&&me=va==lue
```
If the *utf8* parameter is `TRUE`, the query string is encoded in UTF-8 as specified in *XForms 1.0*, otherwise in ASCII as specified in *HTML4*.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2725 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse` on page 2724 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see *Interruption handling in GWS calls (INT_FLAG)* on page 3280

**Related concepts**

These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753

Examples using methods of the `com.HTTPPart` class.

---

**Syntax**

```java
com.HTTPRequest.doRequest
```

Performs the HTTP request.

**Usage**

The `doRequest()` method performs the HTTP request.

Supported methods are GET, HEAD and DELETE.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2725 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse` on page 2724 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see *Interruption handling in GWS calls (INT_FLAG)* on page 3280

**Related concepts**

Examples using `com.HTTPRequest` methods on page 2734

These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753

Examples using methods of the `com.HTTPPart` class.

---

**Syntax**

```java
com.HTTPRequest.doTextRequest
```

Performs the request by sending an entire string at once.

**Usage**

The `doTextRequest()` method performs the HTTP request.

Supported methods are GET, HEAD and DELETE.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2725 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse` on page 2724 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see *Interruption handling in GWS calls (INT_FLAG)* on page 3280

**Related concepts**

Examples using `com.HTTPRequest` methods on page 2734

These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753

Examples using methods of the `com.HTTPPart` class.
str defines a string containing the request.

Usage
Performs the request by sending an entire string at once.
Supported methods are PUT and POST.
The default Content-Type header is text/plain, but it can be changed if of the form */*.
For example: application/json.
Automatic character set conversion from the application locale to the user-defined charset is performed. In case of conversion error, the method throws an exception.

Note: To avoid character conversion problems when sending text over HTTP, consider setting the same user-defined character set as the program defined by the application locale (assuming that the server understands the client application character set).

In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

Related concepts
Examples using com.HTTPRequest methods on page 2734
These examples use methods of the com.HTTPRequest class.
Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPRequest.doXmlRequest
Performs the request by sending an entire XML document at once.

Syntax

doXmlRequest (doc xml.DomDocument)

1. doc defines the XML document containing the data to be sent.

Usage
The doXmlRequest() method performs the request by sending the entire passed xml.DomDocument at once.
Supported methods are PUT and POST.
The default Content-Type header is text/xml, but it can be changed if of the form */xml or */*+xml. For example: application/xhtml+xml.
In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.
The character set used to send the XML data is defined by the encoding attribute in the XML document prolog. It is recommended that you define the HTTP request character set to NULL with the setCharSet() method, or that you use the same character set that was set in the XML Document.
This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` method to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse` method to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**Related concepts**

Examples using com.HTTPRequest methods on page 2734
These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753
Examples using methods of the `com.HTTPPart` class.

---

**com.HTTPRequest.endXmlRequest**

Terminates a streaming HTTP request.

**Syntax**

```java
endXmlRequest(
    stax xml.StaxWriter
)
```

1. `stax` defines the `xml.StaxWriter` object used to write the HTTP request.

**Usage**

The `endXmlRequest()` method terminates a streaming HTTP request by closing the `xml.StaxWriter` object that was created with the `beginXmlRequest()` method.

This HTTP request method is non-blocking: It returns immediately after the call. Use the `com.HTTPRequest.getResponse` method to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going on, use the `com.HTTPRequest.getAsyncResponse` method to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

Examples using com.HTTPRequest methods on page 2734
These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753
Examples using methods of the `com.HTTPPart` class.

---

**com.HTTPRequest.getAsyncResponse**

When available, returns the response produced by one of request methods.

**Syntax**

```java
getAsyncResponse()
RETURNS com.HTTPResponse
```
Usage

If a response is available, the getAsyncResponse() method returns a com.HTTPResponse object corresponding to the response that was produced by a call to one of the request methods: doRequest(), doTextRequest(), doXmlRequest(), doFormEncodedRequest(), or beginXmlRequest() and endXmlRequest().

Unlike getResponse(), the getAsyncResponse() method is non-blocking: it returns immediately and does not stop the program flow when waiting for a response.

The method returns NULL if the HTTP response was not yet received from the server.

This method is typically called just after a do*Request() call, and if the returned value is NULL, it is called again after a short period of time, to check for a response. Within a dialog, use an ON IDLE block to issue a getAsyncRequest() every seconds for example.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

Related concepts

com.HTTPRequest.getResponse on page 2725
Waits and returns the response produced by one of request methods.

Examples using com.HTTPRequest methods on page 2734
These examples use methods of the com.HTTPRequest class.

com.HTTPRequest.getResponse
Waits and returns the response produced by one of request methods.

Syntax

getResponse()  
RETURNS com.HTTPResponse

Usage

The getResponse() method waits for a response from the server and returns a com.HTTPResponse object corresponding to the response that was produced by a call to one of the request methods: doRequest(), doTextRequest(), doXmlRequest(), doFormEncodedRequest(), or beginXmlRequest() and endXmlRequest().

Note: On iOS, a long running HTTP request will display a message box, to let the user cancel the request. If the user cancels the HTTP request, the error -15578 will be raised. This error can be trapped with TRY/CATCH.

Unlike getAsyncResponse(), the getResponse() method is blocking: it stops the program flow until the HTTP response is received from the server.

Define a response timeout with the com.HTTPRequest.setTimeOut on page 2733 method.

Note: On iOS devices, when using this method, it is not possible to distinguish different timeouts for the connection and for read/write operation, defined respectively by the setConnectionTimeOut() and setTimeOut() methods. If both timeouts are defined, the longest timeout will be used for the connection and read/write operations.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.
Related concepts

**com.HTTPRequest.getAsyncResponse** on page 2724
When available, returns the response produced by one of request methods.

**Examples using com.HTTPRequest methods** on page 2734
These examples use methods of the `com.HTTPRequest` class.

**com.HTTPRequest.removeHeader**
Removes an HTTP header for the request according to a name.

**Syntax**

```java
removeHeader (name STRING)
```

1. `name` defines the HTTP header name.

**Usage**

The `removeHeader()` method deletes an HTTP header identified by `name`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See **Error handling in GWS calls (STATUS)** on page 3280.

**Related concepts**

**Examples using com.HTTPRequest methods** on page 2734
These examples use methods of the `com.HTTPRequest` class.

**Examples: Using the com.HTTPPart class** on page 2753
Examples using methods of the `com.HTTPPart` class.

**com.HTTPRequest.setAuthentication**
Defines the user login and password to authenticate to the server.

**Syntax**

```java
setAuthentication (login STRING, pass STRING, scheme STRING, realm STRING)
```

1. `login` defines the login to use for authentication.
2. `password` specifies the password to use for authentication.
3. `scheme` defines the method to be used during authentication. This is optional; it can be set to NULL.
4. `realm` defines the realm. This is optional; it can be set to NULL.

**Usage**

The `setAuthentication()` method defines the mandatory user login and password to authenticate to the server.

The `scheme` parameter defines the method to be used during authentication. The supported values for the `scheme` parameter are **Anonymous**, **Basic** and **Digest**. The default is **Anonymous**.

An optional `realm` can be specified.

With **Anonymous** or **Digest** authentication, you must re-send the request if you get a 401 or 407 HTTP return code (authorization required).
If a user-defined authentication is set and there is an authenticate entry for this URL in the FGLPROFILE file, the user-defined authentication has priority.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**
- Examples using com.HTTPRequest methods on page 2734
- These examples use methods of the com.HTTPRequest class.
- Examples: Using the com.HTTPPart class on page 2753
- Examples using methods of the com.HTTPPart class.

**com.HTTPRequest.setAutoCookies**

Enables automatic cookie management for a given request.

**Syntax**

```java
setAutoCookies( val INTEGER )
```

1. `val` defines the cookie management flag.

**Usage**

Set to TRUE to activate automatic cookie management.

If set to TRUE, it activates the automatic cookies management for that request. For the `com.HTTPRequest` instance:

- If the server returns session cookies (with no expiration date), they will be automatically sent again for a next request.
- If the server returns persistent cookies (with an expiration date), those cookies will be registered globally for the current `fglrun` process, and any other HTTPRequest (including the current one) will automatically send those cookies according to the request path and domain, as long as the expiration date has not expired.

The autocookiesmanagement option of the `com.WebServiceEngine.SetOption` on page 2682 method activates the automatic cookies management for any HTTPRequest.

The maximumpersistentcookies option of the `com.WebServiceEngine.SetOption` on page 2682 method set the maximum number of cookies that can be handled by an `fglrun` process.

Default value is FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**
- Examples using com.HTTPRequest methods on page 2734
- These examples use methods of the com.HTTPRequest class.
- Examples: Using the com.HTTPPart class on page 2753
- Examples using methods of the com.HTTPPart class.

**com.HTTPRequest.setAutoReply**

Defines the auto reply option for response methods.

**Syntax**

```java
setAutoReply()
```
val INTEGER )

1. val defines auto-reply when TRUE.

Usage

The `setAutoReply()` method defines whether `getResponse()` or `getAsyncResponse()` will automatically perform another HTTP GET request if response contains HTTP Authentication, Proxy Authentication or HTTP redirect data.

Available for GET method and the HTTP HEAD method.

The default is TRUE.

Important: On iOS devices, `setAutoReply()` is ignored for redirection in synchronous requests: The iOS HTTP stack does not allow to set an auto reply option when doing synchronous requests.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

When available, returns the response produced by one of request methods.

Examples using com.HTTPRequest methods on page 2734
These examples use methods of the `com.HTTPRequest` class.

`com.HTTPRequest.setCharset`
Defines the charset used when sending text or XML.

Syntax

```
setCharset (
     charset STRING )
```

1. charset defines the character set to use.

Usage

Defines the character set used when sending an HTTP request.

By default, no character set information will be transmitted in the HTTP header. This is also the case when specifying NULL as parameter for this method.

If no character set is specified in HTTP headers, ISO8859-1 will implicitly be used as defined by the HTTP standards.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts

Localization on page 405
Localization support allows you to implement programs that follow specific language and cultural rules.

Examples using com.HTTPRequest methods on page 2734
These examples use methods of the `com.HTTPRequest` class.

`com.HTTPRequest.setConnectionTimeOut`
Defines the timeout for the establishment of the connection.

**Syntax**

```java
setConnectionTimeOut(
    timeout INTEGER
)
```

1. *timeout* defines the number of seconds.

**Usage**

The `setConnectionTimeOut()` method sets the time value in seconds to wait for the establishment of the connection, before a break.

The value of -1 means infinite wait.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

Examples using `com.HTTPRequest` methods on page 2734

Examples using methods of the `com.HTTPPart` class.

**Examples using `com.HTTPRequest` methods**

These examples use methods of the `com.HTTPRequest` class.

**Examples: Using the `com.HTTPPart` class**

Examples using methods of the `com.HTTPPart` class.

---

**Syntax**

```java
setHeader(
    name STRING,
    value STRING
)
```

1. *name* defines the HTTP header name.
2. *value* defines the HTTP header value.

**Usage**

The `setHeader()` method defines an HTTP header with a *name* and *value* for the request.

If a header exists with the same name, it is replaced with the new value.

Setting a header after the body has been sent, or if a streaming operation has been started, will only be taken into account when a new request is reissued.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

Examples using `com.HTTPRequest` methods on page 2734
These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753
Examples using methods of the `com.HTTPPart` class.
Defines whether a connection is kept open if a new request occurs.

**Syntax**

```java
setKeepConnection(
    keep INTEGER
)
```

1. `keep` defines if the connection is kept.

**Usage**

The `setKeepConnection()` method defines whether the connection stays open when a new HTTP request occurs.

The default is `FALSE`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

Examples using com.HTTPRequest methods on page 2734
These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753
Examples using methods of the `com.HTTPPart` class.

---

`com.HTTPRequest.setMaximumResponseLength`

Defines the maximum size in Kbyte of a response.

**Syntax**

```java
setMaximumResponseLength(
    length INTEGER
)
```

1. `length` defines the maximum size in Kbytes.

**Usage**

The `setMaximumResponseLength()` method sets the maximum authorized size in Kbytes of the whole response (including headers, body and all control characters), before a break.

The value of -1 means no limit.

**Note:** Setting the maximum response length is ignored for synchronous requests in a Genero Mobile for iOS (GMI) app: The iOS HTTP stack does not allow you to set a maximum response length when doing synchronous requests.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

Examples using com.HTTPRequest methods on page 2734
These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2753
Examples using methods of the `com.HTTPPart` class.

`com.HTTPRequest.setMethod`
Sets the HTTP method of the request.

**Syntax**

```java
setMethod(
    method STRING
)
```

1. *method* defines the HTTP method of the request.

**Usage**

The `setMethod()` method defines the HTTP method of the request. Supported methods are GET, PUT, POST, HEAD and DELETE. The default is GET.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

- Examples using `com.HTTPRequest` methods on page 2734
  These examples use methods of the `com.HTTPRequest` class.
- Examples: Using the `com.HTTPPart` class on page 2753
  Examples using methods of the `com.HTTPPart` class.

`com.HTTPRequest.setMultipartType`

Switch `HTTPRequest` in multipart mode of given type.

**Syntax**

