addPreviousSibling(  
  newNode xml.DomNode  )
```

1. `newNode` defines the node to add.

**Usage**

Adds a DomNode object as the previous sibling of this DomNode object; `newNode` is the node to add.

**Important:** This method is not part of W3C standard API.

The DomNode object node must be the child of an element or document node; otherwise the operation fails.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.addNextSibling
Adds a DomNode object as the next sibling of a DomNode object.

**Syntax**

```
addNextSibling(
    newNode xml.DomNode )
```

1. *newNode* defines the node to add.

**Usage**

Adds a DomNode object as the next sibling of this DomNode object; *newNode* is the node to add.

**Important:** This method is not part of W3C standard API.

The DomNode object node must be the child of an element or document node; otherwise the operation fails.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

```java
xml.DomNode.appendChild
```

Adds a child DomNode object to the end of the child list for a DomNode object

**Syntax**

```
appendChild(
    newChild xml.DomNode )
```

1. *newChild* defines the node to add

**Usage**

Adds a child DomNode object to the end of the child list for this DomNode object.

The DomNode object node must be the child of an element or document node; otherwise the operation fails.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

```java
xml.DomNode.appendChildElement
```

Creates and adds a child XML Element node to the end of the list of child nodes for an XML Element DomNode object.

**Syntax**

```
appendChildElement(
    name STRING )
    RETURNS xml.DomNode
```

1. *name* defines the XML Element name.

**Usage**

Creates and adds a child XML Element node to the end of the list of child nodes for this XML Element DomNode object.

**Important:** This method is not part of W3C standard API.

Returns the XML element DomNode object, or NULL.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomNode.appendChildElementNS**

Creates and adds a child namespace qualified XML Element node to the end of the list of child nodes for an XML Element DomNode object.

**Syntax**

```java
appendChildElementNS(
    prefix STRING,
    name STRING,
    ns STRING
) RETURNS xml.DomNode
```

1. `prefix` defines the prefix of the XML Element to add.
2. `name` defines the name of the XML Element to add.
3. `ns` defines the namespace URI of the XML Element to add.

**Usage**

Creates and adds a child namespace qualified XML Element node to the end of the list of child nodes for this XML Element DomNode object.

**Important:** This method is not part of W3C standard API.

Returns the XML element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomNode.clone**

Returns a duplicate DomNode object of a node.

**Syntax**

```java
clone(
    deep INTEGER )
RETURNS xml.DomNode
```

1. `deep` defines a boolean. If `deep` is TRUE, child DomNode objects are cloned too; otherwise only the DomNode itself is cloned.

**Usage**

Returns a duplicate DomNode object of this node. If `deep` is TRUE, child DomNode objects are cloned too; otherwise only the DomNode itself is cloned.

Returns a copy of this xml.DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomNode.getAttribute**
Returns the value of a XML Attribute for an XML Element DomNode object

**Syntax**

```java
getAttribute(
    name STRING
) RETURNS STRING
```

1. `name` defines the name of the XML attribute to retrieve.

**Usage**

Returns the value of a XML Attribute for this XML Element DomNode object, where `name` is the name of the XML attribute to retrieve.

Returns the XML attribute value, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getAttributeNode

Returns an XML Attribute DomNode object for an XML Element DomNode object

**Syntax**

```java
getAttributeNode(
    name STRING
) RETURNS xml.DomNode
```

1. `name` defines the name of the attribute to retrieve.

**Usage**

Returns an XML attribute DomNode object for this XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getAttributeNodeItem

Returns the XML Attribute DomNode object at a given position on this XML Element DomNode object.

**Syntax**

```java
getAttributeNodeItem(
    index INTEGER
) RETURNS xml.DomNode
```

1. `index` defines the position of the node to return.

**Usage**

Returns the XML Attribute DomNode object at a given position on this XML Element DomNode object, where `index` is the position of the node to return (Index starts at 1).

Returns the XML Attribute DomNode object at the given position, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.
xml.DomNode.getAttributeNodeNS
Returns a namespace-qualified XML Attribute DomNode object for an XML Element DomNode object

Syntax

```plaintext
getAttributeNodeNS(
    name STRING,
    ns STRING
) RETURNS xml.DomNode
```

1. `name` defines the name of the XML Attribute to retrieve.
2. `ns` defines the namespace URI of the XML Attribute to retrieve.

Usage

Returns a namespace-qualified XML Attribute DomNode object for this XML Element DomNode object, or NULL. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getAttributeNS
Returns the value of a namespace qualified XML Attribute for an XML Element DomNode object

Syntax

```plaintext
getAttributeNS(
    name STRING,
    ns STRING
) RETURNS STRING
```

1. `name` defines the name.
2. `ns` defines the namespace URI of the XML Attribute to retrieve

Usage

Returns the value of a namespace qualified XML Attribute for this XML Element xml.DomNode object, where `name` is the name and `ns` is the namespace URI of the XML Attribute to retrieve.

Returns the XML attribute value, or NULL. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getAttributesCount
Returns the number of XML Attribute DomNode objects on this XML Element DomNode object.

Syntax

```plaintext
getAttributesCount()
RETURNS INTEGER
```

Usage

Returns the number of XML Attribute xml.DomNode objects on this XML Element DomNode object.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getChildNodeItem
Returns the child DomNode object at a given position for a DomNode object.

Syntax

```
getChildNodeItem(
   index INTEGER )
RETURNS xml.DomNode
```

1. index defines the position of the child node in the collection.

Usage
Returns the child DomNode object at a given position for this DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getChildrenCount
Returns the number of child DomNode objects for a DomNode object.

Syntax

```
getChildrenCount ()
RETURNS INTEGER
```

Usage
Returns the number of child xml.DomNode objects for this DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getElementsByTagName
Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name.

Syntax

```
getElementsByTagName (tag STRING )
RETURNS xml.DomNodeList
```

1. tag defines the name of the XML Element tag to match or "*" to match all tags.

Usage
Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name, or NULL; tag is the name of the XML Element tag to match, or "*" to match all tags.

The getElementsByTagName and getElementsByTagNameNS methods return a xml.DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is restricted to objects with the same tag name and/or namespace.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomNode.getElementsByTagNameNS**

Returns a DomNodeList object containing all namespace-qualified XML Element DomNode objects with the same tag name and namespace.

**Syntax**

```java
getElementsByTagNameNS (tag STRING, ns STRING ) RETURNS xml.DomNodeList
```

1. `tag` defines the name of the XML Element tag to match or "*" to match all tags.
2. `ns` defines the namespace URI of the XML Element tag to match or "*" to match any namespace.

**Usage**

Returns a DomNodeList object containing all namespace-qualified XML Element DomNode objects with the same tag name and namespace, or NULL. `tag` is the name of the XML Element tag to match, or "*" to match all tags; `ns` is the namespace URI of the XML Element tag to match, or "*" to match any namespace.

The `getElementsByTagNameNS` and `getElementsByTagName` methods return a DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is restricted to contain objects with the same tag name and/or namespace.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomNode.getFirstChild**

Returns the first child DomNode object for this XML Element DomNode object.

**Syntax**

```java
getFirstChild () RETURNS xml.DomNode
```

**Usage**

Returns the first child DomNode object for this XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomNode.getFirstChildElement**

Returns the first XML Element child DomNode object for this DomNode object.

**Syntax**

```java
getFirstChildElement () RETURNS xml.DomNode
```

**Usage**

Returns the first XML Element child DomNode object for this DomNode object, or NULL.
**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.DomNode.getLastChild`

Returns the last child `DomNode` object for a XML Element `DomNode` object.

**Syntax**

```java
getLastChild()
RETURNS xml.DomNode
```

**Usage**

Returns the last child `DomNode` object for this XML Element `DomNode` object, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.DomNode.getLastChildElement`

Returns the last child XML element `DomNode` object for this `DomNode` object.

**Syntax**

```java
getLastChildElement()
RETURNS xml.DomNode
```

**Usage**

Returns the last child XML element `DomNode` object for this `DomNode` object, or NULL.

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.DomNode.getLocalName`

Gets the local name for a `DomNode` object.

**Syntax**

```java
getLocalName()
RETURNS STRING
```

**Usage**

Gets the local name for this `DomNode` object. If `xml.DomNode` has a qualified name, only the local part is returned.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.DomNode.getNamespaceURI`
Returns the namespace URI for a DomNode object.

**Syntax**

```plaintext
getNamespaceURI ()
RETURNS STRING
```

**Usage**

This method returns the namespace URI for this xml.DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getNextSibling

- Returns the DomNode object immediately following a DomNode object.

**Syntax**

```plaintext
getNextSibling ()
RETURNS xml.DomNode
```

**Usage**

Returns the xml.DomNode object immediately following this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getNextSiblingElement

- Returns the XML Element DomNode object immediately following a DomNode object.

**Syntax**

```plaintext
getNextSiblingElement ()
RETURNS xml.DomNode
```

**Usage**

Returns the XML Element xml.DomNode object immediately following this DomNode object, or NULL.

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getNodeName

- Gets the name for a DomNode object.

**Syntax**

```plaintext
getNodeName ()
RETURNS STRING
```
Usage

Gets the name for this xml.DomNode object. This method returns the qualified name of the DomNode object, or NULL. If DomNode does not have a qualified name, the local part is returned.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getNodeType

Gets the XML type for this DomNode object.

Syntax

```
getNodeType ()
RETURNS STRING
```

Usage

This method returns the XML type for this DomNode object; it returns one of the XML DomNode types, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getNodeValue

Returns the value for a DomNode object.

Syntax

```
getNodeValue ()
RETURNS STRING
```

Usage

Use this method to return the value for this xml.DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getOwnerDocument

Returns the DomDocument object containing this DomNode object.

Syntax

```
getOwnerDocument ()
RETURNS xml.DomDocument
```

Usage

This method returns the xml.DomDocument object containing this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getParentNode

Returns the parent node of this DomNode object.
>Returns the parent DomNode object for this DomNode object.

**Syntax**

```
getParentNode ()
RETURNS xml.DomNode
```

**Usage**

This method returns the parent xml.DomNode object for this DomNode object, or NULL. In the case of a xml.DomDocument node, this method will return NULL (parent is not a DomNode object) but isAttached() will return TRUE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomNode.getPrefix**

Returns the prefix for a DomNode object.

**Syntax**

```
getPrefix ()
RETURNS STRING
```

**Usage**

This method returns the prefix for this xml.DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomNode.getPreviousSibling**

Returns the DomNode object immediately preceding a DomNode object.

**Syntax**

```
getPreviousSibling ()
RETURNS xml.DomNode
```

**Usage**

Use this method to return the xml.DomNode object immediately preceding this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomNode.getPreviousSiblingElement**

Returns the XML Element DomNode object immediately preceding a DomNode object.

**Syntax**

```
getPreviousSiblingElement ()
RETURNS xml.DomNode
```
Usage

Use this method to return the XML Element DomNode object immediately preceding this DomNode object, or NULL.

Important: This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.hasAttribute

Checks whether an XML Element DomNode object has the XML Attribute specified by a specified name.

Syntax

```java
hasAttribute (name STRING)
RETURNS INTEGER
```

1. `name` defines the object name to check.

Usage

Checks whether this XML Element DomNode object has the XML Attribute specified by `name`. Returns TRUE if an XML Attribute with the given name is carried by this XML Element DomNode object, otherwise returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.hasAttributeNS

Checks whether a namespace qualified XML Attribute of a given name is carried by an XML Element DomNode object.

Syntax

```java
hasAttributeNS (name STRING, ns STRING)
RETURNS INTEGER
```

1. `name` defines the name of the XMLAttribute to check
2. `ns` defines the namespace URI of the XML Attribute to check.

Usage

Use this method to check whether a namespace qualified XML Attribute of a given name is carried by this XML Element DomNode object, where `name` is the name of the XMLAttribute to check; `ns` the namespace URI of the XML Attribute to check. Returns TRUE if an XML Attribute with the given name and namespace URI is carried by this XML Element DomNode object, otherwise returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.hasAttributes
Identifies whether a node has XML Attribute nodes.

**Syntax**

```
hasAttributes()
RETURNS INTEGER
```

**Usage**

This method returns TRUE if this node has XML Attribute nodes; otherwise returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

```
xmldomnode.hasChildNodes
```

Returns TRUE if a node has child nodes.

**Syntax**

```
hasChildNodes()
RETURNS INTEGER
```

**Usage**

Use this method to check if a node has child nodes. It returns TRUE if this node has child nodes; otherwise, returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

```
xmldomnode.insertAfterChild
```

Inserts a DomNode object after an existing child DomNode object.

**Syntax**

```
insertAfterChild(
    newChild xml.domnode,
    refChild xml.domnode
)
```

1. `newChild` defines the node to insert.
2. `refChild` defines the reference node (the node before which the new node must be inserted).

**Usage**

Use this method to inserts a DomNode object after an existing child DomNode object; `newChild` is the node to insert, `refChild` is the reference node (the node before which the new node must be inserted).

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

```
xmldomnode.insertBeforeChild
```
Inserts a DomNode object before an existing child DomNode object.

**Syntax**

```
insertBeforeChild(
    newChild xml.DomNode,
    refChild xml.DomNode)
```

1. `newChild` defines the node to insert.
2. `refChild` defines the reference node (the node before which the new node must be inserted).

**Usage**

Use this method to insert a DomNode object before an existing child DomNode object; `newChild` is the node to insert, `refChild` is the reference node (the node before which the new node must be inserted).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomNode.isAttached**

Returns whether the node is attached to the XML document.

**Syntax**

```
isAttached()  
RETURNS INTEGER
```

**Usage**

The returned integer indicates whether the node is attached to the XML document or not.

**Important:** This method is not part of W3C standard API.

This method returns TRUE if the DomNode object is attached to a xml.DomDocument object as a child; otherwise it returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.DomNode.isDefaultNamespace**

Checks whether the specified namespace URI is the default namespace.

**Syntax**

```
isDefaultNamespace(
    ns STRING )  
RETURNS INTEGER
```

1. `ns` defines the namespace URI to look for.

**Usage**

Use this method to check whether the specified namespace URI is the default namespace, where `ns` is the namespace URI to look for. Returns TRUE if the given namespace is the default namespace, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
xml.DomNode.lookupNamespaceURI
Looks up the namespace URI associated to a prefix, starting from a specified node.

**Syntax**

```java
lookupNamespaceURI ( prefix STRING )
RETURNS STRING
```

1. `prefix` defines the prefix to look for.

**Usage**

Use this method to look up the namespace URI associated with a prefix, starting from this node, where `prefix` is the prefix to look for. If `NULL`, the default namespace URI will be returned. A namespace URI, or `NULL`, is returned.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.lookupPrefix
Looks up the prefix associated to a namespace URI, starting from the specified node.

**Syntax**

```java
lookupPrefix ( ns STRING )
RETURNS STRING
```

1. `ns` defines the namespace URI to look for.

**Usage**

Use this method to look up the prefix associated with a namespace URI, starting from this node, where `ns` is the namespace URI to look for. Returns the prefix associated with this namespace URI, or `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.prependChild
Adds a child `DomNode` object to the beginning of the child list for a `DomNode` object.

**Syntax**

```java
prependChild ( newChild xml.DomNode )
```

1. `newChild` defines the node to add.

**Usage**

Use this method to add a child `DomNode` object to the beginning of the child list for this `DomNode` object; `newChild` is the node to add.

**Important:** This method is not part of W3C standard API.

The `DomNode` object node must be the child of an element or document node, otherwise the operation fails.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.prependChildElement

Creates and adds a child XML Element node to the beginning of the list of child nodes for this XML Element DomNode object.

**Syntax**

```plaintext
prependChildElement(
    name STRING
)
RETURNS xml.DomNode
```

1. *name* defines the name of the XML element to add.

**Usage**

Use this method to create and add a child XML Element node to the beginning of the list of child nodes for this XML Element DomNode object; *name* is the name of the XML element to add.

It returns the XML Element DomNode object, or NULL.

**Important**: This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.prependChildElementNS

Creates and adds a child namespace-qualified XML Element node to the beginning of the list of child nodes for an XML Element DomNode object.

**Syntax**

```plaintext
prependChildElementNS(
    prefix STRING,
    name STRING,
    ns STRING
)
RETURNS xml.DomNode
```

1. *prefix* defines the prefix of the XML Element to add.
2. *name* defines the name of the XML Element to add.
3. *ns* defines the namespace URI of the XML Element to add.

**Usage**

Use this method to create and add a child namespace-qualified XML Element node to the beginning of the list of child nodes for this XML Element DomNode object.

It returns the XML Element DomNode object, or NULL.

**Important**: This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.removeAllChildren
Removes all child DomNode objects from a DomNode object.

**Syntax**

```java
removeAllChildren()
```

**Usage**

Use this method to remove all child xml.DomNode objects from this DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.removeAttribute

Removes an XML Attribute for an XML Element DomNode object.

**Syntax**

```java
removeAttribute (name STRING)
```

1. `name` defines the name of the XML attribute to remove.

**Usage**

Use this method to remove an XML Attribute for this XML Element DomNode object, where `name` is the name of the XML attribute to remove. Status is updated with an error code.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.removeAttributeNS

Removes a namespace qualified XML Attribute for an XML Element DomNode object

**Syntax**

```java
removeAttributeNS (name STRING, ns STRING)
```

1. `name` defines the name of the XML Attribute to remove.
2. `ns` defines the namespace URI of the XML Attribute to remove.

**Usage**

Use this method to remove a namespace qualified XML Attribute for this XML Element DomNode object, where `name` is the name and `ns` is the namespace URI of the XML Attribute to remove.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.removeChild
Removes a child DomNode object from the list of child DomNode objects.

**Syntax**

```java
removeChild(
    oldChild xml.DomNode  )
```

1. *oldChild* defines the node to remove.

**Usage**

Use this method to remove a child **DomNode** object from a list of child **DomNode** objects, where *oldchild* is the node to remove.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See **Error handling in GWS calls (STATUS)** on page 3280.

**xml.DomNode.replaceChild**

Replaces an existing child DomNode with another child DomNode object.

**Syntax**

```java
replaceChild(
    newChild xml.DomNode,
    oldChild xml.DomNode  )
```

1. *newChild* defines the replacement child.
2. *oldChild* defines the child to be replaced.

**Usage**

Use this method to replace an existing child **DomNode** with another child **DomNode** object, where *oldChild* is the child to be replaced and *newChild* is the replacement child.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See **Error handling in GWS calls (STATUS)** on page 3280.

**xml.DomNode.selectByXPath**

Returns a DomNodeList object containing all DomNode objects matching an XPath 1.0 expression.

**Syntax**

```java
selectByXPath(  
    expr STRING,
    args ...)
    RETURNS xml.DomNodeList
```

1. *expr* defines the XPath 1.0 expression.
2. *args* defines a list of prefixes bound to namespaces in order to resolve qualified names in the XPath expression.

**Usage**

This method returns a **DomNodeList** object containing all **DomNode** objects matching an XPath 1.0 expression; *expr* is the XPath 1.0 expression, *args* is a list of prefixes bound to namespaces in order to resolve qualified names in the XPath expression. This list must be filled with an even number of arguments, representing the prefix and it corresponding namespace.
Important: This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Example

```xml
selectByXPath("../../d:Record/*[last()]", "d", "http://defaultnamespace")
selectByXPath("ns:Record", NULL)
selectByXPath("ns1:Records/ns2:Record", "ns1", "http://namespace1", "ns2", "http://namespace2")
```

selectByXPath("ns1:Record", "ns1") is invalid because the namespace definition is missing.

If the namespaces list is NULL, the prefixes and namespaces defined in the document itself are used if available.

A namespace must be an absolute URI (ex 'http://', 'file://').

xml.DomNode.setAttribute
Sets (or resets) an XML Attribute for an XML Element DomNode object.

Syntax

```xml
setAttribute (name STRING, value STRING)
```

1. `name` defines the name of the XML Attribute.
2. `value` defines the value of the XML Attribute.

Usage

Use this method to set (or reset) an XML Attribute for this XML Element DomNode object, where `name` is the name of the XML Attribute and `value` is the value of the XML Attribute.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.setAttributeNode
Sets (or resets) an XML Attribute DomNode object to an XML Element DomNode object.

Syntax

```xml
setAttributeNode (attr xml.DomNode)
```

1. `attr` defines the XML Attribute DomNode object to set.
Usage

Use this method to set (or reset) an XML Attribute DomNode object to an XML Element DomNode object, where attr is the XML Attribute DomNode object to set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.setAttributeNodeNS

Sets (or resets) a namespace-qualified XML Attribute DomNode object to an XML Element DomNode object.

Syntax

```
setAttributeNodeNS(
    attr xml.DomNode
)
```

1. attr defines the XML Attribute DomNode object to set.

Usage

Use this method to set (or reset) a namespace-qualified XML Attribute DomNode object to an XML Element DomNode object, where attr is the XML Attribute DomNode object to set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.setAttributeNS

Sets (or resets) a namespace-qualified XML Attribute for an XML Element DomNode object.

Syntax

```
setAttributeNS(
    prefix STRING,
    name STRING,
    ns STRING,
    value STRING
)
```

1. prefix defines the prefix of the XML Attribute.
2. name defines the name of the XML Attribute.
3. ns defines the namespace URI of the XML Attribute.
4. value defines the value of the XML Attribute.

Usage

Use this method to set (or reset) a namespace-qualified XML Attribute for this XML Element DomNode object, where prefix is the prefix of the XML Attribute, name is the name of the XML Attribute, ns is the namespace URI of the XML Attribute, and val is the value of the XML Attribute.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.setIdAttribute

Set the XML Attribute of given name to be of type ID. Declare (or undeclare) the ID as user-determined.

Syntax

```
setIdAttribute()
```

Usage
name STRING,
isd INTEGER )

1. name defines the name of the XML Attribute to set.
2. isd declares whether the attribute is a user-determined ID attribute.

Usage

Use this method to set (or reset) the XML Attribute of given name to be of type ID. Use the value TRUE for the parameter isd, to declare the attribute as a user-determined ID attribute, otherwise use FALSE.

This affects the behavior of getElementById.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.setIdAttributeNS

Set the namespace-qualified XML Attribute of given name and namespace to be of type ID. Declare (or undeclare) the ID as user-determined.

Syntax

setIdAttributeNS( 
   name STRING,
   ns STRING,
   isd INTEGER )

1. name defines the name of the XML Attribute to set.
2. ns defines the namespace URI of the XML Attribute to set.
3. isd declares whether the attribute is a user-determined ID attribute.

Usage

This method sets the namespace-qualified XML Attribute of given name and namespace to be of type ID. Use the value TRUE for the parameter isd, to declare that attribute as a user-determined ID attribute, otherwise use FALSE.

This affects the behavior of getElementById.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.getNodeValue

Sets the node value for a DomNode object.

Syntax

getNodeValue( 
   value STRING )

1. value defines the node value.

Usage

This method sets the node value for this DomNode object, where value is the node value.

Use of this method is only recommended for nodes that are not parents of other nodes, which means it can be used for a node of type:

- ATTRIBUTE_NODE
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.setPrefix
Sets the prefix for a DomNode object.

**Syntax**

```java
setPrefix(
    prefix STRING )
```

1. `prefix` defines the prefix for this DomNode object.

**Usage**

Use this method to set the `prefix` for this xml.DomNode object.

This method is only valid on namespace qualified Element or Attribute nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.DomNode.toString
Returns a string representation of a DomNode object.

**Syntax**

```java
toString()
```

RETURNS STRING

**Usage**

This method returns a string representation of this DomNode object, or NULL.

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**DomNode types**

List of types for the xml.DomNode class.

**Table 601: DomNode types**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ELEMENT_NODE</td>
<td>The DomNode is an XML Element node.</td>
</tr>
<tr>
<td>ATTRIBUTE_NODE</td>
<td>The DomNode is an XML Attribute node.</td>
</tr>
<tr>
<td>TEXT_NODE</td>
<td>The DomNode is an XML Text node.</td>
</tr>
<tr>
<td>CDATA_SECTION_NODE</td>
<td>The DomNode is an XML CData Section node.</td>
</tr>
<tr>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ENTITY_REFERENCE_NODE</td>
<td>The DomNode is an XML Entity Reference node.</td>
</tr>
<tr>
<td>PROCESSING_INSTRUCTION_NODE</td>
<td>The DomNode is an XML Processing Instruction node.</td>
</tr>
<tr>
<td>COMMENT_NODE</td>
<td>The DomNode is an XML Comment node.</td>
</tr>
<tr>
<td>DOCUMENT_TYPE_NODE</td>
<td>The DomNode is an XML DTD node.</td>
</tr>
<tr>
<td>DOCUMENT_FRAGMENT_NODE</td>
<td>The DomNode is an XML Document Fragment node.</td>
</tr>
</tbody>
</table>

**Examples**

xml.DomNode usage examples.

Example Counting the number of nodes in an XML document

This code example counts the number of nodes of each type.

```xml
IMPORT XML

DEFINE nbElt INTEGER
DEFINE nbAttr INTEGER
DEFINE nbComment INTEGER
DEFINE nbPI INTEGER
DEFINE nbTxt INTEGER
DEFINE nbCData INTEGER

MAIN
DEFINE document xml.DomDocument
DEFINE ind INTEGER
# Handle arguments
IF num_args() !=1 THEN
CALL ExitHelp()
END IF
# Create document, load it, and count the nodes
LET document = xml.DomDocument.Create()
CALL document.load(arg_val(1))
CALL CountDoc(document)
# Display result
DISPLAY "Results:"
DISPLAY " Elements: ",nbElt
DISPLAY " Attributes:",nbAttr
DISPLAY " Comments: ",nbComment
DISPLAY " PI: ",nbPI
DISPLAY " Texts: ",nbTxt
DISPLAY " CDATA: ",nbCData
END MAIN

FUNCTION CountDoc(d)
DEFINE d xml.DomDocument
DEFINE n xml.DomNode
LET n = d.getFirstDocumentNode()
WHILE (n IS NOT NULL )
CALL Count(n)
LET n = n.getNextSibling()
END WHILE
END FUNCTION

FUNCTION Count(n)
DEFINE n xml.DomNode
DEFINE child xml.DomNode
DEFINE next xml.DomNode
DEFINE node xml.DomNode
DEFINE ind INTEGER
DEFINE name STRING
IF n IS NOT NULL THEN
   IF n.getNodeType() == "COMMENT_NODE" THEN
      LET nbComment = nbComment + 1
   END IF
   IF n.getNodeType() == "ATTRIBUTE_NODE" THEN
      LET nbAttr = nbAttr + 1
   END IF
   IF n.getNodeType() == "PROCESSING_INSTRUCTION_NODE " THEN
      LET nbPI = nbPI + 1
   END IF
   IF n.getNodeType() == "ELEMENT_NODE" THEN
      LET nbElt = nbElt + 1
   END IF
   IF n.getNodeType() == "TEXT_NODE" THEN
      LET nbTxt = nbTxt +1
   END IF
   IF n.getNodeType() == "CDATA_SECTION_NODE" THEN
      LET nbCData = nbCData + 1
   END IF
   IF n.hasChildNodes() THEN
      LET name = n.getLocalName()
      LET child = n.getFirstChild()
      WHILE (child IS NOT NULL )
         CALL Count(child)
         LET child = child.getNextSibling()
      END WHILE
   END IF
   IF n.hasAttributes() THEN
      FOR ind = 1 TO n.getAttributesCount()
         LET node = n.getAttributeNodeItem(ind)
         CALL Count(node)
      END FOR
   END IF
END IF
END FUNCTION

FUNCTION ExitHelp()
   DISPLAY "DomCount <xml>"
   EXIT PROGRAM
END FUNCTION

The DomNodeList class
The xml.DomNodeList class provides methods to manipulate a list of DomNode objects.

You can create a DomNodeList object using selection methods in the DomDocument and DomNode classes. The relationship between the DomNode objects in the list depends on the method used to create the DomNodeList object.

The STATUS variable is set to zero after a successful method call.
xmlDOMNodeList methods

Methods for the xmlDOMNodeList class.

Table 602: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getCount()</td>
<td>Returns the number of DomNode objects in a DomNodeList object.</td>
</tr>
<tr>
<td>getItem(index)</td>
<td>Returns the DomNode object at a given position in a DomNodeList object.</td>
</tr>
</tbody>
</table>

xmlDOMNodeList.getCount

Returns the number of DomNode objects in a DomNodeList object.

Syntax

```plaintext
getCount()
RETURNS INTEGER
```

Usage

Use this method to return the number of xmlDOMNode objects in this DomNodeList object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xmlDOMNodeList.getItem

Returns the DomNode object at a given position in a DomNodeList object.

Syntax

```plaintext
getItem(index INTEGER)
RETURNS xmlDOMNode
```

1. `index` defines the position of the DomNode object to return (index starts at 1).

Usage

Use this method to return a DomNode object at the given position in this DomNodeList object, where `index` is the position of the DomNode object to return (Index starts at 1).

Returns NULL when no DomNode object is at the given position.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

The streaming API for XML (StAX) classes

The streaming API for XML (StAX) classes use streaming while managing XML documents.

- CLASS StaxWriter
  - Features
• Example
• CLASS StaxReader
  • Event types
  • Features
  • Example

The StaxWriter class
The `xml.StaxWriter` class provides methods compatible with Streaming API for XML (StAX) for writing XML documents.

The `STATUS` variable is set to zero after a successful method call.

`xml.StaxWriter methods`
Methods for the `xml.StaxWriter` class.

Table 603: Class methods: Creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.StaxWriter.create()</code></td>
<td>Constructor of a StaxWriter object.</td>
</tr>
</tbody>
</table>

Table 604: Object methods: Configuration

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getFeature</code></td>
<td>Gets a feature of a StaxWriter object.</td>
</tr>
<tr>
<td><code>property STRING</code></td>
<td>RETURNS STRING</td>
</tr>
<tr>
<td><code>setFeature</code></td>
<td>Sets a feature of a StaxWriter object.</td>
</tr>
<tr>
<td><code>property STRING</code></td>
<td>RETURNS STRING</td>
</tr>
<tr>
<td><code>value STRING</code></td>
<td></td>
</tr>
</tbody>
</table>
### Table 605: Object methods: Output

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>close()</code></td>
<td>Closes the StaxWriter streaming, and releases all associated resources.</td>
</tr>
<tr>
<td>`writeTo(</td>
<td>Sets the output stream of the StaxWriter object to a file or an URL, and starts the streaming.</td>
</tr>
<tr>
<td><code>name STRING )</code></td>
<td></td>
</tr>
<tr>
<td>`writeToDocument(</td>
<td>Sets the output stream of the StaxWriter object to an xml.DomDocument object, and starts the streaming.</td>
</tr>
<tr>
<td><code>doc xml.DomDocument</code></td>
<td></td>

<td>Writes a XML namespace qualified attribute to the StaxWriter stream.</td>
</tr>
<tr>
<td>name STRING,</td>
<td></td>
</tr>
<tr>
<td>ns STRING,</td>
<td></td>
</tr>
<tr>
<td>value STRING )</td>
<td></td>
</tr>
<tr>
<td>cdata (</td>
<td>Writes a XML CData to the StaxWriter stream.</td>
</tr>
<tr>
<td>cdata STRING )</td>
<td></td>
</tr>
<tr>
<td>characters (</td>
<td>Writes a XML text to the StaxWriter stream.</td>
</tr>
<tr>
<td>characters STRING )</td>
<td></td>
</tr>
<tr>
<td>comment (</td>
<td>Writes a XML comment to the StaxWriter stream.</td>
</tr>
<tr>
<td>comment STRING )</td>
<td></td>
</tr>
<tr>
<td>emptyElement (</td>
<td>Writes an empty XML element to the StaxWriter stream.</td>
</tr>
<tr>
<td>name STRING )</td>
<td></td>
</tr>
<tr>
<td>emptyElementNS (</td>
<td>Writes an empty namespace qualified XML element to the StaxWriter stream.</td>
</tr>
<tr>
<td>name STRING,</td>
<td></td>
</tr>
<tr>
<td>ns STRING )</td>
<td></td>
</tr>
<tr>
<td>endElement ()</td>
<td>Writes an end tag to the StaxWriter stream.</td>
</tr>
<tr>
<td>entityRef (</td>
<td>Writes a XML EntityReference to the StaxWriter stream.</td>
</tr>
<tr>
<td>name STRING )</td>
<td></td>
</tr>
<tr>
<td>processingInstruction (</td>
<td>Writes a XML ProcessingInstruction to the StaxWriter stream</td>
</tr>
<tr>
<td>target STRING,</td>
<td></td>
</tr>
<tr>
<td>data STRING )</td>
<td></td>
</tr>
<tr>
<td>startElement (</td>
<td>Writes a XML start element to the StaxWriter stream.</td>
</tr>
<tr>
<td>name STRING )</td>
<td></td>
</tr>
<tr>
<td>startElementNS (</td>
<td>Writes a namespace-qualified XML start element to the StaxWriter stream.</td>
</tr>
<tr>
<td>name STRING,</td>
<td></td>
</tr>
<tr>
<td>ns STRING )</td>
<td></td>
</tr>
</tbody>
</table>
Writes a XML attribute to the StaxWriter stream.

**Syntax**

```java
attribute(
    name STRING,
    value STRING )
```

1. `name` defines the local name of the XML attribute. It cannot be NULL.
2. `value` defines the value of the XML attribute. It cannot be NULL.

**Usage**

Attributes can only be written on the StaxWriter stream if it points to a `START_ELEMENT` or an `EMPTY_ELEMENT`, otherwise the operation fails with an exception. This method can only be called after a `startElement`, `startElementNS`, `emptyElement`, `emptyElementNS`, or `attribute` and `attributeNS`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 3280.

`xml.StaxWriter.attributeNS` writes a XML namespace qualified attribute to the StaxWriter stream.

**Syntax**

```java
attributeNS(
    name STRING,
    ns STRING,
    value STRING )
```

1. `name` defines the local name of the XML attribute, cannot be NULL.
2. `ns` defines the namespace URI of the XML attribute, cannot be NULL.
3. `value` defines the value of the XML attribute, cannot be NULL.

**Usage**

Attributes can only be written on the StaxWriter stream if it points to a `START_ELEMENT` or an `EMPTY_ELEMENT`, otherwise the operation fails with an exception. This method can only be called after a `startElement`, `startElementNS`, `emptyElement`, `emptyElementNS`, or `attribute` and `attributeNS`.

If namespace URI has not been bound to a prefix with one of the methods `setPrefix`, `declareNamespace`, `setDefaultNamespace` or `declareDefaultNamespace`, the operation fails with an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 3280.

`xml.StaxWriter.cdata` writes a XML CData to the StaxWriter stream.

**Syntax**

```java
cdata(
    cdata STRING )
```

1. `cdata` defines the data contained in the CData section, or NULL.
Usage

This method writes XML character data passed as parameter as a CData.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxWriter.characters

Writes a XML text to the StaxWriter stream.

Syntax

```
characters (characters STRING )
```

1. `characters` defines the value to write.

Usage

This method writes the character string passed as parameter as a text element.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxWriter.close

Closes the StaxWriter streaming, and releases all associated resources.

Syntax

```
close ()
```

Usage

This method closes the stream.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxWriter.comment

Writes a XML comment to the StaxWriter stream.

Syntax

```
comment (comment STRING )
```

1. `comment` defines the data in the XML comment, or NULL.

Usage

This method writes a XML comment to the stream.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
Constructor of a StaxWriter object.

**Syntax**

```java
xml.StaxWriter.create()
RETURNS xml.StaxWriter
```

**Usage**

This method returns a StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.StaxWriter.declareDefaultNamespace**

Binds a namespace URI to the default namespace, and forces the output to the StaxWriter stream.

**Syntax**

```java
declareDefaultNamespace(ns STRING)
```

1. *ns* defines the URI to bind to the default namespace. It cannot be NULL.

**Usage**

This method binds a namespace URI to the default namespace, and forces the output of the default XML namespace definition to the StaxWriter stream.

The stream must point to a `START_ELEMENT`, and the prefix scope is the current `START_ELEMENT / END_ELEMENT` pair.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.StaxWriter.declareNamespace**

Binds a namespace URI to a prefix, and forces the output of the XML namespace definition to the StaxWriter stream.

**Syntax**

```java
declareNamespace(prefix STRING, ns STRING)
```

1. *prefix* defines the prefix to bind to the URI, cannot be NULL.
2. *ns* defines the URI to bind to the default namespace, cannot be NULL.

**Usage**

This method binds a namespace URI to a prefix, and forces the output of the XML namespace definition to the StaxWriter stream.

The stream must point to a `START_ELEMENT`, and the prefix scope is the current `START_ELEMENT / END_ELEMENT` pair.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
xml.StaxWriter.dtd
Writes a DTD to the StaxWriter stream.

Syntax

```java
dtd (
    dtd STRING )
```

1. `dtd` defines a string representing a valid DTD, cannot be NULL.

Usage

This method writes a document type definition (DTD) for the StaxWriter stream, where `dtd` represents a valid DTD.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

xml.StaxWriter.emptyElement
Writes an empty XML element to the StaxWriter stream.

Syntax

```java
emptyElement ( 
    name STRING )
```

1. `name` defines the local name of the XML empty element, cannot be NULL.

Usage

This method writes an empty XML element to the StaxWriter stream, where `name` defines the local name of the empty element. It cannot be NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

xml.StaxWriter.emptyElementNS
Writes an empty namespace qualified XML element to the StaxWriter stream.

Syntax

```java
emptyElementNS ( 
    name STRING, 
    ns STRING )
```

1. `name` defines the local name of the XML empty element, cannot be NULL.
2. `ns` defines the namespace URI of the XML empty element, cannot be NULL.

Usage

This method writes an empty namespace qualified XML element to the StaxWriter stream.

If namespace URI has not been bound to a prefix with one of the functions `setPrefix`, `setDefaultNamespace`, or `declareDefaultNamespace`, the operation fails with an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.
xml.StaxWriter.endDocument
Closes any open tags and writes corresponding end tags.

Syntax

```java
endDocument()
```

Usage

This method closes any open tags and writes corresponding ending tags.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxWriter.endElement
Writes an end tag to the StaxWriter stream.

Syntax

```java
endElement()
```

Usage

This method writes an end tag to the StaxWriter stream relying on the internal state to determine the prefix and local name of the last START_ELEMENT.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxWriter.entityRef
Writes a XML EntityReference to the StaxWriter stream.

Syntax

```java
entityRef(
    name STRING )
```

1. `name` defines the name of the entity, cannot be NULL.

Usage

This method writes a XML EntityReference, specified by `name`, to the StaxWriter stream.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxWriter.getFeature
Gets a feature of a StaxWriter object.

Syntax

```java
getFeature(
    property STRING )
```

1. `property` defines the name of a feature.
Usage
This method returns the name of a feature, specified in property, of the StaxWriter stream.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxWriter.processingInstruction
Writes a XML ProcessingInstruction to the StaxWriter stream

Syntax

```java
processingInstruction(
    target STRING,
    data STRING
)
```

1. target defines the target of the Processing Instruction, cannot be NULL.
2. data defines the data of the Processing Instruction, or NULL.

Usage
This method writes a XML ProcessingInstruction to the StaxWriter stream, where target is the target of the Processing Instruction, which cannot be NULL. data is the data of the Processing Instruction, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxWriter.setDefaultNamespace
Binds a namespace URI to the default namespace.

Syntax

```java
setDefaultNamespace(
    ns STRING
)
```

1. ns defines the URI to bind to the default namespace, cannot be NULL.

Usage
This method binds a namespace URI to the default namespace. The default namespace scope is the current START_ELEMENT / END_ELEMENT pair; ns is the URI to bind to the default namespace. It cannot be NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxWriter.setFeature
Sets a feature of a StaxWriter object.

Syntax

```java
setFeature(
    property STRING,
    value STRING
)
```

1. property defines the name of a feature.
2. value is the value of the feature.
**Usage**

Use this method to set a feature of a StaxWriter object, where *property* is the name of a *feature*, and *value* is the value of the feature. The features can be changed at any time, but will only be taken into account at the beginning of a new stream (see `writeTo` or `writeToDocument`).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.StaxWriter.setPrefix**

Binds a namespace URI to a prefix.

**Syntax**

```java
setPrefix(
    prefix STRING,
    ns STRING )
```

1. *prefix* defines the prefix to be bind to the URI, cannot be NULL.
2. *ns* defines the namespace URI to be bind to the prefix, cannot be NULL.

**Usage**

Use this method to bind a namespace URI, specified in *ns*, to a prefix defined in *prefix*.

The prefix scope is the current `START_ELEMENT` / `END_ELEMENT` pair.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.StaxWriter.startDocument**

Writes a XML declaration to the StaxWriter stream.

**Syntax**

```java
startDocument(
    encoding STRING,
    version STRING,
    standalone INTEGER )
```

1. *encoding* defines the encoding declaration in the XML declaration. Passing a NULL value will use the default UTF-8 encoding.
2. *version* defines the XML version in the XML declaration. Passing a NULL value will use the default 1.0 version.
3. *standalone* defines the XML standalone declaration. Possible values are:
   - 1: Set standalone="yes".
   - 0: Set standalone="no".
   - -1: Do not set the standalone attribute.

**Usage**

This method writes a XML declaration to the StaxWriter stream to specify the encoding, the version, and whether the document is standalone.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.
Example
This call:

```java
startDocument("utf-8","1.0",1)
```

Produces:

```xml
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
dtd("note [<!ENTITY writer "Donald Duck." ]"]
```

xml.StaxWriter.startElement
Writes a XML start element to the StaxWriter stream.

Syntax

```java
startElement (name STRING )
```

1. `name` defines the local name of the XML start element, cannot be NULL.

Usage

This method writes a XML start element to the StaxWriter stream. All `startElement` methods open a new scope and set the stream to a START_ELEMENT. Writing the corresponding `endElement`() causes the scope to be closed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxWriter.startElementNS
Writes a namespace-qualified XML start element to the StaxWriter stream.

Syntax

```java
startElementNS (name STRING, ns STRING )
```

1. `name` defines the local name of the XML start element, cannot be NULL.
2. `ns` defines the namespace URI of the XML start element, cannot be NULL.

Usage

All `startElementNS` methods open a new scope and set the stream to a START_ELEMENT. Writing the corresponding `endElement` causes the scope to be closed.

If namespace URI has not been bound to a prefix with one of the functions `setPrefix`, `setDefaultNamespace`, or `declareDefaultNamespace`, the operation fails with an exception.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxWriter.writeTo
Sets the output stream of the StaxWriter object to a file or an URL, and starts the streaming.

**Syntax**

```java
writeTo(  
    name STRING  )
```

1. `name` defines a valid URL or the name of the file that will contain the resulting XML document.

**Usage**

This method sets the output stream of the StaxWriter object to a file or an URL specified in `name`, and starts the streaming.

Only the following kinds of URLs are supported:

- http://
- https://
- tcp://
- tcps://
- file:///
- alias://

See [fglprofile Configuration](#) for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See [Error handling in GWS calls (STATUS)](#) on page 3280.

**Examples**

```java
writeTo("printerList.xml")
writeTo("http://myserver:1100/documents/printerList.xml")
writeTo("https://myserver:1100/documents/printerList.xml")
writeTo("alias://printerlist")
```

In the example `printerlist` alias is defined in fglprofile as `ws.printerlist.url = "http://myserver:1100/documents/printerList.xml"`. 

xml.StaxWriter.writeToDevice

Sets the output stream of the StaxWriter object to an xml.DomDocument object, and starts the streaming.

**Syntax**

```java
writeToDevice(  
    doc xml.DomDocument  )
```

1. `doc` defines the empty `DomDocument` object that will contain the resulting XML document.

**Usage**

This method sets the output stream of the StaxWriter object to a `DomDocument` specified in `doc`, and starts the streaming.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.StaxWriter.writeToPipe**

Sets the output stream of the StaxWriter object to aPIPE, and starts the streaming.

**Syntax**

```java
writeToPipe(
    name STRING )
```

1. *name* defines the command to start the PIPE that will get the resulting XML document.

**Usage**

This method sets the output stream of the StaxWriter object to a PIPE command specified in *name*, and starts the streaming.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.StaxWriter.writeToText**

Sets the output stream of the StaxWriter object to a TEXT large object, and starts the streaming.

**Syntax**

```java
writeToText(
    txt TEXT )
```

1. *txt* defines a TEXT lob located in memory that will contain the resulting XML document.

**Usage**

This method sets the output stream of the StaxWriter object to a text large object in memory, specified in *txt*, and starts the streaming.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**StaxWriter Features**

Features of the xml.StaxWriter class.

**Table 609: StaxWriter features**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>format-pretty-print</td>
<td>Formats the output by adding whitespace to produce a pretty-printed, indented, human-readable form. Default value is FALSE.</td>
</tr>
<tr>
<td>smart-ending-elements</td>
<td>Outputs each tag closed with an endElement() call as empty element if it has no children. Default value is FALSE.</td>
</tr>
</tbody>
</table>
Example
This example uses methods from the `xml.StaxWriter` class.

```plaintext
IMPORT xml

FUNCTION save(file)
    DEFINE file STRING
    DEFINE writer xml.StaxWriter
    TRY
        LET writer = xml.StaxWriter.Create()
        CALL writer.setFeature("format-pretty-print", TRUE)
        CALL writer.writeTo(file)
        CALL writer.startDocument("utf-8", "1.0", true)
        CALL writer.comment("This is my first comment using a stax writer")
        CALL writer.setPrefix("c", "http://www.mycompany.com/c")
        CALL writer.setPrefix("d", "http://www.mycompany.com/d")
        CALL writer.setDefaultNamespace("http://www.mycompany.com/d")
        CALL writer.startElementNS("root", "http://www.mycompany.com/d")
        CALL writer.attribute("attr1", "value1")
        CALL writer.attribute("attr2", "value2")
        CALL writer.attributeNS("attr3", "http://www.mycompany.com/d", "value3")
        CALL writer.comment("This is a comment using a stax writer")
        CALL writer.startElementNS("eltA", "http://www.mycompany.com/d")
        CALL writer.CData("<this is a CData section>")
        CALL writer.endElement()
        CALL writer.startElementNS("eltB", "http://www.mycompany.com/c")
        CALL writer.characters("Hello world, I'm from the development team")
        CALL writer.entityRef("one")
        CALL writer.endElement()
        CALL writer.processingInstruction("command1", "do what you want")
        CALL writer.endElement()
        CALL writer.comment("This is my last comment using a stax writer")
        CALL writer.endDocument()
        RETURN TRUE
    CATCH
        DISPLAY "StaxWriter ERROR ": STATUS, SQLCA.SQLERRM
        RETURN FALSE
    END TRY
    END FUNCTION
```

The StaxReader class
The StaxReader class provides methods compatible with Streaming API for XML(StAX) for reading XML documents.

The `STATUS` variable is set to zero after a successful method call.

Syntax

```plaintext
xml.StaxReader
```

xml.StaxReader methods
Methods for the `xml.StaxReader` class.

Table 610: Class methods: Creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.StaxReader.Create()</code></td>
<td>Constructor of a StaxReader object.</td>
</tr>
</tbody>
</table>
### Table 611: Object methods: Configuration

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>setFeature</code></td>
<td>Sets a feature of a StaxReader object.</td>
</tr>
<tr>
<td><code>property STRING,</code></td>
<td></td>
</tr>
<tr>
<td><code>value STRING</code></td>
<td></td>
</tr>
<tr>
<td><code>getFeature</code></td>
<td>Gets a feature of a StaxReader object.</td>
</tr>
<tr>

<tr>
<td><code>readFromPipe</code></td>
<td>Sets the input stream of the StaxReader object to a PIPE and starts the streaming.</td>
</tr>
<tr>
<td><code>name STRING</code></td>
<td></td>
</tr>
<tr>
<td><code>close()</code></td>
<td>Closes the StaxReader streaming and releases all associated resources.</td>
</tr>
</tbody>
</table>
### Table 613: Object methods: Access

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getEventType()</td>
<td>Returns a string that indicates the type of event the cursor of the StaxReader object is pointing to.</td>
</tr>
<tr>
<td>hasName()</td>
<td>Checks whether the StaxReader cursor points to a node with a name.</td>
</tr>
<tr>
<td>hasText()</td>
<td>Checks whether the StaxReader cursor points to a node with a text value.</td>
</tr>
<tr>
<td>isEmptyElement()</td>
<td>Checks whether the StaxReader cursor points to an empty element node.</td>
</tr>
<tr>
<td>isStartElement()</td>
<td>Checks whether the StaxReader cursor points to a start element node.</td>
</tr>
<tr>
<td>isEndElement()</td>
<td>Checks whether the StaxReader cursor points to an end element node.</td>
</tr>
<tr>
<td>isCharacters()</td>
<td>Checks whether the StaxReader cursor points to a text node.</td>
</tr>
<tr>
<td>isIgnorableWhitespace()</td>
<td>Checks whether the StaxReader cursor points to ignorable whitespace.</td>
</tr>
</tbody>
</table>

### Table 614: Object methods: Document

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getEncoding()</td>
<td>Returns the document encoding defined in the XML Document declaration, or NULL.</td>
</tr>
<tr>
<td>getVersion()</td>
<td>Returns the document version defined in the XML Document declaration, or NULL.</td>
</tr>
<tr>
<td>isStandalone()</td>
<td>Checks whether the document standalone attribute defined in the XML Document declaration is set to yes.</td>
</tr>
<tr>
<td>standaloneSet()</td>
<td>Checks whether the document standalone attribute is defined in the XML Document declaration.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>getPrefix()</code></td>
<td>Returns the prefix of the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getLocalName()</code></td>
<td>Returns the local name of the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getName()</code></td>
<td>Returns the qualified name of the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getNamespace()</code></td>
<td>Returns the namespace URI of the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getText()</code></td>
<td>Returns as a string the value of the current XML node, or NULL.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getPITarget()</code></td>
<td>Returns the target part of a XML Processing Instruction node, or NULL.</td>
</tr>
<tr>
<td><code>getPIData()</code></td>
<td>Returns the data part of a XML Processing Instruction node, or NULL.</td>
</tr>
</tbody>
</table>
Table 617: Object methods: Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getAttributeCount()</code></td>
<td>Returns the number of XML attributes defined on the current XML node, or zero.</td>
</tr>
<tr>
<td><code>getAttributeLocalName(index)</code></td>
<td>Returns the local name of a XML attribute defined at a given position on the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getAttributeNamespace(index)</code></td>
<td>Returns the namespace URI of a XML attribute defined at a given position on the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getAttributePrefix(index)</code></td>
<td>Returns the prefix of a XML attribute defined at a given position on the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getAttributeValue(index)</code></td>
<td>Returns the value of a XML attribute defined at a given position on the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>findAttributeValue(name, ns)</code></td>
<td>Returns the value of an XML attribute of a given name and/or namespace.</td>
</tr>
</tbody>
</table>
### Table 618: Object methods: Namespace

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

</tbody>
</table>

### Table 619: Object methods: Navigation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hasNext</code> ()</td>
<td>Checks whether the StaxReader cursor can be moved to a XML node next to it.</td>
</tr>
<tr>
<td>RETURNS INTEGER</td>
<td></td>
</tr>
<tr>
<td><code>next</code> ()</td>
<td>Moves the StaxReader cursor to the next XML node.</td>
</tr>
<tr>
<td><code>nextTag</code> ()</td>
<td>Moves the StaxReader cursor to the next XML open or end tag</td>
</tr>
<tr>
<td><code>nextSibling</code> ()</td>
<td>Moves the StaxReader cursor to the immediate next sibling XML Element of the current node, skipping all its child nodes.</td>
</tr>
<tr>
<td>xml.StaxReader.close</td>
<td>Closes the StaxReader streaming and releases all associated resources.</td>
</tr>
</tbody>
</table>

**Syntax**

```java
xml.StaxReader.close
```

**Usage**

This method closes the stream.
In case of error, the method throws an exception and sets the \textit{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3280.

\texttt{xml.StaxReader.Create}

Constructor of a StaxReader object.

**Syntax**

```java
xml.StaxReader.Create()
RETURNS xml.StaxReader
```

**Usage**

Use this method to create and return a \texttt{StaxReader} object.

In case of error, the method throws an exception and sets the \textit{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3280.

\texttt{xml.StaxReader.findAttributeValue}

Returns the value of an XML attribute of a given name and/or namespace.

**Syntax**

```java
findAttributeValue(  
    name STRING,  
    ns STRING )  
RETURNS STRING
```

1. \texttt{name} defines the name of the attribute to retrieve. It cannot be \texttt{NULL}.
2. \texttt{ns} defines the namespace URI of the attribute to retrieve, or \texttt{NULL} if the attribute is not namespace-qualified.

**Usage**

This method returns the value of an XML attribute of a given name and/or namespace on the current XML node, where \texttt{name} is the name of the attribute and \texttt{ns} is the namespace or is \texttt{NULL} if not namespace-qualified.

This method is only valid on a \texttt{START_ELEMENT} node.

In case of error, the method throws an exception and sets the \textit{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3280.

\texttt{xml.StaxReader.getAttributeCount}

Returns the number of XML attributes defined on the current XML node, or zero.

**Syntax**

```java
getAttributeCount()
RETURNS INTEGER
```

**Usage**

Use this method to return the number of XML attributes defined on the current XML node.

This method is only valid on a \texttt{START_ELEMENT} node.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getAttributeLocalName

Returns the local name of a XML attribute defined at a given position on the current XML node, or NULL.

Syntax

```java
get AttributeLocalName(
    index INTEGER )
RETURNS STRING
```

1. `index` defines the position of the attribute to return (index starts at 1).

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getAttributeNamespace

Returns the namespace URI of a XML attribute defined at a given position on the current XML node, or NULL.

Syntax

```java
get AttributeNamespace(
    index INTEGER )
RETURNS STRING
```

1. `index` defines the position of the attribute to return (index starts at 1).

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getAttributePrefix

Returns the prefix of a XML attribute defined at a given position on the current XML node, or NULL.

Syntax

```java
get AttributePrefix(
    index INTEGER )
RETURNS STRING
```

1. `index` defines the position of the attribute to return (index starts at 1).

Usage

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getAttributeValue

Returns the value of a XML attribute defined at a given position on the current XML node, or NULL.

Syntax

```java
getAttributeValue (index INTEGER )
RETURNS STRING
```

1. `index` defines the position of the attribute to return (index starts at 1).

Usage

Use this method to return the value of a XML attribute at `index` position, or NULL.

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getEncoding

Returns the document encoding defined in the XML Document declaration, or NULL.

Syntax

```java
goingEncoding ()
RETURNS STRING
```

Usage

This method returns the document encoding as defined in the XML document declaration, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getEventType

Returns a string that indicates the type of event the cursor of the StaxReader object is pointing to.

Syntax

```java
getEventType ()
RETURNS STRING
```

Usage

This method returns the name of the event type the StaxReader object cursor is pointing to. See StaxReader Event Types on page 2875 for the full list of StaxReader event types.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
xml.StaxReader.getFeature

Gets a feature of a StaxReader object.

Syntax

```java
getFeature (  
    property STRING )  
RETURNS STRING
```

1. `property` defines the name of a feature.

Usage

This method returns the name of a feature for the StaxReader object, where `property` is the name of the StaxReader feature.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getLocalName

Returns the local name of the current XML node, or NULL.

Syntax

```java
getLocalName ()  
RETURNS STRING
```

Usage

Use this method to return the local name of the current XML node, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getName

Returns the qualified name of the current XML node, or NULL.

Syntax

```java
getName ()  
RETURNS STRING
```

Usage

This method returns the qualified name of the current XML node, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getNamespace

Returns the namespace URI of the current XML node, or NULL.

Syntax

```java
getNamespace ()
```
**Usage**

This method returns the namespace URI of the current XML node, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.StaxReader.getNamespaceCount**

Returns the number of namespace declarations defined on the current XML node, or zero.

**Syntax**

```java
getNamespaceCount ()
RETURNS INTEGER
```

**Usage**

This method returns the number of namespace declarations in the current XML node, or zero if none.

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.StaxReader.getNamespacePrefix**

Returns the prefix of a namespace declaration defined at a given position on the current XML node, or NULL.

**Syntax**

```java
getNamespacePrefix (index INTEGER )
RETURNS STRING
```

1. `index` defines the position of the namespace declaration (index starts at 1).

**Usage**

This method returns the prefix of a namespace declaration at `index` position on the current XML node, or NULL.

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.StaxReader.getNamespaceURI**

Returns the URI of a namespace declaration defined at a given position on the current XML node, or NULL.

**Syntax**

```java
getNamespaceURI (index INTEGER )
RETURNS STRING
```

1. `index` defines the position of the namespace declaration (index starts at 1).
**Usage**

This method returns the URI of a namespace declaration defined at index position on the current XML node, or NULL.

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getPIData

Returns the data part of a XML Processing Instruction node, or NULL.

**Syntax**

```java
getPIData ()
RETURNS STRING
```

**Usage**

Use this method to return the data part of a XML PROCESSING_INSTRUCTION node, or NULL.

This method is only valid on a PROCESSING_INSTRUCTION node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getPITarget

Returns the target part of a XML Processing Instruction node, or NULL.

**Syntax**

```java
getPITarget ()
RETURNS STRING
```

**Usage**

This method returns the target part of a XML Processing Instruction node, or NULL.

This method is only valid on a PROCESSING_INSTRUCTION node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getPrefix

Returns the prefix of the current XML node, or NULL.

**Syntax**

```java
getPrefix ()
RETURNS STRING
```

**Usage**

This method returns the prefix of the current XML node, or NULL.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getText
Returns as a string the value of the current XML node, or NULL.

Syntax

```java
getText ()
RETURNS STRING
```

Usage

Use this method to return a string containing text in the current XML node, or NULL if there is none.

This method is only valid on CHARACTERS, CDATA, SPACE, COMMENT, DTD, and ENTITY_REFERENCE nodes. For an ENTITY_REFERENCE, this method returns the replacement value, or NULL if none. See StaxReader Event Types on page 2875.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.getVersion
Returns the document version defined in the XML Document declaration, or NULL.

Syntax

```java
getVersion ()
RETURNS STRING
```

Usage

This method returns the document version as defined in the XML document declaration, or NULL if not defined.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.hasName
Checks whether the StaxReader cursor points to a node with a name.

Syntax

```java
hasName ()
RETURNS INTEGER
```

Usage

This method returns TRUE if the current XML node has a name, FALSE otherwise. It returns TRUE for START_ELEMENT and END_ELEMENT, FALSE for all other nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.hasNext
Checks whether the StaxReader cursor can be moved to a XML node next to it.

**Syntax**

```java
hasNext ()
RETURNS INTEGER
```

**Usage**

Use this method to check if there is still a XML node in the stream. It returns TRUE if there is, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.hasText
Checks whether the StaxReader cursor points to a node with a text value.

**Syntax**

```java
hasText ()
RETURNS INTEGER
```

**Usage**

Use this method to check if the StaxReader cursor is pointing to a node with a text value. It Returns TRUE if the current XML node has a text value, FALSE otherwise. This method returns TRUE for CHARACTERS, SPACE, CDATA, COMMENT, ENTITY_REFERENCE, and DTD nodes, FALSE for all other nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.isCharacters
Checks whether the StaxReader cursor points to a text node.

**Syntax**

```java
isCharacters ()
RETURNS INTEGER
```

**Usage**

Use this method to check if the StaxReader cursor is pointing to a text node. It returns TRUE if the current XML node is a text node, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.isEmptyElement
Checks whether the StaxReader cursor points to an empty element node.

**Syntax**

```java
isEmptyElement ()
RETURNS INTEGER
```
Usage

Use this method to check if the StaxReader cursor is pointing to a XML element node that has no children. It returns TRUE if the node has no children, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.isEndElement
Checks whether the StaxReader cursor points to an end element node.

Syntax

**isEndElement()**
RETURNS INTEGER

Usage

Use this method to check if the StaxReader cursor is pointing to an end element node. It returns TRUE if the current XML node is an end element node, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.isIgnorableWhitespace
Checks whether the StaxReader cursor points to ignorable whitespace.

Syntax

**isIgnorableWhitespace()**
RETURNS INTEGER

Usage

Use this method to check if the StaxReader cursor is pointing to a text node with ignorable whitespace. It returns TRUE if there is ignorable whitespace, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.isStandalone
Checks whether the document standalone attribute defined in the XML Document declaration is set to yes.

Syntax

**isStandalone()**
RETURNS INTEGER

Usage

Use this method to check if the document standalone attribute defined in the XML Document declaration is set to yes. It returns TRUE if set to yes, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
xml.StaxReader.isStartElement

Checks whether the StaxReader cursor points to a start element node.

**Syntax**

```
isStartElement ()
    RETURNS INTEGER
```

**Usage**

Use this method to check if the StaxReader cursor is pointing to a start element node. It returns TRUE if the current XML node is a start element node, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.lookupNamespace

Looks up the namespace URI associated with a given prefix starting from the current XML node the StaxReader cursor is pointing to.

**Syntax**

```
lookupNamespace (  
    prefix STRING )
    RETURNS STRING
```

1. *prefix* defines the prefix to look for; if NULL the default namespace URI will be returned.

**Usage**

Use this method to return the namespace URI associated with the prefix specified by *prefix* at the current XML node. It returns a string with the namespace URI associated with the prefix, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.lookupPrefix

Looks up the prefix associated with a given namespace URI, starting from the current XML node the StaxReader cursor is pointing to.

**Syntax**

```
lookupPrefix (  
    ns STRING )
    RETURNS STRING
```

1. *ns* defines the namespace URI to look for. It cannot be NULL.

**Usage**

Use this method to return the prefix associated with the namespace specified by *ns* at the current XML node. It returns the prefix, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
xml.StaxReader.next

Moves the StaxReader cursor to the next XML node.

**Syntax**

\[
\text{next} ()
\]

**Usage**

Use this method to move the StaxReader cursor to the next XML node in the stream.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

xml.StaxReader.nextSibling

Moves the StaxReader cursor to the immediate next sibling XML Element of the current node, skipping all its child nodes.

**Syntax**

\[
\text{nextSibling} ()
\]

**Usage**

Use this method to move the StaxReader cursor to the next sibling of the current XML Element node in the stream, skipping all its child nodes. The cursor points to the parent end tag if there are no siblings.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

xml.StaxReader.nextTag

Moves the StaxReader cursor to the next XML open or end tag

**Syntax**

\[
\text{nextTag} ()
\]

**Usage**

Use this method to move the StaxReader cursor to the next XML open or end tag. The cursor points to the end of the document if there is no next XML open or end tag.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

xml.StaxReader.readFrom

Sets the input stream of the StaxReader object to a file or an URL and starts the streaming

**Syntax**

\[
\text{readFrom} ( \\
\quad \text{name STRING} )
\]

1. `name` defines a valid URL or the name of the file to read.
Usage
This method sets the input stream of the StaxReader object to a file or an URL, where name is a valid URL or the
name of the file.

Only the following kinds of URLs are supported:

- `http://`
- `https://`
- `tcp://`
- `tcps://`
- `file:///`
- `alias://`

See fglprofile Configuration for more details about URL mapping with aliases, and for proxy and security
configuration.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable
description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.readFromDocument
Sets the input stream of the StaxReader object to a DomDocument object and starts the streaming.

Syntax

```java
readFromDocument(
    _doc xml.DomDocument
)
```

Usage
Use this method to set the input stream of the StaxReader object to a xml.DomDocument object, where _doc is a
valid object containing an XML document.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable
description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.readFromPipe
Sets the input stream of the StaxReader object to a PIPE and starts the streaming.

Syntax

```java
readFromPipe(
    name STRING
)
```

1. name defines the command to start the PIPE and where the reader will get the XML from.

Usage
Use this method to set the input stream of the StaxReader object to a PIPE, where name is the command to read from
the PIPE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable
description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.StaxReader.readFromText
Sets the input stream of the StaxReader object to a TEXT large object and starts the streaming.

**Syntax**

```plaintext
readFromText (_txt TEXT )
```

1. `_txt` defines a TEXT lob located in memory and containing the XML to read.

**Usage**

Use this method to set the input stream of the StaxReader object to a TEXT large object, where `_txt` is the text to read. In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.StaxReader.setFeature**

Sets a feature of a StaxReader object.

**Syntax**

```plaintext
setFeature ( property STRING, value STRING )
```

1. `property` defines the name of a feature.
2. `value` defines the value of the feature.

**Usage**

Use this method to set a feature for the StaxReader object, where `property` is the name of a XmlStaxReader feature, and `value` is the value of a feature.

The features can be changed at any time, but they will only be taken into account at the beginning of a new stream (see `readFrom` or `readFromDocument`).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.StaxReader.standaloneSet**

Checks whether the document standalone attribute is defined in the XML Document declaration.

**Syntax**

```plaintext
standaloneSet ()
```

RETURNS INTEGER

**Usage**

Use this method to check if the document standalone attribute is defined in the XML Document declaration. It returns `TRUE` if the standalone attribute is set, `FALSE` otherwise.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.
**StaxReader Features**
Features of the `xml.StaxReader` class.

**Table 620: StaxReader Features**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
</table>
| expand-entity-references | Defines whether XML EntityReference nodes are kept or replaced during the parsing of a XML document.  
                           | Default value is TRUE.                                      |

**StaxReader Event Types**
Event types of the `xml.StaxReader` class.

**Table 621: StaxReader event types**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
<th>XML sample</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_DOCUMENT</td>
<td>StaxReader cursor points to the beginning of the XML document.</td>
<td><code>&lt;?xml version=&quot;1.0&quot; standalone=&quot;no&quot;?&gt;</code></td>
</tr>
<tr>
<td>END_DOCUMENT</td>
<td>StaxReader cursor has reached the end of the XML document.</td>
<td>No additional parsing operation will succeed.</td>
</tr>
<tr>
<td>START_ELEMENT</td>
<td>StaxReader cursor points to a XML start element or empty element node.</td>
<td><code>&lt;p:elt attr=&quot;val&quot;&gt; or </code>&lt;p:elt attr=&quot;val&quot;/&gt;`</td>

</tr>
<tr>
<td>ERROR</td>
<td>StaxReader cursor points to an unexpected XML node.</td>
<td></td>
</tr>
</tbody>
</table>

**Example**

Example using methods of the xml.StaxReader class.

```
IMPORT xml

FUNCTION parse(file)
  DEFINE file STRING
  DEFINE event STRING
  DEFINE ind INTEGER
  DEFINE reader xml.StaxReader
  TRY
    LET reader=xml.StaxReader.Create()
    CALL reader.readFrom(file)
    WHILE (true)
      LET event=reader.getEventType()
      CASE event
        WHEN "START_DOCUMENT"
          DISPLAY "Document reading started"
          DISPLAY "XML Version : ",reader.getVersion()
          DISPLAY "XML Encoding : ",reader.getEncoding()
          IF reader.standaloneSet() THEN
            IF reader.isStandalone() THEN
              DISPLAY "Standalone : yes"
            ELSE
              DISPLAY "Standalone : no"
            END IF
          END IF
        WHEN "END_DOCUMENT"
          DISPLAY "Document reading finished"
        WHEN "START_ELEMENT"
          IF reader.isEmptyElement() THEN
            DISPLAY "<"||reader.getName()||"/>
          ELSE
            DISPLAY "<"||reader.getName()||">
            FOR ind=1 TO reader.getNamespaceCount()
              DISPLAY "xmlns:"||reader.getNamespacePrefix(ind)||"="||reader.getNamespaceURI(ind)
            END FOR
          END IF
          FOR ind=1 TO reader.getAttributeCount()
            IF reader.getAttributePrefix(ind) THEN
              DISPLAY reader.getAttributePrefix(ind)||":"||reader.getAttributeLocalName(ind)||"="||reader.getAttributeValue(ind)
            ELSE
              DISPLAY reader.getAttributeLocalName(ind)||"="||reader.getAttributeValue(ind)
            END IF
          END FOR
          WHEN "END_ELEMENT"
            DISPLAY "</"||reader.getName()||">
          WHEN "CHARACTERS"
            IF reader.hasText() AND NOT reader.isIgnorableWhitespace() THEN
              DISPLAY "CHARACTERS :",reader.getText()
            END IF
          WHEN "COMMENT"
            IF reader.hasText() THEN
              DISPLAY "Comment :",reader.getText()
```

```
XML serialization classes
The XML serialization classes convert BDL variables to XML and XML to BDL variables.

- CLASS Serializer
  - Option flags

The Serializer class
The `xml.Serializer` class provides methods to manage options for the serializer engine, and to use the serializer engine to serialize variables and XML element nodes.

This class is a static class and does not have to be instantiated.

The `STATUS` variable is set to zero after a successful method call.
xml.Serializer methods
Methods for the xml.Serializer class.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.Serializer.CreateXmlSchemas(var RECORD, schemas RECORD)</code></td>
<td>Creates XML schemas corresponding to the given variable, and fills a dynamic array with xml.DomDocument objects each representing a XML schema.</td>
</tr>
<tr>
<td><code>xml.Serializer.DomToVariable(node xml.DomNode, var RECORD)</code></td>
<td>Serializes a XML element node into a BDL variable using a DomNode object.</td>

</tbody>
</table>
xml.Serializer.CreateXmlSchemas

Create XML schemas corresponding to the given variable, and fills a dynamic array with xml.DomDocument objects each representing a XML schema.

**Syntax**

```plaintext
xml.Serializer.CreateXmlSchemas(
    var RECORD,
    schemas RECORD
)
```

1. `var` is a given variable.
2. `schemas` is a dynamic array of `xml.DomDocument` objects, each representing an XML schema.

**Usage**

Use this method to create XML schemas corresponding to the given variable `var`, and fill the dynamic array `schemas` with `xml.DomDocument` objects each representing a XML schema.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Serializer.DomToStax

Serializes a XML DomNode object to a StaxWriter object.

**Syntax**

```plaintext
xml.Serializer.DomToStax(
    node xml.DomNode,
    stax xml.StaxWriter
)
```

1. `node` is a `DomNode` object.
2. `stax` is a `StaxWriter` object.

**Usage**

Use this method to serialize a `xml.DomNode` object to a `StaxWriter` object.

The resulting XML element node of the serialization process will be added at the current cursor position of the `StaxWriter` object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Serializer.DomToVariable

Serializes a XML element node into a BDL variable using a DomNode object.

**Syntax**

```plaintext
xml.Serializer.DomToVariable(
    node xml.DomNode,
    var RECORD
)
```

1. `node` is a `DomNode` object of type `ELEMENT_NODE`.
2. `var` is any Genero BDL variable with optional XML mapping attributes.
Usage

Use this method to serialize a XML element node defined by node as a DomNode object into a BDL variable.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Serializer.getOption

Gets a global option value from the serializer engine.

Syntax

xml.Serializer.GetOption (str STRING )
RETURNS STRING

1. str defines the option flag.

Usage

This method gets an option value from the serializer engine for an option defined by str. It returns the value of the flag.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Serializer.OptimizedDomToVariable

Serializes a XML element node into a BDL variable using a DomNode object.

This API implements the XML-binary Optimized packaging specification. See https://www.w3.org/TR/xop10/.

Syntax

xml.Serializer.OptimizedDomToVariable (node xml.DomNode, var RECORD, xopTable RECORD )

1. node is a DomNode object of type ELEMENT_NODE.
2. var is any Genero BDL variable with optional XML mapping attributes.
3. xopTable is a dynamic array, defined as follows:

```plaintext
DEFINE XOPTable DYNAMIC ARRAY OF RECORD
    cid STRING, # Content-ID to identify the part in a XML Optimized document
    data BYTE, # Blob handled as part in a XML Optimized document
    file STRING # Name of the file handled as part in an XML Optimized document
END RECORD
```

The XOPTable dynamic array is necessary to keep the relation between the data to be handled as separate part in an XML Optimized document via an href attribute containing the Content-ID value. This parameter can be NULL.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
**Optimized APIs**

Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the `XOPTable` (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<m:data xmlns:m='http://example.org/stuff'>
  <m:photo>
    <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include' href='cid:myref@tempuri.org'/>
  </m:photo>
</m:data>
```

If you have NOT used XMLOptimizedContent, the `XOPTable` will contain one element where:
- `cid` contains "myref@tempuri.org".
- `data` contains the BYTE to be sent or to be received as an attachment.
- `file` contains NULL.

If you have used XMLOptimizedContent, the `XOPtable` contains one element where:
- `cid` contains "myref@tempuri.org".
- `data` contains NULL.
- `file` contains the file name to be sent or to be received as an attachment.

xml.Serializer.OptimizedSoapSection5ToVariable
 Serializes an XML element node into a BDL variable in Soap Section 5 encoding.

This API implements the XML-binary Optimized packaging specification. See https://www.w3.org/TR/xop10/.

**Syntax**

```plaintext
xml.Serializer.OptimizedSoapSection5ToVariable(
  node xml.DomNode,
  var RECORD,
  xopTable RECORD)
```

1. `node` is a `DomNode` object of type `ELEMENT_NODE`.
2. `var` is any Genero BDL variable with optional `XML` mapping attributes.
3. `xopTable` is a dynamic array, defined as follows:

```plaintext
DEFINE XOPTable DYNAMIC ARRAY OF RECORD
  cid STRING, # Content-ID to identify the part in a XML Optimized document
  data BYTE, # Blob handled as part in a XML Optimized document
  file STRING # Name of the file handled as part in an XML Optimized document
END RECORD
```

The `XOPtable` dynamic array is necessary to keep the relation between the data to be handled as separate part in an XML Optimized document via an href attribute containing the Content-ID value. This parameter can be NULL.
Usage
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Optimized APIs
Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the XOPTable (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<m:data xmlns:m='http://example.org/stuff'>
  <m:photo>
    <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include'
      href='cid:myref@tempuri.org'/>
  </m:photo>
</m:data>
```

If you have NOT used XMLOptimizedContent, the XOPTable will contain one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains the BYTE to be sent or to be received as an attachment.
- `file` contains NULL.

If you have used XMLOptimizedContent, the XOPTable contains one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains NULL.
- `file` contains the file name to be sent or to be received as an attachment.

xml.Serializer.OptimizedStaxToVariable
Serializes an XML element node into a BDL variable using a StaxReader object.

This API implements the XML-binary Optimized packaging specification. See https://www.w3.org/TR/xop10/.

Syntax
```
xml.Serializer.OptimizedStaxToVariable ( 
  stax xml.StaxReader, 
  var RECORD, 
  xoptable RECORD )
```

1. `stax` is a StaxReader object where the cursor points to an XML Element node.
2. `var` is any Genero BDL variable with optional XML mapping attributes.
3. `xoptable` is a dynamic array, defined as follows:

```
DEFINE XOPTable DYNAMIC ARRAY OF RECORD 
            cid STRING, # Content-ID to identify the part in a XML Optimized document 
            data BYTE,  # Blob handled as part in a XML Optimized document 
            file STRING # Name of the file handled as part in an XML Optimized document 
END RECORD
```
The **XOPTable** dynamic array is necessary to keep the relation between the data to be handled as separate part in an XML Optimized document via an href attribute containing the Content-ID value. This parameter can be NULL.

**Usage**

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (**STATUS**) on page 3280.

**Optimized APIs**

Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the **XOPTable** (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<m:data xmlns:m='http://example.org/stuff'>
  <m:photo>
    <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include'
      href='cid:myref@tempuri.org'/>
  </m:photo>
</m:data>
```

If you have NOT used XMLOptimizedContent, the XOPTable will contain one element where:

- **cid** contains "myref@tempuri.org".
- **data** contains the BYTE to be sent or to be received as an attachment.
- **file** contains NULL.

If you have used XMLOptimizedContent, the XOPtable contains one element where:

- **cid** contains "myref@tempuri.org".
- **data** contains NULL.
- **file** contains the file name to be sent or to be received as an attachment.

**xml.Serializer.OptimizedVariableToDom**

Serializes a BDL variable into a XML element node using a DomNode object.

This API implements the XML-binary Optimized packaging specification. See [https://www.w3.org/TR/xop10/](https://www.w3.org/TR/xop10/).

**Syntax**

```latex
xml.Serializer.OptimizedVariableToDom( 
  var fgl-type, 
  node xml.DomNode, 
  xopTable RECORD )
```

1. **var** is any Genero BDL variable with optional XML mapping attributes.
2. **node** is a DomNode object of type ELEMENT_NODE or DOCUMENT_FRAGMENT_NODE.
3. **xopTable** is a dynamic array, defined as follows:

```latex
DEFINE XOPTable DYNAMIC ARRAY OF RECORD 
  cid STRING, # Content-ID to identify the part in a XML Optimized document 
  data BYTE, # Blob handled as part in a XML Optimized document 
```
The `XOPTable` dynamic array is necessary to keep the relation between the data to be handled as separate part in an XML Optimized document via an href attribute containing the Content-ID value. This parameter can be NULL.

**Usage**

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Optimized APIs**

Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the `XOPTable` (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<Data xmlns:m='http://example.org/stuff'>
  <m:photo>
    <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include'
    href='cid:myref@tempuri.org'/>
  </m:photo>
</Data>
```

If you have NOT used XMLOptimizedContent, the `XOPTable` will contain one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains the BYTE to be sent or to be received as an attachment.
- `file` contains NULL.

If you have used XMLOptimizedContent, the `XOPtable` contains one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains NULL.
- `file` contains the file name to be sent or to be received as an attachment.

**xml.Serializer.OptimizedVariableToSoapSection5**

Serializes a BDL variable into a XML element node in Soap Section 5 encoding.

This API implements the XML-binary Optimized packaging specification. See https://www.w3.org/TR/xop10/.

**Syntax**

```ruby
xml.Serializer.OptimizedVariableToSoapSection5(
  var,
  node xml.dom.Element
)
```

1. `var` is any Genero BDL variable with optional XML mapping attributes.
2. `node` is a `DomNode` object of type `ELEMENT_NODE` or `DOCUMENT_FRAGMENT_NODE`.
3. **xopTable** is a dynamic array, defined as follows:

```plaintext
DEFINE XOPTable DYNAMIC ARRAY OF RECORD
  cid STRING,  # Content-ID to identify the part in a XML Optimized document
data BYTE,    # Blob handled as part in a XML Optimized document
file STRING  # Name of the file handled as part in an XML Optimized document
END RECORD
```

The **XOPTable** dynamic array is necessary to keep the relation between the data to be handled as separate part in an **XML** Optimized document via an href attribute containing the Content-ID value. This parameter can be NULL.

**Usage**

The resulting XML element node of the serialization process will be added at the current cursor position of the **StaxWriter** object.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See Error handling in GWS calls (**STATUS**) on page 3280.

**Optimized APIs**

Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the **XOPTable** (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<m:data xmlns:m='http://example.org/stuff'>
  <m:photo>
    <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include'
                 href='cid:myref@tempuri.org'/>
  </m:photo>
</m:data>
```

If you have NOT used **XMLOptimizedContent**, the **XOPTable** will contain one element where:

- **cid** contains "myref@tempuri.org".
- **data** contains the BYTE to be sent or to be received as an attachment.
- **file** contains NULL.

If you have used **XMLOptimizedContent**, the **XOPtable** contains one element where:

- **cid** contains "myref@tempuri.org".
- **data** contains NULL.
- **file** contains the file name to be sent or to be received as an attachment.

**xml.Serializer.OptimizedVariableToStax**

Serializes a BDL variable into a XML element node using a StaxWriter object.

This API implements the XML-binary Optimized packaging specification. See [https://www.w3.org/TR/xop10/](https://www.w3.org/TR/xop10/).

**Syntax**

```plaintext
xml.Serializer.OptimizedVariableToStax(
  var RECORD,
  stax xml.StaxWriter,
)```
1. var is any Genero BDL variable with optional XML mapping attributes.
2. stax is a StaxWriter object.
3. xopTable is a dynamic array, defined as follows:

```
DEFINE XOPTable DYNAMIC ARRAY OF RECORD
  cid STRING, # Content-ID to identify the part in a XML Optimized document
  data BYTE,  # Blob handled as part in a XML Optimized document
  file STRING # Name of the file handled as part in an XML Optimized document
END RECORD
```

The XOPTable dynamic array is necessary to keep the relation between the data to be handled as separate part in an XML Optimized document via an href attribute containing the Content-ID value. This parameter can be NULL.

**Usage**

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Optimized APIs**

Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the XOPTable (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<m:data xmlns:m='http://example.org/stuff'>
  <m:photo>
    <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include'
      href='cid:myref@tempuri.org'/>
  </m:photo>
</m:data>
```

If you have NOT used XMLOptimizedContent, the XOPTable will contain one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains the BYTE to be sent or to be received as an attachment.
- `file` contains NULL.

If you have used XMLOptimizedContent, the XOPTable contains one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains NULL.
- `file` contains the file name to be sent or to be received as an attachment.
Sets a global option value for the serializer engine

**Syntax**

```xml
xml.Serializer.SetOption(
    optionName STRING,
    optionValue STRING )
```

1. `optionName` specifies the name of the option flag.
2. `optionValue` defines the value of the flag.

**Usage**

This method sets the specified option value for the serializer engine for an option defined by `optionName`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Serializer.SoapSection5ToVariable**

Serializes an XML element node into a BDL variable in Soap Section 5 encoding.

**Syntax**

```xml
xml.Serializer.SoapSection5ToVariable(
    node xml.DomNode,
    var RECORD )
```

1. `node` is a `DomNode` object of type `ELEMENT_NODE`.
2. `var` is any Genero BDL variable with optional XML mapping attributes.

**Usage**

Use this method to serialize a XML element node defined by `node` as a DomNode object into a BDL variable in Soap Section 5 encoding.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Serializer.StaxToDom**

Serializes an XML element node into a DomNode object using a StaxReader object.