```java
setMultipartType(
    type STRING,
    start STRING,
    boundary STRING
)
```

1. *type* defines one of the following:
   - form-data: Browser Xform with attachment
   - mixed: Parts are independent
   - related: Parts are dependent (Required for SOAP)
   - alternative: Parts are different type of a same document
   - *or any other type*
   - NULL: switch multipart mode off
2. *start* defines the Content-ID value of root multipart document. (optional)
3. *boundary* defines a string used as multipart boundary. (optional)

**Usage**

Switch `HTTPRequest` in multipart mode of given type. Calling one of the standard request method will send the HTTP request as given multipart type, even if no other part has been set.

**Important:** Multipart HTTP requests is not supported on GMI mobile devices.

The root HTTP part is the part handled via the standard `HTTPRequest` methods such as `doTextRequest()`, `doXmlRequest()`, `doDataRequest()` and `beginXmlRequest()`.
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (STATUS) on page 3280.

\textbf{Related concepts}

\textbf{Examples using com.HTTPRequest methods} on page 2734
These examples use methods of the \texttt{com.HTTPRequest} class.

\textbf{Examples: Using the com.HTTPPart class} on page 2753
Examples using methods of the \texttt{com.HTTPPart} class.

\texttt{com.HTTPRequest.setProxy}
Configure the proxy URL.

\textbf{Syntax}

\begin{verbatim}
setProxy(
  host STRING,
  port INTEGER)
\end{verbatim}

1. \texttt{host} defines the host of the proxy.
2. \texttt{port} defines the port number of the proxy.

\textbf{Usage}
Defines the proxy URL to be used for the current \texttt{HTTPRequest} request. Even if a proxy URL is configured in \texttt{FGLPROFILE}, the proxy set by the \texttt{setProxy()} method will be used.

If \texttt{proxy_host} is NULL or \texttt{proxy_port} is < 0, error -15535 (Invalid parameter) is raised.

If \texttt{proxy_host} is unreachable, error -15579 (COM_PROXY_ERROR) is raised.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (STATUS) on page 3280.

\textbf{Examples: Using the com.HTTPPart class} on page 2753
Examples using methods of the \texttt{com.HTTPPart} class.

\texttt{com.HTTPRequest.setProxyAuthentication}
Define the login and password to use for proxy authentication.

\textbf{Syntax}

\begin{verbatim}
setProxyAuthentication( 
  login STRING,
  password STRING,
  scheme STRING,
  realm STRING)
\end{verbatim}

1. \texttt{login} defines the login to use for authentication.
2. \texttt{password} specifies the password to use for authentication.
3. \texttt{scheme} defines the method to be used during authentication. This is optional; it can be set to NULL.
4. \texttt{realm} defines the realm. This is optional; it can be set to NULL.
Usage
Defines the login and password to use for proxy authentication for the current HTTPRequest request.

The scheme parameter defines the method to be used during authentication. The supported values for the scheme parameter are Anonymous, Basic and Digest. The default is Anonymous.

If setProxy() has been called, the login and password will be used to authenticate against the proxy set by this API, regardless of whether a proxy is configured in FGLPROFILE.

If setProxy() has not been called and a proxy is configured in FGLPROFILE, the login and password set by this method will be used to authenticate against the proxy defined by FGLPROFILE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts
Examples using com.HTTPRequest methods on page 2734

Examples using methods of the com.HTTPPart class.

com.HTTPRequest.setTimeOut
Defines the timeout for a reading or writing operation.

Syntax

```java
setTimeOut (timeout INTEGER )
```

1. timeout defines the number of seconds.

Usage
The setTimeOut() method defines a delay in seconds, to wait for a HTTP request read or write operation. If the operation is not terminated after the timeout, it returns immediately with an error.

Use the value of -1 to define an infinite timeout.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts
Examples using com.HTTPRequest methods on page 2734
These examples use methods of the com.HTTPRequest class.

Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPRequest.setVersion
Sets the HTTP version of the request.

Syntax

```java
setVersion (version STRING )
```

1. version defines the HTTP version of the request.
**Usage**

The `setVersion()` method defines the HTTP version of the request. Accepted versions are 1.0 and 1.1 (only these two versions are supported). The default is 1.1.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**com.HTTPResponse.beginXmlResponse**

Starts a streaming HTTP response.

**Syntax**

```
beginXmlResponse()
RETURNS xml.StaxReader
```

**Usage**

The `beginXmlResponse()` method starts a streaming HTTP response and returns a `xml.StaxReader` object ready to read XML from the server.

The Content-Type header must be of the form */xml or */*+xml. For example: application/xhtml+xml.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**com.HTTPResponse.endXmlResponse**

Performs the HTTP request.

**Syntax**

```
endXmlResponse()
```
1. *stax* defines an `xml.StaxReader` object used to read the HTTP response.

**Usage**

The `endXmlResponse()` method ends the streaming HTTP response by closing the `xml.StaxReader` object that was created with the `beginXmlResponse()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see *Interruption handling in GWS calls (INT_FLAG)* on page 3280.

```java
com.HTTPResponse.getDataResponse

Returns the entire HTTP response in a BYTE.
```

**Syntax**

```java
getDataResponse (  
    b BYTE  )
```

1. `b` defines a `BYTE` variable receiving the HTTP response data.

**Usage**

The `getDataResponse()` method returns the body of an HTTP response into a `BYTE` variable.

The `BYTE` variable must be located in memory, otherwise operation fails.

Returns binary data as response from a server into a `BYTE`.

Previous content is discarded.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see *Interruption handling in GWS calls (INT_FLAG)* on page 3280.

```java
com.HTTPResponse.getFileResponse

Returns the entire HTTP response in a file on the disk.
```

**Syntax**

```java
getFileResponse ( )
RETURNS STRING
```

**Usage**

Reads an HTTP response and creates a file from it.

The method returns the absolute path to the file containing the HTTP response.

The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file is the basename found in the HTTP Content-Disposition Header. If this basename is not specified, the filename is created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form `/tmp/ABC/filename_index.ext`, where `index` represents the number of files with the same name on disk.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

com.HTTPResponse.getHeader

Returns the value of an HTTP header.

Syntax

```java
getHeader ( name STRING )
RETURNS STRING
```

1. `name` is the name of the parameter that defines the HTTP header.

Usage

The `getHeader()` method returns the value of the HTTP header specified by the `name` parameter, or NULL if not found.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.HTTPResponse.getHeaderCount

Returns the number of headers.

Syntax

```java
getHeaderCount ()
RETURNS INTEGER
```

Usage

The `getHeaderCount()` method returns the number of headers of the HTTP response.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.HTTPResponse.getHeaderName

Returns the name of a header by position.

Syntax

```java
getHeaderName ( pos INTEGER )
RETURNS STRING
```

1. `pos` specifies the ordinal position of the header.

Usage

The `getHeaderName()` method returns the name of the HTTP response header depending on the position passed as parameter.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**com.HTTPResponse.getHeaderValue**

Returns the value of a header by position.

**Syntax**

```plaintext
getHeaderValue (  
    pos INTEGER  )  
RETURNS STRING
```

1. `pos` specifies the ordinal position of the header.

**Usage**

The `getHeaderValue()` method returns the value of the HTTP response header based on the position passed as parameter.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**com.HTTPResponse.getMultipartType**

Returns whether a response is multipart or not, and the kind of multipart if any.

**Syntax**

```plaintext
getMultipartType (  )  
RETURNS STRING
```

**Usage**

Returns whether a response is multipart or not, and the kind of multipart if any.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**Related concepts**

- Examples: Using the `com.HTTPPart` class on page 2753
- Examples using methods of the `com.HTTPPart` class.

**com.HTTPResponse.getPartCount**

Returns the number of additional parts in the HTTP response.

**Syntax**

```plaintext
getPartCount (  )  
RETURNS INTEGER
```

**Usage**

Returns the number of additional parts in the HTTP response. The root part element must be handled via `getXmlResponse()`, `getTextResponse()`, `getDataResponse()` and `beginXmlResponse()`. In other words, there are `getPartCount() +1` parts if `getMultipartType()` does not return NULL.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts
Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPResponse.getPart
Returns the HTTP part object at the specified index of the current HTTP response.

Syntax

```java
getPart(
    pos INTEGER )
RETURNS com.HTTPPart
```

1. `pos` is input parameter that specifies the index number.

Usage
Returns the HTTP part object at the specified index of the current HTTP response.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Can raise error -15554 (Index is out of bounds).

Related concepts
Examples: Using the com.HTTPPart class on page 2753
Examples using methods of the com.HTTPPart class.

com.HTTPResponse.getPartFromContentID
Returns the HTTP part object marked with the given Content-ID value as identifier, or NULL if none.

Syntax

```java
getPartFromContentID(
    id STRING )
RETURNS com.HTTPPart
```

1. `id` defines the HTTP header.

Usage
Returns the HTTP part object marked with the given Content-ID value as identifier, or NULL if none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.HTTPResponse.getServerCookies
Returns all cookies set as response from a server.

Syntax

```java
getServerCookies(
    cookies RECORD )
```
1. cookies defines the dynamic array of all cookies sent as a response from a server. See WSHelper variables and records on page 3246 for more information regarding WSServerCookiesType.

Usage

This method returns all cookies set as response from a server, in a dynamic array. All cookies are returned, even those that have already expired.

If the method setAutoCookies() is enabled, cookies are automatically send back if they are not expired. In other words, the setAutoCookies(true) handles all cookies for you, however you can still consult them with the getServerCookies() method if needed.

If setAutoCookies(false) (the default), you must handle the cookies and not send the expired ones.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

This method may raise exception -15535 if the given dynamic array is not a dynamic array of RECORD with seven (7) members as defined by WSHelper.WSServerCookiesType.

Related concepts

com.HTTPRequest.setAutoCookies on page 2727
Enables automatic cookie management for a given request.

com.HTTPResponse.getStatusCode
Returns the HTTP status code.

Syntax

```java
getStatusCode ()
RETURNS INTEGER
```

Usage

The getStatusCode() method returns the status code for the HTTP response.

When the returned HTTP status code is 401 or 407, authorization is required.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts

com.HTTPRequest.setAuthentication on page 2726
Defines the user login and password to authenticate to the server.

com.HTTPResponse.getStatusDescription
Returns the HTTP status description.

Syntax

```java
getStatusDescription ()
RETURNS STRING
```

Usage

The getStatusDescription() method returns a description of the HTTP response status.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.HTTPResponse.getTextResponse
   Returns the entire HTTP response in a string.

**Syntax**

```java
getTextResponse ()
   RETURNS STRING
```

**Usage**

The `getTextResponse()` method returns a HTTP response as an entire string.

- The Content-Type header can be of the form */*. For example: application/json.
- Automatic conversion to the locale charset is performed when possible, otherwise throws an exception.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280

com.HTTPResponse.getXmlResponse
   Returns the entire HTTP response in a DOM document.

**Syntax**

```java
getXmlResponse ()
   RETURNS xml.DomDocument
```

**Usage**

The `getXmlResponse()` method returns an HTTP response in a `xml.DomDocument` object.

The Content-Type header must be of the form */xml or */*+xml. For example: application/xhtml+xml.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280

**Examples**

Examples using methods of the `com.HTTPResponse` class.

For examples, see Examples using `com.HTTPRequest` methods on page 2734.

**The HTTPPart class**

The `com.HTTPPart` class provides an interface to manage the HTTP attachment sent or received in HTTP.

The STATUS variable is set to zero after a successful method call.
### com.HTTPPart methods
Methods for the `com.HTTPPart` class.

#### Table 579: Class methods of com.HTTPPart

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>CreateAttachment (filename STRING)</code></td>
<td>Creates a new HTTPPart object based on given filename located on disk.</td>
</tr>
<tr>
<td><code>CREATE_FROM_DATA (b BYTE)</code></td>
<td>Creates a new HTTPPart object based on given BYTE located in memory.</td>
</tr>
<tr>
<td><code>CREATE_FROM_DOM_DOCUMENT (doc DOMDocument)</code></td>
<td>Creates a new HTTPPart object based on given XML document.</td>
</tr>
<tr>
<td><code>CREATE_FROM_STRING (str STRING)</code></td>
<td>Creates a new HTTPPart object based on given string.</td>
</tr>
</tbody>
</table>
Table 580: Object methods of com.HTTPPart

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clearHeaders ()</td>
<td>Remove all headers from the HTTP part.</td>
</tr>
<tr>
<td>getAttachment ()</td>
<td>Returns the absolute path to the HTTP part.</td>
</tr>
<tr>
<td>getContentAsData (b BYTE)</td>
<td>Returns the HTTP part as a BYTE.</td>
</tr>
<tr>
<td>getContentAsDomDocument ()</td>
<td>Returns the HTTP part as an XML document.</td>
</tr>
<tr>
<td>getHeader (name STRING)</td>
<td>Setter to handle HTTP multipart headers.</td>
</tr>
<tr>
<td>getContentAsString ()</td>
<td>Returns the HTTP part as a string.</td>
</tr>
<tr>
<td>removeHeader (name STRING)</td>
<td>Remove the header of given name from the current HTTPPart object.</td>
</tr>
<tr>
<td>setHeader (name STRING, value STRING)</td>
<td>Setter to handle HTTP multipart headers.</td>
</tr>
</tbody>
</table>

com.HTTPPart.CreateFromString

Creates a new HTTPPart object based on given string.

**Syntax**

```java
CreateFromString(
    str STRING
) RETURNS com.HTTPPart
```

1. `str` specifies a string value.

**Usage**

Creates a new HTTPPart object based on given string. To be used via the `addPart()` method.

Defaults HTTP multipart headers:

- Content-Type: text/plain
- Content-Transfer-Encoding: 8bits

Notice that the string will be converted during request sending into ISO-8859-1 by default, unless a different charset has been set via setHeader("Content-Type","text/plain; charset=UTF-8") for instance.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.HTTPPart.CreateFromDomDocument
Creates a new HTTPPart object based on given XML document.

**Syntax**

```java
CreateFromDomDocument (
   doc xml.DomDocument )
RETURNS com.HTTPPart
```

1. `doc` specifies an XML document.

**Usage**

Creates a new HTTPPart object based on given XML document. To be used via the addPart() method.

Defaults HTTP multipart headers:

- Content-Type: text/xml; charset=UTF-8
- Content-Transfer-Encoding: 8bits

A different charset can be set with the setHeader method. For example, `setHeader("Content-Type","text/plain; charset=ISO-8859-1")` sets the charset to ISO-8859-1.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

com.HTTPPart.setHeader on page 2752
Setter to handle HTTP multipart headers.

com.HTTPPart.CreateFromData
Creates a new HTTPPart object based on given BYTE located in memory.

**Syntax**

```java
CreateFromData (
   b BYTE )
RETURNS com.HTTPPart
```

1. `b` defines a BYTE object located in memory.

**Usage**

Creates a new HTTPPart object based on given BYTE located in memory. To be used via the addPart() method.

Defaults HTTP headers:

- Content-Type: application/octet-stream
- Content-Transfer-Encoding: binary

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.HTTPPart.CreateAttachment
Creates a new HTTPPart object based on given filename located on disk.

**Syntax**

```java
CreateAttachment(
    filename STRING )
RETURNS com.HTTPPart
```

1. *filename* specifies the name of a file.

**Usage**

Creates a new HTTPPart object based on given filename located on disk. To be used via the `addPart()` method.

The `com.HTTPPart.CreateAttachment()` method automatically sets the following headers for the created HTTPPart object:

- **Content-Type** is defined based on the file name extension. If the file extension is not recognized, `Content-Type` defaults to `application/octet-stream`.
  
  **Note:** File extensions to `Content-Type` mapping can be customized in the file `FGLDIR/lib/wse/mime.cfg`.

- **Content-Transfer-Encoding** is set to "binary".

- **Content-Disposition** is set with the base name of the given `filename` as follows: `attachment; filename="basename"`.

For example, when calling the method as follows:

```java
LET part = com.HTTPPart.CreateAttachment( "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP part headers will look like:

- **Content-Type**: `image/jpeg`
- **Content-Transfer-Encoding**: `binary`
- **Content-Disposition**: `attachment; filename="logo.jpg"`

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

Examples: Using the `com.HTTPPart` class on page 2753
Examples using methods of the `com.HTTPPart` class.

**com.HTTPPart.clearHeaders**

Remove all headers from the HTTP part.

**Syntax**

```java
clearHeaders()
```

**Usage**

This method removes all headers from an HTTP multipart object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.
Example

CALL req.clearHeaders()

Related concepts
com.HTTPPart.removeHeader on page 2752
Remove the header of given name from the current HTTPPart object.

com.HTTPPart.getAttachment
Returns the absolute path to the HTTP part.

Syntax

```
getAttachment ()
RETURNS STRING
```

Usage

Returns the absolute path location of the received part file.

The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file is the basename found in the HTTP Content-Disposition Header. If this basename is not specified, the filename is created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form: /tmp/ABC/filename_index.ext, where index represents the number of files with the same name on disk.

If the file is encoded in base64, you can use the Genero Web Services fglpass -dec64 command to convert it back to binary.

It is up to the programmer to remove the file from the disk when it is no longer needed.

To be used via methods: com.HTTPResponse.getPart on page 2743, com.HTTPResponse.getPartCount on page 2742, and com.HTTPResponse.getPartFromID on page 2743

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.HTTPPart.getContentAsData
Returns the HTTP part as a BYTE.

Syntax

```
getContentAsData (  
   b BYTE  )
```

1. b defines a variable holding the BYTE data.

Usage

Returns the HTTP part as a BYTE. BYTE data cannot be returned from a function with a RETURN statement. Therefore, the b parameter must be handled by reference.

To be used via methods: com.HTTPResponse.getPart on page 2743, com.HTTPResponse.getPartCount on page 2742, and com.HTTPResponse.getPartFromID on page 2743

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The error -15573 is raised if the part cannot be converted to a Genero BYTE.
com.HTTPPart.getContentAsDomDocument

Returns the HTTP part as an XML document.

**Syntax**

```java
getContentAsDomDocument ()
RETURNS xml.DomDocument
```

**Usage**

Returns the HTTP part as an XML document.

To be used via methods: `com.HTTPResponse.getPart` on page 2743, `com.HTTPResponse.getPartCount` on page 2742, and `com.HTTPResponse.getPartFromID` on page 2743.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The error -15573 is raised if the part cannot be converted to a XML DomDocument.

---

com.HTTPPart.getContentAsString

Returns the HTTP part as a string.

**Syntax**

```java
getContentAsString ()
RETURNS STRING
```

**Usage**

Returns the HTTP part as a string.

To be used via methods: `com.HTTPResponse.getPart` on page 2743, `com.HTTPResponse.getPartCount` on page 2742, and `com.HTTPResponse.getPartFromID` on page 2743.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The error -15573 is raised if the part cannot be converted to a Genero string or if the charset is not supported.

---

com.HTTPPart.getHeader

Setter to handle HTTP multipart headers.

**Syntax**

```java
getHeader (name STRING )
RETURNS STRING
```

1. *name* specifies the name of the header part.

**Usage**

Getter to handle HTTP multipart headers.

The method returns the value for the header part specified by *name*.

**Note:** In case of related multipart (i.e., the part is multipart/related and set via the `com.HTTPRequest.setMultipartType("related",NULL,NULL)`), it is mandatory
to set a unique Content-ID header. To set up a unique Content-ID header, you can use the
security.RandomGenerator.CreateUUIDString on page 2972 method for that.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Example

```plaintext
LET val = req.getHeader("MyClientHeader")
```

Related concepts

- com.HTTPPart.setHeader on page 2752
  Setter to handle HTTP multipart headers.

- com.HTTPPart.removeHeader
  Remove the header of given name from the current HTTPPart object.

Syntax

```plaintext
removeHeader (  
   name STRING  )
```

Usage

With an HTTP multipart object, the "Content-Type" header may be optional for each part:

```plaintext
https://tools.abc.org/html/rfc1234#section-1.1
```

A request might be rejected by some providers if the "Content-Type" header is set for a part. This method allows you to remove headers from an HTTPPart object based on the header name.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Example

```plaintext
CALL req.removeHeader("Content-Type")
```

Related concepts

- com.HTTPPart.clearHeaders on page 2749
  Remove all headers from the HTTP part.

- com.HTTPPart.setHeader
  Setter to handle HTTP multipart headers.

Syntax

```plaintext
setHeader (  
   name STRING,  
   value STRING  )
```

Usage

1. `name` specifies the multipart header name.
2. `value` specifies the multipart header value (such as HTTP headers).
**Usage**

Setter to handle HTTP multipart headers.

For instance, when you send a multipart image, it is recommended that you specify the image mime type with this header method. If the image is a png, you have to do `part.setHeader("Content-Type","image/png")`, which allows the peer to know the format of the attached file it has to process.

**Note:** In case of related multipart (i.e., the part is multipart/related and set via the `com.HTTPRequest.setMultipartType("related",NULL,NULL)`), it is mandatory to set a unique Content-ID header. To set up a unique Content-ID header, you can use the `security.RandomGenerator.CreateUUIDString` method for that.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Example**

```
CALL req.setHeader("MyClientHeader","Hello")
```

**Related concepts**

`com.HTTPPart.getHeader` on page 2751
 Setter to handle HTTP multipart headers.

*Examples: Using the `com.HTTPPart` class*

Examples using methods of the `com.HTTPPart` class.

This example consists of two applications: a client and server exchanging an XML document in multipart with an image as an attachment.

**Client Application**

```plaintext
IMPORT com
IMPORT xml

CONSTANT SERVER_URL = "http://localhost:8090/MultipartMixed/Sample"

MAIN

DEFINE req com.HTTPRequest
DEFINE resp com.HTTPResponse
DEFINE doc xml.DomDocument
DEFINE p com.HTTPPart

TCP classes
The TCP classes manage TCP client network operations.

- CLASS TCPRequest
- CLASS TCPResponse

The TCPRequest class
The com.TCPRequest class provides an interface to perform asynchronous XML and TEXT requests over TCP, with additional XML streaming possibilities.

Important: This Web Services class is not supported on GMI mobile devices.
**com.TCPRest methods**
Methods of the `com.TCPRequest` class.

**Table 581: Class methods of com.TCPRequest**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>com.TCPRequest.Create (uri STRING) RETURNS com.TCPRequest</code></td>
<td>Creates a new TCP request object.</td>
</tr>
</tbody>
</table>
### Table 582: Object methods of com.TCPRequest

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>beginXmlRequest()</td>
<td>Starts a streaming XML request.</td>
</tr>
<tr>
<td>doDataRequest(data BYTE)</td>
<td>Performs the request by sending binary data.</td>
</tr>
<tr>
<td>doRequest()</td>
<td>Performs a TCP request.</td>
</tr>
<tr>
<td>doTextRequest(str STRING)</td>
<td>Performs a request with a string.</td>
</tr>
<tr>
<td>doXmlRequest(doc xml.DomDocument)</td>
<td>Performs a request with a DOM document.</td>
</tr>
<tr>
<td>endXmlRequest(stax xml.StaxWriter)</td>
<td>Terminates a streaming TCP request.</td>
</tr>
<tr>
<td>getAsyncResponse()</td>
<td>Returns the response after performing a TCP request, asynchronously.</td>
</tr>
<tr>
<td>getResponse()</td>
<td>Returns the response after performing a TCP request.</td>
</tr>
<tr>
<td>setConnectionTimeOut()</td>
<td>Defines the connection time out.</td>
</tr>
<tr>
<td>setKeepConnection(keep INTEGER)</td>
<td>Defines if the TCP connection is kept open after sending a request.</td>
</tr>
<tr>
<td>setMaximumResponseLength(length INTEGER)</td>
<td>Defines the maximum size in Kbyte of the response.</td>
</tr>
<tr>
<td>setTimeOut(timeout INTEGER)</td>
<td>Defines the time out for read/write operations.</td>
</tr>
</tbody>
</table>

**Syntax**

```java
beginXmlRequest()  
RETURNS xml.StaxWriter
```
**Usage**

The `beginXmlRequest()` method begins a streaming HTTP request and returns an `xml.StaxWriter` object ready to send XML to the server.

After sending all the XML data to the server, you must call the `endXmlRequest()` method with the `xml.StaxWriter` object created by the `beginXmlRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

com.TCPRequest.Create

Creates a new TCP request object.

**Syntax**

```java
com.TCPRequest.Create(
    uri STRING )
RETURNS com.TCPRequest
```

1. `uri` specifies the URL of the TCP request.

**Usage**

This class method creates a new `com.TCPRequest` object based on the URL passed as parameter.

The URL must use the TCP or TCPS protocol. Examples of valid URLs include:

- `tcp://localhost:4242/`
- `tcps://localhost:4343/`

The URL can be an identifier of an URL mapping with an optional `alias://` prefix. See FGLPROFILE configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

com.TCPRequest.doDataRequest

Performs the request by sending binary data.

**Syntax**

```java
doDataRequest(
    data BYTE )
```

1. `data` defines the binary data to be send for a TCP request. The `data` variable must be located IN MEMORY.

**Usage**

Performs the TCP request by sending binary data contained in the `BYTE` variable.

**Note:** The `data` variable must be located IN MEMORY.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

com.TCPRequest.doRequest
Performs a TCP request.

**Syntax**

```
doRequest ()
```

**Usage**

The `doRequest()` method performs the TCP request.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**Example**

```
IMPORT com
IMPORT XML

MAIN
  DEFINE url STRING
  LET url = "tcp://localhost:4242"
  CALL an_example(url)
END MAIN

FUNCTION an_example(url)
  DEFINE url STRING
  DEFINE req com.TCPRequest
  DEFINE resp com.TCPResponse
  DEFINE ret xml.DomDocument

  TRY
    LET req = com.TCPRequest.create(url)
    CALL req.doRequest()
    LET resp = req.getResponse()
    LET ret = resp.getXmlResponse()
  CATCH
    DISPLAY "ERROR : ", STATUS, SQLCA.SQLERRM
    EXIT PROGRAM(-1)
  END TRY
END FUNCTION
```

**com.TCPRequest.doXmlRequest**

Performs a request with a DOM document.

**Syntax**

```
doXmlRequest (  
  doc xml.DomDocument  )
```

1. `doc` specifies the DOM document describing the request.
The doXmlRequest() method performs the TCP request by using the information defined in the xml.DomDocument object passed as parameter.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

com.TCPRequest.doTextRequest
Performs a request with a string.

Syntax

doTextRequest (  
    str STRING )

1. str defines the string describing the request.

Usage

The doTextRequest() method performs the TCP request by using the information defined in string passed as parameter.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

com.TCPRequest.endXmlRequest
Terminates a streaming TCP request.

Syntax

domXmlRequest (  
    stax xml.StaxWriter )

1. stax specifies the xml.StaxWriter object used for streaming.

Usage

The endXmlRequest() method terminates a streaming TCP request performed with the xml.StaxWriter object that what created by the beginXmlRequest() method.

The connection is shutdown for writing, to notify that no data will be sent.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

com.TCPRequest.getResponse
Returns the response after performing a TCP request.

**Syntax**

```java
getResponse()
RETURNS com.TCPResponse
```

**Usage**

The `getResponse()` method returns a TCP response as a `com.TCPResponse` object, after a call to `doRequest()`, `doXmlRequest()`, `doTextRequest()`, or `beginXmlRequest() / endXmlRequest()` calls.

A call to this method will stop the program flow until the response is received.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**com.TCPRequest.getAsyncResponse**

Returns the response after performing a TCP request, asynchronously.

**Syntax**

```java
getAsyncResponse()
RETURNS com.TCPResponse
```

**Usage**

The `getAsyncResponse()` method returns a TCP response as a `com.TCPResponse` object, after a call to `doRequest()`, `doXmlRequest()`, `doTextRequest()`, or `beginXmlRequest() / endXmlRequest()` calls.

Unlike `getResponse()`, the `getAsyncResponse()` method does not stop the program flow: The method returns `NULL` if the response was not yet received.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**com.TCPRequest.setTimeOut**

Defines the time out for read/write operations.

**Syntax**

```java
setTimeout (timeout INTEGER )
```

1. `timeout` specifies a time out value in seconds.

**Usage**

This method defines a value in seconds to wait for a read or write operation to complete, before a break.
If the time out is set to -1, it waits indefinitely.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.TCPRequest.setConnectionTimeOut
Defines the connection time out.

**Syntax**

```
setConnectionTimeOut ( 
    timeout INTEGER )
```

1. `timeout` specifies a time out value in seconds.

**Usage**

This method defines the time in seconds to wait for a connection, before a break.

If the time out is set to -1, it waits indefinitely.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.TCPRequest.setKeepConnection
Defines if the TCP connection is kept open after sending a request.

**Syntax**

```
setKeepConnection ( 
    keep INTEGER )
```

1. `keep` indicates if the TCP connection must be kept open.

**Usage**

This method can be used to force the TCP socket to remain open after a send operation, in order to perform subsequent do*Request() calls, without closing the connection (in write mode).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

com.TCPRequest.setMaximumResponseLength
Defines the maximum size in Kbyte of the response.

**Syntax**