**Syntax**

```xml
xml.Serializer.StaxToDom(
    stax xml.StaxReader,
    node xml.DomNode )
```

1. `stax` is a StaxReader object where the cursor points to an XML Element node.
2. `node` is a DomNode object of type `ELEMENT_NODE` or `DOCUMENT_FRAGMENT_NODE`.

**Usage**

This method serializes a XML element node into a DomNode object using a StaxReader object. The resulting XML element node of the serialization process will be appended to the last child of the given node.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Serializer.StaxToVariable**

Serializes an XML element node into a BDL variable using a StaxReader object.

**Syntax**

```plaintext
xm.Serializer.StaxToVariable(
    stax xml.StaxReader,
    var RECORD )
```

1. `stax` is a StaxReader object where the cursor points to an XML Element node.
2. `var` is any Genero BDL variable with optional XML mapping attributes.

**Usage**

This method serializes a XML element node into a BDL variable using a StaxReader object. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Serializer.VariableToDom**

Serializes a BDL variable into a XML element node using a DomNode object.

**Syntax**

```plaintext
xm.Serializer.VariableToDom(
    var RECORD,
    node xml.DomNode )
```

1. `var` is any Genero BDL variable with optional XML mapping attributes.
2. `node` is a DomNode object of type ELEMENT_NODE or DOCUMENT_FRAGMENT_NODE.

**Usage**

This method serializes a BDL variable into a XML element node using a DomNode object. The resulting XML element node of the serialization process will be appended to the last child of the given node. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Serializer.VariableToSoapSection5**

Serializes a BDL variable into a XML element node in Soap Section 5 encoding.

**Syntax**

```plaintext
xm.Serializer.VariableToSoapSection5(
    var fgl-type,
    node xml.DomNode )
```

1. `var` is any Genero BDL variable with optional XML mapping attributes.
2. `node` is a DomNode object of type ELEMENT_NODE or DOCUMENT_FRAGMENT_NODE.
Usage

Use this method to serialize a BDL variable into a XML element node defined by `node` as a DomNode object using Soap Section 5 encoding. The resulting XML element node of the serialization process will be appended to the last child of the given node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

`xml.Serializer.VariableToStax`

Serializes a BDL variable into a XML element node using a StaxWriter object.

Syntax

```java
xml.Serializer.VariableToStax(
    var RECORD,
    stax xml.StaxWriter )
```

1. `var` is any Genero BDL variable with optional XML mapping attributes.
2. `stax` is a StaxWriter object.

Usage

This method serializes a BDL variable into a XML element node using a StaxReader object.

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

Serialization option flags

Serialization option flags for the xml.Serializer class.

Table 623: Serialization option flags

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml_ignoretimezone</td>
<td>Defines that the serializer ignores the time zone information, during the marshalling and un-marshalling process of a BDL DATETIME data type.</td>
</tr>
<tr>
<td></td>
<td>A value of zero means FALSE. The default is FALSE.</td>
</tr>
<tr>
<td></td>
<td>Throws an exception in case of errors, and updates status with an error code.</td>
</tr>
<tr>
<td>xml_ignoreunkownelemets</td>
<td>Force the XML serializer to ignore unexpected elements that are not defined in the XML schema.</td>
</tr>
<tr>
<td></td>
<td>A value of zero means FALSE. The default is FALSE.</td>
</tr>
<tr>
<td></td>
<td>Throws an exception in case of errors, and updates status with an error code.</td>
</tr>
<tr>
<td>xml_ignoreunknwonattributes</td>
<td>Force the XML serializer to ignore unexpected attributes that are not defined in the XML schema.</td>
</tr>
<tr>
<td></td>
<td>A value of zero means FALSE. The default is FALSE.</td>
</tr>
<tr>
<td></td>
<td>Throws an exception in case of errors, and updates status with an error code.</td>
</tr>
<tr>
<td>Flag</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>xml_usetypedefinition</td>
<td>Defines whether the serializer must specify the type of data during serialization. This will add an &quot;xsi:type&quot; attribute to each XML data type.</td>
</tr>
<tr>
<td></td>
<td>A value of zero means FALSE. The default is FALSE.</td>
</tr>
<tr>
<td></td>
<td>Throws an exception in case of errors, and updates status with an error code.</td>
</tr>
<tr>
<td>xml_useutctime</td>
<td>Defines that BDL DATETIME data type is converted to UTC time during the serializer marshalling process.</td>
</tr>
<tr>
<td></td>
<td>A value of zero means FALSE. The default is FALSE.</td>
</tr>
<tr>
<td></td>
<td>Throws an exception in case of errors, and updates status with an error code.</td>
</tr>
<tr>
<td>xop_threshold</td>
<td>When using the optimized serializer APIs, you can set a size that determines whether the BYTE is handled as a separate part (with an XML-Binary Optimized document created for it) or whether it is transmitted inline and encoded in base64 format.</td>
</tr>
<tr>
<td></td>
<td>CALL xml.serializer.setOption(&quot;xop_threshold&quot;,5000)</td>
</tr>
<tr>
<td></td>
<td>In this example, BYTE variables whose size is greater than 5000 bytes are handled as a separate part, otherwise they are handled inline and encoded in base64 format.</td>
</tr>
<tr>
<td></td>
<td>By default, the size is zero (0), and all BYTE variables are handled as separate parts.</td>
</tr>
<tr>
<td>xs_processcontents</td>
<td>Defines the way to generate wildcard elements and attributes in XML schemas via the XML schema processContents tag. See Table 624: Values for xs_processcontents on page 2891</td>
</tr>
<tr>
<td></td>
<td>Throws an exception in case of errors, and updates status with an error code.</td>
</tr>
</tbody>
</table>

**Table 624: Values for xs_processcontents**

- CLASS Signature
  - Digests
• Transformations
• CLASS KeyStore

The CryptoKey class
The xml.CryptoKey class provides methods to manipulate HMAC, symmetric and asymmetric keys needed for signing, verifying, encrypting and decrypting XML documents or document fragments.

It follows the XML-Signature and XML-Encryption specifications.

The STATUS variable is set to zero after a successful method call.

xml.CryptoKey methods
Methods for the xml.CryptoKey class.

Table 625: Class methods: Creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml.CryptoKey.Create (url STRING) RETURNS xml.CryptoKey</td>
<td>Initializes a xml.CryptoKey object. Constructor of an empty CryptoKey object based on a URL.</td>
</tr>
<tr>
<td>xml.CryptoKey.CreateDerivedKey (url STRING) RETURNS xml.CryptoKey</td>
<td>Constructor of an empty CryptoKey object based on an URL. The crypto key must be derived before use.</td>
</tr>

<td>Loads the given key in BASE64 string format into a CryptoKey object.</td>
</tr>
<tr>
<td><code>loadPEM()</code></td>
<td>Loads an asymmetric DSA key, an asymmetric RSA key, or Diffie-Hellman parameters from a file in PEM format.</td>
</tr>
<tr>
<td><code>loadPrivate()</code></td>
<td>Loads the private asymmetric RSA key from the given XML document.</td>
</tr>
<tr>
<td><code>loadPublic()</code></td>
<td>Loads the public part of an asymmetric RSA or DSA CryptoKey object, or the parameters and the public key of the Diffie-Hellman object from a XML document.</td>
</tr>
<tr>
<td><code>loadPublicFromString()</code></td>
<td>Populate the current CryptoKey object with the passed public key.</td>
</tr>
<tr>
<td><code>savePrivate()</code></td>
<td>Saves the private key part of an asymmetric RSA CryptoKey object into a XML document according to the XKMS2.0 specification.</td>
</tr>
<tr>
<td><code>savePublic()</code></td>
<td>Saves the public part of an asymmetric RSA or DSA CryptoKey object, or the parameters and the public key of the Diffie-Hellman object into a XML document.</td>
</tr>
<tr>
<td><code>savePublicToString()</code></td>
<td>Save the current xml.CryptoKey's public part in the returned base64 string.</td>
</tr>
<tr>
<td><code>saveToString()</code></td>
<td>Saves the CryptoKey object into a BASE64 string format.</td>
</tr>
</tbody>
</table>
### Table 629: Object methods: Feature

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getFeature</td>
<td>Returns the value of the given feature for this CryptoKey object, or NULL.</td>
</tr>
<tr>
<td>setFeature</td>
<td>Sets or resets the value of a feature for a CryptoKey object.</td>
</tr>
</tbody>
</table>

**xml.CryptoKey.compareTo**

Compares a CryptoKey object to a second key.

**Syntax**

```java
compareTo(
    toCompare xml.CryptoKey
) RETURNS INTEGER
```

1. `toCompare` defines the `xml.CryptoKey` object to use for comparison to the current CryptoKey object.

**Usage**

The method verifies if the key's URL, type, size, usage and value are the same. If they are the same, the two identical keys will produce the same encryption cipher.

The key features are not taken into account during comparison.

Returns `TRUE` if they are identical, `FALSE` if they are not identical.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related reference**

- **CryptoKey Features** on page 2909
- Features of the `xml.CryptoKey` class.

**xml.CryptoKey.computeKey**

Computes the shared secret based on the given modulus, generator, the private key, and the other peer's public key. The returned key can be any symmetric/HMAC or symmetric/encryption key type. It can be used for symmetric signature or symmetric encryption.

**Syntax**

```java
computeKey(
    pub xml.CryptoKey,
    url STRING
) RETURNS xml.CryptoKey
```

1. `pub` defines the other peer's public key (`xml.CryptoKey`).
2. `url` defines the shared secret key type as an URL identifier (`STRING`).
Usage

**Important:** This method is for Diffie-Hellman key-agreement algorithm only.

Returns a `xml.CryptoKey` `sharedSecret`: a `xml.CryptoKey` object of the specified type.

In the 3DES case, no key weakness test is done. If the compound shared secret is weak, the other peer involved in the communication may raise an error. It depends on the language used on the other side.

In order to be able to compute an AES256 shared secret of the Java side, you need to add or replace the files `local_policy.jar` and `US_export_policy.jar` located in `$JDK_HOME/jre/lib/security` by the Java Cryptographic Extension corresponding to your JDK version. You can find this extension at [http://www.oracle.com/technetwork/java/javase/downloads/index.html](http://www.oracle.com/technetwork/java/javase/downloads/index.html).

If the shared secret key length is less than the Diffie-Hellman key length, only the first needed bytes will be taken. For example, if the Diffie-Hellman is 512 bits length and the shared secret is a 3DES key, then only the first 192 bits will be used by the computation. In a 3DES shared secret case, `xml.CryptoKey.computeKey()` is calculated, whereas in AES shared secret case, the Diffie-Hellman key is truncated.

If the shared secret key length is bigger than the Diffie-Hellman key length, an error is raised.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

```
xm.CryptoKey.Create
  Initializes a xml.CryptoKey object. Constructor of an empty CryptoKey object based on a URL.
```

**Syntax**

```
xm.CryptoKey.Create (  
  url STRING  )  
RETURNS xml.CryptoKey
```

1. `url` defines a key identifier based on the XML-Signature and XML-Encryption specification or the Diffie-Hellman specification.

**Usage**

Returns a `xml.CryptoKey` object or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

```
xm.CryptoKey.CreateDerivedKey
  Constructor of an empty CryptoKey object based on an URL. The crypto key must be derived before use.
```

**Syntax**

```
xm.CryptoKey.CreateDerivedKey (  
  url STRING  )  
RETURNS xml.CryptoKey
```

1. `url` defines a key identifier based on the XML-Signature and XML-Encryption specification.

**Usage**

Returns a `xml.CryptoKey` object or NULL. Only symmetric and HMAC keys can be derived.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts
xml.CryptoKey.deriveKey on page 2897
Derives the symmetric or HMAC CryptoKey object using the given method identifier and concatenating the optional label, the mandatory seed value and the optional created date as initial random value.

xml.CryptoKey.CreateFromNode
Constructor of a new CryptoKey object based on a URL, from a XML node based on the XML-Signature and XML-Encryption specification.

Syntax

```
xml.CryptoKey.CreateFromNode (  
    url STRING,  
    node xml.DomNode )  
RETURNS xml.CryptoKey
```

1. url defines a key identifier restricted to PUBLIC/PRIVATE keys.
2. node defines an ELEMENT node whose local name is either:
   - DSAKeyValue or RSAKeyValue belonging to the XML-Signature namespace http://www.w3.org/2000/09/xmldsig#
   - RSAKeyPair belonging to the XKMS 2.0 namespace http://www.w3.org/2002/03/xkms#

Usage
Returns a CryptoKey object or NULL.

If the local name is RSAKeyValue or RSAKeyPair, the URL must be a RSA key. If the local name is DSAKeyValue, the URL must be a DSA key.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoKey.deriveKey
Derives the symmetric or HMAC CryptoKey object using the given method identifier and concatenating the optional label, the mandatory seed value and the optional created date as initial random value.

Syntax

```
deriveKey (  
    url STRING,  
    label STRING,  
    seed STRING,  
    created STRING,  
    offset INTEGER,  
    bytes INTEGER )
```

1. url defines the identifier of the algorithm to apply to the password and its inputs.
2. label defines the optional label input.
3. seed defines the mandatory seed input as a valid Base64 string representing random binary data obtained with the security.RandomGenerator.CreateRandomNumber on page 2971 helper method.
4. created defines the optional created date input.
5. offset defines the number of bytes the resulting octet stream must be shifted to obtain the derived key.
6. bytes defines the number of bytes of the resulting derived key.
Usage

If it is a symmetric key, the size can be 0, or must match the original key depending on the identifier of the key type. See Derived keys on page 2908 for more details.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoKey.generateKey

Generates a random key of given size (in bits).

Syntax

```java
generateKey(
    keySize INTEGER
)
```

1. *keySize* defines the size of the key to generate.

Usage

For symmetric keys, the size is fixed by the key identifier and cannot be changed. The only authorized values are the real key size or NULL.

For Diffie-Hellman, the input parameter (size INTEGER) is the size of the Diffie-Hellman modulus. If the given size is greater than zero (0), it populates the Diffie-Hellman object by randomly generating a modulus of the given size and a private key, and computes the public key. The used generator is two (2). If the given size is zero (0), it completes the Diffie-Hellman object by choosing a private key and computing the public key based on the previously loaded parameters. For more details on loading parameters, see Table 636: Object methods: Load and save on page 2913.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoKey.getFeature

Returns the value of the given feature for this CryptoKey object, or NULL.

Syntax

```java
getFeature(
    feature STRING
) RETURNS STRING
```

1. *feature* defines the CryptoKey feature.

Usage

Returns NULL if the feature is not set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related reference

CryptoKey Features on page 2909
Features of the xml.CryptoKey class.
Returns the SHA1 encoded key identifier in a base64 encoded STRING.

**Syntax**

```java
getSHA1()  
RETURNS STRING
```

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoKey.getSize

Returns the size of the key in bits.

**Syntax**

```java
getSize()  
RETURNS INTEGER
```

**Usage**

For a Diffie-Hellman key, it returns the size of the key; the size of a Diffie-Hellman key is actually the size of the modulus. If the modulus is not available (null or equal to zero), the method returns zero. In this situation, a return of zero does NOT mean the key is corrupt or unusable.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related reference**

Supported kind of keys on page 2905
Types of keys supported by the `xml.CryptoKey` class.

xml.CryptoKey.getType

Returns the type of the key.

**Syntax**

```java
getType()  
RETURNS STRING
```

**Usage**

This method returns the key type. It corresponds to the key type used by the identifier.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related reference**

Supported kind of keys on page 2905
Types of keys supported by the `xml.CryptoKey` class.

xml.CryptoKey.getUrl
Returns the key identifier as an URL.

**Syntax**

```java
getUrl()
RETURNS STRING
```

**Usage**

This method returns the cryptographic key as an URL. The key is defined in the XML-Signature and XML-Encryption specification.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related reference**

- Supported kind of keys on page 2905
- Types of keys supported by the `xml.CryptoKey` class.

`xml.CryptoKey.getUrl`

Returns the usage of the key.

**Syntax**

```java
getUsage()
RETURNS STRING
```

**Usage**

This method returns the usage of the key as defined by the `identifier`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related reference**

- Supported kind of keys on page 2905
- Types of keys supported by the `xml.CryptoKey` class.

`xml.CryptoKey.getUsage`

Loads a symmetric or HMAC key from a file in raw format.

**Syntax**

```java
loadBIN(
    filename STRING)
```

1. `filename` defines the file name or an entry in the FGLPROFILE file.

**Usage**

Raw format means that data in the file is read without any transformation, and will be stored as is in the key.

For instance, if your file contains "hello", it has the same effect as calling `xml.CryptoKey.setKey()` with "hello" as parameter.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoKey.loadDER
Loads an asymmetric DSA key, an asymmetric RSA key, or Diffie-Hellman parameters from a file in DER format.

Syntax

```java
loadDER(
    filename STRING )
```

1. `filename` defines the file name or an entry in the FGLPROFILE file.

Usage

If the DSA or RSA private key or Diffie-Hellman parameters is protected with a password, the recommended way is to unprotect it with the openssl tool and to put the key file on a restricted file system. However, you can use a script or the fglpass agent to provide the password to the application.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoKey.loadFromString
Loads the given key in BASE64 string format into a CryptoKey object.

Syntax

```java
loadFromString(
    str STRING )
```

1. `str` defines the string to load.

Usage

For Diffie-Hellman, the input parameter is a base64 encoded string containing the Diffie-Hellman parameters. This method populates the Diffie-Hellman key with the modulus and generator in the base64 encoded string. This is useful for the parameters exchange step between two peers.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoKey.loadPEM
Loads an asymmetric DSA key, an asymmetric RSA key, or Diffie-Hellman parameters from a file in PEM format.

Syntax

```java
loadPEM(
    filename STRING )
```

1. `filename` defines the file name or an entry in the FGLPROFILE file.

Usage

If the DSA or RSA private key or Diffie-Hellman parameters are protected with a password, the recommended way is to unprotect it with the openssl tool and to put the key file on a restricted file system. However, you can use a script or the fglpass agent to provide the password to the application.
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3280.

\texttt{xml.CryptoKey.loadPrivate}

Loads the private asymmetric RSA key from the given XML document.

\begin{verbatim}
Syntax

loadPrivate(
    doc xml.DomDocument
)

1. \texttt{doc} defines a \texttt{xml.DomDocument} object.

Usage

This method loads the private asymmetric RSA key contained in the given \texttt{xml.DomDocument} into the private key element of the CryptoKey object. The RSA private key is based on the \texttt{XKMS2.0 specification}.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3280.

\texttt{xml.CryptoKey.loadPublic}

Loads the public part of an asymmetric RSA or DSA CryptoKey object, or the parameters and the public key of the Diffie-Hellman object from a XML document.

\begin{verbatim}
Syntax

loadPublic(
    doc xml.DomDocument
)

1. \texttt{doc} defines a \texttt{xml.DomDocument} object.

Usage

This method populates the RSA or DSA CryptoKey object with the public key parts contained in the given \texttt{xml.DomDocument}.

The asymmetric RSA CryptoKey object public key part is based on the XML-Signature specification for \texttt{RSA}. The DSA CryptoKey object public key part is based on the \texttt{DSA specification}.

For Diffie-Hellman, the input parameter is a \texttt{xml.DomDocument} object containing a representation of the Diffie-Hellman key based on the XML-Signature specification for the Diffie-Hellman key values. This method populates the Diffie-Hellman object with the parameters and the public key contained in the given \texttt{xml.DomDocument}.

If the public key node exists in the \texttt{xml.DomDocument} but is empty, it won't be possible to use the key unless the document contains valid modulus and generator parameters and you call \texttt{xml.CryptoKey.generateKey} with a size of zero (0). In this case, you won't be in possession of the other peer's public key.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3280.

\texttt{xml.CryptoKey.loadPublicFromString}

Populate the current CryptoKey object with the passed public key.

\begin{verbatim}
Syntax

loadPublicFromString(
    keyString
)

1. \texttt{keyString} defines a string.

Usage

This method populates the current CryptoKey object with the passed public key.

The asymmetric RSA CryptoKey object public key part is based on the XML-Signature specification for \texttt{RSA}. The DSA CryptoKey object public key part is based on the \texttt{DSA specification}.

For Diffie-Hellman, the input parameter is a \texttt{xml.DomDocument} object containing a representation of the Diffie-Hellman key based on the XML-Signature specification for the Diffie-Hellman key values. This method populates the Diffie-Hellman object with the parameters and the public key contained in the given \texttt{xml.DomDocument}.

If the public key node exists in the \texttt{xml.DomDocument} but is empty, it won't be possible to use the key unless the document contains valid modulus and generator parameters and you call \texttt{xml.CryptoKey.generateKey} with a size of zero (0). In this case, you won't be in possession of the other peer's public key.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3280.
1. $str$ defines the public part of the key in base64 form.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.CryptoKey.savePrivate`

Saves the private key part of an asymmetric RSA CryptoKey object into a XML document according to the XKMS2.0 specification.

**Syntax**

```java
savePrivate()
RETURNS xml.DomDocument
```

**Usage**

Returns a `xml.DomDocument` object containing the private key part of an asymmetric RSA key.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.CryptoKey.savePublic`

Saves the public part of an asymmetric RSA or DSA CryptoKey object, or the parameters and the public key of the Diffie-Hellman object into a XML document.

**Syntax**

```java
savePublic()
RETURNS xml.DomDocument
```

**Usage**

This method saves the public key parts of an RSA or DSA CryptoKey object in an `xml.DomDocument`

The asymmetric RSA CryptoKey object public key part is based on the XML-Signature specification for RSA. The DSA CryptoKey object public key part is based on the DSA specification.

For Diffie-Hellman, the method is used for the public key exchanged between the two peers.

See also the CryptoKey RetrievalMethod feature.

Returns a `xml.DomDocument` object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.CryptoKey.savePublicToString`

Save the current `xml.CryptoKey`'s public part in the returned base64 string.

**Syntax**

```java
savePublicToString()
RETURNS STRING
```
Usage

Returns the public part of the key in base64 form (STRING).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoKey.saveToString

Saves the CryptoKey object into a BASE64 string format.

Syntax

```
saveToString()
RETURNS STRING
```

Usage

For Diffie-Hellman, this method returns the Diffie-Hellman key’s modulus and generator in a base64 encoded string. This is used for the parameters exchange step between the two peers.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoKey.setFeature

Sets or resets the value of a feature for a CryptoKey object.

Syntax

```
setFeature(
    feature STRING,
    value STRING )
```

1. `feature` defines the name of the feature.
2. `value` defines the value to set for the named feature.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related reference

CryptoKey Features on page 2909
Features of the xml.CryptoKey class.

xml.CryptoKey.setKey

Defines the value of a HMAC or Symmetric key.

Syntax

```
setKey(
    key STRING )
```

1. `key` defines the value.
**Usage**

The value can be a password and must be of the size corresponding to the key identifier.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**Supported kind of keys**

Types of keys supported by the `xml.CryptoKey` class.

</tbody>
</table>

**Derived keys**

Key derivation is used on symmetric or HMAC keys to avoid the direct usage of a shared secret password in secured operations. If two parties share a secret password that is successfully hacked by a third party, any future operations become insecure, and the initial two parties do not even realize that their exchanges are unsafe. However, if a different password based on that shared secret password is used for each new secured operation, even if one operation is compromised, it will only be insecure for that operation, but not other operations.

The derivation consists of applying an algorithm with some additional inputs (such as a random seed value) to a password in order to obtain another password that is then used in one secured operation. Of course, the algorithm and its additional inputs must also be shared to enable the computation of the same derived key for the decryption of the message by the person it is intended for.

Note that passwords are often only composed of alphanumeric characters, which makes the job of a hacker a little bit easier, whereas a derived key is composed of any binary data produced by the algorithm used for the derivation.

</thead>
<tbody>
<tr>
<td>KeyName</td>
<td>Defines or returns whether a user-defined key name is added during a XML signature or encryption in order to identify it to other applications, or by the xml.key store. The default value is NULL, meaning that no key name is used.</td>
</tr>
<tr>
<td>KeyValue</td>
<td>Defines or returns whether the public part of the asymmetric key is added during a XML signature or encryption. Only for RSA and DSA keys. The default value is FALSE, meaning that no key value is used.</td>
</tr>
<tr>
<td>RetrievalMethod</td>
<td>Defines or returns the URL where the XML form of: • a DSA or RSA public key will be set during a XML signature, and loaded during a XML verification process. • a RSA public key will be set and used to encrypt a XML node during XML encryption • a symmetric key with encryption usage will be used to encrypt a XML node or decrypt it back</td>
</tr>
</tbody>
</table>

Examples
xml.CryptoKey usage examples.

Loading an asymmetric RSA key

```
IMPORT xml

MAIN
DEFINE key xml.CryptoKey
LET key = xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#rsa-1_5")
TRY
CALL key.loadPEM("RSA1024Key.pem")
CALL key.setFeature("KeyName","MyRsaKey")
DISPLAY "Key size (in bits) : ", key.getSize() # displays 1024 (bits)
DISPLAY "Key type : ", key.getType() # displays PRIVATE or PUBLIC
DISPLAY "Key usage : ", key.getUsage() # displays KEYENCRYPTION
CATCH
DISPLAY "Unable to load key :", STATUS
END TRY
```
Note: All keys in PEM or DER format were created with the OpenSSL tool.

Generating a symmetric AES256 key

```plaintext
IMPORT xml

MAIN
DEFINE key xml.CryptoKey
LET key = xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#aes256-cbc")
TRY
CALL key.generateKey(NULL)
DISPLAY "Key size (in bits) : ",key.getSize() # displays 256 (bits)
DISPLAY "Key type : ",key.getType() # displays SYMMETRIC
DISPLAY "Key usage : ",key.getUsage() # displays ENCRYPTION
CATCH
DISPLAY "Unable to generate key :",STATUS
END TRY
END MAIN
```

Note: All keys in PEM or DER format were created with the OpenSSL tool.

Setting a HMAC key

```plaintext
IMPORT xml

MAIN
DEFINE key xml.CryptoKey
LET key = xml.CryptoKey.Create("http://www.w3.org/2000/09/xmldsig#hmac-sha1")
TRY
CALL key.setKey("secretpassword")
# displays 112 (size of secretpassword in bits)
DISPLAY "Key size (in bits) : ",key.getSize()
DISPLAY "Key type : ",key.getType() # displays HMAC
DISPLAY "Key usage : ",key.getUsage() # displays SIGNATURE
CATCH
DISPLAY "Unable to set key :",STATUS
END TRY
END MAIN
```

Note: All keys in PEM or DER format were created with the OpenSSL tool.

Deriving a HMAC key

```plaintext
IMPORT xml
IMPORT security

MAIN
DEFINE key xml.CryptoKey
# will contain a random binary data encoded in Base64
DEFINE seedBase64 STRING
LET key = xml.CryptoKey.CreateDerivedKey("http://www.w3.org/2000/09/xmldsig#hmac-sha1")
TRY
# Creates a random 24 bytes long binary data encoded into a Base64 form string
CALL key.setKey("secretpassword")
# Derives the 14 bytes long "secretpassword" into a 64 bytes long key
# from a random 24 bytes long seed value and shifting the resulting key
# from 255 bytes
```
LET seedBase64 = security.RandomGenerator>CreateRandomString(24)
CALL key.deriveKey(
    "http://schemas.xmlsoap.org/ws/2005/02/sc/dk/p_sha1",
    NULL,seedBase64,NULL,255,64)
# Displays 512 (size of 'secretPassword' derivation in bits)
DISPLAY "Key size (in bits) : ",key.getSize()
# Note: Key is derived and can be used in
# any encryption or signature function
CATCH
    DISPLAY "Unable to derive key :",STATUS
END TRY
END MAIN

**Note:** All keys in PEM or DER format were created with the OpenSSL tool.

Computing the shared secret with Diffie-Hellman

Load the Diffie-Hellman parameters from a PEM file, the other peer's public key from an XML file, and compute the shared secret.

Function **generateKey** is called with a 0, parameters are already filled.

```plaintext
IMPORT xml

FUNCTION BuildSharedSecret(DHdoc) 
DEFINE myKey, othersPubKey, sharedSecret xml.CryptoKey
DEFINE DHdoc xml.DomDocument
LET myKey =  
    xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#DHKeyValue")
LET othersPubKey =  
    xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#DHKeyValue ")
TRY
    CALL othersPubKey.loadPublic(DHdoc)
    # populate myKey with the parameters previously generated by the
    # other peer.
    CALL myKey.loadPEM("DHParam.pem")
    # Randomly generate a private key and compute the public key. Key
    # length is the parameters length.
    CALL myKey.generateKey(0)
    LET sharedSecret = myKey.computeKey(othersPubKey,
        "http://www.w3.org/2000/09/xmldsig#hmac-sha1")
CATCH
    DISPLAY "ERROR : should not raise exception"
    EXIT PROGRAM (-1)
END TRY
END FUNCTION
```

**The CryptoX509 class**

The **xml.CryptoX509** class provides methods to manipulate X509 certificates needed for identification of individual persons, groups or any entities during XML encryption or signature process.

It also provides additional load and save functions to interact with other applications in XML or in BASE64, such as in WS-Security compliant applications. It follows the **XML-Signature** and **XML-Encryption** specifications.

The **STATUS** variable is set to zero after a successful method call.

xml.CryptoX509.Create
Constructor of an empty CryptoX509 object.

Syntax

```
xml.CryptoX509.Create()
RETURNS xml.CryptoX509
```

Usage

Returns a xml.CryptoX509 object or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
xml.CryptoX509.CreateFromNode

Constructor of a new CryptoX509 object from a XML X509 certificate node.

Syntax

```c
xml.CryptoX509.CreateFromNode(
    node xml.DomNode
) RETURNS xml.CryptoX509
```

1. `node` defines an element in `xml.DomNode` node with `X509Data` as local name, which is based on the XML-Signature specification namespace “http://www.w3.org/2000/09/xmldsig#”.

Usage

Returns a `xml.CryptoX509` object or NULL.

If the X509 certificate is incomplete, the certificate will be created from the application global certificate list if one of `SubjectName` or `Issuer` matches. (See `xml.KeyStore.addCertificate` for more details.)

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoX509.createPublicKey

Creates a new public CryptoKey object for the given URL.

Syntax

```c
createPublicKey(
    url STRING
) RETURNS xml.CryptoX509
```

1. `url` defines the given URL.

Usage

This method creates a new public CryptoKey object for the given URL, from the public key embedded in this certificate if any; NULL otherwise.

Returns a `CryptoX509` object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoX509.getFeature

Get the value of a given feature of a CryptoX509 object.

Syntax

```c
getFeature(
    feature STRING
) RETURNS STRING
```

1. `feature` defines a feature of the CryptoX509 object.

Usage

This method returns the value of the given feature for the CryptoX509 object, or NULL if feature is not set.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related reference
CryptoX509 Features on page 2918
Features of the xml.CryptoX509 class.

xml.CryptoX509.getIdentifier
Gets the identification part of a X509 certificate

Syntax

```
getIdentifier ()
RETURNS STRING
```

Usage

Returns the identification part of the X509 certificate in a string.

Example:
/C=FR/ST=France/L=Schiltigheim/O=MC/OU=My Company Name/CN=cert

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoX509.getThumbprintSHA1
Gets the SHA1 encoded thumbprint identifying the X509 certificate.

Syntax

```
getThumbprintSHA1 ()
RETURNS STRING
```

Usage

This method returns the SHA1 encoded thumbprint identifying the X509 certificate in a BASE64-encoded string.

Example: CM4y6z7zzLnTGMe11E46RKIKAPI=

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoX509.load
Loads the given XML document with ds:X509Data as root node in a CryptoX509 object.

Syntax

```
load (doc xml.DomDocument )
```

1. doc defines a xml.DomDocument object.

Usage

This method loads an XML document with ds:X509Data as root node based on the XML-Signature specification as root node in a CryptoX509 object. See the w3.org site for more information on the XML-Signature specification for ds:X509Data as root node.
If the X509 certificate is incomplete, the certificate will be created from the application global certificate list if one of SubjectName or Issuer matches. (See xml.KeyStore.addCertificate for more details.)

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoX509.loadDER
Loads a X509 certificate from a file in DER format.

Syntax

```
loadDER(
    filename STRING )
```

1. `filename` defines the file name or an entry in the FGLPROFILE file.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoX509.loadFromString
Loads the given X509 certificate in BASE64 string format into this CryptoX509 object.

Syntax

```
loadFromString(
    str STRING )
```

1. `str` defines the X509 certificate in BASE64 string format to load.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoX509.loadPEM
Loads a X509 certificate from a file in PEM format.

Syntax

```
loadPEM(
    filename STRING )
```

1. `filename` defines the file name or an entry in the FGLPROFILE file.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoX509.save
Saves the CryptoX509 certificate into a XML document with ds:X509Data element as root node.

**Syntax**

```java
save()
RETURNS xml.DomDocument
```

**Usage**

This method saves a CryptoX509 certificate in an XML document with the ds:X509Data element as root node. See the w3.org site for more information on the XML-Signature specification for ds:X509Data as root node.

(See also the RetrievalMethod feature)

Returns a xml.DomDocument object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoX509.saveToString

Saves the CryptoX509 certificate into a BASE64 string format.

**Syntax**

```java
saveToString()
RETURNS STRING
```

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.CryptoX509.setFeature

Sets or resets the given feature for this CryptoX509 object.

**Syntax**

```java
setFeature (feature STRING, value STRING)
```

1. *feature* defines the *feature* to be set.
2. *value* defines the value to set.

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

</table>

**Examples**
xml.CryptoX509 usage examples.

**Loading a certificate from a PEM file**

```
IMPORT xml

MAIN
  DEFINE x509 xml.CryptoX509
  LET x509 = xml.CryptoX509.Create()
  TRY
    CALL x509.loadPEM("Certificate.crt");
    DISPLAY "Id : ",x509.getIdentifier()
  CATCH
    DISPLAY "Unable to load certificate :",STATUS
  END TRY
END MAIN
```

**Note:** All certificates in PEM format were created with the OpenSSL tool.

**Creating a public key for signature verification from a certificate**

```
IMPORT xml

MAIN
  DEFINE x509 xml.CryptoX509
```

DEFINE key xml.CryptoKey
LET x509 = xml.CryptoX509.Create()
TRY
  CALL x509.loadPEM("RSA1024Certificate.crt");
CATCH
  DISPLAY "Unable to load certificate :",STATUS
  EXIT PROGRAM
END TRY
TRY
  LET key = x509.createPublicKey("http://www.w3.org/2000/09/xmldsig#rsa-sha1")
  DISPLAY "Key size (in bytes) : ",key.getSize() # displays 1024 (bits)
  DISPLAY "Key type : ",key.getType() # displays PUBLIC
  DISPLAY "Key usage : ",key.getUsage() # displays SIGNATURE
CATCH
  DISPLAY "Unable to create public key :",STATUS
END TRY
END MAIN

Note: All certificates in PEM format were created with the OpenSSL tool.

Saving the subjectName of a certificate in XML

IMPORT xml

MAIN
DEFINE x509 xml.CryptoX509
DEFINE doc xml.DomDocument
LET x509 = xml.CryptoX509.Create()
TRY
  CALL x509.loadPEM("RSA1024Certificate.crt");
CATCH
  DISPLAY "Unable to load certificate :",STATUS
  EXIT PROGRAM
END TRY
TRY
  CALL x509.setFeature("X509SubjectName",TRUE)
  LET doc = x509.save()
  CALL doc.setFeature("format-pretty-print",TRUE)
  CALL doc.save("RSAX509SubjectName.xml")
CATCH
  DISPLAY "Unable to save certificate :",STATUS
END TRY
END MAIN

Note: All certificates in PEM format were created with the OpenSSL tool.

The Signature class

The xml.Signature class provides methods to create detached, enveloped or enveloping XML signatures of one or more references of XML documents or document fragments, and to determine whether a signed referenced document has been modified afterwards.

It follows the XML-Signature specifications.

The STATUS variable is set to zero after a successful method call.

</tr>
</tbody>
</table>

`xml.Signature.appendObjectData`

Appends a copy of a XML DomNode to the signature object index.

**Syntax**

`appendObjectData(index INTEGER, node xml.DomNode)`

1. `index` defines the index in this Signature object.
2. `node` defines the `xml.DomNode`. 
xml.Signature.appendReferenceTransformation

Appends transformations related to the specified reference index.

**Syntax**

```java
appendReferenceTransformation(
    referenceIndex INTEGER,
    method STRING,
    args ... )
```

1. `referenceIndex` defines the index in this Signature object.
2. `method` represents an URL as identifier of the transformation algorithm.
3. `args` defines a list of transformations.

**Usage**

This method appends a reference transformation that is executed before any computation.

A transformation modifies the reference URI before signing or validating it. Several transformations are executed one after another, and only once the last transformation has been applied, is the reference really signed or verified.

Depending on the transformation identifier, additional parameters are necessary.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Signature.compute

Computes the signature of all references set in this Signature object.

**Syntax**

```java
compute(
    doc xml.DomDocument )
```

1. `doc` defines the XML document.

**Usage**

If the signature type is:

- Enveloping: then `doc` must be NULL because all document fragment references are inside the Signature itself
- Enveloped: then `doc` must be the XML document where the signature must be added afterwards to get a valid enveloped signature
- Detached: then `doc` can be NULL if all references are absolute, otherwise it can be the XML document fragment references that are referencing

See XML Signature concepts for more details.

Also, see Windows® .NET special recommendation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.
Constructor of a blank Signature object.

**Syntax**

```java
xml.Signature.Create()
RETURNS xml.Signature
```

**Usage**

Returns a XML Signature object or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Signature.CreateFromNode**

Constructor of a new Signature object from a XML Signature node, based on the XML-Signature specification.

**Syntax**

```java
xml.Signature.CreateFromNode(
    node xml.DomNode )
RETURNS xml.Signature
```

1. `node` defines the XML Signature node.

**Usage**

Returns a XML Signature object or NULL.

The `node` must be an element node with Signature as the local name, and it must belong to the XML-Signature namespace `http://www.w3.org/2000/09/xmldsig#`, as defined in www.w3.org.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Signature.createObject**

Creates a new object that will embed additional XML nodes.

**Syntax**

```java
createObject()
RETURNS INTEGER
```

**Usage**

The returned value represents the index for any further manipulation of this signature object.

**Note:** An object is enveloping additional XML nodes, but is not necessarily signed unless there is a reference on it.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Signature.createReference**
Creates a new reference that will be signed with the `compute()` method

**Syntax**

```java
createReference(
    uri STRING,
    digest STRING)
RETURNS INTEGER
```

1. `uri` represents the data to be signed.
2. `digest` defines a URL as identifier for the hash algorithm.

**Usage**

The returned value represents the index for any further manipulation of this reference.

The `uri` can be:

- An absolute URL such as `http://`, `https://`, `tcp://`, `tcps://`, `file://` and `alias://` (see `FGLPROFILE Configuration` for more details about URL mapping with aliases), and where the data can be a XML document or any kind of data such as images or HTML pages.
- NULL to sign the whole document, but only one NULL is allowed in the entire signature.
- A fragment like `#tobesigned`. Note that a DOM node fragment is identified via the value of an attribute of type ID such as `xml:id` or any attribute whose type was changed to ID with `xml.DomNode.setIdAttribute()` or `xml.DomNode.setIdAttributeNS()`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

- `xml.Signature.compute` on page 2924
  Computes the signature of all references set in this Signature object.

  ```java
  xml.Signature.getCanonicalization
  Returns the canonicalization identifier of the signature.
  ```

**Syntax**

```java
getCanonicalization()
RETURNS STRING
```

**Usage**

Returns one of the four canonicalization identifiers of the signature.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

- `xml.Signature.getDocument` on page 2926
  Returns a new `DomDocument` object representing the signature in XML.

**Syntax**

```java
getDocument()
RETURNS xml.DomDocument
```
Usage

Returns a `xml.DomDocument` object.

If the signature type is `enveloped`, it's up to the user to add it at the right place in the XML document it is intended to sign.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.Signature.getID`

Returns the ID value of the signature.

Syntax

```
getID ()
RETURNS STRING
```

Usage

This method returns the ID value of the signature.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.Signature.getObjectCount`

Returns the number of objects in this `Signature` object.

Syntax

```
getObjectCount ()
RETURNS INTEGER
```

Usage

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

`xml.Signature.getObjectId`

Returns the ID value of the signature object.

Syntax

```
getObjectId ( index INTEGER )
RETURNS STRING
```

1. `index` defines the index in this `Signature` object.

Usage

This method returns the ID value of the index (`index`) in this signature object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.
xml.Signature.getReferenceCount

Returns the number of references in this Signature object.

**Syntax**

```java
getReferenceCount ()
RETURNS INTEGER
```

**Usage**

This method returns the number of references in the specified signature object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Signature.getReferenceDigest

Returns the digest algorithm identifier of the reference.

**Syntax**

```java
getReferenceDigest (index INTEGER )
RETURNS STRING
```

1. *index* defines the index in this signature object.

**Usage**

Returns the digest algorithm identifier of the reference of index (*index*) in this signature object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Signature.getReferenceID

Returns the ID value of the reference in this signature object.

**Syntax**

```java
getReferenceID (index INTEGER )
RETURNS STRING
```

1. *index* is the index in this Signature object.

**Usage**

This method returns the ID value of the reference of index (*index*) in this signature object, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Signature.getReferenceTransformation
Gets the transformation identifier related to the reference of index `referenceIndex`.

**Syntax**

```java
getReferenceTransformation(
    referenceIndex INTEGER,
    index INTEGER )
RETURNS STRING
```

1. `referenceIndex` is the index in this Signature object.
2. `index` defines the position in the list of transformation.

**Usage**

Returns the transformation identifier related to the reference of index `referenceIndex`, at the position specified by `index` in the list of transformations.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Signature.getReferenceTransformationCount**

Returns the number of transformations referenced in this signature object.

**Syntax**

```java
getReferenceTransformationCount(
    referenceIndex INTEGER )
RETURNS INTEGER
```

1. `referenceIndex` defines the index in this signature object.

**Usage**

This method returns the number of transformations related to the reference of index `referenceIndex` in this signature object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Signature.getReferenceURI**

Returns the URI of the reference in this signature object.

**Syntax**

```java
getReferenceURI(
    index INTEGER )
RETURNS STRING
```

1. `index` defines the index in this signature object.

**Usage**

This method returns the URI of the reference specified in the index `index` in this signature object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.
xml.Signature.getSignatureMethod
Returns the algorithm method of the signature.

**Syntax**

```java
getSignatureMethod()
RETURNS STRING
```

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Signature.getType
Returns a string with the type of the signature object.

**Syntax**

```java
getType()
RETURNS STRING
```

**Usage**

The string can be `Detached`, `Enveloped`, `Enveloping` or `Invalid` based on the XML-Signature specification.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Signature.RetrieveObjectDataListFromSignatureNode
Returns a DomNodeList containing all embedded XML nodes related to the signature object

**Syntax**

```java
xml.Signature.RetrieveObjectDataListFromSignatureNode(
  signNode xml.DomNode,
  index INTEGER
)
RETURNS xml.DomNodeList
```

1. `signNode` defines the XML Signature `xml.DomNode`.
2. `index` defines the index of the signature object.

**Usage**

This method returns a `xml.DomNodeList` containing all embedded XML nodes related to the signature object specified by the index `index` within the XML signature node, `signNode`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Signature.setCanonicalization
Sets the canonicalization method to use for the signature.

**Syntax**

```java
setCanonicalization(
    url STRING )
```

1. `url` defines one of the four canonicalization identifier.

**Usage**

This method sets the canonicalization method to use for the signature. The default value is the `c14n` method.

**Note:** Windows® .NET default `c14n` canonicalization method is not compatible with the W3C standard, therefore it is recommended to use the `exc-c14n` method when interoperating with a Windows® system.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

xml.Signature.setCertificate

Defines the X509 certificate to be added to the signature object when signing a document.

**Syntax**

```java
setCertificate(
    cert xml.CryptoX509 )
```

1. `cert` defines the X509 certificate to be added.

**Usage**

If NULL, no certificate is added.

During the computation of the signature, some certificate information can be added based on the feature set on that CryptoX509 object. If no features are set, the complete X509 certificate is automatically added.

During the verification of a signature the certificate set with the `setCertificate` method isn't used. See XML Signature concepts for more details.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

xml.Signature.setID

Sets an ID value for the signature.

**Syntax**

```java
setId(
    id STRING )
```

1. `id` defines the ID value to be set.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.
Defines the key used for signing or validation.

**Syntax**

```java
setKey(
    key xml.CryptoKey
)
```

1. `key` defines the `key` to be used for signing or validation.

**Usage**

Only RSA, DSA or HMAC keys intended for SIGNATURE are allowed.

During the computation of the signature, some key information can be added depending on the `feature` set on that CryptoKey object. If no features are set, nothing is added. See XML Signature concepts for more details.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Signature.setObjectID

Sets an ID for the signature object.

**Syntax**

```java
setObjectID(
    index INTEGER,
    id STRING
)
```

1. `index` defines the index value.
2. `id` defines the value to be set.

**Usage**

This method sets the ID defined by `id` value for the signature object specified in the `index` (index).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Signature.setReferenceID

Sets an ID for the signature reference in the specified signature object.

**Syntax**

```java
setReferenceID(
    index INTEGER,
    id STRING
)
```

1. `index` defines the index value.
2. `id` defines the value to be set.

**Usage**

This method sets the ID for the signature reference defined by the `ID` value for the signature object specified in the index (index).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.
xml.Signature.signString
Sign the passed string according to the specified key.

Syntax

```
signString(
    key xml.CryptoKey,
    str STRING
)
RETURNS STRING
```

1. `key` defines the key to be used for the signature.
2. `str` defines the string to be signed.

Usage

The key can be a HMAC key, a RSA private key, or a DSA private key. The signing process is performed with SHA-1 digest, as recommended by the XMLSec specification.

Returns `sig`, or the signature in base64 format.

This method does not belong to the XML encryption specification.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Signature.verify
Verifies that all references in this signature object have not changed.

Syntax

```
verify(
    doc xml.DomDocument
)
RETURNS INTEGER
```

1. `doc` defines the XML document.

Usage

Returns TRUE if valid, FALSE otherwise.

If the signature type is:

- Enveloping: then `doc` must be NULL because all document fragment references are inside the Signature itself
- Enveloped: then `doc` must be the XML document where the signature was enveloped
- Detached: then `doc` can be null if all references are absolute, otherwise it can be the XML document the fragment references are referencing

See XML Signature concepts for more details.

By default, the validation process uses the CryptoKey set with xml.Signature.setKey() to verify the signature. However, if the signature contains a X509 certificate or a X509 retrieval method, it uses the list of trusted certificates, or if the signature contains a RSA or DSA retrieval method, it uses the RSA or DSA public key automatically loaded.

Note: See Windows® .NET special recommendation.

Before loading the XML document to verify the signature, you might need to set some options to retrieve the "id" nodes with the xml.DomDocument.setFeature() method:

```
DEFINE doc xml.DomDocument
```
CALL doc.setFeature(feature, TRUE)

Here feature must be "auto-id-attribute" if the "id" attribute has no namespace, or "auto-id-qualified-attribute", when "id" has a namespace.

This is especially needed when you encounter error messages such as:

Xml security operation failed : libxml2 library function failed :
  expr=xpointer(id('id-1436767651')).

Meaning that the parser was unable to find the "id" attribute in the XML document.

Note that the "auto-id-*" features will declare all XML attributes where the name is "id", "ID", "Id" or "iD" to be of type ID, and thus be usable via xml.DomDocument.getElementById() method used during signature validation.

If needed, you can also set features for a specific attribute with the xml.DomNode.setIdAttribute() method, or with the xml.DomNode.setIdAttributeNS() method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Signature.verifyString
Verify the signature is consistent with the given key and the original message.

Syntax

```
verifyString(
    key xml.CryptoKey,
    originalStr STRING,
    signature STRING
) RETURNS INTEGER
```

1. key defines the key to use for verification.
2. originalStr defines the signed string in its clear form.
3. toBeVerifiedStr defines the signature to be verified.

Usage

The key can be a HMAC key, a RSA private key or a DSA private key. The HMAC key must be the same as the one used for signing. The public RSA and DSA key must be the public key corresponding to the private key used for signing.

Returns 1 when verification is successful; 0 (zero) is returned if verification fails.

This method does not belong to the XML encryption specification.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**XML Signature concepts**

The purpose of a signature is to guarantee the integrity of a XML document, that it was not altered, and that it still contains the same data as when it was created. An additional purpose of a signature is to authenticate the author of the document. There are different ways to achieve this guarantee.

Sign and verify with a common shared HMAC key
Use if the sender of the XML document and the receiver share a common secret key.

**How to sign**

1. Create a HMAC key with the constructor of the CryptoKey class.
2. Set or load the common shared key value in the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

**How to verify**

1. Create a HMAC key with the constructor of the CryptoKey.
2. Set or load the common shared key value in the CryptoKey object.
3. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
4. Assign the CryptoKey object to the Signature object.
5. Verify the signature validity.

**Related concepts**

Examples on page 2943
xml.Signature usage examples.

Sign with the originator private RSA or DSA key, and verify with the originator public RSA or DSA key

Use if the receiver of the XML document has the RSA or DSA public key of the sender.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

**How to sign**

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

**How to verify**

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA public key into the CryptoKey object.
3. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
4. Assign the CryptoKey object to the Signature object.
5. Verify the signature validity.

**Related concepts**

Examples on page 2943
xml.Signature usage examples.

Sign with the originator private RSA or DSA key, and verify with a RSA or DSA retrieval method
Use if the sender of the XML document provides the public RSA or DSA key in XML form (and via http, tcp or a file protocol).

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

**How to sign**

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Set the RetrievalMethod feature on the CryptoKey object with the URL where the XML form of the public RSA or DSA key is available.
4. Create a blank signature with the constructor of the Signature class.
5. Assign the CryptoKey object to the Signature object.
6. Create one or more references to be signed.
7. Compute the signature.
8. Retrieve the XML signature document from the Signature object.

**How to verify**

1. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
2. Verify the signature validity.

   **Note:** There is no key nor certificate to set in the Signature object during validation.

**Related concepts**

*Examples* on page 2943
*xml.Signature* usage examples.

Sign with the originator private RSA or DSA key, and verify with the originator X509 certificate associated to the private RSA or DSA key

Use if the receiver of the XML document has the X509 certificate associated to the RSA or DSA private key.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

**How to sign**

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

**How to verify**

1. Create a X509 certificate with the constructor of the CryptoX509 class.
2. Load the X509 certificate into the CryptoKey object.
3. Create the RSA or DSA public key from the X509 certificate of the CryptoX509 object.
4. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
5. Assign the CryptoKey object containing the public key to the Signature object.
6. Verify the signature validity.
Related concepts
Examples on page 2943
xml.Signature usage examples.

Sign with the originator private RSA or DSA key, and verify with trusted X509 certificates
Use if the sender of the XML document adds a X509 certificate that was signed by another trusted X509 certificate.
Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign
1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a X509 certificate with the constructor of the CryptoX509 class.
4. Load the X509 certificate associated to the RSA or DSA private key into the CryptoKey object.
5. Create a blank signature with the constructor of the Signature class.
6. Assign the CryptoKey object to the Signature object.
7. Assign the CryptoX509 object to the Signature object.
8. Create one or more references to be signed.
9. Compute the signature.
10. Retrieve the XML signature document from the Signature object.

How to verify
1. Create a X509 certificate with the constructor of the CryptoX509 class.
2. Load the X509 certificate that was used to sign the originator X509 certificate into the CryptoX509 object.
3. Add the X509 certificate as trusted certificate to the application.
4. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
5. Verify the signature validity.

Note: Point 1 to 3 can be omitted if entry xml.application.calist has been set in FGLPROFILE file with the trusted certificate.

Note: There is no key nor certificate to set in the Signature object during validation.

xml.Signature usage examples.

Sign with the originator private RSA or DSA key, and verify with a X509 certificate retrieval method and trusted X509 certificates
Use if the sender of the XML document adds a X509 certificate that was signed by another trusted X509 certificate.
Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign
1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a X509 certificate with the constructor of the CryptoX509 class.
4. Set the RetrievalMethod feature on the CryptoX509 object with the URL where the XML form of the originator X509 certificate is available.
5. Create a blank signature with the constructor of the Signature class.
6. Assign the CryptoKey object to the Signature object.
7. Assign the CryptoX509 object to the Signature object.
8. Create one or more references to be signed.
9. Compute the signature.
10. Retrieve the XML signature document from the Signature object.

**How to verify**

1. Create a X509 certificate with the constructor of the CryptoX509 class.
2. Load the X509 certificate that was used to sign the originator X509 certificate into the CryptoX509 object.
3. Add the X509 certificate as trusted certificate to the application.
4. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
5. Verify the signature validity.

**Note:** Steps 1 - 3 can be omitted if entry `xml.application.calist` has been set in FGLPROFILE file with the trusted certificate.

**Note:** There is no key or certificate to set in the Signature object during validation.

**Related concepts**

- xml.Signature usage examples.

Sign with a named key and verify using the keystore

Use if the sender and the receiver exchange multiple XML documents signed with different keys.

**How to sign**

1. Create a HMAC, RSA or DSA key with the constructor of the CryptoKey class.
2. Set the HMAC key or load the RSA or DSA key in the CryptoKey object.
3. Set the KeyName feature with the name identifying the key.
4. Create a blank signature with the constructor of the Signature class.
5. Assign the CryptoKey object to the Signature object.
6. Create one or more references to be signed.
7. Compute the signature.
8. Retrieve the XML signature document from the Signature object.

**How to verify**

1. Create a HMAC, RSA or DSA key with the constructor of the CryptoKey.
2. Set the HMAC key or load the RSA or DSA key in the CryptoKey object.
3. Set the KeyName feature with the name identifying the key.
4. Register the key to be used by key name for any signature verification.
5. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
6. Verify the signature validity.

**Note:** It is recommended that steps 1 to 4 are done once at application start-up for each key used in the application. Steps 5 - 6 can then be executed quickly for any XML signature to be checked.

The Encryption class
The xml.Encryption class provides methods to encrypt and decrypt XML documents, nodes or symmetric keys.

It follows the XML-Encryption specifications.

The STATUS variable is set to zero after a successful method call.

xml.Encryption methods
Methods for the xml.Encryption class.

Table 651: Class methods: Creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RETURNS xml.Encryption</td>
<td></td>
</tr>
</tbody>
</table>
Table 652: Class methods: String encryption and decryption

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.Encryption.DecryptString (key xml.CryptoKey, str STRING)</code></td>
<td>Decrypts an encrypted string encoded in BASE64, using the specified symmetric key, and returns the string in clear text.</td>
</tr>
<tr>
<td><code>xml.Encryption.EncryptString (key xml.CryptoKey, str STRING)</code></td>
<td>Encrypts the specified string using the symmetric key, and returns the encrypted string encoded in BASE64.</td>
</tr>
<tr>
<td><code>xml.Encryption.RSADecrypt (filename STRING, str STRING)</code></td>
<td>Decrypts the BASE64 encrypted string using the RSA key and returns it in clear text.</td>
</tr>
<tr>
<td><code>xml.Encryption.RSAEncrypt (filename STRING, str STRING)</code></td>
<td>Encrypts the specified string using the RSA key and returns it encoded in BASE64.</td>
</tr>
</tbody>
</table>

The methods listed in Table 652: Class methods: String encryption and decryption on page 2949 do not belong to the XML encryption specification, but are helper functions to allow BDL application to encrypt and decrypt short passwords with RSA keys, or big strings by using symmetric keys. Notice that a common way to encrypt data is to use symmetric keys, and to use RSA keys to encrypt the symmetric key value.

Table 653: Object methods: Key and certificate setting

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<td><code>encryptKey (symkey xml.CryptoKey)</code></td>
<td>Encrypts the given symmetric or HMAC key as an encrypted-key node and returns it as root node of a new XML document.</td>
</tr>
</tbody>
</table>
xml.Encryption.Create

Constructor of an Encryption object.

**Syntax**

```java
xml.Encryption.Create()
  RETURNS xml.Encryption
```

**Usage**

Returns an Encryption object or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Encryption.decryptElement

Decrypts the encrypted data DomNode using the symmetric key.

**Syntax**

```java
decryptElement(
  node xml.DomNode
)
```

1. `node` defines the encrypted DomNode.

**Usage**

The EncryptedData DomNode `node` is replaced at the same place in the XML document with the resulting decrypted element DomNode and its children.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Encryption.decryptElementContent

Decrypts the encrypted data DomNode using the symmetric key.

**Syntax**

```java
decryptElementContent(
  node xml.DomNode
)
```

1. `node` defines the encrypted DomNode.

**Usage**

The EncryptedData DomNode `node` is replaced at the same place in the XML document with the resulting child nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Encryption.decryptElementContentDetached
Decrypts the encrypted data DomNode using the symmetric key, and returns all its children in one new document fragment type xml.DomNode.

**Syntax**

```java
decryptElementContentDetached(
    node xml.DomNode
) RETURNS xml.DomNode
```

1. `node` defines the encrypted DomNode.

**Usage**

This method decrypts the EncryptedData DomNode referenced by `node` and returns all its children in one new DOCUMENT_FRAGMENT_NODE node.

The resulting child nodes are not added at any place in the XML document. It's up to the user to insert them in the right place, and to remove the encrypted node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Encryption.decryptElementDetached

Decrypts the specified encrypted data DomNode using the symmetric key, and returns it in a new element xml.DomNode.

**Syntax**

```java
decryptElementDetached(
    node xml.DomNode
) RETURNS xml.DomNode
```

1. `node` defines the encrypted DomNode.

**Usage**

This method decrypts the EncryptedData DomNode `node`. The resulting element DomNode and its children are not added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the encrypted node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.Encryption.decryptKey

Decrypts the EncryptedKey as root in the given XML document, and returns a new CryptoKey of the given kind.

**Syntax**

```java
decryptKey(
    doc xml.DomDocument,
    url STRING
) RETURNS xml.CryptoKeY
```

1. `doc` defines the DomDocument object.
2. `url` defines the string.
**Usage**
Returns a new CryptoKey of the given kind.

Only symmetric or HMAC keys are allowed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

### xml.Encryption.DecryptString

Decrypts an encrypted string encoded in BASE64, using the specified symmetric key, and returns the string in clear text.

#### Syntax

```
xml.Encryption.DecryptString(
    key xml.CryptoKey ,
    str STRING )
RETURNS STRING
```

1. *key* defines the symmetric key to use for decryption.
2. *str* defines the encrypted string for decryption.

**Usage**

This method decrypts the encrypted string *str* encoded in BASE64, using the symmetric key specified in *key*, and returns the string in clear text.

The key's usage must be for encryption, see Supported kind of keys on page 2905.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

### xml.Encryption.encryptElement

Encrypts the element DomNode and all its children using the symmetric key.

#### Syntax

```
encryptElement (
    node xml.DomNode )
```

1. *node* defines the ELEMENT DomNode to encrypt.

**Usage**

The element DomNode specified in *node* and all its children are replaced at the same place in the XML document with the resulting EncryptedData node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

### xml.Encryption.encryptElementContent

Encrypts all child nodes of the element DomNode using the symmetric key.

#### Syntax

```
encryptElementContent ( 
    node xml.DomNode )
```
1. *node* defines the element **DomNode** to encrypt.

**Usage**

The child nodes of the element **DomNode** specified in *node* are replaced at the same place in the XML document with the resulting **EncryptedData** node.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See **Error handling in GWS calls (STATUS)** on page 3280.

```java
xml.Encryption.encryptElementContentDetached
```

Encrypts all child nodes of the element **DomNode** using the symmetric key, and returns them as one new encrypted-data node.

**Syntax**

```java
encryptElementContentDetached(
    node xml.DomNode
)
RETURNS xml.DomNode
```

1. *node* defines the ELEMENT **DomNode** to encrypt.

**Usage**

Encrypts all child nodes of the element **DomNode** specified in *node* using the symmetric key, and returns them as one new **EncryptedData** node.

The resulting **DomNode** is not added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the nodes in clear form.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See **Error handling in GWS calls (STATUS)** on page 3280.

```java
xml.Encryption.encryptElementDetached
```

Encrypts the element **DomNode** and all its children using the symmetric key, and returns them as one new encrypted-data node.

**Syntax**

```java
encryptElementDetached(
    node xml.DomNode
)
RETURNS xml.DomNode
```

1. *node* defines the ELEMENT **DomNode** to encrypt.

**Usage**

Encrypts the element **DomNode** specified in *node* and all its children using the symmetric key, and returns them as one new **EncryptedData** node.

The resulting **DomNode** is not added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the nodes in clear form.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See **Error handling in GWS calls (STATUS)** on page 3280.

```java
xml.Encryption.encryptKey
```
Encrypts the given symmetric or HMAC key as an encrypted-key node and returns it as root node of a new XML document.

**Syntax**

```
encryptKey(
    symkey xml.CryptoKey
) RETURNS xml.DomDocument
```

1. `symkey` defines the given symmetric or HMAC key as an EncryptedKey node.

**Usage**

This method encrypts the symmetric or HMAC key given in `symkey` as an encrypted-key node and returns it as root node of a new XML document. The encryption key must have been set otherwise it will fail.

Depending on the feature set on the key-encryption key, the returned XML document will contain an additional KeyInfo node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Encryption.EncryptString**

Encrypts the specified string using the symmetric key, and returns the encrypted string encoded in BASE64.

**Syntax**

```
xml.Encryption.EncryptString(
    key xml.CryptoKey,
    str STRING
) RETURNS STRING
```

1. `key` defines the key.
2. `str` defines the string to be encrypted.

**Usage**

This method encrypts the string specified in `str` using the symmetric key defined by `key`, and returns the encrypted string encoded in BASE64.

The key's usage must be for encryption, see Supported kind of keys on page 2905.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**xml.Encryption.getEmbeddedKey**

Get a copy of the embedded symmetric key that was used in the last decryption operation.

**Syntax**

```
getEmbeddedKey()
RETURNS xml.CryptoKey
```

**Usage**

Returns a copy of the embedded symmetric key that was used in the last decryption operation, or NULL if there is none.
An embedded symmetric key is always encrypted, and needs therefore a key-encryption key to be set in order to decrypt it.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 3280).

```xml
xml.Encryption.RSADecrypt
Decrypts the BASE64 encrypted string using the RSA key and returns it in clear text
```

**Syntax**

```sql
xml.Encryption.RSADecrypt (  
  filename STRING,  
  str STRING )  
RETURNS STRING
```

1. `filename` defines the file name of a RSA private key in PEM format or an entry in the FGLPROFILE file.
2. `str` defines a string that was encrypted with the `fglpass` tool or with the `xml.Encryption.RSAEncrypt` method.

**Usage**

RSA decryption is only intended for short strings that cannot exceed the size of the RSA key minus 12 bytes. For instance, if you have a RSA key of 512 bits, your password cannot exceed 512/8-12 = 52 bytes. If you need to handle big strings, you must use symmetric keys and the `DecryptString` method. However, you can use RSA keys to decrypt symmetric key values.

**Important:** You must ensure that access to the RSA private key file is restricted only to the authorized person or group of persons.

If the RSA private key is protected with a password, the recommended way is to unprotect it with the `openssl` tool and to put the key file on a restricted file system. But you can also use a script or the `fglpass` agent to provide the password to the application.

For example, you can encrypt a database password with the `fglpass` tool and store it in the FGLPROFILE file, then you can decrypt it with the `base.Application.getResourceEntry` and the `xml.Encryption.RSADecrypt` method to connect to the database.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 3280).

```xml
xml.Encryption.RSAEncrypt
Encrypts the specified string using the RSA key and returns it encoded in BASE64.
```

**Syntax**

```sql
xml.Encryption.RSAEncrypt (  
  filename STRING,  
  str STRING )  
RETURNS STRING
```

1. `filename` defines the file name of a RSA public or private key in PEM format or an entry in the FGLPROFILE file.
2. `str` defines the string to be encrypted.

**Usage**

RSA encryption is only intended for short strings that cannot exceed the size of the RSA key minus 12 bytes. For instance, if you have a RSA key of 512 bits, your password cannot exceed 512/8-12 = 52 bytes. If you need to handle
big strings, you must use symmetric keys and the \texttt{xml.Encryption.EncryptString} method. However, you can use RSA keys to encrypt symmetric key values.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3280.

\texttt{xml.Encryption.setCertificate}
Assigns a copy of the X509 certificate to this encryption object.

\textbf{Syntax}

\begin{verbatim}
setCertificate(
    cert xml.CryptoX509)
\end{verbatim}

1. \textit{cert} defines the copy of the \texttt{X509} certificate.

\textbf{Usage}

The certificate will then be added to any further XML document or node encryption.

- \texttt{NULL} is allowed to avoid the certificate being added.
- To encrypt using a certificate, you must use the \texttt{createPublicKey} method of the X509 class to obtain the public key embedded in the certificate, and then provide it to the encryption object with \texttt{setKeyEncryptionKey} method.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3280.

\texttt{xml.Encryption.setKey}
Assigns a copy of the symmetric key to this encryption object.

\textbf{Syntax}

\begin{verbatim}
setKey(
    key xml.CryptoKey)
\end{verbatim}

1. \textit{key} defines the symmetric \texttt{key}.

\textbf{Usage}

Any further XML document or node encryption or decryption will use that symmetric key.

When decrypting a XML document that has an embedded symmetric key, the embedded key will be used instead.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3280.

\texttt{xml.Encryption.setKeyEncryptionKey}
Assigns a copy of the key-encryption key to this encryption object.

\textbf{Syntax}

\begin{verbatim}
setKeyEncryptionKey(
    key xml.CryptoKey)
\end{verbatim}

1. \textit{key} defines the key-encryption \texttt{key}.
Usage
Any further XML encryption will use that key-encryption key to encrypt the symmetric key set with setKey() within the resulting XML, and any further XML decryption will use that key-encryption key to decrypt the embedded symmetric key.

- NULL is allowed, meaning that embedded symmetric keys will not be encrypted nor decrypted anymore, assuming that they have been exchanged in another way.
- Only public or private RSA keys, or key-wrap keys are allowed.
- Public RSA keys can encrypt but not decrypt.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Examples
xml.Encryption usage examples.
Encrypt a XML node with a symmetric AES128 key

```xml
IMPORT xml

MAIN
    DEFINE doc xml.DomDocument
    DEFINE root xml.DomNode
    DEFINE enc xml.Encryption
    DEFINE symkey xml.CryptoKey
    LET doc = xml.DomDocument.Create()
    # Notice that white spaces are significant in cryptography,
    # therefore it is recommended that you remove unnecessary ones
    CALL doc.setFeature("whitespace-in-element-content",FALSE)
    TRY
        # Load XML file to be encrypted
        CALL doc.load("XMLFileToBeEncrypted.xml")
        LET root = doc.getDocumentElement()
        # Create symmetric AES128 key for XML encryption purposes
        LET symkey = xml.CryptoKey.Create(
            "http://www.w3.org/2001/04/xmlenc#aes128-cbc")
        CALL symkey.setKey(">secretpassword<") # password of 128 bits
        CALL symKey.setFeature("KeyName","MySecretKey") # Name the password
        # in order to identify the key (Not mandatory)
        # Encrypt the entire document
        LET enc = xml.Encryption.Create()
        CALL enc.setKey(symkey) # Set the symmetric key to be used
        CALL enc.encryptElement(root) # Encrypt
        # Save encrypted document back to disk
        CALL doc.setFeature("format-pretty-print",TRUE)
        CALL doc.save("EncryptedXMLFile.xml")
    CATCH
        DISPLAY "Unable to encrypt XML file :",STATUS
    END TRY
END MAIN
```

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Decrypt a XML node with a symmetric AES128 key

```xml
IMPORT xml

MAIN
    DEFINE doc xml.DomDocument
    DEFINE node xml.DomNode
    DEFINE enc xml.Encryption
    DEFINE symkey xml.CryptoKey
```
DEFINE list xml.DomNodeList
DEFINE str String
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in cryptography,
# therefore it is recommended to remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
# Load encrypted XML file
CALL doc.load("EncryptedXMLFile.xml")
# Retrieve encrypted node (if any) from the document
LET list = doc.getElementsByTagNameNS(
    "EncryptedData","http://www.w3.org/2001/04/xmlenc#")
IF list.getCount()==1 THEN
    LET node = list.getItem(1)
ELSE
    DISPLAY "No encrypted node found"
    EXIT PROGRAM
END IF
# Check if symmetric key name matches the expected "MySecretKey"
(Not mandatory)
LET list = node.selectByXPath(
    "dsig:KeyInfo/dsig:KeyName[position()=1 and
    text()='MySecretKey']","dsig",
    "http://www.w3.org/2000/09/xmldsig#")
IF list.getCount()!=1 THEN
    DISPLAY "Key name doesn't match"
    EXIT PROGRAM
END IF
# Create symmetric AES128 key for XML decryption purpose
LET symkey = xml.CryptoKey.Create(
    "http://www.w3.org/2001/04/xmlenc#aes128-cbc")
CALL symkey.setKey(">secretpassword<") # password of 128 bits
# Decrypt the entire document
LET enc = xml.Encryption.Create()
CALL enc.setKey(symkey) # Set the symmetric key to be used
CALL enc.decryptElement(node) # Decrypt
# Save encrypted document back to disk
CALL doc.setFeature("format-pretty-print",TRUE)
CALL doc.save("DecryptedXMLFile.xml")
CATCH
    DISPLAY "Unable to decrypt XML file ":,STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Encrypt a XML node with a generated symmetric key protected with the public RSA key within a X509 certificate

IMPORT xml

MAIN
DEFINE doc xml.DomDocument
DEFINE root xml.DomNode
DEFINE enc xml.Encryption
DEFINE symkey xml.CryptoKey
DEFINE kek xml.CryptoKey
DEFINE cert xml.CryptoX509
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in cryptography,
# therefore it is recommended to remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
    # Load XML file to be encrypted
CALL doc.load("XMLFileToBeEncrypted.xml")
LET root = doc.getDocumentElement()
# Load the X509 certificate and retrieve the public RSA key
# for key-encryption purpose
LET cert = xml.CryptoX509.Create()
CALL cert.loadPEM("RSA1024Certificate.crt")
LET kek = cert.createPublicKey(
    "http://www.w3.org/2001/04/xmlenc#rsa-1_5")
# Generate symmetric key for XML encryption purpose
LET symkey = xml.CryptoKey.Create(
    "http://www.w3.org/2001/04/xmlenc#aes256-cbc")
CALL symkey.generateKey(NULL)
# Encrypt the entire document
LET enc = xml.Encryption.Create()
CALL enc.setKeyEncryptionKey(kek) # Set the key-encryption key to # be used for protecting the symmetric key
CALL enc.setCertificate(cert) # Set the certificate to be added # (not mandatory)
CALL enc.encryptElement(root) # Encrypt
# Save encrypted document back to disk
CALL doc.setFeature("format-pretty-print",TRUE)
CALL doc.save("EncryptedXMLFile.xml")
CATCH
    DISPLAY "Unable to encrypt XML file :",STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Decrypt a XML node encrypted with a symmetric key protected with a private RSA key

IMPORT xml

MAIN
DEFINE doc xml.DomDocument
DEFINE node xml.DomNode
DEFINE enc xml.Encryption
DEFINE symkey xml.CryptoKey
DEFINE kek xml.CryptoKey
DEFINE list xml.DomNodeList
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in cryptography,
# therefore it is recommended to remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
    # Load encrypted XML file
    CALL doc.load("EncryptedXMLFile.xml")
    # Retrieve encrypted node (if any) from the document
    LET list = doc.getElementsByTagNameNS("EncryptedData",
       "http://www.w3.org/2001/04/xmlenc#")
    IF list.getCount()==1 THEN
        LET node = list.getItem(1)
    ELSE
        DISPLAY "No encrypted node found"
        EXIT PROGRAM
    END IF
    # Load the private RSA key
    LET kek = xml.CryptoKey.create(
        "http://www.w3.org/2001/04/xmlenc#rsa-1_5")
    CALL kek.loadPEM("RSA1024Key.pem")
    # Decrypt the entire document
    LET enc = xml.Encryption.Create()
CALL enc.setKeyEncryptionKey(kek) # Set the key-encryption key to 
# decrypted the protected symmetric key
CALL enc.decryptElement(node) # Decrypt 
# Retrieve the embedded symmetric key for further usage and display 
# info about it
LET symkey = enc.getEmbeddedKey()
DISPLAY "Key size (in bytes) : ",symkey.getSize() # displays 1024
DISPLAY "Key type : ",symkey.getType() # displays SYMMETRIC
DISPLAY "Key usage : ",symkey.getUsage() # displays ENCRYPTION
# Encrypted document back to disk
CALL doc.setFeature("format-pretty-print",TRUE)
CALL doc.save("DecryptedXMLFile.xml")
CATCH
  DISPLAY "Unable to decrypt XML file :",STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

The KeyStore class
The xml.KeyStore class provides static methods to handle a key store that is global for the entire application. It enables you to register X509 and trusted certificates, and any kind of key by name for automatic XML signature validation or XML decryption.

The STATUS variable is set to zero after a successful method call.

xml.KeyStore methods
Methods for the xml.KeyStore class.

Table 657: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml.KeyStore.AddCertificate(</td>
<td>Registers in the keystore the given X509 certificate as a certificate for</td>
</tr>
<tr>
<td>global xml.CryptoX509 )</td>
<td>the application.</td>
</tr>
<tr>
<td>xml.KeyStore.AddKey(</td>
<td>Registers in the keystore the given key by name for the application.</td>
</tr>
<tr>
<td>global xml.CryptoX509 )</td>
<td></td>
</tr>
<tr>
<td>xml.KeyStore.AddTrustedCertificate(</td>
<td>Registers in the keystore the given X509 certificate as a trusted certificate for the application.</td>
</tr>
<tr>
<td>global xml.CryptoX509 )</td>
<td></td>
</tr>
</tbody>
</table>

xml.KeyStore.AddCertificate
Registers in the keystore the given X509 certificate as a certificate for the application.

Syntax

xml.KeyStore.AddCertificate( 
    global xml.CryptoX509 )

1. global defines the X509 certificate to register.

Usage

This method registers a given X509 certificate to be used when an incomplete X509 certificate is detected during signature or encryption. To complete the process the certificate's issuer name and serial number are checked.

The method has the same effect as the FGLPROFILE entry xml.keystore.x509list.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.KeyStore.AddKey
Registers in the keystore the given key by name for the application.

**Syntax**

```plaintext
default xml.KeyStore.AddKey(
global xml.CryptoX509 )
```

1. `global` defines the key object `xml.CryptoX509` to add to the keystore.

**Usage**

This method adds a key to the keystore to be used for XML signature verification or XML decryption when a key has been specified in the XML KeyInfo node and no other key has been set in the Signature or Encryption object.

The CryptoKey must have the KeyName feature set, and the name must be unique in the application.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

xml.KeyStore.AddTrustedCertificate
Registers in the keystore the given X509 certificate as a trusted certificate for the application.

**Syntax**

```plaintext
default xml.KeyStore.AddTrustedCertificate(
global xml.CryptoX509 )
```

1. `global` defines the X509 certificate to register.

**Usage**

This method registers the given X509 certificate as a trusted certificate for the application. It will be used for signature verification if no other certificate was set for that purpose.

The method has the same effect as the FGLPROFILE entry xml.keystore.calist.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**XML transformation classes**

The XML transformation classes transform XML.

**Important:** The XML transformation classes are not supported on GMI mobile devices.

**The XSLTTransformer class**

The `xml.XSLTtransformer` class handles XML transformation following the XSLT version 1.0 specification.

**Important:** This class is not available on iOS, as it is based on libxslt library, which is not allowed on the Apple® store.
**xml.XSLTTransformer methods**
Methods for the xml.XSLTTransformer class.

**Table 658: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.XSLTTransformer.CreateFromDocument(doc xml.DomDocument)</code></td>
<td>Returns a new instance of a XSLTTransformer object to be used to transform a XML document based on a given style sheet.</td>
</tr>
</tbody>
</table>

**Table 659: Object methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.XSLTTransformer.setParameter(param STRING, value STRING)</code></td>
<td>Set parameters in an instance of an XSLTTransformer corresponding to the XSLT entries named by param.</td>
</tr>
<tr>
<td><code>xml.XSLTTransformer.getParameter(param STRING)</code></td>
<td>Get the value of a given parameter in an instance of an XSLTTransformer corresponding to the XSLT entry named by param.</td>
</tr>
<tr>
<td><code>xml.XSLTTransformer.clearParameters()</code></td>
<td>Clear all parameters in an instance of an XSLTTransformer object.</td>
</tr>
<tr>
<td><code>xml.XSLTTransformer.doTransform(doc xml.DomDocument)</code></td>
<td>Transforms the input source based on the XSLT style sheet used to create the XSLTTransformer instance and returns the transformed document.</td>
</tr>
<tr>
<td><code>xml.XSLTTransformer.getErrorDescription(index INTEGER)</code></td>
<td>Returns the exact description of the error referenced by the index.</td>
</tr>
<tr>
<td><code>xml.XSLTTransformer.getErrorsCount()</code></td>
<td>Returns the number of errors.</td>
</tr>
</tbody>
</table>

**xml.XSLTTransformer.clearParameters**
Clear all parameters in an instance of an XSLTTransformer object.

**Syntax**

```xml
xml.XSLTTransformer.clearParameters()
```

**Usage**

Clears all parameters corresponding to the XSLT entries named by `param`.

For example, this XSLT sample contains two `param` definitions:

```xml
<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform" >
```
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Related concepts
xml.XSLTransformer.getParameter on page 2967
Get the value of a given parameter in an instance of an XSLTTransformer corresponding to the XSLT entry named by param.

xml.XSLTransformer.setParameter on page 2966
Set parameters in an instance of an XSLTTransformer corresponding to the XSLT entries named by param.

xml.XSLTransformer.CreateFromDocument
Returns a new instance of a XSLTTransformer object to be used to transform a XML document based on a given style sheet.

Syntax

```
xml.XSLTransformer.CreateFromDocument (  
    doc xml.DomDocument  )  
RETURNS xml.XSLTransformer
```

1. doc defines the given style sheet.

Usage
Returns a new instance of an XSLTTransformer object to be used to transform a XML document based on the given style sheet. It may raise a XML_ERROR_LOAD_EXCEPTION exception if the XML document is not loadable.

There may be non-critical errors when loading a given style sheet document; you can check with the xml.XSLTTransformer.getErrorsCount() method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

To see these methods in a working example, see Example: Using xml.XSLTransformer methods.

xml.XSLTransformer.doTransform
Transforms the input source based on the XSLT style sheet used to create the XSLTTtransformer instance and returns the transformed document.

Syntax

```
xml.XSLTransformer.doTransform (  
    doc xml.DomDocument  )  
RETURNS xml.DomDocument
```
1. *doc* defines the input source.

**Usage**

This method transforms the input source based on the XSLT style sheet used to create the XSLTTransformer instance and returns the transformed document. It raises a `XML_ERROR_FAILED` exception in case of critical error.

The operation may return a new document that may be incomplete. You must check for errors that may occur during the transformation with the `xml.XSLTTransformer.getErrorsCount()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

To see these methods in a working example, see Example: Using xml.XSLTTransformer methods.

**xml.XSLTTransformer.getErrorDescription**

Returns the exact description of the error referenced by the index.

**Syntax**

```sql
xml.XSLTTransformer.getErrorDescription(index INTEGER )
RETURNS STRING
```

1. *index* defines the index of the error returned by `xml.XSLTTransformer.getErrorsCount()`.

**Usage**

This method returns the exact description of the error referenced by the index during the `doTransform()` call or during the `CreateFromDocument()` when the style sheet contains some errors.

This method is typically used in conjunction with `getErrorsCount()`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

To see these methods in a working example, see Example: Using xml.XSLTTransformer methods.

**Related concepts**

- `xml.XSLTTransformer.CreateFromDocument` on page 2964
  - Returns a new instance of a XSLTTransformer object to be used to transform a XML document based on a given style sheet.

- `xml.XSLTTransformer.doTransform` on page 2964
  - Transforms the input source based on the XSLT style sheet used to create the XSLTTransformer instance and returns the transformed document.

**xml.XSLTTransformer.getErrorsCount**

Returns the number of errors.

**Syntax**

```sql
xml.XSLTTransformer.getErrorsCount()
RETURNS INTEGER
```

**Usage**

Return the number of errors during the `doTransform()` call or during the `CreateFromDocument()` when the style sheet contains errors.
It is recommended to check if errors have been encountered after both operations, because even with errors, it is possible to transform a document.

The errors count is reset between CreateFromDocument() and doTransform().

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

To see these methods in a working example, see Example: Using xml.XSLTtransformer methods.

**Related concepts**
xml.XSLTtransformer.getErrorDescription on page 2965
Returns the exact description of the error referenced by the index.
xml.XSLTtransformer.CreateFromDocument on page 2964
Returns a new instance of a XSLTTransformer object to be used to transform a XML document based on a given style sheet.
xml.XSLTtransformer.doTransform on page 2964
Transforms the input source based on the XSLT style sheet used to create the XSLTTransformer instance and returns the transformed document.

xml.XSLTtransformer.setParameter
Set parameters in an instance of an XSLTTransformer corresponding to the XSLT entries named by param.

**Syntax**

```xml
xml.XSLTtransformer.setParameter(
    param STRING,
    value STRING )
```

1. *param* defines the name of the parameter.
2. *value* specifies the value to set the parameter.

**Usage**

Set parameters corresponding to the XSLT entries named by param.