```
setMaximumResponseLength ( 
    length INTEGER )
```

1. `length` specifies the max size of a response in Kbytes.

**Usage**

This method sets the maximum authorized size in Kbyte of the whole response, before a break.

A length of -1 defines no limit.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**The TCPResponse class**
The `com.TCPResponse` class provides an interface to perform XML and TEXT responses over TCP, with additional XML streaming possibilities.

**Important:** This Web Services class is not supported on GMI mobile devices.

**com.TCPResponse methods**
Methods of the `com.TCPResponse` class.

### Table 583: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>beginXmlResponse()</code></td>
<td>Starts a streaming TCP response.</td>
</tr>
<tr>
<td></td>
<td><code>RETURNS xml.StaxReader</code></td>
</tr>
<tr>
<td><code>endXmlResponse( stax xml.StaxReader )</code></td>
<td>Ends a streaming TCP response.</td>
</tr>
<tr>
<td><code>getDataResponse( data BYTE )</code></td>
<td>Returns a TCP response in binary format.</td>
</tr>
<tr>
<td><code>getTextResponse()</code></td>
<td>Returns a TCP response in string format.</td>
</tr>
<tr>
<td><code>getXmlResponse()</code></td>
<td>Returns an entire DOM document as TCP response.</td>
</tr>
<tr>
<td></td>
<td><code>RETURNS xml.DomDocument</code></td>
</tr>
</tbody>
</table>

**com.TCPResponse.beginXmlResponse**
Starts a streaming TCP response.

**Syntax**
```java
beginXmlResponse ()
RETURNS xml.StaxReader
```

**Usage**
Begin the streaming TCP response and returns an `xml.StaxReader` object ready to read XML from the server.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3280.

**com.TCPResponse.endXmlResponse**
Ends a streaming TCP response.

**Syntax**

```java
endXmlResponse(
    stax xml.StaxReader)
```

1. `stax` defines the `xml.StaxReader` object created with `beginXmlResponse()`.

**Usage**

Terminates the streaming TCP response identified by the `xml.StaxReader` object passed as parameter. This object must have been created with the `beginXmlResponse()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (`INT_FLAG`) on page 3280.

**com.TCPResponse.getDataResponse**

Returns a TCP response in binary format.

**Syntax**

```java
getDataResponse(
    data BYTE)
```

1. `data` defines a `BYTE` variable that will hold the response data in binary format. The `BYTE` variable must be located IN MEMORY.

**Usage**

This method retrieves the TCP response in binary format into the `data` variable passed as parameter. The method will read the TCP stream, until the peer closes the connection.

**Note:** The `data` variable must be located IN MEMORY.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (`INT_FLAG`) on page 3280.

**com.TCPResponse.getTextResponse**

Returns a TCP response in string format.

**Syntax**

```java
getTextResponse()
    RETURNS STRING
```

**Usage**

This method returns a complete streaming TCP response from the server as a string.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (`INT_FLAG`) on page 3280.

`com.TCPResponse.getXmlResponse`
Returns an entire DOM document as TCP response.

**Syntax**

```java
getXmlResponse()
RETURNS xml.DomDocument
```

**Usage**

This method returns a complete `xml.DomDocument` as streaming TCP response from the server.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (`INT_FLAG`) on page 3280.

**Helper classes**
The Helper classes provide utility classes.

- The `Util` class on page 2765

**The Util class**
The `com.Util` class provides static helper methods.

This class does not have to be instantiated.

**Important:** This Web Services class is not supported on GMI mobile devices.

`com.Util` methods
Methods of the `com.Util` class.

**Table 584: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| `com.Util.UniqueApplicationInstance(file STRING)
RETURNS INTEGER` | Checks that the calling application is the only one to run. |

`com.Util.UniqueApplicationInstance`
Checks that the calling application is the only one to run.

**Syntax**

```java
com.Util.UniqueApplicationInstance(file STRING)
RETURNS INTEGER
```

1. `file` specifies the string for the lock file.
Usage
This method checks that the calling application is the only one to run, by trying to get an exclusive lock on the given file.

If the lock could be set, the method returns TRUE. Otherwise, it returns FALSE and updates STATUS with an error code.

Specific classes
Several classes support specific features.

• The APNS class on page 2766

The APNS class
The com.APNS class implements Apple® Push Notification Service APIs.

The com.APNS class implements a set of methods to build and handle push messages to be broadcast by the Apple Push Notification service.

Related concepts
Apple Push Notification Service (APNs) on page 3351
Follow this procedure to implement push notification with APNs.

APNs SSL/TLS certificate
Get and configure an SSL/TLS certificate to establish secure connections to the Apple Push Notification service.

Basics
The Apple® Push Notification Certificate identifies the push notification service for a given mobile app. This certificate is created from an App ID (also known as Bundle ID) and is used by the APNs system to dispatch the notification message to the registered devices.

You can create two types of APN certificates for a given App ID:

• Sandbox (for development and test purpose)
• Production (for deployment)

An APNS push notification provider or an APNS feedback handler needs to establish a secure connection to Apple's APNs server.

Get an APNs certificate for your app
In this section we will produce the myapp.cer file and myapp-key.p12 file.

To create an Apple® Push Notification Certificate:

1. Log in to Apple's Member Center with your iOS developer or enterprise account.
2. Select Certificates, Identifiers & Profiles.
3. Under App IDs, make sure that you have created an App ID with the Push Notification service enabled, for development and/or distribution.
4. Under Certificates, select the + symbol.
5. Select Apple® Push Notification service SSL (Sandbox) for development, or Apple® Push Notification service SSL (Sandbox & Production) for production.
6. Choose the App ID with push notifications service enabled.
7. Follow the instructions to create a Certificate Signing Request (CSR) file from your Mac, then click Continue.
8. Back in the web browser and IOS Certificate page, upload the CSR file you have generated.
9. Generate the certificate.
10. Once the certificate is generated, download it. The certificate will be downloaded into your Downloads folder, as a .cer file (for example, myapp.cer).
11. Double-click this file to import the certificate into the Mac® Keychain®.
12. The new certificate is now listed in the Certificates list.
13. Open your Keychain® app and locate the certificate you created, export the private key in p12 format (for example, myapp-key.p12). Note that you will be asked for a password to encode the .p12 file, and for your session password, to exported Keychain® files.

**Configure Genero to use the APNs certificate**

On the Genero push provider server, you will need the public certificate (myapp.crt file) and the private key (myapp-key.pem file) for your app. These files will be referenced in the security.global.certificate and security.global.privatekey entries of FGLPROFILE.

In order to authenticate the APNs server, you will also need the root certificate authority (apple_entrust_root_certification_authority.pem), that can be downloaded from Apple's web site. This file will be referenced by the security.global.ca entry in FGLPROFILE.

**Note:** When executing on a Mac, the root certificate (security.global.ca entry) is not required: The Web Services library reads the Keystore of the Mac® computer, to authenticate the APNs server.

Create the myapp.crt file (public certificate) from the myapp.cer file, with the openssl x509 command:

```
$ openssl x509 -in myapp.cer -inform der -out myapp.crt
```

Convert the myapp-key.p12 file (containing the private key) to a myapp-key.pem format, with the openssl pkcs12 command:

```
$ openssl pkcs12 -nocerts -in myapp-key.p12 -out myapp-key.pem
```

**Note:** You need to enter the passphrase for the .p12 file so that openssl can read it. Then you need to enter a new passphrase that will be used to encrypt the .pem file.

The FGLPROFILE entry security.global.privatekey expects unencrypted private key files. Therefore, you need to remove the passphrase from the myapp-key.pem file, with the openssl rsa command:

```
$ openssl rsa -in myapp-key.pem -out myapp-key-noenc.pem
```

Set up your FGLPROFILE with the appropriate security.* entries:

```
security.global.ca = "apple_entrust_root_certification_authority.pem"
security.global.certificate = "myapp.crt"
security.global.privatekey = "myapp-key-noenc.pem"
```

In the above example:

1. apple_entrust_root_certification_authority.pem is the HTTPS root certificate authenticating the APNs server (if the computer is not a Mac).
2. myapp.crt is the public certificate for your app.
3. myapp-key-noenc.pem is the unencrypted private key file for your app.

**Note:** If you want to keep the private key encrypted, you need to configure a password agent, as described in Using the password agent.
**com.APNS methods**
Methods of the com.APNS class.

**Table 585: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.APNS.DecodeError (data BYTE) RETURNS (uuid STRING, error INTEGER)</td>
<td>Decodes content of BYTE data returned from the APNS server in case of error.</td>
</tr>
<tr>
<td>com.APNS.DecodeFeedback (data BYTE, unregs RECORD)</td>
<td>Decodes content of BYTE data returned from the APNS feedback service.</td>
</tr>
<tr>
<td>com.APNS.EncodeMessage (data BYTE, deviceIdBase64 STRING, json STRING, uuidBase64 STRING, expiration INTEGER, priority INTEGER) RETURNS INTEGER</td>
<td>Encodes an APNS specific push notification message into a BYTE.</td>
</tr>
</tbody>
</table>

**com.APNS.DecodeError**
Decodes content of BYTE data returned from the APNS server in case of error.

**Syntax**

```java
com.APNS.DecodeError (data BYTE) RETURNS (uuid STRING, error INTEGER)
```

1. `data` is the BYTE variable containing the error data. This BYTE variable must be located IN MEMORY.
2. `uuid` is a Base64 encoded string containing the push notification identifier.
3. `error` is the APNS error code returned by the server.

**Usage**

This method decodes the content of the BYTE variable passed as a parameter and received as response for a push notification message in the event of an error from the APNs server.

**Note:** This BYTE variable must be located IN MEMORY.

The `uuid` is a binary value that identifies the push notification message. It is returned as a Base64-encoded string.

The `error` returned value defines the APNs error code. For example, error will be set to 10 if the APNs server was shutdown. See the Apple® Push Notification Service error reference for more details.

In the case of a decoding error, the method will raise the exception -15566, with details in the SQLCA.SQLERRM register.

**Example**

```sql
DEFINE error_data BYTE,
    uuid STRING,
```
error INTEGER

LOCATE error_data IN MEMORY

-- Send push notification message TCP request
...
CALL req.doDataRequest(data)
LET resp = req.getResponse()
TRY
    CALL resp.getDataResponse(error_data)
    CALL com.APNS.DecodeError(error_data)
    RETURNING uuid, ecode
...

For a complete example, see APNs push provider on page 2772.

com.APNS.DecodeFeedback
Decodes content of BYTE data returned from the APNS feedback service.

Syntax

com.APNS.DecodeFeedback(
    data BYTE,
    unregs RECORD
)

1. data defines a BYTE variable containing the feedback data. This BYTE variable must be located IN MEMORY.
2. unregs defines a structured dynamic array that contains the list of unregistered device tokens.
   a. timestamp is the number of seconds since UNIX® Epoch (in UTC)
   b. deviceToken is an APNS device token that has been unregistered (encoded in Base-64)

Usage

Apple® recommends connecting frequently to the APNS feedback server in order to verify that your applications are still registered for push notifications.

To get APNS feedback, you must perform a TCP request (using SSL/TLS), to the following specific URI:

tcps://feedback.push.apple.com:2196

The DecodeFeedback() method decodes the content of the BYTE variable, which was passed as a parameter and received as response for the TCP request to the APNS feedback server.

Note: This BYTE variable must be located IN MEMORY.

For the second parameter, this method takes a structured dynamic array that will be filled with the list of unregistered APNS device tokens. It is up to the push program to stop sending push notification messages for these unregistered device tokens.

The timestamp member of an unregs dynamic array element can be used to verify that device tokens have not been re-registered since the feedback entry was generated. This timestamp is returned as a number of seconds since the UNIX® epoch, in UTC. Use the util.Datetime.fromSecondsSinceEpoch on page 2578 utility API to convert timestamp to a DATETIME value in the current local time.

The deviceToken member of an unregs dynamic array element identifies iOS devices that have been unregistered from the APNS server. Note that these identifier is encoded in Base64.

In the event of a decoding error, the method will raise the exception -15566, with details in the SQLCA.SQLERRM register.
Example

```plaintext
DEFINE feedback_data BYTE,
    unregs DYNAMIC ARRAY OF RECORD
        timestamp   INTEGER,
        deviceToken STRING
    END RECORD,
    i INTEGER

LOCATE feedback_data IN MEMORY

... TCP request to APNS feedback server ...

CALL com.APNS.DecodeFeedback(feedback_data, unregs)

FOR i=1 TO unregs.getLength()
    DISPLAY i, " ", unrefs[i].deviceToken
END FOR
```

For a complete example, see APNs feedback handler on page 2773.

**com.APNS.EncodeMessage**

Encodes an APNs specific push notification message into a BYTE.

**Syntax**

```plaintext
com.APNS.EncodeMessage(
    data BYTE,
    deviceIdBase64 STRING,
    json STRING,
    uuidBase64 STRING,
    expiration INTEGER,
    priority INTEGER)
RETURNS INTEGER
```

1. *data* defines a BYTE variable holding the APNs message. This BYTE variable must be located IN MEMORY.
2. *deviceIdBase64* defines an APNs device token (encoded in Base-64).
3. *json* defines a JSON string containing the APNs push message data.
4. *uuidBase64* defines the 4 bytes-long push message identifier (encoded in Base64).
5. *expiration* defines a number of seconds since UNIX® Epoch defining the expiration date of the message.
6. *priority* defines an integer as the priority of the message.

**Usage**

This method builds the APNS push notification message into a BYTE variable, for a given device token.

**Note:** This BYTE variable must be located IN MEMORY.

**Note:** The size of an APNS notification payload cannot exceed 2 Kilobytes. Make sure that the resulting BYTE variable does not exceed this size limitation. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The APNS push notification message protocol requires some binary data to be encoded in the message content before it is sent to the APNS server with a TCP (over SSL/TLS) request, to specific URIs, namely:

- "tcps://gateway.sandbox.apple.com:2195" (for development)
- "tcps://gateway.push.apple.com:2195" (for production)

You need to provide several parameters in order to build the push notification message:
The `deviceToken` parameter is an APNS device token encoded in Base-64. It's used to identify the target device that must receive the push message. The device token identifies a single iOS device: If you have N devices registered to your push notification provider, you will have N different device tokens. If you want to send one push notification message to all the devices, you must send N different messages, where the only difference between the messages is the device token.

**Note:** It's in your hands to handle the list of registered device tokens. A device token is assigned to a physical iOS device when the mobile app issues a `registerForRemoteNotifications` on page 2556 front call. The app must then provide its device token to the push provider program using a method such as a web service mechanism.

Fill the `json` parameter with a JSON string containing the APNS push message data. For example:

```plaintext
LET json = '{"aps":{"alert":"Hello,
world","sound":"default","badge":1,"content-available":1}}'
```

See APNS documentation for more details about the JSON content of a message.

The `uuid` parameter is the 4 bytes-long push message identifier, encoded in Base64. This parameter can be used later to identify the message in push notification errors (`com.APNS.DecodeError` on page 2768). This parameter can be NULL. To create the `uuid` parameter, use the `security.RandomGenerator.CreateRandomString` on page 2972 API, with a size of 4:

```plaintext
LET uuid = security.RandomGenerator.createRandomString(4)
```

The `expiration` parameter is a number of seconds since UNIX® Epoch. It defines the expiration date of the message if it can not be sent by the APNS server to the target devices. This parameter can be NULL, to indicate that there is no expiration date:

```plaintext
LET dt = CURRENT + INTERVAL (10) MINUTE TO MINUTE
LET expiration = util.Datetime.toSecondsSinceEpoch(dt)
```

The `priority` parameter can be used to define a priority for the push notification message. Typically, use a value of 10 for immediate, 5 for delayed. This parameter can be NULL. See APNS documentation for more details.

If there's an encoding error, the method will raise the exception `-15566`, with details in the `SQLCA.SQLERRM` register.

**Example**

```plaintext
DEFINE push_data BYTE,
    deviceTokenHexa STRING,
    dt DATETIME YEAR TO FRACTION(3),
    expiration INTEGER,
    json_data STRING,
    uuid STRING
LOCATE push_data IN MEMORY

LET deviceTokenHexa = "84e3................."

LET dt = CURRENT + INTERVAL (10) MINUTE TO MINUTE
LET expiration = util.Datetime.toSecondsSinceEpoch(dt)

LET json_date = util.JSON.stringify(...)  
LET uuid = security.RandomGenerator.createRandomString(4)

CALL com.APNS.EncodeMessage(
    push_data,
    security.HexBinary.ToBase64(deviceTokenHexa),
    json_data,
    uuid,
```
Expiration,

IF LENGTH(push_data) > 2000 THEN
    -- Must reduce the message content...
    RETURN FALSE
END IF

-- Do the TCP request with the push_data variable
...

For a complete example, see APNs push provider on page 2772.

**APNs examples**

The com.APNS class can be used to implement an APNs push provider.

The following code example implements a push program using the com.APNS API to send a notification message to devices by using the TCP request API. See also com.APNS methods on page 2768 for more details about the APNs API.

**Note:** An SSL/TLS certificate needs to be defined in FGLPROFILE, as described in APNs SSL/TLS certificate on page 2766.

**Note:** The size of the resulting BYTE variable containing the APNS payload cannot exceed 2 Kilobytes.

**Important:** In order to check that the push message was properly handled by the APNs server, you need to define a TCP request timeout (2 seconds in this example). In case of error, the APNs server will return a response immediately. In case of success, there is no response from the APNs server. For more details about this protocol, see Apple's APNs documentation.

```java
IMPORT com
IMPORT security
IMPORT util

MAIN
    DEFINE json STRING
    DEFINE deviceTokenHexa STRING
    DEFINE req com.TCPRequest
    DEFINE resp com.TCPResponse
    DEFINE uuid STRING
    DEFINE ecode INTEGER
    DEFINE dt DATETIME YEAR TO SECOND
    DEFINE exp INTEGER
    DEFINE data, err BYTE
    LOCATE data IN MEMORY
    LOCATE err IN MEMORY
    LET deviceTokenHexa = "84e3................."
    LET dt = CURRENT + INTERVAL(10) MINUTE TO MINUTE
    LET exp = util.Datetime.toSecondsSinceEpoch(dt)
    TRY
        LET req = com.TCPRequest.create( "tcps://gateway.push.apple.com:2195" )
        CALL req.setKeepConnection(true)
        CALL req.setTimeout(2) # Wait 2 seconds for APNs to return an error code
        LET uuid = security.RandomGenerator.createRandomString(4)
        LET json = '{"aps":{"alert":"Hello, world","sound":"default","badge":1,"content-available":1}}'
        CALL com.APNS.EncodeMessage(
            data,
            security.HexBinary.ToBase64(deviceTokenHexa),
```
json,
  uuid,
  exp,
  10
)
IF LENGTH(data) > 2000 THEN
  DISPLAY "APNS payload cannot exceed 2 kilobytes"
  EXIT PROGRAM 1
END IF
DISPLAY "Sending notif with ID:", uuid," and expiring at ", dt
CALL req.doDataRequest(data)
LET resp = req.getResponse()
TRY
  CALL resp.getDataResponse(err)
  CALL com.APNS.DecodeError(err) RETURNING uuid, ecode
  DISPLAY "ERROR code ", ecode
  DISPLAY "ERROR uuid ", uuid

Related concepts
Implementing a token maintainer on page 3357
The token maintainer is a BDL Web Services server program that handles push token registration from mobile apps.

The xml package
The Genero Web Services XML package provides classes and methods to handle any kind of XML documents, including documents with namespaces.

The library provides a W3C-compatible DOM API, integrating additional XML Schema and DTD validation methods. There is also an API compatible with StAX for writing or reading XML documents where performance and speed are important.

Use the IMPORT statement at the top of the module using this library:

IMPORT xml

Note: The DOM API of the om package is designed to handle specific FGL files or to manipulate the user interface tree (the AUI tree). For all other cases/scenarios, we recommend that you use the DOM API of the Web Services xml package.

• The Document Object Modeling (DOM) classes on page 2774
• The streaming API for XML (StAX) classes on page 2841
• XML serialization classes on page 2877
• XML security classes on page 2891
• OM to XML Migration on page 2969

The Document Object Modeling (DOM) classes
The Document Object Modeling (DOM) classes manage XML documents entirely in memory with support of XML Schema and DTD validation.

• CLASS DomDocument
  • Features
• CLASS DomNode
  • Types
• **CLASS DomNodeList**

**The DomDocument class**
The `xml.DomDocument` class provides methods to manipulate a data tree, following the DOM standards.

The `STATUS` variable is set to zero after a successful method call.

**`xml.DomDocument` methods**
Methods for the `xml.DomDocument` class.

<td>Returns the error description at the given position.</td>
</tr>
</tbody>
</table>

xml.DomDocument.appendDocumentNode

Adds a child DomNode object to the end of the DomNode children for this DomDocument object.

**Syntax**

```plaintext
appendDocumentNode(n xml.DomNode)
```

1. *n* defines the node to add.

**Usage**

Adds a child `xml.DomNode` object to the end of the DomNode children for this DomDocument object, where *n* is the node to add.

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node, and one Document Type node allowed.

**Note:** A fragment is a structure created to receive XML nodes that are not always valid. Once a fragment is added to a valid node, the fragment becomes empty as all nodes are moved from the fragment as a child to a valid node. So developers can work on the fragment until it is added to another node. At that time developers should no longer work on the fragment but rather on the valid node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.clone

Returns a copy of a DomDocument object.

**Syntax**

```plaintext
clone()
```

**Usage**

Returns a copy of this `DomDocument` object, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.create
Constructor of an empty DomDocument object.

**Syntax**

```python
xml.DomDocument.create()
RETURNS xml.DomDocument
```

**Usage**

Constructor of an empty DomDocument object.

Returns a DomDocument object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Example**

Create a DomDocument without a root node:

```python
xml.domDocument.create()
```

Create a DomDocument with an initial root node named ARoot:

```python
xml.domDocument.create("ARoot")
```

**xml.DomDocument.createAttribute**

Creates a XML Attribute DomNode object for a DomDocument object.

**Syntax**

```python
createAttribute ( 
  elt STRING )
RETURNS xml.DomNode
```

1. `elt` defines the name of the XML attribute.

**Usage**

Creates a XML Attribute DomNode object for a DomDocument object, where `elt` is the name of the XML attribute. It cannot be NULL.

Returns the XML element DomNode object, or NULL.

To create a default namespace declaration attribute use xmlns as the name. (Using `declareNamespace` instead is recommended)

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomDocument.createAttributeNS**

Creates a XML namespace-qualified Attribute DomNode object for a DomDocument object.

**Syntax**

```python
createAttributeNS ( 
  prefix STRING,
  elt STRING,
  ns STRING )
```
1. **prefix** defines the prefix of the XML attribute.
2. **elt** defines the name of the XML attribute.
3. **ns** defines the namespace URI of the XML attribute.

**Usage**

Creates a XML namespace-qualified Attribute `DomNode` object for this `DomDocument` object where **prefix** is the prefix of the XML attribute, it cannot be `NULL`; **elt** is the name of the XML attribute; it cannot be `NULL`; **ns** is the namespace URI of the XML attribute, it cannot be `NULL`.

Returns the XML element `DomNode` object, or `NULL`.

To create a namespace declaration attribute use `xmlns` as the prefix and `http://www.w3.org/XML/1998/namespace` as the namespace. Using `declareNamespace` instead is recommended.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**xml.DomDocument.createCDATASection**

Creates an XML CData `DomNode` object for a `DomDocument` object.

**Syntax**

```sql
createCDATASection(
    data STRING )
RETURNS xml.DomNode
```

1. **data** defines the data of the XML CData node.

**Usage**

Creates a XML CData `DomNode` object for this `DomDocument` object, where **data** is the data of the XML CData node, or `NULL`.

Returns the XML element `DomNode` object, or `NULL`.

Only the characters `#x9`, `#xA`, `#xD`, `[#x20-#xD7FF]`, `[#xE000-#xFFFD]` and `[#x10000-#x10FFFF]` are allowed in the content of an XML CDATASection node.

The character sequence (Double-Hyphen) `''--''` is not allowed in the content of a XML CDATASection node. The save and normalize methods will fail if the sequence of characters other than those allowed exist in a CDATASection node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**xml.DomDocument.createComment**

Creates a XML Comment `DomNode` object for a `DomDocument` object.

**Syntax**

```sql
createComment(
    cmt STRING )
RETURNS xml.DomNode
```

1. **cmt** defines the data of the XML Comment node.
Usage

Creates a XML Comment DomNode object for this DomDocument object, where \textit{cmt} is the data of the XML Comment node, or NULL.

Returns the XML element \texttt{DomNode} object, or NULL.

Only the characters \#x9, \#xA, \#xD, [\#x20-\#xD7FF], [\#xE000-\#xFFFD] and [\#x10000-\#x10FFFF] are allowed in the content of an XML Comment node.

The character sequence (Double-Hyphen) \textquote{--} is not allowed in the content of a XML CDATASection node.

The \texttt{save} and \texttt{normalize} methods will fail if the sequence of characters other than those allowed exist in a CDATASection node.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

\texttt{xml.DomDocument.createDocument}

Constructor of a DomDocument with a XML root element.

Syntax

\begin{verbatim}
xm1.DomDocument.createDocument ( 
   name STRING ) 
RETURNS xml.DomDocument
\end{verbatim}

1. \textit{name} defines the XML element.

Usage

Constructor of a \texttt{xml.DomDocument} with a XML root element; where \textit{name} is the name of the XML Element.

Returns a \texttt{xml.DomDocument} object or NULL.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

\texttt{xml.DomDocument.createDocumentFragment}

Creates a XML Document Fragment DomNode object for a DomDocument object.

Syntax

\begin{verbatim}
createDocumentFragment () 
RETURNS xml.DomNode
\end{verbatim}

Usage

Creates a XML Document Fragment DomNode object for this DomDocument object.

Returns the XML element \texttt{DomNode} object, or NULL.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
Constructor of a DomDocument with a root namespace-qualified XML root element

Syntax

```java
xml.DomDocument.createDocumentNS(
    prefix STRING,
    name STRING,
    ns STRING )
RETURNS xml.DomDocument
```

1. `prefix` defines the prefix of the XML Element or NULL.
2. `name` defines the XML element.
3. `ns` is the namespace of the XML Element.

Usage

Constructor of a `xml.DomDocument` with a root namespace-qualified XML root element where `prefix` is the prefix of the XML element or NULL, `name` is the name of the XML element, and `ns` is the namespace of the XML element. Returns a `xml.DomDocument` object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Example

Create a DomDocument with an initial root node named "List" with abc as the prefix and http://www.mysite.com/xmlapi as the namespace:

```java
xml.domdocument.createDocumentNS("abc","List","http://www.mysite.com/xmlapi")
```

Produces:

```xml
<abc:List xmlns:abc="http://www.mysite.com/xmlapi">
[...]
</abc:List>
```

xml.DomDocument.createDocumentType

Creates a XML Document Type (DTD) DomNode object for a DomDocument object.

Syntax

```java
createDocumentType(
    name STRING,
    publicID STRING,
    systemID STRING,
    internalSubset STRING )
RETURNS xml.DomNode
```

1. `name` defines the name of the document type.
2. `publicID` defines the URI of the public identifier.
3. `systemID` defines the URL of the system identifier (Specifies the file location of the external DTD subset).
4. `internalSubset` defines the internal DTD subset.
Usage

Creates a XML Document Type (DTD) DomNode object for this DomDocument object; name is the name of the document type; publicID is the URI of the public identifier or NULL; systemID is the URL of the system identifier or NULL (Specifies the file location of the external DTD subset); internalSubset is the internal DTD subset or NULL.

Returns a xml.DomNode object, or NULL if internalSubset is malformed.

Important: This method is not part of W3C standard API.

Only internal DTDs are supported.

The public identifier cannot be set without the system identifier.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.createElement

Creates a XML Element DomNode object for a DomDocument object

Syntax

```java
createElement ( 
    elt STRING ) 
RETURNS xml.DomNode
```

1. elt defines the name of the XML element.

Usage

Creates a XML Element DomNode object for this DomDocument object, where elt is the name of the XML element, which cannot be NULL.

Returns the XML element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.createElementNS

Creates a XML namespace-qualified Element DomNode object for a DomDocument object.

Syntax