For example, this XSLT sample contains two param definitions:

```xml
<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform" >
  <xsl:param name="QADIR" />
  <xsl:param name="NODE_NAME"/>
  ...
  <MyNode><xsl:value-of select="$QADIR" /></MyNode>
  ...
  <xsl:when test="name()=$NODE_NAME">
    <xsl:copy>
      <xsl:copy-of select="@*"/>
    </xsl:copy>
  </xsl:when>
</xsl:stylesheet>
```

To set the parameter QADIR:

```sql
CALL xslt.setParameter("QADIR","'/work/tmp'" ) # Literal
```

**Note:** If a parameter is a literal, you must quote it before calling the setParameter()
To set the parameter NODE_NAME:

```sql
CALL xslt.setParameter("NODE_NAME","BOOK")
```

If the parameter is already set, the previous value will be replaced by the new one.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

- `xml.XSLTtransformer.getParameter` on page 2967
  
  Get the value of a given parameter in an instance of an XSLTTransformer corresponding to the XSLT entry named by param.

- `xml.XSLTtransformer.clearParameters` on page 2963
  
  Clear all parameters in an instance of an XSLTTransformer object.

**Syntax**

```sql
xml.XSLTtransformer.getParameter(
    param STRING
) RETURNS STRING
```

1. `param` defines the name of the parameter.

**Usage**

Get parameters corresponding to the XSLT entries named by param.

For example, this XSLT sample contains two `param` definitions:

```xml
<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform" >
    <xsl:param name="QADIR" />
    <xsl:param name="NODE_NAME"/>
    ...
    <MyNode><xsl:value-of select="$QADIR" /></MyNode>
    ...
    <xsl:when test="name()=$NODE_NAME">
        <xsl:copy>
            <xsl:copy-of select="@*"/>
        </xsl:copy>
    </xsl:when>
</xsl:stylesheet>
```

To get the parameter QADIR:

```sql
DEFINE dir STRING
SET dir=xslt.getParameter("QADIR")
```

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
To see these methods in a working example, see Example: Using xml.XSLTTransformer methods.

**Related concepts**

- `xml.XSLTTransformer.setParameter` on page 2966
  - Set parameters in an instance of an `XSLTTransformer` corresponding to the XSLT entries named by `param`.
- `xml.XSLTTransformer.clearParameters` on page 2963
  - Clear all parameters in an instance of an `XSLTTransformer` object.

**Example: Using xml.XSLTTransformer methods**

This Genero application provides a working example using methods from the `XSLTTransformer` class.

```genero
IMPORT XML

MAIN
  DEFINE ok BOOLEAN
  IF num_args() != 3 THEN
    DISPLAY "Usage: DoXslp <stylesheet> <source> <result>"
    EXIT PROGRAM 1
  ELSE
    LET ok = RunXSLP(arg_val(1),arg_val(2),arg_val(3))
    IF NOT OK THEN
      DISPLAY "Error: failed"
      EXIT PROGRAM 1
    ELSE
      DISPLAY "Done"
      EXIT PROGRAM
    END IF
  END IF
END MAIN

FUNCTION RunXSLP(style,src,ret)
  DEFINE style,src,ret STRING
  DEFINE ind INTEGER
  DEFINE xslt xml.XSLTTransformer
  DEFINE styleSheet xml.DomDocument
  DEFINE source xml.DomDocument
  DEFINE result xml.DomDocument

  # Load StyleSheet
  TRY
    LET styleSheet = xml.DomDocument.Create()
    CALL styleSheet.load(style)
  CATCH
    DISPLAY "Error: unable to load stylesheet",style
    RETURN FALSE
  END TRY

  # Create XSLT transformer
  TRY
    LET xslt = xml.XSLTTransformer.CreateFromDocument(styleSheet)
    FOR ind=1 TO xslt.getErrorsCount()
      DISPLAY "StyleSheet error #"||ind||" : ",xslt.getErrorDescription(ind)
    END FOR
  CATCH
    DISPLAY "Error: unable to create XSLT transformer from ",styleSheet
    RETURN FALSE
  END TRY

  # Load Source
  TRY
    LET source = xml.DomDocument.Create()
    CALL source.load(src)
  CATCH
    DISPLAY "Error: unable to load source",src
    RETURN FALSE
  END TRY
END FUNCTION
```
CATCH
    DISPLAY "Error : unable to load Source from ", src
    RETURN FALSE
END TRY

# Execute XSLT
TRY
    LET result = xslt.doTransform(source)
    FOR ind=1 TO xslt.getErrorsCount()
        DISPLAY "Error #" || ''ind'' || " : ", xslt.getErrorDescription(ind)
    END FOR
    CATCH
        DISPLAY "Error : unable to apply XSLT stylesheet"
        FOR ind=1 TO xslt.getErrorsCount()
            DISPLAY "Fatal Error #" || ''ind'' || " : ", xslt.getErrorDescription(ind)
        END FOR
        RETURN FALSE
    END TRY

# Save resulting
TRY
    CALL result.save(ret)
    CATCH
        DISPLAY "Error : unable to save result on disk"
        RETURN FALSE
    END TRY

RETURN TRUE
END FUNCTION

OM to XML Migration
Code using the OM classes can be converted to XML classes in most cases.

The build-in om package provides basic XML handling. The Web Services extensions xml package provides full support for XML document processing. You may need to change code from om to xml classes. Before you convert code, make sure that you are using the classes from the appropriate package:

• Classes from the om package exist to manipulate the AUI tree and also provide basic XML handling.
• Classes from the xml package provides classes and methods to handle any kind of XML document processing, and are recommended for XML document manipulation.

Why would you migrate from om to xml classes and methods?

• You need to be able to utilize a feature (such as a StyleSheet) that requires use of methods from the xml library classes.

Note: The DOM API of the om package is designed to handle specific FGL files and to manipulate the user interface tree (the AUI tree). For all other cases, we recommend that you use the DOM API of the Web Services xml package.

OM - XML Mapping
A reference guide to the DOM APIs of the om and xml classes.

### The security package

The Genero Web Services security package provides classes and methods to support basic cryptographic features. Use the `IMPORT` statement at the top of the module using this library:

```plaintext
IMPORT security
```

- The RandomGenerator class on page 2971
- The Base64 class on page 2973
- The HexBinary class on page 2980
- The Digest class on page 2986

### The RandomGenerator class

The `security.RandomGenerator` class includes methods for creating random strings or numbers.

#### security.RandomGenerator methods

Methods of the `security.RandomGenerator` class.

#### Table 661: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>security.RandomGenerator.CreateRandomNumber()</code> RETURNS <code>BIGINT</code></td>
<td>Generates an 8-byte strong random number.</td>
</tr>
<tr>
<td><code>security.RandomGenerator.CreateRandomString(size INTEGER)</code> RETURNS <code>STRING</code></td>
<td>Creates a random base64 string.</td>
</tr>
<tr>
<td><code>security.RandomGenerator.CreateUUIDString()</code> RETURNS <code>STRING</code></td>
<td>Creates a new universal unique identifier (UUID).</td>
</tr>
</tbody>
</table>

**security.RandomGenerator.CreateRandomNumber**
Generates an 8-byte strong random number.

**Syntax**

```plaintext
security.RandomGenerator.CreateRandomNumber() RETURNS BIGINT
```
Usage

This method generates an 8-byte strong random number and returns it as a \texttt{BIGINT}.

The generated number can then be used for advanced cryptographic features.

This method is based on OpenSSL, using \texttt{/dev/random} on UNIX\textsuperscript{®} and \texttt{CryptGenRandom()} on Microsoft\textsuperscript{®} Windows\textsuperscript{®}, which are based on the cryptographically secure pseudo-random number generator (CSPRNG) specifications.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3280.

\texttt{security.RandomGenerator.CreateRandomString}

Creates a random base64 string.

Syntax

\begin{verbatim}
security.RandomGenerator.CreateRandomString(
    size INTEGER
) RETURNS STRING
\end{verbatim}

1. \textit{size} defines the size of the random string.

Usage

This method generates a random string of binary data of \textit{size} bytes long and returns it in a \texttt{STRING} encoded in a Base64 form.

The size must be greater than 0.

Use this function when randomness is required, such as in \texttt{xml.CryptoKey.deriveKey()} or \texttt{security.Digest.CreateDigestString()}.

This method is based on OpenSSL, using \texttt{/dev/random} on UNIX\textsuperscript{®} and \texttt{CryptGenRandom()} on Microsoft\textsuperscript{®} Windows\textsuperscript{®}, which are based on the cryptographically secure pseudo-random number generator (CSPRNG) specifications.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3280.

\texttt{security.RandomGenerator.CreateUUIDString}

Creates a new universal unique identifier (UUID).

Syntax

\begin{verbatim}
security.RandomGenerator.CreateUUIDString()
\end{verbatim}

RETURNS STRING

Usage

This method generates an universal unique identifier and returns the value as \texttt{STRING}.

The generated string follows the UUID version 4 specification. Version 4 UUIDs have the form \texttt{xxxxxxxx-xxxx-4xxx-yxxx-xxxxxxxxxxxx} where \textit{x} is any hexadecimal digit and \textit{y} is one of 8, 9, A, or B.

Note: This method replaces \texttt{com.Util.CreateUUIDString()}.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3280.
The Base64 class
The `security.Base64` class includes methods for encoding to base64 or decoding from base64.

security.Base64 methods
Methods of the `security.Base64` class.
Table 662: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>security.Base64.FromByte</code> (&lt;br&gt;<code>data BYTE</code>)</td>
<td>Encodes the given BYTE data in base64.</td>
</tr>
<tr>
<td><code>security.Base64.FromHexBinary</code> (&lt;br&gt;<code>hexBinVal STRING</code>)</td>
<td>Decodes the given hexadecimal string to base64.</td>
</tr>
<tr>
<td><code>security.Base64.FromString</code> (&lt;br&gt;<code>clearVal STRING</code>)</td>
<td>Encodes the given string in base64.</td>
</tr>
<tr>
<td><code>security.Base64.FromStringWithCharset</code> (&lt;br&gt;<code>clearVal STRING, charset STRING</code>)</td>
<td>Encodes the given string in base64, based on a given charset.</td>
</tr>
<tr>
<td><code>security.Base64.LoadBinary</code> (&lt;br&gt;<code>path STRING</code>)</td>
<td>Reads data from a file and encodes to base64.</td>
</tr>
<tr>
<td><code>security.Base64.SaveBinary</code> (&lt;br&gt;<code>path STRING, base64Data STRING</code>)</td>
<td>Decodes the given base64 string and writes the data to a file.</td>
</tr>
<tr>
<td><code>security.Base64.ToByte</code> (&lt;br&gt;<code>val64 STRING, ret BYTE</code>)</td>
<td>Decodes the given base64 string into a BYTE.</td>
</tr>
<tr>
<td><code>security.Base64.ToHexBinary</code> (&lt;br&gt;<code>val64 STRING</code>)</td>
<td>Decodes the given base64 string to hexadecimal.</td>
</tr>
<tr>
<td><code>security.Base64.ToString</code> (&lt;br&gt;<code>val64 STRING</code>)</td>
<td>Decodes the given base64 string.</td>
</tr>
<tr>
<td><code>security.Base64.ToStringWithCharset</code> (&lt;br&gt;<code>val64 STRING, charset STRING</code>)</td>
<td>Decodes the given base64 string, based on a given charset.</td>
</tr>
<tr>
<td><code>security.Base64.Xor</code> (&lt;br&gt;<code>clearVal1 STRING, clearVal2 STRING</code>)</td>
<td>Computes the exclusive disjunction between two base64 encoded strings.</td>
</tr>
</tbody>
</table>
security.Base64.FromByte
Encodes the given BYTE data in base64.

Syntax

```plaintext
security.Base64.FromByte(
    data BYTE )
RETURNS STRING
```

1. `data` defines the data of type BYTE to be encoded.

Usage

This method encodes the given BYTE data in base64 and returns the string.

Important: The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

security.Base64.FromHexBinary
Decodes the given hexadecimal string to base64.

Syntax

```plaintext
security.Base64.FromHexBinary(
    hexBinVal STRING )
RETURNS STRING
```

1. `hexBinVal` defines the string in hexadecimal form.

Usage

This method decodes the given hexadecimal string and returns it in base64.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

security.Base64.FromString
Encodes the given string in base64.

Syntax

```plaintext
security.Base64.FromString(
    clearVal STRING )
RETURNS STRING
```

1. `clearVal` defines the string to be encoded.

Usage

This method encodes the given string, `clearVal`, and returns it in base64.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
security.Base64.FromStringWithCharset
Encodes the given string in base64, based on a given charset.

Syntax

```csharp
security.Base64.FromStringWithCharset(
    clearVal STRING,
    charset STRING )
RETURNS STRING
```

1. `clearVal` defines the string to be encoded.
2. `charset` defines the character set to be used.

Usage

This method encodes the string, `clearVal`, based on the specified charset, `charset`, and returns it in base64.

Before conversion, the string is converted from the local DVM charset to the specified encoding.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See `Error handling in GWS calls (STATUS)` on page 3280.

security.Base64.LoadBinary
Reads data from a file and encodes to base64.

Syntax

```csharp
security.Base64.LoadBinary(
    path STRING )
RETURNS STRING
```

1. `path` defines the path to the binary file.

Usage

Reads the file located at `path` and encodes this binary data in Base64 format.

For example, this method can be used to send images through a network.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See `Error handling in GWS calls (STATUS)` on page 3280.

security.Base64.SaveBinary
Decodes the given base64 string and writes the data to a file.

Syntax

```csharp
security.Base64.SaveBinary(
    path STRING,
    base64Data STRING )
```

1. `path` defines the path to the binary file.
2. `base64Data` defines base64 string to be written.

Usage

Decodes the given Base64 string and writes the binary data to the file defined by `path`. 
This method can be used to save data from a network on the disk.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**security.Base64.ToHexBinary**
Decodes the given base64 string to hexadecimal.

**Syntax**

```c
security.Base64.ToHexBinary(
  val64 STRING
) RETURNS STRING
```

1. `val64` defines a string encoded in base64.

**Usage**
Decodes the base64 string, `val64`, and returns it in its hexadecimal form.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**security.Base64.ToByte**
Decodes the given base64 string into a BYTE.

**Syntax**

```c
security.Base64.ToByte(
  val64 STRING,
  ret BYTE
)
```

1. `val64` defines the string in base64.
2. `ret` defines a parameter of type BYTE to fill with data.

**Usage**
Decodes the base64 string specified in `val64` and fills the BYTE variable with binary data.

**Important:** The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**security.Base64.ToString**
Decodes the given base64 string.

**Syntax**

```c
security.Base64.ToString(
  val64 STRING
) RETURNS STRING
```

1. `val64` defines the string in base64.
Usage

Decodes the given base64 string and returns it in its clear (human readable) form.

If the base64 string does not contain human readable data, the method will raise an exception.

If the base64 string contains bytes sequences that do not match a valid character in the current encoding, the method raises a conversion error.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

security.Base64.ToStringWithCharset
Decodes the given base64 string, based on a given charset.

Syntax

```
security.Base64.ToStringWithCharset(
    val64 STRING,
    charset STRING
)
RETURNS STRING
```

1. `val64` defines the string in base64.
2. `charset` defines the character set to be used.

Usage

Decodes the given base64 string and returns it in its clear human readable form, based on a given charset.

The original base64 encoded string is first decoded to a string that will be converted from the specified charset to the local DVM charset. In case of charset conversion error, the error -15700 is raised.

If the base64 string does not contain human readable data, the method will raise an exception.

If the base64 string contains bytes sequences that do not match a valid character in the current encoding, the method raises a conversion error.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

security.Base64.Xor
Computes the exclusive disjunction between two base64 encoded strings.

Syntax

```
security.Base64.Xor(
    clearVal1 STRING,
    clearVal2 STRING
)
RETURNS STRING
```

1. `clearVal1` defines the first string encoded in base64.
2. `clearVal2` defines the second string encoded in base64.

Usage

Decodes the two given strings and does an exclusive disjunction between the two binary inputs. The result is returned encoded in base64.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
The HexBinary class
The `security.HexBinary` class includes methods for encoding to hexadecimal or decoding from hexadecimal.

security.HexBinary methods
Methods of the `security.HexBinary` class.
### Table 663: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>security.HexBinary.FromBase64</code>&lt;br&gt;val64 STRING&lt;br&gt;RETURNS STRING</td>
<td>Converts a base64 string to the hexadecimal equivalent.</td>

<td><code>security.HexBinary.ToString</code>&lt;br&gt;hexVal STRING&lt;br&gt;RETURNS STRING</td>
<td>Decodes an hexadecimal string to a clear, human-readable string.</td>
</tr>
<tr>
<td><code>security.HexBinary.ToStringWithCharset</code>&lt;br&gt;hexVal STRING,&lt;br&gt;charset STRING&lt;br&gt;RETURNS STRING</td>
<td>Decodes an hexadecimal string to a clear, human-readable string, based on a given charset.</td>
</tr>
<tr>
<td><code>security.HexBinary.Xor</code>&lt;br&gt;hexVal1 STRING,&lt;br&gt;hexVal2 STRING&lt;br&gt;RETURNS STRING</td>
<td>Computes the exclusive disjunction between two hexadecimal encoded strings.</td>
</tr>
</tbody>
</table>
**security.HexBinary.FromBase64**  
Converts a base64 string to the hexadecimal equivalent.

**Syntax**

```
security.HexBinary.FromBase64(  
    val64 STRING  )  
RETURNS STRING
```

1. `val64` defines a string encoded in base64.

**Usage**

This method decodes the given base64 string and returns it in its hexadecimal form.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**security.HexBinary.FromByte**  
Encodes BYTE data in hexadecimal.

**Syntax**

```
security.HexBinary.FromByte(  
    data BYTE  )  
RETURNS STRING
```

1. `data` defines the data of type BYTE to be encoded.

**Usage**

This method encodes the given BYTE data in hexadecimal and returns the string.

**Important:** The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**security.HexBinary.FromString**  
Encodes a given string in hexadecimal.

**Syntax**

```
security.HexBinary.FromString(  
    clearVal STRING  )  
RETURNS STRING
```

1. `clearVal` defines the string to be encoded.

**Usage**

Encodes the given string and returns it in hexadecimal.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
**security.HexBinary.FromStringWithCharset**
Encodes a given string in hexadecimal, based on a given charset.

**Syntax**

```csharp
security.HexBinary.FromStringWithCharset(
    clearVal STRING,
    charset STRING
) RETURNS STRING
```

1. `clearVal` defines the string to be encoded.
2. `charset` defines the character set to be used.

**Usage**

Encodes the given string and returns it in hexadecimal.
Before conversion, the string is converted from the local DVM charset to the specified encoding.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**security.HexBinary.LoadBinary**
Reads binary data from a file and converts it to hexadecimal.

**Syntax**

```csharp
security.HexBinary.LoadBinary(
    path STRING
) RETURNS STRING
```

1. `path` defines the path to the binary file.

**Usage**

Reads the file located at `path` and returns this binary data in hexadecimal format.
For example, this method can be used to send images through a network.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3280.

**security.HexBinary.SaveBinary**
Decodes an hexadecimal strings and writes the binary data to a file.

**Syntax**

```csharp
security.HexBinary.SaveBinary(
    path STRING,
    hexBinData STRING
)
```

1. `path` defines the path to the binary file.
2. `hexBinData` defines the hexadecimal string to be written.

**Usage**

Decodes the given hexadecimal string and writes the binary data to the file defined by `path`. 
This method can be used to save data from a network on the disk.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

security.HexBinary.ToBase64
Converts an hexadecimal string to the base64 equivalent

Syntax

```java
security.HexBinary.ToBase64(
    hexBinVal STRING
) RETURNS STRING
```

1. `hexBinVal` defines the string in hexadecimal form

Usage

Decodes the given hexadecimal string and returns it in base64.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

security.HexBinary.ToByte
Decodes an hexadecimal string into a BYTE variable.

Syntax

```java
security.HexBinary.ToByte(
    hex STRING,
    ret BYTE
)
```

1. `hex` defines a string in hexadecimal.
2. `ret` defines the input parameter to fill with data of type BYTE.

Usage

Decodes the given hexadecimal string and fills the BYTE variable with binary data.

Important: The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

security.HexBinary.ToString
Decodes an hexadecimal string to a clear, human-readable string.

Syntax

```java
security.HexBinary.ToString(
    hexVal STRING
) RETURNS STRING
```

1. `hexVal` defines the string in hexadecimal.
Usage
Decodes the given hexadecimal string and returns it in its clear, human readable, form. If the hexadecimal string does not contain a human readable string, the method will raise an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See `Error handling in GWS calls (STATUS)` on page 3280.

`security.HexBinary.ToStringWithCharset`
Decodes an hexadecimal string to a clear, human-readable string, based on a given charset.

Syntax

```csharp
security.HexBinary.ToStringWithCharset (    hexVal STRING,    charset STRING ) RETURNS STRING
```

1. `hexVal` defines the string in hexadecimal.
2. `charset` defines the character set to be used.

Usage
Decodes the given hexadecimal string and returns it in its clear human readable form, based on a given charset.

The original hexadecimal encoded string is first decoded to a string that will then be converted from the specified charset to the local DVM charset. In case of charset conversion error, the error -15700 is raised.

If the hexadecimal string does not contain a human readable string, the method will raise an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See `Error handling in GWS calls (STATUS)` on page 3280.

`security.HexBinary.Xor`
Computes the exclusive disjunction between two hexadecimal encoded strings.

Syntax

```csharp
security.HexBinary.Xor (    hexVal1 STRING,    hexVal2 STRING ) RETURNS STRING
```

1. `hexVal1` defines the first string in hexadecimal.
2. `hexVal2` defines the second string in hexadecimal.

Usage
Decodes the two given strings and does an exclusive disjunction between the two binary inputs. The result is returned in hexadecimal.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See `Error handling in GWS calls (STATUS)` on page 3280.
The Digest class
The `security.Digest` class implements digest algorithms to process data.

The class implements several methods that allow you to add data piece by piece and process these data with a specified digest algorithm.

Steps to process data with a digest algorithm:

1. Define the digest algorithm with the `security.Digest.CreateDigest` method.
3. When all data pieces are added, the buffer can be processed by calling methods like `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

Alternatively, a simple data string can be processed with the `security.Digest.CreateDigestString` method.

security.Digest methods
Methods of the `security.Digest` class.

Table 664: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>security.Digest.CreateDigest (algo STRING)</code></td>
<td>Defines a new digest context by specifying the algorithm to be used.</td>
</tr>
<tr>
<td>RETURNS <code>security.Digest</code></td>
<td></td>
</tr>
</tbody>
</table>
### Table 665: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>security.Digest.AddData ( <code>toDigest</code> BYTE )</td>
<td>Adds data from a BYTE variable to the digest buffer.</td>
</tr>
<tr>
<td>security.Digest.AddBase64Data ( <code>toDigest</code> STRING )</td>
<td>Adds data in base64 format to the digest buffer.</td>
</tr>
<tr>
<td>security.Digest.AddHexBinaryData ( <code>toDigest</code> STRING )</td>
<td>Adds data in hexadecimal format to the digest buffer.</td>
</tr>
<tr>
<td>security.Digest.AddStringData ( <code>toDigest</code> STRING )</td>
<td>Adds a data string to the digest buffer.</td>
</tr>
<tr>
<td>security.Digest.AddStringDataWithCharset ( <code>toDigest</code> STRING, <code>charset</code> STRING )</td>
<td>Adds a data string to the digest buffer, after converting to the specified character set.</td>
</tr>
<tr>
<td>security.Digest.CreateDigestString ( <code>toDigest</code> STRING, <code>randomBase64</code> STRING ) RETURNS STRING</td>
<td>Creates a SHA1 digest from the given string.</td>
</tr>
<tr>
<td>security.Digest.DoBase64Digest () RETURNS STRING</td>
<td>Creates a digest of the buffered data and returns the result in base64 format.</td>
</tr>
<tr>
<td>security.Digest.DoHexBinaryDigest () RETURNS STRING</td>
<td>Creates a digest of the buffered data and returns the result in hexadecimal format.</td>
</tr>
</tbody>
</table>

**security.Digest.AddData**

Adds data from a `BYTE` variable to the digest buffer.

**Syntax**

```plaintext
security.Digest.AddData ( toDigest BYTE )
```

1. `toDigest` defines the binary data to be added to the digest buffer.

**Usage**

Adds the binary data contained in the given `BYTE` to the digest context.

After adding all the data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

**Important:** The `BYTE` must be located in memory.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**security.Digest.AddBase64Data**
Adds data in base64 format to the digest buffer.

### Syntax

```java
security.Digest.AddBase64Data ( 
    toDigest STRING )
```

1. `toDigest` defines the base64 data string to be added to the digest buffer.

### Usage

Use the method to decode the given base64 string and add the binary data to the digest buffer.

After adding all the data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**security.Digest.AddHexBinaryData**
Adds data in hexadecimal format to the digest buffer.

### Syntax

```java
security.Digest.AddHexBinaryData ( 
    toDigest STRING )
```

1. `toDigest` defines the hexadecimal data string to be added to the digest buffer.

### Usage

Use the method to decode the given hexadecimal string and add the binary data to the digest buffer.

After adding all the data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**security.Digest.AddStringData**
Adds a data string to the digest buffer.

### Syntax

```java
security.Digest.AddStringData ( 
    toDigest STRING )
```

1. `toDigest` defines the human-readable character string to be added to the digest buffer.

### Usage

This method adds the specified string data to the digest buffer.
After adding all the data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

- `security.Digest.AddStringDataWithCharset` on page 2989
  Adds a data string to the digest buffer, after converting to the specified character set.

- `security.Digest.AddStringDataWithCharset`
  Adds a data string to the digest buffer, after converting to the specified character set.

**Syntax**

```java
security.Digest.AddStringDataWithCharset ( 
    toDigest STRING, 
    charset STRING )
```

1. `toDigest` defines the human-readable character string to be added to the digest buffer.
2. `charset` defines the charset to be used.

**Usage**

This method adds the specified string data based on the given charset to the digest buffer.

Before adding the string, it is converted from the local DVM charset to the specified encoding.

After adding all the data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3280.

**Related concepts**

- `security.Digest.AddStringData` on page 2988
  Adds a data string to the digest buffer.

- `security.Digest.CreateDigest`
  Defines a new digest context by specifying the algorithm to be used.

**Syntax**

```java
security.Digest.CreateDigest ( 
    algo STRING )
RETURNS security.Digest
```

1. `algo` defines the digest algorithm to be used.

**Usage**

Use this method to create and initialize a digest context to compute data digest based on the specified algorithm.

Available digest algorithms are:

- "SHA1"
- "SHA224"
- "SHA256"
- "SHA384"
- "SHA512"
- "MD5"

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

`security.Digest.CreateDigestString`
Creates a SHA1 digest from the given string.

**Syntax**

```plaintext
security.Digest.CreateDigestString(
    toDigest STRING,
    randomBase64 STRING
)
RETURNS STRING
```

1. `toDigest` defines the password to be digested.
2. `randomBase64` defines a random string in Base64.

**Usage**

Use this method to compute the SHA1 digest from the string in `toDigest` and an optional random Base64 form string, and return it in a string encoded in Base64 form.

The random value must be a valid Base64 string. You typically generate this value with the `security.RandomGenerator.CreateRandomString()` method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

**Example**

```plaintext
DEFINE password, digest STRING
...
LET digest =
    security.Digest.CreateDigestString(
        password,
        security.RandomGenerator.CreateRandomString(16) )
```

`security.Digest.DoBase64Digest`
Creates a digest of the buffered data and returns the result in base64 format.

**Syntax**

```plaintext
security.Digest.DoBase64Digest()
RETURNS STRING
```

**Usage**

This method processes the digest on all data previously added to the context and encodes it in base64.

After that call, the internal buffer is cleaned and ready to be populated again with new data to be digested.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.
security.Digest.DoHexBinaryDigest

Creates a digest of the buffered data and returns the result in hexadecimal format.

Syntax

```plaintext
security.Digest.DoHexBinaryDigest ()
RETURNS STRING
```

Usage

This method processes the digest on all data previously added to the context and returns it in hexadecimal. After that call, the internal buffer is cleaned and ready to be populated again with new data to be digested. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

Example

Computing a hash value of a string.

Program example ComputeHash.4gl:

```plaintext
IMPORT SECURITY

MAIN

DEFINE result STRING

IF num_args() != 2 THEN
  DISPLAY "Usage: ComputeHash <string> <hashcode>"
  DISPLAY "  string: the string to digest"
  DISPLAY "  hashcode: SHA1, SHA512, SHA384, SHA256, SHA224, MD5"
ELSE
  LET result = ComputeHash(arg_val(1), arg_val(2))
  IF result IS NOT NULL THEN
    DISPLAY "Hash value is ":result
  ELSE
    DISPLAY "Error"
  END IF
END IF

FUNCTION ComputeHash(toDigest, algo)

DEFINE toDigest, algo, result STRING
DEFINE dgst security.Digest

TRY
  LET dgst = security.Digest.CreateDigest(algo)
  CALL dgst.AddStringData(toDigest)
  LET result = dgst.DoBase64Digest()
CATCH
  DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
  EXIT PROGRAM(-1)
END TRY

RETURN result
END FUNCTION
```

Example execution:
The PBKDF2 class
The security.PBKDF2 class generates passwords using the Password-Based Key Derivation Function 2 (PBKDF2).

security.PBKDF2 methods
Methods of the security.PBKDF2 class.

Table 666: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>security.PBKDF2.GenerateKey (password STRING, salt STRING, hash STRING, iter INTEGER, keySize INTEGER ) RETURNS STRING</td>
<td>Generates a password of a given size based on a human readable password using Password-Based Key Derivation Function 2 (PBKDF2)</td>
</tr>
<tr>
<td>security.PBKDF2.CheckKey (password STRING, salt STRING, hash STRING, iter INTEGER, hashedkey STRING ) RETURNS BOOLEAN</td>
<td>Validates a hashed key.</td>
</tr>
</tbody>
</table>

security.PBKDF2.GenerateKey
Generates a password of a given size based on a human readable password using Password-Based Key Derivation Function 2 (PBKDF2)

Syntax

```plaintext
security.PBKDF2.GenerateKey (password STRING, salt STRING, hash STRING, iter INTEGER, keySize INTEGER ) RETURNS STRING
```

1. `password` defines the human readable password to derive using the PBKDF2 method.
2. `salt` defines the base64 random value created using `Security.RandomGenerator.CreateRandomString()`. Can be NULL.
3. `hash` defines the hash operation. By default, it is "SHA1". Valid values include:
   - SHA1
   - SHA224
   - SHA256
   - SHA384
   - SHA512
   - MD5

Hash value is: Ck1VqNd45QIvq3AZd8XYQLvEhtA=

$ fglrun ComputeHash "Hello World" SHA1

The PBKDF2 class
The security.PBKDF2 class generates passwords using the Password-Based Key Derivation Function 2 (PBKDF2).

security.PBKDF2 methods
Methods of the security.PBKDF2 class.

Table 666: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>security.PBKDF2.GenerateKey (password STRING, salt STRING, hash STRING, iter INTEGER, keySize INTEGER ) RETURNS STRING</td>
<td>Generates a password of a given size based on a human readable password using Password-Based Key Derivation Function 2 (PBKDF2)</td>
</tr>
<tr>
<td>security.PBKDF2.CheckKey (password STRING, salt STRING, hash STRING, iter INTEGER, hashedkey STRING ) RETURNS BOOLEAN</td>
<td>Validates a hashed key.</td>
</tr>
</tbody>
</table>

security.PBKDF2.GenerateKey
Generates a password of a given size based on a human readable password using Password-Based Key Derivation Function 2 (PBKDF2)

Syntax

```plaintext
security.PBKDF2.GenerateKey (password STRING, salt STRING, hash STRING, iter INTEGER, keySize INTEGER ) RETURNS STRING
```

1. `password` defines the human readable password to derive using the PBKDF2 method.
2. `salt` defines the base64 random value created using `Security.RandomGenerator.CreateRandomString()`. Can be NULL.
3. `hash` defines the hash operation. By default, it is "SHA1". Valid values include:
4. \textit{iter} defines the number of iterations to compute the derived password. This value must be greater than or equal to zero (\textgreater{}=0).
5. \textit{keySize} defines the size in bytes of the returned key. Must be greater than zero (>0)

**Usage**

This method generates a password of a given size based on a human readable password using PBKDF2.

In practice, with the same salt value and the same human readable password, the same key can be regenerated in another application and therefore used as symmetric key to decrypt data encrypted in the initial application.

This method may raise exception -15700 (operation failed) or -15701 (invalid parameter).

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3280.

For an example using PBKDF2 methods, see Example: Using security.PBKDF2 methods on page 2994.

**security.PBKDF2.CheckKey**

Validates a hashed key.

**Syntax**

```java
security.PBKDF2.CheckKey(
    password STRING,
    salt STRING,
    hash STRING,
    iter INTEGER,
    hashedkey STRING
) RETURNS BOOLEAN
```

1. \textit{password} defines the human readable password to derive using the PBKDF2 method.
2. \textit{salt} defines the base64 random value created using
   \texttt{Security.RandomGenerator.CreateRandomString()}. Can be \texttt{NULL}.
3. \textit{hash} defines the hash operation. By default, it is "SHA1". Valid values include:
   - SHA1
   - SHA224
   - SHA256
   - SHA384
   - SHA512
   - MD5
4. \textit{iter} defines the number of iterations to compute the derived password. This value must be greater than or equal to zero (\textgreater{}=0).
5. \textit{hashedkey} defines the key created by the \texttt{Security.PBKDF2.GenerateKey()} class method.

**Usage**

This method validates a hashed key produced by the \texttt{security.PBKDF2.GenerateKey} method.

The method returns \texttt{TRUE}, if the hashed key is valid, and returns \texttt{FALSE}, if the hashed key is not valid.

This method may raise exception -15700 (operation failed) or -15701 (invalid parameter).

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3280.
Example: Using security.PBKDF2 methods
This example generates a key size of 128-bits based on a given password.

The 128-bits key can then be used in xml.CryptoKey, for instance.

```plaintext
IMPORT SECURITY

MAIN
DEFINE salt STRING
DEFINE result STRING
LET salt = Security.RandomGenerator.CreateRandomString(8)
TRY
  CALL Security.PBKDF2.GenerateKey(arg_val(1), salt, "sha1", 1000, 16)
  RETURNING result
  DISPLAY "Generate Key of 128bits value is ": result # 128/8==16
CATCH
  IF status == -15700 THEN
    DISPLAY "Generation failed ": SQLCA.SQLERRM
  ELSE
    IF status == -15701 THEN
      DISPLAY "Invalid parameter ": SQLCA.SQLERRM
    ELSE
      DISPLAY "Unknown error ": STATUS
    END IF
  END IF
END TRY
END MAIN
```

The BCrypt class
The security.BCrypt class lets you save passwords as BCrypt results instead of clear text.

If you need to store passwords on a database for instance, you can save them as BCrypt results instead of clear text. This makes them difficult to hack, as the time to generate one is expensive.

security.BCrypt methods
Methods of the security.BCrypt class.

Table 667: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

</tr>
<tr>
<td>RETURNS INTEGER</td>
<td></td>
</tr>
</tbody>
</table>
security.BCrypt.GenerateSalt
Generates the encoded value needed as input to the HashPassword method.

Syntax

```security.BCrypt.GenerateSalt(
    cost INTEGER )
RETURNS STRING```

1. `cost` defines the number of rounds of hashing to apply. The default value is 10. This value must be between 4 and 30. It represents $2^\text{cost}$ iteration. An iteration above 14 may take several minutes to compute.

   **Warning:** Using a high cost value for the salt is very CPU consuming, and can really slow down the application depending on the system it is running. Be forewarned that this is expected!

Usage

This method generates the encoded value needed as input to the HashPassword method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

For an example using BCrypt methods, see Example: Using security.BCrypt methods on page 2996.

Related concepts

security.BCrypt.CheckPassword on page 2996
Checks the hash password.

security.BCrypt.HashPassword on page 2995
Creates a hash password.

security.BCrypt.HashPassword
Creates a hash password.

Syntax

```security.BCrypt.HashPassword(
    password STRING,
    salt STRING )
RETURNS STRING```

1. `password` defines the password to hash. The password is limited to 72 bytes.

2. `salt` defines an encoded value generated by GenerateSalt() that has a dedicated format. If the same hash value is computed again on another application, the same salt must be used. The format of the salt value follows this example: $2a$cost$modified_base64_encoded$(random value of 16-byte length). If `salt` is NULL, the HashPassword method will generate one with a cost of 10.

Usage

The resulting hash password is composed of the version, the cost, and the salt+cipher separated by $, as in this example:

```
$2a$12$EXrkfkdmXn2gzs2SSitue.MW9.qAVqa9eLS1//RYtYCMbeLHg.9q
```

where:

- "2a" is the version of BCrypt. The current API supports 2a to 2z.
- "12" is the cost.
- The remainder is the salt + cipher result concatenated and encoded in "modified" base64:
• The first 22 characters ("EXRkfkmXn2gzs2SSitu." in our example) decode to a 16-byte value for the salt.
• The remaining characters ("MW9.gAVqa9eLS1//RYtYcmBleLHg.9q" in our example) are cipher text.

This method may raise exception -15700 (operation failed) or -15701 (invalid parameter).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

For an example using BCrypt methods, see Example: Using security.BCrypt methods on page 2996.

Related concepts

security.BCrypt.CheckPassword on page 2996
Checks the hash password.

security.BCrypt.GenerateSalt on page 2995
Generates the encoded value needed as input to the HashPassword method.

security.BCrypt.CheckPassword
Checks the hash password.

Syntax

security.BCrypt.CheckPassword(
    password STRING,
    hashedPass STRING )
RETURNS INTEGER

1. password defines the password to hash. The password is limited to 72 bytes.
2. hashedPass defines the hash password created by the HashPassword method.

Usage

The method returns TRUE, the hashed password is valid.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3280.

For an example using BCrypt methods, see Example: Using security.BCrypt methods on page 2996.

Related concepts

security.BCrypt.HashPassword on page 2995
Creates a hash password.

security.BCrypt.GenerateSalt on page 2995
Generates the encoded value needed as input to the HashPassword method.

Example: Using security.BCrypt methods

This example creates (and checks) a hash password as BCrypt results.

IMPORT SECURITY

MAIN
    DEFINE salt STRING
    DEFINE hashed_pass STRING
    LET salt = Security.BCrypt.GenerateSalt(12)

    CALL Security.BCrypt.HashPassword(arg_val(1), salt) RETURNING hashed_pass
    DISPLAY "Hashed password is :",hashed_pass
IF Security.BCrypt.CheckPassword(arg_val(1), hashed_pass) THEN
   DISPLAY "OK: password check done."
ELSE
   DISPLAY "KO: password check failed."
END IF
END MAIN

File extensions

This page describes the file extensions used by the language.

Related concepts

Form specification files on page 1132
Form specification files are the source files defining the layout and content of application forms.

Topmenus on page 1334
Topmenus define typical pull-down menus that appear at the top of application forms.

Toolbars on page 1327
Toolbars define a bar of buttons that appears at the top of application forms.

Presentation styles on page 1065
Use presentation styles to specify decoration attributes for window and form elements.

Start menus on page 1918
Start menus define a tree of application programs that can be started.

Localized strings on page 430
Localized strings provide a means of writing applications in which the text of strings can be customized on site.

Database schema on page 476
Defines database table structures with column type information to be reused in program variable definitions.

Message files on page 1059
Message files centralize strings and larger texts identified by a number, that can be used in programs.

**Genero BDL errors**

System error messages sorted by error number.

**Table 669: Genero system error messages**

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -201   | A syntax error has occurred.  
This general SQL error message indicates mistakes in the syntax of an SQL statement. Look for missing or extra punctuation; keywords misspelled, misused, or out of sequence, or a reserved word used as an identifier. |
| -204   | An illegal floating point number has been found in the statement.  
A numeric constant that is punctuated like a floating-point number (with a decimal point and/or an exponent starting with e) is unacceptable. Possibly the exponent is larger than can be processed. |
| -206   | The specified table table-name is not in the database.  
The database server cannot find a table or view specified in the statement. The table or view might have been renamed or dropped from the database. |
| -213   | Statement interrupted by user.  
The database server received an interrupt signal from the user. The statement ended early. The program is expected to roll back the current transaction and terminate gracefully. |
| -217   | Column column-name not found in any table in the query.  
The column specified does not exist in the database tables used in this SQL statement. |
| -235   | Character column size is too big.  
The SQL statement specifies a width for a character data type that is greater than 65,534 bytes. If you need a column of this size, use the TEXT data type, which allows unlimited lengths. Otherwise, inspect the statement for typographical errors. |
| -236   | Number of columns in INSERT does not match number of VALUES.  
Each column that is named or implied in an INSERT statement must have a separate value expression. If the statement does not list specific columns, review the definition of the table for the number of columns and their data types. Also check that the list of expressions in the VALUES clause has no extra or missing comma that might result in an incorrect number of values. Be especially careful of long character strings and expressions with parentheses. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -239   | Could not insert new row - duplicate value in a UNIQUE INDEX column.  
The row that is being inserted (or being updated to have a new primary key) contains a duplicate value of some row that already exists, in a column or columns that are constrained to have unique values. |
| -244   | Could not do a physical-order read to fetch next row.  
The database server cannot read the data block for this SQL client program. The database server returns this error when a record is locked by another process, and the lock timeout defined by the current program has expired.  
Consider using the `SET LOCK MODE TO WAIT` instruction to define a lock timeout. By default, with most databases, this timeout is zero and error -244 is returned immediately when a lock conflict occurs. If all programs do short transactions (holding locks for a short period of time), it is usually safe to define a lock timeout of 5 to 10 seconds to avoid this SQL error. |
| -250   | Cannot read record from file for update.  
The database server cannot get a row of a table prior to update. |
| -251   | ORDER BY or GROUP BY column number is too big.  
The ORDER BY or GROUP BY clause uses column-sequence numbers, and at least one of them is larger than the count of columns in the select list. |
| -253   | Cannot read record from file for update.  
The database server cannot get a row of a table prior to update. |
| -254   | Too many or too few host variables given.  
The number of host variables that you named in the INTO clause of this statement does not match the number of columns that you referenced in the SQL statement. |
| -255   | Not in transaction.  
The database server cannot execute this COMMIT WORK or ROLLBACK WORK statement because no BEGIN WORK was executed to start a transaction. Because no transaction was started, you cannot end one. |
| -256   | Transaction not available.  
The database server does not support transactions. |
| -257   | System limit on maximum number of statements exceeded, maximum is count.  
The database server can handle only a fixed number of prepared SQL statements for each user. This limit includes statements that were prepared with the PREPARE statement and cursors that were declared with the DECLARE statement. |
| -259   | Cursor not open.  
The current statement refers to a cursor that has not been opened. Review the logic of the program to see how it failed to execute the OPEN statement before it reached this point. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -263   | Could not lock row for UPDATE.  
This statement, probably a FETCH statement that names a cursor declared FOR UPDATE,  
failed to get a lock on the row it tried to fetch. |
| -266   | There is no current row for UPDATE/DELETE cursor.  
The current statement uses the WHERE CURRENT OF cursor-name clause, but that cursor  
has not yet been associated with a current row. Either no FETCH statement has been executed  
since it was opened, or the most recent fetch resulted in an error so that no row was returned.  
Revise the logic of the program so that it always successfully fetches a row before it executes  
this statement. |
| -268   | Unique constraint constraint-name violated.  
The current statement uses the WHERE CURRENT OF cursor-name clause, but that cursor  
has not yet been associated with a current row. Either no FETCH statement has been executed  
since it was opened, or the most recent fetch resulted in an error so that no row was returned.  
Revise the logic of the program so that it always successfully fetches a row before it executes  
this statement. |
| -272   | No SELECT permission for table/column.  
The person who created this table has not granted SELECT privilege to your account name or  
to the public for the table or the column. The owner of the table or the DBA must grant this  
privilege before you can select data from the table or column. |
| -273   | No UPDATE permission for table/column.  
The person who created this table has not granted UPDATE privilege to your account name  
or to the public for the table or the column. The owner of the table or the DBA must grant this  
privilege before you can update a row in this table or update the column. |
| -274   | No DELETE permission for table.  
The person who created this table has not granted DELETE privilege to your account name or to  
the public. The owner of the table or the DBA must grant this privilege before you can delete a  
row in this table. |
| -275   | The Insert privilege is required for this operation.  
The Insert access privilege on this table or column is not currently held by your account name,  
nor by the PUBLIC group, nor by your current role. The owner of the table or the DBA must  
grant the Insert privilege before you can insert a row into this table. |
| -280   | A quoted string exceeds 256 bytes.  
A character literal in this statement exceeds the maximum length. Check the punctuation and  
length of all quoted strings in the statement. Possibly two missing quotes make a long string out  
of two short ones. You must revise the statement to use a shorter character string. |
| -282   | Found a quote for which there is no matching quote.  
Inspect the current statement, examining the punctuation of all quoted strings. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -284  | A subquery has returned not exactly one row.  
A subquery that is used in an expression in the place of a literal value must return only a single row and a single column. In this statement, a subquery has returned more than one row, and the database server cannot choose which returned value to use in the expression. You can ensure that a subquery will always return a single row. Use a WHERE clause that tests for equality on a column that has a unique index. Or select only an aggregate function. Review the subqueries, and check that they can return only a single row.  
This error can also occur when you use a singleton SELECT statement to retrieve multiple rows. You must use the DECLARE/OPEN/FETCH series of statements or the EXECUTE INTO statement to retrieve multiple rows. |
| -285  | Invalid cursor received by sqlexec.  
The cursor that this statement uses has not been properly declared or prepared, or the FREE statement has released it, or an automatic re-prepare has been attempted while opening the cursor but that operation failed, leaving the cursor unavailable. Review the program logic to ensure that the cursor has been declared. If it has, and if the DECLARE statement refers to a statement identifier, check that the referenced statement has been prepared. |
| -290  | Cursor not declared with FOR UPDATE clause.  
This statement attempts to update with a cursor that was not declared for update. To use a cursor with the UPDATE or DELETE statements, you must declare it FOR UPDATE. Review the program logic to make sure that this statement uses the intended cursor. |
| -294  | The column column-name must be in the GROUP BY list.  
In a grouping SELECT, you must list every nonaggregate column in the GROUP BY clause to ensure that a well-defined value exists for each selected column in each grouped row. A column contains either a single aggregate value or a value unique to that group. If a selected column were neither an aggregate nor in the list, two or more values for that column might possibly exist in some group, and the database server is unable to choose which value to display. Revise the query to include either the column name or its positional number in the clause. |
| -307  | Illegal subscript.  
The substring values (two numbers in square brackets) of a character variable are incorrect. The first is less than zero or greater than the length of the column, or the second is less than the first.  
Review all uses of square brackets in the statement to find the error. Possibly the size of a column has been altered and makes a substring fail that used to work. |
| -309  | ORDER BY column or expression must be in SELECT list.  
An expression or column name is in the ORDER BY clause of this SELECT statement, but the expression or column name is not in the select list (the list of values that follows the word SELECT). This action is not supported when a UNIQUE or DISTINCT operator is being used in a query. |
| -316  | Index index-name already exists in database.  
This statement tries to create an index with the name shown, but an index of that name already exists. Only one index of a given name can exist in a single database. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -324   | Ambiguous column column-name.  
The column name appears in more than one of the tables that are listed in the FROM clause of this query. The database server needs to know which columns to use. Revise the statement so that this name is prefixed by the name of its table (table-name.column) wherever it appears in the query. |
| -329   | Database not found or no system permission.  
The database you tried to connect to is not known by the db server.  
Check database client configuration settings and make sure that there is no spelling error in the name of the database |
| -330   | Cannot create or rename the database.  
Possibly you tried to create a database with the same name as one that already exists or rename a database to a name that already exists; if so, choose a different name. |
| -349   | Database not selected yet.  
The SQL statement cannot be executed because no current database exists. You must issue a DATABASE or CONNECT TO instruction before executing other SQL statements. |
| -350   | Index already exists on the column (or on the set of columns).  
This CREATE INDEX statement cannot be executed because an index on the same column or combination of columns already exists. For a given collation order, at most two indexes can exist on any combination of columns, one ascending and one descending. |
| -354   | Incorrect database or cursor name format.  
This statement contains the name of a database or a cursor in some invalid format. If the statement is part of a program, the name might have been passed in a host variable. |
| -360   | Cannot modify a table or view that is also used in subquery.  
The UPDATE, INSERT, or DELETE statement uses data taken from the same table in a subquery. Because of the danger of entering an endless loop, this action is not allowed, except in the case of an uncorrelated subquery in the WHERE clause of the DELETE or UPDATE statement. |
| -363   | CURSOR not on SELECT statement.  
The cursor named in this statement (probably an OPEN) has been associated with a prepared statement that is not a SELECT statement.  
Review the program logic, especially the DECLARE for the cursor, the statement id specified in it, and the PREPARE that set up that statement. If you intended to use a cursor with an INSERT statement, you can only do that when the INSERT statement is written as part of the DECLARE statement. If you intended to execute an SQL statement, do that directly with the EXECUTE statement, not indirectly through a cursor.
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -366   | The scale exceeds the maximum precision specified.  
A problem exists with the precision or scale of a DECIMAL or a MONEY data type usage, for example in a DEFINE statement. It is recommended to declare DECIMAL as DECIMAL(p) or DECIMAL(p,s), where p is the precision (total number of digits) between 1 and 32, and s, is the scale (number of digits to the right of the decimal point) greater or equal to zero and not greater than p. The MONEY type follows the same rules.  
Review the DECIMAL or MONEY type definition, and make sure that the precision is in the range [1,32] and that the scale is in the range [0,precision]. |
| -371   | Cannot create unique index on column with duplicate data.  
This CREATE UNIQUE INDEX statement cannot be completed because the column (or columns) contains one or more duplicate rows. |
| -382   | Same number of columns must be specified for view and select clause.  
In this VIEW statement, you have listed the names of the columns of the view. However, their number is different from the number of columns in the SELECT statement for the view. Check the punctuation of the two lists, and make sure that you have supplied a name for each item in the select list. |
| -387   | No connect permission.  
You cannot access the database that this statement requests because you have not been granted CONNECT privilege to it. Contact a person who has Database Administrator privilege to that database and ask to be granted CONNECT privileges to it. |
| -388   | No resource permission.  
If you issued a CREATE TABLE, CREATE INDEX, or CREATE PROCEDURE statement, you cannot execute this statement because your account has not been granted the RESOURCE privilege for this database. You need the RESOURCE privilege to create permanent tables, indexes on permanent tables, and procedures. |
| -389   | No DBA permission.  
This statement cannot be executed because you have not been granted DBA privilege for this database. Contact a person who has DBA privilege for the database and ask to be granted DBA privilege (or simply ask to have this statement executed for you). |
| -391   | Cannot insert a null into column column-name.  
This statement tries to put a null value in the noted column. However, that column has been defined as NOT NULL. Roll back the current transaction. If this is a program, review the definition of the table, and change the program logic to not use null values for columns that cannot accept them. |
| -400   | Fetch attempted on unopen cursor.  
This FETCH statement names a cursor that has never been opened or has been closed. Review the program logic, and check that it will open the cursor before this point and not accidentally close it. Unless a cursor is declared WITH HOLD, it is automatically closed by a COMMIT WORK or ROLLBACK WORK statement. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-404</td>
<td>The cursor or statement is not available. You used a statement that names a cursor that is was destroyed. Review the program logic and check that the cursor specified is declared and opened, but not freed, prior to reaching this statement.</td>
</tr>
<tr>
<td>-410</td>
<td>Prepare statement failed or was not executed. This EXECUTE statement refers to a statement id that has not been prepared. Either no PREPARE statement was done, or one was done but returned an error code. Review the program logic to ensure that a statement is prepared and the PREPARE return code is checked. A negative error code from PREPARE usually reflects an error in the statement being prepared.</td>
</tr>
<tr>
<td>-412</td>
<td>Command pointer is NULL. This statement (probably an EXECUTE or DECLARE) refers to a dynamic SQL statement that has never been prepared or that has been freed. Review the program logic to ensure that the statement has been prepared, the PREPARE did not return an error code, and the FREE statement has not been used to release the statement before this point.</td>
</tr>
<tr>
<td>-413</td>
<td>Insert attempted on unopen cursor. This INSERT statement names a cursor that has never been opened or that has been closed. Review the program logic, and check that it will open the cursor before this point and not accidentally close it. An insert cursor is automatically closed by a COMMIT WORK or ROLLBACK WORK statement.</td>
</tr>
<tr>
<td>-422</td>
<td>Flush attempted on unopen cursor. This FLUSH statement names a cursor that has never been opened or has been closed. Review the program logic to ensure that it will open the cursor before this point and not accidentally close it. An insert cursor is automatically closed by a COMMIT WORK or ROLLBACK WORK.</td>
</tr>
<tr>
<td>-450</td>
<td>Illegal ESQL locator, or uninitialized blob variable in BDL. An SQL statement is using a TEXT or BYTE variable that was not initialized with LOCATE IN FILE or MEMORY. LOCATE the TEXT or BYTE variable before using it in SQL statements.</td>
</tr>
<tr>
<td>-458</td>
<td>Long transaction aborted. The database server ran out of log space in which to record this transaction. A transaction that is not fully recorded cannot be rolled back. To preserve database integrity, the operating system ended the transaction and rolled it back automatically. All changes made since the start of the transaction have been removed. Terminate the application, and replan it so that it modifies fewer rows per transaction. Alternatively, contact the database server administrator to discuss increasing the number or the size of the logical logs. Be prepared to talk about the number of rows being updated or inserted and the size of each row.</td>
</tr>
<tr>
<td>-481</td>
<td>Invalid statement name or statement was not prepared. The statement has not been prepared, or the format of the statement name is not valid. A valid statement name does not exceed the maximum length, begins with a letter or underscore, does not contain any blanks or nonalphanumeric characters except underscores.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>-482</td>
<td>Invalid operation on a non-SCROLL cursor.</td>
</tr>
<tr>
<td></td>
<td>You cannot issue a FETCH PRIOR, FETCH FIRST, FETCH LAST, FETCH CURRENT, FETCH RELATIVE n, or FETCH ABSOLUTE n statement with a non-scroll cursor. To do so, you must first declare the cursor as a scroll cursor.</td>
</tr>
<tr>
<td>-507</td>
<td>Cursor cursor-name not found.</td>
</tr>
<tr>
<td></td>
<td>The cursor that is named in the WHERE CURRENT OF clause in this UPDATE or DELETE statement does not exist. Review the spelling of the name. If it is as you intended, check the DECLARE statement to ensure that it has been executed. Also make sure that the cursor has not been freed with the FREE statement or during a failed automatic re-prepare attempt.</td>
</tr>
<tr>
<td>-513</td>
<td>Statement not available with this database server.</td>
</tr>
<tr>
<td></td>
<td>The SQL statement used by the program is not valid for the target database server. Review the code, the SQL instruction cannot be used.</td>
</tr>
<tr>
<td>-517</td>
<td>The total size of the index is too large or too many parts in index.</td>
</tr>
<tr>
<td></td>
<td>All database servers have limits on the number of columns that can be included in an index and on the total number of bytes in a key (the sum of the widths of the columns). This CREATE INDEX statement would exceed that limit for this database server.</td>
</tr>
<tr>
<td>-522</td>
<td>Table table-name not selected in query.</td>
</tr>
<tr>
<td></td>
<td>The table name used in an expression (for example, in the WHERE clause) has not been listed in the clause defining the tables to be used in the query (typically the FROM clause in SELECT statements).</td>
</tr>
<tr>
<td>-526</td>
<td>Updates are not allowed on a scroll cursor.</td>
</tr>
<tr>
<td></td>

</tbody>
</table>
| -681   | Column specified more than once in the INSERT list.  
The error occurs if the user specifies a column name more than once in the INSERT column list. |
| -691   | Missing key in referenced table for referential constraint constraint-name.  
A referential constraint has been violated. This condition usually occurs when you are trying to insert a value into or update the value of a column that is part of a referential constraint. The value you are trying to enter does not exist in the referenced (parent-key) column. |
| -692   | Key value for constraint constraint-name is still being referenced.  
You have violated a referential constraint. This situation usually occurs when you are trying to delete a row in a column (parent key) that another row (child key) is referencing. If you are using cascading deletes, database logging must be on. |
| -743   | Object object_name already exists in database.  
You are trying to define an object that already exists in the database. |
| -768   | Internal error in routine routine-name.  
If this internal error recurs, note all circumstances and contact your technical support. |
| -805   | Cannot open file for load.  
The input file that is specified in this LOAD statement is unable to be opened.  
Check the statement. Possibly a more complete path name is needed, the file does not exist, or your account does not have read permission for the file or a directory in which it resides. |
| -806   | Cannot open file for unload.  
The output file that is specified in this UNLOAD statement is unable to be opened.  
Check the statement. Possibly a more complete path name is needed; the file exists, but your account does not have write permission for it; or the disk is full. |
| -809   | SQL Syntax error has occurred.  
The INSERT statement in this LOAD/UNLOAD statement has invalid syntax.  
Review it for punctuation and use of keywords. |
| -846   | Number of values in load file is not equal to number of columns.  
The LOAD processor counts the delimiters in the first line of the file to determine the number of values in the load file. One delimiter must exist for each column in the table, or for each column in the list of columns if one is specified.  
Check that you specified the file that you intended and that it uses the correct delimiter character. An empty line in the text can also cause this error. If the LOAD statement does not specify a delimiter, verify that the default delimiter matches the delimiter that is used in the file. If you are in doubt about the default delimiter, specify the delimiter in the LOAD statement. |
| -930   | Cannot connect to database server servername.  
The application is trying to access the database server but failed. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -942   | Transaction commit failed - transaction will be rolled back.  
This error can occur at transaction-commit time if the database server is unable to commit the transaction. |
| -1102  | Field name not found in form.  
A field name listed in an INPUT, INPUT ARRAY, CONSTRUCT, SCROLL or DISPLAY statement does not appear in the form specification of the screen form that is currently displayed.  
Review the program logic to ensure that the intended window is current, the intended form is displayed in it, and all the field names in the statement are spelled correctly. |
| -1107  | Field subscript out of bounds.  
The subscript of a screen array in an INPUT, DISPLAY, or CONSTRUCT statement is either less than 1 or greater than the number of fields in the array.  
Review the program source in conjunction with the form specification to see where the error lies. |
| -1108  | Record name not in form.  
The screen record that is named in an INPUT ARRAY or DISPLAY ARRAY statement does not appear in the screen form that is now displayed.  
Review the program source in conjunction with the form specification to see if the screen record names match. |
| -1109  | List and record field counts differ.  
The number of program variables does not agree with the number of screen fields in a CONSTRUCT, INPUT, INPUT ARRAY, DISPLAY, or DISPLAY ARRAY statement.  
Review the statement in conjunction with the form specification to see where the error lies. Common problems include a change in the definition of a screen record that is not reflected in every statement that uses the record, and a change in a program record that is not reflected in the form design. |
| -1110  | Form file (file-name) not found.  
The form file that is specified in an OPEN FORM or OPEN WINDOW WITH FORM statement was not found.  
Inspect the form name used in the statement. The form file suffix is not required. If the form is not in the current directory, verify that FGLRESOURCEPATH / DBPATH environment variables contain the path to the form file. |
| -1112  | A form is incompatible with the current BDL version. Rebuild your form.  
The form file that is specified in an OPEN FORM statement is not acceptable. Possibly it was corrupted in some way, or it was compiled with a version of the Form Compiler that is not compatible with the version of the BDL compiler that compiled this program.  
Use a current version of the Form Compiler to recompile the form specification. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1114  | No form has been displayed.  
The current statement requires the use of a screen form. For example, DISPLAY...TO or an INPUT statement must use the fields of a form. However, the DISPLAY FORM statement has not been executed since the current window was opened.  
Review the program logic to ensure that it opens and displays a form before it tries to use a form. |
| -1119  | NEXT FIELD name not found in form.  
This statement (INPUT or INPUT ARRAY) contains a NEXT FIELD clause that names a field that is not defined in the form.  
Review the form and program logic. Perhaps the form has been changed, but the program has not. |
| -1129  | Field ( field-name ) in BEFORE/AFTER clause not found in form.  
This statement includes a BEFORE FIELD clause or an AFTER FIELD clause that names a field that is not defined in the form that is currently displayed.  
Review the program to ensure that the intended form was displayed, and review this statement against the form specification to ensure that existing fields are named. |
| -1133  | The NEXT OPTION name is not in the menu.  
This MENU statement contains a NEXT OPTION clause that names a menu-option that is not defined in the statement.  
The string that follows NEXT OPTION must be identical to one that follows a COMMAND clause in the same MENU statement. Review the statement to ensure that these clauses agree with each other. |
| -1140  | NEXT OPTION is a hidden option.  
The option that is named in this NEXT OPTION statement has previously been hidden with the HIDE OPTION statement. Because it is not visible to the user, it cannot be highlighted as the next choice.  
Use the SHOW OPTION statement to unhide the menu option. |
| -1141  | Cannot close window with active INPUT, DISPLAY ARRAY, or MENU statement.  
This CLOSE WINDOW statement cannot be executed because an input operation is still active in that window. The CLOSE WINDOW statement must have been contained in, or called from within, the input statement itself.  
Review the program logic, and revise it so that the statement completes before the window is closed. |
| -1143  | Window is already open.  
This OPEN WINDOW statement names a window that is already open.  
Review the program logic to see if it contains a CLOSE WINDOW statement. It may be possible that you simply need to use a CURRENT WINDOW statement to bring the open window to the top. |
<table>

<td>PROMPT message is too long to fit in the window. Although BDL truncates the output of MESSAGE and COMMENT to fit the window dimensions, it does not do so for PROMPT and the user’s response. Reduce the length of the prompt string, or make the window larger. Another option is to display most of the prompting text with DISPLAY and then prompt with a single space or colon.</td>
</tr>
<tr>
<td>-1150</td>
<td>Window is too small to display this menu. The window must be at least two rows tall, and it must be wide enough to display the menu title, the longest option name, two sets of three-dot ellipses, and six spaces. Revise the program to make the window larger or to give the menu a shorter name and shorter options. Review the OPEN WINDOW statement for the current window in conjunction with this MENU statement.</td>
</tr>
<tr>
<td>-1168</td>
<td>Command does not appear in the menu. The SHOW OPTION, HIDE OPTION, or NEXT OPTION statement cannot refer to an option (command) that does not exist. Check the spelling of the name of the option.</td>
</tr>
<tr>
<td>-1170</td>
<td>The type of your terminal is unknown to the system. Check the setting of your TERM environment variable and the setting of your TERMCAP or TERMINFO environment variable. Check with your system administrator if you need help with this action.</td>
</tr>
<tr>
<td>-1202</td>
<td>An attempt was made to divide by zero. Zero cannot be a divisor. Check that the divisor is not zero. In some cases, this error arises because the divisor is a character value that does not convert properly to numeric.</td>
</tr>
<tr>
<td>-1204</td>
<td>Invalid year in date. The year in a DATE value or literal is invalid. For example, the number 0000 is not acceptable as the year. Check the value of year.</td>
</tr>
<tr>
<td>-1205</td>
<td>Invalid month in date. The month in a DATE value or literal must be a one- or two-digit number from 1 to 12. Check the value of month.</td>
</tr>
<tr>
<td>-1206</td>
<td>Invalid day in date. The day number in a DATE value or literal must a one- or two-digit number from 1 to 28 (or 29 in a leap year), 30, or 31, depending on the month that accompanies it. Check the value of day.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -1210  | Date could not be converted to month/day/year format.  
        | The DATE type is compatible with the INTEGER type, but not all integer values are valid dates.  
        | The range of valid integer values for dates is from -693,594 to +2,958,464. Numbers that are outside this range have no representation as dates.  
        | Check the value of the number used to assign the date variable. |
| -1212  | Date conversion format must contain a month, day, and year component.  
        | When a date value is converted between internal binary format and display or entry format, a pattern directs the conversion. When conversion is done automatically, the pattern comes from the environment variable DBDATE. When it is done with an explicit call to the rfmtdate(), rdefmtdate(), or USING functions, a pattern string is passed as a parameter. In any case, the pattern string (the format of the message) must include letters that show the location of the three parts of the date: 2 or 3 letters d; 2 or 3 letters m; and either 2 or 4 letters y.  
        | Check the pattern string and the value of DBDATE. |
| -1213  | A character to numeric conversion process failed.  
        | A character value is being converted to numeric form for storage in a numeric column or variable. However, the character string cannot be interpreted as a number.  
        | Check the character string. It must not contain characters other than white space, digits, a sign, a decimal, or the letter e. Verify the parts are in the right order. If you are using NLS, the decimal character or thousands separator might be wrong for your locale. |
| -1214  | Value too large to fit in a SMALLINT.  
        | The SMALLINT data type can accept numbers with a value range from -32,767 to +32,767.  
        | To store numbers that are outside this range, redefine the column or variable to use INTEGER or DECIMAL type. |
| -1215  | Value too large to fit in an INTEGER.  
        | The INTEGER data type can accept numbers with a value range from -2,147,483,647 to +2,147,483,647.  
        | Check the other data types available, such as DECIMAL. |
| -1218  | String to date conversion error.  
        | The data value does not properly represent a date: either it has non-digits where digits are expected, an unexpected delimiter, or numbers that are too large or are inconsistent.  
        | Check the value being converted. |
| -1222  | Value will not fit in a SMALLFLOAT.  
        | A statement tries to assign a value that exceeds the limits of the SMALLFLOAT data type.  
        | Review the code and consider using a FLOAT or DECIMAL type. |
| -1223  | Value will not fit in a FLOAT.  
        | A statement tries to assign a value that exceeds the limits of the FLOAT data type.  
<pre><code>    | Review the code and consider using a DECIMAL type. |
</code></pre>
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1226  | Decimal or money value exceeds maximum precision.  
The data value has more digits to the left of the decimal point than the declaration of the variable allows.  
Revise the program to define the variable with an appropriate precision. |
| -1260  | It is not possible to convert between the specified types.  
Data conversion does not make sense, or is not supported.  
Possibly you referenced the wrong variable or column. Check that you have specified the data types that you intended and that literal representations of data values are correctly formatted. |
| -1261  | Too many digits in the first field of datetime or interval.  
The first field of a DATETIME literal must contain 1 or 2 digits (if it is not a YEAR) or else 2 or 4 digits (if it is a YEAR). The first field of an INTERVAL literal represents a count of units and can have up to 9 digits, depending on the precision that is specified in its qualifier.  
Review the DATETIME and INTERVAL literals in this statement, and correct them. |
| -1262  | Non-numeric character in datetime or interval.  
A DATETIME or INTERVAL literal can contain only decimal digits and the allowed delimiters: the hyphen between year, month, and day numbers; the space between day and hour; the colon between hour, minute, and second; and the decimal point between second and fraction. Any other characters, or these characters in the wrong order, produce an error.  
Check the value of the literal. |
| -1263  | A field in a datetime or interval is out of range.  
At least one of the fields in a datetime or interval is incorrect.  
Inspect the DATE, DATETIME, and INTERVAL literals in this statement. In a DATE or DATETIME literal, the year might be zero, the month might be other than 1 to 12, or the day might be other than 1 to 31 or inappropriate for the month. Also in a DATETIME literal, the hour might be other than 0 to 23, the minute or second might be other than 0 to 59, or the fraction might have too many digits for the specified precision. |
| -1264  | Extra characters at the end of a datetime or interval.  
Only spaces can follow a DATETIME or INTERVAL literal.  
Inspect this statement for missing or incorrect punctuation. |
| -1265  | Overflow occurred on a datetime or interval operation.  
An arithmetic operation involving a DATETIME and/or INTERVAL produced a result that cannot fit in the target variable.  
Check if the data type can hold the result of the operation. For example, extend the INTERVAL precision by using YEAR(9) or DAY(9). |
| -1266  | Intervals or datetimes are incompatible for the operation.  
An arithmetic operation mixes DATETIME and/or INTERVAL values that do not match.  
Check the data types of the variable used in the operation. |

| -1305  | This field requires an entered value.  
The cursor is in a form field that has been designated REQUIRED.  
You must enter some value before the cursor can move to another field. To enter a null value, type any printable character and then backspace. Alternatively, you can cancel the form entry with the Interrupt key. |
| -1306  | Please type again for verification.  
The cursor is in a form field that has been designated VERIFY. This procedure helps to ensure that no typographical errors occur during data entry.  
You must enter the value twice, identically, before the cursor can move to another field. Alternatively, you can cancel the form entry with the Interrupt key. |
| -1307  | Cannot insert another row - the input array is full.  
You are entering data into an array of records that is represented in the program by a static array of program variables. That array is now full; no place is available to store another record.  
Press the ACCEPT key to process the records that you have entered. |
| -1308  | Cannot delete row - it has no data.  
You try to delete a row in an empty row. Nothing was deleted. |
| -1309  | There are no more rows in the direction you are going.  
You are attempting to scroll an array of records farther than it can go, either scrolling up at the top or scrolling down at the bottom of the array. Further attempts will have the same result. |
| -1312  | FORMS statement error number error-num.  
An error occurred in the form at runtime.  
Edit your source file: go to the specified line, correct the error, and recompile the file. |
| -1313  | SQL statement error number error-num.  
The current SQL statement returned this error code number. |
| -1314  | Program stopped at 'filename', line number line-number.  
At runtime an error occurred in the specified file at the specified line. No .err file is generated.  
Edit your source file, go to the specified line, correct the error, and recompile the file. |
| -1318  | A parameter count mismatch has occurred between the calling function and the called function.  
Either too many or too few parameters were given in the call to the function.  
The call is probably in a different source module from the called functions. Inspect the definition of the function, and check all places where it is called to ensure that they use the number of parameters that it declares. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1320  | A function has not returned the correct number of values expected.  
        | A function that returns several variables has not returned the correct number of parameters.  
        | Check your source code and recompile. |
| -1321  | A validation error has occurred as a result of the VALIDATE command.  
        | The VALIDATE LIKE statement tests the current value of variables against rules that are stored in the syscolval table. It has detected a mismatch.  
        | Ordinarily, the program would use the WHENEVER statement to trap this error and display or correct the erroneous values. Inspect the VALIDATE statement to see which variables were being tested and find out why they were wrong. |
| -1322  | A report output file cannot be opened: description  
        | The file that the REPORT TO statement specifies cannot be opened. See the description for more details.  
        | Check that your account has permission to write such a file, that the disk is not full, and that you have not exceeded some limit on the number of open files. |
| -1323  | A report output pipe cannot be opened.  
        | The pipe that the REPORT TO PIPE statement specifies is unable to be started.  
        | Check that all programs that are named in it exist and are accessible from your execution path. Also look for operating-system messages that might give more specific errors. |
| -1324  | A report output file cannot be written to.  
        | The file that the REPORT TO statement specifies was opened, but an error occurred while writing to it.  
        | Possibly the disk is full. Look for operating-system messages that might give more information. |
| -1326  | An array variable has been referenced outside of its specified dimensions.  
        | The subscript expression for an array has produced a number that is either less than one or greater than the number of elements in the array.  
        | Review the program logic that leads up to this statement to determine how the error was made. |
| -1327  | An insert statement could not be prepared for inserting rows into a temporary table used for a report.  
        | Within the report function, BDL generated an SQL statement to save rows into a temporary table. The dynamic preparation of the statement (see the reference material on the PREPARE statement) produced an error.  
<pre><code>    | Probably the database tables are not defined now, at execution time, as they were when the program was compiled. Either the database has been changed, or the program has selected a different database than the one that was current during compilation. Possibly the database administrator has revoked SELECT privilege from you for one or more of the tables that the report uses. Look for other error messages that might give more details. |
</code></pre>

</tbody>
</table>
| -1337  | The variable variable-name has been redefined with a different type or length, definition in module-name-1.4gl, redefinition in module-name-2.4gl.  
The variable that is shown is defined in the GLOBALS section of two or more modules, but it is defined differently in some modules than in others.  
Possibly modules were compiled at different times, with some change to the common GLOBALS file between. Possibly the variable is declared as a module variable in some module that does not include the GLOBALS file. |
| -1338  | The function 'function-name' has not been defined in any module in the program.  
The named function is called from at least one module of the program, but it is defined in none.  
Verify that the module containing the function is a part of the program, and that the function name is correctly spelled. |
| -1340  | The error log has not been started.  
The program called the errorlog() function without first calling the startlog() function.  
Review the program logic to find out the cause of this error. |
| -1349  | Character to numeric conversion error.  
A character value is being converted to numeric form for storage in a numeric column or variable. However, the character string cannot be interpreted as a number. It contains some characters other than white space, digits, a sign, a decimal, or the letter e, or else the parts are in the wrong order so that the number cannot be deciphered. |
| -1353  | Use '!!' to edit TEXT and BYTE fields.  
This is a normal message text used outside an error context. |
| -1355  | Cannot build temporary file.  
A TEXT or BYTE variable has been located in a temporary file using the LOCATE statement.  
The current statement assigns a value into that variable, so BDL attempted to create the temporary file, but an error occurred.  
Possibly no disk space is available, or your account does not have permission to create a temporary file. Look for operating-system error messages that might give more information. |
| -1359  | Read error on blob file 'file-name'.  
The operating system signaled an error during output to a temporary file in which a TEXT or BYTE variable was being saved.  
Possibly the disk is full, or a hardware failure occurred. For more information, look for operating-system messages. |
| -1360  | No PROGRAM= clause for this field.  
No external program has been designated for this field using the PROGRAM attribute in the form-specification file (For Text User Interface mode on ASCII terminals only) |

<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -2024  | There is already a record 'record-name' specified.  
A screen record is automatically defined for each table that is used in the ATTRIBUTES section to define a field. If you define a record with the name of a table, it is seen as a duplicate.  
Check that the record-name of every screen record and screen array is unique in the form specification. |
| -2028  | The symbol 'symbol-name' does not represent a table prefix used in this form.  
In a SCREEN RECORD statement, each component must be introduced by the name of the table as defined in the TABLES section or by the word FORMONLY.  
Review the spelling of the indicated name against the TABLES section, and check the punctuation of the rest of the statement. |
| -2029  | Screen record array 'record-name' has different component sizes.  
The screen record array name has component sizes which either differ from the specified dimension of the array or differ among themselves. This error message appears when one or more of the columns appear a different number of times.  
The dimension of the screen array is written in square brackets that follow its name. Verify that the dimensions of the screen array match the screen fields. |
| -2039  | The attributes AUTONEST, DEFAULT, INCLUDE, VERIFY, RIGHT and ZEROFILL are not supported for BLOB fields.  
Columns of the data type specified cannot be used in the ways that these attributes imply.  
Check that the table and column names are as you intended, and verify the current definition of the table in the database that the DATABASE statement names. |
| -2041  | The form 'form-name' cannot be opened.  
The form filename cannot be opened. This is probably because it does not exist, or the user does not have read permission.  
Check the spelling of filename. Check that the form file exists in your current directory. If it is in another directory, check that the correct pathname has been provided. On a UNIX™ system, if these things are correct, verify that your account has read permission on the file. |
| -2045  | The conditional attributes of a field cannot depend on the values of other fields.  
The boolean expression in a WHERE clause of a COLOR attribute can use only the name of that field and constants.  
Revise this attribute, and recompile the form. |
| -2100  | Field 'field-name' has validation string error, String = string.  
One of the formatting or validation strings that is stored in the syscolval or syscolatt tables is improperly coded. The string is shown as is the field to which it applies.  
Update the string in the tables. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -2810  | The name 'database-name' is not an existing database name.  
This name, which was found in the DATABASE statement at the start of the form specification, is not a database that can be found.  
Check the spelling of the database name and the database entries in the fglprofile file. |
| -2820  | The label name between brackets is incorrectly given or the label is missing.  
In the layout section of a form specification, it is recommended that brackets contain a simple name. Instead, they contain spaces or an invalid name.  
Check the layout section of the form for invalid form item labels. |
| -2830  | A left square bracket has been found on this line, with no right square bracket to match it.  
Every left square bracket field delimiter must have a right square bracket delimiter on the same line.  
Review the form definition file to make sure all fields are properly marked. |
| -2840  | The field label 'label-name' was not defined in the form.  
The indicated name appears at the left of this ATTRIBUTES statement, but it does not appear within brackets in the SCREEN section.  
Review the field tags that have been defined to see why this one was omitted. |
| -2843  | The column 'column-name' does not appear in the form specification.  
A name in this ATTRIBUTES statement has not been defined in the form specification.  
Check that all names in the statement are spelled correctly and defined properly. |
| -2846  | The field 'field-name' is not a member of the table 'table-name'.  
Something in this statement suggests that the name shown is part of this table, but that is not true in the current database.  
Review the spelling of the two names. If they are as you intended, check that the correct database is in use and that the table has not been altered. |
| -2859  | The column 'column-name' is a member of more then one table -- you must specify the table name.  
Two or more tables that are named in the TABLES section have columns with the name shown.  
You must make clear which table you mean. To do this, write the table name as a prefix of the column name, as table.column, wherever this name is used in the form specification. |
| -2860  | There is a column/value type mismatch for 'column-name'.  
This statement assigns a value to the field with the DEFAULT clause or uses its value with the INCLUDE clause, but it does so with data that does not agree with the data type of the field.  
Review the data type of the field (which comes from the column with which it is associated), and make sure that only compatible values are assigned. |

<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -4333  | The function 'function-name' has already been called with a different number of parameters.  
Earlier in the program, there is a call to this same function or event with a different number of parameters in the parameter list. At least one of these calls must be in error.  
Examine the FUNCTION statement for the named function to find out the correct number of parameters. Then examine all calls to it, and make sure that they are written correctly. |
| -4334  | The variable 'variable-name' in its current form is too complex to be used in this statement.  
The variable has too many component parts. Only simple variables (those that have a single component) can be used in this statement.  
If variable-name is an array, you must provide a subscript to select just one element. If it is a record, you must choose just one of its components. (However, if this statement permits a list of variables, as in the INITIALIZE statement, you can use asterisk or THRU notation to convert a record name into a list of components) |
| -4335  | The symbol 'field-name' is not an element of the record 'record-name'.  
The field name used in a record.field expression is not identified as a member of the record variable.  
Find the definition of the record (it may be in theGLOBALS file), verify the names of its fields, and correct the spelling of field-name. |
| -4336  | The parameter 'param-name' has not been defined within the function or report.  
The name variable-name appears in the parameter list of the FUNCTION statement for this function. However, it does not appear in a DEFINE statement within the function. All parameters must be defined in their function before use.  
Review your code. Possibly you wrote a DEFINE statement but did not spell variable-name the same way in both places. |
| -4338  | The symbol 'symbol-name' has already been defined once as a parameter.  
The name that is shown appears in the parameter list of the FUNCTION statement and in at least two DEFINE statements within the function body.  
Review your code. Only one appearance in a DEFINE statement is permitted. |
| -4340  | The variable 'variable-name' is too complex a type to be used in an expression.  
In an expression, only simple variables (those that have a single component) can be used.  
If the variable indicated is an array, you must provide a subscript to select just one element. If it is a record or object, you must choose just one of its components. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -4341  | Aggregate functions are only allowed in reports and SELECT statements.  
Aggregation functions such as SUM, AVG, and MAX can only appear in SQL statements and within certain statements that you use in the context of a report body. They are not supported in ordinary expressions in program statements.  
Review the code and check that the aggregate functions are in an SQL statement or in the correct blocks of the REPORT routine. |
| -4343  | Subscripting cannot be applied to the variable 'variable-name'.  
You tried to use a [x,y] subscript expression with a variable that is neither a character data type or an array type.  
Check the variable data type and make sure it can be used with a subscript expression. |
| -4347  | The variable 'variable-name' is not a record. It cannot reference record elements.  
In this statement variable-name appears followed by a dot, followed by another name. This is the way you would refer to a component of a record variable; however, variable-name is not defined as a record.  
Either you have written the name of the wrong variable, or else variable-name is not defined the way you intended. |
| -4353  | The type of this ORDER BY or GROUP item specified for the report is not valid for sorting.  
A REPORT routine defines an ORDER BY or GROUP clause using a variable defined with a type such as TEXT and BYTE, that is too complex to be used in comparisons. As result, columns with such types cannot be used to sort or group rows.  
Review the report and sort or group rows by using items defined with simple data types. |
| -4356  | A PAGE HEADER has already been specified within this report.  
Only one PAGE HEADER control block is allowed in a REPORT.  
Search for other PAGE HEADER sections and combine all statements in a unique control block. |
| -4357  | A PAGE TRAILER has already been specified within this report.  
Only one PAGE TRAILER control block is allowed in a REPORT.  
Search for other PAGE TRAILER sections and combine all statements in a unique control block. |
| -4358  | A FIRST PAGE HEADER has already been specified within this report.  
Only one FIRST PAGE TRAILER control block is allowed in a REPORT.  
Search for other FIRST PAGE TRAILER sections and combine all statements in a unique control block. |
<table>