```java
createElementNS ( 
    prefix STRING, 
    elt STRING, 
    ns STRING ) 
RETURNS xml.DomNode
```

1. prefix defines the prefix of the XML element, or NULL to use the default namespace.
2. elt defines the name of the XML element.
3. ns defines the namespace URI of the XML element.

Usage

Creates a XML namespace-qualified Element DomNode object for this DomDocument object, where prefix is the prefix of the XML element, or NULL to use the default namespace. elt is the name of the XML element, this cannot be NULL. ns is the namespace URI of the XML element, this cannot be NULL.

Returns the XML element DomNode object, or NULL.
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (STATUS) on page 3280.

\texttt{xml.DomDocument.createEntityReference}

Creates a XML EntityReference \texttt{DomNode} object for a \texttt{DomDocument} object

**Syntax**

\begin{verbatim}
createEntityReference(  
  entity STRING  
)  
RETURNS xml.DomNode
\end{verbatim}

1. \textit{entity} defines the name of the entity reference.

**Usage**

Creates a XML EntityReference \texttt{DomNode} object for this \texttt{DomDocument} object, where \textit{entity} is the name of the entity reference.

Returns the XML element \texttt{DomNode} object, or NULL.

An Entity Reference node is read-only and cannot be modified.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (STATUS) on page 3280.

\texttt{xml.DomDocument.createNode}

Creates a XML \texttt{DomNode} object from a string for a \texttt{DomDocument} object.

**Syntax**

\begin{verbatim}
createNode(  
  str STRING  
)  
RETURNS xml.DomNode
\end{verbatim}

1. \textit{str} defines the string representation of the \texttt{DomNode} to be created.

**Usage**

Creates a XML \texttt{DomNode} object from a string for this \texttt{DomDocument} object; \textit{str} is the string representation of the \texttt{DomNode} to be created.

Returns the XML element \texttt{DomNode} object, or NULL.

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (STATUS) on page 3280.

\texttt{xml.DomDocument.createProcessingInstruction}

Creates a XML Processing Instruction \texttt{DomNode} object for this \texttt{DomDocument} object.

**Syntax**

\begin{verbatim}
createProcessingInstruction(  
  target STRING,  
  data STRING  
)  
RETURNS xml.DomNode
\end{verbatim}
1. *target* defines the target part of the XML Processing Instruction.
2. *data* defines the data part of the XML Processing Instruction.

**Usage**

Creates a XML Processing Instruction DomNode object for this DomDocument object, where *target* is the target part of the XML Processing Instruction, cannot be NULL; *data* is the data part of the XML Processing Instruction, or NULL.

Returns the XML element DomNode object, or NULL.

Only the characters #x9, #xA, #xD, [#x20-#xD7FF], [#xE000-#xFFFD] and [#x10000-#x10FFFF] are allowed in the content of an XML Processing Instruction node.

The character sequence (Double-Hyphen) ‘--’ is not allowed in the content of an XML Processing Instruction. The *save()* and *normalize()* methods will fail if this sequence or characters other than those allowed exist in a Processing Instruction node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomDocument.createTextNode**

Creates a XML Text DomNode object for a DomDocument object.

**Syntax**

```java
createTextNode(
    txt STRING )
RETURNS xml.DomNode
```

1. *txt* defines the data of the XML Text node.

**Usage**

Creates a XML Text DomNode object for this DomDocument object, where *txt* is the data of the XML Text node, or NULL.

Returns the XML element DomNode object, or NULL.

Only the characters #x9, #xA, #xD, [#x20-#xD7FF], [#xE000-#xFFFD] and [#x10000-#x10FFFF] are allowed in the content of an XML Text node. The *save()* and *normalize()* methods will fail if characters other than those allowed exist in a Text node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomDocument.declareNamespace**

Forces namespace declaration to a XML Element DomNode for a DomDocument object.

**Syntax**

```java
declareNamespace(
    node xml.DomNode,
    alias STRING,
    ns STRING )
```

1. *node* defines the XML Element DomNode that carries the namespace definition.
2. *alias* defines the alias of the namespace to declare.
3. *ns* defines the URI of the namespace to declare.
**Usage**

Forces namespace declaration to a XML Element `DOMNode` for this `DomDocument` object; `node` is the XML Element `DOMNode` that carries the namespace definition; `alias` is the alias of the namespace to declare, or `NULL` to declare the default namespace; `ns` is the URI of the namespace to declare (can only be `NULL` if alias is `NULL`).

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.DomDocument.getDocumentElement`

Returns the root XML Element `DOMNode` object for this `DomDocument` object.

**Syntax**

```
getDocumentElement ()
RETURNS xml.DomNode
```

**Usage**

Returns the root XML Element `DOMNode` object for this `DomDocument` object.

Returns the XML element `DOMNode` object, or `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.DomDocument.getDocumentNodesCount`

Returns the number of child `DOMNode` objects for a `DomDocument` object.

**Syntax**

```
getDocumentNodesCount ()
RETURNS INTEGER
```

**Usage**

Returns the number of child `DOMNode` objects in this `DomDocument` object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.DomDocument.getDocumentNodeItem`

Returns the child `DOMNode` object at a given position for this `DomDocument` object.

**Syntax**

```
getDocumentNodeItem ( index INTEGER )
RETURNS xml.DomNode
```

1. `index` defines the position of the node to return (index starts at 1).
**Usage**

Returns the child `xml.DomNode` object at a given position for this `DomDocument` object where `index` is the position of the node to return (index starts at 1), or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

`xml.DomDocument.getElementById`

Returns the element that has an attribute of type ID with the given value.

**Syntax**

```
getElementById(
   id STRING
)
RETURNS xml.DomNode
```

1. `id` defines the Id value.

**Usage**

Use this method to return the `xml.DomNode` element that has an attribute of type ID with the given value, or NULL if there is none.

Attributes with the name "ID" or "id" are not of type ID unless so defined with `setIdAttribute` or `setIdAttributeNS`. However, there is a specific attribute called `xml:id` belonging to the namespace http://www.w3.org/XML/1998/namespace that is always of type ID even if not set with `setIdAttributeNS`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

`xml.DomDocument.getElementsByTagName`

Returns a `DomNodeList` object containing all XML Element `DomNode` objects with the same tag name in the entire document.

**Syntax**

```
getElementsByTagName(
   tag STRING
)
RETURNS xml.DomNodeList
```

1. `tag` defines the name of the XML Element tag to match or "*" to match all tags.

**Usage**

Use this method to return a `DomNodeList` object containing all XML Element `DomNode` objects with the same tag name in the entire document. The `tag` string contains the name of the XML Element tag to match, or use "*" to match all tags.

Returns a `DomNodeList` object, or NULL.

The returned list is ordered using a Depth-First pass algorithm.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

`xml.DomDocument.getElementsByTagNameNS`
Returns a DomNodeList object containing all namespace qualified XML Element DomNode objects with the same tag name and namespace in the entire document.

Syntax

```javascript
getElementsByTagNameNS(
tag STRING,
    ns STRING)
RETURNS xml.DomNodeList
```

1. `tag` defines the name of the XML Element tag to match or "*" to match all tags.
2. `ns` defines the namespace URI of the XML Element tag to match, or "*" to match all namespaces.

Usage

Use this method to return a `xml.DomNodeList` object containing all namespace qualified XML Element DomNode objects with the same tag name and namespace in the entire document. The `tag` string contains the name of the XML Element tag to match, or use "*" to match all tags. `ns` is the namespace URI of the XML Element tag to match, or use "*" to match all namespaces.

Returns a `DomNodeList` object, or NULL.

The returned list is ordered using a Depth-First pass algorithm.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

```
xml.DomDocument.getErrorDescription
```

Returns the error description at the given position.

Syntax

```javascript
getErrorDescription(
    index INTEGER)
RETURNS STRING
```

1. `index` defines the position of the error description (index starts at 1).

Usage

This method returns the error description at the given position. `index` is the position of the error description (index starts at 1). It returns a string with an error description.

**Important:** This method is not part of W3C standard API.

Example error management

```sql
FOR i=1 TO doc.getErrorsCount()
    DISPLAY "[", i, "] ", doc.getErrorDescription(i)
END FOR
```

Displays all the errors encountered in the save, load, or validate of the `doc` DomDocument.

To display other errors, use the global variable `STATUS` to get the error code and `err_get(status)` or `SQLCA.SQLERRM` to get the description of the error. See `error code` for more details.
Returns the number of errors encountered during the loading, saving or validation of a XML document.

Syntax

```plaintext
getErrorsCount() 
RETURNS INTEGER
```

Usage

This method returns the number of errors encountered during the loading, saving, or the validation of a XML document.

Returns the number of errors, or zero if there are none.

**Important:** This method is not part of W3C standard API.

**Example error management**

```plaintext
FOR i=1 TO doc.getErrorsCount()
   DISPLAY "[", i, "]", doc.getErrorDescription(i)
END FOR
```

Displays all the errors encountered in the save, load, or validate of the doc DomDocument.

To display other errors, use the global variable STATUS to get the error code and `err_get(status)` or `SQLCA.SQLERRM` to get the description of the error. See `error code` for more details.

xml.DomDocument.getFirstDocumentNode

Returns the first child DomNode object for a DomDocument object.

Syntax

```plaintext
getFirstDocumentNode() 
RETURNS xml.DomNode
```

Usage

Use this method to return the first child xml.DomNode object for this DomDocument object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See `Error handling in GWS calls (STATUS)` on page 3280.

xml.DomDocument.getFeature

Gets a feature for a DomDocument object.

Syntax

```plaintext
getFeature( 
   property STRING 
) 
RETURNS STRING
```

1. `property` is the name of the input parameter defining the name of a DomDocument feature.

Usage

This method returns the name of a feature for the DomDocument object, where `property` is the name of the DomDocument feature.

Returns the value of the feature.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.getLastDocumentNode
Returns the last child DomNode object in a DomDocument object.

**Syntax**

```
getLastDocumentNode ()
RETURNS xml.DomNode
```

**Usage**

Use this method to return the last child xml.DomNode object in this DomDocument object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.getXmlEncoding
Returns the document encoding as defined in the XML document declaration.

**Syntax**

```
getXmlEncoding ()
RETURNS STRING
```

**Usage**

This method returns the document encoding as defined in the XML document declaration, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.getXmlVersion
Returns the document version as defined in the XML document declaration.

**Syntax**

```
getXmlVersion ()
RETURNS STRING
```

**Usage**

This method returns the document version as defined in the XML document declaration, which is 1.0. No other versions are supported.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.importNode
Imports a DomNode from a DomDocument object into its new context (attached to a DomDocument object).

**Syntax**

```
importNode ()
```
```sql
xml.DomNode
  deep INTEGER )
RETURNS xml.DomNode
```

1. `n` defines the node to import.
2. `deep` defines a boolean identifying whether to import the node only or the node and all its child nodes.

**Usage**

Imports a `xml.DomNode` object from a DomDocument object into its new context (attached to this DomDocument object), where `n` is the node to import. When `deep` is FALSE only the node is imported; when TRUE the node and all its child nodes are imported.

Returns the `xml.DomNode` object that has been imported to this DomDocument, or NULL.

Document and Document Type nodes cannot be imported.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**`xml.DomDocument.insertBeforeDocumentNode`**

Inserts a child `xml.DomNode` object before another child DomNode for this DomDocument object.

**Syntax**

```sql
insertBeforeDocumentNode(
    newNode xml.DomNode,
    ref xml.DomNode )
```

1. `newNode` defines the node to insert.
2. `ref` defines the reference node (the node before which the new node must be inserted).

**Usage**

Inserts a child `xml.DomNode` object before another child DomNode for this DomDocument object; `newNode` is the node to insert, `ref` is the reference node (the node before which the new node must be inserted).

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node, and one Document Type node allowed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**`xml.DomDocument.insertAfterDocumentNode`**

Inserts a child DomNode object after another child DomNode in a DomDocument object.

**Syntax**

```sql
insertAfterDocumentNode(
    newNode xml.DomNode,
    ref xml.DomNode )
```

1. `newNode` defines the node to insert.
2. `ref` defines the reference node (the node after which the new node must be inserted).
**Usage**

Inserts a child `xml.DomNode` object after another child `DomNode` in this `DomDocument` object; `newNode` is the node to insert; `ref` is the reference node (the node after which the new node must be inserted).

**Important:** This method is not part of W3C standard API.

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node, and one Document Type node allowed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomDocument.isXmlStandalone**

Checks whether the XML standalone attribute is set in the XML declaration.

**Syntax**

```
isXmlStandalone()
RETURNS INTEGER
```

**Usage**

Use this method to check if the XML standalone attribute is set in the XML declaration or not. It returns `TRUE` if set to yes, `FALSE` if not.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomDocument.load**

Loads a XML Document into a `DomDocument` object from a file or an URL.

**Syntax**

```
load(
    filename STRING )
```

1. `filename` defines a valid URL or the name of the file.

**Usage**

This method loads a XML Document into a `DomDocument` object from a file or an URL, where `filename` is a valid URL or the name of the file.

Use `setFeature()` to specify how the document can be loaded. HTML parsing is possible when `enable-html-compliancy` is enabled.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

**Note:** When loading a document, if `xml.DomNode` objects are still referenced in other variables of the program, the entire document is kept in memory. Otherwise, the DOM nodes of the document are deleted before loading the new document. For more details about object references and garbage collection in BDL, see Working with objects on page 461.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Important:** On Mac® OS X versions prior to 10.9, the libxml library (used by Genero Web Services classes) has a bug when parsing HTML documents. If you set the HTML compliancy option with CALL doc.setFeature("enable-html-compliancy",TRUE), loading an HTML document with xml.DomDocument.load() may produce additional blank TEXT nodes, because the libxml library loads some ignorable white-space nodes from the HTML document. Starting with Mac® OS X 10.9, the libxml library of the system has fixed this bug.

xml.DomDocument.loadFromPipe

Loads a XML Document into a DomDocument object from a PIPE.

**Syntax**

```plaintext
loadFromPipe(
    name STRING)
```

1. *name* defines the command to read from the PIPE.

**Usage**

Use this method to load a XML Document into a DomDocument object from a PIPE, where *name* is the command to read from the PIPE.

**Important:** This method is not part of W3C standard API.

Use `setFeature()` to specify how the document can be loaded. HTML parsing is possible when enable-html-compliancy is enabled.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

**Note:** When loading a document, if xml.DomNode objects are still referenced in other variables of the program, the entire document is kept in memory. Otherwise, the DOM nodes of the document are deleted before loading the new document. For more details about object references and garbage collection in BDL, see Working with objects on page 461.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.loadFromString

Loads a XML Document into a DomDocument object from a string.

**Syntax**