<td>An ON LAST ROW clause has already been specified within this report. Only one ON LAST ROW control block is allowed in a REPORT. Search for other ON LAST ROW sections and combine all statements in a unique control block.</td>
</tr>
<tr>
<td>-4361</td>
<td>Group aggregates can occur only in AFTER GROUP clauses. The aggregate functions that apply to a group of rows (GROUP COUNT/PERCENT/SUM/AVG/MIN/MAX) can only be used at the point in the report when a complete group has been processed, namely, in the AFTER GROUP control block. Make sure that the AFTER GROUP block exists and was recognized. If you need the value of a group aggregate at another time (for instance, in a PAGE TRAILER control block), you can save it in a module variable with a LET statement in the AFTER GROUP block.</td>
</tr>
<tr>
<td>-4363</td>
<td>The report cannot skip lines while in a loop within a header or trailer. BDL needs to know how many lines of space will be devoted to the page header and trailer (otherwise it does not know how many detail rows to allow on the page). It cannot predict how many times a loop will be executed, so it has to forbid the use of SKIP statements in loops in the PAGE HEADER, PAGE TRAILER, and FIRST PAGE HEADER sections. Review the report header or trailer to avoid SKIP in loops.</td>
</tr>
<tr>
<td>-4369</td>
<td>The symbol 'symbol-name' does not represent a defined variable. The name shown appears where a variable would be expected, but it does not match any variable name in a DEFINE statement that applies to this context. Check the spelling of the name. If it is the name you intended, look back and find out why it has not yet been defined. Possibly the GLOBALS statement has been omitted from this source module, or it names an incorrect file. Possibly this code has been copied from another module or another function, but the DEFINE statement was not copied also.</td>
</tr>
<tr>
<td>-4371</td>
<td>Cursors must be uniquely declared within one program module. In the statement DECLARE cursor-name CURSOR, the identifier cursor-name can be used in only one DECLARE statement in the source file. This is true even when the DECLARE statement appears inside a function. Although a program variable made with the DEFINE statement is local to the function, a cursor within a function is still global to the whole module Search for duplicated cursor names and change the name to have unique identifiers.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -4372  | The cursor 'cursor-name' has not yet been declared in this program.  
The name shown appears where the name of a declared cursor or a prepared statement is expected; however, no cursor (or statement) of that name has been declared (or prepared) up to this point in the program.  
Check the spelling of the name. If it is the name you intended, look back in the program to see why it has not been declared. Possibly the DECLARE statement appears in a GLOBALS file that was not included. |
| -4374  | This type of statement can only be used within a MENU statement.  
This statement only makes sense within the context of a MENU statement.  
Review the program in this vicinity to see if an END MENU statement has been misplaced. If you intended to set up the appearance of a menu before displaying it, use a BEFORE MENU block within the scope of the MENU. |
| -4375  | The page length is too short to cover the specified page header and trailer lengths.  
A REPORT defines page header and trailer sections with a total number of lines that is not sufficiently less than the specified page length in order to print some detail lines.  
Review the [FIRST] PAGE HEADER and PAGE TRAILER blocks to use less lines or increase the page length. |
| -4379  | The input file 'file-name' cannot be opened.  
Either the file does not exist, or, on UNIX™, your account does not have permission to read it.  
Possibly the filename is misspelled, or the directory path leading to the file was specified incorrectly. |
| -4380  | The listing file 'file-name' cannot be created.  
The file cannot be created.  
Check that the directory path leading to the file is specified correctly and, on UNIX™ systems, that your account has permission to create a file in that directory. Look for other, more explicit, error messages from the operating system. Possibly the disk is full, or you have reached a limit on the number of open files. |
| -4382  | Record variables that contain array type elements may not be referenced by the ".*" or THROUGH shorthand, or used as a function parameter.  
The .* and THROUGH/THRU notation is used to expand a record with an array member.  
It is allowed to define a record with an array member, but this element must always be used with its full designation of record.array[n]. The .* or THROUGH/THRU notation only expands simple members of the record. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -4383   | The elements 'name-1' and 'name-2' do not belong to the same record.  
The two names shown are used where two components of one record are required; however, they are not components of the same record.  
Check the spelling of both names. If they are spelled as you intended, go back to the definition of the record and see why it does not include both names as component fields. |
| -4402   | In this type of statement, subscripting may be applied only to array.  
The statement contains a name followed by square brackets, but the name is not that of an array variable.  
Check the punctuation of the statement and the spelling of all names. Names that are subscripted must be arrays. If you intended to use a character substring in this statement, you will have to revise the program. |
| -4403   | The number of dimensions for the variable 'variable-name' does not match the number of subscripts.  
In this statement, the array whose name is shown is subscripted by a different number of dimensions than it was defined to have.  
Check the punctuation of the subscript. If it is as you intended, then review the DEFINE statement where variable-name is defined. |
| -4410   | There is a numeric constant in the previous line that is too large or too small.  
The compiler is unable to process a numeric constant because it is too big or too small to represent a valid SMALLINT, INTEGER, BIGINT or DECIMAL constant.  
Check the number of digits and the punctuation of the numeric constant. Make sure you have not typed a letter for a digit for example. |
| -4414   | The label 'label-name' has been used but has never been defined within the above main program or function.  
A GOTO or WHENEVER statement refers to the label shown, but there is no corresponding LABEL statement in the current function or main program.  
Check the spelling of the label. If it is as you intended it, find and inspect the LABEL statement that defines it. You cannot transfer out of a program block with GOTO; labels must be defined in the same function body where they are used. |
| -4415   | An ORDER BY or GROUP item specified within a report must be one of the report parameters.  
The names used in a ORDER BY, AFTER GROUP OF, or BEFORE GROUP OF statement must also appear in the parameter list of the REPORT statement. It is not possible to order or group based on a global variable or other expression.  
Check the spelling of the names in the statement and compare them to the REPORT statement. |

</table>
| -4485  | Only blob variables of type BYTE or TEXT may be used in a LOCATE statement.  
The LOCATE statement is using a variable defined with a data type different from BYTE or TEXT.  
Make sure the variables used with LOCATE are defined as BYTE or TEXT. |
| -4488  | The program cannot CONTINUE or EXIT statement-type at this point because it is not immediately within statement-type statement.  
This CONTINUE or EXIT statement is not appropriate in its context.  
Review your code. Possibly the statement is misplaced, or the statement type was specified incorrectly. |
| -4489  | A variable used in the above statement must be a global variable.  
A REPORT routine is defining an OUTPUT REPORT TO using a local function variable or report parameter.  
Review the report clause to use a global or module variable instead. |
| -4490  | You cannot have multiple BEFORE clauses for the same field.  
You cannot specify more than one BEFORE FIELD clause for the same field.  
Review your code to eliminate multiple BEFORE FIELD clauses. |
| -4491  | You cannot have multiple AFTER clauses for the same field.  
You cannot specify more than one AFTER FIELD clause for the same field.  
Review your code to eliminate multiple AFTER FIELD clauses. |
| -4534  | Wordwrap may not be used within report headers or trailers.  
The report routine uses the WORDWRAP clause in the FIRST PAGE HEADER, PAGE HEADER or PAGE TRAILER sections.  
Remove the WORDWRAP clause from the expression. |
| -4631  | Startfield of DATETIME or INTERVAL qualifiers must come earlier in the time-list than its endfield.  
The qualifier for a DATETIME or INTERVAL consists of start TO end, where the start and end are chosen from this list: YEAR MONTH DAY HOUR MINUTE SECOND FRACTION.  
The keyword for the start field must come earlier in the list than, or be the same as, the keyword for the end field.  
Check the order of the startfield and endfield qualifiers. For example, qualifiers of DAY TO FRACTION and MONTH TO MONTH are valid but one of MINUTE TO HOUR is not. |

<tbody>
<tr>
<td>-6179</td>
<td>License validity time is reached. The users control is reactivated. The CPU license is time limit is reached. The CPU license is degraded and user control is reactivated. Contact your support center.</td>
</tr>
<tr>
<td>-6180</td>
<td>CPU limit exceeded. The users control is reactivated. The CPU license has less CPUs available than the number of CPUs on the connected host, resulting in one or more hosts running in degraded mode. When running in degraded mode, the number of users allowed is the number of available CPUs in the license * 100 users. User control is activated for license request coming from that host. For example, if you have a 5 CPU license and are using the license manager. • Host A with 2 CPUs connects. It consumes 2 CPUs of the 5 CPU license. 3 CPUs remain free on the license. • Host B with 2 CPUs connects. It consumes 2 CPUs of the 5 CPU license. 1 CPU remains free on the license. • Host C with 2 CPU connects. It expects to be able to consume 2 CPUs, but only 1 CPU remains on the license. User control for Host C is enabled, with 1 CPU (the remaining free CPU) * 100 users allowed. • Host D connects with N CPU, however there are no CPUs free on the license. Host D is rejected. In summary, Host A and B can have unlimited sessions, Host C is limited to 100 sessions as the license is degraded by CPU, and any other host is rejected. In the case of a single host, user control applies to local licenses as well. If Host A has 6 CPUs, yet has a 5 CPU license, it consumes all of the CPUs for the license and runs in degraded mode. That means 5 * 100 users are allowed. Contact your support center.</td>
</tr>

</table>
| -6218  | No runtime. You must call `fgl_start()` before calling `fgl_call()`.
This error occurs when a C extension has redefined the main() routine, but then does not call
`fgl_start()` to initialize the BDL runtime environment.
Check the C extension and call `fgl_start()` before any other operation. |
| -6219  | WHENEVER ERROR CALL: The error-handler recursively calls itself.
The function specified with the WHENEVER ERROR CALL instruction raises an error that
would call itself recursively.
Review the function called by the WHENEVER ERROR CALL and make sure it does not
produce a runtime error. |
| -6220  | Could not load C extension library 'library-name'. Reason: description
Runtime system is unable to find the shared library for the reason given.
Check if the C extension library exists in one of the directories defined by FGLLDPATH.
If the C extension module depends on other shared libraries, make sure that these libraries
can be found by the library loader of the operating system (check the LD_LIBRARY_PATH
environment variable on UNIX™ or the PATH environment variable on Windows®). |
| -6221  | C extension initialization failed with status number.
C extension failed to initialize and returned the status shown in the error message.
Check the C extension source or documentation. |
| -6222  | class-name class not found.
The program was compiled with the built-in class class-name but at execution time the class is
not found.
Check you installation, it is possible that you are executing program that was compiled with a
younger version as the version used in the execution context, which certainly is missing that
class in the runtime library. |
| -6223  | No such symbol: symbol-name.
The runtime system loads a module dynamically (on demand) and searches for the symbol in a
given module. But the symbol is not found, for example, because of an invalid FGLLDPATH,
or because the installed module no longer contains the symbol (after a recompilation). |
| -6300  | Can not connect to GUI: description
You have run a GUI application but the environment variable FGLSERVER is not set correctly,
or the Genero client (graphical front-end) is not running.
It is recommended that the FGLSERVER environment variable is set to the hostname and
port of the graphical front end used by the runtime system to display the application windows.
Check that the network connection is still available, make sure no firewall denies access to the
workstation, and make sure the front-end is still running. |
<table>
<thead>

<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6301  | Can not write to GUI: description  
You are running a GUI application but for an unknown reason the front-end no longer responds and the runtime system is unable to write to the GUI socket.  
Check that the network connection is still available, make sure no firewall denies access to the workstation, and see whether the front-end is still running. |
| -6302  | Can not read from GUI: description  
You are running a GUI application but for an unknown reason the front-end no longer responds and the runtime system is unable to read from the GUI socket.  
Check that the network connection is still available, make sure no firewall denies access to the workstation, and see whether the front-end is still running. |
| -6303  | Invalid user interface protocol.  
You are trying to execute a program with a runtime system that uses a different AUI protocol version as the front-end.  
Install either a new front-end or a new runtime environment that matches (2.0x with 2.0x, 1.3x with 1.3x). |
| -6304  | Invalid abstract user interface definition.  
You are trying to execute a program with a runtime system that uses a different AUI protocol version as the front-end.  
Install either a new front-end or a new runtime environment that matches (2.0x with 2.0x, 1.3x with 1.3x). |
| -6305  | Can not open char table file. Check your fglprofile.  
This error occurs if the conversion file defined by the gui.chartable entry, in the $FGLDIR/etc/fglprofile file, is not readable by the current user.  
Check if the gui.chartable entry is correctly set and if the specified file is readable by the current user. |
| -6306  | Can not open server file. Check installation.  
A file on the server side cannot be sent to the graphical interface.  
Check the permissions of the file located in the $FGLDIR/etc directory. These files must have at least read permission for the current user. |
| -6307  | GUI server autostart: can not identify workstation.  
GUI Server autostart configuration is wrong. Either DISPLAY, FGLSERVER or fglprofile settings are invalid.  
Set the required environment variables and check for fglprofile autostart entries. |
| -6308  | GUI server autostart: unknown workstation: check gui.server.autostart entries.  
The computer described by the X11 DISPLAY environment variable is neither the local host, nor is it listed in the fglprofile entries.  
Check if the X11 DISPLAY name is correctly set, or review the fglprofile entries. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6309  | Not connected. Cannot write to GUI.  
For unknown reasons there was an attempt to write on the GUI socket before the connection was initiated.  
Check the program for invalid GUI operations. |
| -6310  | Not connected. Cannot read from GUI.  
For unknown reasons there was an attempt to read on the GUI socket before the connection was initiated.  
Check the program for invalid GUI operations. |
| -6311  | No current window.  
The program tries to issue a MENU instruction with no current window open.  
Review the program logic and make sure a window is open before MENU. |
| -6312  | The type of the user interface (FGLGUI) is invalid.  
While initiating the user interface, the runtime system did not recognize the GUI type and stopped.  
Make sure the FGLGUI environment variable has a correct value. |
| -6313  | The UserInterface has been destroyed.  
The error occurs when the front-end sends a DestroyEvent event, indicating some inconsistency with the starting program. This can happen, for example, when multiple StartMenus are used, or when you try to run an MDI child without a parent container, or when two MDI containers are started with the same name, etc.  
Check for inconsistency and fix it. |
| -6314  | Wrong connection string. Check client version.  
While starting the program, the runtime received a wrong or incorrectly constructed answer from the front-end.  
Make sure you are using a front-end that is compatible with the runtime system. |
| -6315  | The form is too complex for the console-ui.  
The program tries to display a form with a complex layout that cannot be displayed in text mode.  
Review the form file and use a simple grid with a SCREEN section instead of LAYOUT. |
| -6316  | Error error-num returned from client: description  
Front end returned the specified error during GUI connection initialization.  
Check the front-end documentation for more details. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6317  | Invalid or unsupported client protocol feature.  
The GUI protocol feature you are trying to use is not supported by the front-end. For example, you are trying to use protocol compression but the runtime is not able to compress data.  
Make sure that the front-end component is compatible with the runtime system (versions must be close). Check the runtime system version for supported protocol features. If compression is enabled, check that the zlib library is installed on your system. |
| -6318  | Choosing the DIALOG implementation by setting the environment variable FGL_USENDIALOG=0 has been desupported since version 2.20.03.  
You try to use the old dialog implementation by setting FGL_USENDIALOG to zero.  
The old dialog implementation has been removed, you must unset the FGL_USENDIALOG environment variable. |
| -6319  | Internal error in the database library. Set FGLSQLDEBUG to get more details.  
An unexpected internal error occurred in the database driver.  
Set the FGLSQLDEBUG environment variable to level 1, 2, 3 or 4 to get detailed debug information. |
| -6320  | Can't open file 'file-name'.  
The runtime system tried to open a resource file in FGLDIR but access is denied or file no longer exists.  
Check for file permissions and existence in FGLDIR. |
| -6321  | No such interface capability: 'feature-name'.  
The runtime system tried to use a front-end protocol capability, but is not able to use it.  
Check if the front-end is compatible with the runtime system. |
Some resource files of FGLDIR have been identified as too old for the current runtime system.  
Re-install the runtime system environment. |
| -6323  | Can't load factory profile 'file-name'.  
The default fglprofile file located in FGLDIR/etc is missing or is unreadable.  
Check the permission of the file. If the file is missing, reinstall the software. |
| -6324  | Can't load customer profile 'file-name'.  
The configuration file defined by the FGLPROFILE environment variable is missing or unreadable.  
Check if the FGLPROFILE environment variable is correctly set and if the file is readable by the current user. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6325  | Can't load application resources 'file-name'.  
The directory specified by the fglrun.default entry in FGLDIR/etc/fglprofile is missing or not readable for the current user.  
Check if the entry fglrun.default is correctly set in FGLDIR/etc/fglprofile and if the directory specified is readable by the current user. |
| -6327  | Internal error in the run time library file library-name.  
Something unpredictable has occurred, generating an error.  
Contact your Technical Support. |
| -6328  | Bad format of resource 'entry-name' value 'entry-value': you must use the syntax: entry-name='VARNAME=envvar-value'.  
The FGLPROFILE file contains an invalid environment variable definition format.  
Check the content of the profile file. |
| -6329  | All TABLE columns must be defined with the same height.  
The form layout defines a TABLE with field tags using different heights.  
Review all cells of the table to use the same height in all columns. |
| -6330  | Syntax error in profile 'file-name', line number lineno , near 'token'.  
The FGLPROFILE file shown in the error message contains a syntax error.  
Check the content of the profile file. |
| -6331  | Front end module could not be loaded.  
A front call failed because the module does not exist.  
The front end is probably not supporting this module. |
| -6332  | Front end function could not be found.  
A front call failed because the function does not exist.  
The front end is probably not supporting this function. |
| -6333  | Front end function call failed. Reason: description  
For some reason, the front call failed and produced this runtime error.  
Check the content of the error message to get more information. |
| -6334  | Front end function call stack problem.  
A front call failed because the number of parameter or returning values does not match.  
Make sure the number of parameters and return values are correct. |
| -6340  | Can't open file: description  
The channel object failed to open the file specified.  
Make sure the filename is correct and user has permissions to read/write to the file. |

</tbody>
</table>
| -6366  | Could not load database driver `driver-name`.  
The runtime system failed to load the specified database driver. The database driver shared object (.so or .DLL) or a dependent library could not be found.  
Make sure that the name of the specified driver is spelled correctly. If the driver name is correct, there is probably an environment problem. Make sure the database client software is installed.  
Check the UNIX™ `LD_LIBRARY_PATH` environment variable or the `PATH` variable on Windows®. These must point to the database client libraries. |
| -6367  | Incompatible database driver interface.  
The database driver interface does not match the interface expected by the runtime system. This can occur if you copy an old database driver into a younger FGLDIR installation.  
Call the support to get a valid database driver. |
| -6368  | SQL driver initialization function failed.  
The runtime system failed to initialize the database driver, program must stop because no database connection can be established.  
There is probably an environment problem (for example, `INFORMIXDIR` or `ORACLE_HOME` is not set). Check your environment and try to connect with a database vendor tool (dbaccess, sqlplus) to identify the problem. |
| -6369  | Invalid database connection mode.  
You try to mix `DATABASE` and `CONNECT` statements, but this is not allowed.  
Use either `DATABASE` or `CONNECT`. |
| -6370  | Unsupported SQL feature.  
This SQL command or statement is not supported with the current database driver.  
Review the code and use a standard SQL feature instead. |
| -6371  | SQL statement error number `error-num` (native-error).  
An SQL error has occurred having the specified error number.  
You can query `SQLERRMESSAGE` or the `SQLCA` record to get a description of the error. |
A general SQL error has occurred.  
You can query `SQLERRMESSAGE` or the `SQLCA` record to get a description of the error. The native SQL error code is in `SQLCA.SQLERRD[2]`. |
| -6373  | Invalid database connection string.  
The database connection string that you have used is not valid.  
Verify the format of the connection string. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6374  | Wrong database driver context.  
You try to EXECUTE, OPEN, FETCH, PUT, FLUSH, CLOSE or FREE a cursor that was declared or prepared in a different connect and driver.  
Issue a SET CONNECTION before the statement to select the same connection and driver as when the cursor was created. |
| -6375  | LOAD cannot get describe information for table columns.  
The LOAD instructions needs column description to allocate the automatic fetch buffers, but the database driver is not able to describe the table columns used in the INSERT statement.  
If the underlying database client API does not provide result set column description, the LOAD statement cannot be supported. |
| -6601  | Can not open Database dictionary 'directory-name'. Run database schema extraction tool.  
The schema file does not exist or cannot be found.  
If the schema file exists, verify that the filename is spelled correctly, and that the file is in the current directory or the FGLDBPATH environment variable is set to the correct path. If the file does not exist, run the database schema extraction tool to create a schema file. |
| -6602  | Can not open globals file 'file-name'.  
The globals file does not exist or cannot be found.  
Verify that the globals file exists. Check the spelling of the filename, and verify that the path is set correctly. |
| -6603  | The file 'file-name' cannot be created for writing.  
The compiler failed to create the file shown in the error message for writing.  
Check for user permissions to make sure that the .42m file can be created. |
| -6604  | The function 'function-name' can only be used within an INPUT [ARRAY], DISPLAY ARRAY or CONSTRUCT statement.  
The language provides built-in functions that can only be used within specific interactive statements.  
Review your code and make the necessary corrections. Check that the function is within the interactive statement and that appropriate END statements (END INPUT/ARRAY/DISPLAY ARRAY/CONSTRUCT) have been used. |
| -6605  | The module 'module-name' does not contain function 'function-name'.  
The module shown in the error message does not hold the function name as expected.  
The specified function needs to be defined in this module. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6606  | No member function 'function-name' for class 'class-name' defined.  
The function name is misspelled or is not a method of the class for which it is called.  
Review your code and the documentation for the method you are attempting to use. If the function is an object method, make sure the referenced object in your code is of the correct class. |
| -6608  | Resource error: entry-name :parameter expected  
This is a generic error message for resource file problems. |
| -6609  | A grammatical error has been found at 'seen-token' expecting: expected-token.  
A general syntax error message that indicates the location of the problem code and what code was expected.  
Review your code, particularly for missing END statements such as END FUNCTION or END INPUT, etc., and make the necessary corrections. |
| -6610  | The function 'function-name' has already been called with a different number of parameters.  
Earlier in the program, there is a call to this same function or event with a different number of parameters in the parameter list.  
Check the correct number of parameters for the specified function. Then examine all calls to it, and make sure that they are written correctly. |
| -6611  | Function 'function-name': unexpected number of returned values.  
The function shown returned a different number of values as expected.  
Check the body of the function for RETURN instructions. |
| -6612  | Redeclaration of function 'function-name'.  
The function shown was defined multiple times.  
Change the name of conflicting functions. |
| -6613  | The library function 'function-name' is not declared.  
The function shown was not declared.  
Change the name of the function. |
| -6614  | The function 'function-name' may return a different number of values.  
The function shown contains multiple RETURN instructions which may return different number of values.  
Review the RETURN instructions to return the same number of values. |
| -6615  | The symbol 'symbol-name' is unused.  
This is a warning indicating that the shown symbol is defined but never used.  
Useless definition can be removed. |

The license is CPU limited and the system has more CPUs as allowed.  
Call the support center to get a new license number. |
Check permissions on the lock/token directory (in FGLDIR or FLMDIR). |
| -6787  | This GRW license requires a DVM license with a valid maintenance date.  
GRW licenses with the option 'DVM under maintenance' require that the DVM maintenance key expiration date not be expired.  
Update the DVM maintenance key. |
| -6788  | Cannot get GRW report token information.  
Contact your support center. |
| -6789  | The installed license is invalid and cannot be used by this product.  
The current license is not valid for the product you have installed.  
Contact your support center to get a license corresponding to the current installed product. |
| -6802  | Can not open Database dictionary 'schema-name'. Run schema extraction tool.  
The schema file does not exist or cannot be found.  
If the schema file exists, verify that the filename is spelled correctly, and that the file is in the current directory or the FGLDBPATH environment variable is set to the correct path. If the file does not exist, run the database schema extraction tool to create a schema file. |
| -6803  | A grammatical error has been found at 'line-number', expecting token-name.  
This is a generic message for errors. |
| -6804  | 'form-name' form compilation was successful.  
This is an information message indicating that the form was compiled without problem. |
You have compiled your form with a version of the form compiler that is not compatible with that used for compiling the other source code.  
Compile your form file and related source code files using the same or compatible versions of the compilers. |
| -6807  | The label 'label-name' could not be used as column-title.  
The form file defines an invalid TABLE column title.  
Check for column titles which are not corresponding to column positions. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6808  | The widget 'widget-name' can not be defined as array.  
The form file defines an item which is used as a matrix column.  
Review your form definition. |
| -6809  | The layout tag 'tag-name' is invalid, expecting: token-name.  
The form compiler detected an invalid layout tag specification.  
Review your form definition. |
| -6810  | The attribute 'attribute-name' is invalid for item type 'type-name'.  
The form compiler detected an invalid attribute definition for this item type.  
Review your form definition and check for invalid attributes. |
| -6811  | Syntax error near 'token-1', expecting token-2.  
A general syntax error message that indicates the location of the problem code and what code was expected.  
Review your code and make the necessary corrections. |
| -6812  | Unterminated char constant.  
The form compiler detected an unterminated character constant.  
Review your form definition and check for missing quotes or double-quotes. |
| -6813  | The element 'element-name' conflicts with group-box 'group-name'.  
You have used the same name for an element and for a group-box.  
Review your form definition and ensure that the names used are unique. |
| -6814  | All members of the SCREEN RECORD 'screen-record-name' must reference the same Table or ScrollGrid.  
The shown screen record references multiple tables or scrollgrids in your form file.  
Review your form definition and use one unique table for a given screen record. |
| -6815  | Invalid indentation in between braces.  
The LAYOUT section of your form defines an invalid indentation.  
Review your form definition and check for corresponding indentations. |
| -6817  | TABLE container defined without a SCREEN RECORD in the INSTRUCTION section.  
The minimum value of the defined attribute must be lower than the maximum value.  
Review your code and make the necessary corrections. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6818  | Min value must be lower than Max value.  
The minimum value of the defined attribute must be lower than the maximum value.  
Review your code and make the necessary corrections. |
| -6819  | Number of elements in the SCREEN RECORD must match the number of columns in TABLE container.  
The elements defined in the screen record differs from the columns used for the TABLE container.  
Review your form definition and add missing table columns to the screen record, order does not matter. |
| -6820  | ScrollGrid and/or Group layout tags cannot be nested.  
The form definition has nested ScrollGrid and/or Group layout tags. These tags cannot be nested.  
Review your form definition and make the necessary corrections. |
| -6821  | HBOX tags cannot be used for ARRAYS.  
The form definition is using an HBOX tag for an array, which is not permitted.  
Review your form definition and make the necessary corrections. |
| -6822  | Escaped graphical characters are not accepted in GRID sections.  
You try to use Text User Interface graphics in the new GRID container.  
This is not allowed, use GROUPs instead. |
| -6823  | Close tag does not have a matching tag above.  
The form definition has a close tag without a prior matching open tag. Open tags and close tags must match.  
Review your form definition file and make the necessary corrections. |
| -6824  | The table 'table-name' is empty.  
The form layout defines a table layout tag identified by tablename, but nothing was found directly under this table that defines a column or a column title.  
Append columns to the table layout region. |
| -6825  | The tag 'tag-name' overlaps with table 'table-name'.  
In the form layout, tagname overlaps the layout region of tablename and makes it invalid.  
Move or remove tagname, or redefine the layout region of tablename. |
| -6826  | Checked value must be different from unchecked value for field 'field-name'.  
The VALUECHECKED and VALUEUNCHECKED attributes have the same value. This makes no sense because these attributes define the values corresponding to the checked and unchecked states of a checkbox.  
Use different values for these attributes. |

<tr>
<td>-6834</td>
<td>Invalid TREE definition: the field 'field-name' must be defined for the SCREEN RECORD. The form defines a TREE container with an invalid field set. Check that mandatory fields such as node name, parent id and node id fields are defined.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -6835  | The fields specified in the THRU option appear in the reverse order.  
The form defines a screen record by using the THRU or THROUGH keyword, but the first field is defined after the last field in the ATTRIBUTES section.  
Exchange the field names specified in the screen record definition, or review the declaration order in ATTRIBUTES. |
| -6836  | Invalid TREE definition: the attribute 'attribute-name' conflicts with id or parentid.  
The .per form defines a TREE with invalid configuration. You have probably used the same field for the named attribute and for IDCOLUMN or PARENTIDCOLUMN.  
Review the form definition and configure the TREE properly. You must use dedicated columns for the attributes mentioned. |
| -6837  | Invalid AGGREGATE definition: must be located below a table column.  
The .per form defines an AGGREGATE form item with a field tag that is not aligned under a table column field tag.  
Review the table layout and make sure that all aggregate fields are properly aligned and placed below column tags. |
| -6838  | This area is reserved for AGGREGATES.  
The .per form defines a TABLE with aggregate fields, but not all aggregate fields are declared with the AGGREGATE item type.  
Review the field definitions in the ATTRIBUTES section. |
| -6839  | The screen tag 'tag-name' can not be defined in a TABLE.  
The .per form defines a TABLE with columns using different field tag names, an no AGGREGATE field is defined.  
Review columns of the TABLE, each field tag of a given column must use the same tag name, except if you want to define an AGGREGATE field. |
| -6841  | FORM not contain TOPMENU or TOOLBAR.  
The form layout includes an external form specification file containing a TOPMENU or a TOOLBAR. Remove these sections from the included form file. |
| -6842  | FORM is out of date.  
The form layout includes an external form specification file the was compiled with a older version. |
| -6843  | A resizable SCROLLGRID requires the definition of exactly one template.  
A resizable SCROLLGRID (WANTFIXEDPAGESIZE=NO) must define a single row template. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6844  | INITIALPAGESIZE requires a resizable SCROLLGRID.  
When using the INITIALPAGESIZE attribute, the SCROLLGRID must be defined as resizable with the WANTFIXEDPAGESIZE=NO attribute. |
| -6845  | The display field label 'field-name' has already been defined.  
The field item tag is defined several times in different containers of the LAYOUT section. |
| -6846  | The screen tag 'tagname' can not be defined in a SCROLLGRID  
A SCROLLGRID contains a layout tag such as <TABLE> or <TREE>. This is not allowed. |
| -6847  | TABINDEX has to be unique  
Some elements of the form define the same TABINDEX. Review the ATTRIBUTE section and make sure that all TABINDEX values are unique. |
| -6848  | All TABLE columns must have the same size.  
In a TABLE or TREE container, all columns must be defined with the same width and height in the LAYOUT section. |
| -8000  | Dom: Node not found.  
The node was not found in the current document. Review your code. |
The document passed to the DOM API is not a valid document. Review your code. |
| -8002  | Dom: Invalid usage of NULL as parameter.  
NULL cannot be used at this place. Review your code. |
| -8003  | Dom: A node is inserted somewhere it doesn't belong.  
You try to insert a node under a parent node which does not allow this type of nodes. Check for the possible nodes and review your code. |
| -8004  | Sax: Invalid hierarchy.  
The SAX handler encountered an invalid hierarchy. Make sure parent/child relations are respected. |
| -8005  | Deprecated feature: feature-name  
The feature you are using will be removed in a next version. A replacement for the feature is normally available. |
| -8006  | The string resource file 'file-name' cannot be found.  
The given string file was not found. Check if file exists and if path is valid. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8007  | The string resource file 'file-name' cannot be read.  
The given string file was unable to be read.  
Check if file exists and if user has read permissions. |
| -8008  | There is no string text defined for the 'key-name' string key.  
The runtime system was unable to find a string resource corresponding to the shown key.  
Check if the key is defined in one of the resource files. |
| -8009  | String resource syntax error near 'token-name', expecting token.  
The string file compiler detected a syntax error.  
Check for invalid syntax in the .str file. |
| -8012  | Duplicate string key 'key-name' (file-name : line) IGNORE LINE.  
The string file compiler detected duplicated string keys.  
Review the .str file and remove duplicated keys. |
| -8013  | The string file 'file-name' can not be opened for writing.  
The string file compiler was unable to write to the specified string file.  
Make sure the user has write permissions and file name is valid. |
| -8014  | The string file 'file-name' can not be read.  
The runtime system was unable to read from the specified string file.  
Make sure the user has read permissions. |
| -8015  | Field (field-name) in ON CHANGE clause not found in form.  
The field used in the ON CHANGE clauses was not found in the form specification file.  
Make sure the field name of the ON CHANGE clause matches a valid form field. |
| -8016  | You cannot have multiple ON CHANGE clauses for the same field.  
It is not possible to specify multiple ON CHANGE clauses using the same field.  
Remove unnecessary ON CHANGE clauses. |
| -8017  | SFMT: Invalid % index used.  
The format string is not valid.  
Check for invalid % positions. |
| -8018  | SFMT: Format error.  
The format string is not valid.  
Check for invalid % positions. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8020  | Multiple ON ACTION clauses with the same action name appear in the statement.  
        It is not possible to specify multiple ON ACTION clauses using the same action name.  
        Remove unnecessary ON ACTION clauses. |
| -8021  | Multiple ON KEY clauses with the same key name appear in the statement.  
        It is not possible to specify multiple ON KEY clauses using the same key.  
        Remove unnecessary ON KEY clauses. |
| -8022  | Dom: Cannot open xml-file.  
        The given file failed to load.  
        Check file name and user permissions. |
| -8023  | Dom: The attribute 'attribute-name' does not belong to node 'node-type'.  
        You try to set an attribute to a node which does not have such attribute.  
        This is not allowed, review your code. |
| -8024  | Dom: Character data can not be created here.  
        You try to create a text node under a node which does not allow such nodes.  
        This is not allowed, review your code. |
| -8025  | Dom: Cannot set attributes of a character node.  
        You try to set attributes in a text node.  
        This is not allowed, review your code. |
| -8026  | Dom: The attribute 'attribute-name' can not be removed: the node 'node-type' belongs to the user-interface.  
        You try to remove a mandatory attribute from an AUI node.  
        You can only change the value of this attribute, try 'none' or an empty string. |
| -8027  | Sax: can not write.  
        The SAX handlers were unable to write to the destination file.  
        Make sure the file path is correct and the user has write permissions. |
| -8029  | Multiple inclusion of the source file 'file-name'.  
        The preprocessor detected that the specified file was included several times by the same source.  
        Remove unnecessary file inclusions. |
| -8030  | The full path to the source file 'file-name' is too long.  
        The preprocessor does not support very long file names.  
        Rename the file. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8031  | The source file 'file-name' cannot be read.  
The preprocessor failed to read the file specified.  
Make sure the user has read permissions. |
| -8032  | The source file 'file-name' cannot be found.  
The preprocessor failed to find the file specified.  
Make sure the file exists. |
| -8033  | Extra token found after 'directive-name' directive.  
The preprocessor detected an unexpected token after the shown directive.  
Review your code and make the necessary corrections. |
| -8034  | feature-name : This feature is not implemented.  
This preprocessor feature is not supported.  
Review your code and make the necessary corrections. |
| -8035  | The macro 'macro-name' has already been defined.  
The preprocessor found a duplicated macro definition.  
Review your code and make the necessary corrections. |
| -8036  | A &else directive found without corresponding &if, &ifdef or &ifndef directive.  
The preprocessor detected an unexpected &else directive.  
Review your code and make the necessary corrections. |
| -8037  | A &endif directive found without corresponding &if, &ifdef or &ifndef directive.  
The preprocessor detected an unexpected &endif directive.  
Review your code and make the necessary corrections. |
| -8038  | Invalid preprocessor directive & name found.  
The preprocessor directive shown in the error message does not exist.  
Review your code and check valid macros. |
| -8039  | Invalid number of parameters for macro-name.  
The number of parameters of the preprocessor macro shown in the error message does not match de number of parameters in the definition of this macro.  
Review your code and check for the number of parameters. |
| -8040  | Lexical error: Unclosed string.  
The compiler detected an unclosed string and cannot continue.  
Review your code and make the necessary corrections. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8041  | Unterminated condition `&if` or `&else`.  
The preprocessor found an un-terminated conditional directive.  
Review the definition of this directive. |
| -8042  | The operator `'##'` can only be used with identifiers and numbers.  
A token is not allowed.  
The preprocessor found an invalid usage of the `##` string concatenation operator.  
Review the definition of this macro. |
| -8043  | Could not run `FGLPP`, command used: `command`  
The compiler failed to run the preprocessor command shown in the error message.  
Make sure the preprocessor command exists. |
| -8044  | Lexical error: Unclosed comment.  
The compiler detected an unclosed comment and cannot continue.  
Review your code and make the necessary corrections. |
| -8045  | This type of statement can only be used within an `INPUT`, `INPUT ARRAY`, `DISPLAY ARRAY`, `CONSTRUCT` or `MENU` statement.  
This statement has not been used within a valid interactive statement, which must be terminated appropriately with `END INPUT`, `END INPUT ARRAY`, `END DISPLAY ARRAY`, `END CONSTRUCT`, or `END MENU`.  
Review your code and make the necessary corrections. |
| -8046  | This type of statement can only be used within an `INPUT`, `INPUT ARRAY`, `DISPLAY ARRAY` or `CONSTRUCT` statement.  
This statement has not been used within a valid interactive statement, which must be terminated appropriately with `END INPUT`, `END INPUT ARRAY`, `END DISPLAY ARRAY`, or `END CONSTRUCT`.  
Review your code and make the necessary corrections. |
| -8047  | Invalid use of 'dialog'. Must be used within an `INPUT`, `INPUT ARRAY`, `DISPLAY ARRAY` or `CONSTRUCT` statement.  
The predefined keyword `DIALOG` has not been used within a valid interactive statement, which must be terminated appropriately with `END INPUT`, `END INPUT ARRAY`, `END DISPLAY ARRAY`, or `END CONSTRUCT`.  
Review your code and make the necessary corrections. |
| -8048  | An error occurred while preprocessing the file 'file-name'.  
Compilation ends.  
The Genero BDL preprocessor failed to parse the whole source file and stopped compilation.  
Review the source code and check for not well formed & preprocessor macros. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>

<td>---</td>
</tr>
</tbody>
</table>
| -8058 | XPath: Unexpected token/string 'token-name' at position pos.  
The XPath parser found an unexpected token or string at the given position.  
Review the XPath expression. |
| -8059 | SQL statement or language instruction with vendor proprietary syntax.  
The compiler found an SQL statement which is using a database specific syntax. This statement will probably not run on other database servers as the current.  
Review the SQL statement and use standard/common syntax and features. |
| -8060 | Spacer items are not allowed inside a SCREEN sections.  
The form contains spacer items in a SCREEN section, while these are only allowed in LAYOUT.  
Review the form specification file. |
| -8061 | A TABLE row should not be defined on multiple lines.  
All columns of a row in a TABLE container must be in a single line.  
Use a SCROLLGRID if you want to show row cells on multiple lines. |
| -8063 | The client connection timed out.  
The runtime system failed to establish the connection with the front-end after a given time. This can for example happen during a file transfer, when the front-end takes too much time to respond to the runtime system.  
Check that your network connection is working properly. |
| -8064 | File transfer interrupted.  
An interruption was caught during a file transfer.  
File was not transferred, you need to redo the operation. |
| -8065 | Network error during file transfer.  
A socket error was caught during a file transfer.  
Check that your network connection is working properly. |
| -8066 | Could not write destination file for file transfer.  
The runtime system failed to write the destination file for a transfer.  
Make sure the file path is correct and check that user has write permissions. |
| -8067 | Could not read source file for file transfer.  
The runtime system was unable to read the source file to transfer.  
Make sure the file path is correct and check that user has read permissions. |
<table>
<thead>

<td>-8077</td>
<td>The attribute 'attribute-name' has been defined more than once. The variable attribute shown in the error message was defined multiple times. Review the variable definition and remove duplicated attributes.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -8078  | The attribute 'attribute-name' is not allowed.  
The variable attribute shown in the error message is not allowed for this type of variable.  
Review the possible variable attributes. |
| -8079  | An error occurred while parsing the XML file.  
The runtime system failed to parse an XML file, which is probably not using a valid XML format.  
Check for XML format typos and if possible, validate the XML file with a DTD. |
| -8080  | Could not open xml file.  
The specified XML file cannot be opened.  
Make sure the file exists and has access permissions for the current user. |
| -8081  | Invalid multibyte character has been encountered.  
A compiler found an invalid multibyte character in the source and cannot compile the form or module.  
Check locale settings (LANG) and verify if there are no invalid characters in your sources. |
| -8082  | The item 'item-name' is used in an invalid layout context.  
The form item name is used in a layout part which does not support this type of form item. This error occurs for example when you try to define a BUTTON as a TABLE column.  
Review your form definition file and use correct item types. |
| -8083  | NULL pointer exception.  
The program is using calling a method thru an object variable which is NULL.  
You must assign an object reference to the variable before calling a method. |
| -8084  | Can't open socket: description  
The channel object failed to open a TCP socket. See the description for more details.  
Make sure the IP address and port are correct. |
| -8085  | Unsupported mode for 'open socket'.  
You try to open a channel with an unsupported mode.  
See channel documentation for supported modes. |
| -8086  | The socket connection timed out.  
Socket failed to establish a connection and timeout expired.  
Check all network layers and try again. |
| -8087  | File error in BYTE or TEXT readFile or writeFile.  
File I/O error occurred while reading from or writing to a file.  
Verify the file name, content and access permissions. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8088   | The dialog attribute 'attribute-name' is not supported.  
          A dialog instruction was declared with an ATTRIBUTES clause containing an unsupported option.  
          Review the ATTRIBUTES clause and remove unsupported option. |
| -8089   | Action 'action-name' not found in dialog.  
          You try to use an action name that does not exist in the current dialog.  
          Verify if name of the action is defined by an ON ACTION clause. |
| -8090   | Field 'field-name' already used in this DIALOG.  
          The DIALOG instruction binds the same field-name or screen-record multiple times.  
          Review all sub-dialog blocks and check the field-names / screen-records. |
| -8091   | The clause 'clause-name' appears more than once.  
          You have defined the same dialog control block multiple times. For example, AFTER ROW was defined twice.  
          Remove the un-necessary control blocks. |
| -8092   | At least one field for this INPUT ARRAY must be editable.  
          An INPUT ARRAY is executed on fields that are read-only. At least one field must be editable and active.  
          Review the form specification file or check that at least one field is active. |
| -8093   | Multi-range selection is not available in this context.  
          You try to use multi-range selection but it is not possible in the current dialog type.  
          Disable this feature. |
| -8094   | Multi-range selection is not available in this context.  
          You try to use multi-range selection but it is not possible in the current dialog type.  
          Disable this feature. |
| -8095   | Cannot change selection flag for this range of rows.  
          An attempt of selection flag modification with DIALOG.setSelectionRange() failed because the range is out of bounds or because there is no multi-range selection available in this context.  
          Make sure you can use multi-range selection, and check the start and end index of the range. |
| -8096   | General SQL Warning, check SQLCA.SQLERRD[2] or SQLSTATE.  
          The last SQL statement has generated an SQL warning setting the SQLCA.SQLAWARN flags.  
          Program execution can continue. However, it is recommended that you take care and check the native SQL code and the SQL message in SQLERRMESSAGE. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8097  | Value too large to fit in a TINYINT.  
The TINYINT data type can accept numbers with a value range from -128 to +127.  
To store numbers that are outside this range, redefine the column or variable to use the SMALLINT or INTEGER type. |
| -8098  | ON FILL BUFFER conflicts with DISPLAY ARRAY as a tree.  
The DISPLAY ARRAY instruction is using a treeview as decoration, but it implements also an ON FILL BUFFER trigger to do paged mode. The paged mode is not possible when using a treeview, because all rows of visible nodes are required (i.e. the dialog cannot display a tree only with a part of the dataset).  
To populate dynamically the array for a treeview, use the ON EXPAND to add new nodes and ON COLLAPSE to remove nodes. |
| -8099  | The form 'form-name' is incompatible with the current runtime version. Rebuild you forms.  
The .42f form was probably compiled with an earlier version as the current runtime system.  
Recompile the form with the fglform compiler corresponding to the current fglrun. |
| -8100  | Attempt to access a closed dialog.  
A call to a DIALOG class method is done with a dialog object that has terminated.  
Review the program logic and call the DIALOG methods only for active running dialogs. |
| -8101  | The TABLE column tag 'tag-name' appears multiple times in the row definition.  
A TABLE column can only be used once in the row definition, you have probably repeated the same screen tag by mistake.  
Modify the TABLE row definition in the layout section in order to use each column only once. |
| -8102  | Syntax error in preprocessor directive.  
The source file contains a preprocessor macro with an invalid syntax.  
Check the preprocessor manual page and fix the syntax error. |
| -8103  | The source and destination file name of a file transfer must not be NULL or empty.  
The program is doing an fgl_getfile() or fgl_putfile() and the source or destination file name is NULL or empty.  
Provide a valid file name for both source and destination parameters. |
| -8104  | Cannot read from TUI: system-error.  
A program running in text mode (FGLGUI=0) failed to read from console input stream.  
Check the console/terminal settings. |

</table>
| -8131  | SQL parameter index out of bounds.  
The index passed as argument to the `setParameterValue()` method of `base.SqlHandle` is lower as 1, or is greater as the number of ? placeholders in the SQL statement. |
| -8200  | `apidoc`: parameter name 'param-name' is invalid.  
The compiler has detected a comment error while extracting the source documentation: The `@param` variable name is not in the list of parameters in the next FUNCTION definition.  
Check the function parameter name. |
| -8201  | `apidoc`: tag missing: `@param` param-name.  
The compiler has detected a comment error while extracting the source documentation: There is a missing `@param` tag that describes a parameter of the next FUNCTION definition.  
Check the function parameter name. |
| -8202  | `apidoc`: invalid tag name @ tag-name.  
The compiler has detected a comment error while extracting the source documentation: The `@` tag-name tag is not a known tag name.  
Check for typo errors in the tag name. |
| -8300  | Cannot load java shared library. Reason: system-error  
The runtime system failed to load the JVM shared library (or DLL).  
Make sure that a JRE is installed on the machine and check the environment (LD_LIBRARY_PATH on UNIX™ or PATH on Windows®). |
| -8301  | Cannot create java VM.  
The runtime system loaded the JVM shared library (or DLL), but was unable to initialize the Java VM with a call to JNI_CreateJavaVM().  
Check that the Java requirements and resources needs to create a Java VM. |
| -8302  | Array element type is not a Java type.  
The fglcomp compiler detected a Java Array definition which is not using a Java type for the elements.  
Review the DEFINE statement and use a Java type. |
| -8303  | Java is not supported.  
The platform you are using does not support a recent Java version required by Genero.  
You cannot use the Java interface in this operating system, you must review your source code and remove all Java related parts. |
| -8304  | Cannot assign a value to final variable 'variable-name'.  
The program tries to set a Java class variable which is not writable.  
Review the program logic. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8305  | The Java variable 'variable-name' can not be used here.  
The program tries to use a Java class variable in an invalid context. For example, a Java class variable is used in an INPUT instruction.  
Review the program logic and use a regular Genero BDL variable. |
| -8306  | Java exception thrown: java-exception-text.  
A Java exception has been thrown while executing Java code.  
Check the exception text and review the code. |
| -8307  | Java object required.  
A Java object reference is expected by the instruction. This error typically occurs in a CAST() or INSTANCEOF().  
Check the expression used in the instruction and make sure it references a Java object. |
| -8400  | module.name has private access.  
An instruction references a module function or module variable which is declared as private.  
Make the function or variable public in the imported module. |
| -8401  | Reference to name is ambiguous.  
A function or variable referenced without the module prefix, but exists in several imported modules. This error can also be printed by the compiler for Java calls.  
Add the module prefix before the object name to remove the ambiguity. |
| -8402  | Cyclic IMPORT FGL involving module.  
Some modules are importing each other and introduce a cyclic reference which is impossible to resolve.  
Extract common language elements into a new module. |
| -8403  | Module name does not exist.  
The module name to be imported was not found.  
Make sure the module name matches the file name. |
| -8404  | Module name has not been imported.  
A statement is referencing a module name which has not been imported.  
Import the module before usage. |
| -8405  | category-name qualifier-name.symbol-name has not been defined.  
The symbol identified by qualifier-name.symbol-name cannot be found. For example, a START REPORT or SUBDIALOG is referencing a report or sub-dialog symbol with module prefix, but the symbol is not found in the specified module.  
You must import the module defining the referenced symbol. |

Web services

Create a Web service client or server with Genero BDL.

The Genero APIs for creating Web services can be found in the Library section of this manual. See The com package on page 2658, The xml package on page 2774, and The util package on page 2574.

- General on page 3102
- Concepts on page 3108
- Security on page 3125
- SOAP Web Services on page 3146
- RESTful Web services on page 3193
- How Do I ... ? on page 3219
- Deploy a Web Service on page 3232
- Reference on page 3236

General

These topics provide you with an introduction to Genero Web Services and the information needed to get working with the latest version of the software.

- Introduction to Web services on page 3103
- GWS demos and examples on page 3106
- Debugging on page 3106
- Platform-specific notes on page 3106
- Known issues on page 3107
- Legal Notices on page 3108
Introduction to Web services

Web services are a standard way of communicating between applications over an intranet or Internet. They define how to communicate between two entities:

- A server that exposes services
- A client that consumes services

Server usage example

A server exposes a "StockQuotation" service that responds to an operation "getQuote". For the "getQuote" operation, the input message is a stock symbol as a string, and the output message is a stock value as a decimal number.

The "getQuote" operation is a function written in Genero BDL, and it is published on the server. This function retrieves the stock value for the stock symbol passed in, and returns it.

Client usage example

The Web service client application calls the function as if it were a local function. It passes the stock symbol in to the function, and stores the returned value in a variable. If the Web Service operation is named `WebService_StockQuotation_getQuote` and the local variable is `svalue`, the Web Service is called as follows:

```plaintext
LET svalue = WebService_StockQuotation_getQuote( "MyStockSymbol" )
```

Service Oriented Architecture (SOA) and Web services

Service Oriented Architecture (SOA) is a philosophy of how to connect systems and exchange data to solve business problems. Rather than concentrating on a specific task or transaction, SOA addresses how to use data from various sources, reduce human involvement, and mitigate the effects of change in a business process and its supporting systems.

The SOA defines the services to be provided. Web services are the means of implementing those services. Web services provide a platform-neutral technology to connect multiple systems in a flexible manner, where the platform-neutrality helps insulate the SOA from changes to the underlying systems.

Web services work by answering requests for information and returning JSON documents or XML documents.

Because JSON and XML are simple text formats, Web Services can be invoked via the HyperText Transfer Protocol (HTTP), it does not matter what platform runs the Web Service or what platform receives the JSON or XML document.

An SOA's resilience to change is accomplished by adhering to good Web services design practices:

- Build a Web Service that performs a specific task
- Have a rigid structure for the data

SOAP Web services tell exactly how to ask for the information in an XML document written using the Web services Descriptive Language (WSDL). This self-describing document describes the service the Web Service will perform and how to form the request for its data. Each Web Service must have an associated WSDL document, so that developers and applications know what to expect from the Web Service, and how to invoke it.

Migrating to SOA and Web services

Developing an SOA and moving to Web services is an iterative and evolutionary process. It requires work and diligent design. When switching to Web services from another integration method, it is recommended to initially focus on shorter term business benefits, targeting an SOA and Web services project that has tangible goals with measurable benefits.

Once an SOA contains some useful services, these services can be arranged together in a workflow that automates a business process. Web services can be reused to answer new questions, and implemented as new business services in an SOA. A well-defined Web service does not contain business logic or business process information. Because each Web service in an SOA can be called individually to perform a specific task, they can be arranged (orchestrated)
together to perform many different business functions. As a result, companies with a mature SOA in place can change business processes through configuring of the orchestration software as opposed to programming individual links between systems.

**Planning a web service**

When creating a Web Service, you not only have to think of the task at hand, but you must also consider growth. You likely want the Web Service to be flexible; to be able to handle different types of input. Prepare the Web Service for what is probable. Developers should think bigger than the needs of a single application. Consider how you might reuse existing services, and how your services might be reused by others.

Security will likely play a larger role than it did previously with existing in-house application infrastructures using programmed links between systems; you will need to become versed in security issues.

Keep the goals of SOA in mind when designing and coding Web services: **Flexibility. Reusability. Interoperability.**

**Genero Web Services extension**

The Genero Web Services Extension (GWS) is an extension to the Genero Business Development Language. It installs within the Genero Business Development Language directory. The fglgws package includes both Genero Business Development Language and Genero Web Services.

The Genero Application Server is required to manage your Web services in a deployment environment. It is not required for Web services development, unless you are interested in testing deployment issues.

**Important:** When programming a Web service, your applications must include `IMPORT com` at the top of each module. This imports the Genero Web Services Extension library named `com`:

```
IMPORT com
```

**Web services standards**

Web services are platform-independent and programming language-independent. The World Wide Web consortium defines the Web services standards. For more information about these standards, refer to the "Web services" section of their web site at [http://www.w3.org](http://www.w3.org). The Genero Web Services package supports the WSDL 1.1 specification of March 15, 2002 as well as some previous specifications.

The standards involved in what is commonly called "Web services" include XML, XML Schema, SOAP, WSDL, and HTTP.

**XML**

XML (eXtensible Markup Language) defines a machine-independent way of exchanging data. For example, an XML representation of the following BDL data structure:

```
DEFINE Person
  RECORD Attribute (XMLName="Person")
    FirstName VARCHAR(32) Attribute (XMLName="FirstName"),
    LastName VARCHAR(32) Attribute (XMLName="LastName"),
    Age INTEGER Attribute (XMLName="Age")
END RECORD
```

Could be:

```
<Person>
  <FirstName>John</FirstName>
  <LastName>Smith</LastName>
  <Age>35</Age>
</Person>
```

The record definition allows you to specify XML attributes for data types. This feature was added with Genero 2.00.
XML schema

XML Schema defines the elements, entities, and content model of an XML document. For example, for the example document shown in the topic XML on page 3104, the schema might indicate that the XML document contains an element "Person", and that each "Person" contains one and only one element "FirstName", "LastName", and "Age".

The XML Schema has additional capabilities, such as data type control and content restrictions.

An XML Schema allows an XML document to be validated for correctness.

SOAP

SOAP (Simple Object Access Protocol) is a high-level communication protocol that defines an XML data flow between a server and a client.

The "StockQuote" service mentioned in the Introduction to Web services on page 3103 exchanges messages using the following syntax:

Request

```xml
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
  <soap:Body>
    <getQuote>
      <stockSymbol>MyCompany</stockSymbol>
    </getQuote>
  </soap:Body>
</soap:Envelope>
```

Response

```xml
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
  <soap:Body>
    <getQuoteResponse>
      <stockValue>999.99</stockValue>
    </getQuoteResponse>
  </soap:Body>
</soap:Envelope>
```

SOAP relies on a lower-level protocol for the transport layer.

Genero Web Services use SOAP over HTTP, and can also perform low-level XML and TEXT over HTTP communications on the client side. This allows communication between applications using the core Web technology, taking advantage of the large installed base of tools that can process XML delivered plainly over HTTP, as well as SOAP over HTTP.

WSDL

The WSDL (Web services Description Language) file describes the services offered by a server. It contains:

- The description of the operations offered by the server, and each operation's input and output messages.
- The location of the SOAP server.
- Internal connection and protocol details (transport layer, encoding, namespaces, and so on).

A WSDL description is sufficient to provide all the information required to communicate with the SOAP server.

Genero Web Services package provides a tool, fglwsdl, that enables Genero client applications to obtain the WSDL description of a Web Service.

HTTP

HTTP (Hypertext Transfer Protocol) is the set of rules for exchanging files (text, graphic images, sound, video, and other multimedia files) on the World Wide Web.

Web services style options

The Web services Style options available for created Genero Web services are WS-I (Web services Interoperability organization) compliant:
• **RPC Style Service (RPC/Literal)** is generally used to execute a function, such as a service that returns a stock option.

• **Document Style Service (Doc/Literal)** is generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document.

• **RPC Style Service (RPC/Encoded)** is the legacy style, now provided for backwards compatibility. You most likely will not be using the RPC/Encoded style to create new Web services.

### GWS demos and examples

Demos and examples are provided for both SOAP and RESTful Web services.

**Demos**

Web Services demos are located in `FGLDIR/demo/WebServices`. Each demo sits in its own folder, and includes the code for both the client and the server. A `readme.txt` file provides details about the demo.

For SOAP demos, the description in the `readme.txt` file will indicate a Web service such as: an RPC style Web service demonstration, a Document Style Web service demonstration, RPC encoded Web service demonstration, Stateful Web service demonstration, or Doc Literal Web service demonstration with XML-Security.

For RESTful demos, the description in the `readme.txt` file will indicate a Web service such as: a REST service demonstration, or a low-level Web service demonstration.

**Tutorials and Examples**

Examples are provided within this manual.

For a tutorial-style example of a SOAP Web service, start with Writing a Web Services client application on page 3146 and Writing a Web Services server application on page 3163.

For a tutorial-style example of a RESTful Web service, start with Writing a Web services client application on page 3195 and Writing a Web Services server application on page 3204. The full application code can be viewed at The RESTful calculator demo source on page 3210.

### Debugging

Turn on the debug mode to log the data sent or received by your Web service application.

Debug information is written to the standard error stream of the console. If needed, it can be redirected to a file.

To turn on the debugging feature, set the `FGLWSDEBUG` environment variable before starting the application.

The level of debugging depends on the value set for the `FGLWSDEBUG` variable. See `FGLWSDEBUG` on page 247.

**Note:** To debug a Web Service application managed by the Genero Application Server (GAS), you have to modify the value of the `FGLWSDEBUG` environment variable in the GAS configuration file. Refer to the Genero Application Server User Guide.

### Platform-specific notes

Some platforms have specific requirements.

**Web Services on IBM® AIX®**

Requirements for IBM® AIX®.

- The "IBM® C++ Runtime Environment Components for AIX®" must be installed in order to use Genero Web Services. See the IBM® support center for more information about downloading the component.

  **Note:** If not installed, you will get the following error message:

  Could not load C extension library 'com'. Reason: A file or directory in the path name does not exist.
• Due to an IBM® issue on 64-bit platforms, the openssl library is unable to open the system /dev/urandom device to generate a PRNG number.

If you want to use security APIs in your GWS application (especially if you access a server in HTTPS), install Entropy Gathering Daemon (a.k.a EGD).

**Web Services on GMI (iOS)**
Requirements to use Web services on iOS platforms (GMI).

**Web services configuration options**
GWS configuration FGLPROFILE entries related to SSL/TLS keys (security.*) are not supported (uses iOS native SSL/TLS).

**Long running HTTP request**
When executing an HTTP request (for example with com.HTTPRequest.doRequest()), if the request takes a long time to complete (for example, several minutes), the app will go into background mode. If the user taps the app icon to return to foreground mode, the program will get the runtime error -15553.

**The XSLTTransformer class**
The XSLTTransformer class is not available on iOS.

**Web Services on GMA (Android™)**
Requirements to use Web services on Android™ platforms.

**V3 SSL Certificates**
The SSL certificates for secured servers must be of type V3: Android does not support other types of SSL certificates. When creating your own self-signed certificates (to be installed in the "Install from storage" Keystore of Android), make sure that type V3 is used.

**Known issues**
There are some known issues when working with Web services.

**Forcing RPC style convention when no input message**
In RPC style, the convention defines names for input messages and output messages, but if there is no input message, its name cannot be redefined.

To workaround this issue, respect RPC style convention in wsdl, or force RPC convention (on client and server side) by using the -fRPC option of the fglwsdl tool.

**Variable names conflicts with library names**
The fglwsdl tool can generate variable names conflicting with IMPORT library names.

For example:

```plaintext
DEFINE xml xml.DomDocument
```

will conflict with the xml library, if the code defines also the instruction:

```plaintext
IMPORT xml
```

Concepts

These topics cover various Genero Web Services concepts.

- High-level and low-level web services APIs on page 3108
- SOAP features on page 3108
- Stateful web services on page 3110
- Encryption, base64 and password agent with fglpass tool on page 3117
- HTTP compression on page 3121
- SOAP multipart style requests in GWS on page 3123
- Message Transmission Optimization Mechanism (MTOM) on page 3123
- swaRef (SOAP with attachments using wsi:swaRef) on page 3124

High-level and low-level web services APIs

With Genero, we distinguish two type of APIs to implement web services.

- High-level web services are SOAP web services managed on server side with the high-level APIs WebService and WebOperation, or if you have generated code via the fglwsdl tool (client and server side).
- Low-level web services are implemented with HTTPRequest, HTTPResponse and HTTPServiceRequest classes, where you have to write all the HTTP code of your services by hand.

Related concepts

Writing a Web Services server application on page 3163
These topics cover creating a Genero Web Services server using the SOAP protocol.

Writing a Web Services client application on page 3146
Create, configure and deploy a Genero Web Services client using the SOAP protocol.

SOAP features

SOAP 1.1 and 1.2

Since 2.40, Genero Web Services (GWS) supports SOAP 1.2. GWS is able to communicate with Web services provided with SOAP 1.1 or SOAP 1.2.

Server side

A Genero Web Services server can deliver a service in SOAP 1.1 or SOAP 1.2 using the com.WebService.setFeature function.

For example in $FGLDIR/demo/WebServices/calculator/server/calculatorServer.4gl, the calculator server offers the service in SOAP 1.1 and SOAP 1.2.

```
CALL serv.setFeature("Soap1.1",TRUE)
```
Client side

A GWS client can consume a service in SOAP 1.1 or SOAP 1.2.

For example:
- To create a client that consumes the Calculator service in SOAP 1.1 use command:
- To create a client that consumes the Calculator service in SOAP 1.2 use command:

Be aware to generate different clients for each SOAP versions. Even if the same operations are provided, the services are using different protocols so the underlying generated stubs are also different.

SOAP Fault

Since 2.40, Genero Web Services supports SOAP fault.

For backward compatibility, the fglwsdl tool provides the `-ignoreFaults` option to disable SOAP fault management.

Server side

A Genero Web Services server can throw a SOAP fault if any processing error is encountered.

To generate a SOAP fault you need to:
- create the fault variable with `com.WebService.createFault()`
- add it to your operation with `com.WebOperation.addFault`
- use it with `com.WebServiceEngine.SetFaultDetail`

For example in `$FGLDIR/demo/WebServices/calculator/server/calculatorServer.4gl`, the calculator server has a `divide_by_zero` SOAP fault. The SOAP fault is raised when you try to divide a number by zero. To generate a SOAP fault proceed as follow:

Create a SOAP fault

You define the variable to send as a SOAP fault. It can be a simple string like in this example or a complex type. Remember to assign a XMLName to the variable.

```
DEFINE divide_by_zero STRING ATTRIBUTES (XMLName="DividedByZero")
```

Then you inform the service that it can use this fault variable using function `com.WebService.createFault()`.

```
CALL serv.createFault(divide_by_zero,FALSE)
```

Add the SOAP fault to an operation

A SOAP fault can be used by an operation to inform the client that an error has occurred. An operation can use different SOAP faults but only one at a time.

```
LET op =
  com.WebOperation.CreateRPCStyle("divide","Divide",divide_in,divide_out)
CALL op.addFault(divide_by_zero,NULL)
```

Here, the SOAP fault is added to the "divide" operation.
**Send the SOAP fault**

Set the values to the fault variable. The fault message is be sent to the client at the end of the operation processing.

```
LET divide_by_zero = "Cannot divide "||divide_in.a||" by zero"
CALL com.WebServiceEngine.SetFaultDetail(divide_by_zero)
```

**Client side**

A Genero Web Services client can receive a SOAP fault number in the operation status and act accordingly.

If a SOAP fault occurs, the operation returns the SOAP fault number in the operation status. The SOAP fault number is defined in the generated stubs as a BDL constant prefixed with the string `FaultID_`.

**Note:** A SOAP fault can occur in case of HTTP error 200 and 500.

For example in `$FGLDIR/demo/WebServices/calculator/client/ws_calculator.inc`, the `Divide` operation has a SOAP fault that informs the client when a number is divided by zero.

```
# List of Soap fault constants
CONSTANT FaultID_DividedByZero = 1
...
# VARIABLE : DividedByZero
DEFINE DividedByZero STRING ATTRIBUTES(XMLName="DividedByZero",
   XMLNamespace="http://tempuri.org/")
...
# Operation: Divide
# FAULT #1: GLOBALS DividedByZero
```

You can test the operation status code accordingly and display the SOAP fault message.

For example in `$FGLDIR/demo/WebServices/calculator/client/calculatorClient.4gl`, when the divide operation status is 1, `DividedByZero` message is displayed.

```
ON ACTION divide
   CALL Divide(op1, op2) RETURNING wsstatus, result, remaind
   CASE wsstatus
      WHEN 0
         DISPLAY BY NAME result,remaind
      DISPLAY "OK" TO msg
      WHEN FaultID_DividedByZero
         DISPLAY DividedByZero TO msg
      OTHERWISE
         DISPLAY wsError.description TO msg
   END CASE
```

**Stateful web services**

**Concept**

A stateful service is a service that maintains a context between a web services client and server. It enables the service to keep trace of previous requests from that context, in order to manage different states in the web service server.

Genero Web Services supports two kinds of stateful services:

- Based on the WS-Addressing 1.0 specification to define the XML format used to convey the context from client to the server
- Based on an HTTP session cookie to convey the context from client to the server

The Genero Web Service engine uses a BDL variable defined at stateful service creation via `createStatefulWebService()` as service context. Use that variable to hold a service state in a database.

It is up to the BDL programmer to create, store and remove the service state in the database.
The SOAP engine is responsible for:

- Deserializing the state variable when getting an new incoming request. *The programmer can then read the state variable for any published BDL web service operation and restore the service state corresponding to that variable.*
- Serializing a new instance of the state variable in a web service response for all BDL web service operations set as session initiator via `initiateSession()`.* The programmer must instantiate a new state by filling the state variable and storing it into a database for further use.*

**WS-Addressing 1.0 stateful services**

A stateful service based on WS-Addressing uses the WS-Addressing EndpointReference type as state variable and is independent from the transport layer used. (See [WS-Addressing 1.0 EndpointReferenceType](#).) The session state is conveyed from the client to the server as WS-Addressing 1.0 reference parameters.

**Server side**

Perform these steps to create a WS-Addressing stateful service.

*Step 1: Declare a W3CEndpointReference record to be used as state variable*

This record **MUST** have:

- A mandatory member of type STRING, where you can define a different service end point URL, otherwise the current server URL will be used.
- A sub record to contain one or more BDL variables used as state variables and defined as reference parameter in the WS-Addressing 1.0 specification.

For example:

```CONTEXT-SCRIPT
DEFINE EndpointReferenceState RECORD ATTRIBUTES(W3CEndpointReference)
  address STRING, # Mandatory
  ref RECORD # Sub-record Reference parameters containing one
  # or more state variables
  OpaqueID STRING ATTRIBUTES(XMLName="OpaqueID"), # Unique ID to
  # identify the service state in the database
  Expiration DATE ATTRIBUTES(XMLName="Expiration",
  # Session state expiration date
  XMLNamespace="http://tempuri.org")
END RECORD
END RECORD
```

You can use a unique ID of a database table to manage the web services sessions in place of OpaqueID.

*Step 2: Create a stateful WS-Addressing enabled web service with W3CEndpointReference record as a parameter*

The Genero Web Service extension provides a new Web service constructor called `createStatefulWebService()` to perform stateful services. This function works as the stateless constructor, but expects a W3CEndpointReference record as parameter.

For example:

```CONTEXT-SCRIPT
DEFINE serv com.WebService
  EndpointReferenceState) # Create a stateful service
  # with a W3CEndpointReference state variable
CALL serv.setFeature("WS-Addressing1.0","REQUIRED") # enable
  # support of WS-Addressing 1.0
```

*Step 3: Publish a web service operation returning the W3CEndpointReference state variable and set it as session initiator*

You must define which web service operation will initiate the session on your service and return the W3CEndpointReference state variable.
All other web service operations (not defined as session initiator) will return an error if they don't get reference parameters defined in the W3CEndpointReference state variable as WS-Addressing 1.0 headers.

For example:

```
DEFINE op com.WebOperation
CALL op.initiateSession(TRUE)
CALL serv.publishOperation(op, NULL)
```

There is no restriction regarding the input parameter of the web service initiator function, but the output parameter must be the same W3CEndpointReference record passed to the service creation constructor.

It is not required to have a web operation which initiate the session in the same service, but then you have to return the same W3CEndpointReference record in another web service to instantiate the session, such as a Factory service that instantiates all sessions for other stateful services.

**Step 4: Create the BDL session initiator function and instantiate a new session**

In your BDL function declared as session initiator, you have to:

- Handle the creation of the session
- Fill the state variable before to return from the function
- Store the new session in a database based on the state variable (in order to keep the session across consecutive requests from the same client).

For example:

```
FUNCTION GetInstance()
    LET EndpointReferenceState.address = NULL
    # Use default end point location
    LET EndpointReferenceState.ref.OpaqueID = com.Util.CreateUUIDString()
    # Generate an unique string (can come from a database table id)
    LET EndpointReferenceState.ref.Expiration = CURRENT + INTERVAL HOUR TO HOUR (1)
    # Create expiration date in one hour to discard request after that date
    ... Store OpaqueID into database or use directly a database table entry
    ... to hold the session
END FUNCTION
```

**Step 5: Restore the session in any BDL web operation from the W3CEndpointReference record**

In any publish BDL web function, the SOAP engine deserializes the WS-Addressing 1.0 reference parameter headers into the W3CEndpointReference sub-record so that you can retrieve the session from the state variable.

For example:

```
FUNCTION MyFunction()
    IF EndpointReferenceState.ref.OpaqueID IS NULL THEN
        CALL com.WebServiceEngine.SetFaultString("Invalid session id")
        RETURN
    ELSE
        ... Restore the service session based on the OpaqueID state
        ... variable from the database
    END IF
    ... Process the operation
END FUNCTION
```
Client side
Perform these steps to communicate with a stateful web service based on WS-Addressing 1.0.

Step 1: Generate the client stub from your WS-Addressing stateful service

Use the fglwsdl tool as usual. It will detect that the service returns a W3CEndpointReference and generate the appropriate code.

The WSDL imports the WS-Addressing 1.0 schema, so the fglwsdl tool requires an access to the W3C server. Use the option -proxy if you need to connect via a proxy server.

For example:

```sh
gflwsdl -o ws_stub http://localhost:8090/StatefulWSAddressingService?WSDL
```

The generated .inc file contains a variable of type tWSAGlobalEndpointType to be used to transmit the WS-Addressing 1.0 reference parameters.

Example of a global variable name

```haskell
DEFINE
StatefulWSAddressingService_StatefulWSAddressingServicePortTypeEndpoint
tGlobalWSAEndpointType
```

Step 2: Create the MAIN application

In your main application:

1. Import the XML library. This is due to the support of WS-Addressing 1.0 with IMPORT XML.
2. Import the generated .inc file with GLOBALS "ws_stub.inc"
3. Manage the WS-Addressing 1.0 reference parameters representing the session state (if your client has to handle several instances of a same service).

For example:

```haskell
IMPORT XML # Import the XML library required for WS-Addressing 1.0
GLOBAL "ws_stub.inc" # Import service global definition
TYPE InstanceType DYNAMIC ARRAY OF xml.DomDocument # End point WSA reference parameters
DEFINE instance1,instance2,instance3 InstanceType # Store the different sessions the client will have to manage
MAIN ...
END MAIN
```

Step 3: Instantiate a new session by calling the web service operation set as session initiator

Call the BDL function generated from the WSDL that is defined as session initiator on the server. This function returns a W3CEndpointReference parameter that contains the WS-Addressing 1.0 reference parameters representing the new instance created on server side.

If your application handles several instances, you will have to copy and store those parameters in your application to identify a service instance for further requests.

As the WS-Addressing 1.0 reference parameters are defined as any XML document, they are represented as a dynamic list of xml.DomDocument in BDL.

For example:

```haskell
DISPLAY "Creating a new instance ..."
```
LET wsstatus = GetInstance_g()  # call the service session initiator  
    # web function

IF wsstatus == 0 THEN
    FOR ind=1 TO
        ns1GetInstanceResponse.return.ReferenceParameters._LIST_0.getLength()
        LET instance1[ind]=
            ns1GetInstanceResponse.return.ReferenceParameters._LIST_0[ind].clone()
            # copy the service returned WS-Addressing 1.0 reference parameters
    END FOR
ELSE
    ... handle soap errors
END IF

When creating a new instance, ensure that the Parameters member of the generated global variable of type tWSAGlobalEndpointType has been set to NULL, otherwise the server will complain.

**Step 4: Call any web service operation with previously returned WS-Addressing 1.0 reference parameters**

Before calling any web service operation, you must set the WS-Addressing 1.0 reference parameters returned by a session initiator function to identify the session to the server.

For example:

LET StatefulWSAddressingService_StatefulWSAddressingServicePortTypeEndpoint.Address.Parameters.* = instance1.*  
    # assign WS-Addressing 1.0 reference parameters dynamic array by reference
CALL MyFunction("Hello") RETURNING wsstatus,ret  
    # Call web operation MyFunction of instance 1

**Stateful services based on HTTP cookies**

A stateful service based on HTTP cookies uses the HTTP transport protocol and its ability to convey cookies, used as session context. **Notice** that it works only if the communication path between the client and the server is performed in HTTP, otherwise it is recommended to use WS-Addressing stateful services.

**Server side**

Perform these steps to create an HTTP cookie based stateful service.

**Step 1: Declare any BDL simple variable to be used as state variable**

For example:

DEFINE ServiceState STRING # Unique ID to identify the service state in the database

For instance, you can use a unique ID of a database table to manage the web services sessions.

**Step 2: Create a stateful web service with state variable as parameter**

The Genero Web Service extension provides a new Web service constructor called createStatefulWebService() to perform stateful services. This function works as the stateless constructor, but expects a simple state variable as parameter.

**Example**

DEFINE serv com.WebService
    "http://4js.com/services", ServiceState)  
    # Create a stateful service with a simple BDL variable as state variable
Step 3: Publish a web service operation defined as session initiator

Define which web service operation will initiate the session on your service and instantiate a new session. All other web service operations (not defined as session initiator) will return an error if they don't get an HTTP cookie called GSESSIONID.

For example:

```
DEFINE op com.WebOperation
LET op =
CALL op.initiateSession(true)
CALL serv.publishOperation(op,NULL)
```

There is no restriction on the web service session initiator function regarding to the input and output parameters.

Step 4: Create the BDL session initiator function and instantiate a new session

In your BDL function declared as session initiator, you must:

- Handle the creation of the session.
- Fill the state variable before to return from the function.
- Store the state variable in a database based on the state variable (in order to keep the session across consecutive requests from a same client).

For example:

```
FUNCTION GetInstance()
    # Generate an unique string (can come from a database table id)
    LET ServiceState = com.Util.CreateUUIDString()
    ... Store ServiceState value into database or use directly a database table entry to hold the session
END FUNCTION
```

Step 5: Restore the session in any BDL web operation from the state variable

In any publish BDL web function, the SOAP engine deserializes the HTTP Cookie called GSESSIONID from the HTTP layer into the state variable. You can then retrieve the session in BDL via that state variable.

For example:

```
FUNCTION MyFunction()
    IF ServiceState IS NULL THEN
        CALL com.WebServiceEngine.SetFaultString("Invalid session id")
        RETURN
    ELSE
        ... Restore the service session based on the ServiceState variable from the database
    END IF
    ... Process the operation
END FUNCTION
```

Step 6: Deployment recommendation

When deploying stateful web services based on HTTP cookies, the complete server path will be added into the cookie when first instantiated, so you must pay attention to that URL. In other words, you MUST always call the service via the complete URL containing the service name inside. For instance if your service is named MyService and if you GAS configuration file is called Server.xcf, the stateful service is accessible at URL: http://localhost:6394/ws/r/group/Server/MyService.
Client side
Perform the following steps to communicate with a stateful web service based on HTTP cookies.

Step 1: Generate the client stub from your stateful service
Use the fglwsdl tool as usual.

For example:

```
$ fglwsdl -o ws_stub http://localhost:8090/StatefulCookieService?WSDL
```

The generated .inc file contains a variable of type `tGlobalEndpointType` to be used to transmit the HTTP Cookie.

Example of a global variable name

```
DEFINE StatefulCookieService_StatefulCookieServicePortTypeEndpoint
tGlobalEndpointType
```

Step 2: Create the MAIN application
In your main application:

- Import the generated .inc file with `GLOBALS "ws_stub.inc"`.
- Manage the HTTP cookies representing the session state (if your client has to handle several instances of a same service).

For example:

```
GLOBALS "ws_stub.inc" # Import service global definition
# Store the different sessions the client will have to manage
# in a string
DEFINE instance1,instance2,instance3 String
MAIN ...
END MAIN
```

Step 3: Instantiate a new session by calling the web service operation set as session initiator
Call the BDL function generated from the WSDL that was defined as session initiator on the server. This function returns a new HTTP Cookie saved into the `Binding.Cookie` member of the global service variable of type `tGlobalEndpointType`. If your application handles several instances, you will have to copy and store that cookie in your application to identify a service instance for further requests.

For example:

```
DISPLAY "Creating a new instance ..."
LET wsstatus = GetInstance_g() # call the service session # initiator web function
IF wsstatus == 0 THEN
  # copy the service returned HTTP cookie
  LET instance1 =
    StatefulCookieService_StatefulCookieServicePortTypeEndpoint.Binding.Cookie
ELSE
  ... handle soap errors
END IF
```

When creating a new instance, ensure that the `Binding.Cookie` member of the generated global variable of type `tGlobalEndpointType` has been set to NULL, otherwise the server will complain.
**Step 4: Call any web service operation with previously returned HTTP cookie**

Before calling any web service operation, set the HTTP cookie returned by a session initiator function to identify the session to the server.

For example:

```plaintext
# use instance1
LET
 StatefulCookieService_StatefulCookieServicePortTypeEndpoint.Binding.Cookie = instance1
# Call web operation MyFunction of instance 1
CALL MyFunction("Hello") RETURNING wsstatus, ret
```

**Step 5: Troubleshooting**

If your Genero application doesn't set the HTTP cookie when accessing a stateful service via the GAS, it is possible that you didn't use the complete URL when accessing the service.

For instance if your service is named `MyService` and if you GAS configuration file is called `Server.xcf`, the stateful service is accessible at URL: `http://localhost:6394/ws/r/group/Server/MyService`.

**Encryption, base64 and password agent with fglpass tool**

For security reasons, it is recommended that you avoid storing clear passwords in a file. The Genero Web Services enables the password encryption of a HTTP Authenticate entry in the FGLPROFILE file. The encrypted password is decrypted by the Genero Web Services engine when required.

**The fglpass tool**

The Genero Web Services package provides a command line tool called `fglpass`. The `fglpass` tool can encrypt a password from a X.509 certificate or a RSA private key. The encrypted password is displayed on the console in a Base64 form, composed only of alphanumeric characters, and therefore easily usable in any text file.

See `fglpass` for more details.

**Encrypt a HTTP authenticate password**

1. Find the HTTP Authenticate entry with the password you want to encrypt:

   ```plaintext
   authenticate.myentry.login = "mylogin"
   authenticate.myentry.password = "mypassword"
   ``

2. Add the certificate and its private key in the FGLPROFILE file as follows:

   ```plaintext
   security.mykey.certificate = "MyCertificate.crt"
   security.mykey.privatekey = "MyPrivateKey.pem"
   ``

3. Encrypt the password with `fglpass`:

   ```sh
   $ fglpass -e -c MyCertificate.crt
   Enter password :mypassword
   ``

   The `fglpass` output looks like the following:

   ```plaintext
   BASE64 BEGIN
dBy3E5jCvxuoxxsR+aOBVfp1j0SwQPt+hdjpMKr1WvO2xMd5rPnFEwv+sPPd4w/onWviGOM5qubBe7QUl1t/ZK0D1aO9/R5Rva5wy1Qu//6vxfyd8NG/ SFJm1VH63kuyXf1Vfq6bHo5+n1Q2pVJHff2msET399HTpZUt4NblP4=BASE64 END
   ``

   **Note:** The encrypted password is enclosed between `BASE64 BEGIN` and `BASE64 END`. In the above example, the cyphertext is wrapped for display purposes only.
4. Replace the clear password with the encrypted one, and specify the key used to encrypt it (mykey in our case):

```yaml
authenticate.myentry.login = "mylogin"
authenticate.myentry.password.mykey = "dBy3E5JCxuoxxS+r+aOBVfp1j0SwQPt+hdjpMKriWvO2xMd5rFnFEwv+sPPd4w/onWv10G5mqubBeSTQUlZ/K0D1aO9/R5RVa5wy1Qu/6vxfyd8NG/SFJm1VH63kuyXfiVf6bHo5+n1Q2pVjSHfF2msET3S9HTp2Ut4Nb1P4=
```

**Note:** Do not forget to put quotes around the base64 form; otherwise the '=' character is interpreted during the loading of FGLPROFILE. The long line of text is wrapped for display purposes only.

**Encrypt a HTTP authenticate password using a certificate in the Windows™ key store**

1. Find the HTTP Authenticate entry with the password you want to encrypt:

```yaml
authenticate.myentry.login = "mylogin"
authenticate.myentry.password = "mypassword"
```

2. Add the subject of the certificate registered in the Windows™ key store:

```yaml
security.mykey.subject = "Georges"
```

3. Encrypt the password with `fglpass`:

```bash
$ fglpass -c Georges
Enter password :mypassword
```

**Note:** The encrypted password corresponds to the big suite of alphanumeric characters between BASE64 BEGIN and BASE64 END. The long line of text is wrapped for display purposes only.

4. Replace the clear password with the encrypted one, and specify the key used to encrypt it (mykey in our case):

```yaml
authenticate.myentry.login = "mylogin"
authenticate.myentry.password.mykey = "dBy3E5JCxuoxxS+r+aOBVfp1j0SwQPt+hdjpMKriWvO2xMd5rFnFEwv+sPPd4w/onWv10G5mqubBeSTQUlZ/K0D1aO9/R5RVa5wy1Qu/6vxfyd8NG/SFJm1VH63kuyXfiVf6bHo5+n1Q2pVjSHfF2msET3S9HTp2Ut4Nb1P4=
```

**Note:** Do not forget to put quotes around the base64 form; otherwise the '=' character is interpreted during the loading of FGLPROFILE. The long line of text is wrapped for display purposes only.