```plaintext
loadFromString(
    xmlstr STRING)
```

1. *xmlstr* defines the string to load.

**Usage**

Use this method to load a XML Document into a DomDocument object from a string, where *xmlstr* is the string to load.

**Important:** This method is not part of W3C standard API.

Use `setFeature()` to specify how the document can be loaded. HTML parsing is possible when enable-html-compliancy is enabled.
See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

**Note:** When loading a document, if `xml.DomNode` objects are still referenced in other variables of the program, the entire document is kept in memory. Otherwise, the DOM nodes of the document are deleted before loading the new document. For more details about object references and garbage collection in BDL, see Working with objects on page 461.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.DomDocument.normalize`

Normalizes the entire Document.

**Syntax**

```
normalize()
```

**Usage**

Normalizes the entire Document. This method merges adjacent text nodes, removes empty text nodes, and sets namespace declarations as if the document had been saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.DomDocument.prependDocumentNode`

**Syntax**

```
prependDocumentNode (n xml.DomNode )
```

1. `n` defines the node to add.

**Usage**

Adds a child `xml.DomNode` object to the beginning of the `DomNode` children in this `DomDocument` object; `n` is the node to add.

**Important:** This method is not part of W3C standard API.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.DomDocument.removeDocumentNode`

Removes a child `DomNode` object from the `DomNode` children in a `DomDocument` object.

**Syntax**

```
removeDocumentNode (n xml.DomNode )
```

1. `n` defines the node to remove.
**Usage**

Removes a child DomNode object from the DomNode children in this DomDocument object, where \( n \) is the node to remove.

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node, and one Document Type node allowed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.save

Saves a DomDocument object as a XML Document to a file or URL.

**Syntax**

```py
save(
    filename STRING
)
```

1. `filename` defines a valid URL or the name of a file.

**Usage**

Saves a DomDocument object as a XML Document to a file or URL, where `filename` is a valid URL or the name of the file.

Only the following kinds of URLs are supported:

- http://
- https://
- tcp://
- tcps://
- file:///
- alias://

See fglprofile Configuration for more details about URL mapping with aliases, and for proxy and security configuration.

See `setFeature()` to specify how the document can be saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.saveToPipe

Saves a DomDocument object as an XML Document to a PIPE.

**Syntax**

```py
saveToPipe(
    name STRING
)
```

1. `name` defines the command to start the pipe.

**Usage**

Saves a DomDocument object as a XML Document to a PIPE, where `name` is the command to start the pipe.

See `setFeature()` to specify how the document can be saved.
See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

xml.DomDocument.saveToString
Saves a `DomDocument` object as a XML Document to a string.

**Syntax**

```java
saveToString()
RETURNS STRING
```

**Usage**

Saves a `DomDocument` object as a XML Document to a string. Returns the string that will contain the resulting document.

**Important:** This method is not part of W3C standard API.

See `setFeature()` to specify how the document can be saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

xml.DomDocument.selectByXPath
Returns a `DomNodeList` object containing all `DomNode` objects matching a XPath 1.0 expression.

**Syntax**

```java
selectByXPath(expr STRING, args ...) 
RETURNS xml.DomNodeList
```

1. `expr` defines the XPath 1.0 expression
2. `args` defines a list of prefixes bound to namespaces in order to resolve qualified names in the XPath expression.

**Usage**

Returns a `xml.DomNodeList` object containing all `DomNode` objects matching a XPath 1.0 expression. `expr` is the XPath 1.0 expression. `args` is a list of prefixes bound to namespaces in order to resolve qualified names in the XPath expression. This list must be filled with an even number of arguments, representing the prefix and its corresponding namespace.

**Important:** This method is not part of W3C standard API.

Valid example:

```java
selectByXPath(
    "/d:Record",
    "d",
    "http://defaultnamespace"
)
selctByXPath(
    "/ns1:Record",
    NULL
)
selctByXPath(
    "/ns1:Records/ns2:Record",
    "ns1",
    "http://defaultnamespace"
)
selctByXPath(
    "/ns1:Records/ns2:Records/ns3:Record",
    "ns1",
    "http://defaultnamespace"
)
```
Invalid example:

```java
selectByXPath(
   "//ns1:Record",
   "ns1"
)
```

This example is invalid because the namespace definition is missing.

If the namespaces list is NULL, the prefixes and namespaces defined in the document itself are used if available.

A namespace must be an absolute URI (for example, 'http://', 'file://').

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomDocument.setFeature**

Sets a feature for a DomDocument object.

**Syntax**

```java
setFeature(
   property STRING,
   value STRING)
```

1. `property` is the name of the input parameter defining the name of a DomDocument feature.
2. `value` is the value of a feature.

**Usage**

Use this method to set a feature for the DomDocument object, where `property` is the name of a DomDocument feature, and `value` is the value of a feature.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomDocument.setXmlEncoding**

Sets the XML document encoding in the XML declaration.

**Syntax**

```java
setXmlEncoding(
   encoding STRING)
```

1. `encoding` defines the XML document encoding.

**Usage**

Sets the XML document encoding in the XML declaration, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomDocument.setXmlStandalone**
Sets the XML standalone attribute in the XML declaration to "yes" or "no" in the XML declaration, or removes the standalone attribute.

**Syntax**

```xml
setXmlStandalone(
    alone INTEGER )
```

1. `alone` defines a boolean flag.
   - `1` sets the standalone attribute to "yes".
   - `0` sets the standalone attribute to "no".
   - `-1` removes the standalone attribute.

**Usage**

This sample sets the standalone attribute to "no":

```xml
IMPORT XML

MAIN
    DEFINE doc xml.DomDocument
    LET doc = xml.DomDocument.Create()
    CALL doc.setXmlStandalone(0)
    DISPLAY doc.saveToString()
END MAIN
```

The output displayed by the above example is `<?xml version="1.0" encoding="UTF-8" standalone="no"?>`.

This sample sets the standalone attribute to "yes":

```xml
IMPORT XML

MAIN
    DEFINE doc xml.DomDocument
    LET doc = xml.DomDocument.Create()
    CALL doc.setXmlStandalone(1)
    DISPLAY doc.saveToString()
END MAIN
```

The output displayed by the above example is `<?xml version="1.0" encoding="UTF-8" standalone="yes"?>`.

This sample removes the standalone attribute:

```xml
IMPORT XML

MAIN
    DEFINE doc xml.DomDocument
    LET doc = xml.DomDocument.Create()
    CALL doc.setXmlStandalone(-1)
    DISPLAY doc.saveToString()
END MAIN
```
The output displayed by the above example is `<?xml version="1.0" encoding="UTF-8"?>`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.validate
Performs a DTD or XML Schema validation for a DomDocument object.

**Syntax**

```java
define ( )
    RETURNS INTEGER
```

**Usage**

Performs a DTD or XML Schema validation for this DomDocument object. Returns the number of validation errors, or zero if there are none.

**Important:** This method is not part of W3C standard API.

See `setFeature()` to specify what kind of validation to do.

See `getErrorsCount()` and `getErrorMessage()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomDocument.validateOneElement
Performs a DTD or XML Schema validation of a XML Element DomNode object.

**Syntax**

```java
validateOneElement ( 
    elt xml.DomNode )
    RETURNS INTEGER
```

1. `elt` defines the XML element DomNode to validate.

**Usage**

Performs a DTD or XML Schema validation of a XML Element DomNode object; `elt` is the XML Element DomNode to validate.

Returns the number of validation errors, or zero if there are none.

**Important:** This method is not part of W3C standard API.

See `setFeature()` to specify what kind of validation to do.

See `getErrorsCount()` and `getErrorMessage()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
Navigation methods usage examples
Examples using the navigation methods of the xml.DomDocument class.

DomDocument navigation functions deal with nodes immediately under the DomDocument object, except for search features. To navigate through all the nodes, you can refer to the navigation functions of the class xml.DomNode.

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
<?xml-stylesheet type="text/xsl" href="card.xsl"?>
<!-- demo card -->
<CardList xml:id="1" >[...]
</CardList>
```

In the example the first node of the document is xml-stylesheet. Use getFirstDocumentNode to get the node. The element at position 2 is the comment <!-- demo card -->. Use getDocumentNodeItem function to get the node.

The last node of the document is CardList. Use getLastDocumentNode to get the node.

The number of nodes in the document is 3. This is the result of the function getDocumentNodesCount. This function only counts the number of children immediately under the DomDocument.

Note: The first line of the example, <?xml version="1.0" encoding="ISO-8859-1"?>, is not considered as a node. To access the information of the first line, use getXmlVersion() and getXmlEncoding functions.

Caution, if the example is in pretty printed format, the results are not the same. There are additional text nodes representing the carriage returns.

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
<?xml-stylesheet type="text/xsl" href="card.xsl"?>
<!-- demo card -->
<CardList xml:id="1" >[...]
</CardList>
```

See Cautions section for more details.

You can select nodes using their tag names, by XPath, or by their attributes value (if of type ID, xml:id for example). The getElementsByTagName and getElementsByTagNameNS methods return a DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is restricted to containing objects with the same tag name and/or namespace. The selectByXPath method also returns a DomNodeList object, but each node can have a different name.

getElementsByTagNameNS("message","http://schemas.xmlsoap.org/wsd1/")

Get the message nodes that have http://schemas.xmlsoap.org/wsd1/ as the namespace.

getElementsByTagNameNS("message","*")

Get all the message nodes, regardless of the namespace they have.

getElementsByTagName("message")

Get all the message nodes that do not have any namespace.

selectByXPath("//xs:element",NULL)

Get all the xs:element nodes that have a namespace corresponding to the prefix xs.
Get all the Card nodes that do not have any namespace.

```javascript
getElementById("1")
```

Get the unique node whose attribute of type ID has a value of "1".

**Node creation methods usage examples**

Node creation methods usage examples for the `xml.DomDocument` class.

Creating a node for the `DomDocument` is done in two steps:

- Create the node.
- Add the node to the `DomDocument`.

Each time you create a node, you need to append it at the right place in the `DomDocument`. To add a node to the document use the `DomDocument` management methods or the `DomNode` manipulation methods.

```javascript
createNode("<LastName>PATTERSON</LastName><FirstName>Andrew</FirstName>")
```

Creates a structure of nodes.

```javascript
createElement("CardList")
```

Produces

```xml
<CardList/>
```

```javascript
createElementNS("cny", "Company", "http://www.mysite.com/")
```

Produces `<cny:Company xmlns:cny="http://www.mysite.com/">` or `<cny:Company />`. See **Cautions** for more details.

```javascript
createAttribute("Country")
```

Creates a `Country` attribute node.

- To set a value to the attribute, use the method `setNodeValue` of the `xml.DomNode` class.
- To add the attribute to an element node, use the method `setAttributeNode` of the `xml.DomNode` class.

```javascript
createAttributeNS("tw","Town","http://www.mysite.com/cities")
```

Produces `xmlns:tw="http://www.mysite.com/cities" tw:Town="`

- To set a value to the attribute use the method `setNodeValue` of the `xml.DomNode` class.
- To add the attribute to an element node use the method `setAttributeNodeNS` of the `xml.DomNode` class.
- For optimization reasons, the namespace is not written beside the attribute until the saving of the `DomDocument`.
- When accessing the element node, the namespace is not listed in the list of children. In the example above, `tw:Town=""` is in the list of children, not `xmlns:tw="http://www.mysite.com/cities"`.
- To access the namespace during the `DomDocument` building, use the method `normalize` first. Normalize writes the namespace declaration at the appropriate place. If there is no previous declaration, it will be accessible as an attribute of this element, otherwise it will be an attribute of one of the ancestors of the element.

```javascript
createTextNode("My Company")
```

Creates a text node.

```javascript
createComment("End of the card")
```
createCDATASection("<website><a href="www.mysite.com">My Company</a></website>")

Produces <!--End of the card-->

createEntityReference("title")

Creates the entity reference &title.

createProcessingInstruction("xml-stylesheet", "type="text/xsl" href="card.xsl")

Produces <?xml-stylesheet type="text/xsl" href="card.xsl"?>

createDocumentType("Card", NULL, NULL, "<!ELEMENT Card (lastname, firstname, company, location)>")

Produces <!DOCTYPE Card [ <!ELEMENT Card (lastname, firstname, company, location)>]>
DEFINE nodeLst xml.DomNodeList
TRY
  LET myDoc = xml.DomDocument.create()
  CALL myDoc.setFeature("enable-html-compliancy", 1)
  CALL myDoc.load("testHtml.html")
  LET myEltNode = myDoc.CreateElement("script")
  LET myCdataNode = myDoc.CreateCDATASection("document.write("CDATA");")
  LET myAttrNode = myDoc.CreateAttribute("type")
  CALL myAttrNode.setNodeValue("text/javascript")
  LET nodeLst = myDoc.getElementsByTagName("body")
  LET bodyNode = nodeLst.getItem(1)
  CALL bodyNode.appendChild(myEltNode)
  CALL myEltNode.setAttributeNode(myAttrNode)
  CALL myEltNode.appendChild(myCdataNode)
CATCH
  DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
  EXIT PROGRAM(-1)
END TRY
END MAIN

Load and save methods usage examples
Load and save method usage examples for the xml.DomDocument class.

You can load an existing XML document. Before loading an XML document you need to create the DomDocument object.

A DomDocument can load files using different URI: http://, https://, tcp://, tcps://, file:// and alias://.

See getErrorsCount() and getErrorDescription() to retrieve error messages related to XML document.

```
load("data.xml")
load("http://www.w3schools.com/xml/cd_catalog.xml")
load("https://localhost:6394/ws/r/calculator?WSDL")
load("file:///data/cd_catalog.xml")
load("tcp://localhost:4242/")
load("tcps://localhost:4243/")
load("alias://demo")
```

In the example the demo alias is defined in fglprofile as ws.demo.url = "http://www.w3schools.com/xml/cd_catalog.xml"

```
loadfromstring("<List> <elt>First element</elt> <elt>Second element</elt> <elt>Third element</elt> </List>")
```

The example, produces a subtree with a root node List and three nodes elt and three textnode.

A DomDocument can be saved at different URI beginning with: http://, https://, tcp://, tcps://, file:// and alias://.