**Use the password agent**

The `fglpass` tool can be started as an agent with the `-agent:tcp-port` option, to allow BDL applications requiring passwords, to grant access to a private keys without providing the passwords.

Passwords are provided once for each private key at the `fglpass` agent startup.

The fglpass agent has the following `fglrun` authentication methods:

- By default, the agent allows only `fglrun` to access the passwords, if the OS user executing `fglpass` and `fglrun` are the same.
On UNIX platforms, the fglpass agent can be started with the \texttt{-gid} option, to allow all users belonging to the OS group of the user executing the fglpass program:

\begin{verbatim}
fglpass -gid -agent:4242 myprivate1.pem myprivate2.pem ...
\end{verbatim}

For fglrun programs requiring the group-based agent authentication method, you need to set the following FGLPROFILE entry:

\begin{verbatim}
security.global.agent.gid=true
\end{verbatim}

Authentication and data encryption are performed between the BDL application and the agent to guarantee passwords confidentiality, and the passwords are also stored encrypted in the agent memory.

1. To start the password agent at port number \texttt{4242} and to serve the BDL applications with the passwords of the private key \texttt{RSAKey1.pem} and \texttt{DSAKey2.der}, specify the option \texttt{-agent}, followed by a colon, followed by the port number where it will be reachable, followed by the list of private keys the agent will handle for all BDL applications.

\begin{verbatim}
fglpass -agent:4242 RSAKey1.pem DSAKey2.der
\end{verbatim}

2. The agent will ask you to silently enter the password of the different keys\texttt{(the passwords are not displayed to the console when being typed)}. In this example, you have:

Enter pass phrase for RSAKey1.pem:

Followed by:

Enter pass phrase for DSAKey2.der:

3. Once all keys have been treated, it displays following message to notify that the agent is ready to serve.

Agent started

4. To enable one BDL application to use the password agent capability, set the entry called \texttt{security.global.agent} in the FGLPROFILE file with the port number of the agent.

In our example, with value \texttt{4242}:

\begin{verbatim}
security.global.agent = "4242"
\end{verbatim}

\textbf{Encrypt a password}

The fglpass tool can encrypt a password using an RSA key or certificate, and then encode it in BASE64 form. This allows you to easily add a protected password in the FGLPROFILE file for future use by any BDL application.

1. To encrypt a password from an RSA key and encoded in BASE64, enter:

\begin{verbatim}
fglpass -e -k RSAPub.pem
\end{verbatim}

2. You are prompted to enter the password you want to encrypt.

Enter password :hello

The fglpass tool outputs the BASE64 form of the encrypted password on the console.

\begin{verbatim}
BASE64 BEGIN
Pzk/fNRhetdJDZz5kJNg7P0XET4XsW6bys/fi0DvugxRPh9d/s4loAws65
JY0EPb2zytQjxZ/dwaar2zJPYoQmA==
BASE64 END
\end{verbatim}

\textbf{Note:} The BASE64 encrypted password is the string between the BASE64 BEGIN and BASE64 END.
Decrypt a password

The fglpass tool can decrypt a BASE64 encoded and encrypted password using the RSA private key that was used to encrypt it or that is associated to a certificate containing the public part of that private key.

1. To decrypt a BASE64 encoded and encrypted password from a RSA private key, enter:

```
fglpass -d -k RSAPriv.pem
```

2. If the RSA key is protected with a password, you are asked to silently enter that password (the password is not displayed to the console when being typed).

```
Enter pass phrase for RSAPriv.pem:
```

3. You are prompted to enter the BASE64 encoded and encrypted password you want to decrypt.

```
Enter password :Pzk/fNRhetdJDZz5kjNg7F0XET4XsW6bys/f10DvugxFPh9d/s4loA沃尔65Y0EPb2zytQjxZ/dwaaRzJYoQmA==
```

The fglpass tool outputs the password in clear text on the console.

```
hello
```

Encode a file in BASE64 form

The fglpass tool can encode a file in BASE64 form.

1. To encode the file MyFile in BASE64, enter:

```
fglpass -enc64 MyFile
```

The fglpass tool outputs the BASE64 form of the file to the console.

```
BASE64 BEGIN
c2VjdXJpdpHkuZ2xvYmFsdmFzZm5zLm9uZ3Nvdmk6MTYzMDAzMDk2MjU1MDY1OTQwNjY2OTU3MjgyNzY5Mg0K
BASE64 END
```

Note:

- The BASE64 encoded file is the string between BASE64 BEGIN and BASE64 END.
- You can redirect the output of fglpass tool to a file. For example:

```
fglpass -enc64 MyFile > Base64filename
```

Decode a BASE64 form encoded file

The fglpass tool can decode a BASE64 encoded file.

1. To decode a file encoded in BASE64 form, enter:

```
fglpass -dec64 Base64filename
```

The fglpass tool outputs the file in clear form on the console.

```
security.global.agent      = "4242"
crypto.id1.key             = "RSA1024Key.pem"
```
crypto.id2.key = "RSA2048Key.pem"
crypto.id3.key = "DSA1024Key.pem"
crypto.id4.key = "RSA512Protected.pem"
crypto.id5.key = "DSA512ReallyProtected.pem"

**Note:**
- You don't have to remove the BASE64 BEGIN and BASE64 END tags, if they are present in the file, because the fglpass tool detects and removes them automatically.
- You can redirect the output of the fglpass tool to a file. For example:
  
  ```
  fglpass -dec64 Base64MyFile > MyFile2
  ```

**HTTP compression**

HTTP compression is a capability that can be built into web servers and web clients to make better use of available bandwidth, and provide greater transmission speeds between both.

There are a variety of places where you can set up HTTP compression.

- You can set up the Web services client to send and receive compressed requests. See Compression and a Web services client on page 3121.
- You can enable compression for the Web server. Refer to your Web server documentation for details.
- You can enable compression in the Genero Application Server. Compression is enabled by default in $FGLASDIR/etc/imt.cfg. Refer to the Genero Application Server User Guide for more information.
- You can set up the Web services server to send and receive compressed requests. See Compression and a Web services server on page 3122.

**Compression and a Web services client**

Send and receive compressed requests from a Web services client.

When you create a low-level Web service and do not have any stubs created by fglwsdl, you need to manage it by setting the HTTP headers.

**Important:** HTTP request compression for POST/PUT is not supported on GMI mobile devices.

**Send a compressed request**

The method used to set up the client for sending a compressed request depends on whether the Genero Web Services client is a high-level or low-level Web services client. A high-level client is a Genero Web Services client that includes the stub files created by the fglwsdl tool. A low-level client is a Genero Web Services client that does not utilize stub files created by the fglwsdl tool.

Regardless of the type of client, the server must be set up to handle such compression, otherwise the request will be rejected.

**Send a compressed request from a high-level client**

A high-level client is a Genero Web Services client that includes the stub files created by the fglwsdl tool.

Set the variable Binding.CompressRequest to either "gzip" or "deflate".

```
LET EchoDocStyle_EchoDocStylePortTypeEndpoint.Binding.CompressRequest = "gzip"
```

The Binding.CompressRequest variable is defined in the stub file, specifically the client's global (inc) file.

```
#
# Global Endpoint user-defined type definition
#
TYPE tGlobalEndpointType RECORD   # End point
```
Send a compressed request from a low-level client

A low-level client is a Genero Web Services client that does not utilize stub files created by the fglwsdl tool. Set the Content-Encoding field in the request header to either "gzip" or "deflate". This example sets the Content-Encoding field to "gzip", where the request is a com.HTTPRequest object.

```
CALL request.setHeader("Content-Encoding","gzip")
```

Accept a compressed response

A Genero Web Services client can accept a compressed request if it sets the Accept-Encoding field in the header to "gzip, deflate". These values represent supported compression schema names (called content-coding tokens) separated by commas.

This example sets the Accept-Encoding field with the setHeader method, where the request is a com.HTTPRequest object.

```
CALL request.setHeader("Accept-Encoding","gzip, deflate")
```

SOAP multipart style requests in GWS

This topic describes multipart support with Genero Web Services

What is multipart style in SOAP?

Multipart style SOAP is the ability to send and receive a SOAP request in multiple pieces. The sending of attached files in separate parts of the SOAP request is one example of a multipart style SOAP request.

Multipart SOAP on the client

When using a WSDL with multipart style, fglwsdl generates a client-side stub handling multipart requests. For more details, see Multipart in the client stub on page 3156.

Multipart SOAP on the server

Multipart style is not yet supported with the high-level WS API of Genero.

- It is not possible to write a GWS server handling multipart style SOAP requests with the high-level API.
- When generating code from a WSDL using multipart style, the fglwsdl will produce a warning message:

  WARNING : Unable to manage MIME Mutilpart binding on message 'name', where name is the name of the message in XML.

Implementing multipart using the low-level APIs

If required, you can implement a WS server handling multipart with the low-level APIs of Genero Web Services. For more details, see com.HTTPServiceRequest.getRequestMultipartType on page 2698.

Related concepts

- High-level and low-level web services APIs on page 3108
- With Genero, we distinguish two type of APIs to implement web services.
  - fglwsdl on page 1980
  - The fglwsdl tool produces web services stub files for client or server programs (from WSDL / XSD).

Message Transmission Optimization Mechanism (MTOM)

The W3C Message Transmission Optimization Mechanism (MTOM) is a method of efficiently sending binary data to and from Web services.

When to use MTOM

Use MTOM when you have a Web service transmitting large documents. MTOM must be used when you have to optimize the transfer of binary data located in a BLOB. Any 4GL BYTE will be transferred as an HTTP part over the wire. Nothing changes from the programmer perspective: the program manipulates a 4GL BLOB on the client side as well as on the server side. The programmer may not even know that an HTTP part was used.

MTOM and a GWS server application

If you are creating a server application from scratch, use setFeature to enable MTOM. See Enabling MTOM on the server side on page 3174.

If you are using the -s option of the fglwsdl command to generate the server stubs, you can also use the -mtom option of the fglwsdl command to override the WS-Policy; you normally do not have to override the WS-Policy. See fglwsdl on page 1980.
**MTOM and a GWS client application**

For a GWS client, if the Web service enabled MTOM, then the generated WSDL should include the MTOM policy and it should work transparently. If the MTOM policy is not included in the WSDL and you know that the Web service is using MTOM, you can force the generation of stubs with MTOM support by with the -mtom option of the fglwsdl command. The -mtom option is only needed if you want to override the WS-Policy; you normally do not have to override the WS-Policy. See fglwsdl on page 1980.

**Optimization Layer 1: Using MTOM**

Optimization has layers.

When MTOM is used, GWS manages the large documents using BYTE variables. When MTOM is enabled, a 4GL BLOB is transmitted transparently via a HTTP attachment. Your Genero program receives a BLOB variable, filled as before, oblivious to how the content was transmitted. It is “seen” as a BYTE, as if it was inline.

**Optimization Layer 2: Using STRING variables**

In addition to enabling MTOM, you can further optimize by using STRING variables instead of BYTE variables.

Note: A BYTE variable contains the data value, located in memory. A STRING variable contains the path to a file. The -hexb64AsString option of the fglwsdl command forces the stub generation with STRING instead of BYTE.

For example, you can avoid loading a big file into a BYTE entirely in memory. Instead of doing this:

```sql
DEFINE req RECORD
   data BYTE
END RECORD
DEFINE resp RECORD
   data2 BYTE
END RECORD
LOCATE req.data IN MEMORY
LOCATE resp.data2 IN MEMORY
CALL rec.data.readFile("myfile.jpg")
... Do SOAP Operation
CALL resp.data2.writeFile("retfile.jpg")
```

You can do this:

```sql
DEFINE req RECORD
   data STRING ATTRIBUTES(XMLOptimizedContent)
END RECORD
DEFINE resp RECORD
   data2 STRING ATTRIBUTES(XMLOptimizedContent)
END RECORD
LET rec.data = "myfile.jpg"
... Do SOAP Operation
handle returned file at resp.data2
```

**Related information**

https://www.w3.org/TR/soap12-mtom/

**swaRef (SOAP with attachments using wsi:swaRef)**

swaRef must be used when you have to transfer files as attachment and located on disk.

swaRef refers to "Soap with attachments using the wsi:swaRef XML type from WS-I”. It is a specific case of the SoapWithAttachment specification.

Warning: Java handles swaRef automatically. DotNet does not.
With swaRef, you can set an attribute with a dedicated value of "swaRef" on a STRING. When set, a Web service automatically sends the file in that string as an HTTP part or receives it as an HTTP part.

In the following example, a sendAttachment operation computes the MD5 of a file. The program sets XMLOptimizedContent="swaRef" on the DataIn string and the SOAP engine carries it over the wire as an HTTP part.

```plaintext
# Request Type
TYPE tsendAttachment RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="sendAttachment",XSTypeNamespace="http://4js.com/services/swa")
    Name STRING ATTRIBUTES(XMLName="Name",XMLOptional),
    DataIn STRING ATTRIBUTES(XMLOptimizedContent="swaRef",XMLAttribute,XMLName="DataIn",XMLOptional)
END RECORD

# Response Type
TYPE tsendAttachmentResponse RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="sendAttachmentResponse",XSTypeNamespace="http://4js.com/services/swa")
    return STRING ATTRIBUTES(XMLName="return",XMLOptional)
END RECORD

# VARIABLE : sendAttachment
DEFINE sendAttachment tsendAttachment
  ATTRIBUTES(XMLName="sendAttachment",XMLNamespace="http://4js.com/services/swa")

# VARIABLE : sendAttachmentResponse
DEFINE sendAttachmentResponse tsendAttachmentResponse
  ATTRIBUTES(XMLName="sendAttachmentResponse",XMLNamespace="http://4js.com/services/swa")

... # Publish Operation : sendAttachment
LET operation =
  com.WebOperation.CreateDOCStyle("sendAttachment","sendAttachment",sendAttachment,sendAttachmentResponse)
CALL service.publishOperation(operation,"")
...
```

**Encryption and authentication**

A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

**Secured communications**

Secured communications are important. If an application wants to send or receive messages from a financial, business, or personnel application on the web, it must be able to authenticate the origin of the message, ensure that no malicious application has altered the original message, and ensure that no third party application can intercept the message.

Suppose that a person named Georges wants to send a message to his bank to transfer some money on the Internet. In this scenario, he faces the following concerns:

1. **The privacy** of the message, since it includes his account number and the transfer amount.
2. **The integrity** of the message, since someone might try to modify the original message or substitute a different message in order to transfer the money to another account.
3. **The authentication** of the message, since the bank must ensure that the message was sent from the right person.

**Message privacy**

To keep a message private, use a cryptographic algorithm - a technique that transforms a message into an encrypted form unreadable except by those it is intended for. Once it is in this form, the message may only be interpreted through the use of a secret key. There are two kinds of cryptography algorithms: symmetric and asymmetric.

*Symmetric* means the sender and the receiver of a message have to share the same key used to encrypt a clear message into an encrypted form, and then to decrypt it back into the original message. If that key is kept secret, nobody other than the sender and the receiver can read the message. However, the task of choosing a private key before communicating can be problematic.

*Asymmetric* means that there are two different keys working as a key-pair. One key is used to encrypt a message, and the second one is used to decrypt the encrypted message back into its original form. This solves the problem of key sharing in the symmetric cryptography algorithm, and makes it possible to receive secure messages, simply by publishing the key used to encrypt messages (the public key), and keeping secret the key used to decrypt messages (the private key). Anyone can encrypt a message using the public key, but only the owner of the private key can read it.

**Important:** The use of an asymmetric key-pair (public and private key), allows Georges to send private messages to his bank, simply by using the bank's public key to encrypt a message. Only the owner of the corresponding private key (the bank in this scenario) is able to read it.

**Message integrity**

To guarantee the integrity of a message, send a concise summary of the original message. The receiver of the message can create its own summary and compare it to the sender's summary. If they are similar, the message is considered intact, meaning that no third party has modified the original message.

Such a summary is called a **message digest** and is based on hash algorithms that produce a fixed-length representation of variable-length messages. Message digests are designed to make it very difficult (if not impossible) to determine the original message from a summary.

The message digest must be sent to the receiver in a secure way to assure the message integrity. This is achieved with a digital signature authenticating the sender and containing the sender's message digest.

**Important:** The use of message digests allows Georges' bank to verify that no one has modified the original message he sent.

**Message authentication**

To authenticate a message, add a digital signature to that message.

*A digital signature* is another message, created by encrypting the message digest, along with some other information, with the sender's private key. Anyone with the corresponding public key can decrypt the digital signature. If an
application is able to decrypt it, it means the owner of the private key was able to encrypt it, proving that the message comes from this sender and not from someone else.

Once the sender has been authenticated, the receiver can compare the message digest integrated into the digital signature to the one it created from the message it receives, in order to check the message integrity.

**Important:** The use of digital signatures allows Georges' bank to verify that the message really comes from him.

**Certificates**

An SSL/TLS certificate is a kind of digital identity card that associates the public key with a unique digital thumbprint identifying an individual, a server, or any other entity.

Now that Georges is able to send a secured message to his bank, there is still a problem. How can Georges be sure that the server he is connected to is really the bank's server and not a malicious server?

Georges must be sure that the public key he is using to encrypt his message corresponds to the bank's private key. Similarly, the bank needs to verify that the message signature it receives corresponds to Georges' signature.

To identify a remote peer, use a certificate - a kind of digital identity card that associates the public key with a unique digital thumbprint identifying an individual, a server, or any other entity (known as the subject). It also includes the identification and signature of the Certificate Authority that issued the certificate, and the period of time during which the certificate is valid. It may have additional information (or extensions) as well as administrative information for the Certificate Authority's use, such as a serial number.

A standard X.509 certificate contains the following standard fields:

- Certificate version
- Serial number of the certificate
- The distinguished name of the certificate issuer
- The distinguished name of the certificate owner
- The validity period of the certificate
- The public key
- The digital signature of the issuer
- Signature algorithm used
- Zero or more certificate extensions

**Note:**

1. An example of a distinguished name is: **CN=Georges,E=georges@mycompany.com,OU=Sales,O=My Company Name,C=FR,S=France**
2. The CN (Common Name) of the distinguished name of the certificate owner corresponds to the certificate subject, and identifies the owner of that certificate.

**Certificate authorities**

When a certificate authority signs a certificate, it is validating that the certificate is valid.

Each time Georges sends a message to his bank, he will present his own certificate to the bank, and will get the bank's certificate back. But as every one can create a certificate in the name of Georges, a higher authority that confirms the validity of a certificate is necessary. The bank must be sure it is Georges' certificate, and that no one else has taken his identity. Similarly, Georges needs an authority that confirms that the certificate coming from the server is really the bank's certificate.

The solution to validating a certificate is to sign it with a trusted certificate called certificate authority. This is a certificate in which an application has total confidence concerning the validity of the certificates it has signed. Before signing a certificate, a certificate authority must proceed with a strict identification of the owner of that certificate.

**Note:** The private key associated to a Certificate Authority must be managed with care, as it is the entity in charge of the validity of all other certificates it has signed.
There are several companies (such as VeriSign, GlobalSign or RSA Security) that have established themselves as certificate authorities and provide the following services over the Internet:

- Verifying certificate requests
- Processing certificate requests
- Issuing and managing certificates

**Note:** It is also possible to create your own Certificate Authority, but it is up to you to manage it securely.

### Root Certificate Authority

A Certificate Authority signed by itself is called a Root Certificate Authority, meaning that the certificate issuer is the same as the certificate subject. Most of the time, such a certificate belongs to a company established as a Certificate Authority, and is used to sign certificate requests coming from different companies that want their own Certificate Authority. If a client certificate is signed by a Certificate Authority previously signed by a Root Certificate Authority, the client certificate can be validated by the Root Certificate Authority even if the Certificate Authority is not present.

For example, if a company wants to buy a Certificate Authority from VeriSign, VeriSign signs that Certificate Authority with its own Root Certificate Authority. The company can then create certificates with the Certificate Authority provided by VeriSign and connect to secure servers without providing them their own Certificate Authority. The secure server, of course, has to know the VeriSign Root Certificate Authority.

### Certificate Chains

A certificate authority may issue a certificate for another certificate authority. This means that when an application wants to examine the certificate of the issuer, it must check all parent certificates of that issuer until it reaches one in which it has confidence.

The certificate chain corresponds to the number of parent certificate authorities allowed to validate a certificate.

### Certificate Authority List

A Certificate Authority List is a list of all certificate authorities considered as trusted by one application, classified by order of importance. Each of these certificates allows the authentication of a certificate presented to that application from a remote peer.

**Note:** With most applications, the Certificate Authority List is a concatenated file of all certificate authorities.

### Certificates and private keys storage

The entire concept of security is based on the publication of the public key, and the privacy of the associated private key. For maximum security, it is critical to restrict the access of the private key to the owner of the certificate and associated private key.

**Note:** Some companies provide systems to manage certificates and private keys in complete security.

#### UNIX™ systems

As the UNIX™ system is already able to restrict the access of a file to only one person, simply restrict access to the private key to the owner of that key to achieve a good level of security. This provides enough security to allow a Genero Web Services client to perform secured communications in the name of the certificate and private key owner, because access to the private key file is granted only if the correct user has logged in.

#### Windows® systems

Windows® has an integrated **key store** system to manage certificates and private keys. It allows the registration and the storage of X.509 certificate authorities, as well as personal X.509 certificates and their associated private keys accessible only if the correct user has logged in. It is recommended that you store the certificate and associated private key in the Windows® key store instead of in files on the disk.

When a client connects to a server using HTTPS, the client needs to trust the server it is in communication with. So the client needs to add the server's CAs (certificate authorities lists) to its trusted CAs.

**Accessing secured services**

Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web Service.

**Figure 114: Communications options for a client to connect to a Web Service**

**HTTP**  
Client connects to a Web Server (or a Web Service) using HTTP as the communication protocol. *(No security, No authentication).*

**HTTP with Basic Authentication**  
Client connects to a Web Server using HTTP as the communication protocol, but a valid login and password are required from the Web server to grant access to the Web Service. *(No security, Weak Authentication).* The login and password are sent in clear text on the communication layer.

**HTTP with Digest Authentication**  
Client connects to the Web Server using HTTP as the communication protocol, but a valid login and password are required from the Web server to grant access to the Web Service. *(No security, Authentication).* The login and password are encoded using a digest algorithm, requiring additional information from the Web server. This means that the first connection will always fail, but it is necessary in order to return Web server additional information back to the client.

**HTTPS**  
Client connects to a Web server using HTTPS as the communication protocol. *(Security, No authentication).* The communication channel is encrypted by SSL/TLS.

**HTTPS with Basic Authentication**  
Client connects to a Web server using HTTPS as the communication protocol, but a valid login and password are required from the Web server to grant access to the Web Service. *(Security, Weak Authentication).* The login and password are sent in clear text on the communication layer, but the communication channel is encrypted by SSL/TLS.

**HTTPS with Digest Authentication**  
Client connects to the Web Server using HTTPS as the communication protocol, but a valid login and password are required from the Web server to grant access to the
Web Service. (Security, Authentication). The login and password are encoded using a digest algorithm, requiring additional information from the Web server. This means that the first connection will always fail, but it is necessary in order to return Web server additional information back to the client. The communication channel is encrypted by SSL/TLS.

To improve communication speed with the cache mechanism, or to restrict internet access to specific clients, Genero Web Services allows a client to connect via proxies. The proxy is in charge of dispatching the client request to the server, and uses the same protocol as that used by the server. So, when a client connects via a proxy to access a HTTP server, the configuration of the HTTP proxy is used, and when the client communicates in HTTPS, the HTTPS proxy configuration is used.

<table>
<thead>
<tr>
<th>HTTP proxy</th>
<th>Client connects via a proxy using HTTP as the communication protocol.</th>
</tr>
</thead>
<tbody>
<tr>
<td>HTTP proxy with Basic Authentication</td>
<td>Client connects via a proxy using HTTP as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. The login and password are sent in clear text on the communication layer between client and proxy.</td>
</tr>
<tr>
<td>HTTP proxy with Digest Authentication</td>
<td>Client connects via a proxy using HTTP as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. Configure a WS client to access an HTTPS server

Configuration steps to access a server in HTTPS.

To configure access to an HTTPS server, you need a client certificate.

**Important:** On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain® typically holds the server certificate authority list. Therefore, the fglprofile security settings are ignored with the exception of the following: `security.global.ca`, `security.global.ca.lookuppath`, and `security.global.systemca`.

Important: On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain® typically holds the server certificate authority list. Therefore, the fglprofile security settings are ignored with the exception of the following: `security.global.ca`, `security.global.ca.lookuppath`, and `security.global.systemca`.

Before you begin, there are options to consider depending on how you wish to use the client certificate:

- If you do not have the certificate information in your fglprofile, Genero Web Services creates a certificate for you. This is an implicit or temporary certificate that is valid for a session only. For more information see HTTPS configuration on page 3132.

  **Note:** For the implicit certificate, no configuration is required.

- Alternatively, for stronger security, you generate a client certificate of your own, configure your application to use the client certificate generated, and add the configuration details to fglprofile. Follow the steps outlined in this procedure.

  **Note:** In a production environment, some servers provide a client certificate and you use the certificate as provided, and add the configuration details to fglprofile.

The openssl command line tool can be used to create your own certificates for the configuration of secured communication. The following steps outline the configuration process:

1. To create the client certificate, follow the procedure described in Create the client certificate on page 3132.
2. To configure fglprofile for the client certificate, follow the procedure in Configure for the client certificate on page 3134.
3. To configure fglprofile for the certificate authority list, see Configure for the certificate authority list on page 3134.
4. Add configuration entries for the server to fglprofile. For an example, see FGLPROFILE: HTTP(S) Proxy Authentication on page 3243.

The Genero Web Services client needs a set of configuration entries that specify the security configuration when accessing an HTTPS server. The following entries must be defined with an unique identifier (such as myserver):

```
ws.myserver.security = "id1"
```

(line breaks added for document readability)

- The unique identifier myserver can be used in the BDL client code in place of the actual URL.
- The security entry value (id1 in this example) must match the unique identifier defined by the client security entry created in Configure for the client certificate on page 3134.

**Related concepts**

- Encryption and authentication on page 3126
- A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.
- Accessing secured services on page 3129
Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web Service.

**HTTPS configuration**
If no client certificate is provided, Genero Web Services (GWS) does the HTTPS request transparently.

GWS can use an implicit certificate when no HTTPS configuration is provided. For stronger security, you can provide HTTPS configuration with your own certificates and CA list.

**The implicit client certificate**
For the implicit certificate, no configuration is required. GWS creates a temporary certificate for the HTTPS request. The temporary certificate is valid for the application session.

**The explicit client certificate**
For the explicit certificate, configure your certificate with entries for your HTTPS and password encryption on page 3237 settings of your FGLPROFILE file.

For access to a specific site, specify `security.idsec.certificate` and `security.idsec.privatekey`.

If you use the same certificate across all sites, specify `security.global.certificate` and `security.global.privatekey`.

**Certificate authorities**
Certificate authorities (file extension `.crt`) are usually provided by the system (the operating system keystore). If they are not provided by the system, the certificate authorities are searched for in the following locations:

1. The `$FGLDIR/web_utilities/certs` directory
2. The file specified by the FGLPROFILE file entry `security.global.ca`
3. The keystore specified by the FGLPROFILE file entry `security.global.windowsca` (Windows® systems) or `security.global.systemca` (all systems).
4. The directories listed in the FGLPROFILE file entry `security.global.ca.lookuppath`.

**Mobile platforms**
On mobile platforms, no HTTPS configuration is required, because the Web Service library uses the SSL/TLS certificates installed in the key database of the device (Keystore for Android™ and Keychain® for iOS).

See also Web Services on GMA (Android) on page 3107.

**Related concepts**
FGLPROFILE entries on page 3237
The fglprofile entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

**Create the client certificate**
You generate a client certificate.

In this task you create your own root certificate authority and client certificate using the OpenSSL command line tool.

1. Create the root certificate authority.
   a) Create the root certificate authority serial file.
      ```
      $ echo 01 > MyCompanyCA.srl
      ```
      This command creates a serial file with an initial HEX value 01. OpenSSL uses this file to track the serial numbers of certificates it creates. The serial file is typically given the same name as the CA with the extension `.srl`.
   b) Create the Root Authority's Certificate Signing Request and private key.
c) Create the Root Certificate Authority for a period of validity of 2 years.

(Note: The private key file (MyCompanyCA.pem) of a Root Certificate Authority must be handled with care. This file is responsible for the validity of all other certificates it has signed. As a result, it must not be accessible by other users.)

2. Create the client's X.509 certificate and private key.
   a) Create the client serial file.
      $ echo 01 > MyClient.srl
      This command creates a serial file with the initial HEX value 01. OpenSSL uses this file to track the serial numbers of certificates it creates.
   b) Create the client's Certificate Signing Request and private key.
      $ openssl req -new -out MyClient.csr
      (Note: By default, openssl outputs the private key in the privkey.pem file. If you want to specify a different file name, or if your openssl version does not output the private key by default, add the -keyout <myprivkey>.pem to the command.)
   c) Remove the password from the RSA private key.
      $ openssl rsa -in privkey.pem -out MyClient.pem
      (Note: The key is also renamed in MyClient.pem.)
   d) Create the client's certificate (self-signed X.509 certificate valid for a period of 1 year) trusted by the Root Certificate Authority created in step 1.
      (Note: Most servers do not check the identity of the clients. For these servers, the client's certificate does not necessarily need to be trusted; it is only used for data encryption purpose. If, however, the server performs client identification, you must trust a Certificate Authority in which it has total confidence concerning the validity of the client's certificates."
      (Note: The purpose of the client's Certificate is to identify the client to any server; therefore the subject of the certificate must correspond to the client's identity as it is known by the servers.)
      (Note: To import the certificate in a keystore you can create a pkcs12 certificate. See Import a certificate and its private key into the Windows key store on page 3139.)

What to do next
Configure your fglprofile file for the client certificate. See Configure for the client certificate on page 3134.

Related concepts
Encryption and authentication on page 3126
A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

The OpenSSL (openssl) tool on page 3137
The `openssl` command line tool creates certificates for the configuration of secured communications.

**Related tasks**
View a certificate on page 3140
This procedure allows you to view a certificate using the `openssl` command.

**Configure for the client certificate**
You configure your application to use the client certificate generated. For production systems, you add the configuration details to `fglprofile`.

You have generated a client certificate as described in Create the client certificate on page 3132.

In this task you add the certificate information to the `fglprofile`.

Add the client's security configuration to `fglprofile`.

The client security entry defines the certificate and the associated private key used by the Genero Web Services client during an HTTPS communication. The security entry must be defined with an unique identifier (id1 in this example).

```
security.id1.certificate = "MyClient.crt"
security.id1.privatekey = "MyClient.pem"
```

**Note:** If the private key is protected with a password, you must remove it or create a script that returns the password on demand. See Create the client certificate.

Your applications are configured to use the client certificate.

**What to do next**
Create the client's certificate authority list by saving the HTTPS server certificate to disk and creating a CA list from this. Then set the global certificate authority list (`security.global.ca`) in your `fglprofile`. See Configure for the certificate authority list on page 3134.

**Related concepts**

A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

**Related tasks**
View a certificate on page 3140
This procedure allows you to view a certificate using the `openssl` command.

**Configure for the certificate authority list**
When a client accesses a server with a certificate, the server sends back its certificate. The client needs to check to see if that certificate is trusted. This is done using a certificate authority list.

In this task you create the client's certificate authority list using the OpenSSL command line tool, and set the global certificate authority list in your FGLPROFILE file.

**Important:** On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain® typically holds the server certificate authority list. Therefore, the fglprofile security settings are ignored with the exception of the following: `security.global.ca, security.global.ca.lookuppath, and security.global.systemca`.

1. Create the client's certificate authority list.
   a) Save the certificates of the HTTPS server to disk.
Type the server's URL in your browser. When prompted, save all the certificates from the Certificate Hierarchy. For more information see, Selecting the certificate to add on page 3141 and Missing certificates on page 3141.

b) Create the client's Certificate Authority List by running the following command for each of the certificates that you saved to disk.

$ openssl x509 -in ServerCertificate.crt -text >> ClientCAList.pem

**Note:** All trusted certificate authorities are listed. These are checked following a chain of child to parent certificates until a certificate is reached which is trusted. All other certificates that were trusted by the Root Certificate Authority will also be considered as trusted by the client. For more information see Certificate authorities on page 3127.

2. Set the global certificate authority list in your FGLPROFILE file.

The global certificate authority list entry defines the file containing the certificate authority list used by the Genero Web Services client to validate all certificates coming from the different servers it will connect to.

```plaintext
security.global.ca = "ClientCAList.pem"
```

**Note:** The file is located based on the current execution directory. If you use Genero Studio, for instance, fglrun may not be executed in the same directory as when you use the command line. The recommended practice therefore is to specify an absolute path for the .pem, for example:

```plaintext
security.global.ca = "/opt/usr/certs/ClientCAList.pem"
```

If `security.global.ca` is not defined, Genero Web Services will look to see whether the operating system has a keystore, otherwise `security.global.ca.lookuppath` will be used. For further information, see Certificate authorities in HTTPS configuration on page 3132.

The client application is configured to use the appropriate certificate authority list to validate a server's certificate.

**Related concepts**

- **Error: Peer certificate is issued by a company not in our CA list** on page 3136
  When a client connects to a server using HTTPS, the client needs to trust the server it is in communication with. So the client needs to add the server's CAs (certificate authorities lists) to its trusted CAs.

- **Enable OCSP** on page 3135
  To enable OCSP (Online Certificate Status Protocol), set the `security.global.ocsp.enable` and `security.global.ocsp.url` entries in fglprofile.

  **FGLPROFILE entries** on page 3237
  The fglprofile entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

  **FGLPROFILE: HTTP(S) Proxy Authentication** on page 3243
  FGLPROFILE entries can be used to define a connection to an HTTPS server via a proxy, and with HTTP and Proxy Authentication.

  **Accessing secured services** on page 3129
  Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web Service.

- **Enable OCSP**
  To enable OCSP (Online Certificate Status Protocol), set the `security.global.ocsp.enable` and `security.global.ocsp.url` entries in fglprofile.

  When these options are set, for each HTTPS connection, once the X509 certificate has been validated, the Web service will check whether all certificates used for that validation are still valid and have not been revoked at the time of the connection.

  **Related concepts**
  **FGLPROFILE entries** on page 3237
The fglprofile entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

**Troubleshoot certificate issues**

You may encounter known (and common) issues when completing the Genero Web Services tutorials or when adding Web services of your own. These issues and their solutions are presented in the following topics.

**Error: Peer certificate is issued by a company not in our CA list**

When a client connects to a server using HTTPS, the client needs to trust the server it is in communication with. So the client needs to add the server's CAs (certificate authorities lists) to its trusted CAs.

This error means the client CA list is missing a certificate authority in its CA list.

To display the client CA list, use the following command:

```
openssl x509 -in ClientCAList.pem -noout -text
```

Solution:

1. Add the missing CA list to the client CA list.

```
openssl x509 -in MyCompanyCA.crt -text >> ClientCAList.pem
```

**Theory**

Usually certificates work in pairs: a public key and a private key.

![Diagram of certificate pairs](image)

**Figure 115: Certificates working in pairs: a public key and a private key**

The certificate which appears at the top of the list on the client and server side is the Certificate Authority (CA) root. This means that the client has a certificate that can be signed by an authority signed itself by a root authority. Likewise, the server has a certificate that can be signed by an authority signed itself by a root authority. In some instances, a certificate can be signed by itself.

Things to note:

- The server certificate is expected to have its host name set as CN (Common Name). For example, if you want to access the server `https://www.mycompany.com` the CN is expected to be "www.mycompany.com".
- In the client CA list it is recommended that you have all the CA of the server. In this example you need the server CA (5) and the server CA Root (4). If the server is self-signed then add the server certificate (6) to the client CA list.
Sometimes, the needed CAs are not listed in the certificates hierarchy. Setting environment variable FGLWSDEBUG=3, will give you information about the missing CA.

**Related concepts**

- **HTTPS configuration** on page 3132

**The OpenSSL (openssl) tool**

The openssl command line tool creates certificates for the configuration of secured communications.

It requires a configuration file with the default parameters such as the key size or the private key name. OpenSSL is provided with a default configuration file openssl.cnf.

The openssl tool looks for the openssl.cnf file in the directory where it is executed; it stops if the file is not present. To use the openssl tool from any directory, set the OPENSSL_CONF environment variable to specify the location of the configuration file.

For information on how the openssl tool works, refer to the openssl documentation at [http://www.openssl.org/docs/apps/openssl.html](http://www.openssl.org/docs/apps/openssl.html).

**Create a root certificate authority**

This procedure allows you to create a root certificate authority.

In this task you use the openssl command tool to create the root certificate authority.

1. Create the root certificate authority serial file:

   ```
   $ echo 01 > MyRootCA.srl
   ```

   This command creates a serial file with an initial HEX value 01. OpenSSL uses this file to track the serial numbers of certificates it creates. The serial file is typically given the same name as the CA with the extension .srl.
2. Create a CSR (Certificate Signing Request):

   $ openssl req -new -out MyRootCA.csr

   This creates a `privkey.pem` file containing the RSA private key of that certificate that is protected by a password.

3. Remove the password of the private key (Optional):

   $ openssl rsa -in privkey.pem -out MyRootCA.pem

   **Note:** Removing the password of a certificate authority's private key is not recommended.

4. Create a self-signed certificate from the Certificate Signing Request for a validity period of 365 days:

   **Note:** If you want an official Root Certificate Authority, you must send the CSR file to one of the self-established Certificate Authority companies on the Internet (instead of creating it with `openssl`).

**Related tasks**

Create a certificate authority on page 3138
This procedure allows you to create a certificate authority.

**Create a certificate authority**
This procedure allows you to create a certificate authority.

In this task you use the `openssl` command tool to create the certificate authority.

1. Create a certificate signing request (CSR):

   $ openssl req -new -out MyCA.csr

   This creates a `privkey.pem` file containing the RSA private key of that certificate and protected by a password.

2. Remove the private key password (Optional):

   $ openssl rsa -in privkey.pem -out MyCA.pem

   **Note:** Removing the password of a certificate authority's private key is not recommended.

3. Create a certificate from the Certificate Signing Request that is trusted by the Root Certificate Authority:

   $ openssl x509 -in MyCA.csr -out MyCA.crt -req -signkey MyCA.pem -CA MyRootCA.crt -CAkey MyRootCA.pem -days 365

   **Note:** If you want an official Certificate Authority, you must send the CSR file to one of the self-established Certificate Authority companies on the Internet (instead of creating it with `openssl`. See Encryption and authentication on page 3126).

**Related tasks**

Create a root certificate authority on page 3137
This procedure allows you to create a root certificate authority.

**Create a certificate**
This procedure allows you to create a certificate.

In this procedure you use the `openssl` command tool to perform the certificate creation tasks.

1. Create the certificate serial file:

   $ echo 01 > MyCA.srl
This command creates a serial file with an initial HEX value 01. OpenSSL uses this file to track the serial numbers of certificates it creates. The serial file is typically given the same name as the CA with the extension .srl.

2. Create a CSR (Certificate Signing Request):

   $ openssl req -new -out MyCert.csr

   This command creates a privkey.pem file containing the RSA private key of that certificate and protected by a password.

3. Remove the private key password (Optional):

   $ openssl rsa -in privkey.pem -out MyCert.pem

4. Create a certificate from the Certificate Signing Request and trusted by the Certificate Authority:

   $ openssl x509 -in MyCert.csr -out MyCert.crt -req -signkey MyCert.pem -CA MyCA.crt -CAkey MyCA.pem -days 365

   **Note:** If you want an official Certificate, you must send the CSR file to one of the self-established Certificate Authority companies on the Internet (instead of creating it with openssl).

**Create a certificate authority list**

This procedure allows you to create a certificate authority list using the openssl command.

Concatenate all certificate authorities by order of importance, listing the most important first:

```
$ openssl x509 -in MyCA1.crt -text >> CAList.pem
$ openssl x509 -in MyCA2.crt -text >> CAList.pem
$ openssl x509 -in MyCA3.crt -text >> CAList.pem
```

**Import a certificate and its private key into the Windows® key store**

This procedure allows you to import a certificate and its private key.

1. Create a certificate.
   
   See Create a certificate.

2. Create a specific PKCS12 file containing the certificate and its private key in one file using the following openssl command:

   ```
   $ openssl pkcs12 -export -inkey MyCert.pem -in MyCert.crt -out MyCert.p12
   ```

   **Note:** The .p12 generated file is protected by a password and can then be transported without any risk.

3. On a Windows® system, open this .p12 file and follow the instructions provided.

   **Note:** If you select strong verification during the importation process, a pop-up displays each time an application accesses the private key asking the user whether the application is allowed to use it.

**Import a certificate authority into the Windows® key store**

This procedure allows you to import a certificate authority.

1. Create a certificate authority.
   
   See Create a certificate Authority.

2. Open the .crt certificate file

3. Click Install Certificate and follow the instructions provided.

   Windows® automatically places the certificate in the certificate authority list of the key store.

**Related tasks**

Import a certificate and its private key into the Windows key store on page 3139
This procedure allows you to import a certificate and its private key.

**View a certificate**
This procedure allows you to view a certificate using the `openssl` command.

To view a certificate, enter the `x509` command:

```
openssl x509 -in MyCompanyCA.crt -noout -text
```

**Examining certificates**
When you receive a URL in HTTPS, you are prompted to either accept a certificate or the certificate has already been accepted. In the second case, you can still check the server certificate.

- **Check the server certificate using FireFox** on page 3140
- **Check the server certificate using Internet Explorer** on page 3141
- **Selecting the certificate to add** on page 3141
- **Missing certificates** on page 3141

**Check the server certificate using FireFox**
This procedure allows you to check the server certificate using FireFox.

1. Type the https URL.
2. Once the page is displayed, click on the padlock.
   The Page Info for the certificate displays.
3. In the Security tab, click on the View button.
   The Certificate Viewer opens.
4. In the Details tab, view the Certificate Hierarchy.

![Certificate Viewer; Details tab.](image)

**Figure 116: Certificate Viewer; Details tab.**
Check the server certificate using Internet Explorer
This procedure allows you to check the server certificate using Internet Explorer.

1. Type the https URL.
2. Once the page is displayed, click on the padlock.
   The Certificate window displays.
3. On the Certification Path, view the certificate hierarchy.

Selecting the certificate to add
The certificate authority (CA) is the authority that validates the server. The certificate to add to the CA list is the
authority certificate, not the server certificate.

There are default certificates known by browsers like:

Get the server issuer certificate (and all the parents, grandparents, and so on).

For example, if your server is validated by Thawte, add the Thawte certificate to the list.

To check whether your certificate is the CA certificate, search for the CNs (Common Names) in the .cer files.
The CA Subject entry should be the Issuer CN in the server certificate. Running the openssl command as follows outputs the CN:

```bash
openssl x509 -in server.pem -noout -subject
```

```bash
subject= /C=ZA/ST=Western Cape/L=Cape Town/O=Thawte Consulting cc/OU=CertificationServices Division/
CN=Thawte Server CA /emailAddress=server-certs@thawte.com
```

To convert a .cer certificate to the .pem format used by Genero Web Services run the following openssl command:

```bash
openssl x509 -inform DER -in server.cer -outform PEM -out server.crt
```

Missing certificates
Identifying missing certificates.

Sometimes the CA hierarchy described in the server certificate is incomplete or needs another certificate (default ones used by browsers or private ones).
Figure 117: Certificate Viewer in Firefox Web Browser; Details Tab
When this occurs, you will get this kind of error message when you set FGLWSDEBUG:

```
WS-DEBUG (Security error)
Error with certificate at depth: 3
  issuer = /C=US/O=VeriSign, Inc./OU=Class 3 Public Primary Certification Authority
  subject = /C=US/O=VeriSign, Inc./OU=Class 3 Public Primary Certification Authority
  err 19:self signed certificate in certificate chain
WS-DEBUG END
```

This means OpenSSL is looking for a third ancestor that is not listed in the hierarchy above. In this example, gatewaybeta.fedex.com only has two ancestors, and none are named "Class 3 Public Primary Certification Authority". You need to download the root certificates from VeriSign and add "Class 3 Public Primary Certification Authority" in your CA list.

If the certificate authorities are not found in the operating system keystore, you need to download them and place them in $FGLDIR/web_utilities/certs. Make sure to name them with extension .crt.

**Related concepts**
- Error: Peer certificate is issued by a company not in our CA list on page 3136
- The OpenSSL (openssl) tool on page 3137

**Troubleshoot common issues**

You may encounter known (and common) issues when completing the Genero Web Services tutorials or when adding Web services of your own. These issues and their solutions are presented in the following topics.

**HTTP 401 error message**

An HTTP 401 error message means the server is requesting, but not receiving, user authentication (login and password).

This error message means `authenticate.xxx.login` and `authenticate.xxx.password` are not correctly configured. The login and password should be provided in the FGLPROFILE.

Solution:

1. Open the FGLPROFILE used by the application.
2. Add entries for `authenticate.xxx.login` and `authenticate.xxx.password`.
3. Save your changes.

**Related concepts**
- Web services configuration on page 3236

The Genero Web Services secured communication and the support of XML-Security is based on the OpenSSL engine. It allows a BDL Web Services client, or a BDL application using the `com` or `xml` API, to communicate with any secured server over HTTP or HTTPS, and to handle encrypted and/or signed XML document in BDL coming from any other application.

**The Diffie-Hellman key agreement algorithm**

Diffie-Hellman is a key-agreement algorithm. It allows two peers to agree on the same symmetric key, the shared secret, without exchanging confidential data.

The Diffie-Hellman key agreement algorithm is a method that allows two devices to communicate over a network by establishing a shared secret without exchanging any secret data. Knowing the used key-agreement algorithm, the two devices only need to exchange their public key. Then, using the other peer's public key and its own private key,
each device performs the algorithm specific key generation operation to obtain the shared secret. The shared secret is a ready-to-use symmetric key for further signed or encrypted exchanges between the two peers.

Genero Web Services provides several shared secret type for signature, encryption, or key encryption purposes. Using the Diffie-Hellman key agreement algorithm, one of the following types of shared secrets can be computed:

- Symmetric AES128 encryption key
- Symmetric AES192 encryption key
- Symmetric AES256 encryption key
- Symmetric TripleDES encryption key
- Symmetric key wrap AES128 key encryption key
- Symmetric key wrap AES192 key encryption key
- Symmetric key wrap AES256 key encryption key
- Symmetric key wrap TripleDES key encryption key
- Symmetric HMAC-SHA1 signature key

In the Diffie-Hellman key agreement algorithm, two shared constants (called parameters) are used in addition to the private and public key. These two parameters are:

- The modulus (called P): A very big prime number chosen at random.
- The generator (called g): A prime number between two and five. Genero Web Services only uses two (2) for the generator.

If the private key (Priv) is a big number (not necessarily prime) chosen randomly, the public key (Pub) is calculated using P, g, and Priv as follows:

\[ \text{Pub} = g^{\text{Priv}} \mod P \]

Both devices need to use the same parameters for P and g. There are two ways to ensure this happens: Either P and g are chosen by a third party (such as a security authority) or one of the devices chooses them and sends them to the other peer with its public key.

Genero Web Services allows the Web service to generate the parameters itself, to load them from a string or from a PEM or DER file. The public key and the parameters can also be exchanged using an XML file.

This diagram shows the Diffie-Hellman algorithm steps between two devices, A and B, that need to communicate. Device A is in charge of generating the parameters. The shared secret is labeled K.
Figure 118: The Diffie-Hellman algorithm

For complete details about the mathematical basics underlying the Diffie-Hellman algorithm, see [RFC2631].
It is nearly impossible to get the private key from the public key, even knowing the values of parameters P and g. Therefore, a middle man will not be able to obtain the shared secret K. While devices A and B exchange their public key, and maybe the parameters as well, these values pass through different intermediate points. It is critical that A receives the correct public key from B, and that B receives the correct public key from A, in order to establish a common shared secret. It may be possible for a middle man to corrupt or replace one public key with his own. If that happens, A and B would be able to communicate because they don't compute the same shared secret. No secret data will be exchanged that is readable to the middle man. To avoid this situation, one can use Digital Certificate that helps to deliver the public key and the parameters in an authenticated method.

Once the shared secret is established, the Diffie-Hellman public key, private key and parameters are no longer useful. The Diffie-Hellman key agreement algorithm is achieved.

With the library provided as part of Genero Web Services, the shared secret has been computed to fit given specifications such as HMAC, 3DES, AES128, AES192, AES256, KW-3DES, KW-AES128, KW-AES192, or KW-AES256. The shared secret is actually a symmetric key ready to be used in a signature (HMAC) or cipher algorithm. It allows devices A and B to finally communicate via an authenticated (HMAC) or encrypted method.

Steps to write a WS client

The Genero Web Services package (GWS) allows a BDL program to access Web services found on the Internet. GWS supports the WSDL1.1 specification of March 15, 2002. This example illustrates a client application that accesses the Add operation in the GWS Web Service MyCalculator.

See Writing a Web server application on page 3168 for information about the Service.

- Obtaining the WSDL information on page 3147
- Calling a web service on page 3148
- Setting a time period for the response on page 3149
- Handling GWS server errors on page 3149
- Compiling the client application on page 3149
Obtaining the WSDL information

To access a remote Web service, you must get the WSDL information from the service provider. Sample services can be found through UDDI registries or on other sites such as XMethods (http://www.xmethods.net).

You can use the fglwsdl tool provided by the Genero Web Services package to obtain the necessary WSDL information. The following example obtains the WSDL information for the GWS Service MyCalculator created by the Writing a Web server application on page 3168:

```shell
fglwsdl -soap12 -o Example2Client http://localhost:8090/MyCalculator?WSDL
```

This generates two files:
- Example2Client.inc - the globals file containing the definitions of the input and output records, and the prototypes of the operations.
- Example2Client.4gl - a module containing the definitions of the functions that can be used in your GWS client application to perform the requested Web Service operation, and the code that manages the Web Service request.

**Note:** The MyCalculator GWS Service must be running on the specified port in order to provide the WSDL information.

The following definitions were generated in the globals file, Example2Client.inc:

**Input and Output records**

```plaintext
DEFINE Add RECORD
    ATTRIBUTES( XMLName="Add",
                XMLNamespace="http://tempuri.org/webservices" )
    a INTEGER ATTRIBUTES( XMLName="a", XMLNamespace="" ),
    b INTEGER ATTRIBUTES( XMLName="b", XMLNamespace="" )
END RECORD

DEFINE AddResponse RECORD
    ATTRIBUTES( XMLName="AddResponse",
                XMLNamespace="http://tempuri.org/webservices" )
    r INTEGER ATTRIBUTESXMLName="r",XMLNamespace="" )
END RECORD
```

Since BDL functions cannot have complex structures as parameters, the data types are defined as global or modular variables.

**Function prototypes for the Operations**

This globals file contains the prototype of two functions for the Add operation.

The **Add** function uses input and output parameters, and returns the status and result. This function can only be used if the input and output parameters are not complex structures such as arrays or records. Using this function, developers do not access the global records directly.

The **Add_g** function can be used with the global input and output records. Before calling this function, you must set the values in the variables of the global input record.

```plaintext
Operation: Add
#  # FUNCTION: Add_g()
# RETURNING: soapStatus
# INPUT: GLOBAL Add
# OUTPUT: GLOBAL AddResponse
#  # FUNCTION: Add(p_a, p_b)
```
See fglwsdl on page 1980 and WS client stubs and handlers on page 3152 for more details regarding the fglwsdl tool, its output and the generated functions.

**Related concepts**
- SOAP 1.1 and 1.2 on page 3108

**Calling a web service**

**Step 1: Import the COM library of the GWS package**

The methods associated with creating and publishing a Web Service are contained in the classes that make up the Genero Web Services Library (com). If you use any of these methods in your client application, you must import the library. Since this example application sets the timeout period that the client will wait for the Service to respond, include the following line at the top of the module:

```
IMPORT com
```

If your generated .inc file uses xml class data types, you need to add
```
IMPORT xml.
```

**Related concepts**
- The com package on page 2658

The Genero Web Services com package provides classes and methods that allow you to perform tasks associated with creating Services and Clients, and managing the services.

**Step 2: Specify the globals file**

Use a GLOBALS statement to specify the generated globals file.

```
GLOBALS "Example2Client.inc"
```

**Step 3: Write the MAIN program block**

Provide values for the input and output messages of the operation, and call one of the generated functions. Since the input and output messages are simple integers, we can call the Add function.

```
MAIN
    DEFINE op1        INTEGER
    DEFINE op2        INTEGER
    DEFINE result     INTEGER
    DEFINE wsstatus   INTEGER

    LET op1 = 1
    LET op2 = 2
    CALL Add(op1, op2) RETURNING wsstatus, result
    IF wsstatus = 0 THEN
        DISPLAY "Result: ", result
    ELSE
        -- Use the global wsError record
        DISPLAY "Error: ", wsError.description
    END IF
END MAIN
```

Alternatively, we can use the global input and output records directly, calling the Add_g function:

```
MAIN
    DEFINE wsstatus INTEGER

    LET Add.a = 1
    LET Add.b = 2
    LET wsstatus = Add_g()
    IF wsstatus != 0 THEN
```
These examples are very basic versions of the code. For complete examples, see the code samples provided with the package in demo/WebServices.

**Setting a time period for the response**

To protect against remote server failure or unavailability, set a timeout value that indicates how long you are willing to wait for the server to respond to your request.

Use the `SetOption()` method of the `WebServiceEngine` class to set the `readwritetimeout` option.

For example, to wait no more than 10 seconds:

```
CALL com.WebServiceEngine.SetOption( "readwritetimeout", 10 )
```

A timeout value of `-1` means "wait forever". This is the default value.

**Related concepts**

- [The WebServiceEngine class](#)
- The `com.WebServiceEngine` class provides an interface to manage the Web Services engine.

**Handling GWS server errors**

When a Genero Web Services service operation returns a status that is non-zero, you can get a more detailed error description from the global record `wsError`.

This record is defined in the globals `.inc` file.

```plaintext
DEFINE wsError RECORD
  code STRING, -- Short description of the error
  codeNS STRING, -- The namespace of the error code
  description STRING, -- Long description of the error
  action STRING -- internal "SOAP action"
END RECORD
```

**Compiling the client application**

It is recommended that the library file `WSHelper.42m`, included in the `$FGLDIR/lib` directory of the Genero Web Services package, is linked into every client or server program.

Assuming the example client code is in a module named `clientmain.4gl`, you can compile and link the client program:

```
fglcomp clientmain.4gl Example2Client.4gl
fgllink -o myclient.42r clientmain.42m Example2Client.42m WSHelper.42m
```

**Change WS client behavior at runtime**

Genero Web Services generates a global record called `tGlobalEndpointType` to change the client behavior at runtime without the need to modify any generated client stub. If WS-Addressing 1.0 is enabled, the global generated record is called `tWSAGlobalEndpointType`, and if needed you can also access the HTTP layer via the Request and Response record of the binding section.

- [Global Endpoint type definition](#) on page 3150
- [WS-Addressing 1.0 Global Endpoint type definition](#) on page 3150
- [Change server location](#) on page 3151
- [Change the HTTP protocol version](#) on page 3151
- **Set an HTTP cookie** on page 3151
- **Set the connection timeout for a service** on page 3151
- **Set the read and write timeout for a service** on page 3151
- **Access HTTP request and response headers for a service** on page 3152

**Global Endpoint type definition**

The following global type is used by any generated client stub to allow the programmer to change the client behavior at runtime.

```
TYPE tGlobalEndpointType RECORD # End point
    Address RECORD # Address
        Uri STRING # URI
    END RECORD,
    Binding RECORD # Binding
        Version STRING, # HTTP Version (1.0 or 1.1)
        Cookie STRING, # Cookie to be set
        ConnectionTimeout INTEGER,# Connection timeout
        ReadWriteTimeout INTEGER # Read write timeout
    END RECORD
END RECORD
```

**Description of variables:**

- **Address.Uri**: Represents the location of the server.
  
  **Important**: It replaces the global variable of type STRING generated prior to version 2.40, therefore it is mandatory to regenerate the client stub and to modify the location assignment in your application.
- **Binding.Version**: Represents the HTTP version to use for communication (only 1.0 or 1.1 allowed, default is 1.1).
- **Binding.Cookie**: Represents the HTTP cookie to use for communication (or NULL if there is no cookie to send).
- **Binding.ConnectionTimeout**: Represents the maximum time in seconds to wait for the establishment of the connection to the server.
- **Binding.ReadWriteTimeout**: Represents the maximum time in seconds to wait for a connection read or write operation before breaking the connection.

**WS-Addressing 1.0 Global Endpoint type definition**

The following global type is used by any generated client stub where support of WS-Addressing 1.0 is enabled. It allows the programmer to change the client behavior at runtime, and to send additional WS-Addressing 1.0 reference parameters to a server.

If this global type is used in your main application, you must add the `IMPORT xml` instruction.

```
TYPE tWSAGlobalEndpointType RECORD # End point
    Address RECORD # Address
        Uri STRING, # URI
    Parameters DYNAMIC ARRAY OF xml.DomDocument
        ATTRIBUTES(XMNamespace="##any",XMLAny) # End point WSA reference parameters
    END RECORD,
    Binding RECORD # Binding
        Version STRING, # HTTP Version (1.0 or 1.1)
        Cookie STRING, # Cookie to be set
        ConnectionTimeout INTEGER,# Connection timeout
        ReadWriteTimeout INTEGER # Read write timeout
    END RECORD
END RECORD
```

**Description of variables:**
• **Address.Parameters**: Represents the WS-Addressing 1.0 reference parameter to send to a WS-Addressing 1.0 compliant server.

### Change server location

To change the server location at runtime, set the record `Uri` member with a valid URL of another service. All services must respect the same WSDL contract. If you leave the variable unset, the client will connect to the server URL defined in the WSDL at code generation time.

Example:

```let
```

You can assign this variable with a URL set in the FGLPROFILE (see Logical Service location).

If you are migrating from a version prior to 2.40, see also Web Services changes on page 148.

### Change the HTTP protocol version

To communicate with a service that speaks only a given version of HTTP, set the record `Version` member with the desired value. If you let the variable unset, the client will communicate in HTTP 1.1.

Example:

```let
LET Calculator_CalculatorPortTypeEndpoint.Binding.Version = "1.0"
```

If you do not want the request to be split into chunks, set the HTTP protocol version to 1.0.

**Important:** On GMI mobile devices, the HTTP protocol version definition is ignored, it will always be version 1.1.

### Set an HTTP cookie

To send an HTTP cookie to the service, set the record `Cookie` member with the cookie value. If you let the variable unset, the client won't send any cookie.

Example:

```let
LET Calculator_CalculatorPortTypeEndpoint.Binding.Cookie = "MyCookie=AValue"
```

Unset that variable if you don't need the cookie to be sent anymore.

### Set the connection timeout for a service

To change the default timeout value to establish a connection to the service, set the record member `ConnectionTimeout` with the timeout value in seconds. The `ConnectionTimeout` is a maximum time to establish the connection. If the server is not available you can get the response sooner than `ConnectionTimeout`. The `ConnectionTimeout` also avoids indefinitely waiting for a response when a server is reachable but not responding to request.

Example:

```let
LET Calculator_CalculatorPortTypeEndpoint.Binding.ConnectionTimeout = 15
```

**Important:** On GMI mobile devices, the max of `ConnectionTimeout` and `ReadWriteTimeout` will be used.

### Set the read and write timeout for a service

To change the default time of reading and writing to or from a service, set the record `ReadWriteTimeout` member with the time out value in seconds.

Example:

```let
LET Calculator_CalculatorPortTypeEndpoint.Binding.ReadWriteTimeout = 5
```
Important: On GMI mobile devices, the max of ConnectionTimeout and ReadWriteTimeout will be used.

Access HTTP request and response headers for a service

To access HTTP headers exchanged between the Genero client and a web service, you must use following records in the binding section:

• one record called Request in order to customize HTTP headers to be sent to a web service
• one record called Response in order to retrieve all HTTP headers returned by a web service

```
TYPE tGlobalEndpointWithHttpLayerType RECORD # End point
  Address RECORD # Address
    Uri STRING # URI
  END RECORD,
  Binding RECORD # Binding
    Version STRING, # HTTP Version (1.0 or 1.1)
    Cookie STRING, # Cookie to be set
    Request RECORD
      Headers DYNAMIC ARRAY OF RECORD # HTTP Headers
        Name STRING,
        Value STRING
    END RECORD,
  Response RECORD
    Headers DYNAMIC ARRAY OF RECORD # HTTP Headers
      Name STRING,
      Value STRING
    END RECORD,
    ConnectionTimeout INTEGER,# Connection timeout
    ReadWriteTimeout INTEGER # Read write timeout
    CompressRequest STRING # HTTP compression mode (gzip or deflate)
  END RECORD
END RECORD
```

Description of additional Request and Response variables:

• Binding.Request.Headers: Represents the additional HTTP headers to be sent to the web service. (Notice that client stub headers will replace user ones if the same name).
• Binding.Response.Headers: Represents the HTTP headers returned by a web service.

WS client stubs and handlers

To access a remote Web Service, you first must get the WSDL information from the service provider. Sample services can be found through UDDI registries (http://www.uddi.org), or on other sites such as XMethods (http://www.xmethods.net).

• Generating stub files for a GWS Client on page 3152
• Handling GWS server errors on page 3149
• Global Endpoint user-defined type definition on page 3153
• The generated functions on page 3154
• The generated callback handlers on page 3154
• Example output on page 3156
• Using the generated functions on page 3157

Generating stub files for a GWS Client

Use the fglwsdl tool to generate the BDL stub from a WSDL URL or file.

This example requests the Calculator Web Service information from the specified URL, and the output files will have the base name ws_calculator:

```
```

For a client application, fglwsdl generates two output files. It is not advised to modify these files:
• *filename*.inc - the globals file, containing declarations of global variables that can be used as input or output for functions accessing Web Service operations, and the global wsError record. In our example, the file is `ws_calculator.inc`.

This file must be listed in a GLOBALS statement at the top of any `.4gl` modules that you write for your GWS Client application.

• *filename*.4gl - containing the definitions of the functions that can be used in your GWS client application to perform the requested Web Service operation, and the code that manages the Web Service request. In our example, the file is `ws_calculator.4gl`.

This file must be compiled and linked into your GWS Client application.

**Related concepts**

SOAP 1.1 and 1.2 on page 3108

**Handling GWS server errors**

When a Genero Web Services service operation returns a status that is non-zero, you can get a more detailed error description from the global record `wsError`.

This record is defined in the globals `.inc` file.

```plaintext
DEFINE wsError RECORD
    code STRING,         -- Short description of the error
    codeNS STRING,       -- The namespace of the error code
    description STRING,  -- Long description of the error
    action STRING        -- internal "SOAP action"
END RECORD
```

**Global Endpoint user-defined type definition**

The `fglwsdl` tool generates the globals (inc) file to use for a Web services client. Part of this globals file is a global endpoint user-defined type definition.

```plaintext
# Global Endpoint user-defined type definition
#
TYPE tGlobalEndpointType RECORD   # End point
    Address RECORD # Address
    Uri STRING                 # URI
END RECORD,

Binding RECORD # Binding
    Version STRING,             # HTTP Version (1.0 or 1.1)
    Cookie STRING,              # Cookie to be set
    ConnectionTimeout INTEGER,  # Connection timeout
    ReadWriteTimeout INTEGER,   # Read write timeout
    CompressRequest STRING      # HTTP request compression mode (gzip or deflate)
END RECORD

# Location of the SOAP endpoint.
# You can reassign this value at run-time.
#
DEFINE EchoDocStyle_EchoDocStylePortTypeEndpoint tGlobalEndpointType
```

The `CompressRequest` entry is of type string. It is NULL by default, meaning that no request is compressed. To compress a request, set this variable to `gzip` or `deflate`. The server must support compression, otherwise the request will be rejected.
The generated functions

Genero Web Services (GWS) client functions have the following requirements:

- The function cannot have input parameters.
- The function cannot have return values.
- The function's input message must be defined as a global or module RECORD.
- The function's output message must be defined as a global or module RECORD.

As a result, two types of GWS functions are generated for the Web Service operation that you requested:

- One function type uses global records for the input and output. The names of these functions end in "_g". Before calling the function in your GWS Client application, you must set the values in the global input record. After the function call, the status of the request is returned from the server, and the output message is stored in the global output record. In addition to performing the desired operation, this function handles the communication for the SOAP request and response, and sets the values in the wsError record as needed.

- The other function type serves as a "wrapper" for the "_g" function. It passes the values of input parameters to the "_g" function, and returns the output values and status received from the "_g" function. Your client application does not need to directly access the global records. This function can only be used if the parameters are simple variables (no records or arrays).

The generated .inc globals file contains comments that list the prototypes of the functions for the GWS operation, and the definitions of the global INPUT and OUTPUT records.

The generated callback handlers

More and more Web Services provide support of the different WS-* specifications. To enable a better interoperability with such services, the fgwsl tool allows the programmer to modify the SOAP request before it is sent, and to perform additional verifications of the SOAP response before it is returned from the BDL function.

When option -domHandler is used, the fgwsl tool performs the following two operations at once:

- It generates the client stub based entirely on the DOM API to ease the manipulation of the XML requests and responses.
- It generates additional calls for each operation of a service to execute one of the three callback handlers the programmer has to implement.

Handler definition

There are three kind of callbacks you must implement for each service generated with the -domHandler option.

- The request handler that allows the modification of the entire SOAP request before it is send over the net.

  It must be named ServiceName(HandleRequest, where ServiceName is the name of the service following the different prefix options used during generation.

  It must return TRUE if you want the caller function to continue normally or FALSE to return from the caller function with a SOAP error you can define via the wsError record.

  FUNCTION ServiceName(HandleRequest (operation, doc, header, body)
      DEFINE operation STRING -- Operation name of the request to be modified.
      DEFINE doc xml.DomDocument -- Entire XML document of the request
      DEFINE header xml.DomNode -- XML node of the SOAP header of the request
      DEFINE body xml.DomNode -- XML node of the SOAP body of the request
      CASE operation
         WHEN "Add"
            ... -- Use the DOM APIs to modify the request of the Add operation
         WHEN "Sub"
            ... -- Use the DOM APIs to modify the request of the Sub operation
         OTHERWISE
            DISPLAY "No modification for operation ",operation
      END
• The response handler that allows the validation of the entire SOAP response before it is de-serialized into the corresponding record.

It must be named `ServiceName_HandleResponse`, where `ServiceName` is the name of the service following the different prefix options used during generation.

It must return `TRUE` if you want the caller function to continue normally or `FALSE` to return from the caller function with a SOAP error you can define via the `wsError` record.

```plaintext
FUNCTION ServiceName_HandleResponse(operation,doc,header,body)
DEFINE operation STRING -- Operation name of the response to be checked.
DEFINE doc xml.DomDocument -- Entire XML document of the response
DEFINE header xml.DomNode -- XML node of the SOAP header of the response
DEFINE body xml.DomNode -- XML node of the SOAP body of the response
CASE operation
  WHEN "Add"
    ... -- Use the DOM APIs to check the response of the Add operation
  WHEN "Sub"
    ... -- Use the DOM APIs to check the response of the Sub operation
  OTHERWISE
    DISPLAY "No verification for operation ::",operation
END CASE
RETURN TRUE -- Continue normally in Add_g() or Sub_g()
END FUNCTION
```

• The fault response handler that allows the verification of the entire SOAP fault response before it is de-serialized into the `wsError` record.

It must be named `ServiceName_HandleResponseFault`, where `ServiceName` is the name of the service according to the different prefix options used during generation. It must return `TRUE` if you want the caller function to continue normally or `FALSE` to return from the caller function with a SOAP error you can define via the `wsError` record.

```plaintext
FUNCTION ServiceName_HandleResponseFault(operation,doc,header,body)
DEFINE operation STRING -- Operation name of the fault response to be checked.
DEFINE doc xml.DomDocument -- Entire XML document of the fault response
DEFINE header xml.DomNode -- XML node of the SOAP header of the fault response
DEFINE body xml.DomNode -- XML node of the SOAP body of the fault response
CASE operation
  WHEN "Add"
    ... -- Use the DOM APIs to verify the SOAP fault response of the Add operation
  WHEN "Sub"
    ... -- Use the DOM APIs to verify the SOAP fault response of the Sub operation
  OTHERWISE
    DISPLAY "No verification for operation ::",operation
END CASE
RETURN TRUE -- Continue normally in Add_g() or Sub_g()
END FUNCTION
```
Example output

The example WSDL file for the Calculator Web Service provides information about the service.

The generated file `ws_calculator.inc` lists the prototype for the following functions: Add and Add_g functions, the asynchronous AddRequest_g and AddResponse_g functions, as well as the definitions of the global variables Add and AddResponse:

```plaintext
# Operation: Add## FUNCTION: Add_g()  -- Function that uses the global input
#   RETURNING: soapStatus             -- An integer where 0 represents
success  #   INPUT: GLOBAL Add
#   OUTPUT: GLOBAL AddResponse
#   OUTPUT: GLOBAL AddResponse
# FUNCTION: Add(p_a, p_b)             -- Function with input parameters
#   RETURNING: soapStatus ,p_r       -- correspond to the a and b
variables  -- of the global INPUT record
#   INPUT: GLOBAL Add                 -- Return values are the status
#   OUTPUT: GLOBAL AddResponse        -- and the value in the r variable
integer   -- the global OUTPUT record
# FUNCTION: AddRequest_g()            -- Asynchronous function that uses
the  -- global input record
#   RETURNING: soapStatus             -- An integer where 0 represents
#   INPUT: GLOBAL Add                 -- success, -1 error and -2 means
that -- a previous request was sent
-- and that a response is in progress.
# FUNCTION: AddResponse_g()           -- Asynchronous function that uses
#   RETURNING: soapStatus             -- the global output record
#   OUTPUT: GLOBAL AddResponse        -- An integer where 0 represents
#   OUTPUT: GLOBAL AddResponse        -- success, -1 error and -2 means that
-- the response was not
-- yet received, and that a new call
-- should be done later.
#VARIABLE : Add   -- defines the global INPUT record
DEFINE Add RECORD ATTRIBUTES(XMLName="Add",
   XMLNamespace="http://tempuri.org/"
   a INTEGER ATTRIBUTES(XMLName="a",XMLNamespace=""),
   b INTEGER ATTRIBUTES(XMLName="b",XMLNamespace=""
END RECORD
# VARIABLE : AddResponse   -- defines the global OUTPUT record
DEFINE AddResponse RECORD ATTRIBUTES(XMLName="AddResponse",
XMLNamespace="http://tempuri.org/"
   r INTEGER ATTRIBUTES(XMLName="r",XMLNamespace=""
END RECORD
```

Multipart in the client stub

You can generate a client stub for a Web service that has multiple parts.

If the WSDL for a Web service indicates that the Web service uses multiple parts, the client stub generated will support multiple parts.
For the request

There are as many `com.HTTPPart` input parameters as parts defined for the input request, plus one `AnyInputParts` DYNAMIC ARRAY OF `com.HTTPPart` parameter, to manage the optional parts a user can add to the request.

For example:

```plaintext
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n, AnyInputParts)
  DEFINE InputHttpPart_1 com.HTTPPart
  ...
  DEFINE InputHttpPart_n com.HTTPPart
  DEFINE AnyInputParts DYNAMIC ARRAY OF com.HTTPPart
  ...
  RETURN wstatus
END FUNCTION
```

For the response

There are as many `com.HTTPPart` variables are described in the WSDL, plus one `AnyOutputParts` DYNAMIC ARRAY OF `com.HTTPPart` to handle the optional parts that may be returned by a service.

For example:

```plaintext
FUNCTION xxx_g()
  DEFINE wstatus INTEGER
  DEFINE OutputHttpPart_1 com.HTTPPart
  DEFINE AnyOutputParts DYNAMIC ARRAY OF com.HTTPPart
  ...
  RETURN wstatus, OutputHttpPart_1, AnyOutputParts
END FUNCTION
```

Related concepts

[SOAP multipart style requests in GWS](#) on page 3123
This topic describes multipart support with Genero Web Services

Using the generated functions

The WSDL information obtained from the Web Service allows you write client applications that use the service.

The information about the Add function from the `ws_calculator.inc` file, for example, allows you to write code in your own `.4gl` module that uses this operation as part of your Client application.

Using parameters and return values

You call the `Add` function in your Client application, defining variables for the parameters and return values. The input variables for our example are simple integers.

```plaintext
FUNCTION myWScall()
  DEFINE op1 INTEGER
  DEFINE op2 INTEGER
  DEFINE result INTEGER
  DEFINE wsstatus INTEGER
  ...
  LET op1 = 6
  LET op2 = 8
  CALL Add(op1, op2)
  RETURNING wsstatus, result ...
  DISPLAY result
```
Using global records

An alternative option is to call the Add_g function instead, using the global records Add and AddResponse directly. If the input variables are complex structures like records or arrays, you are required to use this function.

```genero
FUNCTION myWScall()
  DEFINE wsstatus INTEGER
  ...
  LET Add.a = 6
  LET Add.b = 8
  LET wsstatus = Add_g()
  ...
  DISPLAY AddResponse.r
```

In this case, the status is returned by the function, which has also put the result in the AddResponse global record.

See Tutorial: Writing a Client Application for more information. The demo/WebServices subdirectory of your Genero installation directory contains complete examples of Client Applications.

Using asynchronous calls

If you don't want your application to be blocked when waiting for the response to a request, it is recommended that you first call AddRequest_g; this will send the request using the global Add record to the server. It returns a status of 0 (zero) if everything goes well, -1 in case of error, or -2 if you tried to resend a new request before the previous response was retrieved.

```genero
FUNCTION sendMyWScall()
  DEFINE wsstatus INTEGER
  ...
  LET Add.a = 6
  LET Add.b = 8
  LET wsstatus = AddRequest_g()
  IF wstatus <> 0 THEN
    DISPLAY "ERROR ":, wsError.code
  END IF
  ...
```

You can then call AddResponse_g to retrieve the response in the AddResponse global record of the previous request. If the returned status is 0 (zero), the response was successfully received; -1 means that there was an error, and -2 means that the response was not yet received and that the function needs to be called later.

```genero
FUNCTION retrieveMyWScall()
  DEFINE wsstatus INTEGER
  ...
  LET wsstatus = AddResponse_g()
  CASE wstatus
    WHEN -2
      DISPLAY "No response available, try later"
    WHEN 0
      DISPLAY "Response is ":, AddResponse.r
    OTHERWISE
      DISPLAY "ERROR ":, wsError.code
  END CASE
  ...
```

You can mix the asynchronous call with the synchronous one as they are using two different requests. In other words, you can perform an asynchronous request with AddRequest_g, then a synchronous call with Add_g, and then retrieve the response of the previous asynchronous request with AddResponse_g.

**Important:** In development mode, a single BDL Web Service server can only handle one request at a time, and several asynchronous requests in a row without retrieving the corresponding response will lead to a deadlock. To
support several asynchronous requests in a row, it is recommended that you are in deployment mode with a GAS as the front end.

**Using logical names for service locations**

Genero Web Services, starting with version 2.00, provides a repository for Web Service locations using FGLPROFILE. To achieve maximum flexibility, you can map a logical reference used by your Web Services Client application to an actual URL. This is subject to the network configuration and access rights management of the deployment site.

**Important:** On GMI mobile devices, FGLPROFILE settings for logical names are not supported.

- FGLPROFILE entry on page 3159
- Logical reference in the client application on page 3159
- Logical reference in the URL on page 3159

**FGLPROFILE entry**

The following entry in the FGLPROFILE file maps the logical reference "myservice" to an actual URL:

```
```

**Logical reference in the client application**

When you generate a Client stub from WSDL information using the tool fglwsdl, a global variable for the URL of the Web Service is contained in the .inc file.

For example:

```
# Location of the SOAP server.
# You can reassign this value at run-time.
#
DEFINE Calculator_CalculatorPortTypeEndpoint tGlobalEndpointType
```

You can assign a logical name to this global variable in your Web Services Client application:

```
LET Calculator_CalculatorPortTypeEndpoint.Address.Uri = "alias://myservice"
```

When the client application accesses the service, the actual location will be supplied by the entry in FGLPROFILE on the client machine. This allows you to provide the same compiled .42r application to different customers. The entries in FGLPROFILE on each customer's machine would customize the Web Service location for that customer.

If you are migrating from a version prior to 2.40, see also Web Services changes on page 148.

**Logical reference in the URL**

When you deploy a Genero Web Service with a GAS behind a Web Server, the service can be accessed by two different URLs. You can use a logical name in the URL, mapping the actual location of the Web Service in FGLPROFILE, depending on the location of the client machine.

For example:

- For internal Clients: http://zeus:6394/ws/r/myservice
- For Clients using the Web: http://www.myServer.com/...

These two URLS can be mapped in the FGLPROFILE file on the Client machine, each specifying the location of the Service.

**Configure a WS client to connect via an HTTP Proxy**

Configuration steps to connect via a HTTP proxy.

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.
1. Add the location of the proxy to `fglprofile` with the `proxy.http.location` entry.
   
   Add the entry `proxy.http.location` to your `fglprofile`. For the value, provide the IP address of the HTTP proxy and the port number where the HTTP proxy is listening, separated by a colon. For example, to have a client connect via a HTTP proxy located at the IP address "10.0.0.170" and listening on port number "8080", add this entry to your `fglprofile`:
   
   ```
   proxy.http.location = "10.0.0.170:8080"
   ```
   
   **Note:** To configure the client to connect via an HTTPS proxy, replace `http` with `https`.

2. Define the list of host names the client will not have to connect to via a proxy with the `proxy.http.list` entry.
   
   Add the entry `proxy.http.list` to your `fglprofile`. For the value, provide a semi-colon separated list of clients. For example, to exclude all hosts beginning with "www.mycompany.com" or "www.google." from connecting via a HTTP proxy, add this entry to your `fglprofile`:
   
   ```
   proxy.http.list = "www.mycompany.com;www.google."
   ```

**Configure a WS client to use IPv6**

Configuration steps to customize IPv6 for a WS client.

A Web Services client program can access a WS server using IPv6.

URLs that map to IPv6 addresses will be automatically handled by the Web Services library. It is also possible to specify an IPv6 address directly as URL in your BDL code by enclosing the address in `[]` square brackets, for example:

```plaintext
LET myURL = "http://[fe80::20c:29ff:fe05:9ca3]:80/index.html"
```

By default, the WS library will automatically use IPv6 addresses if available, and fallback to IPv4 if not. To overcome the default behavior, you can explicitly specify the IP version.

Indeed, the platform where WS client programs execute must support IPv6.

1. If needed, force the IP version with the `ip.global.version` entry in `fglprofile`, by specifying "4" for IPv4 or "6" for IPv6.
   
   For example, to force IPv4 (when IPv6 is available):
   
   ```
   ip.global.version = "4"
   ```

2. When using IPv6 for link-local addresses, if several network interfaces exist on the machine, you can explicitly specify what interface must be used with the `ip.global.v6.interface.name` or `ip.global.v6.interface.id` entry in `fglprofile`.
   
   In order to specify the IPv6 network interface by name, use:
   
   ```
   ip.global.v6.interface.name = "eth0"
   ```

   **Important:** The `ip.global.v6.interface.name` entry is not supported on Microsoft™ Windows® platforms.

   In order to specify the IPv6 network interface by id, use:
   
   ```
   ip.global.v6.interface.id = "2"
   ```

**Related reference**

IPv6 configuration on page 3240

**Authenticate the WS client to a server**

Configuration steps to authenticate the client to a server (HTTP authentication).

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: Use the `com.HTTPRequest.setAuthentication` on page 2726 API instead.

1. Add HTTP authenticate entries to `fglprofile`. 
To connect to a server with HTTP Authentication, define the client login and password with the same values as registered on the server side. These entries must be defined with an unique identifier (httpauth in this example) to define a HTTP Authentication with "mylogin" as login and "mypassword" as password:

```plaintext
authenticate.httpauth.login = "mylogin"
authenticate.httpauth.password = "mypassword"
```

See [RFC2617] for more details.

2. Encrypt the password.

Due to security leaks, it is recommended that you NOT have a password in clear text. The Genero Web Services package provides the tool `fglpass`, which encrypts a password with a certificate that is readable only with the associated private key. To encrypt the HTTP authentication password:

a) Encrypt the clear text password with `fglpass` using the client certificate.

```
$ fglpass -e -c MyClient.crt
Enter password :mypassword
```

**Note:** `fglpass` outputs the encrypted password on the console but can be redirected to a file.

b) Modify the HTTP authentication password entry by specifying the security configuration to use to decrypt it (id1 in our case)

```
authenticate.id2.password.id1="HWTFu8QE2t3e5D4joy7js8mB95oOGTzLmcAor9j5DS+C1oiilGCwZvZ9eWpfmIWSON9IwoiJheYxfnu20uaGOmniUGiHxT6341ePXNSicu32Nt1Vp9t6RcS0wN/p9a6D4XtiD9iHW7iQvXhqC9uam3gI9Q3GhHwX0MM1Y//c8Y=
```

**Note:** Hard returns have been added to the code sample above, for the purpose of printing and viewing within this document. The value for `authenticate.id2.password.id1` is a single string with no spaces.

**Note:** The size of the encrypted password depends on the size of the public key, and can change based on the certificate used to encrypt it.

3. Configure the client to authenticate to a server.

As a client is able to connect to different servers that do not know the client with the same login and password, it is necessary to specify the login and password that correspond to each server. To authenticate the client known as "myclient" and with the password `passphrase` by the server `myserver`, add the following entry:

```
ws.myserver.authenticate = "httpauth"
```

**Related tasks**

- Configure a WS client to access an HTTPS server on page 3131
- Configuration steps to access a server in HTTPS.

**Authenticate the WS client to a proxy**

Configuration steps to authenticate the client to a proxy (proxy authentication).

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.

1. Add an HTTP authenticate entry to fglprofile.

To connect via a proxy with HTTP Proxy Authentication, it is necessary to define the client login and password as registered on the HTTP proxy.

The following two entries must be defined with an unique identifier (proxyauth for our example) to define a HTTP Proxy Authentication with `myapplication` as login and `mypassword` as password:

```plaintext
authenticate.proxyauth.login = "myapplication"
authenticate.proxyauth.password = "mypassword"
```

See [RFC2617] for more details.
2. For proxy authentication, an entry must be made to the HTTP proxy configuration in order to authenticate a client.

   To authenticate a client known as myapplication and with mypassword as password by the HTTP Proxy, add the following entry to the HTTP proxy configuration:

   ```
   proxy.http.authenticate = "proxyauth"
   ```

   **Note:** To authenticate the client to a HTTPS proxy, replace `http` with `https`.

**Configure a WS client to access an HTTPS server**

Configuration steps to access a server in HTTPS.

To configure access to an HTTPS server, you need a client certificate.

**Important:** On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain typically holds the server certificate authority list. Therefore, the fglprofile security settings are ignored with the exception of the following: security.global.ca, security.global.ca.lookuppath, and security.global.systemca.

Before you begin, there are options to consider depending on how you wish to use the client certificate:

- If you do not have the certificate information in your fglprofile, Genero Web Services creates a certificate for you. This is an implicit or temporary certificate that is valid for a session only. For more information see HTTPS configuration on page 3132.

  **Note:** For the implicit certificate, no configuration is required.

- Alternatively, for stronger security, you generate a client certificate of your own, configure your application to use the client certificate generated, and add the configuration details to fglprofile. Follow the steps outlined in this procedure.

  **Note:** In a production environment, some servers provide a client certificate and you use the certificate as provided, and add the configuration details to fglprofile.

The openssl command line tool can be used to create your own certificates for the configuration of secured communication. The following steps outline the configuration process:

1. To create the client certificate, follow the procedure described in Create the client certificate on page 3132.

2. To configure fglprofile for the client certificate, follow the procedure in Configure for the client certificate on page 3134.

3. To configure fglprofile for the certificate authority list, see Configure for the certificate authority list on page 3134.

4. Add configuration entries for the server to fglprofile. For an example, see FGLPROFILE: HTTP(S) Proxy Authentication on page 3243.

The Genero Web Services client needs a set of configuration entries that specify the security configuration when accessing an HTTPS server. The following entries must be defined with an unique identifier (such as myserver):

```
ws.myserver.security = "id1"
```

(line breaks added for document readability)

- The unique identifier myserver can be used in the BDL client code in place of the actual URL.
- The security entry value (id1 in this example) must match the unique identifier defined by the client security entry created in Configure for the client certificate on page 3134.

Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web Service.

### Writing a Web Services server application

These topics cover creating a Genero Web Services server using the SOAP protocol.

- **Writing a Web services server function** on page 3163
- **WS server stubs and handlers** on page 3164
- **Writing a Web server application** on page 3168
- **Get HTTP headers information at WS server side** on page 3176
- **Choosing a web services style** on page 3178

### Writing a Web services server function

Writing a Web service with Genero is quite simple. You create a standard Genero function and publish it as a Web function (Web services operation) using methods from the classes in the COM library. There are restrictions on the function - input and output parameters are not allowed. By using global or module variables, however, to work around this exception.

See also Tutorial: Writing a GWS Server Application

The steps for writing a Web Services function:

1. **Define the input parameters** on page 3163
2. **Define the output parameters** on page 3163
3. **Write the BDL function** on page 3164
4. **Create and publish the Web services operation** on page 3164

#### Define the input parameters

As stated in the introduction, input parameters in Genero Web Service operations are not allowed. However, each Web Function can have one global variable or module variable that defines the input message of the function. This variable must be a record in which each field represents one of the input parameters of the Web Function.

The name of each field corresponds to the name used in the SOAP request. These fields are filled with the contents of the SOAP request by the Web Services engine just before executing the corresponding BDL function.

**Example**

```groovy
DEFINE add_in RECORD
  a INTEGER,
  b INTEGER
END RECORD
```

**Note:** Genero version 2.0 allows you to add optional attributes to the definition of data types. You can use attributes to map the BDL data types in a Genero application to their corresponding XML data types. See [Attributes to Customize XML Mapping](#) for additional information.

#### Define the output parameters

Output parameters in Genero Web Functions are not allowed, but each Web Function can have one global variable or module variable that defines the output message of the function. This message must be a record where each field represents one of the output parameters of the Web Function.

The name of each field corresponds to the name used in the SOAP request. These fields are retrieved from the Web Services engine immediately after executing the BDL function, and sent back to the client.
Example

```plaintext
DEFINE add_out RECORD
   r INTEGER
END RECORD
```

Note: GWS 2.0 allows you to add optional attributes to the definition of data types. You can use attributes to map the BDL data types in a Genero application to their corresponding XML data types. See Attributes to Customize XML Mapping for additional information.

Write the BDL function

A Web Function is a normal BDL function that uses the input and output records that you have defined.

Example

```plaintext
FUNCTION add()
   LET add_out.r = add_in.a + add_in.b
END FUNCTION
```

Create and publish the Web services operation

Methods are available in the Genero Web Services library (com) to:

- Define the Web Service, by creating a WebService object
- Define the Web Services operation for your function, by creating a WebOperation object
- Publish the operation - associate it with the Web Service object that you defined.

The com library must be imported into each module of a Web Services Server application.

The following abbreviated example is from the Web Services Server tutorial:

```plaintext
IMPORT com
...
FUNCTION createservice()
   DEFINE serv com.WebService      # A WebService
   DEFINE op com.WebOperation      # Operation of a WebService
   
   --Create WebService object
      "http://tempuri.org/webservices")
   
   --Create WebOperation object
   LET op = com.WebOperation.CreateRPCStyle("add", "Add", add_in, add_out)
   
   --Publish the operation, associating it with the WebService object
   CALL serv.publishOperation(op,NULL)
...
END FUNCTION
```

See the Writing a Web server application on page 3168 and Choosing a web services style on page 3178 for complete examples and explanations.

WS server stubs and handlers

To access a remote Web Service, you first must get the WSDL information from the service provider. Sample services can be found through UDDI registries (http://www.uddi.org), or on other sites such as XMethods (http://www.xmethods.net).

Generating files for a GWS server

You can write a Genero Web Services Server application for a Web Service that you have created; see Tutorial: Writing a Server Application.
If you want to make sure your Web Service is compatible with that of a third-party (an accounting application vendor, for example), you can use the fglwsdl tool to obtain the WSDL information that complies with that vendor’s standards, and to generate corresponding files that can be used in your GWS Server application.

This example requests the Calculator Web Service information from the specified URL, and the output files will have the base name "ws_calculator".

```bash
```

For a server application, fglwsdl generates two files. It is not advised to modify these files:

- `filename.inc` - the globals file, containing declarations of global variables that can be used as input or output to functions accessing the Web Service operations. In our example, the file is `ws_calculatorService.inc`.
  
  This file must be listed in a GLOBALS statement at the top of any .4gl modules that you write for your GWS Server application.

- `filename.4gl` - containing a function that creates the service described in the WSDL, publishes the operations of the service, and registers the service. In our example, the file is `ws_calculatorService.4gl`.
  
  This file must be compiled and linked into your GWS Server application.

**Server handlers**

The COM library enables to intercept high-level web services operation on server side. You can now define three BDL functions via the following methods of the web service class. They will be executed at different steps of a web service request processing in order to modify the SOAP request, response or the generated WSDL document before or after the SOAP engine has processed it. This helps handle WS-* specifications not supported in the web service API.

- Method `registerWSDLHandler()`
- Method `registerInputChangeRequestHandler()`
- Method `registerOutputRequestHandler()`

All three kinds of BDL callback functions must conform to this prototype:

```bash
FUNCTION CallbackHandler( doc xml.DomDocument )
RETURNING xml.DomDocument
```

**Example 1: Modify the generation of a WSDL**

Register your handler with:

```bash
CALL serv.registerWsdhandler("WSDLHandler")
```

where `serv` is of class `com.WebService` and `WSDLHandler` is the following function:

```bash
FUNCTION WSDLHandler(wsdl)
  DEFINE wsdl Xml.DomDocument
  DEFINE node Xml.DomNode
  DEFINE list Xml.DomNodeList
  DEFINE ind INTEGER
  DEFINE name STRING
  # Add a comment
  LET node = wsdl.createComment("First modified WSDL via a BDL callback function")
  CALL wsdl.prependDocumentNode(node)
  # Rename input and output parameter in UPPERCASE
  -- first input parameter for selectByXPath above
  -- one string, no spaces!
```
If NULL is returned from the callback function, an HTTP error will be sent and the \texttt{ProcessServices()} returns error code -20.

\textbf{Example 2: Change the SOAP incoming request}

Register your handler with:

\begin{verbatim}
CALL serv.registerInputRequestHandler("InputRequestHandler")
\end{verbatim}

where \texttt{serv} is of class \texttt{com.WebService} and \texttt{InputRequestHandler} is this function:

\begin{verbatim}
FUNCTION InputRequestHandler(in)
    DEFINE in Xml.DomDocument
    DEFINE ind INTEGER
    DEFINE node Xml.DomNode
    DEFINE copy Xml.DomNode
    DEFINE tmp Xml.DomNode
    DEFINE parent Xml.DomNode
    DEFINE name STRING
    DEFINE list Xml.DomNodeList
    # Change input parameter below myrecord in lower case
    # to follow high-level web service
    LET list = in.SelectByXPath("
        //SOAP:Envelope/SOAP:Body/fjs:EchoDOCRecordRequest/fjs:myrecord/*",
        "SOAP","http://schemas.xmlsoap.org/soap/envelope/",
        "fjs","http://www.mycompany.com/webservices")
    FOR ind = 1 TO list.getCount()
        LET node = list.getItem(ind)
        LET parent = node.getParentNode()
        LET name = node.getLocalName()
        LET copy = in.createElementNS(node.getPrefix(),
            name.toLowerCase(),node.getNamespaceURI())
        LET tmp = node.getFirstChild()
        LET tmp = tmp.clone(true)
        CALL copy.appendChild(tmp)
        CALL parent.replaceChild(copy,node)
    END FOR
    RETURN in
END FUNCTION
\end{verbatim}

If NULL is return from the callback function, a SOAP fault will be sent (but can be changed from the output handler) and the \texttt{ProcessServices()} returns error code -18.

\textbf{Example 3: Modify the SOAP outgoing request}

Register your handler with:

\begin{verbatim}
CALL serv.registerOutputRequestHandler("OutputRequestHandler")
\end{verbatim}

where \texttt{serv} is of class \texttt{com.WebService} and \texttt{OutputRequestHandler} is this function:

\begin{verbatim}
FUNCTION OutputRequestHandler(out)
END FUNCTION
\end{verbatim}
DEFINE out Xml.DomDocument
DEFINE ind INTEGER
DEFINE node Xml.DomNode
DEFINE copy Xml.DomNode
DEFINE tmp Xml.DomNode
DEFINE parent Xml.DomNode
DEFINE name STRING
DEFINE list Xml.DomNodeList

# Change output parameter below myrecord in uppercase
# before sending back to the client
LET list = out.SelectByXPath(
    "//SOAP:Envelope/SOAP:Body/fjs:EchoDOCRecordResponse/fjs:myrecord/*",
    "SOAP","http://schemas.xmlsoap.org/soap/envelope/",
    "fjs","http://www.mycompany.com/webservices")
FOR ind = 1 TO list.getCount()
    LET node = list.getItem(ind)
    LET parent = node.getParentNode()
    LET name = node.getLocalName()
    LET copy = out.createElementNS(node.getPrefix(),name.toUpperCase(),
                                  node.getNamespaceURI())
    LET tmp = node.getFirstChild()
    LET tmp = tmp.clone(true)
    CALL copy.appendChild(tmp)
    CALL parent.replaceChild(copy,node)
END FOR
RETURN out
END FUNCTION

If NULL is return from the callback function, a SOAP fault will be sent and the ProcessServices() returns error code -19.

Example output

In the generated file ws_calculatorService.inc, the definitions of the variables for the input and output record are the same as those generated for the Web Service Client application:

#VARIABLE : Add -- defines the global INPUT record
DEFINE Add RECORD ATTRIBUTES(XMLName="Add",
    XMLNamespace="http://tempuri.org/")
    a INTEGER ATTRIBUTES(XMLName="a",XMLNamespace=""),
    b INTEGER ATTRIBUTES(XMLName="b",XMLNamespace="")
END RECORD

# VARIABLE : AddResponse -- defines the global OUTPUT record
DEFINE AddResponse RECORD ATTRIBUTES(XMLName="AddResponse",
    XMLNamespace="http://tempuri.org/")
    r INTEGER ATTRIBUTES(XMLName="r",XMLNamespace="")
END RECORD

The generated file ws_calculatorService.4gl contains a single function that creates the Calculator service, creates and publishes the service operations, and registers the Calculator service:

FUNCTION CreateWs_calculatorService()
DEFINE service com.WebService
DEFINE operation com.WebOperation
...  # Create Web Service
LET service = com.WebService.CreateWebService("Calculator",
    "http://tempuri.org/")
# Publish Operation : Add
LET operation = com.WebOperation.CreateRPCStyle("Add","Add",
    Add,AddResponse)
CALL service.publishOperation(operation,"") ...  # Register Service
CALL com.WebServiceEngine.RegisterService(service)
RETURN 0
...
END FUNCTION

Writing your functions

The ws_calculator.inc WSDL file provides you with the global input and output records and function names that allow you to write your own code implementing the operations.

Your new code should not be written in the generated modules. For example, do not add your own version of the Add function to the generated ws_calculator.4gl module; it can be included in your module containing the MAIN program block, or in a separate module to be included as part of the Web server application. The function must use the generated definitions for the global input and output records.

In your version of the Add operation, for example, this function adds 100 to the sum of the variables in the input record:

FUNCTION Add()
  LET AddResponse.r = (Add.a + Add.b) + 100
END FUNCTION

See Tutorial: Writing a Server application for more information. The demo/WebServices subdirectory of your Genero installation directory contains complete examples of Server Applications.

Writing a Web server application

This tutorial guides you through the steps to create a Server application for a Genero Web Service that can be accessed over the web by Client applications. A complete example is provided at $FGLDIR/demo/WebServices.

You can write your Server application based on input/output records that you have defined. Or, you can use the fglwsdl tool to include third-party WSDL information in your Server application.

Including the web services library

The methods associated with creating and publishing a Web Service are contained in the classes that make up the Genero Web Services Library (com). Include this line at the top of each module of your GWS Server application to import the library:

IMPORT com

Example 1: Writing the entire server application

You can define a Web Service in your application and write definitions for the input and output records that will be used by the Service. This example illustrates a Service that has one operation, Add, to provide the sum of two numbers.

Step 1: Define input and output records
Step 2: Write a BDL function for each service operation
Step 3: Create the service and operations
Step 4: Register the service
Step 5: Start the GWS server and process requests

Step 1: Define input and output records

Based on the desired functionality of the operations that you plan for the Service, define the input and output records for each operation. BDL functions that are written to implement a Web Service operation cannot have input parameters or return values. Instead, each function's input and output message must be defined as a global or module RECORD.
The Input message

The fields of the global or module record represent each of the input parameters of the Web Function. The name of each field in the record corresponds to the name used in the SOAP request. These fields are filled with the contents of the SOAP request by the Web Services engine just before executing the corresponding BDL function.

The Output message

The fields of the global or module record represent each of the output parameters of the Web Function. The name of each field in the record corresponds to the name used in the SOAP request. These fields are retrieved from the Web Services engine immediately after executing the BDL function, and sent back to the client.

Your Genero Web Services service has one planned operation that adds two integers and returns the result. The input and output records are defined as follows:

```gen
GLOBALS
DEFINE
    add_in RECORD   # input record
        a INTEGER,
        b INTEGER
    END RECORD,
    add_out RECORD  # output record
        r INTEGER
    END RECORD
END GLOBALS
```

Step 2: Write a BDL function for each service operation

You will need to write a function to implement each operation, using the input and output global records.

To implement your Add operation:

```gen
#User Public Functions
FUNCTION add()
    LET add_out.r = add_in.a + add_in.b
END FUNCTION
```

Step 3: Create the service and operations

The Genero Web Services library (com) provides classes and methods that allow you to use Genero BDL to configure a Web Service and its operations.

- **WebService** - this is a container for web operations.
- **WebOperation** - describes the operation.

Define variables for the WebService and WebOperation objects

```gen
FUNCTION createservice()
    DEFINE serv com.WebService    # A WebService
    DEFINE op    com.WebOperation  # Operation of a WebService
```

Choose a Namespace

XML uses namespaces to group the element and attribute definitions, and to avoid conflicting names. In practice, a namespace must be a unique identifier (URI: Uniform Resource Identifier). If you do not know the unique identifier to use, your company's Web site domain name is guaranteed to be unique (such as "www.mycompany.com"); then, append any string.

Examples of valid namespaces for the fictional My Company company:

- "http://www.mycompany.com/MyServices"
- "http://www.mycompany.com/any_string"
Another option (for testing only) is to use the temporary namespace "http://tempuri.org/".

**Create the WebService object**

Call the constructor method of the WebService class. The parameters are:

1. Service name
2. Valid namespace

This example uses the temporary namespace and creates a Service named "MyCalculator".

```plaintext
LET serv = 
```

**Create the WebOperation object**

A WebService object can have multiple operations. The operations can be created in RPC style or Document style by calling the corresponding constructor method of the WebOperation class. The parameters are:

1. the name of the BDL function that is executed to process the XML operation
2. the name you wish to assign to the XML operation
3. the input record defining the input parameters of the operation (or NULL if there is none)
4. the output record defining the output parameters of the operation (or NULL if there is none)

To create the operation for the previously defined add function in RPC style:

```plaintext
LET op = com.WebOperation.CreateRPCStyle("add", "Add", add_in, add_out)
```

To create the operation for the previously defined add function in Document style:

```plaintext
LET op = com.WebOperation.CreateDOCStyle("add", "Add", add_in, add_out)
```

Mixing RPC style and Document style operations in the same service is not recommended, as it is not WS-I compliant. See Web Services Styles for additional information about styles.

The rest of the code in your application is the same, regardless of the Web Services style that you have chosen.

**Publish the operation**

Once an operation is defined, it must be associated with its corresponding WebService (the operation must be published). The publishOperation method of the WebService object has the following parameters:

- the WebOperation to be published
- a string to identify the operation if several operations have the same name; if this is NULL, the default value is an empty string

For example, to publish the Add operation of the Calculator service, which was defined as op:

```plaintext
CALL serv.publishOperation(op, NULL)
```

**Step 4: Register the service**

Once the Service and operations are defined and the operations are published, the WebService and WebOperation objects have completed their work. Registering a service puts the Genero DVM in charge of the execution of all the operations of that service - dispatching the incoming message to the right service, returning the correct output, and so on. The same service may be registered at different locations on the Web.

The WebServiceEngine is a global built-in object that manages the Server part of the Genero DVM. Use the RegisterService class method of the WebServiceEngine class. The parameter is:
1. The name of the WebService object

To register the Calculator service example created in Step 3: Create the service and operations on page 3169:

```
CALL com.WebServiceEngine.RegisterService(serv)
END FUNCTION
```

**Note:** If you want to create a single GWS Server DVM containing multiple Web Services, define additional input and output records and repeat steps 2 through 6 for each Web Service. In Step 5: Start the GWS server and process requests on page 3171, a GWS Server DVM is started, containing as many Web Services as you have defined. See Web services server program deployment on page 3232 for additional discussion of GWS Services and GWS Servers.

**Step 5: Start the GWS server and process requests**

Once you have registered the Web Service(s), you are ready to start the Genero Web Services (GWS) Server and process the incoming SOAP requests.

The GWS Server is located on the same physical machine where the application is being executed (In other words, where fglrun executes).

This is the **MAIN** program block of your application.

**Define a variable for status**

Define a variable to hold the returned status of the request:

```
MAIN
  DEFINE ret INTEGER
```

Call the function that you created, which defined and registered the service and its operations:

```
CALL createservice()
```

**Start the GWS Server**

Use the **Start** class method of the **WebServiceEngine** class to start the server.

```
CALL com.WebServiceEngine.Start()
```

**Process the requests**

This example uses the **ProcessServices** method of the **WebServiceEngine** class to process each incoming request. It returns an integer representing the status. The parameter specifies the timeout period (in seconds) the method may wait to process a service. The value -1 specifies an infinite waiting time.

```
WHILE TRUE
  # Process each incoming requests (infinite loop)
  LET ret = com.WebServiceEngine.ProcessServices(-1)
  CASE ret
    WHEN 0
      DISPLAY "Request processed."
    WHEN -1
      DISPLAY "Timeout reached."
    WHEN -2
      DISPLAY "Disconnected from application server."
      EXIT PROGRAM
    WHEN -3
      DISPLAY "Client Connection lost."
    WHEN -4
      DISPLAY "Server interrupted with Ctrl-C."
```

WHEN -10
   DISPLAY "Internal server error."
   EXIT PROGRAM
WHEN -15
   DISPLAY "Server was not started."
   EXIT PROGRAM
OTHERWISE
   DISPLAY "ERROR: ", STATUS, SQLCA.SQLERRM
END CASE
IF int_flag<>0 THEN
   LET int_flag=0
   EXIT WHILE
END IF
END WHILE
DISPLAY "Server stopped"

END MAIN

Note: For testing purposes only, the GWS Server can be started in standalone mode. In a production environment, the Genero Application Server (GAS) is required to manage your application. For deployment, the GWS Server application must be added to the GAS configuration. See Adding Applications in the Genero Application Server User Guide.

Example 2: Writing a server using third-party WSDL (the fglwsdl tool)

To write a Web Service that is compatible with the specification of the input and output records defined by a third-party (for example, a vendor of manufacturing software, or a WSDL specialist in your company) you can use the fglwsdl tool to obtain the WSDL information and generate a part of the Server application. See fglwsdl on page 1980 for a complete description of the tool and its use.

• Step 1: Get the WSDL description and generate files on page 3172
• Step 2: Write a BDL function for your service operation on page 3173
• Step 3: Create service, start server and process requests on page 3174

Step 1: Get the WSDL description and generate files

This tutorial uses fglwsdl and the Calculator Service defined in Example 1: Writing the entire server application on page 3168 to obtain the WSDL information and generate two corresponding BDL files:

• the globals file, containing declarations of global variables that can be used as input or output to functions accessing the Web Service operations.
• a .4gl file containing a function that creates the service described in the WSDL, publishes the operations of the service, and registers the service.

fglwsdl -s -o example1 http://localhost:8090/MyCalculator?WSDL

Note: the MyCalculator Genero Web Services Service created in Example 1: Writing the entire server application on page 3168 must be running in order to obtain the WSDL information.

The generated globals file

The globals file example1Service.inc provides the definition of the global input and output records as described in the Step 1: Define input and output records on page 3168 of the Example 1: Writing the entire server application on page 3168 GWS Server program. The names of the input and output records have been assigned by fglwsdl, in accordance with the Style of the Web Service MyCalculator (created as RPCStyle in the Example1 program). Do not modify this file.

Input and output records:

# VARIABLE : Add
DEFINE Add RECORD
The generated .4gl file

The example1Service.4gl file contains a single function that creates the service, publishes the operation, and registers the Service. The Web Service Style that is created is determined by the style specified in the WSDL information. The functions in this file accomplish the same tasks as Step 3: Create the service and operations on page 3169 and Step 4: Register the service on page 3170 of Example 1. Do not modify this file.

Step 2: Write a BDL function for your service operation

Using the information from these generated files, the Add operation from Example 1: Writing the entire server application on page 3168 is rewritten to have different functionality but to still be compatible with the WSDL description of the operation. This step accomplishes the same thing as Step 2: Write a BDL function for each service
operation on page 3169 in Example 1. In this version of the add operation, the sum of the two numbers in the input record is increased by 100.

```gml
# my_function.4gl -- file containing the function
IMPORT com -- definition
GLOBALS "example1Service.inc" -- import the Web Services library
#User Public Functions
FUNCTION add() -- use the generated globals file
    LET AddResponse.r = (Add.a + Add.b)+ 100 -- new version of the add function
    -- the global input and output records are used
END FUNCTION
```

**Step 3: Create service, start server and process requests**

Create your own Main module that calls the function from the generated .4gl file to create the service, and then starts the Genero Web Services Server and manages requests as in Step 5: Start the GWS server and process requests on page 3171 of Example 1: Writing the entire server application on page 3168.

```gml
# example2main.4gl file -- contains the MAIN program block
IMPORT com
GLOBALS "example1Service.inc"
MAIN
    DEFINE create_status INTEGER
    DEFER INTERRUPT
    CALL Createexample1Service() -- call the function generated in example1Service.4gl
        RETURNING create_status
        IF create_status <> 0 THEN
            DISPLAY "error"
        ELSE
            # Start the server and manage requests
            CALL ManageService()
        END IF
    END IF
END MAIN

FUNCTION ManageService()
    DEFINE ret INTEGER
    CALL com.WebServiceEngine.start()
    WHILE TRUE
        # continue as in Step 5 of Example 1...
    END FUNCTION
```

**Enabling MTOM on the server side**

Enable Message Transmission Optimization Mechanism (MTOM) to efficiently send binary data to and from Web services.

By default, MTOM is not enabled. As a result, any BYTE represented as xsd:base64 or xsd:hexbinary will be inlined in the SOAP request or response.

To enable MTOM on server side, set the MTOM feature to TRUE.

```gml
# Create Web Service
```
LET service = 
CALL service.setFeature("MTOM",true)

With MTOM enabled on the server side, the generated WSDL includes the MTOM policy.

**Compiling GWS server applications**

It is recommended that the library file WSHelper.42m, included in the $FGLDIR/lib directory of the Genero Web Services package, is linked into every GWS Server application.

If your application uses the fglwsdl tool to generate information, link the .4gl generated file into the application.

**Examples**

Compiling the [Example 1: Writing the entire server application](#) on page 3168 program:

```
fglcomp example1.4gl
fgllink -o example1.42r example1.42m WSHelper.42m
```

Compiling the [Example 2: Writing a server using third-party WSDL (the fglwsdl tool)](#) on page 3172 program:

```
fglcomp example2main.4gl my_function.4gl example1Service.4gl
fgllink -o example2.42r example2main.42m my_function.42m example1Service.42m WSHelper.42m
```

**Testing the GWS service in stand-alone mode**

For testing and development purposes only, the Genero Web Services Server application can be executed directly, without using the Genero Application Server (GAS).

1. Use the Genero **fglrun** command to execute the GWS Server application. The application must reside on the same machine:

   ```
   fglrun <gws-application>
   ```

   This will start the GWS Server on the port specified by the FGLAPPSERVER environment variable. For example, if FGLAPPSERVER is set to 8090, the server will be started on that port. If this environment variable is not set for the user, port number 80 is used.

   **Warning:** The user must not set the FGLAPPSERVER variable in production environments, since the port number is selected by the Genero Application Server.

2. Obtain the WSDL information for your Service and write a test Client application. For example, if the GWS Server in step 1 was started on your local machine and FGLAPPSERVER was set to 8090, the command to get the WSDL information would be:

   ```
   fglwsdl -o <test-client> http://localhost:8090/<service-name>?WSDL
   ```

**Configuring the Genero application server for the GWS Application**

The final step is to configure the Genero Application Server (GAS) to handle the GWS application. In a production environment, Genero Web Services becomes a part of a global application architecture handled by the application server of the GAS package. See [Web services server program deployment](#) on page 3232, as well as *Adding Applications* in the GAS manual.

**Making the GWS service available**

Once you compile and deploy your Genero Web Services Server application (see [Web services server program deployment](#) on page 3232), it can be used by others to obtain the WSDL information and write a client application that accesses your Genero Web Service. See [Steps to write a WS client](#) on page 3146.
Your company can provide the location of the GWS Server to potential users of your Web Service in various ways. For example:

- Provide the location on a company web site
- Register the Web Service with UDDI (Universal Description, Discovery, and Integration) - the XML-based registry providing Internet listings for companies worldwide
- Communicate directly with your potential users

**Get HTTP headers information at WS server side**

In high level Web services, we now give access to the HTTP headers request and response.

The Web service can get information from the request headers and reply with custom headers and status.

1. Declare variables to receive or send HTTP headers.
2. Register these variables to the Web service server.

**Declare variables to receive or send HTTP headers**

The variable for the request headers:

```plaintext
DEFINE http_in RECORD
  verb STRING,
  url STRING,
  headers DYNAMIC ARRAY OF RECORD
    name STRING,
    value STRING
  END RECORD
END RECORD
```

After the Web service operation has been processed, the variable is set to NULL.

The variable for the response headers:

```plaintext
DEFINE http_out RECORD
  code INTEGER,
  desc STRING,
  headers DYNAMIC ARRAY OF RECORD
    name STRING,
    value STRING
  END RECORD
END RECORD
```

After the Web service operation has been processed, the variable is set to NULL.

**Note:** While the variables must follow the structure shown, the variable name can be any name you choose.

The Web service engine headers have precedence. For example, if you set the "Content-Length" value, the one that is taken into account is the one defined by the Genero Web Services engine.

**Register the variables to the server**

This code example uses two methods, which use the defined variables:

- `com.WebService.registerInputHttpVariable(http_in)` where `http_in` is the RECORD variable for the request headers.
- `com.WebService.registerOutputHttpVariable(http_out)` where `http_out` is the RECORD variable for the response headers

**Example**

```plaintext
FUNCTION CreateService()
```
DEFINE serv com.WebService # WebService
DEFINE op com.WebOperation # Operation of a WebService

TRY
#
# Create a Web Service
#
LET serv = com.WebService.CreateWebService("EchoHttpHeadersService",
    Namespace)
#
# Create Document Style Operations
#
# EchoDOCRecord
LET op = com.WebOperation.CreateDOCStyle("echoDocRecord",
    "EchoDOCRecord",
    echoRecordDoc_in,
    echoRecordDoc_out)

CALL serv.publishOperation(op,NULL)

# Register HTTP input
CALL serv.registerInputHttpVariable(http_in)

# Register HTTP output
CALL serv.registerOutputHttpVariable(http_out)
#
# Register service
#
CALL com.WebServiceEngine.RegisterService(serv)
DISPLAY "EchoHttpHeadersService Service registered"
CATCH
    DISPLAY "Unable to create 'EchoHttpHeadersService' Web Service : ",
    STATUS||" ("||SQLCA.SQLERRM||")"
    EXIT PROGRAM (-1)
END TRY

END FUNCTION

FUNCTION echoDocRecord()
    DEFINE ind INTEGER
    DEFINE ok BOOLEAN

    # Check incoming VERB
    IF http_in.verb != "POST" THEN
        LET http_out.code = 400
        LET http_out.desc = "Bad request: method should be POST"
        RETURN
    END IF

    # Check incoming query string
    IF http_in.url.getIndexOF("?MyQuery=OK",1)<=0 THEN
        LET http_out.code = 400
        LET http_out.desc = "Bad request: URL should have MyQuery=OK"
        RETURN
    END IF

    # Check incoming header called MyPersonal
    LET ok = FALSE
    FOR ind = 1 TO http_in.headers.getLength()
        DISPLAY ind||" ",http_in.headers[ind].name,
        ","||http_in.headers[ind].value
        IF http_in.headers[ind].name == "MyPersonal" THEN
            IF http_in.headers[ind].value == "Header" THEN
                LET ok = TRUE
            END IF
        END IF
    END FOR

END FUNCTION
Related concepts
The WebService class on page 2658
The com.WebService class provides an interface to create and manage Genero Web Services.

Choosing a web services style
Genero Web Services 2.0 allows you to create Web Services operations in the following styles:

Table 670: Web Services Styles

<table>
<thead>
<tr>
<th>Web Services Style</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RPC Style Service (RPC/Literal)</td>
<td>Generally used to execute a function, such as a service that returns a stock option.</td>
</tr>
<tr>
<td>Document Style Service (Doc/Literal)</td>
<td>Generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document; this is the MS.Net default.</td>
</tr>
<tr>
<td>RPC Style Service (RPC/Encoded)</td>
<td>Provided only for backwards compatibility with older versions of web services already published.</td>
</tr>
<tr>
<td>Important: This feature is deprecated, and may be removed in a future version.</td>
<td>Important: This style is deprecated by the WS-I organization, and is not recommended, as most Web Service implementations won't support it in the future.</td>
</tr>
</tbody>
</table>

The style of service to be created is specified in the Genero application for the Web Service, using the following methods of the WebOperation class from from the Web Services COM Library (com). The parameters are the same for both methods:

1. The name of the BDL function that is executed to process the Web Service operation
2. The name you wish to assign to the Web Service operation
3. The input record defining the input parameters of the operation (or NULL if there is none)
4. The output record defining the output parameters of the operation (or NULL if there is none)

```groovy
LET op = com.WebOperation.CreateRPCStyle("add","Add", add_in,add_out)
LET op = com.WebOperation.CreateDOCStyle("checkInvoice", "CheckInvoice", invoice_in,invoice_out)
```

Calling the appropriate function for the desired style is the only difference in your Genero code that creates the service. The remainder of the code that describes the service is the same, regardless of whether you want to create an RPC or Document style of service.

**Important:** Do not use the `setInputEncoded()` and `setOutputEncoded()` methods of the `WebService` class from the Web Services COM Library (com), as they apply only to RPC/Encoded Style, which is not recommended.

**Note:** If you add headers to your RPC Style service, choose the Literal serialization mechanism by setting the `encoded` parameter of the `createHeader()` method to FALSE:

```groovy
CALL serv.createHeader(var,FALSE)
```

**Note:** GWS release 2.0 allows you to create RPC Style and Document Style operations in the same Web Service. However, we do not recommend this, as it is not WS-I compliant.

**How Do I ... ?**

These topics provide you with the information needed to perform specific tasks related to Genero Web Services using the SOAP protocol.

**Tip:** See [here](#) for other Web services "How Do I ... ?" topics.

- [Fix Genero 2.10 to 2.11 WSDL generation issue](#) on page 3179
- [How to handle WS security](#) on page 3181
- [How to migrate I4GL web service to Genero](#) on page 3186

**Fix Genero 2.10 to 2.11 WSDL generation issue**

How to convert a WSDL generated from a Genero 2.11 (or later) application to a WSDL as generated by Genero 2.10.

Since Genero 2.11, each BDL variable generates a associated named complexType in the WSDL and references it. While this does not impact the Web service, some tools will generate additional client stubs to follow the WSDL definition with the named complexType. As a result, any client program written from a WSDL generated in 2.10 must be reviewed if it uses a WSDL generated in 2.11 or later.

If you do not want to modify your application, you can use the WSDL conversion tool program to remove the named complexType and add the unnamed equivalent as child node of the parameter variable of all Web service operations, as if the WSDL would have been generated in 2.10.

**WSDL conversion tool**

This program reads a WSDL, looks for all named complexType used in all the web operation parameters and modifies them in order to have unnamed complexType instead.

```groovy
IMPORT XML
MAIN
DEFINE
  doc xml.DomDocument,
  list, elist, tlist xml.DomNodeList,
  node, enode, nnode xml.DomNode,
  i, j, k, idx INTEGER,
  ename, tname STRING

IF num_args() <> 1 THEN
```
CALL display_help()
RETURN 0
END IF

TRY
LET doc = xml.DomDocument.Create()
CALL doc.setFeature("whitespace-in-element-content",FALSE)
CALL doc.load(arg_val(1))
# get the list of input/output message
# check if their names (x) are defined as elements with types (y)
# if yes then
# copy the complextype y definition to element name x
# and remove the complexe type y definition
# for example:
# message
# <wsdl:message name="is_OKIn">
#  <wsdl:part name="parameters" element="fjs:is_OKRequest" />
# </wsdl:message>
# <wsdl:message name="is_OKOut">
#  <wsdl:part name="parameters" element="fjs:is_OKResponse" />
# </wsdl:message>
# element
# <xsd:element name="is_OKResponse"
#  type="s1:is_OKResponse_is_OKResponse" />
# type
# <xsd:complexType name="is_OKRequest_is_OKRequest">
LET list =
  doc.selectByXPath("//wsdl:part[@name='parameters']/@element",
    "wsdl","http://schemas.xmlsoap.org/wsdl/"
)
IF list IS NULL THEN
  DISPLAY "Nothing to convert."
END IF
FOR i=1 TO list.getCount()
  LET node = list.getItem(i)
  LET ename = node.getNodeValue()
  LET idx = ename.getIndexOf(":" ,1)
  IF idx <> 0 THEN
    LET ename = ename.subString(idx+1,ename.getLength())
  END IF
  # get the element
  LET elist =
    doc.selectByXPath("//xsd:element[@name='" || ename || "]",
      "xsd","http://www.w3.org/2001/XMLSchema"
)
  IF elist IS NOT NULL THEN
    FOR j=1 TO elist.getCount()
      LET enode = elist.getItem(j)
      LET tname = enode.getAttribute("type")
      CALL enode.removeAttribute("type")
      LET idx = tname.getIndexOf(":" ,1)
      IF idx <> 0 THEN
        LET tname = tname.subString(idx+1,tname.getLength())
      END IF
      # get the type
      LET tlist =
        doc.selectByXPath("//xsd:complexType[@name='" || tname || "]",
          "xsd","http://www.w3.org/2001/XMLSchema"
)
      IF tlist IS NOT NULL THEN
        FOR k=1 TO tlist.getCount()
          LET node = tlist.getItem(k)
          LET nnnode = node.clone(TRUE)
          CALL nnnode.removeAttribute("name")
          CALL enode.appendChild(nnnode)
        END FOR
      END IF
    END FOR
  END IF
END FOR
FOR k=1 TO tlist.getCount()
    LET node = tlist.getItem(k)
    LET nnode = node.getParentNode()
    CALL nnode.removeChild(node)
END FOR
END IF
END FOR
END FOR
CALL doc.setFeature("format-pretty-print", TRUE)
CALL doc.save("result.wsdl")
DISPLAY "Document is saved in result.wsdl"
CATCH
    DISPLAY "ERROR[" || STATUS || "]"
    FOR i=1 TO doc.getErrorsCount()
        DISPLAY "[", i, "] " , doc.getErrorDescription(i)
    END FOR
END TRY
END MAIN

FUNCTION display_help()
    DISPLAY "Usage: fglrun " || arg_val(0) || " wsdlfile"
END FUNCTION

Example of use:

$ fglrun Convert Genero2_21.wsdl
$ Document is saved in result.wsdl

How to handle WS security
Genero Web Services does not entirely manage WS-Security. We provide XML APIs to help the development of Web Services with security.

Introduction
This topic describes how to handle Web Services security using the demo wssecuritymessage. It is a sample that you can adapt to your needs. The demo will be enhanced to illustrate new features that will be introduced to fully support WS Security.

The demo involves three clients exchanging secured messages. Those clients post and retrieve messages on a secured server. Each client is identified by a certificate and sign their messages.

We assume that you are familiar with security concepts described in topic "Encryption and Authentication Concepts".

The demo assumes that all the clients have sent their public keys to the other clients and to the server. Those keys are kept in each host's (server or clients) keystore. The certificates included in this package are provided for demonstration purposes only. As they are distributed with this package, anybody using this product can decrypt the messages exchanged. Do NOT use them in production.

Server side
We provide 3 handlers to handle WS Security:

- Method com.WebService.registerWSDLHandler() to modify the wsdl to add WS policy.

In this demo, a received message is processed:

1. Identify the sender and validate the sender (search in keystore)
2. Decrypt the symmetric key with the server private key
3. Decrypt the body
4. Check the signature with the sender public key
5. Store the message in the box (thanks to the "To" field, "subject" and "message")
6. Create the outgoing message
7. Sign the outgoing message
8. Encrypt the outgoing message with a generated symmetric key. This symmetric key is then encrypted with the client public key.

**Client side**

The client consists in sending a message and retrieving messages clients sent to it.

Before that, create the client stub from the wsdl:

- `fglwsdl -domHandler myservice.wsdl`

The client stub reference handlers:

- SecureMessageBox_HandleRequest
- SecureMessageBox_HandleResponse
- SecureMessageBox_HandleResponseFault

For more details about client SOAP handlers see Client stub and handlers.

What to do when a message is sent:

- Sign and encrypt the request for the server (WS-Security)
  - sign with client private key
  - encrypt with server public key
- Send key information in the request
  - key to identify the sender/client
  - key to identify the recipient/server
  - key used to encrypt the data (usually a symmetric key encrypted by the recipient public key)
- If the message has to be encrypted for the final recipient (XML-Security)
  - sign the message
  - encrypt the message

What to do to retrieve messages:

- Identify the sender and validate the sender (search in keystore)
- Identify the recipient (should be the server itself)
- Decrypt the request
- Check the signature
- Retrieve messages for the recipient

**SOAP security standards**

The policy documentation can be found [here](#).

The demo policy is divided into sections (make sure that they are named correctly and that the structure is understandable):

- **Security bindings** on page 3183
- **SOAP message security options** on page 3185
- **SignedParts** on page 3185
- **EncryptedParts** on page 3185

WS Security section begins with:

```xml
```
It defines rules.

<wsp:ExactlyOne>

Only one assertion is fulfilled.

<wsp:All>

All the assertions are fulfilled.

Security bindings

There are 3 types of security bindings:

- TransportBinding
- SymmetricBinding
- AsymmetricBinding

The current demo uses Asymmetric binding.

**Asymmetric Binding**

This section is divided in sub sections:

- InitiatorToken
- RecipientToken
- AlgorithmSuite
- Layout
- Additional assertions

AsymmetricBinding is the root node for protection description.

<sp:AsymmetricBinding xmlns:sp=
"http://schemas.xmlsoap.org/ws/2005/07/securitypolicy">

InitiatorToken

InitiatorToken is the message sender (client)

For example:

<sp:InitiatorToken>
  <wsp:Policy>
    <sp:X509Token sp:IncludeToken=
"http://schemas.xmlsoap.org/ws/2005/07/securitypolicy/IncludeToken/AlwaysToRecipient">
      <wsp:Policy>
        <sp:RequireThumbprintReference />
        <sp:WssX509V1Token10 />
      </wsp:Policy>
    </sp:X509Token>
  </wsp:Policy>
</sp:InitiatorToken>

**Note:** The value for the sp:IncludeToken attribute is one contiguous string with no spaces. For this document, it is shown covering two lines.

The token is used for the message signature from initiator to recipient and encryption from recipient to initiator.

The initiator key is a X509 certificate that is always sent to the recipient.

sp:IncludeToken attribute indicates if the token must be included.
IncludeToken/AlwaysToRecipient means each requests sent to the recipient must include the initiator token. But the token is not to be included in messages from recipient to initiator.

The token must send its Thumbprint Reference.

The token must be of type X509 version 1 as defined in "X509 token profile 1.0".

What needs to be done in BDL is described in Client Side section.

To retrieve the thumbprint reference you can use the API function `xml.CryptoX509.getThumbprintSHA1`

To create the x509 certificate use an appropriate tool like `openssl`.

**RecipientToken**

RecipientToken is the message receiver (server)

```xml
<sp:RecipientToken>
  <wsp:Policy>
      <wsp:Policy>
        <sp:RequireThumbprintReference />
        <sp:WssX509V3Token10 />
      </wsp:Policy>
    </sp:X509Token>
  </wsp:Policy>
</sp:RecipientToken>
```

**Note:** The value for the `sp:IncludeToken` attribute is one contiguous string with no spaces. For this document, it is shown covering two lines.

The token is used for encryption from initiator to recipient, and for the message signature from recipient to initiator.

The recipient key is a X509 certificate that is never sent to the initiator.

`sp:IncludeToken` attribute indicates if the token must be included.

Use of the `IncludeToken/Never` means the token is never to be included in any requests between the initiator and the recipient. This is the required and recommended setting.

Instead the recipient ThumbprintReference is sent.

The token must be of type X509 version 3 as defined in "X509 token profile 1.0"

What needs to be done in BDL is described in Server Side section. To retrieve the thumbprint reference you can use the API function `xml.CryptoX509.getThumbprintSHA1`. To create the appropriate certificate use an appropriate tool like `openssl`.

**AlgorithmSuite**

AlgorithmSuite specifies which algorithm is used to encrypt the data.

```xml
<sp:AlgorithmSuite>
  <wsp:Policy>
    <sp:TripleDesRsa15 />
  </wsp:Policy>
</sp:AlgorithmSuite>
```

`TripleDesRsa15` refers to key [http://www.w3.org/2001/04/xmlenc#tripledes-cbc](http://www.w3.org/2001/04/xmlenc#tripledes-cbc).
Layout

Layout describes the way information is added to the message header.

```
<sp:Layout>
  <wsp:Policy>
    <sp:Strict />
  </wsp:Policy>
</sp:Layout>
```

For example, with Strict layout, tokens that are included in the message must be declared before use. For more details on the rules to follow see the security policy specifications section 7.7.

Additional Assertions

PartsToSign

```
<sp:OnlySignEntireHeadersAndBody />
```

The assertion means if there is any signature on the header or the body it applies to the entire header and the entire body not to their child element.

SOAP message security options

```
  <sp:MustSupportRefKeyIdentifier />
  <sp:MustSupportRefIssuerSerial />
</sp:Wss10>
```

- MustSupportRefKeyIdentifier means that initiator and recipient are able to generate and process key identifier reference.
- MustSupportRefIssuerSerial means that initiator and recipient are able to generate and process issuer and token serial reference.

SignedParts

The SignedParts section tells which part of the message should be signed.

```
  <sp:Body />
</sp:SignedParts>
```

- Only the body needs to be signed

EncryptedParts

The section EncryptedParts tells which part of the message should be encrypted.

```
  <sp:Body />
</sp:EncryptedParts>
```

- sp:Body indicates the body message needs to be encrypted

Encrypt the body using the algorithm referenced in assertion AlgorithmSuite:

- create an encryption key using TripleDesRsa15 algorithm (i.e. generate a TripleDES symmetric key and then encrypt it with a RSA1.5 public key) like example2 in crypto key chapter that uses AES256.
- encrypt the body with the created key

To find the exact syntax of security message read the specifications "Web Services Security: SOAP Message Security 1.0".

How to migrate I4GL web service to Genero
Migrate an I4GL web service provider to Genero

This section explains how to migrate a I4GL web service provider to a Genero application providing the same web service in order to let all clients, already accessing that service, unmodified (excepted for the hostname of course).

**Note:** The migration will be based on the SOA zipcode demo in the I4GL package.

**Step 1: Use the I4GL function and the I4GL .4cf configuration file**

Use the I4GL .4cf configuration file to get all information about the I4GL web service

For example, the I4GL zipcode demo has following .4cf configuration file:

<table>
<thead>
<tr>
<th>SERVICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE = publisher</td>
</tr>
<tr>
<td>INFORMIXDIR = /dbs/32bits/ifx/11.70.uc2</td>
</tr>
<tr>
<td>DATABASE = i4glsoa</td>
</tr>
<tr>
<td>CLIENT_LOCALE = en_US.8859-1</td>
</tr>
<tr>
<td>DB_LOCALE = en_US.8859-1</td>
</tr>
<tr>
<td>INFORMIXSERVER = ol_moscou1170uc2</td>
</tr>
<tr>
<td>HOSTNAME = moscou.strasbourg.4js.com</td>
</tr>
<tr>
<td>PORTNO = 9876</td>
</tr>
<tr>
<td>I4GLVERSION = 7.50.xC4</td>
</tr>
<tr>
<td>WSHOME = /dbs/32bits/ifx/11.70.uc2/AXIS2C</td>
</tr>
<tr>
<td>WSVERSION = AXIS1.5</td>
</tr>
<tr>
<td>TMPDIR = /tmp/zipcodedemo</td>
</tr>
<tr>
<td>SERVICENAME = ws_zipcode</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>FUNCTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME = zipcode_details</td>
</tr>
<tr>
<td>[INPUT]</td>
</tr>
<tr>
<td>[VARIABLE]NAME = pin TYPE = CHAR(10) [END-VARIABLE]</td>
</tr>
<tr>
<td>[END-INPUT]</td>
</tr>
<tr>
<td>[OUTPUT]</td>
</tr>
<tr>
<td>[VARIABLE]NAME = city TYPE = CHAR(100) [END-VARIABLE]</td>
</tr>
<tr>
<td>[VARIABLE]NAME = state TYPE = CHAR(100) [END-VARIABLE]</td>
</tr>
<tr>
<td>[END-OUTPUT]</td>
</tr>
<tr>
<td>[END-FUNCTION]</td>
</tr>
<tr>
<td>[DIRECTORY]</td>
</tr>
<tr>
<td>NAME = /home/f4gl/fg/i4gl</td>
</tr>
<tr>
<td>FILE = soademo.4gl,</td>
</tr>
<tr>
<td>[END-DIRECTORY]</td>
</tr>
<tr>
<td>[END-SERVICE]</td>
</tr>
</tbody>
</table>

Then simply copy your I4GL function without any modification into a new Genero file and add the Genero **IMPORT com** instruction at the beginning of the file.

For example, the I4GL soa demo contains the zipcode_details service (soademo.4gl)

```import com

FUNCTION zipcode_details(pin)
    DEFINE state_rec RECORD
        pin CHAR(10),
        city CHAR(100),
        state CHAR(100)
    END RECORD,
    pin CHAR(10),```
sel_stmt CHAR(512);

LET sel_stmt= "SELECT * FROM statedetails WHERE pin = ?";
PREPARE st_id FROM sel_stmt;
DECLARE cur_id CURSOR FOR st_id;
OPEN cur_id USING pin;
FETCH cur_id INTO state_rec.*;
CLOSE cur_id;
FREE cur_id;
FREE st_id;
RETURN state_rec.city, state_rec.state
END FUNCTION

**Note:** you may need some minor code modification for compatibility.

**Step 2: Create a BDL RECORD for the input parameters**

Add a new modular BDL record where all members map to one of your I4GL web service input parameter, and keep the parameter order as defined in I4GL .4cf file.

You must then specify the web service input message name via the Genero XML attribute called XMLName, and assign it to the FUNCTION NAME as defined in the I4GL .4cf file.

For example, in the I4GL zipcode demo there is only one parameter: **pin**. So add the following record at the beginning of the Genero file:

```
DEFINE zipcode_details_in RECORD ATTRIBUTES(XMLName="zipcode_details")
  pin CHAR(10)
END RECORD
```

**Note:** Genero Web Services supports complex data type as input parameters.

**Step 3: Create a BDL RECORD for the output parameters**

Add another modular BDL record where all members map to one of your I4GL web service output parameter, and keep the parameter order as defined in I4GL .4cf file.

You must then specify the web service output message name via the Genero XML attribute called XMLName, and assign it to the FUNCTION NAME as defined in the I4GL .xcf file concatenated to response.

For example, in the I4GL zipcode demo there are two parameters: **city** and **state**. So add following record at the beginning of the Genero file:

```
DEFINE zipcode_details_out RECORD
  ATTRIBUTES(XMLName="zipcode_detailsresponse")
  city CHAR(100),
  state CHAR(100)
END RECORD
```

**Note:** Genero Web Services supports complex data type as output parameters.

**Step 4: Create a BDL wrapper function**

Create a Genero BDL wrapper function without any parameters that will then use the input and output record created at Step 2 and 3 to call the I4GL function passing it the parameters retrieved from the records.

For example, in the I4GL zipcode demo there are 1 input and 2 output parameters. So the BDL wrapper function must use these records to call the I4GL function as following:

```
FUNCTION zipcode_details_g()
  CALL zipcode_details(zipcode_details_in.pin)
  RETURNING zipcode_details_out.city,zipcode_details_out.state
END FUNCTION
```
Step 5: Publish the wrapper function as a Genero web service

Use the COM APIs to publish the I4GL function as a web service based on I4GL .4cf configuration file to get a compatible Genero Web service.

To create a new BDL function in charge of the service publication, you will need the following elements of the I4GL .4cf configuration file:

- The name of the service that is defined in the SERVICENAME entry
- The namespace of the service that is defined as http://www.ibm.com/ concatenated to the FUNCTION NAME
- The name of the function to be published that is defined in the FUNCTION NAME entry

For example, the I4GL zipcode demo has one function published as a Doc/Literal service.

```c
FUNCTION create_zipcode_details_web_service()
    DEFINE serv com.WebService
    DEFINE op   com.WebOperation

    # Create the web service based on the entries of the .4cf file
    # SERVICENAME: The name of service is 'ws_zipcode'
    # FUNCTION NAME: The namespace of the service is built from
    # the base url 'http://www.ibm.com/' concatenated to
    # the NAME of the I4GL function 'zipcode_details'
    #
        "http://www.ibm.com/zipcode_details")

    # Create and publish the Doc/Literal web function based on
    # step 2, step 3 and step 4
    # and from the FUNCTION NAME defined in the .4cf file
    #
    LET op = com.WebOperation.CreateDOCStyle("zipcode_details_g",
        "zipcode_details",
        zipcode_details_in,
        zipcode_details_out)
    CALL serv.publishOperation(op,NULL)

    # Register the service into the SOAP engine
    #
    CALL com.WebServiceEngine.RegisterService(serv)
END FUNCTION
```

Note:  I4GL supports only Doc/Literal services.

Note:  Genero Web Services can contain several BDL functions in the same service. In other words, you can group several I4GL services into the same Genero service.

Step 6: Create the server

I4GL uses Axis as server for its services, but Genero has its own server programmable via the COM library. Create a new file and add the IMPORT com instruction at beginning of the server file, then simply create the main loop in BDL that will process any incoming HTTP request.

The port of the service defined in the I4GL .4cf configuration file (via the PORTNO entry) can be reused by setting the FGLAPPSERVER environment variable to the same value before to run the server. However, only on development or for tests, on production Genero Web Services requires an application server called GAS in charge of load balancing. See the GAS documentation for more details about port configuration for deployment purpose.
For example, to migrate the I4GL zipcode demo, the service must be created in the server before run the main loop as following:

```
MAIN
  DEFINE ret INTEGER
  DEFER INTERRUPT

  # Create zipcode_details service
  CALL create_zipcode_details_web_service()

  # Start the server on port set in FGLAPPSERVER
  # (to be set to same value as PORTNO defined in the .4cf file)
  CALL com.WebServiceEngine.Start()

  # Handle any incoming request in a WHILE loop...
  WHILE TRUE
    LET ret = com.WebServiceEngine.ProcessServices(-1)
    CASE ret
      WHEN 0
        DISPLAY "Request processed."
      WHEN -1
        DISPLAY "Timeout reached."
      WHEN -2
        DISPLAY "Disconnected from application server."
        EXIT PROGRAM  # The Application server has closed the connection
      WHEN -3
        DISPLAY "Client Connection lost."
      WHEN -4
        DISPLAY "Server interrupted with Ctrl-C."
      WHEN -10
        DISPLAY "Internal server error."
    END CASE
    IF int_flag<>0 THEN
      LET int_flag=0
      EXIT WHILE
    END IF
  END WHILE
END MAIN
```

**Note:** With Genero Web Services, one server can contain several services. In other words, you can put all your I4GL services into one server.

**Related information**

Process the requests on page 3171

**Step 7: Configure the database**

Based on the DATABASE entry in the I4GL .4cf configuration file, use the Genero instruction to connect to the informix database at server startup.

For example, in the I4GL zipcode demo the service access the database called: `i4glsoa`. So add following instruction at the beginning of the server file created in step 6:

```
DATABASE i4glsoa
```

**Step 8: Compile and run the Genero service**

Compile and link the 2 Genero files created above and run your Genero service. It will be directly available for any client, and provide the WSDL when requested via a HTTP GET with WSDL as query string.
Example

The Genero web service is accessible on URL: http://hostname:9876/ws_zipcode and can return the WSDL on URL: http://hostname:9876/ws_zipcode?WSDL.

```bash
$ fglcomp -M genero_service.4gl
$ fglcomp -M genero_server.4gl
$ fgllink -o genero_zipcode genero_service.42m genero_server.42m
$ export FGLAPPSEVER=9876
$ fgllrun genero_zipcode.42r
```

Note: The hostname depends on the machine your Genero application is started.

Note: For deploying the service on production you will need the Genero application server (GAS) to load-balance the service. See the GAS documentation about Web services when deployment is required.

Migrate an I4GL web service consumer to Genero

This section explains how to migrate a I4GL web service consumer to a Genero application accessing the same web service. Notice that the migration will be based on the SOA demo in the I4GL package.

**Step 1: Generate the Genero web service stub from an I4GL WSDL**

Use the I4GL WSDL located on the Axis server to generate the Genero web service client stub via the tool called fglwsdl.

For example, the WSDL file of the I4GL zipcode demo is located on $INFORMIXDIR/AXIS2C/services/ws_zipcode/zipcode_details.wsdl. So run the following command:

```bash
$ fglwsdl -noFacets zipcode_details.wsdl
```

It will generate these two Genero files:

- `ws_zipcode_zipcode_detailsservice.4gl`
  - It contains the Genero functions to connect to the server in SOAP over HTTP.
  - Take a look at the file if you are interested in Genero HTTP and XML low-level APIs.
- `ws_zipcode_zipcode_detailsservice.inc`
  - It contains the Genero data types and variables used for XML serialization.
  - Take a look at the file if you are interested in Genero XML to BDL variable mapping.

Note: Option -noFacets is required for this demo because the I4GL CHAR data type will be generated as string in Genero, which can lead to XML serialization error if not present.

**Step 2: Modify the Genero .inc stubs to fix wrong I4GL WSDL**

The I4GL WSDL contains namespace declaration for all I4GL web service data types, but in practice the I4GL axis server doesn't care about namespaces, but Genero does. So you have to open the generated Genero .inc file and remove all attributes called `XMLNamespace` and `XSTypeNamespace`.

For example, the generated .inc file from the I4GL WSDL must be modified as following:

```bash
# File: ws_zipcode_zipcode_detailsservice.inc
# GENERATED BY fglwsdl 101601
# THIS FILE WAS GENERATED. DO NOT MODIFY.

GLOBALS
...`

` # TYPE : tzipcode_details`
# TYPE tzzipcode_details RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="zipcode_details")
  #,XSTypeNamespace="http://www.ibm.com/zipcode_details")
  pin STRING ATTRIBUTES(XMLName="pin")
END RECORD

# TYPE : tzzipcode_detailsresponse
#
TYPE tzzipcode_detailsresponse RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="zipcode_detailsresponse")
  #,XSTypeNamespace="http://www.ibm.com/zipcode_details")
  city STRING ATTRIBUTES(XMLName="city")
  state STRING ATTRIBUTES(XMLName="state")
END RECORD

# Operation: zipcode_details
#
# FUNCTION: zipcode_details_g()
#   RETURNING: soapStatus
#   INPUT: GLOBAL zipcode_details
#   OUTPUT: GLOBAL zipcode_detailsresponse
#
# FUNCTION: zipcode_details(p_pin)
#   RETURNING: soapStatus ,p_city ,p_state
#
# FUNCTION: zipcode_detailsRequest_g()
#   RETURNING: soapStatus
#   INPUT: GLOBAL zipcode_details
#
# FUNCTION: zipcode_detailsResponse_g()
#   RETURNING: soapStatus
#   OUTPUT: GLOBAL zipcode_detailsresponse
#
# DEFINE zipcode_details tzzipcode_details
# ATTRIBUTES(XMLName="zipcode_details")
# ,XMLNamespace="http://www.ibm.com/zipcode_details")
#---
# DEFINE zipcode_detailsresponse tzzipcode_detailsresponse
# ATTRIBUTES(XMLName="zipcode_detailsresponse")
# ,XMLNamespace="http://www.ibm.com/zipcode_details")
END GLOBALS

Note: Genero Web Services provides a lots of XML mapping attributes.

Step 3: Include the generated stub into your I4GL application

Add in all I4GL files calling a web service the generated .inc stub with a GLOBALS instruction.

For example, in the I4GL zipcode demo, only the clsoademo.4gl file uses Web services. So add following line at beginning of the file:

```
GLOBALS "ws_zipcode_zipcode_detailservice.inc"
```

MAIN
...
END MAIN
**Note:** This allows access to the Genero global variables and data types used in the web service call, so as the Genero global `wsError` record to retrieve error codes if any.

**Step 4: Modify the I4GL web service function call**

The Genero Web service function name is defined in the generated .4gl file and must be used instead of the I4GL function name.

For example, in the I4GL zipcode demo, the web service function name is `cons_ws_zipcode` and must be renamed to `zipcode_details` as following:

```plaintext
FUNCTION func_cons_ws_zipcode()
  DEFINE state_rec RECORD
    pin CHAR(10),
    city CHAR(100),
    state CHAR(100)
  END RECORD;

  # Genero web service status returning
  # whether web function call was successful or not
  # DEFINE soapstatus INTEGER

  # I4GL web service function name is 'cons_ws_zipcode'
  CALL cons_ws_zipcode("97006")
  # RETURNING state_rec.city, state_rec.state

  # Genero web service function name is 'zipcode_details'
  CALL zipcode_details("97006")
    RETURNING soapstatus, state_rec.city, state_rec.state
  ...
END FUNCTION
```

**Note:** In Genero Web Services there is an additional returned parameter, `soapstatus`. If it contains 0 the operation was a success, otherwise an error occurred.

**Step 5: Handle Genero Web Services errors**

I4GL web service errors are returned on a non conventional SOAP fault what cannot be handled in Genero. However the errors are handled through the additional returned parameter `soapstatus` that must be checked after each web service call. If its value is not zero, an error has occurred and can be retrieved via the global Genero `wsError` record defined in the above generated .inc file.

**Example**

In the Genero Web Service you must check the soap status after each web service call:

```plaintext
FUNCTION func_cons_ws_zipcode()
  DEFINE state_rec RECORD
    pin CHAR(10),
    city CHAR(100),
    state CHAR(100)
  END RECORD;

  # Genero web service status returning
  # whether web function call was successful or not
  # DEFINE soapstatus INTEGER

  # Genero web service function call
  CALL zipcode_details("97006")
    RETURNING soapstatus, state_rec.city, state_rec.state

  # Check soap status for errors after zipcode_details call
  IF soapstatus<>0 THEN
```
# Display error information from the server
DISPLAY "Error:
DISPLAY " code ":,wsError.code
DISPLAY " ns ":,wsError.codeNS
DISPLAY " desc ":,wsError.description
DISPLAY " actor ":,wsError.action
ELSE

# Display results
DISPLAY "n------------------------n"
DISPLAY "SUPPLIED ZIP CODE: 97006 n"
DISPLAY "------------------------n"
DISPLAY "RESPONSE FROM WEB SERVICE n"
DISPLAY "------------------------n"
DISPLAY "CITY",state_rec.city
DISPLAY "n STATE",state_rec.state
DISPLAY "n------------------------n"
END IF

END FUNCTION

---

**Step 6: Compile and run the Genero client**

Then simply compile your modified I4GL application for Genero and execute it. Your application will then connect to the web service passing and returning the parameters as it were only simple BDL function calls.

For example, to compile your I4GL web service application for Genero, you must do the following commands:

```shell
$ fglcomp -M ws_zipcode_zipcode_detailsservice.4gl
$ fglcomp -M clsoademo.4gl
$ fgllink -o clsoademo.42r clsoademo.42m ws_zipcode_zipcode_detailsservice.42m
$ fgllink clsoademo.42r
```

**Standalone Axis server is buggy**

The I4GL standalone axis server adds an extra CR LF after the body of the SOAP HTTP post response what leads the Genero client to return the error message: **Body content bigger than expected.** This is not allowed as defined in HTTP [RFC2616].

**Important:** Axis works as expected if loaded from Apache server.

---

**RESTful Web services**

With Genero Business Development Language, you can write a RESTful Web Services client or server application.

**The Calculator tutorial**

There are several ways to implement REpresentational State Transfer (REST) Web services. This documentation uses a tutorial based on a *calculator Web services application*, using the HTTP interface with URIs and verbs.

This tutorial is provided from both the client and the server perspective. In Writing a Web services client application on page 3195, you learn how to create a client application that accesses the Add function in a calculator Genero Web services server application, with the option to perform the data exchange in either JSON or XML. In Writing a Web Services server application on page 3204, you learn how to implement the Web service on the server side.

**REST Client-Server Separation**

In REST architecture there is a client-server separation and each works independent of the other. Clients or user interfaces do not know, for instance, about data storage on the server side, and servers are not concerned with the user interface or the user state. Each can be developed independently.
To work, there must be a uniform interface which links the client and server. HTTP is the uniform interface REST uses for the communication between the client and the server. In terms of the design of a REST Web service client you use:

- HTTP verbs (GET, PUT, POST, DELETE) to indicate the action to be performed on the Web service resource.
- URIs (with resource name) to identify the server function or resource needed.

The following is an example of a request to calculator "add" resource on a Web service listening on port 8090 on localhost.

```
GET http://localhost:8090/add?a=1&b=2
```

- HTTP request headers are needed (Accept and Content-type), to specify how to receive and deliver content, JSON or XML).

**REST Web Service Resources**

The RESTful Web services server provides access to resources that a RESTful Web services client can both access and modify, if allowed to do so. Web service resources are manipulated through representations. Representations are the state of the resource transferred between the client and the server. Typically, these representations are sent and received in JSON or XML format. If the client representation is to get some records from a database, the server does not send its database, instead it sends some JSON or XML that represents these records.

**HTTP Request/Response Messages**

Each HTTP request–response message between the client and the server must be self-descriptive and include enough information to process the message.

**Note:** To see incoming and outgoing messages (URI, HTTP headers, and HTTP bodies), set the FGLWSDEBUG environment variable before starting the GWS application. For more information on setting the debug mode, see *Debugging* on page 3106.

The Web services client application request delivers state via body contents, query parameters, request headers, and the requested URI (the resource name). If you were to view the request in the standard output, you would see an interaction similar to that shown here. Comment lines (#) have been added to highlight the exchange.

```
# Connecting to Web server
Host :localhost
Port :8090
Via proxy :no
IPv :4

# Send request to the add resource with query parameters (a & b), values (1 & 2), and HTTP version
GET /add?a=1&b=2 HTTP/1.1

# send header information
Accept: application/json
Content-Type: application/json
User-Agent: GWS Agent (Build 1449830511)
Host: localhost:8090
Connection: close
Date: Tue, 29 Mar 2016 08:28:02 GMT
Content-Length: ???
Content-Encoding: ???

The Web services server response delivers state to the client via body content, response codes, and response headers. An example of the standard output of the response from the Calculator Web service is shown.

```
# Processing request... GET http://localhost:8090/add?
HTTP/1.1 200 OK

# Send HTTP response headers
Web Services APIs

The Genero APIs for creating Web services can be found in the Library section of this manual. See The com package on page 2658, The xml package on page 2774, and The util package on page 2574.

Writing a Web services client application

Create, configure and deploy a RESTful Genero Web Services (GWS) client.

In this section, you will learn about the basic steps of creating a client application to access the "Add" function in the calculator RESTful GWS Web Service that is detailed in the Calculator RESTful Web services server application. The topics explain:

1. What functions are available on the Server, and which query parameters/arguments to use with the URIs (resource). See Step 1: Obtain information about Web service resources on page 3195.
2. What GWS packages you need, see Step 2: Import extension packages (com, xml, util) on page 3196.
3. What Genero Business Development Language records you need to define, see Step 3: Define the records on page 3197.
4. How to request the Web service functions. Step 4: Build the HTTP request on page 3198
5. How to get the result and handle errors. Step 5: Process the HTTP response on page 3199.

In discussing the above five steps, the Calculator RESTful Web services client application is used to provide code examples.

Step 1: Obtain information about Web service resources

To access a remote RESTful Web services server, you must first get information about the services offered by a server from the service provider.

Note: This is in contrast to how you get this information when using the Simple Object Access Protocol (SOAP), where a Web Services Description Language (WSDL) file provides you with the necessary information and you can download the WSDL directly from the Web Service.

In REST, the name of the resources or functions and what query parameters or arguments to use with them are generally all that you require, as this information contains everything the client needs to interact with the required resource.

Add Function

In the code example for the Calculator RESTful Web services server application, we know that the calculator demo service performs various calculator functions. Our client application simply wants to access the function to add values.

```gws
# Calculator Web Service add function
FUNCTION add()
    LET add_out.r = add_in.a + add_in.b
    LET add_out.status.code = 0
    LET add_out.status.desc = "OK"
```
The HTTP request must therefore use an URI with a resource name and the required parameters that matches the calculator function defined in the calculator Web service server side. Therefore, **Add** becomes the resource name part of the URI we need to include in our code.

```
# Sample request to add two numbers
GET http://localhost:8090/add?a=1&b=2
```

In the next step we start to code the client application, **Step 2: Import extension packages (com, xml, util)** on page 3196

**Step 2: Import extension packages (com, xml, util)**
The functions you need to create a REST Web Service client application are contained in the classes that make up the **com** package of the Genero Web Services (GWS). Use the `IMPORT` statement to include the required packages.

Since this example application also uses **json** and **xml** class data types for the data exchange, you need to include the following lines at the top of your module as instructions to import the required packages:

```
IMPORT com    # imports the Genero Web Services Extension package
IMPORT xml    # imports the Genero Web Services xml package
IMPORT util   # imports the util package which provides a set of classes to convert to and from JSON
```

Inside your module's "MAIN" code block:

- Declare variables of the **com** class to handle the HTTP request and response.
- Declare **xml.DomDocument** and **xml.DomNode** objects of the **xml** class to handle the XML option for data exchange.

```
MAIN
    DEFINE req com.HttpRequest   # Declare a variable of the com.HttpRequest class
    DEFINE resp com.HttpResponse # Declare a variable of the com.HttpResponse class
    DEFINE doc xml.DomDocument   # Declare two variables of the xml class for XML data serialization
    DEFINE node xml.DomNode
    ...
END MAIN
```

In the next step we define some records **Step 3: Define the records** on page 3197

**Related concepts**
The **com package** on page 2658
The Genero Web Services **com** package provides classes and methods that allow you to perform tasks associated with creating Services and Clients, and managing the services.

The **util package** on page 2574
These topics cover the classes for the **util** package.

The **xml package** on page 2774
The Genero Web Services XML package provides classes and methods to handle any kind of XML documents, including documents with namespaces.

**Step 3: Define the records**
In this step you define the records you need for the HTTP Request and Response and the processing of the data.

Declare a record to use for HTTP Request/Response status. The calculator demo application creates a user-defined `TYPE(TYP_status)` to reference when defining variables.

```plaintext
TYPE TYP_status RECORD
code INTEGER, # The HTTP status code
desc STRING    # The HTTP status description
END RECORD
```

Declare a public record called `info` to hold the pieces of information that make up the HTTP request you send out and that comes back in the response from the Web service. You will use this when processing the data and outputting it for display.

```plaintext
PUBLIC DEFINE info RECORD
  url     STRING,       # URI of resource on the server
  verb    STRING,       # HTTP method (e.g. POST, PUT, GET, or DELETE )
    # For HTTP Request
  reqtype STRING,       # Request type identifier (e.g. Content-Type)
  request STRING,       # Request data format (e.g. application/json, or
  application/xml)
  status STRING,       # Status of the HTTP Request
    # For HTTP Response
  resptype STRING,      # Response type identifier (e.g. Accept)
  response STRING,      # Response data format (e.g. application/json, or
  application/xml)
  result RECORD         # Use this record for runtime execution errors
    code INT,
    desc STRING
END RECORD
END RECORD
```

Declare two records, one (`add_in`) to hold operands for the add calculation and another (`add_out`) to hold the result of the calculation and response status. Recall that the type `TYP_status` was defined at the top of the module.

```plaintext
DEFINE
  add_in RECORD         # Declare a record with 2 integer variables to
    # hold operands for add calculation
    a INTEGER,
    b INTEGER
END RECORD,
  add_out RECORD        # Declare a record to hold result
    status TYP_status,  # A record of TYP_status for HTTP response status
    r INTEGER           # A variable for calculation result
END RECORD
```

At this stage we are ready to code the HTTP Request, **Step 4: Build the HTTP request** on page 3198.
**Step 4: Build the HTTP request**

In this step you code the HTTP request and perform the request to the server to add two numbers.

Include code inside a **TRY/CATCH** block to trap runtime exceptions. Assign two values to fields in the *add_in* record as operands for the calculation. For details about the *add_in* record we use in this topic, see **Step 3: Define the records** on page 3197.

```
TRY
    LET add_in.a = 1
    LET add_in.b = 2
CATCH
    ...
    ...
END TRY
```

Recall we defined the variable `req` as an object of the `com.HTTPRequest` class earlier, see **Step 2: Import extension packages (com, xml, util)** on page 3196. We instantiate this now by invoking the `com.HttpRequest.Create` class method to create an URI for our HTTP request; adding to the URI string:

- The resource name or name of the server function, "add" in our case.
- A question mark ("?"), to indicate a query string.
- A query string that contains two key/value pairs in the format "field=value" separated by an ampersand ("&"), for example ("a=1&b=2"). They make up the query parameters or arguments required by the server's "add" function which will be extracted for processing by the Web service. We assign the values for the calculation from the "add_in" record.

```
LET req = com.HttpRequest.Create("http://localhost:8090/add?a=" || add_in.a || ";b=" || add_in.b)
```

**Note:** In our example, we anticipate the calculator Web server is on the localhost. For a production environment you need to take care of URI parsing: making sure that the URI matches what your service expects.

Set the HTTP method with the "GET" verb to request the service from the calculator Web resource. We do this by calling the `com.HTTPRequest` object's `setMethod` function referenced by the `req` variable.

```
CALL req.setMethod("GET")
```

Next we add the Accept and Content-Type headers to the `com.HTTPRequest` object referenced by the `req` variable by calling the `setHeader` function. These headers specify to the Web service how we intend to receive and deliver content in the message body's media type, JSON or XML. Our preference is for JSON.

```
CALL req.setHeader("Content-Type", "application/json")
CALL req.setHeader("Accept", "application/json")
```

Finally, we are ready to perform the HTTP request and call the `com.HTTPRequest` object's `doRequest` function.

```
CALL req.doRequest()
```

In the next step we handle the response from the Web service, **Step 5: Process the HTTP response** on page 3199.

**Related concepts**

`com.HTTPRequest methods` on page 2714
Methods for the `com.HTTPRequest` class.

**Step 5: Process the HTTP response**

In the final step you process the HTTP response; check for errors, and process the data.

At this stage a response to our request from the Web service has been received and is stored in the variable, `resp`. We defined the variable `resp` as an object of the `com.HttpResponse` class earlier, see Step 2: Import extension packages (com, xml, util) on page 3196. Now it is time to process the response.

```plaintext
LET resp = req.getResponse()
```

Start checking for errors. First get the HTTP status code returned in the response by calling the `com.HttpResponse` object's `getStatusCode` function referenced by the `resp` variable. Assign the status code to the "status" field of the `info` record (for details about this record see Step 3: Define the records on page 3197).

```plaintext
LET info.status = resp.getStatusCode()
```

The standard HTTP code of 200 indicates a successful operation, so we check for this before looking at the data.

```plaintext
IF info.status = 200 THEN
```

If the HTTP response was good, we save the value for Content-type response header to the "resptype" field of the `info` record. The Content-type header defines the type associated with the message body's byte sequence. REST APIs commonly use "application/json" or "application/xml" to reveal the format of the message body.

```plaintext
LET info.resptype = resp.getHeader("Content-Type")
```

**Process for XML**

```plaintext
IF info.resptype.indexOf("/xml",1) THEN
  LET doc = resp.getXmlResponse()
  LET node = doc.getDocumentElement()
  CALL xml.Serializer.DomToVariable(node, add_out)
  LET info.response = node.toString()
ELSE # JSON response processing
  [...]
END IF
```

If the Content-type indicates XML format, we store the HTTP response as data in the `xml.DomDocument` object referenced by the `doc` variable using the `getXmlResponse` function. We then get a reference to the root node of the `doc` variable object by instantiating the `node` variable defined as an object of the `xml.DomNode` class using the `getDocumentElement` function.

Recall the `doc` and `node` variables were defined earlier, see Step 2: Import extension packages (com, xml, util) on page 3196.

To serialize the XML data into the `add_out` variable, we pass a reference to the `node` object variable in a call to the `xml Serializer.DomToVariable` function. To convert the data referenced in the `node` object variable to string, we use the `xml.DomNode.toString` function to store it in the "response" field of the `info` record.

**Process for JSON**

If the Content-type does not indicate XML format, then we process the response for JSON, as we anticipate this as the only other option REST APIs use to format the message body.

We store the HTTP response as a string in the "response" field of the `info` record with a reference to the `resp` variable, object of the `com.HttpResponse` class, using the `getTextResponse` function. Then we pass a
reference to the info record in a call to the util.JSON.parse() function to convert the HTTP response to JSON format into the add_out record.

```plaintext
IF info.resptype.getIndexOf("/xml",1) THEN  
  # XML response processing  
  [...]  
ELSE # JSON response processing  
  LET info.response = resp.getTextResponse()  
  CALL util.JSON.parse(info.response, add_out)  
END IF
```

### Outputting to the display

Finally, we output the HTTP response to the display depending on the status code.

```plaintext
IF add_out.status.code = 0 THEN  
  DISPLAY add_in.a, "+", add_in.b, "+", add_out.r # Display the response, status and result  
ELSE  
  DISPLAY ", add_out.status.code, "] ", add_out.r  
END IF
```

### Handling Errors

If the HTTP request failed, we handle the error by formatting the HTTP response status code and description into the "response" field of the info record. Other program errors are caught in the CATCH block and stored in "result" fields of the info record.

```plaintext
TRY  
  [...]  
  IF info.status = 200 THEN  
    [...]  
  ELSE  
    LET info.response = SFMT("[%1] %2",resp.getStatusCode(),  
    resp.getStatusDescription())  
    END IF  
CATCH  
  # Catch other runtime execution errors from the SQLCA diagnostic record  
  LET info.result.code = status  
  LET info.result.desc = sqlca.sqlerrm  
END TRY
```

This completes the tutorial for the calculator demo client application. We have seen the basic steps that a RESTful client application must perform in order to carry out a simple request to a Web service. To review the complete source code, see The RESTful calculator demo source on page 3210.

Each Web services client application will be different in the type of processing that is done. For more examples of Web service applications, see the code samples provided with the package in demo/WebServices.

**Related concepts**
- com.HTTPResponse methods on page 2738
  Methods for the com.HTTPResponse class.
- **Configure a WS client to connect via an HTTP Proxy**
  Configuration steps to connect via a HTTP proxy.

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.

1. Add the location of the proxy to fglprofile with the proxy.http.location entry.
Add the entry `proxy.http.location` to your `fglprofile`. For the value, provide the IP address of the HTTP proxy and the port number where the HTTP proxy is listening, separated by a colon. For example, to have a client connect via a HTTP proxy located at the IP address "10.0.0.170" and listening on port number "8080", add this entry to your `fglprofile`:

`proxy.http.location = "10.0.0.170:8080"`

**Note:** To configure the client to connect via an HTTPS proxy, replace `http` with `https`.

2. Define the list of host names the client will **not** have to connect to via a proxy with the `proxy.http.list` entry.

Add the entry `proxy.http.list` to your `fglprofile`. For the value, provide a semi-colon separated list of clients. For example, to exclude all hosts beginning with "www.mycompany.com" or "www.google." from connecting via a HTTP proxy, add this entry to your `fglprofile`:

`proxy.http.list = "www.mycompany.com;www.google."`

**Configure a WS client to use IPv6**

Configuration steps to customize IPv6 for a WS client.

A Web Services client program can access a WS server using IPv6.

URLs that map to IPv6 addresses will be automatically handled by the Web Services library. It is also possible to specify an IPv6 address directly as URL in your BDL code by enclosing the address in [ ] square brackets, for example:

```
LET myURL = "http://[fe80::20c:29ff:fe05:9ca3]:80/index.html"
```

By default, the WS library will automatically use IPv6 addresses if available, and fallback to IPv4 if not. To overcome the default behavior, you can explicitly specify the IP version.

Indeed, the platform where WS client programs execute must support IPv6.

1. If needed, force the IP version with the `ip.global.version` entry in `fglprofile`, by specifying "4" for IPv4 or "6" for IPv6.

   For example, to force IPv4 (when IPv6 is available):

   `ip.global.version = "4"
```

2. When using IPv6 for link-local addresses, if several network interfaces exist on the machine, you can explicitly specify what interface must be used with the `ip.global.v6.interface.name` or `ip.global.v6.interface.id` entry in `fglprofile`.

   In order to specify the IPv6 network interface by name, use:

   `ip.global.v6.interface.name = "eth0"

   **Important:** The `ip.global.v6.interface.name` entry is not supported on Microsoft™ Windows® platforms.

   In order to specify the IPv6 network interface by id, use:

   `ip.global.v6.interface.id = "2"

**Related reference**

*IPv6 configuration* on page 3240

**Authenticate the WS client to a server**

Configuration steps to authenticate the client to a server (HTTP authentication).

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: Use the `comHTTPRequest.setAuthentication` on page 2726 API instead.

1. Add HTTP authenticate entries to `fglprofile`. 
To connect to a server with HTTP Authentication, define the client login and password with the same values as registered on the server side. These entries must be defined with an unique identifier (`httpauth` in this example) to define a HTTP Authentication with "mylogin" as login and "mypassword" as password:

```
authenticate.httpauth.login = "mylogin"
authenticate.httpauth.password = "mypassword"
```

See [RFC2617] for more details.

2. Encrypt the password.

Due to security leaks, it is recommended that you NOT have a password in clear text. The Genero Web Services package provides the tool `fglpass`, which encrypts a password with a certificate that is readable only with the associated private key. To encrypt the HTTP authentication password:

a) Encrypt the clear text password with `fglpass` using the client certificate.