```
save("myfile.xml")
save("http://myserver:8080/data/save1.xml")
save("file:///data/save.xml")
save("tcp://localhost:4242/"
save("alias://test")
```

In the example the test alias is defined in fglprofile as ws.test.url = "http://localhost:8080/data/save3.xml"

The saveToString method saves the DomDocument in a string.

See getErrorsCount() and getErrorDescription() to retrieve error messages related to XML document.
The `normalize` function emulates a `DomDocument` save and load. It can be called at any stage of the `DomDocument` building. This removes empty Text nodes and sets namespace declarations as if the document had been saved.

**Cautions**
Some things you need to be aware of when working with the `xml.DomDocument` class.

Whitespaces, line feeds and carriage returns between elements are represented as text nodes in memory. A XML document written in a single line and a human readable (pretty printed format) do not have the same representation in the `DomDocument`. Take this into account when navigating in the document.

If a `xml.DomNode` is not attached to a `DomDocument` and not referenced by any variable it can be destroyed. If one child of this node is still referenced, this child is not destroyed but its parent and the other nodes of the subtree are destroyed. To check if a node is attached to a `DomDocument` use `isAttached` method.

The `DomDocument` remains in memory if any of its nodes are still referenced in a variable.

**DomDocument Features**
A list of features for the `xml.DomDocument` class.

**Table 594: DomDocument Features**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>format-pretty-print</code></td>
<td>Formats the output by adding white space to produce a pretty-printed, indented, human-readable form.</td>
</tr>
<tr>
<td></td>
<td>Possible values are TRUE or FALSE.</td>
</tr>
<tr>
<td></td>
<td>Default value is FALSE.</td>
</tr>
<tr>
<td><code>comments</code></td>
<td>Defines whether the XML comments are kept during the loading of a document into a <code>DomDocument</code> object.</td>
</tr>
<tr>
<td></td>
<td>Possible values are TRUE or FALSE.</td>
</tr>
<tr>
<td></td>
<td>Default value is TRUE.</td>
</tr>
<tr>
<td><code>whitespace-in-element-content</code></td>
<td>Defines whether XML Text nodes that can be considered &quot;Ignorable&quot; are kept during the loading of an XML document into a <code>DomDocument</code> object.</td>
</tr>
<tr>
<td></td>
<td>Possible values are TRUE or FALSE.</td>
</tr>
<tr>
<td></td>
<td>Default value is TRUE.</td>
</tr>
<tr>
<td><code>cdata-sections</code></td>
<td>Defines whether XML CData nodes are kept or replaced by XML Text nodes during the loading of an XML document into a <code>DomDocument</code> object.</td>
</tr>
<tr>
<td></td>
<td>Possible values are TRUE or FALSE.</td>
</tr>
<tr>
<td></td>
<td>Default value is TRUE.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>expand-entity-references</td>
<td>Defines whether XML EntityReference nodes are kept or replaced during the loading of an XML document into a DomDocument object. Possible values are TRUE or FALSE. Default value is FALSE. <strong>Note:</strong> See security issues with expand-entity-references.</td>
</tr>
<tr>
<td>validation-type</td>
<td>Defines what kind of validation is performed. Possible values are: DTD, Schema. Default is Schema.</td>
</tr>
<tr>
<td>external-schemaLocation</td>
<td>Defines a list of namespace-qualified XML schemas to use for validation on a DomDocument object. Value is a space-separated string of one or several pairs of strings representing the namespace URI of the schema, followed by its location.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td>external-noNamespaceSchemaLocation</td>
<td>Defines a list of XML schemas to use for validation on a DomDocument object. Value is a space-separated string of one or several strings representing the location of a schema.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>&quot;mySchema1.xsd mySchema2.xsd&quot;</td>
</tr>
<tr>
<td>schema-uriRecovery</td>
<td>Changes the schema location of an XML schema referenced by import tags in other schemas. Value is a space-separated string of one or several pairs of strings representing the original schema location followed by the new schema location.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>&quot;<a href="http://www.w3.org/2001/xml.xsd">http://www.w3.org/2001/xml.xsd</a> myXML.xsd <a href="http://www.mycompany.com/GWS.xsd">http://www.mycompany.com/GWS.xsd</a> myGWS.xsd&quot;</td>
</tr>
<tr>
<td>load-save-base64-string</td>
<td>Changes methods loadFromString() and saveToString() to handle Base64 strings. Parsing an XML document is done from a BASE64 encoded string, and saving an XML document results in a BASE64 encoded string. Possible values are TRUE or FALSE. Default is FALSE.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>auto-id-attribute</td>
<td>Changes the parsing of an XML document in order to set all unqualified attributes named ID, Id, iD or id to be of type ID.</td>
</tr>
<tr>
<td></td>
<td>They can then be retrieved with method getElementById() or with an XPath expression without calling setIdAttribute().</td>
</tr>
<tr>
<td></td>
<td>Possible values are TRUE or FALSE.</td>
</tr>
<tr>
<td></td>
<td>Default is FALSE.</td>
</tr>
<tr>
<td>auto-id-qualified-attribute</td>
<td>Changes the parsing of an XML document in order to set all qualified attributes named ID, Id, iD or id to be of type ID.</td>
</tr>
<tr>
<td></td>
<td>They can then be retrieved with method getElementById() or with an XPath expression without calling setIdAttributeNS().</td>
</tr>
<tr>
<td></td>
<td>Possible values are TRUE or FALSE.</td>
</tr>
<tr>
<td></td>
<td>Default is FALSE.</td>
</tr>
<tr>
<td>enable-html-compliancy</td>
<td>Changes methods to parse, normalize and save HTML document via the DomDocument object.</td>
</tr>
<tr>
<td></td>
<td>Possible values are TRUE or FALSE.</td>
</tr>
<tr>
<td></td>
<td>Default value is FALSE.</td>
</tr>
<tr>
<td></td>
<td>The HTML parsing isn't namespace qualified, and document is considered as an XML document after loading.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This feature works only for HTML 4, it is not supported for HTML 5.</td>
</tr>
</tbody>
</table>

**Security issues with expand-entity-references**

For example, in its DTD, the following XML file defines the myref ENTITY element referencing the /etc/passwd file:

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
<!DOCTYPE foo [  
  <!ELEMENT foo ANY >
  <!ENTITY myref SYSTEM "file:///etc/passwd">
  ]>  
<foo>&myref;</foo>
```

When loading this XML file with expand-entity-references set to TRUE, the resulting DOM document will have a `<foo>` node containing a text node with the content of `/etc/passwd`. 
Examples
xml.DomDocument usage examples.
Example 1: Create a namespace qualified document with processing instructions

To create the following XML document on disk:

```xml
<?Target1 This is my first PI ?>
<MyPre:RootNode xmlns:MyPre="http://www.tempuri.org">
<MyPre:Element />
</MyPre:RootNode>
<?Target2 This is my last PI ?>
```

Write the following code:

```xml
IMPORT xml

MAIN
DEFINE doc xml.DomDocument
DEFINE pi xml.DomNode
DEFINE node xml.DomNode
DEFINE elt xml.DomNode

# Create a document with an initial namespace qualified root node
# Create a Processing instruction
LET pi = doc.createProcessingInstruction("Target1", "This is my first PI")
# And add it at the begining of the document
CALL doc.prependDocumentNode(pi)
# Create another Processing instruction
LET pi = doc.createProcessingInstruction("Target2", "This is my last PI")
# And add it at the end of the document
CALL doc.appendDocumentNode(pi)
# Retrieve initial root node of the document
LET elt = doc.getDocumentElement()
# Create a new Element node
LET node = doc.createElementNS("MyPre", "Element", "http://www.tempuri.org")
# And add it as child of the RootNode
CALL elt.appendChild(node)
# Then save the document on disk
CALL doc.save("MyFile.xml")
END MAIN
```

Example 2: Validating a document against XML schemas or a DTD

This code example loads one or more XML schemas or uses an embedded DTD to validate against a XML document:

```xml
IMPORT xml

MAIN
DEFINE location STRING
DEFINE xmlfile STRING
DEFINE doc xml.DomDocument
DEFINE ind INTEGER

IF num_args() < 2 THEN
    # Checks the number of arguments
    CALL ExitHelp()
ELSE
    LET doc = xml.DomDocument.Create()
    LET xmlfile = arg_val(num_args())
    IF num_args() == 2 AND arg_val(1) == "-dtd" THEN
```
# User choosed DTD validation
CALL doc.setFeature("validation-type", "DTD")
ELSE
# User choosed XML Schema validation
IF arg_val(1) == "-ns" THEN
  # Handle namespace qualified XML schemas
  IF num_args() MOD 2 != 0 THEN
    CALL ExitHelp()
  END IF
  FOR ind = 2 TO num_args()-1 STEP 2
    IF location IS NULL THEN
      LET location = arg_val(ind) || " " || arg_val(ind+1)
    ELSE
      LET location = location || " " || arg_val(ind) || " " || arg_val(ind+1)
    END IF
  END FOR
  TRY
    CALL doc.setFeature("external-schemaLocation", location)
  CATCH
    FOR ind = 1 TO doc.getErrorsCount()
      DISPLAY "Schema error (" || ind || ") :", doc.getErrorDescription(ind)
    END FOR
    EXIT PROGRAM (-1)
  END TRY
ELSE
  # Handle unqualified XML schemas
  FOR ind = 1 TO num_args()-1
    IF location IS NULL THEN
      LET location = arg_val(ind)
    ELSE
      LET location = location || " " || arg_val(ind)
    END IF
  END FOR
  TRY
    CALL doc.setFeature("external-noNamespaceSchemaLocation", location)
  CATCH
    FOR ind = 1 TO doc.getErrorsCount()
      DISPLAY "Schema error (" || ind || ") :", doc.getErrorDescription(ind)
    END FOR
    EXIT PROGRAM (-1)
  END TRY
END IF
END IF
TRY
  # Load XML document from disk
  CALL doc.load(xmlfile)
CATCH
  # Display errors if loading fails
  IF doc.getErrorsCount()>0 THEN
    FOR ind = 1 TO doc.getErrorsCount()
      DISPLAY "LOADING ERROR #" || ind || ":", doc.getErrorDescription(ind)
    END FOR
    EXIT PROGRAM(-1)
  ELSE
    DISPLAY "Unable to load file ":xmlfile
    EXIT PROGRAM(-1)
  END IF
END TRY
TRY
# Validate loaded document
LET ind = doc.validate()
IF ind == 0 THEN
    # Successful validation
    DISPLAY "OK"
ELSE
    # Display validation errors
    FOR ind = 1 TO doc.getErrorsCount()
        DISPLAY "VALIDATING ERROR #"||ind||":",doc.getErrorDescription(ind)
    END FOR
    EXIT PROGRAM(-1)
END IF
CATCH
    DISPLAY "Unable to validate file :",xmlfile
    EXIT PROGRAM(-1)
END TRY
END MAIN

# Display help
FUNCTION ExitHelp()
    DISPLAY "Validator < -dtd | -ns [namespace schema]+ | [schema]+ > xmlfile"
    EXIT PROGRAM
END FUNCTION

Example

$ fglrun Validator -dtd MyFile.xml
Validates XML file using DTD embedded in the XML file.

$ fglrun Validator Schema1.xsd Schema2.xsd MyFile.xml
Validates unqualified XML file using two unqualified XML schemas.

Validates namespace qualified XML file using two namespace qualified XML schemas.

The DomNode class
The xml.DomNode class provides methods to manipulate a node of a DomDocument object.

You can create a DomNode object using creation methods in the DomDocument class.

The STATUS variable is set to zero after a successful method call.
**xml.DomNode methods**
Methods for the xml.DomNode class.

Table 595: Object methods: Navigation

### Table 596: Object methods: Manipulation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| `clone(  
  deep INTEGER  
) RETURNS xml.DomNode`               | Returns a duplicate DomNode object of a node.                                |
| `appendChild(  
  newChild xml.DomNode  
)`                                   | Adds a child DomNode object to the end of the child list for a DomNode object. |
| `appendChildElement(  
  name STRING  
) RETURNS xml.DomNode`                       | Creates and adds a child XML Element node to the end of the list of child nodes for an XML Element DomNode object. |
| `appendChildElementNS(  
  prefix STRING,  
  name STRING,  
  ns STRING  
) RETURNS xml.DomNode`                 | Creates and adds a child namespace qualified XML Element node to the end of the list of child nodes for an XML Element DomNode object. |
| `addNextSibling(  
  newNode xml.DomNode  
)`                                    | Adds a DomNode object as the next sibling of a DomNode object.               |
| `addPreviousSibling(  
  newNode xml.DomNode  
)`                                   | Adds a DomNode object as the previous sibling of a DomNode object.            |
| `insertBeforeChild(  
  newChild xml.DomNode,  
  refChild xml.DomNode  
)`                          | Inserts a DomNode object before an existing child DomNode object.            |
| `insertAfterChild(  
  newChild xml.DomNode,  
  refChild xml.DomNode  
)`                           | Inserts a DomNode object after an existing child DomNode object.             |
| `prependChild(  
  newChild xml.DomNode  
)`                                    | Adds a child DomNode object to the beginning of the child list for a DomNode object. |
| `prependChildElement(  
  name STRING  
) RETURNS xml.DomNode`                       | Creates and adds a child XML Element node to the beginning of the list of child nodes for this XML Element DomNode object. |
| `prependChildElementNS(  
  prefix STRING,  
  name STRING,  
  ns STRING  
) RETURNS xml.DomNode`                 | Creates and adds a child namespace-qualified XML Element node to the beginning of the list of child nodes for an XML Element DomNode object. |
| `removeAllChildren()`                                                      | Removes all child DomNode objects from a DomNode object.                    |
| `removeChild(  
  oldChild xml.DomNode  
)`                                    | Removes a child DomNode object from the list of child DomNode objects.       |

</tbody>
</table>

xml.DomNode.addPreviousSibling

Adds a DomNode object as the previous sibling of a DomNode object.

**Syntax**

```plaintext