```bash
$ fglpass -e -c MyClient.crt
Enter password :mypassword
```

**Note:** `fglpass` outputs the encrypted password on the console but can be redirected to a file.

b) Modify the HTTP authentication password entry by specifying the security configuration to use to decrypt it (id1 in our case)

```
authenticate.id2.password.id1="HWTFu8QE2t3e5D4joy7js8mB95oOGTzLmcAor9j5DS+C
loillGCwZvZ9eWpfmIWSON9IwoiJheYxfnu20uaGQmmiUGiHxT634lePXNSi0u32Nt1Vp9t6RcsO
Wn/p9a6D4Xti9iH7w71QvXhqC9uam391Q3GhHwXOMM1Y/c8Y="
```

**Note:** Hard returns have been added to the code sample above, for the purpose of printing and viewing within this document. The value for `authenticate.id2.password.id1` is a single string with no spaces.

**Note:** The size of the encrypted password depends on the size of the public key, and can change based on the certificate used to encrypt it.

3. Configure the client to authenticate to a server.

As a client is able to connect to different servers that do not know the client with the same login and password, it is necessary to specify the login and password that correspond to each server. To authenticate the client known as "myclient" and with the password `passphrase` by the server `myserver`, add the following entry:

```
ws.myserver.authenticate = "httpauth"
```

**Related tasks**

Configure a WS client to access an HTTPS server on page 3131

Configuration steps to access a server in HTTPS.

**Authenticate the WS client to a proxy**

Configuration steps to authenticate the client to a proxy (proxy authentication).

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.

1. Add an HTTP authenticate entry to `fglprofile`.

   To connect via a proxy with HTTP Proxy Authentication, it is necessary to define the client login and password as registered on the HTTP proxy.

   The following two entries must be defined with an unique identifier (`proxyauth` for our example) to define a HTTP Proxy Authentication with `myapplication` as login and `mypassword` as password:

```
authenticate.proxyauth.login = "myapplication"
authenticate.proxyauth.password = "mypassword"
```

See [RFC2617] for more details.
2. For proxy authentication, an entry must be made to the HTTP proxy configuration in order to authenticate a client.

   To authenticate a client known as myapplication and with mypassword as password by the HTTP Proxy, add the following entry to the HTTP proxy configuration:

   ```
proxy.http.authenticate = "proxyauth"
   ```

   **Note:** To authenticate the client to a HTTPS proxy, replace `http` with `https`.

**Configure a WS client to access an HTTPS server**

Configuration steps to access a server in HTTPS.

To configure access to an HTTPS server, you need a client certificate.

**Important:** On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain® typically holds the server certificate authority list. Therefore, the fglprofile security settings are ignored with the exception of the following: security.global.ca, security.global.ca.lookuppath, and security.global.systemca.

Before you begin, there are options to consider depending on how you wish to use the client certificate:

- If you do not have the certificate information in your fglprofile, Genero Web Services creates a certificate for you. This is an implicit or temporary certificate that is valid for a session only. For more information see HTTPS configuration on page 3132.

  **Note:** For the implicit certificate, no configuration is required.

- Alternatively, for stronger security, you generate a client certificate of your own, configure your application to use the client certificate generated, and add the configuration details to fglprofile. Follow the steps outlined in this procedure.

  **Note:** In a production environment, some servers provide a client certificate and you use the certificate as provided, and add the configuration details to fglprofile.

The openssl command line tool can be used to create your own certificates for the configuration of secured communication. The following steps outline the configuration process:

1. To create the client certificate, follow the procedure described in Create the client certificate on page 3132.
2. To configure fglprofile for the client certificate, follow the procedure in Configure for the client certificate on page 3134.
3. To configure fglprofile for the certificate authority list, see Configure for the certificate authority list on page 3134.
4. Add configuration entries for the server to fglprofile. For an example, see FGLPROFILE: HTTP(S) Proxy Authentication on page 3243.

   The Genero Web Services client needs a set of configuration entries that specify the security configuration when accessing an HTTPS server. The following entries must be defined with an unique identifier (such as myserver):

   ```
   ws.myserver.security = "id1"
   ```

   (line breaks added for document readability)

   - The unique identifier myserver can be used in the BDL client code in place of the actual URL.
   - The security entry value (id1 in this example) must match the unique identifier defined by the client security entry created in Configure for the client certificate on page 3134.

**Related concepts**

- Configuring the apache web server for HTTPS on page 3233
- Certificates in practice on page 3137
- Procedures and tools for creating, importing, and viewing certificates and keys.
- Encryption and authentication on page 3126
A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

**Accessing secured services** on page 3129

Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web Service.

**Writing a Web Services server application**

To create a RESTful Genero Web services server application, there are a minimum of five steps that the server application must handle.

In discussing the five steps, the **Calculator RESTFul Web services server application** is used to provide code examples.

**Step 1: Import extension packages**

Extension packages include classes and functions necessary for your Web services server application. Use the IMPORT statement to include these packages.

Include the following lines at the top of your module as instructions to import the required libraries:

```
IMPORT com   # imports the Genero Web Services Extension package
IMPORT util  # imports the util package which provides a set of classes to convert to and from JSON
```

Methods to create a REST Web Service server application are contained in the classes that make up the com library of the Genero Web Services (GWS). See The com package on page 2658.

The calculator demo application also uses methods from the util.JSON class for data exchange. See The util package on page 2574.

**Step 2: Listen for requests**

Listen for an incoming request.

Define an object variable using the com.HTTPServiceRequest class identifier. This variable will reference the incoming HTTP service request. In addition, define an INTEGER variable to hold an error status, if needed.

```
DEFINE ret INTEGER
DEFINE req com.HTTPServiceRequest
```

Start the server engine with the method com.WebServiceEngine.Start().

```
DEFER INTERRUPT
   # Start the server
   DISPLAY " Starting server...."
   # Starts the server on the port number specified by the FGLAPPSERVER environment variable
   # (EX: FGLAPPSERVER=8090)
   CALL com.WebServiceEngine.Start()
   DISPLAY "The server is listening."
```

Listen for an incoming request using com.WebServiceEngine.getHTTPServiceRequest. When a request is received, the variable req references the HTTP service request object. You can use the same object to send a response.
Include a CATCH block to trap runtime exceptions. For a RESTful Web service, include a check for error -15565, which is returned when an incoming request cannot be returned.

```plaintext
# create the server
WHILE TRUE
  TRY
    LET req = com.WebServiceEngine.getHTTPServiceRequest(-1)
    ... parse and process the request
  CATCH
    LET ret = STATUS
    CASE ret
      WHEN -15565
        DISPLAY "Disconnected from application server."
        EXIT WHILE
      OTHERWISE
        DISPLAY "[ERROR] " || ret
        EXIT WHILE
    END CASE
  END TRY
END WHILE
```

For more information:
- [com.WebServiceEngine methods](#) on page 2676
- [The HTTPServiceRequest class](#) on page 2688

**Step 3: Parse the request**

A request is stored in an instance of a com.HTTPServiceRequest object. Use methods of the com.HTTPServiceRequest class (among others) to parse out the details of the request.

An HTTP service request has been received and stored in an instance of a com.HTTPServiceRequest object. To use the details of the request, the next step is to parse the request into a record designed to hold the pieces of the request.

This topic details how the calculator demo server application parses the instance of the HTTPServiceRequest object. While your specific HTTP service requests may differ in the details, the parsing needs will be similar.

Define a record to hold the pieces of information that come in with a request. The demo creates a user-defined type (reqInfoTyp) to reference when defining the record.

```plaintext
TYPE reqInfoTyp RECORD
  method STRING,
  ctype STRING,       # check the Content-Type
  informat STRING,   # short word for Content Type
  caccept STRING,    # check which format the client accepts
  outformat STRING,  # short word for Accept
  path STRING,
  query STRING,      # the query string
  items DYNAMIC ARRAY OF RECORD
    name STRING,
    value STRING
  END RECORD
END RECORD
```

Define a variable based on the type.

```plaintext
DEFINE m_reqInfo reqInfoTyp
```
Call a function that takes the variable referencing the instance of the `com.HTTPServiceRequest` object as input. The purpose of the function will be to parse the HTTP service request into its components.

```call
CALL getReqInfo(req)
```

### The `getReqInfo` function

This function uses both the `HTTPServiceRequest` and `StringTokenizer` classes and methods to parse the request into the `reqInfoTyp` record.

```function
FUNCTION getReqInfo(req)
```

Define the variables needed. The variable `req` references the instance of the HTTP service request object. The variables `str`, `val`, `token`, and `i` are used when parsing out details with the `StringTokenizer` classes and methods.

```define
DEFINE req com.HTTPServiceRequest
DEFINE str, val base.StringTokenizer
DEFINE token STRING
DEFINE i INT
```

For the remainder of this topic, you are retrieving data from the instance of the HTTP service request object (referenced by the variable `req`) and populating the record variable designed to hold this data (`m_reqInfo`). Initialize `m_reqInfo` to NULL. This ensures that there are no pre-existing values in the record variable.

**Note:** The variable `m_reqInfo` record was defined at the top of the module, and therefore can be used in this function.

```initialize
INITIALIZE m_reqInfo TO NULL
```

Retrieve the value of the Content-Type request header. The Content-Type request header defines the format of the incoming message body. REST APIs commonly use "application/json" or "application/xml" to reveal the format of the message body. The server application anticipates the Content-Type to be either JSON or XML. The custom `getHeaderByName` function retrieves the value of the Content-Type header, and based on the return value, populates the input format variable (`m_reqInfo.informat`) with either "XML" or "JSON".

```let
LET m_reqInfo.c_type = getHeaderByName(req,"Content-Type")
IF m_reqInfo.c_type.getIndexOf("/xml",1) THEN
    LET m_reqInfo.informat = "XML"
ELSE
    LET m_reqInfo.informat = "JSON"
END IF
```

Retrieve the value for Accept request header. The Accept request header is where the client application conveys its response preference. The server application expects the Accept request header to be either JSON or XML. The custom `getHeaderByName` function retrieves the value of the Accept header, and based on the returned value, populates the output format variable (`m_reqInfo.outformat`) with either "XML" or "JSON".

```let
LET m_reqInfo.c_accept = getHeaderByName(req,"Accept")
IF m_reqInfo.c_accept.getIndexOf("/xml",1) THEN
    LET m_reqInfo.outformat = "XML"
ELSE
    LET m_reqInfo.outformat = "JSON"
END IF
```
Parse out the HTTP method (verb) of the HTTP service request with the function 
com.HTTPServiceRequest.getMethod(), and populate the method variable (m_reqInfo.method) with 
the result.

LET m_reqInfo.method = req.getMethod()

While possible values could include GET, POST, PUT, HEAD, and DELETE, our demo server application expects 
GET, and the processing part of the server application code does not test or code for any verbs aside from GET.

Parse out the path and the query. Retrieve the URL resource using the function 
com.HTTPServiceRequest.getUrl. To parse out the path and the query from the URL, call the custom 
parseUrl function. The path is placed in the path variable (m_reqInfo.path) and the query string is placed in 
the query variable (m_reqInfo.query).

CALL parseUrl(req.getUrl()) RETURNING m_reqInfo.path, m_reqInfo.query

Take the query variable (m_reqInfo.query) and parse out the value pairs using the StringTokenizer class 
and methods. The value pairs of variable name and value are stored in the m_reqInfo.items dynamic array.

LET str = base.StringTokenizer.create(m_reqInfo.query,"&")
LET i=1
CALL m_reqInfo.items.clear()
WHILE str.hasMoreTokens()
    LET token = str.nextToken()
    LET val = base.StringTokenizer.create(token,"=")
    IF val.hasMoreTokens() THEN LET m_reqInfo.items[i].name = 
        val.nextToken() END IF
    IF val.hasMoreTokens() THEN LET m_reqInfo.items[i].value = 
        val.nextToken() END IF
    LET i=i+1
END WHILE

By the end of the custom getReqInfo() function, the HTTP service request object is parsed into the variables that 
comprise a reqInfoType record. The application can now access the values it needs to process the request.

**getHeaderByName function**

The purpose of this function is to take as input two things:

- The HTTP service request object in an com.HTTPServiceRequest variable.
- The name of the header type whose value you want to return.

In the demo application, this function is used to parse out the value for the Content-Type header request and the 
Accept header request.

To do this, the function uses the API methods getRequestHeaderCount, getRequestHeaderName, and 
getRequestHeaderValue against the com.HTTPServiceRequest object. The function first counts the 
number of header requests, and then cycles through them until it finds the specific header request that is being asked 
for. When the match happens, the value for that header is returned; if no match is found, then NULL is returned.

FUNCTION getHeaderByName(areq,hname)
    DEFINE areq com.HTTPServiceRequest
    DEFINE hname STRING

    DEFINE aname STRING
    DEFINE iname STRING
    DEFINE i INT
    DEFINE n INT

    LET aname = hname.toLowerCase()
    LET n = areq.getRequestHeaderCount()
FOR i=1 TO n
    LET iname = areq.getRequestHeaderName(i)
    IF aname.equals(iname.toLowerCase()) THEN
        RETURN areq.getRequestHeaderValue(i)
    END IF
END FOR
RETURN NULL
END FUNCTION

parseUrl function

For this function, the URL is passed in. This function divides the URL into two parts, the path (up to and including the question mark) and the query. The path and the query are then returned to the calling function.

FUNCTION parseUrl(url)
    DEFINE url STRING
    DEFINE i INT

    LET i = url.getIndexOf(“?”,1)
    IF i = 0 THEN
        RETURN url, NULL
    ELSE
        RETURN url.substring(1,i), url.substring(i+1,url.getLength())
    END IF
END FUNCTION

For example, the URL being passed in by the demo client application is "http://localhost:8090/add?a=1&b=2". The function then returns the path ("http://localhost:8090/add?") and the query ("a=1&b=2").

For more information:
• com.WebServiceEngine methods on page 2676
• The HTTPServiceRequest class on page 2688

Step 4: Process the request

Having parsed the HTTPServiceRequest object into its parts, you can now process the request.

In the previous step, the m_reqInfo record was populated with the values of the HTTPServiceRequest object. The application now needs to work with these values.

Each Web services server application will be different in the type of processing that is done. For completeness, this topic will highlight some of the processing that is happening in the calculator demo server application.

Despite having variables in the m_reqInfo record, four additional STRING variables are defined to hold the method, the URL, the query, and the output format. In addition, an INTEGER variable is defined to hold an index value, used by some of the custom processing functions.

DEFINE method STRING
DEFINE url STRING
DEFINE qry STRING
DEFINE acc STRING
DEFINE idx INT

With the record populated, the server application then populates the additional variables.

# Get the type of method
LET method = m_reqInfo.method
# Get the request path
LET url = m_reqInfo.path
# Get the query string
LET qry = m_reqInfo.query
# Get the output format
LET acc = m_reqInfo.outformat

In the demo server application, the CASE statement only tests for the GET method.

```plaintext
CASE method
  WHEN "GET"
    ... processing instructions
  OTHERWISE
    CALL setError("Unknown request:\n" || url || "\n" || method)
    LET err.code = -3
    LET err.desc = ERR_METHOD
    CALL req.sendTextResponse(200,"OK",util.JSON.stringify(err))
END CASE
```

For the remainder of the processing code, the demo server application:

- Determines whether the request is for addition, subtraction, multiplication, or division
- Retrieves the values for the variables a and b
- Handles errors appropriately

For example, the source code that would process an addition request:

```plaintext
IF url.getIndexOf("/add?",1) > 0 THEN
  LET idx = getParameterIndex("a")
  IF idx = 0 THEN
    LET add_out.status.code = -1
    LET add_out.status.desc = ERR_PARAM_A
    CALL req.setResponseHeader("Content-Type","application/json")
    CALL req.sendTextResponse(200, "OK", util.JSON.stringify(add_out))
    EXIT CASE
  ELSE
    LET add_in.a = getParameterValue(idx)
  END IF
  LET idx = getParameterIndex("b")
  IF idx = 0 THEN
    LET add_out.status.code = -1
    LET add_out.status.desc = ERR_PARAM_B
    CALL req.setResponseHeader("Content-Type","application/json")
    CALL req.sendTextResponse(200, "OK", util.JSON.stringify(add_out))
    EXIT CASE
  ELSE
    LET add_in.b = getParameterValue(idx)
  END IF
  CALL add()
  ... send response
END IF
```

**Step 5: Send response**

Having completed the processing, the server sends the response back to the client.

The server application has the value or values that must be returned to the client. It now needs to format and send the response.

In the demo server application, the setResponseHeader() method sets the Content-Type to JSON.

```plaintext
CALL req.setResponseHeader("Content-Type","application/json")
```
The `sendTextResponse()` sends three things: a code, a description, and the response data. In this case, the data is formatted as JSON using the `util.JSON.stringify()` method, which transforms a record variable into a flat JSON formatted string.

```c
CALL req.sendTextResponse(200, "OK", util.JSON.stringify(add_out))
```

### Step 6: Provide information about your service

You must provide information about the services offered by your application to the developers of the Web services client applications that will interact with your server.

Information that the client application developer will need to know:

- The names of the resources or functions, and the query parameters and arguments to use with them.
- What media type the server expects for receiving, and then delivering, the message body (such as "JSON" or "XML").
- The HTTP method the server is expecting (such as "GET")

See also Step 1: Obtain information about Web service resources on page 3195.

### The RESTful calculator demo source

This calculator demo is an example of a RESTful Web services server and client.

Comparing the client to the server
Comparing the code between the RESTful calculator client and server.

The purpose of this side-by-side comparison is to provide a glimpse of how the client code and the server code relate.
In some cases, only the initial line of server code has been provided; you can look at the full source for either the client or the server for the complete code.

- Calculator client source on page 3216
- Calculator server source on page 3210

How Do I ... ?

These topics provide you with the information needed to perform specific tasks related to Genero Web Services (SOAP or RESTful).

**Tip**: See [here](#) for SOAP-specific "How Do I … ?" topics.

- Call Java APIs from Genero in a SOA environment on page 3219
- Call .NET APIs from Genero in a SOA environment on page 3224
- Compute a hash value from a BDL string on page 3231

### Call Java APIs from Genero in a SOA environment

How to call a Java library from Genero in a SOA environment, using Genero and Java Web services.

This can easily be done using the Java JAX-WS framework on a server, and a Genero application for the client part.

**Note**: There is no strong linkage between Genero and a java JVM.

These topics are presented as a tutorial that uses a Java barcode creation library to build a picture from a code.

#### Related concepts

- Call .NET APIs from Genero in a SOA environment on page 3224

How to call a .NET library from Genero in a SOA environment, using Genero and Web services, and IIS and Visual Studio .NET.

#### Recommendation

The usage of Genero Web Services to call a Java service is recommended in a SOA environment. It enables several Genero applications to connect to a centralized Java service without the need to start a new JVM for each running Genero application. It also provides more flexibility because there is no strong linkage between Genero and the Java virtual machine. You can for instance upgrade the Java service without changing anything in your Genero code.

However, due to the XML serialization process and the HTTP transport protocol in Web Services, there can be some performance issues. So if your main concern is performance, it is recommended to use the Genero Java bridge.

#### Prerequisites

- A JRE 1.5 or above
- The Java barcode library (available [here](#))
  - You must add these JARs to the Java CLASSPATH: barcode.jar and BarcodeReader.jar
  - The trial version has some functions partially implemented.
- Download the JAX-WS framework from the Sun metro project [here](#); add this JAR to the java CLASSPATH: webservices-tools.jar

#### Using the barcode library

The **barcode library** is composed of two libraries:

- A library for building a barcode image from a numeric code
- A library for reading a barcode image to return the numeric code

This section depends on the library you want to use in Genero.

In our tutorial, we create two functions called **buildImage** and **readImage**.

This is the Java implementation:

```java
try {
    Barcode builder=new Barcode();
    builder.setType(GetBarcodeBuilderType(type));
}
```
Web services

```java
builder.setData(data);
builder.setAddChecksum(true);
ByteArrayOutputStream out = new ByteArrayOutputStream();
if (builder.createBarcodeImage(out)) {
    byte[] ret = out.toByteArray();
    return ret;
} else {
    return null;
}
}
```

```java
readImage( type : String, img : byte[] ) : String
try {
    File f = new File("tmp.jpg");
    FileOutputStream stream = new FileOutputStream(f);
    stream.write(img);
    stream.close();
    String[] datas =
        BarcodeReader.read(f, GetBarcodeReaderType(type));
    if (datas == null) {
        return null;
    } else {
        String ret = datas[0];
        return ret;
    }
} catch (Exception e) {
    return null;
}
```

The following two functions convert the type of a code bar to the type expected by the library:

```java
private int GetBarcodeBuilderType(String str) {
    if (str.equals("CODABAR")) {
        return Barcode.CODABAR;
    } else if (str.equals("CODE11")) {
        return Barcode.CODE11;
    } else if (str.equals("CODE128")) {
        return Barcode.CODE128;
    } else if (str.equals("CODE128A")) {
        return Barcode.CODE128A;
    } else if (str.equals("CODE128B")) {
        return Barcode.CODE128B;
    } else if (str.equals("CODE128C")) {
        return Barcode.CODE128C;
    } else if (str.equals("CODE128F5")) {
        return Barcode.CODE128F5;
    } else if (str.equals("CODE39")) {
        return Barcode.CODE39;
    } else if (str.equals("CODE39EX")) {
        return Barcode.CODE39EX;
    } else if (str.equals("CODE93")) {
        return Barcode.CODE93;
    } else if (str.equals("CODE93EX")) {
        return Barcode.CODE93EX;
    } else if (str.equals("EAN13")) {
        return Barcode.EAN13;
    } else if (str.equals("EAN13_2")) {
        return Barcode.EAN13_2;
    } else if (str.equals("EAN13_5")) {
        return Barcode.EAN13_5;
    } else if (str.equals("EAN8")) {
```
return Barcode.EAN8;
} else if (str.equals("EAN8_2")) {
    return Barcode.EAN8_2;
} else if (str.equals("EAN8_5")) {
    return Barcode.EAN8_5;
} else if (str.equals("INTERLEAVED25")) {
    return Barcode.INTERLEAVED25;
} else if (str.equals("ITF14")) {
    return Barcode.ITF14;
} else if (str.equals("ONECODE")) {
    return Barcode.ONECODE;
} else if (str.equals("PLANET")) {
    return Barcode.PLANET;
} else if (str.equals("POSTNET")) {
    return Barcode.POSTNET;
} else if (str.equals("RM4SCC")) {
    return Barcode.RM4SCC;
} else if (str.equals("UPCA")) {
    return Barcode.UPCA;
} else if (str.equals("UPCE")) {
    return Barcode.UPCE;
} else {
    return -1;
}
}

private int GetBarcodeReaderType(String str) {
    if (str.equals("CODABAR")) {
        return BarcodeReader.CODABAR;
    } else if (str.equals("CODE11")) {
        return BarcodeReader.CODE11;
    } else if (str.equals("CODE128")) {
        return BarcodeReader.CODE128;
    } else if (str.equals("CODE39")) {
        return BarcodeReader.CODE39;
    } else if (str.equals("CODE39EX")) {
        return BarcodeReader.CODE39EX;
    } else if (str.equals("CODE93")) {
        return BarcodeReader.CODE93;
    } else if (str.equals("DATAMATRIX")) {
        return BarcodeReader.DATAMATRIX;
    } else if (str.equals("EAN13")) {
        return BarcodeReader.EAN13;
    } else if (str.equals("EAN8")) {
        return BarcodeReader.EAN8;
    } else if (str.equals("INTERLEAVED25")) {
        return BarcodeReader.INTERLEAVED25;
    } else if (str.equals("ITF14")) {
        return BarcodeReader.ITF14;
    } else if (str.equals("ONECODE")) {
        return BarcodeReader.ONECODE;
    } else if (str.equals("PLANET")) {
        return BarcodeReader.PLANET;
    } else if (str.equals("POSTNET")) {
        return BarcodeReader.POSTNET;
    } else if (str.equals("QRCODE")) {
        return BarcodeReader.QRCODE;
    } else if (str.equals("RM4SCC")) {
        return BarcodeReader.RM4SCC;
    } else if (str.equals("RSS14")) {
        return BarcodeReader.RSS14;
    } else if (str.equals("RSSLIMITED")) {
        return BarcodeReader.RSSLIMITED;
    } else if (str.equals("UPCA")) {

Calling Java from Genero

The integration of one or several Java libraries with multiple methods in a Genero application can be performed, as described in the following topics.

Step 1: Write a new java class

Instead of writing the functions in 4GL, you simply need to write them in a Java class with the methods you want to use in 4GL. In our example, the two functions are `buildImage` and `readImage`. And of course, don't forget to import the necessary Java import instructions.

```java
import com.barcodelib.barcodereader.BarcodeReader;
import com.barcodelib.barcode.Barcode;
import java.io.*;
import javax.jws.*;
import javax.jws.soap.SOAPBinding;
import javax.xml.ws.Endpoint;

public class BarcodeService {
    public byte[] buildImage(String type, String data) {
        // BUILDIMAGE IMPLEMENTATION CODE DESCRIBED ABOVE*
    }
    public String readImage(String type, byte[] img) {
        // READIMAGE IMPLEMENTATION CODE DESCRIBED ABOVE*
    }
}
```

If you want the service to run standalone, you must also add following the main method to tell the system the port number on which the service will run:

```java
public static void main(String[] args) {
    String endpointUri = "http://localhost:9090/";
    Endpoint.publish(endpointUri, new BarcodeService());
    System.out.println("BarcodeService started at " + endpointUri);
}
```

Step 2: Transform the Java class in a web service

To transform the previous java class in a Web Service, simply add a WebService annotation:

```java
@WebService(targetNamespace = http://www.mycompany.com/barcode",
    name="Barcode",
    serviceName="BarcodeService")
public class BarcodeService{
    ...
}
```

This defines all public and non static methods of the class as operations of the `BarcodeService` Web Service.
**Step 3: Start the service**

Compile the previously created java class, and run it.

Commands to compile and execute the service in standalone mode:

```
$ javac BarcodeService.java
$ java BarcodeService
```

Once the service is started, it is ready to accept requests and you can also retrieve its WSDL at following URL:

```
http://localhost/9090/BarcodeService?WSDL
```

**Note:** If you want the service to be started on a web server, you must deploy it first using Eclipse or the Web Server deployment tools.

**Step 4: Generate BDL stub to access the Java library**

Use the `fglwsdl` tool to generate the client stub to access the BarcodeService:

```
$ fglwsdl http://localhost:9090/BarcodeService?WSDL
```

This will create two .4gl files that must be compiled and linked into your BDL application in order to call the Java barcode library functions. These files contain the BDL interface to access the Java library where you will find the two functions, `readImage` and `buildImage`, defined in BDL.

**Step 5: Modify your BDL application**

The last step is to modify the existing application where you want to use the Java library, by calling the BDL functions generated in the stub. Then compile your application and the previously generated stubs, and link everything together.

Your application is now ready to use the different features of your Java library.

**Example program**

This program calls the `buildImage` function of the Barcode Java library.

```
GLOBALS "BarcodeService_BarcodePort.inc"

MAIN

DEFINE wsstatus INTEGER

IF num_args() != 3 THEN
   CALL ExitHelp()
END IF

LET nslbuildImage.arg0 = arg_val(1)
LET nslbuildImage.arg1 = arg_val(2)
LOCATE nslbuildImageResponse.return IN MEMORY

LET wsstatus = buildImage_g()
IF wsstatus <> 0 THEN
   DISPLAY "Error ("||wsError.code||") : ",wsError.description
ELSE IF
   IF nslbuildImageResponse.return IS NULL THEN
      DISPLAY "Encoding failed"
   ELSE
      CALL nslbuildImageResponse.return.writeFile(arg_val(3))
   END IF
END IF

FREE nslbuildImageResponse.return
```
FUNCTION ExitHelp()
    DISPLAY arg_val(0) || " <type> <data> <filename>"
    DISPLAY "type : barcode type such as EAN8 or CODE128"
    DISPLAY "data : data to be encoded with a barcode [0-9A-D]"
    DISPLAY "filename : resulting image filename"
    DISPLAY "example : createImage EAN8 12358723A mybarcode.jpg"
    EXIT PROGRAM (-1)
END FUNCTION

Conclusion

In a SOA environment, you can call any Java library from Genero using Web Services, and without a strong dependency to a JVM. This follows SOA principles - it allows you to reuse the Java library in another BDL application without any new development, you can update the Java part without recompiling any .4gl source, and integrate any function available from a SOA platform.

Call .NET APIs from Genero in a SOA environment

How to call a .NET library from Genero in a SOA environment, using Genero and Web services, and IIS and Visual Studio .NET.

There is no strong linkage between Genero and .NET. You can call a .NET library from a non-Windows® Genero platform.

These topics are presented as a tutorial that uses a .NET barcode creation library to build a picture from a numeric code, and C# as the development language. This works with any .NET language.

Related concepts

Call Java APIs from Genero in a SOA environment on page 3219
How to call a Java library from Genero in a SOA environment, using Genero and Java Web services.

Prerequisites

- IIS (Internet Information Services) Web server
- Visual Studio Professional Edition C#
  - Visual Studio in only needed for development. Once the service is built, you can deploy on any IIS Web Server.
- The .NET barcode library (available here)
  - The trial version has some functions partially implemented.
  - The .NET library is called BarcodeLib.Barcode.dll, and must be added to the Visual Studio Project.

Using the barcode library

This section depends on the library you want to use in Genero. In our tutorial, we create one function called buildImage. This is the C# implementation:

```
buildImage( type : String, code : String) : byte[]

Linear barcode = new Linear();
barcode.Data = code;
barcode.Type = GetBarcodeBuilderType(type);
barcode.AddCheckSum = true;
// save barcode image into your system
barcode.ShowText = true;
byte[] ret = barcode.drawBarcodeAsBytes();
if (ret != null) return ret;
else return null;
```
private BarcodeType GetBarcodeBuilderType(String str)
{
    if (str.Equals("CODABAR")) {
        return BarcodeType.CODABAR;
    } else if (str.Equals("CODE11")) {
        return BarcodeType.CODE11;
    } else if (str.Equals("CODE128")) {
        return BarcodeType.CODE128;
    } else if (str.Equals("CODE128A")) {
        return BarcodeType.CODE128A;
    } else if (str.Equals("CODE128B")) {
        return BarcodeType.CODE128B;
    } else if (str.Equals("CODE128C")) {
        return BarcodeType.CODE128C;
    } else if (str.Equals("CODE2OF5")) {
        return BarcodeType.CODE2OF5;
    } else if (str.Equals("CODE39")) {
        return BarcodeType.CODE39;
    } else if (str.Equals("CODE39EX")) {
        return BarcodeType.CODE39EX;
    } else if (str.Equals("CODE93")) {
        return BarcodeType.CODE93;
    } else if (str.Equals("COE13") ) {
        return BarcodeType.EAN13;
    } else if (str.Equals("EAN13_2")) {
        return BarcodeType.EAN13_2;
    } else if (str.Equals("EAN13_5")) {
        return BarcodeType.EAN13_5;
    } else if (str.Equals("EAN8")) {
        return BarcodeType.EAN8;
    } else if (str.Equals("EAN8_2")) {
        return BarcodeType.EAN8_2;
    } else if (str.Equals("EAN8_5")) {
        return BarcodeType.EAN8_5;
    } else if (str.Equals("INTERLEAVED25")) {
        return BarcodeType.INTERLEAVED25;
    } else if (str.Equals("ITF14")) {
        return BarcodeType.ITF14;
    } else if (str.Equals("ONECODE")) {
        return BarcodeType.ONECODE;
    } else if (str.Equals("PLANET")) {
        return BarcodeType.PLANET;
    } else if (str.Equals("POSTNET")) {
        return BarcodeType.POSTNET;
    } else if (str.Equals("RM4SCC")) {
        return BarcodeType.RM4SCC;
    } else if (str.Equals("UPCA")) {
        return BarcodeType.UPCA;
    } else if (str.Equals("UPCE")) {
        return BarcodeType.UPCE;
    } else {
        throw new Exception();
    }
}

Calling .NET from Genero
Step 1: Create an ASP.NET Web Service Application

Start Visual Studio, and create a new web project with the name BarCodeService.
Figure 119: Visual Studio New Project; ASP .NET Web Service Application selected

Step 2: Rename the generated files

Rename the generated class called Service1 with an appropriate name such as BarCode, and the file Service1.asmx to BarCodeService.asmx, for instance. The .asmx file is the file that is accessible from the IIS web server once the application is deployed. The .asmx file also contains a reference to the default generated class, Service1, which must also be renamed to the new name (BarCode in our tutorial), in case Visual Studio didn't make the change automatically.

The class view after renaming the class:

Figure 120: Class View; BarCode selected
The file view after renaming the asmx file:

![Image of file view]

**Figure 121: File View; BarCodeService selected**

**Step 3: Add the barcode library as a reference**

Right-click on the solution explorer, select **Add Reference** and use the **Browse** panel to enter the location of the barcode library called **BarcodeLib.Barcode.dll**:

![Image of Add Reference dialog]

**Note:** By default, the barcode library will be copied to the right place when deploying on the IIS web server.

**Step 4: Add the buildImage method**

Remove the default generated HelloWorld method, and create the buildImage method.

Add the three **using** instructions to import the barcode library, and to declare **buildImage** as a WebMethod. Use the **GetBarcodeBuilderType()** method to convert a string to a code as expected by the barcode library.

```csharp
using BarcodeLib;
```
using BarcodeLib.Barcode;
using BarcodeLib.Barcode.Linear;

namespace BarCodeService
{
    /// <summary>
    /// Summary description for Service1
    /// </summary>
    [WebService(Namespace = "http://tempuri.org/")]  
    [WebServiceBinding(ConformsTo = WsiProfiles.BasicProfile1_1)]
    [ToolboxItem(false)]
    // To allow this Web Service to be called from script, using ASP.NET
    {

        [WebMethod]
        public byte[] buildImage(String type, String code)
        {
            try
            {
                Linear barcode = new Linear();
                barcode.Data = code;
                barcode.Type = GetBarcodeBuilderType(type);
                barcode.AddCheckSum = true;

                // save barcode image into your system
                barcode.ShowText = true;
                byte[] ret = barcode.drawBarcodeAsBytes();
                if (ret != null) return ret;
                else return null;
            }
            catch (Exception e)
            {
                return null;
            }
        }
    }
}
Step 5: Publish the service

Build the entire application, right-click on the solution, and select the publish operation. This will copy all necessary files to your IIS web server and make your application available at an URL, depending on where you deploy it on your IIS web server.

In our tutorial, the service will be located at the root of the server. In other words, it will be available at http://localhost/BarCodeService.asmx and the WSDL at URL http://localhost/BarCodeService.asmx?WSDL
Step 6: Generate .4gl stub to access the .NET library

Use the fglwsl tool to generate the client stub to access the BarcodeService, as follows:

```
$ fglwsl http://localhost/BarCodeService.asmx?WSDL
```

This will create two .4gl files, which must be compiled and linked into your BDL application in order to call the .NET barcode library functions. These files contain the BDL interface to access the .NET library where you will find the function `buildImage`, defined in BDL.

**Step 7: Modify your BDL application**

Modify your existing application, where you want to use the .NET library, by calling the BDL functions generated in the stub. Then compile your application and the previously generated stubs, and link everything together.

Your application is now ready to use the different features of your .NET library.

**Example BDL program**

This program calls the `buildImage` function of the Barcode .NET library.

```
GLOBALS "BarCode_BarCodeSoap.inc"
MAIN
  DEFINE wsstatus INTEGER
  IF num_args() != 3 THEN
    CALL ExitHelp()
  END IF

  LET buildImage.type = arg_val(1)
  LET buildImage.code = arg_val(2)
  LOCATE buildImageResponse.buildImageResult IN MEMORY

  LET wsstatus = buildImage_g()
  IF wsstatus <> 0 THEN
    DISPLAY "Error ("||wsError.code||") : ",wsError.description
  ELSE
    IF buildImageResponse.buildImageResult IS NULL THEN
      DISPLAY "Encoding failed"
    ELSE
      CALL buildImageResponse.buildImageResult.writeFile(arg_val(3))
  END IF
```
Conclusion

It is quite easy to interact with a .NET library from Genero using .NET Visual Studio and the web services. Of course you also need an IIS web server installed on your Windows system. This means that you can, in the same Genero application, interact with .NET and Java libraries without any strong linkage between Genero and the third party libraries you want to use. This meets the SOA principles that provide more flexibility to your entire BDL application.

You can integrate any new library from another vendor, without the risk of conflicts between different libraries that can occur happen if you had to link everything together in C or Java.

You can upgrade a third party library without recompiling the BDL application, which will still work.

You can use all these third party libraries in other BDL or other applications.

Compute a hash value from a BDL string

How to compute a hash value of a BDL string using the security.Digest API.

Program Example

This retrieves the hash value from the signature and returns it. The computed hash value is encoded in Base64, so you may have additional conversion to do.

Program example ComputeHash.4gl:

```
IMPORT SECURITY

MAIN

DEFINE result STRING

IF num_args() != 2 THEN
    DISPLAY "Usage: ComputeHash <string> <hashcode>"
    DISPLAY " string: the string to digest"
    DISPLAY " hashcode: SHA1, SHA512, SHA384, SHA256, SHA224, MD5"
ELSE
    LET result = ComputeHash(arg_val(1), arg_val(2))
    IF result IS NOT NULL THEN
        DISPLAY "Hash value is: ", result
    ELSE
        DISPLAY "Error"
    END IF
END IF

FUNCTION ComputeHash(toDigest, algo)
```
DEFINE toDigest, algo, result STRING
DEFINE dgst security.Digest

TRY
   LET dgst = security.Digest.CreateDigest(algo)
   CALL dgst.AddStringData(toDigest)
   LET result = dgst.DoBase64Digest()
CATCH
   DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
   EXIT PROGRAM(-1)
END TRY

RETURN result
END FUNCTION

Example execution:
$fgrun ComputeHash "Hello World" SHA1
$ Hash value is: Ck1VqNd45QIvq3AZd8XYQLvEhtA=

Deploy a Web Service

Web services server program deployment

Introduction
In a production environment, Genero Web Services becomes a part of a global application architecture handled by the Genero Application Server (GAS). The GWS DVMs are managed by the GAS.

This architecture takes care of:
• Security issues
• Scalability
  • Load management
  • Balancing of the Web service requests amongst the available virtual machines
• Runtime monitoring

GAS configuration
For deployment, the GWS Server application must be added to the GAS configuration. See Configure applications for Web service in the Genero Application Server User Guide.

The web services application can be added to the GAS in different ways:
• GWS Server application implementing a single Web service.
  
  This application can be deployed on various physical machines. A Genero Web Services VMProxy (GWSProxy) is started on each machine where the GWS Server application is executed, to manage the requests for a service and manage the DVMs that handle the requests. A single VMProxy can communicate with multiple GWS DVMs, and manage the load balancing.
• GWS Server application implementing multiple Web Services.
  
  The GWSProxy would manage the client requests, dispatching the request to the appropriate DVM and the appropriate web service.
Note: A Web Service Server must be stateless; several instances of the same Service can be created to support load balancing.

The basic deployment strategy can be implemented in varying permutations, depending on your business needs and the volume of requests.

Figure 124: Deployment strategy

- Using the World Wide Web, a Web Service client requests WSDL information for a particular Web Service from the Web Server.
- The Web Service client uses this information to make a Web Service request from the Web Server.
- The Web server passes the request to the GAS dispatcher.
- The GAS dispatcher starts a GWSProxy, which will be in charge of the pool of DVMs that will serve the web service application.
- The GWSProxy will start the number of DVMs specified by the START element defined for the web service application.

For a more detailed explanation of the Services Pool for web services, refer to the GAS Architecture topic in the Genero Application Server manual.

Access the web services server from a client application

To reach the web service from the internet, client applications must use the following URL form:

```
http://host_name/ws/r/app_id
```

1. `host_name` defines the web server host name where the GAS is running.
2. `app_id` is the XCF file of the GAS web services application.

Configuring the apache web server for HTTPS

The first three steps are for the creation of all X.509 certificates.

- Step 1: Create the Root Certificate Authority
- Step 2: Create the server’s certificate and private key
- Step 3: Create the server’s certificate authority list

The next three steps are for server configuration.

- Step 4: Register the server as a Web Service in the GAS
- Step 5: Configure apache for HTTPS
- Step 6: Configure apache for HTTP basic authentication

Step 1: Create the root certificate authority

- Create the root certificate authority serial file:

```
$ echo 01 > MyCompanyCA.srl
```
• Create the Root Authority's Certificate Signing Request and private key:

```bash
$ openssl req -new -out MyCompanyCA.csr -keyout MyCompanyCA.pem
```

• Create the Root Certificate Authority for a period of validity of 2 years:

```bash
$ openssl x509 -trustout -in MyCompanyCA.csr -out MyCompanyCA.crt -req -signkey MyCompanyCA.pem -days 730
```

**Important:** The private key file (MyCompanyCA.pem) of a RootCertificate Authority must be handled with care. This file is responsible for the validity of all other certificates it has signed. As a result, it must not be accessible by other users.

In the next step we create the server's certificate and private key, **Step 2: Create the server's certificate and private key** on page 3234.

**Step 2: Create the server's certificate and private key**

• Create the server's serial file:

```bash
$ echo 01 > MyServer.srl
```

• Create the server's Certificate Signing Request and private key:

```bash
$ openssl req -new -out MyServer.csr
```

**Note:** By default, openssl outputs the private key in the privkey.pem file.

• Remove the password from the private key:

```bash
$ openssl rsa -in privkey.pem -out MyServer.pem
```

**Note:** The key is also renamed in MyServer.pem.

• Create the server's Certificate trusted by the Root Certificate Authority:

```bash
$ openssl x509 -in MyServer.csr -out MyServer.crt -req -signkey MyServer.pem -CA MyCompanyCA.crt -CAkey MyCompanyCA.pem
```

**Note:** The purpose of the server's Certificate is to identify the server to any client that connects to it. Therefore, the subject of that server's certificate must match the host name of the server as it is known on the network; otherwise the client will not trust the server's identity and the communication is stopped. For instance, if the URL of the server is https://www.MyServer.com/fastcgi/ws/r/MyWebService, the subject must be www.MyServer.com.

In the next step we create the server's certificate authority list, **Step 3: Create the server's certificate authority list** on page 3234.

**Step 3: Create the server's certificate authority list**

• Create the server's Certificate Authority List:

```bash
$ openssl x509 -in MyCompanyCA.crt -text >> ServerCAList.pem
```

**Note:** As the server trusts only the Root Certificate Authority, the list contains only that one certificate authority; all other certificates that were trusted by the Root Certificate Authority will also be considered as trusted by the server.

In the next step we register the server's certificate authority list, **Step 4: Register the server as a web service in the GAS** on page 3235.
**Step 4: Register the server as a web service in the GAS**

As the Web server is in charge of the complete HTTPS protocol with all the clients, there is no additional GAS configuration needed to add security. Simply register the BDL server to the list of Web Services of the GAS. For more information, refer to the *Genero Application Server User Guide*.

For more details, see Web services server program deployment on page 3232.

**Step 5: Configure apache for HTTPS**

You must configure Apache to support HTTPS by adding the required modules. Please refer to the Apache Web server documentation for more information.

- For the Apache 1.3 manual, go to http://httpd.apache.org/docs/1.3.
- For the Apache 2.0 manual, go to http://httpd.apache.org/docs/2.0/.

Once the Apache Web server supports HTTPS, you must change or add the following directives to the Apache configuration file:

- Set the Apache Web server Certificate Authority List directive created in Step 3:
  
  SSLCACertificateFile D:/Apache-Server/conf/ssl/ServerCAList.pem

- Set the Apache Web server Certificate and associated private key directives created in Step 2:
  
  SSLCertificateFile D:/Apache-Server/conf/ssl/MyServer.crt
  
  SSLCertificateKeyFile D:/Apache-Server/conf/ssl/MyServer.pem

- Require the Apache Web server to verify the validity of all client certificates:

  SSLVerifyClient require

**Note:** The Apache Web server must be started on a machine where the host is the same as the one defined in the subject of the server's certificate (www.MyServer.com in our case).

**Step 6: Configure Apache for HTTP basic authentication**

You must configure Apache to support HTTP basic authentication by adding the required modules.

Refer to the Apache Web server documentation for more information.

- For the Apache 1.3 manual, go to http://httpd.apache.org/docs/1.3.
- For the Apache 2.0 manual, go to http://httpd.apache.org/docs/2.0/.

Once the Apache Web server supports HTTP basic authentication, you must:

1. Add an user to the Apache Web server basic authentication file with the same login and password as defined for the client.

   Apache provides the tool **htpasswd** that you can use to create the file and add the user. To add the user **mylogin** with the password **mypassword** to a new file called **myusers**:

   ```bash
   $ htpasswd -c myusers mylogin mypassword
   ```

   **Note:** To add additional users, remove the option `-c`.

2. Add an Apache Web server location directive that enables you to group several directives for one URL. (In the example, the URL is /fastcgi/ws/r/MyWebService).

   The following example (based on Apache 2.0) defines the HTTP authentication type (Basic), with a user file (user-basic) containing the login and password of those who are allowed to access the service.

   ```
   <Location /fastcgi/ws/r/MyWebService>
   AllowOverride None
   Order allow,deny
   Allow from all
   ```
# Basic HTTP authenticate configuration

AuthName "Top secret"
AuthType Basic
AuthUserFile "D:/Apache-Server/conf/authenticate/myusers"

</Location>

For more information about Apache Web server directives, refer to the Apache Web Server manual.

**Web services configuration**

The Genero Web Services secured communication and the support of XML-Security is based on the OpenSSL engine. It allows a BDL Web Services client, or a BDL application using the com or xml API, to communicate with any secured server over HTTP or HTTPS, and to handle encrypted and/or signed XML document in BDL coming from any other application.

The configuration is defined from entries in the fglprofile file. When using BDL Web Services on server side, it is the Web Server that is in charge of the BDL Web Services server security, not the BDL server application itself. You must refer to your Web Server manual to secure the server part of the Web Services.

**Note:** This is useful for deployment purposes, as no additional code modification is necessary, even if the location of the different servers changes, or if different cryptography keys or X509 certificates are necessary for the same application but intended for several customers with their own needs.

**Related concepts**

- The FGLPROFILE file(s) on page 220
- FGLPROFILE environment variable defines Genero BDL configuration files
- The com package on page 2658
- The Genero Web Services com package provides classes and methods that allow you to perform tasks associated with creating Services and Clients, and managing the services.
- The xml package on page 2774
- The Genero Web Services XML package provides classes and methods to handle any kind of XML documents, including documents with namespaces.

**Related information**

http://www.openssl.org
**FGLPROFILE entries**
The fglprofile entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

- HTTPS and password encryption on page 3237
- Basic or digest HTTP authentication on page 3239
- Proxy configuration on page 3240
- Server configuration on page 3240
- XML configuration on page 3241

**HTTPS and password encryption**
The following table lists the FGLPROFILE file entries specifying the security certificates and algorithms the Web Services client uses for HTTPS and password encryption. These entries specify how an application using the low-level com or xml APIs performs secured communications.

**Important:** On iOS platform the security entries are not available because iOS SSL/TLS layer is used. However, you can configure the following security Web Services FGLPROFILE entries for GMI mobile devices: `security.global.ca`, `security.global.ca.lookuppath`, and `security.global.systemca`.

**Note:** Any entry defining a file on disk, for example `security.global.ca`, `xml.keystore.ca.lalist`, etc., can be set with a relative or an absolute path. If set as relative, the file is located based on the current execution directory. The recommended practice is to specify an absolute path in case `fglrun` is not always executed from the same directory.

**Table 672: Security Configuration FGLPROFILE entries**

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>security.global.script</td>
<td>File name of a script executed each time a password of a private key is required by the client. The security script accepts one argument corresponding to the file name of the private key for which the password is required, and must return the correct password or the client stops. For script examples, see Windows® Password Script Example or UNIX™ Password Script Example. This entry cannot be used if <code>security.global.agent</code> is set.</td>
</tr>
<tr>
<td>security.global.agent</td>
<td>Port number where the fglpass agent is waiting for requests. It returns the password that grants access to a private key when needed by a BDL application. The DVM and the fglpass agent perform authentication and exchange encrypted data over the local host network only. Refer to Using the password agent for details. This entry cannot be used if <code>security.global.script</code> is set.</td>
</tr>
<tr>
<td>security.global.agent.gid</td>
<td>Set this entry as <code>true</code> to specify agent authentication based on OS user group. This entry is only for UNIX® platforms. For more details, see Use the password agent on page 3118.</td>
</tr>
<tr>
<td>security.global.protocol</td>
<td>The SSL/TLS protocol to use for secured communications. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>- TLSv1.2</td>
</tr>
<tr>
<td></td>
<td>- TLSv1.1</td>
</tr>
<tr>
<td></td>
<td>- TLSv1 (version 1.0)</td>
</tr>
<tr>
<td></td>
<td>- SSLv3</td>
</tr>
<tr>
<td></td>
<td>- SSLv23 (The default, enabling all supported protocols)</td>
</tr>
<tr>
<td>Entry</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>security.global.ca</td>
<td>File name of the Certificate Authority list, with the concatenated PEM-encoded third party X.509 certificates considered as trusted, and in order of preference.</td>
</tr>
<tr>
<td>security.global.ca.lookuppath</td>
<td>A list of directories containing certificate authorities. Genero Web Services will load the CA from the directories in this list. The entry is a list of directories separated by a semicolon.</td>
</tr>
<tr>
<td>security.global.windowsca</td>
<td>If set to true, build the Certificate Authority list from the Certificate Authorities stored in the Windows® key store. This entry is only valid on Windows® systems where security.global.ca is not set.</td>
</tr>
<tr>
<td>security.global.cipher</td>
<td>The list of encryption, digest, and key exchange algorithms the client is allowed to use during a secured communication. If this entry is omitted, all algorithms are supported. For more details about cipher, refer to <a href="http://www.openssl.org">www.openssl.org</a>.</td>
</tr>
<tr>
<td>security.global.certificate</td>
<td>File name of the PEM-encoded client X.509 certificate to be used for any secured connection if not redefined in a specific server configuration.</td>
</tr>
<tr>
<td>security.global.privatekey</td>
<td>File name of the PEM-encoded private key associated to the above X.509 certificate and to be used for any secured connection if not redefined in a specific server configuration. If the PEM file is password protected, you need to use the security.global.script or security.global.agent entries to supply the passphrase to decrypt the private key.</td>
</tr>
<tr>
<td>security.global.keyssubject</td>
<td>The subject string of a X.509 certificate and its associated private key registered in the Windows® key store to be used for any secured connection if not redefined in a specific server configuration. This entry is valid only on Windows® systems.</td>
</tr>
<tr>
<td>security.global.systemca</td>
<td>When set to true, the Certificate Authority is loaded from the key store on Mac® OS X or Windows® systems, and from a predefined directory on Unix/Linux®. If set to false, the Certificate Authority is not loaded from the system-default location. Default is true. This entry is only valid where security.global.ca is not set.</td>
</tr>
<tr>
<td>security.global.ocsp.enable</td>
<td>If set to true, once the server has been validated against local certificate authority, an additional request is performed to the certificate issuer's URL to ensure that no certificate has been revoked at time of connection. Default value is false (no additional request is done)</td>
</tr>
<tr>
<td>security.global.ocsp.url</td>
<td>Instead of checking revocation to the URL inside the issuer's certificate, you can specify a fixed URL where all OCSP requests will be sent. For example: security.global.ocsp.url = &quot;http://any_url&quot; By default, this entry is not set and the URL inside the certificate is used.</td>
</tr>
<tr>
<td>security.idsec.certificate</td>
<td>File name of the PEM-encoded client X.509 certificate.</td>
</tr>
<tr>
<td>security.idsec.privatekey</td>
<td>File name of the PEM-encoded private key associated to the above X.509 certificate. If the PEM file is password protected, you need to use the security.idsec.script or security.idsec.agent entries to supply the passphrase to decrypt the private key.</td>
</tr>
</tbody>
</table>
security.idsec.keysubject | The subject string of a X.509 certificate and its associated private key registered in the Windows® key store. This entry is valid only on Windows® systems.

Note:
1. The idsec keyword must be replaced with your own identifier, and all necessary entries must be set. See FGLPROFILE setting.
2. If an entry is defined more than once, only the last occurrence is taken into account.

Basic or digest HTTP authentication
The following table lists the FGLPROFILE entries that specify the login and password to use in the case of HTTP authentication to a server or a proxy. The entries also specify the login and password to use in an application using the low-level com or xml API.

Table 673: HTTP basic or digest Authentication FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authenticate.ident.login</td>
<td>The login identifying the client to a server during HTTP Authentication.</td>
</tr>
<tr>
<td>authenticate.ident.password</td>
<td>The password validating the login of a client to a server during HTTP Authentication. As passwords are never recommended to be in clear text, you must encrypt them with the fglpass tool. For more information, see FGLPROFILE password encryption.</td>
</tr>
<tr>
<td>authenticate.ident.realm</td>
<td>The string identifying the server to the client during HTTP Authentication. If the string does not match the server's string, authentication fails. This parameter is optional, but it is recommended that you check the server identity, especially if the server's location is suspicious.</td>
</tr>
<tr>
<td>authenticate.ident.scheme</td>
<td>One of the following strings representing the different HTTP Authentication mechanisms.</td>
</tr>
<tr>
<td>• Anonymous (default value)</td>
<td>The client does not know anything about the server, and performs a first request to retrieve the server authentication mechanism. It then uses the login and password to authenticate to the server using the Basic or Digest mechanism, depending on the server's returned value.</td>
</tr>
<tr>
<td>• Basic</td>
<td>The client authenticates itself to the server at first request, by sending the login and the password using the Basic authentication mechanism.</td>
</tr>
<tr>
<td>• Digest</td>
<td>The client performs a first request without any login and password, to retrieve the server information before authenticating itself to the server in a second request using the Digest mechanism.</td>
</tr>
</tbody>
</table>

Note:
1. The ident keyword must be replaced with your own identifier, and all necessary entries must be set. See FGLPROFILE setting.
2. If an entry is defined more than once, only the last occurrence is taken into account.
Proxy configuration

The following table lists the FGLPROFILE entries that specify how the Web Services client communicates with a proxy. The entries specify the way an application using the low-level com or xml API communicates with a proxy.

**Table 674: Proxy Configuration FGLPROFILE entries**

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proxy.http.location</td>
<td>Location of the HTTP proxy defined as host:port or ip:port. If the port is omitted, the port 80 is used.</td>
</tr>
<tr>
<td>proxy.http.list</td>
<td>The list of beginning host names, separated with semicolons, for which the Web Services client does not go via the HTTP proxy.</td>
</tr>
<tr>
<td>proxy.http.authenticate</td>
<td>The HTTP Authenticate identifier the Web Services client uses to authenticate itself to the HTTP proxy.</td>
</tr>
<tr>
<td>proxy.https.location</td>
<td>Location of the HTTPS proxy defined as host:port or ip:port. If the port is omitted, the port 443 is used.</td>
</tr>
<tr>
<td>proxy.https.list</td>
<td>The list of beginning host names, separated with semicolons, for which the Web Services client does not go via this HTTPS proxy.</td>
</tr>
<tr>
<td>proxy.https.authenticate</td>
<td>The HTTP Authenticate identifier the Web Services client uses to authenticate itself to the HTTPS proxy.</td>
</tr>
</tbody>
</table>

**Note:** If an entry is defined more than once, only the last occurrence is taken into account.

IPv6 configuration

The following table lists the FGLPROFILE entries that specify how the Web Services client uses the IPv6 network protocol.

**Table 675: IPv4 and IPv6 FGLPROFILE entries**

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip.global.version</td>
<td>Defines the IP version to be used. Possible values are &quot;4&quot; (IPv4) or &quot;6&quot; (IPv6). By default, when this entry is not defined, the WS library will try to use IPv6 and fallback to IPv4, depending on the operating system.</td>
</tr>
<tr>
<td>ip.global.v6.interface.name</td>
<td>Defines the name of the network interface to be used for IPv6 link-local addresses. For example, this entry can get values such as &quot;eth0&quot;, &quot;en0&quot;, &quot;ethernet_5&quot;. Important: This entry is not supported on Microsoft™ Windows™ platforms.</td>
</tr>
<tr>
<td>ip.global.v6.interface.id</td>
<td>Defines the id of the network interface to be used for IPv6 link-local addresses. For example, this entry can get values such as &quot;1&quot;, &quot;2&quot;, &quot;11&quot;.</td>
</tr>
</tbody>
</table>

**Note:** If an entry is defined more than once, only the last occurrence is taken into account.

Server configuration

The following table lists the FGLPROFILE entries that specify the correct way a Web Services client connects to an end point (usually a server). Notice that the entries specify also the way an application using the low-level com or xml API connects to an end point.
### Table 676: Server Configuration FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ws.ident.url</td>
<td>The end point URL of the server.</td>
</tr>
<tr>
<td></td>
<td>See Using * wildcards in server URLs on page 3244.</td>
</tr>
<tr>
<td>ws.ident.regex.url</td>
<td>A regular expression to define all possible URLs that can be used in this server configuration.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If the <code>ws.ident.url</code> is defined, the <code>regex.url</code> entry is ignored.</td>
</tr>
<tr>
<td></td>
<td>This regex entry follows W3C rules as described in <a href="https://www.w3.org/TR/xmlschema-2/#regexs">https://www.w3.org/TR/xmlschema-2/#regexs</a>.</td>
</tr>
<tr>
<td></td>
<td>See Using regular expressions in server URLs on page 3245.</td>
</tr>
<tr>
<td>ws.ident.cipher</td>
<td>The list of encryption, digest and key exchange algorithms the client is allowed to use during a secured communication to that server. It overwrites the global definition.</td>
</tr>
<tr>
<td>ws.ident.verifyserver</td>
<td>If set to <code>true</code>, the client performs a strict server identity validation. If not fulfilled, it stops the communication; otherwise no server identity verification is performed. The default value is <code>true</code>.</td>
</tr>
<tr>
<td>ws.ident.security</td>
<td>The security identifier the client uses to perform an HTTPS communication to the server.</td>
</tr>
<tr>
<td>ws.ident.authenticate</td>
<td>The HTTP authenticate identifier the client uses to authenticate itself to the server.</td>
</tr>
</tbody>
</table>

**Note:**

1. The `ident` keyword must be replaced with your own identifier. All necessary entries, depending on the remote server's configuration, must be set. See FGLPROFILE setting.
2. You can use the unique identifier in the `.4gl` code instead of the server URL, with the `alias://` prefix. For example, `alias://ident`.
3. If an entry is defined more that once, only the last occurrence is taken into account.

**XML configuration**

The following table lists the FGLPROFILE entries that control XML to Genero values conversion, and XML cryptography key or certificate mapping.
Table 677: XML configuration FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml.keystore.calist</td>
<td>The list of PEM-encoded third party X.509 certificates, separated with semicolons, of the Certificate Authority considered as trusted, in order of preference.</td>
</tr>
<tr>
<td>xml.keystore.x509list</td>
<td>The list of PEM-encoded third party X.509 certificates, separated with semicolons, to be used to find out the correct X.509 certificate when getting an incomplete one in a XML signature or an encrypted XML document.</td>
</tr>
<tr>
<td>xml.ident.key</td>
<td>The file name of a cryptography key. For instance RSA.pem, DSA.der or HMAC.bin.</td>
</tr>
<tr>
<td>xml.ident.x509</td>
<td>The file name of a cryptography x509 certificate. For instance Cert.crt.</td>
</tr>
</tbody>
</table>
| xml.serializer.supportEmptyStrings | Controls empty string XML nodes conversion to Genero STRING values.  
The default is false, empty XML tags are converted to NULL.  
If set to true, an empty XML tag is converted to an empty STRING value.  
As result, in Genero, the LENGTH() function will return zero and the IS NULL comparison operator will evaluate to FALSE.  
Note that this entry only works for the STRING data type, and if the tag is not present, the STRING is set to NULL. |
| xml.signature.prefix   | Defines the prefix for an XML Signature.                                                                                                         |
| xml.encryption.prefix  | Defines the prefix for an XML Encrypted data.                                                                                                       |

Note:
1. The ident keyword must be replaced with your own identifier. See FGLPROFILE sample 2.
2. You can use the unique identifier in the .4gl code instead of the filename.
3. If an entry is defined more that once, only the last occurrence is taken into account.

Examples
SSL/TLS configuration examples.

Windows® BAT script for private key password
Windows BAT script sample returning a password, depending on the .pem file passed as parameter.

```plaintext
@echo off
REM -- Windows password script
IF "%1" == "Cert/MyPrivateKeyA.pem" GOTO KeyA
IF "%1" == "Cert/MyPrivateKeyB.pem" GOTO KeyB
GOTO end
:KeyA
ECHO PasswordA
GOTO end
:KeyB
ECHO PasswordB
```
UNIX™ shell script for private key password
UNIX shell script sample returning a password, depending on the .pem file passed as parameter.

```bash
# UNIX password script
if [ "$1" == "Cert/MyPrivateKeyA.pem" ]
then
    echo PasswordA
fi
if [ "$1" == "Cert/MyPrivateKeyB.pem" ]
then
    echo PasswordB
fi
```

FGLPROFILE: HTTP(S) Proxy Authentication
FGLPROFILE entries can be used to define a connection to an HTTPS server via a proxy, and with HTTP and Proxy Authentication.

```bash
# Security configuration
security.global.script   =  "Cert/password.sh"
security.global.ca       =  "Cert/CAList.pem"
security.global.cipher   =  "HIGH" # Use only HIGH encryption ciphers
security.mykey.certificate =  "Cert/MyCertificateA.crt"
security.mykey.privatekey  =  "Cert/MyPrivateKeyA.pem"

# Proxy HTTP Authentication
authenticate.proxyauth.login    =  "myapplication"
authenticate.proxyauth.password =  "mypswd"
authenticate.proxyauth.scheme   =  "Basic"

# HTTPS Proxy configuration
proxy.https.location     =  "10.0.0.170"
proxy.https.list         =  "www.mycompany.com;www.mycompany.com"
proxy.https.authenticate =  "proxyauth"

# Server HTTP Authentication
authenticate.serverauth.login    =  "mylogin"
authenticate.serverauth.password =  "password"

# Server configuration
ws.myserver.authenticate =  "serverauth"
ws.myserver.security     =  "mykey"
```

Related concepts
FGLPROFILE: XML cryptography on page 3243
Use FGLPROFILE to define XML cryptography and use the fglpass agent to get the private key passwords.

FGLPROFILE: XML cryptography
Use FGLPROFILE to define XML cryptography and use the fglpass agent to get the private key passwords.

```bash
# Security configuration
security.global.agent     = "4444"

# Crypto configuration
xml.keystore.calist     = "RSARootCertificate.crt;DSARootCertificate.crt"
xml.keystore.x509list   = "RSA1024Certificate.crt;DSA1024Certificate.crt"
xml.id1.x509           = "RSA1024Certificate.crt"
```
Related concepts
FGLPROFILE: HTTP(S) Proxy Authentication on page 3243
FGLPROFILE entries can be used to define a connection to an HTTPS server via a proxy, and with HTTP and Proxy Authentication.

FGLPROFILE: Server URL patterns
FGLPROFILE entries can be used to define multiple server URLs, by using URL patterns.

Understanding URL patterns
By using URL patterns, you can create a URL base that applies to multiple server applications. URLs matching the pattern can share server configuration (such as authentication and HTTPS).

FGLPROFILE entries using URL patterns apply to the following APIs:
- `com.HTTPRequest.Create()`
- `xml.DomDocument.load()`
- `xml.DomDocument.save()`
- `xml.StaxReader` methods
- `xml.StaxWriter` methods
- `com.TCPRequest.create()`

Using * wildcards in server URLs
To create a URL base, add a wildcard (`/*`) to the end of a URL in the `fglprofile` entry. A server application that starts with this URL (and that is not explicitly defined elsewhere) shares the configuration with other applications that also start with the same base URL. If an application has its own server configuration explicitly defined, it uses its specific entries instead of those defined by the wildcard configuration.

Consider this excerpt from a hypothetical `fglprofile`:

```
authenticate.auth.login = "xxx"
authenticate.auth.password = "yyy"
authenticate.auth.scheme = "Basic"
security.sec.certificate = "client.crt"
security.sec.privatekey = "client.pem"

ws.myapp.url = "http://mycompany.com/sample/*"
ws.myapp.authenticate = "auth"
ws.myapp.security = "sec"

ws.thirdapp.url = "http://mycompany.com/sample/application3"
ws.thirdapp.authenticate = "auth3"
authenticate.auth3.login = "aaa"
authenticate.auth3.password = "bbb"
authenticate.auth3.scheme = "Basic"
```

Based on this example:
- Requests to "http://mycompany.com/sample/application1" and "http://mycompany.com/sample/demos/shoppingcart" use the same authentication and HTTPS configuration.
• A request to "http://mycompany.com/sample/application3" uses its specific authentication "auth3". No security configuration is defined for this URL, nor does it fall back on the shared security configuration defined for the base URL.

Using regular expressions in server URLs

To create a URL regex pattern, use the `ws.ident.regex.url` FGLPROFILE entry, and define a regular expression that matches all server URLs to be associated with the "ident" server configuration.

**Note:** If the `ws.ident.url` is defined, the `regex.url` entry is ignored.

```
authenticate.auth.login    =  "xxx"
authenticate.auth.password =  "yyy"
authenticate.auth.scheme   =  "Basic"

ws.myident.regex.url = "http://.*\strasbourg\4js\com:[0-9]{4}/.*"
ws.myident.authenticate = "auth"
```

XML to BDL serialization options

By default, Genero Web Services XML to BDL serialization will raise errors, if the XML content does not match the BDL variable receiving the data.

To relax the serialization, you can specify the options `xml_ignoreunknownattributes` and `xml_ignoreunknownelements` to the `xml.Serializer` class.

For example, if the BDL variable is defined as follows:

```
DEFINE data RECORD ATTRIBUTES(XMLName="Demo"),
   val1 INTEGER ATTRIBUTES(XMLName= "Value1"),
   val2 STRING ATTRIBUTES(XMLName= "Value2")
   attr INTEGER ATTRIBUTES(XMLAttribute,XMLName= "MyAttr")
END RECORD
```

The following XML document will by default raise conversion errors because the "badAttr" attribute and the "Unexpected" node are not defined in the corresponding BDL variable:

```
<Demo MyAttr="hello" badAttr= "BAD">
 <Value1>128</Value1>
 <Unexpected>Will be ignored</Unexpected1>
 <Value2>Hello</Value2>
</Demo>
```

To avoid the conversion error, set the following options:

```
CALL xml.Serializer.setOption( "xml_ignoreunknownattributes", TRUE )
CALL xml.Serializer.setOption( "xml_ignoreunknownelements", TRUE )
...
CALL xml.Serializer.DomToVariable( doc, data )
```

**Note:** The options to relax the serialization cannot apply in complex cases, and the conversion error may still occur.

For more details, see `xml.Serializer.SetOption` on page 2887.
WSHelper library
The WSHelper library.

The WSHelper file
It is recommended that the WSHelper.42m library file is linked into every Genero Web Services Server or Client program. It is located in $FGLDIR/lib.

WSHelper variables and records
The WSHelper library provides public variables and records.

WSQueryType
The WSHelper library defines WSHelper.WSQueryType as a dynamic array:

```plaintext
PUBLIC TYPE WSQueryType DYNAMIC ARRAY OF RECORD
    name    STRING,
    value   STRING
END RECORD
```

The fields of the record are:
1. `name` is the name of the query argument.
2. `value` is the value of the query argument.

WSServerCookiesType
The WSHelper library defines WSHelper.WSServerCookiesType as a dynamic array:

```plaintext
PUBLIC TYPE WSServerCookiesType DYNAMIC ARRAY OF RECORD
    name     STRING,  # Cookie name
    value    STRING,  # Cookie value
    path     STRING,  # Cookie path (or null)
    domain   STRING,  # Cookie domain (or null)
    expires  DATETIME YEAR TO SECOND, # Cookie expiration date (or null)
    httpOnly BOOLEAN,
    secure   BOOLEAN
END RECORD
```

The fields of the record are:
1. `name` is the name of the cookie to be set. This field is mandatory. It will be URL-encoded on the wire.
2. `value` is the value of the cookie to be set. This field is mandatory. It will be URL-encoded on the wire.
3. `path` is the main path the cookie has to be set for. Any path containing that main path will then return the cookie. If no name is set, the cookie will be set by the path the client has provided.
4. `domain` : the domain (hostname) or sub-domain (ex: .strasbourg.4js.com) the cookie will be set on client side. If not set, the domain will be the hostname provided by the client.
5. `expires` : a DATETIME YEAR TO SECOND (on local time) from where that cookie will expire, and thus not be sent by the client anymore. If NULL, the cookie is called session cookie and will be sent as long as the client keeps the session open.
6. `http_only` is set to TRUE if the cookie is only for the HTTP layer, FALSE if cookie can be accessible in JavaScript.
7. `secure` : true if cookie must only be sent in HTTPS, false for HTTP and HTTPS.
**WSHelper APIs**
The WSHelper library provides Genero BDL HTTP helper functions.

**Table 678: WSHelper functions**

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SplitUrl</strong> (url STRING)</td>
<td>Splits a complete URL string into pieces.</td>
</tr>
<tr>
<td>RETURNS (scheme STRING, host STRING, port STRING, path STRING, query STRING)</td>
<td></td>
</tr>
</tbody>
</table>

| **FindQueryStringValue** (query STRING, name STRING) | Get a query string value by name.                                           |
| RETURNS STRING                                              |                                                                             |

| **SplitQueryString** (query STRING) | Splits the query string of an URL into an array or key-value pairs.          |
| RETURNS WSHelper.WSQueryType                                          |                                                                             |

**WSHelper.FindQueryStringValue**
Get a query string value by name.

**Syntax**

```plaintext
FindQueryStringValue (query STRING, name STRING) RETURNS STRING
```

1. *query* is the query string where to look for a value.
2. *name* is the name of the value wanted.

**Usage**
Get a query string value by name.

In case of error, a NULL value will be returned.

**WSHelper functions example**

```plaintext
IMPORT FGL WSHelper
MAIN
DEFINE val, scheme, host, port, path, query STRING
DEFINE ind INTEGER
DEFINE ret WSHelper.WSQueryType
CALL WSHelper.SplitQueryString("name1=val1&name2=val2&name3=val3")
RETURNING ret
FOR ind = 1 TO ret.getLength()
  DISPLAY "Query", ind
```
DISPLAY " name is",ret[ind].name
DISPLAY " value is ",ret[ind].value
END FOR

LET val = WSHelper.FindQueryStringValue("name1=val1&name2=val2","name1")

CALL WSHelper.SplitUrl("https://cube.strasbourg.4js.com:3128/GWS-492/TestSplitURL/test1")
  RETURNING scheme, host, port, path, query

END MAIN

Output:

<table>
<thead>
<tr>
<th>Query</th>
<th>1</th>
<th>2</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>name is</td>
<td>name1</td>
<td>name2</td>
<td>name3</td>
</tr>
<tr>
<td>value is</td>
<td>val1</td>
<td>val2</td>
<td>val3</td>
</tr>
</tbody>
</table>

**WSHelper.SplitQueryString**
Splits the query string of an URL into an array or key-value pairs.

**Syntax**

```
SplitQueryString(
    query STRING )
RETURNS WSHelper.WSQueryType
```

1. *query* is the query string to be split into a dynamic array.

**Usage**

Split a given query string into a dynamic array of key-value pairs, defined as WSHelper.WSQueryType. The pieces are returned in dynamic array of key-value pairs defined as a WSHelper.WSQueryType. See **WSHelper variables and records** on page 3246 for more information regarding WSQueryType.

NULL may be returned if a value is not found.

In case of error, a NULL value will be returned.

**WSHelper functions example**

```
IMPORT FGL WSHelper

MAIN

DEFINE val, scheme, host, port, path, query STRING
DEFINE ind INTEGER
DEFINE ret WSHelper.WSQueryType

CALL WSHelper.SplitQueryString("name1=val1&name2=val2&name3=val3")
  RETURNING ret

FOR ind = 1 TO ret.getLength()
  DISPLAY "Query",ind
  DISPLAY " name is",ret[ind].name
```
DISPLAY " value is ",ret[ind].value
END FOR

LET val = WSHelper.FindQueryStringValue("name1=val1&name2=val2","name1")

CALL WSHelper.SplitUrl("https://cube.strasbourg.4js.com:3128/GWS-492/TestSplitURL/test1")
  RETURNING scheme, host, port, path, query
END MAIN

Output:

<table>
<thead>
<tr>
<th>Query</th>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>name1</td>
<td>val1</td>
</tr>
<tr>
<td>2</td>
<td>name2</td>
<td>val2</td>
</tr>
<tr>
<td>3</td>
<td>name3</td>
<td>val3</td>
</tr>
</tbody>
</table>

**WSHelper.SplitUrl**
Splits a complete URL string into pieces.

**Syntax**

```
SplitUrl(
  url STRING )
RETURNS ( scheme STRING,
  host STRING,
  port STRING,
  path STRING,
  query STRING )
```

1. `url` is a STRING with the URL to be split in pieces.
2. `scheme` is the URL scheme (http, https, file, ...). It includes all parts before : //
3. `host` is the hostname.
4. `port`: the port number, or NULL if there is none.
   
   **Note:** If NULL is returned, there is always a default port depending on the scheme: 443 for https, and 80 for http.
5. `path` is the path of the URL.
6. `query` is the query string of the URL, or NULL if there is none.

**Usage**
Splits a complete URL string into pieces.

In case of error, a NULL value will be returned.

**WSHelper functions example**

```
IMPORT FGL WSHelper

MAIN

DEFINE val, scheme, host, port, path, query STRING
DEFINE ind INTEGER
DEFINE ret WSHelper.WSQueryType

CALL WSHelper.SplitQueryString("name1=val1&name2=val2&name3=val3")
```
RETURNING ret

FOR ind = 1 TO ret.getLength()
    DISPLAY "Query", ind
    DISPLAY " name is", ret[ind].name
    DISPLAY " value is ", ret[ind].value
END FOR

LET val = WSHelper.FindQueryStringValue("name1=val1&name2=val2","name1")

CALL WSHelper.SplitUrl("https://cube.strasbourg.4js.com:3128/GWS-492/TestSplitURL/test1")
    RETURNING scheme, host, port, path, query

END MAIN

Output:

Query          1
    name is name1
    value is val1
Query          2
    name is name2
    value is val2
Query          3
    name is name3
    value is val3

Attributes to customize XML serialization

See The Serializer class on page 2877 for information on setting serialization options when mapping BDL and XML data.

BDL to/from XML type mappings

Starting with Genero 2.0, you can add optional attributes to the definition of program variables to be used for XML serialization. These attributes can be used to map a BDL data type used in the input or output message of a Genero Web Service application to a specific XML data type, rather than using the default.

For example, if an XML Schema boolean data type is required for an application, and the corresponding BDL type is a SMALLINT, you can use an attribute to map the BDL SMALLINT variable to the XML boolean.

The following example uses the XSDBoolean attribute to map a BDL SMALLINT variable to an XML Schema boolean type, and assigns an uppercase name as the XMLName attribute:

GLOBALS
DEFINE invoice_out RECORD
    ok SMALLINT ATTRIBUTES(XSDBoolean,XMLName="OK")
END RECORD
END GLOBALS

If you assign your own XMLName attributes, be sure to respect the conventions when using the RPC Service Style.

See the Tutorial: Writing a GWS Server application for additional information about input and output messages.

Default BDL/XML mapping

By default, Genero Web Services maps BDL variables in the input or output messages of a WS application to their corresponding XML data types, enabling values to be passed between applications and Web Services. The XML data types conform to the standard XML Schema Definition (XSD):
<table>
<thead>
<tr>
<th>Data type of BDL variable</th>
<th>Default XML data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>xsd:base64binary</td>
</tr>
<tr>
<td>CHAR</td>
<td>xsd:string</td>
</tr>
<tr>
<td>DATE</td>
<td>xds:date</td>
</tr>
<tr>
<td>DATETIME YEAR TO FRACTION(1-5)</td>
<td>xsd:dateTime</td>
</tr>
<tr>
<td>DATETIME YEAR TO SECOND</td>
<td>xsd:dateTime</td>
</tr>
<tr>
<td>DATETIME YEAR TO HOUR</td>
<td>xsd:dateTime</td>
</tr>
<tr>
<td>DATETIME YEAR TO MINUTE</td>
<td>xsd:dateTime</td>
</tr>
<tr>
<td>DATETIME YEAR TO YEAR</td>
<td>xsd:gYear</td>
</tr>
<tr>
<td>DATETIME YEAR TO MONTH</td>
<td>xsd:gYearMonth</td>
</tr>
<tr>
<td>DATETIME YEAR TO DAY</td>
<td>xsd:date</td>
</tr>
<tr>
<td>DATETIME MONTH TO MONTH</td>
<td>xsd:gMonth</td>
</tr>
<tr>
<td>DATETIME MONTH TO DAY</td>
<td>xsd:gMonthDay</td>
</tr>
<tr>
<td>DATETIME DAY TO DAY</td>
<td>xsd:gDay</td>
</tr>
<tr>
<td>DATETIME HOUR TO HOUR</td>
<td>xsd:time</td>
</tr>
<tr>
<td>DATETIME HOUR TO MINUTE</td>
<td>xsd:time</td>
</tr>
<tr>
<td>DATETIME HOUR TO SECOND</td>
<td>xsd:time</td>
</tr>
<tr>
<td>DATETIME HOUR TO FRACTION(1-5)</td>
<td>xsd:time</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>xsd:decimal</td>
</tr>
<tr>
<td>FLOAT</td>
<td>xsd:double</td>
</tr>
<tr>
<td>INTEGER</td>
<td>xsd:int</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>xsd:duration</td>
</tr>
<tr>
<td>SMALLFLOAT</td>
<td>xsd:float</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>xsd:short</td>
</tr>
<tr>
<td>STRING</td>
<td>xsd:string</td>
</tr>
<tr>
<td>TEXT</td>
<td>xsd:string</td>
</tr>
<tr>
<td>VARCHAR</td>
<td>xsd:string</td>
</tr>
<tr>
<td>TINYINT</td>
<td>xsd:byte</td>
</tr>
<tr>
<td>BIGINT</td>
<td>xsd:long</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>xsd:boolean</td>
</tr>
</tbody>
</table>

In addition, the Web Service Style that you use determines what default XMLName attributes are assigned to variables.

**Type mapping attributes**

The attributes listed in this table cannot have values.
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSDAnySimpleType</td>
<td>Map BDL STRING or VARCHAR to XML Schema simpleType.</td>
</tr>
<tr>
<td>XSDAnyType</td>
<td>Map BDL STRING or VARCHAR to XML Schema anyType.</td>
</tr>
<tr>
<td>XSDAnyURI</td>
<td>Map BDL STRING or VARCHAR to XML Schema anyURI.</td>
</tr>
<tr>
<td>XSBBase64binary</td>
<td>Map BDL BYTE to the XML Schema base64binary.</td>
</tr>
<tr>
<td>XSDBoolean</td>
<td>Map BDL BOOLEAN, SMALLINT or INTEGER to XML Schema boolean.</td>
</tr>
<tr>
<td>XSDByte</td>
<td>Map BDL TINYINT, SMALLINT or BIGINT to XML Schema byte.</td>
</tr>
<tr>
<td>XSDDate</td>
<td>Map BDL DATE or DATETIME to XML Schema date.</td>
</tr>
<tr>
<td>XSDDateTime</td>
<td>Map BDL DATETIME to XML Schema dateTime.</td>
</tr>
<tr>
<td>XSDDecimal</td>
<td>Map BDL DECIMAL to XML Schema decimal.</td>

<tr>
<td>XSDNCName</td>
<td>Map BDL STRING or VARCHAR to XML Schema NCName.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Definition</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>XSDName</td>
<td>Map BDL STRING or VARCHAR to XML Schema Name.</td>
</tr>
<tr>
<td>XSDNegativeInteger</td>
<td>Map BDL DECIMAL to XML Schema negativeInteger.</td>
</tr>
<tr>
<td>XSDNMTOKEN</td>
<td>Map BDL STRING or VARCHAR to XML Schema NMToken.</td>
</tr>
<tr>
<td>XSDNMTOKENS</td>
<td>Map BDL STRING or VARCHAR to XML Schema NMTokens.</td>
</tr>
<tr>
<td>XSDNonNegativeInteger</td>
<td>Map BDL DECIMAL to XML Schema nonNegativeInteger.</td>
</tr>
<tr>
<td>XSDNonPositiveInteger</td>
<td>Map BDL DECIMAL to XML Schema nonPositiveInteger.</td>
</tr>
<tr>
<td>XSDNormalizedString</td>
<td>Map BDL STRING or VARCHAR to XML Schema normalizedString.</td>
</tr>
<tr>
<td>XSDNotation</td>
<td>Not supported.</td>
</tr>
<tr>
<td>XSDPositiveInteger</td>
<td>Map BDL DECIMAL to XML Schema positiveInteger.</td>
</tr>
<tr>
<td>XSDQName</td>
<td>Map BDL STRING or VARCHAR to XML Schema QName.</td>
</tr>
<tr>
<td>XSDShort</td>
<td>Map BDL SMALLINT or BIGINT to XML Schema short.</td>
</tr>
<tr>
<td>XSDString</td>
<td>Map BDL STRING, Char, Text or VarChar to XML Schema string.</td>
</tr>
<tr>
<td>XSDTime</td>
<td>Map BDL DATETIME to XML Schema time.</td>
</tr>
<tr>
<td>XSDToken</td>
<td>Map BDL STRING or VARCHAR to XML Schema token.</td>
</tr>
<tr>
<td>XSDUnsignedByte</td>
<td>Map BDL SMALLINT or BIGINT to XML Schema unsignedByte.</td>
</tr>
<tr>
<td>XSDUnsignedInt</td>
<td>Map BDL BIGINT or DECIMAL to XML Schema unsignedInt.</td>
</tr>
<tr>
<td>XSDUnsignedLong</td>
<td>Map BDL DECIMAL to XML Schema unsignedLong.</td>
</tr>
<tr>
<td>XSDUnsignedShort</td>
<td>Map BDL INTEGER or BIGINT to XML Schema unsignedShort.</td>
</tr>
</tbody>
</table>

**XSDAnySimpleType**
Map BDL STRING or VARCHAR to XML Schema anySimpleType.

**XSDAnyType**
Map BDL STRING or VARCHAR to XML Schema anyType.

**XSDAnyURI**
Map BDL STRING or VARCHAR to XML Schema anyURI.

**XSDBase64binary**
Map BDL BYTE to XML Schema base64binary.
Example

```c
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 BYTE ATTRIBUTES(XSDBase64Binary,XMLName="Val")
END RECORD

<Root>
  <Val>F0FFC8D27FF001547FC219E1FFF09F0FFC8D27FF001547D</Val>
</Root>
```

**XSDBoolean**

Map BDL BOOLEAN, SMALLINT or INTEGER to XML Schema boolean.

Example

```c
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XSDBoolean,XMLName="Val")
END RECORD

<Root>
  <Val>true</Val>
</Root>
```

**XSDByte**

Map BDL TINYINT, SMALLINT or BIGINT to XML Schema byte.

Example

```c
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 SMALLINT ATTRIBUTES(XSDByte,XMLName="Val")
END RECORD

<Root>
  <Val>-126</Val>
</Root>
```

**XSDDate**

Map BDL DATE or DATETIME to XML Schema date.

Example

```c
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATE ATTRIBUTES(XSDDate,XMLName="Val")
END RECORD

<Root>
  <Val>2006-06-29+01:00</Val>
</Root>
```

**XSDDateTime**

Map BDL DATETIME to XML Schema dateTime.

Example

```c
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME ATTRIBUTES(XSDDateTime,XMLName="Val")
END RECORD

<Root>
  <Val>2006-06-29+01:00</Val>
</Root>
```
**XSDDecimal**

Map BDL DECIMAL to XML Schema `decimal`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val DECIMAL(5,3) ATTRIBUTES(XSDDecimal,XMLName="Val")
END RECORD

<Root>
    <Val>12.345</Val>
</Root>
```

**XSDDouble**

Map BDL FLOAT to XML Schema `double`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val FLOAT ATTRIBUTES(XSDDouble,XMLName="Val")
END RECORD

<Root>
    <Val>12.78e-2</Val>
</Root>
```

**XSDDuration**

Map BDL INTERVAL to XML Schema `duration`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val INTERVAL DAY TO SECOND ATTRIBUTES(XSDDuration,XMLName="Val")
END RECORD

<Root>
    <Val>P3DT10H30M45S</Val>
</Root>
```

**XSDEntities**

Map BDL STRING or VARCHAR to XML Schema `ENTITIES`.

**XSDEntity**

Map BDL STRING or VARCHAR to XML Schema `ENTITY`.

**XSDFloat**

Map BDL SMALLFLOAT to XML Schema `float`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
```
XSDGDay
Map BDL DATETIME to XML Schema gDay.

Example

```xml
<Root>
  <Val>126.435</Val>
</Root>
```

XSDGMonth
Map BDL DATETIME to XML Schema gMonth.

Example

```xml
<Root>
  <Val>--25</Val>
</Root>
```

XSDGMonthDay
Map BDL DATETIME to XML Schema gMonthDay.

Example

```xml
<Root>
  <Val>--12-31</Val>
</Root>
```

XSDGYear
Map BDL DATETIME to XML Schema gYear.

Example

```xml
<Root>
  <Val>2006</Val>
</Root>
```
XSDGYearMonth
Map BDL DATETIME to XML Schema gYearMonth.
Example

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  vall DATETIME YEAR TO MONTH ATTRIBUTES(XSDGYearMonth,XMLName="Val")
END RECORD

<Root>
  <Val>2006-06</Val>
</Root>
```

XSDHexBinary
Map BDL BYTE to XML Schema hexBinary.
Example

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  vall BYTE ATTRIBUTES(XSDHexBinary,XMLName="Val")
END RECORD

<Root>
  <Val>0FB6</Val>
</Root>
```

XSDID
Map BDL STRING or VARCHAR to XML Schema ID.

XSDIDREF
Map BDL STRING or VARCHAR to XML Schema IDREF.

XSDIDREFS
Map BDL STRING or VARCHAR to XML Schema IDREFS.

XSDInt
Map BDL INTEGER or BIGINT to XML Schema int.
Example

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  vall INTEGER ATTRIBUTES(XSDInt,XMLName="Val")
END RECORD

<Root>
  <Val>-1258</Val>
</Root>
```

XSDInteger
Map BDL DECIMAL to XML Schema integer.
Example

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  vall DECIMAL(32,0) ATTRIBUTES(XSDInteger,XMLName="Val")
```
XSDLanguage
Map BDL STRING or VARCHAR to XML Schema language.

XSDLong
Map BDL BIGINT or DECIMAL to XML Schema long.

Example
```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(19,0) ATTRIBUTES(XSDLong,XMLName="Val")
END RECORD
```

XSDNCName
Map BDL STRING or VARCHAR to XML Schema NCName.

XSDName
Map BDL STRING or VARCHAR to XML Schema Name.

XSDNonNegativeInteger
Map BDL DECIMAL to XML Schema nonNegativeInteger.

Example
```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(32,0) ATTRIBUTES(XSDNonNegativeInteger,XMLName="Val")
END RECORD
```

XSDNMTOKEN
Map BDL STRING or VARCHAR to XML Schema NMToken.

XSDNMTOKENS
Map BDL STRING or VARCHAR to XML Schema NMTokens.

XSDNonNegativeInteger
Map BDL DECIMAL to XML Schema nonNegativeInteger.

Example
```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(32,0) ATTRIBUTES(XSDNonNegativeInteger,XMLName="Val")
END RECORD
```
**XSDNonPositiveInteger**

Map BDL DECIMAL to XML Schema `nonPositiveInteger`.

**Example**

```xml
define myVar record attributes(xmlname="Root")
  val1 decimal(32,0) attributes(xsdnonpositiveinteger,xmlname="Val")
declare record
declare end record
<root>
  <val>-1589</val>
</root>
```

**XSDNormalizedString**

Map BDL STRING or VARCHAR to XML Schema `normalizedString`.

**XSDnotation**

Not supported.

**XSDPositiveInteger**

Map BDL DECIMAL to XML Schema `positiveInteger`.

**Example**

```xml
define myVar record attributes(xmlname="Root")
  val1 decimal(32,0) attributes(xsdpositiveinteger,xmlname="Val")
declare record
declare end record
<root>
  <val>+41893</val>
</root>
```

**XSDQName**

Map BDL STRING or VARCHAR to XML Schema `QName`.

**XSDShort**

Map BDL SMALLINT or BIGINT to XML Schema `short`.

**Example**

```xml
define myVar record attributes(xmlname="Root")
  val1 smallint attributes(xsdshort,xmlname="Val")
declare record
declare end record
<root>
  <val>12678</val>
</root>
```

**XSDString**

Map BDL STRING, CHAR, TEXT or VARCHAR to XML Schema `string`. 
Example

```
DEFINE myVar RECORD
  ATTRIBUTES(XMLName="Root")
  val1 STRING
END RECORD

<Root>
  <Val>Hello world, how are you ?</Val>
</Root>
```

**XSDTime**

Map BDL DATETIME to XML Schema **time**.

Example

```
DEFINE myVar RECORD
  ATTRIBUTES(XMLName="Root")
  val1 DATETIME
END RECORD

<Root>
  <Val>23:16:03.589+01:00</Val>
</Root>
```

**XSDToken**

Map BDL STRING or VARCHAR to XML Schema **token**.

**XSDUnsignedByte**

Map BDL SMALLINT or BIGINT to XML Schema **unsignedByte**.

Example

```
DEFINE myVar RECORD
  ATTRIBUTES(XMLName="Root")
  val1 SMALLINT
END RECORD

<Root>
  <Val>254</Val>
</Root>
```

**XSDUnsignedInt**

Map BDL BIGINT or DECIMAL to XML Schema **unsignedInt**.

Example

```
DEFINE myVar RECORD
  ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(32,0)
END RECORD

<Root>
  <Val>1267896754</Val>
</Root>
```

**XSDUnsignedLong**

Map BDL DECIMAL to XML Schema **unsignedLong**.
Example

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DECIMAL(32,0) ATTRIBUTES(XSDUnsignedLong,XMLName="Val")
END RECORD

<Role>
    <Val>12678967543233</Val>
</Root>
```

**XSDUnsignedShort**

Map BDL INTEGER or BIGINT to XML Schema `unsignedShort`.

Example

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 INTEGER ATTRIBUTES(XSDUnsignedShort,XMLName="Val")
END RECORD

<Role>
    <Val>65535</Val>
</Root>
```

**XML facet constraint attributes**

The following attributes are facet constraints depending on the XSD data type used on a simple BDL variable to restrict the allowed value-space.

(Notice that some attributes are allowed only on some XSD data types).

Several facet constraints can be set on the same data type, and a mandatory values is expected (for example, `XSDMinLength="8"`).

**Table 681: Facet constraints between simple BDL and XML data types**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSDLength</td>
<td>Define the exact number of XML character or bytes.</td>
</tr>
<tr>
<td>XSDMinLength</td>
<td>Define the minimum number of XML character or bytes.</td>
</tr>
<tr>
<td>XSDMaxLength</td>
<td>Define the maximum number of XML character or bytes.</td>
</tr>
<tr>
<td>XSDEnumeration</td>
<td>Define a list of allowed values separated by the character</td>
</tr>
<tr>
<td>XSDWhiteSpace</td>
<td>Perform a XML string manipulation before serialization or deserialization.</td>
</tr>
<tr>
<td>XSDPattern</td>
<td>Define the regular expression the value has to match.</td>
</tr>
<tr>
<td>XSDMinInclusive</td>
<td>Define the inclusive minimum value based on the data type where it is set.</td>
</tr>
<tr>
<td>XSDMaxInclusive</td>
<td>Define the inclusive maximum value based on the data type where it is set.</td>
</tr>
<tr>
<td>XSDMinExclusive</td>
<td>Define the exclusive minimum value based on the data type where it is set.</td>
</tr>
<tr>
<td>XSDMaxExclusive</td>
<td>Define the exclusive maximum value based on the data type where it is set.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Definition</td>
</tr>
<tr>
<td>--------------------</td>
<td>----------------------------------------------------------</td>
</tr>
<tr>
<td>XSDTotalDigits</td>
<td>Define the total number of digits.</td>
</tr>
<tr>
<td>XSFractionDigits</td>
<td>Define the number of digits of the fraction part.</td>
</tr>
</tbody>
</table>

**XSDL**

Restrict the length of the data to the exact number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

**Note:**

1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater than XSDMinLength
2. XSDMaxLength cannot be used with XSDL

**Example**

```plaintext
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDL="12", XMLName="MyString")
```

```plaintext
DEFINE myByte BYTE ATTRIBUTES(XSDBase64Binary, XSDL="8000", XMLName="MyPicture")
```

**XSDMinL**

Restrict the length of the data to the minimum number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

**Note:**

1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater than XSDMinLength
2. XSDMaxLength cannot be used with XSDL

**Example**

```plaintext
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDMinL="12", XMLName="MyString")
```

```plaintext
DEFINE myByte BYTE ATTRIBUTES(XSDBase64Binary, XSDMinL="8000", XMLName="MyPicture")
```

**XSDMaxL**

Restrict the length of the data to the maximum number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

**Note:**

1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater than XSDMinLength
2. XSDMaxLength cannot be used with XSDL

**Example**

```plaintext
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDMaxL="12", XMLName="MyString")
```

```plaintext
DEFINE myByte BYTE ATTRIBUTES(XSDBase64Binary, XSDMaxL="8000", XMLName="MyPicture")
```
**XSDEnumeration**
Restrict the allowed value-space to a list of values separated by the characters `|`.

**Note:**
1. To escape the separator character, simply double it like the following `||`.
2. This attribute can be set on any simple BDL variable excepted on XSDBoolean.

**Example**

```plaintext
DEFINE myStr STRING ATTRIBUTES(XSDString,
    XSDEnumeration="one|two|three|four", XMLName="MyString")

DEFINE myDec DECIMAL(3,1) ATTRIBUTES(XSDDecimal,
    XSDEnumeration="12.1|11.8|-24.7", XMLName="MyDecimal")
```

**XSDWhiteSpace**
Perform a XML string manipulation before serialization or deserialization depending on the following possible values:

- **preserve**: the XML string is not modified.
- **replace**: the XML string is modified by replacing each `
`, `	`, `` by a single space.
- **collapse**: the XML string is modified by replacing each `
`, `	`, `` by a single space, then each sequence of several spaces are replaced by one single space. Leading and trailing spaces are removed too.

**Note:**
1. The whiteSpace facet is always performed before any other facet constraints, or serialization or deserialization process.
2. For any BDL variable excepted STRING, CHAR and VARCHAR, only collapse is allowed.

**Example**

```plaintext
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDWhiteSpace="replace",
    XMLName="MyString")

DEFINE myDec DECIMAL(3,1) ATTRIBUTES(XSDDecimal,
    XSDWhiteSpace="collapse", XMLName="MyDecimal")
```

**XSDPattern**
Define a regular expression the value has to match to be serialized or deserialized without any error.

**Note:**
1. The regular expression is defined in the XML Schema Part 2 specification available here.
2. Backslash characters `\` in a regular expression must be escaped by duplicating it.

**Example**

```plaintext
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDPattern="A.*Z",
    XMLName="MyString")

DEFINE myZipCode INTEGER ATTRIBUTES(XSDDecimal,
    XSDPattern="[0-9]{5}", XMLName="MyZipCode")

DEFINE myOtherZipCode INTEGER ATTRIBUTES(XSDDecimal,
    XSDPattern="\\d{5}", XMLName="myOtherZipCode") # regex is \d{5} see note
```
**XSDMinInclusive**

Define the minimum inclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

**Note:** The minimum value cannot exceed the implicit minimum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the minimum value is -32768.

**Example**

```cpp
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDMinInclusive="-1000", XMLName="MyCode")
```

```cpp
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDMinInclusive="100.01", XMLName="MyRate")
```

**XSDMaxInclusive**

Define the maximum inclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

**Note:** The maximum value cannot exceed the implicit maximum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the maximum value is 32767.

**Example**

```cpp
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDMaxInclusive="1000", XMLName="MyCode")
```

```cpp
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDMaxInclusive="299.99", XMLName="MyRate")
```

**XSDMinExclusive**

Define the minimum exclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

**Note:** The minimum value cannot exceed or be equal to the implicit minimum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the minimum value is -32768.

**Example**

```cpp
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDMinExclusive="-1000", XMLName="MyCode")
```

```cpp
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDMinExclusive="100.01", XMLName="MyRate")
```

**XSDMaxExclusive**

Define the maximum exclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

**Note:** The maximum value cannot exceed or be equal to the implicit maximum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the maximum value is 32767.

**Example**

```cpp
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDMaxExclusive="1000", XMLName="MyCode")
```

```cpp
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDMaxExclusive="299.99", XMLName="MyRate")
```
**XSDTotalDigits**

Define the maximum number of digits allowed on a numeric data type, fraction part inclusive if there is one.

**Note:**

1. The total digits value cannot be equal or lower than 0.
2. On a BDL decimal, the total digits value cannot be lower than the precision of the BDL decimal itself.
3. Notice that a decimal without any precision and scale value is a decimal(16), therefore the total digits value must be equal or greater than 16.

**Example**

```plaintext
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDTotalDigits="4", XSDMaxExclusive="1000", XMLName="MyCode")

DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDTotalDigits="5", XSDMaxExclusive="299.99", XMLName="MyRate")
```

**XSDFractionDigits**

Define the maximum number of digits allowed on the fraction part of a numeric data type.

**Note:**

1. The fraction digits value set on a BDL data type without XSDDecimal set, can only be 0.
2. On a BDL DECIMAL, the fraction digits value cannot be lower than the scale of the BDL DECIMAL itself, and must be lower than the XSDTotalDigits value if set.

**Example**

```plaintext
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDFractionDigits="0", XSDMaxExclusive="1000", XMLName="MyCode")

DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDFractionDigits="3", XSDMaxExclusive="299.99", XMLName="MyRate")
```

**Customizing XML serialization**

The following attributes are used to change the default serialization of BDL into XML, and vice versa. Some attributes cannot have values, some may have values, and some attributes have mandatory values.

The following attributes cannot have values:

**Table 682: XML Serialization customizing - Attributes that cannot have values**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLHttpRequest</td>
<td>Define whether the variable can be missing.</td>
</tr>
<tr>
<td>XMLNillable</td>
<td>Define an XML element to be explicitly null and serialized with the xsi:nil=&quot;true&quot; value.</td>
</tr>
<tr>
<td>XMLBase</td>
<td>Set the base type of an XML Schema simpleContent.</td>
</tr>
<tr>
<td>XMLAttribute</td>
<td>Map a BDL simple data type to an XML Attribute.</td>
</tr>
<tr>
<td>XMLElement</td>
<td>Map a BDL simple data type to an XML Element.</td>
</tr>
<tr>
<td>XMLElementNillable</td>
<td>Define the default for all element members in a RECORD (defined by TYPE or DEFINE) to be serialized as xsi:nil=&quot;true&quot; if NULL.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Definition</td>
</tr>
<tr>
<td>----------------</td>
<td>---------------------------------------------------------------------------</td>
</tr>
<tr>
<td>XMLAll</td>
<td>Map a BDL Record to an XML Schema all structure.</td>
</tr>
<tr>
<td>XMLChoice</td>
<td>Map a BDL Record to an XML Schema choice structure.</td>
</tr>
<tr>
<td>XMLSequence</td>
<td>Map a BDL Record to an XML Schema sequence structure.</td>
</tr>
<tr>
<td>XMLSimpleContent</td>
<td>Map a BDL Record to an XML Schema simpleContent structure.</td>
</tr>
<tr>
<td>XSComplexType</td>
<td>Map a BDL Record type definition to an XML Schema complexType.</td>
</tr>
<tr>
<td>XMLList</td>
<td>Map a one-dimensional array to an XML Schema list.</td>
</tr>
<tr>
<td>XMLSelector</td>
<td>Define which member of an XMLChoice record is selected.</td>
</tr>
<tr>
<td>XMLAny</td>
<td>Map a xml.DomDocument object to a wildcard XML element node.</td>
</tr>
<tr>
<td>XMLAnyAttribute</td>
<td>Map a BDL one-dimensional dynamic array of a record with 3 strings to XML wildcard attributes.</td>
</tr>
</tbody>
</table>

Values are mandatory for the following attributes: (for example, XMLName="myname")

**Table 683: XML Serialization customizing - Attributes that must have values**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLName</td>
<td>Define the XML Name of a variable in an XML document.</td>
</tr>
<tr>
<td>XMLNamespace</td>
<td>Define the XML Namespace of a variable in an XML document.</td>
</tr>
<tr>
<td>XMLType</td>
<td>Force the XML type name of a variable.</td>
</tr>
<tr>
<td>XMLTypenamespace</td>
<td>Force the XML type namespace of a variable.</td>
</tr>
<tr>
<td>XSTypename</td>
<td>Define the XML Type Name of a BDL type definition.</td>
</tr>
<tr>
<td>XSTypenamespace</td>
<td>Define the XML Type Namespace of a BDL type definition.</td>
</tr>
<tr>
<td>XMLElementNamespace</td>
<td>Define the default XML namespace of all children defined as XMLElement in a Record.</td>
</tr>
<tr>
<td>XMLAttributeNamespace</td>
<td>Define the default XML namespace of all children defined as XMLAttribute in a Record.</td>
</tr>
</tbody>
</table>

Values may be required for the following attributes: (for example, XMLOptimizedContent="image/*")

**Table 684: XML Serialization customizing - Attributes that may have values**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLOptimizedContent</td>
<td>Set on STRING or BYTE data type so that such string content represents a file on disk to be transmitted as base64 binary in SOAP via HTTP attachment.</td>
</tr>
</tbody>
</table>

**XMLOptional**

Define whether a variable can be omitted or not. It specifies how a NULL value is interpreted in XML if it is optional. For an option to set an XML node nillable when the BDL variable is NULL but not optional, see the XMLNillable on page 3267 attribute.

**Note:**

1. The attribute cannot be set on a type definition.
2. The attribute cannot be set if the main variable is not a RECORD.
Example

The variable "ValTwo" is optional when null.

```bsh
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 INTEGER ATTRIBUTES(XSDint,XMLName="ValOne"),
    val2 FLOAT ATTRIBUTES(XSDdouble,XMLName="ValTwo",XMLOptional)
END RECORD
```

In the resulting XML document, "ValTwo" is defined when not NULL

```xml
<Root>
    <ValOne>458</ValOne>
    <ValTwo>58.48</ValTwo>
</Root>
```

In the resulting XML document, "ValTwo" is not defined when NULL.

```xml
<Root>
    <ValOne>458</ValOne>
</Root>
```

XMLNillable

Define an XML element to be explicitly null and serialized with the `xsi:nil="true"` value. It specifies how a NULL value is set on an XML node when the BDL variable is NULL but not optional.

**Note:** The XMLNillable attribute cannot be set on a TYPE definition.

The XMLNillable attribute is used on its own, or in combination with the `XMLOptional` attribute to specify conditions for the XML node depending on how you want the BDL variable value to be serialized:

- XML node optional (when null)
- XML node nillable (when null)
- Option of either XML node optional or nillable, with preference for nillable.

Examples are shown for each use.

**Example optional**

The variable "val2" is optional when null

```bsh
DEFINE var RECORD
    val1 STRING,
    val2 INTEGER ATTRIBUTES(XMLOptional),
    val3 FLOAT
END RECORD
```

The resulting XML document is:

```xml
<var>
    <val1>Hello</val1>
    <val3>3.1415</val3>
</var>
```

**Example nillable**

The variable "val2" is nillable when BDL variable is NULL but not optional.

```bsh
DEFINE var RECORD
    val1 STRING,
    val2 INTEGER ATTRIBUTES(XMLNillable),
    val3 FLOAT
END RECORD
```
In the resulting XML document "val2" is serialized with the xsi:nil="true" value:

```xml
<var>
  <val1>Hello</val1>
  <val2 xsi:nil="true"/>
  <val3>3.1415</val3>
</var>
```

**Example optional or nillable**

The variable "val2" is either optional or nillable if BDL variable is NULL.

```bdl
DEFINE var RECORD
  val1 STRING,
  val2 INTEGER ATTRIBUTES(XMLNillable,XMLOptional),
  val3 FLOAT
END RECORD
```

In the resulting XML document "val2" is missing as it is defined by XMLOptional (the default).

```xml
<var>
  <val1>Hello</val1>
  <val3>3.1415</val3>
</var>
```

Or the resulting XML document can show "val2" nillable:

```xml
<var>
  <val1>Hello</val1>
  <val2 xsi:nil="true"/>
  <val3>3.1415</val3>
</var>
```

**Note:** If both XMLOptional and XMLNillable are set and the BDL variable is NULL, the serialization process from BDL to XML uses XMLOptional by default. If you prefer to serialize as xsi:nil="true", you must specify the "preferred" value as a parameter of XMLNillable.

```bdl
DEFINE var RECORD
  val1 STRING,
  val2 INTEGER ATTRIBUTES(XMLNillable="preferred",XMLOptional),
  val3 FLOAT
END RECORD
```

**XML transformation into BDL**

When getting an XML transformation into BDL, the Web Service engine will not raise an error and the variable is set correctly whether the variable tag is missing or has xsi:nil="true" set. In either case, the BDL variable is set as NULL.

**XMLElement (Optional)**

Map a BDL simple data type to an XML Element.

**Note:** The attribute cannot be set on a type definition.

**Example**

```bdl
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XMLElement, XSDunsignedShort, XMLName="Val1"),
  rec RECORD ATTRIBUTES(XMLName="Rec")
```
val2 FLOAT  ATTRIBUTES(XMLElement, XMLName="Val2"),  
  val3 STRING ATTRIBUTES(XMLElement, XMLName="Val3")  
END RECORD  
END RECORD  

<Root>  
  <Val1>148</Val1>  
  <Rec1>  
    <Val2>25.8</Val2>  
    <Val3>Hello world</Val3>  
  </Rec1>  
</Root>  

XMLElementNillable  

The XMLElementNillable attribute specifies that all members of a RECORD have to be serialized as  
  xsi:nil="true"  when NULL. This has the same effect as defining each individual element with the XMLNillable  
on page 3267 attribute.  

Note: The XMLElementNillable attribute can only be set on records defined by TYPE or DEFINE.  
The XMLElementNillable attribute supports the record defined with LIKE clause to use the table definition from a  
database schema:  

DEFINE var RECORD ATTRIBUTE(XMLElementNillable) LIKE customer.*  

If columns in the database table are allowed to be null, you must add the XMLElementNillable attribute to the record  
definition.  
The XMLElementNillable attribute is not inherited by sub records.  

Basic example  

DEFINE var RECORD ATTRIBUTE(XMLElementNillable)  
  val1 STRING,  
  val2 STRING  
END RECORD  
LET var.val1 = "Hello"  
LET var.val2 = NULL  

In the resulting XML document, "val2" is serialized with the xsi:nil="true":  

<var>  
  <val1>Hello</val1>  
  <val2 xsi:nil="true"/>  
</var>  

Example using a sub record  

Since XMLElementNillable attribute is not inherited by sub records, you must set it on each sub-record if needed:  

DEFINE var RECORD ATTRIBUTE(XMLElementNillable)  
  val1 STRING,  
  val2 STRING,  
  subrec RECORD  
    val3 STRING  
  END RECORD  
END RECORD  

In the resulting XML document, for instance, only "val1" and "val2" are serialized as xsi:nil="true" when  
NULL, but "val3" is not.
To have "val3" serialized as xsi:nil="true" when NULL, define:

```
DEFINE var RECORD ATTRIBUTE(XMLElementNillable)
  val1 STRING,
  val2 STRING,
  subrec RECORD ATTRIBUTE(XMLElementNillable)
    val3 STRING
  END RECORD
END RECORD
```

**Examples with XMLNillable and XMLOptional**

The XMLElementNillable attribute does not allow values, so you cannot write XMLElementNillable="preferred" as you do for XMLNillable.

If XMLOptional on page 3266 is set on a record member, XMLElementNillable is not taken into account.

If you need XMLNillable to take precedence over XMLOptional, you must then specify XMLNillable="preferred" on the record member.

In the following sample, if "val2" is NULL, it will serialize to the tag not being present because XMLOptional hides XMLElementNillable. On the other hand, if "val3" is NULL, it will be serialized as xsi:nil="true", because the record member is defined with XMLOptional and XMLNillable (preferred):

```
DEFINE var RECORD ATTRIBUTE(XMLElementNillable)
  val1 STRING,
  val2 STRING ATTRIBUTE(XMLOptional),
  val3 STRING ATTRIBUTE(xmloptional,XMLNillable="preferred")
END RECORD

LET var.val1 = "Hello"
LET var.val2 = NULL
LET var.val3 = NULL
```

Will be serialized as:

```
<var>
  <val1>Hello</val1>
  <val3 xsi:nil="true"/>
</var>
```

**XMLAttribute**

Map a BDL simple data type to an XML Attribute.

**Note:**

1. The attribute cannot be set on a type definition.
2. The attribute can only be set on a RECORD's member.

**Example**

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XMLOptional,XSDUnsignedShort,XMLName="Val1"),
  rec RECORD ATTRIBUTES(XMLName="Rec1")
    val2 FLOAT ATTRIBUTES(XMLOptional,XMLName="Val2"),
    val3 STRING ATTRIBUTES(XMLElement,XMLName="Val3")
  END RECORD
END RECORD

<Role Val1="1480"/>
<Rec1 Val2="25.8">
  <Val3>Hello world</Val3>
</Rec1>
```
XMLBase
Define the simple BDL variable used as the base type of an XML Schema simpleContent structure.
The attribute can be set on one and only one member of a RECORD defined with the XMLSimpleContent attribute.

XMLAll
Map a BDL Record to an XML Schema all structure.
The order in which the record members appear in the XML document is not significant.

Example
```bdl
DEFINE myall RECORD ATTRIBUTES(XMLAll,XMLName="Root")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT  ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  val3  STRING ATTRIBUTES(XMLName="Val3")
END RECORD
```
```xml
<Root Val2="25.8">
  <Val3>Hello world</Val3>
  <Val1>148</Val1>
</Root>
```
```xml
<Root Val2="25.8">
  <Val1>148</Val1>
  <Val3>Hello world</Val3>
</Root>
```

XMLChoice
Map a BDL Record to an XML Schema choice structure. The choice of the record’s member is performed at runtime,
and changes dynamically depending on a mandatory member. This specific member must be of type SMALLINT
or INTEGER, and have an XMLSelector attribute set. The XMLChoice attribute also supports a "nested" value that
removes the surrounding XML tag.

Note:
1. Valid selector values are indexes referring to members considered as XML element nodes. All other values will
   raise XML runtime errors.
2. Nested choice records cannot be defined as main variables; there must always be a surrounding variable.

Example
```bdl
DEFINE mychoice RECORD ATTRIBUTES(XMLChoice,XMLName="Root")
  val1  INTEGER   ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT     ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  sel   SMALLINT  ATTRIBUTES(XMLSelector),
  val3  STRING    ATTRIBUTES(XMLName="Val3")
END RECORD
```
```xml
Case where "sel" value is 4
```
```xml
<Root Val2="25.8">
  <Val3>Hello world</Val3>
</Root>
```
Case where "sel" value is 1

```xml
<Root Val2="25.8">
  <Val1>148</Val1>
</Root>
```

Nested example:

```bdl
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XMLName="Val1"),
  val2 FLOAT ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  choice RECORD ATTRIBUTES(XMLChoice="nested")
    choice1 INTEGER ATTRIBUTES(XMLName="ChoiceOne"),
    choice2 FLOAT ATTRIBUTES(XMLName="ChoiceTwo"),
  nestedSel SMALLINT ATTRIBUTES(XMLSelector)
END RECORD,
  val3 STRING ATTRIBUTES(XMLName="Val3")
END RECORD
```

Case where "nestedSel" value is 1

```xml
<Root Val2="25.8">
  <Val1>148</Val1>
  <ChoiceOne>6584</ChoiceOne>
  <Val3>Hello world</Val3>
</Root>
```

Case where "nestedSel" value is 2

```xml
<Root Val2="25.8">
  <Val1>148</Val1>
  <ChoiceTwo>85.8</ChoiceTwo>
  <Val3>Hello world</Val3>
</Root>
```

**XMLSequence (Optional)**

Map a BDL RECORD to an XML Schema sequence structure. The order in which the record members appear in the XML document must match the order of the BDL RECORD. The XMLSequence attribute also supports a "nested" value that removes the surrounding XML tag.

**Note:** Nested sequence records cannot be defined as main variables; there must always be a surrounding variable.

**Example**

```bdl
DEFINE mysequence RECORD ATTRIBUTES(XMLSequence,XMLName="Root")
  val1 INTEGER ATTRIBUTES(XMLName="Val1"),
  val2 FLOAT ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  val3 STRING ATTRIBUTES(XMLName="Val3")
END RECORD
```

```xml
<Root Val2="25.8">
  <Val1>-859</Val1>
  <Val3>Hello world</Val3>
</Root>
```

Nested example:

```bdl
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XMLName="Val1"),
  val2 FLOAT ATTRIBUTES(XMLAttribute,XMLName="Val2"),
```
sequence RECORD ATTRIBUTES(XMLSequence="nested")
  seq1 INTEGER ATTRIBUTES(XMLName="SeqOne"),
  seq2 FLOAT ATTRIBUTES(XMLName="SeqTwo")
END RECORD,
val3 STRING ATTRIBUTES(XMLName="Val3")
END RECORD

<Root Val2="25.8">
  <Val1>148</Val1>
  <SeqOne>6584</SeqOne>
  <SeqTwo>85.597</SeqTwo>
  <Val3>Hello world</Val3>
</Root>

XMLSimpleContent
Map a BDL RECORD to an XML Schema simpleContent structure.

Note: One member must have the XMLBase attribute; all other members must have an XMLAttribute attribute. If not, the compiler complains.

Example

DEFINE mysimpletype RECORD ATTRIBUTES(XMLSimpleContent,XMLName="Root")
  base STRING ATTRIBUTES(XMLBase),
  val1 INTEGER ATTRIBUTES(XMLAttribute,XMLName="Val1"),
  val2 FLOAT ATTRIBUTES(XMLAttribute,XMLName="Val2")
END RECORD

<Root Val1="148" Val2="25.8">
  Hello
</Root>

XSComplexType
Map a BDL RECORD type definition to an XML Schema complexType.

Note: You can have one member as a nested sequence or choice, or as an XMLList array with a nested sequence or choice as the array's elements; all other members must have an XMLAttribute attribute. If not, the compiler raises an error.

Example

TYPE mycomplextype RECORD ATTRIBUTES(XSComplexType,
  XSTypeName="MyComplexType",XSTypeNamespace="http://tempuri.org")
  name DYNAMIC ARRAY ATTRIBUTES(XMLList) OF RECORD
    ATTRIBUTES(XMLSequence="nested")
      firstname STRING ATTRIBUTES(XMLName="FirstName"),
      lastname STRING ATTRIBUTES(XMLName="LastName")
  date DATE ATTRIBUTES(XMLAttribute,XMLName="Date")
END RECORD

<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  targetNamespace="http://tempuri.org" elementFormDefault="qualified">
  <xsd:complexType name="MyComplexType">
    <xsd:sequence maxOccurs="unbounded">
      <xsd:element name="FirstName" type="xsd:string" />
      <xsd:element name="LastName" type="xsd:string" />
    </xsd:sequence>
    <xsd:attribute name="Date" type="xsd:date" use="required" />
  </xsd:complexType>
</xsd:schema>
XMLList
Map a one dimensional array to an XML Schema element that has more than one occurrence.

Example

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XMLName="Val1"),
  list DYNAMIC ARRAY ATTRIBUTES(XMLList) OF STRING
  ATTRIBUTES(XMLName="Element"),
  val2 FLOAT   ATTRIBUTES(XMLName="Val2")
END RECORD

<Root>
  <Val1>148</Val1>
  <Element>hello</Element>
  <Element>how</Element>
  <Element>are</Element>
  <Element>you</Element>
  <Val2>0.58</Val2>
</Root>
```

Note: It is not possible to define an XMLList attribute on a main array.

XMLSelector
Define the index of the candidate among all members of an XMLChoice record that will be serialized or de-serialized at runtime.

The index starts at 1.

The selector data type must be a SMALLINT or a INTEGER.

XMLAny
Map a Xml.DomDocument object to a wildcard XML element:

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",XMLNamespace="http://tempuri.org")
  val1 INTEGER ATTRIBUTES(XMLName="Val1"),
  any Xml.DomDocument ATTRIBUTES(XMLAny,XMLNamespace="##other"),
  val2 FLOAT   ATTRIBUTES(XMLName="Val2")
END RECORD

<pre:Root xmlns:pre="http://tempuri.org">
  <pre:Val1>148</pre:Val1>
  <pre2:Doc xmlns:pre2="http://www.mycompany.com">
    <pre2:Element>how</pre2:Element>
    <pre2:Element>are</pre2:Element>
    <pre2:Element>you</pre2:Element>
  </pre2:Doc>
  <pre:Val2>0.58</pre:Val2>
</pre:Root>
```

Note: Associated with XMLAny, the XMLNamespace attribute requires either:
- A list of space-separated URIs to accept each attribute belonging to one of this namespace URI as a wildcard attribute.
- The value ##any to accept any attribute as a wildcard attribute.
- The value ##other to accept any attribute not in the main schema namespace as a wildcard attribute.
For example:

- If XMLNamespace="http://tmpuri.org http://www.mycompany.com", then only the XML documents belonging to one of those namespaces will be accepted and serialized (or de-serialized) into the Xml.DomDocument object.
- If XMLNamespace="##any", then any XML document will be accepted and serialized (or de-serialized) into the Xml.DomDocument object.
- If XMLNamespace="##other", then any XML document not belonging to the targetNamespace of the XML Schema where the any definition is used will be accepted and serialized (or de-serialized) into the Xml.DomDocument object.

**XMLAnyAttribute**

Map a one-dimensional dynamic array to wildcard XML attributes.

**Example**

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root", XMLNamespace="http://tempuri.org")
  val1 INTEGER ATTRIBUTES(XMLName="Val1"),
  val2 FLOAT ATTRIBUTES(XMLName="Val2"),
  attr STRING ATTRIBUTES(XMLName="Attr", XMLAttribute),
  any DYNAMIC ARRAY ATTRIBUTES(XMLAnyAttribute, XMLNamespace="##other")OF
    RECORD
      ns STRING,
      name STRING,
      value STRING
    END RECORD
END RECORD
```

```
<pre:Root xmlns:pre="http://tempuri.org" pre:Attr="10"
  xmlns:pre2="http://www.mycompany.com" pre2:AnyAttr1="10" pre2:AnyAttr2="">
  <pre:Val1>148</pre:Val1>
  <pre:Val2>0.58</pre:Val2>
</pre:Root>
```

**Note:**

1. The attribute XMLAnyAttribute is only allowed on a one-dimensional dynamic array of a record with three members of type STRING. The first member is for the namespace of the wildcard attribute, the second member is for the name of the wildcard attribute, and the third member is for the value of the wildcard attribute. The name cannot be null.
2. Associated with the XMLAnyAttribute, the XMLNamespace attribute requires either:
   - A list of space-separated URIs to accept each attribute belonging to one of the namespace URIs as a wildcard attribute.
   - The value ##any to accept any attribute as a wildcard attribute.
   - The value ##other to accept any attribute not in the main schema namespace as a wildcard attribute.

For example:

- If XMLNamespace="http://tmpuri.org http://www.mycompany.com", then only the attributes belonging to one of those namespaces will be accepted and serialized (or deserialized) into the array.
- If XMLNamespace="##any", then any attribute will be accepted and serialized (or deserialized) into the array.
- If XMLNamespace="##other", then any attributes not belonging to the targetNamespace of the XML Schema where the anyAttribute definition is used will be accepted and serialized (or deserialized) into the array.

**XMLName**

Define the name of a variable in an XML document.

**Note:** The attribute cannot be set on a type definition.
Example

DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XMLName="Val1"),
  val2 FLOAT,
  val3 INTEGER ATTRIBUTES(XMLName="Val3")
END RECORD

<Root>
  <Val1>148</Val1>
  <val2>0.5</val2>
  <Val3>-18547</Val3>
</Root>

XMLNamespace

Define the namespace of a variable in an XML document.

Note:
1. If the attribute is set on a Record, by default all members defined as XMLElement of that record are in the same namespace.
2. If the attribute is set on an Array, by default all elements defined as XMLElement of that array are in the same namespace.
3. The attribute cannot be set on a type definition.

Example

DEFINE myVar RECORD ATTRIBUTES(XMLName="Root", XMLNamespace="http://tempuri.org")
  attr1 INTEGER ATTRIBUTES(XMLAttribute,XMLName="Attr1"),
  val1 FLOAT ATTRIBUTES(XMLName="Val1", XMLNamespace="http://www.mycompany.com"),
  val2 INTEGER ATTRIBUTES(XMLName="Val2"),
  attr2 STRING ATTRIBUTES(XMLAttribute, XMLName="Attr2",
    XMLNamespace="http://anyuri.org")
END RECORD

<fjs1:Root xmlns:fjs1="http://tempuri.org" Attr1="158"
  xmlns:fjs3="http://anyuri.org" fjs3:Attr2="Hello">
  <fjs2:Val1 xmlns:fjs2="http://www.mycompany.com">0.5</fjs2:Val1>
  <fjs1:Val2>-18547</fjs1:Val2>
</fjs1:Root>

XMLType

Force the XML type name of a variable by adding xsi:type at serialization or by checking xsi:type at deserialization.

Note: The attribute must be used with the XMLTypenamespace attribute; otherwise, the compiler complains.

Example

DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
  XMLNamespace="http://tempuri.org")
  val1 FLOAT ATTRIBUTES(XMLName="Val1"),
  val2 INTEGER ATTRIBUTES(XMLName="Val2",
    XMLType="MyRecord",
    XMLTypenamespace="http://mynamespace.org")
END RECORD

<fjs1:Root xmlns:fjs1="http://tempuri.org">
  <fjs1:Val1>0.5</fjs1:Val1>
</fjs1:Root>
XMLTypenamespace

Force the XML type namespace of a variable by adding xsi:type at serialization or by checking xsi:type at de-
serialization.

Note: The attribute must be used with the XMLType attribute; otherwise the compiler complains.

Example

```bdll
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root", XMLNamespace="http://tempuri.org")
  val1 FLOAT ATTRIBUTES(XMLName="Val1"),
  val2 INTEGER ATTRIBUTES(XMLName="Val2", XMLType="MyRecord", XMLTypenamespace="http://mynamespace.org")
END RECORD
```

```xml
<fjs1:Root xmlns:fjs1="http://tempuri.org">
  <fjs1:Val1>0.5</fjs1:Val1>
</fjs1:Root>
```

XSTypenamespace

Define the XML Schema name of a BDL type definition.

Note:
1. The attribute must be used with the XSTypenamespace attribute; otherwise the compiler complains.
2. The attribute is only allowed on a type definition.

Example

```bdll
TYPE myType RECORD ATTRIBUTES(XMLSequence, XSTypeName="MyFirstType", XSTypeNamespace="http://tempuri.org")
  val1 FLOAT ATTRIBUTES(XMLElement,XMLName="Val1"),
  val2 INTEGER ATTRIBUTES(XMLElement,XMLName="Val2",XMLOptional),
  attr STRING ATTRIBUTES(XMLAttribute,XMLName="Attr")
END RECORD
```

```xml
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema" targetNamespace="http://tempuri.org" elementFormDefault="qualified">
  <xsd:complexType name="MyFirstType">
    <xsd:sequence>
      <xsd:element name="Val1" type="xsd:double" />
      <xsd:element name="Val2" type="xsd:int" minOccurs="0" />
    </xsd:sequence>
    <xsd:attribute name="Attr" type="xsd:string" use="required" />
  </xsd:complexType>
</xsd:schema>
```

XSTypenamespace

Define the XML Schema namespace of a BDL type definition.

Note:
1. The attribute must be used with the XSType attribute; otherwise the compiler complains.
2. The attribute is only allowed on a type definition.

Example

```xml
<xs:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema" targetNamespace="http://tempuri.org" elementFormDefault="qualified">
  <xs:complexType name="MyFirstChoice">
    <xs:choice>
      <xs:element name="Val1" type="xsd:double" />  
      <xs:element name="Val2" type="xsd:int" minOccurs="0" />  
    </xs:choice>  
    <xs:attribute name="Attr" type="xsd:string" />
  </xs:complexType>
</xs:schema>
```

**XMLElementNamespace**

Define the default namespace of all members of a record also defined as XML elements.

Example

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",  
  XMLNamespace="http://tempuri.org",  
  XMLElementNamespace="http://www.mycompany.com")
  val1 FLOAT ATTRIBUTES(XMLElement,XMLName="Val1"),
  val2 INTEGER ATTRIBUTES(XMLElement,XMLName="Val2"),
  attr STRING ATTRIBUTES(XMLAttribute,XMLName="Attr"),
END RECORD

  <fjs2:Val1>0.5</fjs2:Val1>
  <fjs2:Val2>-18547</fjs2:Val2>
</fjs1:Root>
```

**XMLAttributeNamespace**

Define the default namespace of all members of a record also defined as XML attributes.

Example

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",  
  XMLNamespace="http://tempuri.org",  
  XMLAttributeNamespace="http://www.mycompany.com")
  val1 FLOAT ATTRIBUTES(XMLElement,XMLName="Val1"),
  val2 INTEGER ATTRIBUTES(XMLElement,XMLName="Val2"),
  attr1 STRING ATTRIBUTES(XMLAttribute,XMLName="Attr1"),
  attr2 DATE ATTRIBUTES(XMLAttribute,  
  XMLName="Attr2",XMLNamespace="http://anyuri.org"),
END RECORD

  fjs2:Attr1="Hello" xmlns:fjs2="http://www.mycompany.com"
XMLOptimizedContent
Set on STRING or BYTE data type so that such string content represents a file on disk to be transmitted as base64 binary in SOAP via HTTP attachment.

The XMLOptimizedContent attribute is allowed on BYTE or STRING data type.

The XMLOptimizedContent attribute adds value when used in one of these scenarios:

1. When MTOM is enabled and the XMLOptimizedContent attribute is set on a BYTE, it sets the variable that must be transmitted transparently as an HTTP part on the wire. See Message Transmission Optimization Mechanism (MTOM) on page 3123 for more information.

2. When MTOM is enabled and the XMLOptimizedContent attribute is set on a STRING, it contains the name of the file to be transmitted as a Base64 binary, with an optional mime-type hint, in order to avoid loading a file in a BYTE. See Message Transmission Optimization Mechanism (MTOM) on page 3123 for more information.

3. If the XMLOptimizedContent attribute is set to "swaRef" (XMLOptimizedContent="swaRef") and set on a STRING, the contents of the file are transmitted according to the SoapWithAttachmentRef specification. See swaRef (SOAP with attachments using wsi:swaRef) on page 3124 for more information.

If the XMLOptimizedContent attribute is set on a 4GL STRING data type, it is expected to contain the name of the file that the Genero Web Service will load based on the current directory during transport of the MTOM request.

If the XMLOptimizedContent attribute is set on a 4GL STRING data type, it will contain the absolute path of the file GWS has received during the transport of a MTOM response. The absolute path is based on the Genero temp directory settings and contains a UUID generated name. The programmer is in charge of moving the file or removing the file from disk.

The optional value is a hint to specify the mime-type of the data. The hint may be used by Java or .NET to generate different kinds of objects, depending on the information provided by the hint. For instance, on Java a mime type of "image" will generate a java.awt.Image object instead of a byte[] object.

Example
The Genero code:

```
DEFINE rec RECORD
  data1 BYTE ATTRIBUTES(XMLOptimizedContent,XMLName="MyData"),
  date2 STRING ATTRIBUTES(XMLOptimizedContent="image/*",XMLName="MyImage"),
  data3 BYTE
END RECORD
```

The XSD representation:

```
<xsd:complexType name="rec">
  <xsd:sequence>
    <xsd:element type="xsd:base64Binary" name="MyData"/>
    <xsd:element xmime:expectedContentTypes="image/*" type="xsd:base64Binary" name="MyImage"/>
    <xsd:element type="xsd:base64Binary" name="data3"/>
  </xsd:sequence>
</xsd:complexType>
```

Things to observe:
1. With the BYTE data type, regardless of whether the XMLOptimizedContent attribute is set, the same type (xsd:base64Binary) appears in the XSD.
2. The STRING holds the path to the document to transfer and is viewed as a BYTE in the XML exchange.
3. With the STRING data type, a mime type is specified.
Error handling in GWS calls (STATUS)

In case of problem, the methods of GWS classes can throw an exception and set the STATUS variable with the appropriate error number.

By default, the program will stop if an exception is thrown. You can trap the GWS errors with a WHENEVER ERROR handler or with a TRY/CATCH block. In the next example, the readTextRequest() API is surrounded by a TRY/CATCH block:

```generation
define req com.HTTPServiceRequest,  
data STRING
...
let req = com.WebServiceEngine.getHTTPServiceRequest(5)
...
try
 ... 
call req.readTextRequest() returning data
 ...
catch
 call show_err(sfmt("Unexpected HTTP request read exception: %1", status))
end try
```

For some errors, a human-readable description of the error code is available in the SQLCA.SQLERRM register.

Related concepts
- Exceptions on page 451
  Describes exception (error) handling in the programs.

Related reference
- Genero BDL errors on page 2998
  System error messages sorted by error number.

Interruption handling in GWS calls (INT_FLAG)

Genero Web Services (GWS) tests INT_FLAG to check if an application has been interrupted.

If INT_FLAG is set to TRUE, the DVM interrupts the GWS function processing and an exception is raised with error code -15553.

Important: Set the INT_FLAG register to FALSE before calling a GWS function. For example, after a dialog was stopped with a cancel action, the INT_FLAG is set to TRUE. If you do not reset INT_FLAG to FALSE, the next GWS function may be canceled.

As a general rule, surround GWS calls with a TRY/CATCH block (or WHENEVER ERROR handler), to detect both communication errors and interruptions.

```generation
try
 ... let int_flag=false
 ... 
call req.sendXMLRequest(doc)
 ...
catch
 case status
 when -15553 -- TCP socket error
 if int_flag then
 message "An interruption occurred."
 else
 error "TCP socket error: ", sqlca.sqlerrm
 end if
 ... 
end case
end try
```
Server API functions - version 1.3 only

Server API functions can create a Web Services server in Genero BDL.

Note: These functions are valid for backwards compatibility, but they are not the preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Table 685: APIs to create a Web Services server in Genero BDL (version 1.3 only)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fgl_ws_server_setNamespace( namespace VARCHAR )</td>
<td>Defines the namespace of the service on the Web and must be called first, before all other functions of the API.</td>
</tr>
<tr>
<td>fgl_ws_server_start( tcpPort VARCHAR )</td>
<td>Creates and starts the Web services server.</td>
</tr>
<tr>
<td>fgl_ws_server_publishFunction( operationName VARCHAR, inputNamespace VARCHAR, inputRecordName VARCHAR, outputNamespace VARCHAR, outputRecord VARCHAR, functionName VARCHAR)</td>
<td>Publishes the given BDL function as a Web-Function on the Web.</td>
</tr>
<tr>
<td>fgl_ws_server_generateWSDL( serviceName VARCHAR, serviceLocation VARCHAR, fileName VARCHAR )</td>
<td>Generates the WSDL file based on the BDL-server program.</td>
</tr>
<tr>
<td>fgl_ws_server_process( timeout INTEGER)</td>
<td>Waits for an incoming SOAP request for a given time (in seconds) and then processes the request, or returns, if there has been no request during the given time.</td>
</tr>
<tr>
<td>fgl_ws_server_setFault( faultMessage VARCHAR )</td>
<td>Return a SOAP fault string to the client at the end of the function's execution.</td>
</tr>
<tr>
<td>fgl_ws_server_getFault()</td>
<td>Retrieves the last fault string the user has set in a Web-Function, or an empty string if there is none.</td>
</tr>
</tbody>
</table>

fgl_ws_server_setNamespace() (version 1.3)

Defines the namespace of the service on the Web and must be called first, before all other functions of the API.

Note: This function is valid for backwards compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

<table>
<thead>
<tr>
<th>Syntax</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>fgl_ws_server_setNamespace( namespace VARCHAR )</td>
<td></td>
</tr>
</tbody>
</table>

1. namespace is the name of the namespace.
Example

```c
CALL fgl_ws_server_setNamespace("http://tempuri.org/")
```

**fgl_ws_server_start() (version 1.3)**

Creates and starts the Web services server.

**Note:** This function is valid for backwards compatibility, but is not a preferred way to handle Genero Web Services. See the **com** package for the preferred classes and methods for handling Web services.

**Syntax**

```c
fgl_ws_server_start(
    tcpPort VARCHAR
)
```

1. *tcpPort* is a string representing either:
   - the **socket port number** (for a single Web Service server)
   - the **host and port** value separated by a colon (for a Web Service server connecting to an application server).
     The value of **port** is an offset beginning at 6400.

**Note:** If the FGLAPPSERVER environment variable is set, the tcpPort value is ignored, and replaced by the value of FGLAPPSERVER.

**Usage**

For development or testing purposes, you may start a Web Service server as a single server where only one request at a time will be able to be processed. For deployment, you may start a Web Service server with an application server able to handle several connections at one time using a load-balancing algorithm. The value of the parameter passed to the function determines which method is used.

**Examples:**

To start a standalone Web Service server:

```c
CALL fgl_ws_server_start("8080") # A single Server is listening
    # on port number: 8080
```

To start a Web Service server attempting to connect to an application server:

```c
CALL fgl_ws_server_start("zeus:5") # The server attempt to connect
    # to an application server located
    # on host zeus and listening
    # on the port number 6405
```

**Possible runtime errors**

- -15504: PORT_ALREADY_USED
- -15514: PORT_NOT_NUMERIC
- -15515: NO_AS_FOUND
- -15516: LICENSE_ERROR

**fgl_ws_server_publishFunction() (version 1.3)**

Publishes the given BDL function as a Web-Function on the Web.

**Note:** This function is valid for backwards compatibility, but is not a preferred way to handle Genero Web Services. See the **com** package for the preferred classes and methods for handling Web services.
Syntax

```sql
fgl_ws_server_publishFunction(
    operationName VARCHAR,
    inputNamespace VARCHAR,
    inputRecordName VARCHAR,
    outputNamespace VARCHAR,
    outputRecord VARCHAR,
    functionName VARCHAR)
```

1. `operationName` is the name by which the operation will be defined on the Web. The name is case sensitive.
2. `inputNamespace` is the namespace of the incoming operation message.
3. `inputRecordName` is the name of the BDL record representing the Web Function input message or "" if there is none.
4. `outputNamespace` is the namespace of the outgoing operation message.
5. `outputRecord` is the name of the BDL record representing the Web Function output message or "" if there is none.
6. `functionName` is the name of the BDL function that is executed when the Web Service engine receives a request with the operation name defined above.

Example

```sql
CALL fgl_ws_server_publishFunction(
    "MyWebOperation",
    "http://www.tempuri.org/webservices/", "myfunction_input",
    "http://www.tempuri.org/webservices/", "myfunction_output",
    "my_bdl_function")
```

Possible runtime errors

- -15503: FUNCTION_ALREADY_EXISTS
- -15501: FUNCTION_ERROR
- -15502: FUNCTION_DECLARATION_ERROR
- -15512: INPUT_VARIABLE_ERROR
- -15513: OUTPUT_VARIABLE_ERROR
- -15503: BDL_XML_ERROR
- -15518: INPUT_NAMESPACE_MISSING
- -15519: OUTPUT_NAMESPACE_MISSING

`fgl_ws_server_generateWSDL()` (version 1.3)

Generates the WSDL file based on the BDL-server program.

**Note:** This function is valid for backwards compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

```sql
fgl_ws_server_generateWSDL(
    serviceName VARCHAR,
    serviceLocation VARCHAR,
    fileName VARCHAR )
```

1. `serviceName` is the name of the web service.
2. `serviceLocation` is the URL of the server.
3. `fileName` is the name of the file that will be generated.
Usage

The function returns:

- 0 if the file has been correctly generated.
- Any other values if the operation has failed.

Example

```plaintext
DEFINE mystatus INTEGER

LET mystatus=fgl_ws_server_generateWSDL(
    "CustomerService",
    "http://localhost:8080",
    "C:/mydirectory/myfile.wsdl"
)

IF mystatus=0 THEN
    DISPLAY "Generation of WSDL done..."
ELSE
    DISPLAY "Generation of WSDL failed!"
END IF
```

fgl_ws_server_process() (version 1.3)
Waits for an incoming SOAP request for a given time (in seconds) and then processes the request, or returns, if there has been no request during the given time.

If a DEFER INTERRUPT or DEFER QUIT instruction has been defined, the function returns even if it is an infinite wait.

Note: This function is valid for backwards compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

```plaintext
fgl_ws_server_process(
    timeout INTEGER
) RETURNS INTEGER
```

1. `timeout` is the maximum waiting time for an incoming request (or -1 for an infinite wait)

Usage

The function can return one of the following values:

- 0 Request has been processed
- -1 Timeout has been reached
- -2 The application server asks the runner to shutdown
- -3 A client connection has been unexpectedly broken
- -4 An interruption has been raised
- -5 The HTTP header of the request was incorrect
- -6 The SOAP envelope was malformed
- -7 The XML document was malformed

Example

```plaintext
MAIN

    DEFINE mystatus INTEGER

    DEFER INTERRUPT
```
LET mystatus=fgl_ws_server_process(5)# wait for 5 seconds

IF mystatus=0 THEN
    DISPLAY "Request processed."
END IF
IF mystatus=-1 THEN
    DISPLAY "No request."
END IF
IF mystatus=-2 THEN # terminate the application properly
    EXIT PROGRAM # if connected to application server
END IF
IF mystatus=-3 THEN
    DISPLAY "Client connection unexpectedly broken."
END IF
IF mystatus=-4 THEN
    DISPLAY "Server process has been interrupted."
END IF
IF mystatus=-5 THEN
    DISPLAY "Malformed or bad HTTP request received."
END IF
IF int_flag<>0 THEN
    LET int_flag=0
    EXIT PROGRAM
END IF

END MAIN

fgl_ws_server_setFault() (version 1.3)
Return a SOAP fault string to the client at the end of the function’s execution.

This function can be called in a published Web-Function.

Note: This function is valid for backwards compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

fgl_ws_server_setFault(
    faultMessage VARCHAR )

1. faultMessage is a string containing the SOAP Fault string that will be returned to the client.

Example

CALL fgl_ws_server_setFault(
    "The server is not able to manage this request.")

fgl_ws_server_getFault() (version 1.3)
Retrieves the last fault string the user has set in a Web-Function, or an empty string if there is none.

Note: This function is valid for backwards compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

fgl_ws_server_getFault ()
RETURNS STRING
Usage
The function returns a string containing the SOAP fault string.
This function is only for testing the Web Services functions before they are published on the Web.

Example

```
DEFINE div_input RECORD
   a INTEGER,
   b INTEGER
END RECORD

DEFINE div_output RECORD
   result INTEGER
END RECORD

FUNCTION TestServices()
   DEFINE string VARCHAR(100)
   ...
   # Test divide by zero operation
   LET div_input.a=15
   LET div_input.b=0
   CALL service_operation_div()
   LET string=fgl_ws_server_getFault()
   DISPLAY "Operation div error: ", string
   ...
END FUNCTION

FUNCTION service_operation_div()
   ...
   IF div_input.b = 0 THEN
      CALL fgl_ws_server_setFault("Divide by zero")
      RETURN
   END IF
   ...
END FUNCTION
```

Configuration API functions - version 1.3 only
Configuration API functions can modify the behavior of the Web Services engine for the client and/or server.

Note: These functions are valid for backwards compatibility, but they are not the preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Table 686: Configuration API functions for Web Services engine behavior modification

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fgl_ws_setOption(optionName VARCHAR, optionValue INTEGER)</td>
<td>Sets an option flag with a given value, changing the global behavior of the Web Services engine.</td>
</tr>
<tr>
<td>fgl_ws_getOption(optionName VARCHAR) RETURNS INTEGER</td>
<td>Returns the value of an option flag.</td>
</tr>
</tbody>
</table>
fgl_ws_setOption()
Sets an option flag with a given value, changing the global behavior of the Web Services engine.

Note: This function is valid for backwards compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

```
fgl_ws_setOption(
    optionName VARCHAR,
    optionValue INTEGER)
```

1. `optionName` is one of the global option flags.
2. `optionValue` is the value of the flag.

Example

```
CALL fgl_ws_setOption("http_invoketimeout",5)
```

Possible runtime errors

- -15511: INVALID_OPTION_NAME

fgl_ws_getOption()
Returns the value of an option flag.

Note: This function is valid for backwards compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

```
fgl_ws_getOption(
    optionName VARCHAR
) RETURNS INTEGER
```

1. `optionName` is one of the global option flags.

Example

```
DEFINE value INTEGER
LET value=fgl_ws_getOption("http_invoketimeout")
```

Possible runtime errors

- -15511: INVALID_OPTION_NAME
## Option flags

### Table 687: Option flags

<table>
<thead>
<tr>
<th>Flag</th>
<th>Client or Server</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>http_invoketimeout</td>
<td>Client</td>
<td>Defines the maximum time in seconds a client has to wait before the client connection raises an error because the server is not responding. A value of -1 means that it has to wait until the server responds. The default value is -1.</td>
</tr>
<tr>
<td>tcp_connectiontimeout</td>
<td>Client</td>
<td>Defines the maximum time in seconds a client has to wait for the establishment of a TCP connection with a server. A value of -1 means infinite wait. The default value is 30 seconds except for Windows™, where it is 5 seconds.</td>
</tr>
<tr>
<td>soap_ignoretimezone</td>
<td>Both</td>
<td>Defines if, during the marshalling and unmarshalling process of a BDL DATETIME data type, the SOAP engine should ignore the time zone information. A value of zero means false. The default value is false.</td>
</tr>
<tr>
<td>soap_usetypedefinition</td>
<td>Both</td>
<td>Defines if the Web Services engine must specify the type of data in all SOAP requests. This will add an &quot;xsi:type&quot; attribute to each parameter of the request. A value of zero means false. The default value is false.</td>
</tr>
<tr>
<td>wsdl_decimalsize</td>
<td>Server</td>
<td>Defines if, during the WSDL generation, the precision and scale of a DECIMAL variable will be taken into account. See WSDL generation option notes on page 3289. A value of zero means false. The default value is true.</td>
</tr>
</tbody>
</table>
### Table

<table>
<thead>
<tr>
<th>Flag</th>
<th>Client or Server</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>wsdl_arraysize</td>
<td>Server</td>
<td>Defines if, during the WSDL generation, the size of a BDL array will be taken into account. See WSDL generation option notes on page 3289. A value of zero means false. The default value is true.</td>
</tr>
<tr>
<td>wsdl_stringsize</td>
<td>Server</td>
<td>Defines if, during the WSDL generation, the size of a CHAR or VARCHAR variable will be taken into account. See WSDL generation option notes on page 3289. A value of zero means false. The default value is true.</td>
</tr>
</tbody>
</table>

### WSDL generation option notes

1. For a BDL type **DECIMAL(5,2)**, when `wsdl_decimalsize` is TRUE, the generated WSDL file contains the total size and the size of the fractional part of the decimal:

   ```xml
   <types>
   <schema xmlns="http://www.w3.org/2001/XMLSchema"
    targetNamespace="http://www.mycompany.com/types/">
   <simpleType name="echoDecimal5_2_a_dec5_2_out_FGLDecimal">
    <restriction base="decimal">
    <totalDigits value="5" />
    <fractionDigits value="2" />
    </restriction>
   </simpleType>
   </schema>
   </types>
   <message name="echoDecimal5_2">
   <part name="dec5_2" type="f:echoDecimal5_2_a_dec5_2_in_FGLDecimal" />
   </message>
   
   When `wsdl_decimalsize` is FALSE, the total size and the size of the fractional part are not mentioned:

   ```xml
   <message name="echoDecimal5_2">
   <part name="dec5_2" type="xsd:decimal" />
   </message>
   
   2. If the WSDL file does not contain the size, the client application has no way of knowing the size. In this scenario, a default value for the size is generated. For example, the exported server type **DECIMAL(5,2)** becomes a **DECIMAL(32)** on the client side.

   3. It is better to keep the options `wsdl_arraysize`, `wsdl_stringsize` and `wsdl_decimalsize` set to TRUE (default) so that the BDL client application can do an exact type mapping.

### Using fglwsdl to generate code from WSDL or XSD schemas

The `fglwsdl` tool generates Genero (.4gl) code from WSDL / XSD schemas. See `fglwsdl` on page 1980 for a complete description of the tool and its options.
Generate TYPE definitions from global XML elements or attributes

If a WSDL or a XSD has global XML elements or attributes defined with an inlined type, the -fInlineTypes option of fglwsdl generates a TYPE definition representing that inline type, using the original WSDL/XSD name of the element or attribute, concatenated with the string 'GlobalAttributeType' or 'GlobalElementType'.

For example, when using fglwsdl -fInlineTypes, the following schema:

```xml
<xs:element name="getAlertListRequestFlow">
  <xs:complexType>
    <xs:sequence>
      <xs:element name="getAlertListRequest" type="amp:getAlertListRequest" />
    </xs:sequence>
  </xs:complexType>
</xs:element>
```

will produce:

```plaintext
TYPE tgetAlertListRequestFlowGlobalElementType RECORD
  ATTRIBUTES(XMLSequence)
    getAlertListRequest tgetAlertListRequest
      ATTRIBUTES(XMLName="getAlertListRequest")
  END RECORD
DEFINE getAlertListRequestFlow tgetAlertListRequestFlowGlobalElementType
  ATTRIBUTES(XMLName="getAlertListRequestFlow")
```

Instead of:

```plaintext
DEFINE getAlertListRequestFlow RECORD
  ATTRIBUTES(XMLName="getAlertListRequestFlow",XMLSequence)
    getAlertListRequest tgetAlertListRequest
      ATTRIBUTES(XMLName="getAlertListRequest")
  END RECORD
```

Mobile applications

These topics cover programming subjects about mobile applications

- Cordova plugins on page 3370
**Types of Genero Mobile apps**

Genero supports different types of mobile app architectures: development mode, standalone apps, partially-connected apps, and client-server apps.

When you are developing your app, and you execute the app on your development machine for display on a device or emulator, you are running the app in *development mode*.

When you follow the procedure to deploy your application to the device for testing or to distribute your app to your end users, you have a *deployed app*. A deployed app might be an app that executes irrespective of network availability, it might be an app that accesses device peripherals, it might be an app that requires network access.

**Note:** The DVM refers to the dynamic virtual machine, which is the process that executes the app code.

**Development mode**

In *development mode*, the app process is running on a server, and the forms are displayed on a mobile front-end.

This architecture is typically used when developing your application, as you can easily modify, recompile and execute your sources on the development machine, without the need to deploy the app on the device.

**Figure 125: Development mode**

**Standalone apps**

A *standalone app* has the DVM and display client entirely on the mobile device. This app executes irrespective of network availability and can access device peripherals such as the camera, contacts, email, calendar, GPS, and storage via exposed APIs (front calls). For database needs, this app can only connect to a local SQLite database.
Partially-connected apps

A partially-connected app has the DVM and display client entirely on the mobile device, yet this app includes items that require a network connection. This app must be able to run when no network connection is available. This app uses a network API to talk to any back-end.

Examples include:

- Web Services performed with JSON over HTTP; use RESTful methods to write data synchronization routines. With this example, business logic executes within the device’s Virtual Machine and the user is able to store captured data to a local SQLite database. When the network becomes available, the user synchronizes the stored data with the remote server’s database.

  **Note:** As of Genero Mobile 1.1, you can also write a Web Service using SOAP.

- A web component that runs Google Maps.

This app first operates without a network connection, and must be able to run without a network connection. Once network connectivity is restored, the app can perform network-dependent tasks such as synchronizing with a remote database, make a web service call, or use a web component.

If you are using GMI, and the device goes into standby mode, the application does not run in the background and activities with the network are suspended.
Client-server apps

With a client-server app or connected app, the bulk of the app runs on a remote server and the display client sits on the mobile device.

As with any deployed app, this app first starts on the mobile device; the DVM for the deployed app runs on the mobile device. The role of the deployed app, however, is to connect to a remote corporate server as an online terminal. It is the deployed app that launches the remote application using the runOnServer frontcall. The remote application's DVM and business logic reside on the remote server, somewhere in the network. The remote application is not limited to a SQLite database.

In the event that the network is interrupted, the Genero Mobile client app is suspended until service resumes.
Licensing considerations

Note: For specific mobile app license details, see your Software License Agreement, or contact your nearest Four Js sales office.

When deploying a Genero Mobile app, the type of mobile app architecture you need may have additional requirements for Genero licenses as follows:

- Development mode needs a development license.
- Partially-connected app consumes a Genero runtime license when the app connects to the Web service to synchronize with the network database.
- Client-server app consumes a Genero runtime license on the Genero Application Server.

Mobile development mode

Set up a development environment to display app forms on a mobile front-end.

In a command-line development environment, the runtime system (DVM) executes the application code on the development machine, displaying app forms through a mobile front-end installed on a device or emulator.

Once the app development is complete, you can build the real mobile app to be deployed on devices, as described in Deploying mobile apps on page 3315.

Important: When the Genero Mobile Development Client is running on a device, a Genero BDL program can connect and execute front calls. To avoid any security issues, stop the Genero Mobile Development Client app when you have completed your work, and consider uninstalling the app before giving the mobile device to another person or department.

Genero mobile development client for Android™

Set up a development environment to display app forms on an Android™ device.

Using the GMA front-end on Android™ devices

To display Genero application forms on an Android™ device in development mode (with programs executing on a computer), the GMA front-end app must be installed on the device (or emulator).

Note: With the GMA front-end installed on the mobile device, you can perform a classic GUI connection based on FGLSERVER.

Installing the GMA front-end application

Before installing the GMA front-end, fulfill the prerequisites to build an Android™ app, as described in Building Android apps with Genero on page 3317.

Perform the following steps, to install the GMA front-end from the archive:

1. Get the GMA package (for example, fjs-gma-1.30.00-build201703031626-allos.zip), contact your support channel for download details.
2. Unzip the archive, containing an APK ready to install.
3. Plug your device via USB cable to the computer.
4. Install the GMA front-end APK with the gmabuildtool command with the test option.

For example:

```bash
$ . ~/genero/devel/fgl/mobile/java-1.8.env
$ . ~/genero/devel/fgl/mobile/android-sdk.env
$ mkdir /tmp/gma
$ cd /tmp/gma
$ unzip ~/Download/fjs-gma-1.30.00-build201703031626-allos.zip
```
Configure FGLSERVER and run the app

Once the GMA front-end is installed on the device, make sure that WIFI is enabled (or check that the TCP port is forwarded when using an emulator), you can start the GMA app.

The main GMA screen shows the IP address of the device and the TCP port it is listening to (0=6400).

On the development machine, define the `FGLSERVER` environment variable with the IP address of the device (or .)

Now you are ready to run your app on the server and display on the Android™ device.

**TCP port forwarding for GMA on Android emulator**

When using an Android™ emulator, you can forward the TCP port with the `adb forward` command:

```
adb forward tcp:local_port tcp:gma_device_port
```

For example:

```
adb forward tcp:6401 tcp:6400
```

You can then connect to GMA with:

```
FGLSERVER=127.0.0.1:1
```

**Related concepts**

- [Deploying mobile apps on Android devices](#) on page 3315
  
  This section contains information to create a mobile application to be deployed on Android™ devices.

**Genero mobile development client for iOS**

Set up a development environment to display app forms on an iOS device.

**Installing the GMI front-end on iOS devices**

To display Genero application forms on a device, the GMI front-end must be installed on the iOS device (or emulator).

Genero supports two types of GMI front-end apps for iOS:

- The ready-to-use "Genero Mobile Development Client" for iOS, available through the App Store.
  
  **Important:** Due to Apple® limitations, the Genero Mobile Development Client app is not allowed to listen to a TCP port to provide a GUI service. In order to establish the GUI front-end connection, the front-end must connect to the runtime system running on the development machine.

- A self-made GMI front-end, using the `gmibuildtool` to build a GMI front-end app with your own Apple® developer account.
  
  **Note:** With this configuration, you can perform a classic GUI connection based on FGLSERVER.

**Using the Genero Mobile Development Client for iOS**

Go to the App Store. Search for "Genero Mobile". Select and install the "Genero Mobile Development Client".

Once the GMI development client is installed on the device, make sure that WIFI is enabled and start the GMI app.
Note: Because of iOS app limitations defined by Apple, an app shipped on the App Store cannot listen to a TCP port to provide a GUI service. In order to display Genero form on the GMI development client, you will have to establish the GUI connection from the device to the server, after starting the fglrun process with the --gui-listen option.

The main GMI screen shows a URL field to let you enter the IP address / hostname and the TCP port the runtime system will listen to.

Note: Make sure that the firewall on the development machine allows incoming connections for the TCP port number specified with the --gui-listen fglrun option.

Start the application on the development server, by using the fglrun --gui-listen=portnum command:

```bash
fglrun --gui-listen=6500 main.42m
```

On the iOS device, enter the following in the URL field:

```
fgl://dev-server-hostname:6500
```

Then tap the [Connect] button to establish the GUI connection.

**Build your own GMI front-end**

In order to use the classic GUI connection mode with fglrun connecting to the mobile front-end via FGLSERVER, it is possible to create your own GMI front-end, with your own Apple® certificate and provisioning profile.

Note: As with other iOS apps, a self-made GMI front-end can only be created on a macOS® computer.

The generated GMI can then be deployed on your device or simulator. The GMI front-end will listen on the port 6400, to display applications running on a server through the FGLSERVER setting.

Before creating your own GMI front-end, fulfill the prerequisites to build an iOS app as described in Building iOS apps with Genero on page 3332.

In order to build your own GMI front-end:

1. Make sure that the installed the fjs-fglgmi*.zip archive into FGLDIR.
2. Go to the FGLDIR/demo/MobileDemo/gmiclient directory.
3. Delete the complete build directory if it exists (can be done with a make clean command).
4. Compile the GMI front-end program files (main.42m, main.42f, etc): See Makefile for details.
5. Build the GMI front-end:
   - To build and install the GMI front-end on the simulator, first make sure that the simulator is started (open -a Simulator command), then execute the make command with the gmi.install rule:
     ```bash
     $ open -a Simulator
     $ make gmi.install
     ```
   - To build and install the GMI front-end on the device plugged to your Mac, get a development certificate and provisioning profile, then execute the make command with the gmi.install rule, by specifying the TARGET, the IDENTITY and the PROVISIONING_PROFILE variables:
     ```bash
     $ make TARGET=phone IDENTITY=WKRRJZ999 \ PROVISIONING_PROFILE="/Library/MobileDevice/Provisioning Profiles/myapp.mobileprovision" \ gmi.install
     ```

Once the GMI front-end is installed on the device, make sure that WIFI is enabled and start the GMI app.

The main GMI screen shows the IP address of the device and the TCP port it is listening to (0=6400).

On the development machine, define the FGLSERVER environment variable with the IP address of the device.
Now you are ready to run your app on the server and display on the iOS device.

Related concepts
Deploying mobile apps on iOS devices on page 3330
This section contains information to create a mobile application to be deployed on iOS devices.

Language limitations
Genero language features not supported on mobile devices.

Important: This topic is provided as a quick glance at Genero Business Development Language limitations in mobile applications. Details can be found in the BDL reference topics.

Platform specifics

Features with limited support
The following language options have limited support:

- The RUN instruction has limited support on mobile platforms.
  - The RUN instruction is not supported on mobile devices, because of operating system limitations.
  - RUN command WITHOUT WAITING is not supported when programs run on an application server and display on a mobile device, because the Genero GUI protocol is not able to handle multiple connections at the same time.

Unsupported features
The following language features are not supported:

- The INPUT ARRAY instruction is not supported.
- The base.Channel.openPipe method is not supported.
- The Java interface cannot be used in apps running on iOS devices: There is no standard free JVM available.

Environment variables
You may need to set environment variables for your app.

Automatic environment variables
When executing on a mobile device:

- DBDATE defaults to the regional settings defined on the device.
- FGLAPPDIR is automatically defined to the application directory (appdir).

Set environment variables
Setting environment variables for your app must be done in an fglprofile file. This fglprofile file must be located in the appdir directory, beside the main program module.

To add an environment variable for your mobile app, use the following syntax:

```
mobile.environment.DBFORMAT="$:::"
```

Any existing environment variable setting is overwritten by the value set (using mobile.environment.envvarname) in the fglprofile file.

For more details, see Setting environment variables in FGLPROFILE (mobile) on page 227.
Note: Environment variables set in an FGLPROFILE file are only read when the deployed application runs on the mobile device. They are not read during development mode (that is when the VM runs on the development machine and the mobile client displays on the device). The FGLPROFILE environment variable settings are only for the VM component and are ignored by the GMA/GMI front-end component.

App localization

Mobile apps can be designed to display localized texts based on the language selected on the device.

Application locale definition

Make sure that your application locale is defined properly for development and deployment environments.

Note: With Genero mobile applications, the application locale must be UTF-8.

For more details, see Quickstart guide for locale settings on page 408.

Using localized strings

Localized string files (.42s) must be deployed in directories matching the language identifiers (en for English, zh_TW for simplified Chinese, etc), beside the program module.

Default string files can be provided in APPDIR/defaults as fallback directory, if the current mobile language does not match one of the language-specific directories provided by the application.

The list of .42s files required by the application must be defined in the unique fglprofile configuration file located beside the program module of your application.

For more details, see Localized string files on mobile devices on page 438 and Deploying mobile apps on page 3315.

Querying user's preferred language

The application can get the user's preferred language and regional settings as configured on the mobile device, by using the standard.feInfo front call with the userPreferredLang argument.

For more details, see User's preferred language on page 425 and feInfo on page 2500.

App execution

Mobile apps are started and stopped, and can switch between foreground and background states when running.

- Mobile app execution modes on page 3298
- Background/foreground modes on page 3299

Mobile app execution modes

Mobile apps can be fully embeeed as a standalone or can execute on a server and display forms on the mobile device.

On iOS and on Android™, standalone Genero apps are installed and started on the device as other apps. In this configuration, the application program files, the runtime system and the database are present on the mobile device.

When a permanent network connection is available (WIFI), it is also possible to have a lightweight app installed on the device, that executes the real application code on a server, displaying forms on the device. With this architecture, your mobile app benefits from the processing power of the server, and can access a large database.

For more details, see Starting programs on a mobile device on page 520.
Background/foreground modes

Describes how to handle background or foreground modes in mobile apps.

Mobile apps foreground and background modes

Mobile apps can change their state from background mode to foreground mode and vice-versa. For example, when the user switches to another app, or when going back to the home screen, the current app goes to background mode. An app goes to foreground mode, when it is re-selected from the active apps list.

Detecting foreground/background mode changes

Genero BDL provides two predefined actions, to detect when the state of a mobile app changes:

1. The action \texttt{enterbackground} is fired, when the app goes to background mode.
2. The action \texttt{enterforeground} is fired, when the app goes to foreground mode.

\textbf{Note:} The \texttt{enterforeground} action is not fired when the app starts. This action is only fired when returning to foreground mode, after it was in background mode.

To execute code when the app goes to background or foreground mode, use the \texttt{ON ACTION} handler:

\begin{verbatim}
ON ACTION enterbackground
  LET skip_timers = TRUE
ON ACTION enterforeground
  IF NOT ask_password() THEN
    EXIT PROGRAM
  ENF IF
\end{verbatim}

For example, when the app enters background mode, it is recommended that the program suspend any activity, and skip code that would be executed in \texttt{ON TIMER} triggers.

On the other hand, when the app enters foreground mode, the program can for example ask the user's login/password again, for security reasons, to make sure that the mobile device did not end up in other hands while the app was in background mode.

To control action view rendering defaults and current field validation behavior when the \texttt{enterforeground/enterbackground} actions are used, consider setting action default attributes for these action in your .4ad file as follows:

\begin{verbatim}
<ActionDefaultList>
  ...
  <ActionDefault name="enterbackground" validate="no" defaultView="no" contextMenu="no"/>
  <ActionDefault name="enterforeground" validate="no" defaultView="no" contextMenu="no"/>
  ...
</ActionDefaultList>
\end{verbatim}

Another option is to define these action defaults attributes in the \texttt{ON ACTION} handlers:

\begin{verbatim}
ON ACTION enterbackground (VALIDATE=NO, DEFAULTVIEW=NO)
  ...
ON ACTION enterforeground (VALIDATE=NO, DEFAULTVIEW=NO)
  ...
\end{verbatim}

See also \texttt{List of predefined actions} on page 1642.
Checking if the app is currently in foreground mode

To know the current state of a mobile app, use the `mobile.isForeground` front call:

```plaintext
DEFINE fg BOOLEAN
CALL ui.Interface.frontCall("mobile", "isForeground", []. [fg] )
IF fg THEN
...
END IF
```

What does the app when in background mode?

On iOS, when the app is in background mode, the program cannot do anything meaningful outside push notifications or audio play.

On Android™, when the app is in background mode, the program can continue its execution.

Avoid Android™ to terminate app when in background (GMA)

On Android™ devices, an app can switch between foreground to background states. The Android™ system can decide to stop an app in background state, for example when resources are required for other apps.

Genero programs running on servers are typically not prepared to be stopped at any time; except in case of major failure, it’s the program that decides when it terminates. On mobile devices, Android™ can decide to stop the app when it is in background state.

By default, when the app goes to background state, a notification is shown by GMA, to keep the app in foreground state, and avoid Android™ stopping the app. The notification disappears, when the app returns to foreground state.

Use the `androidKeepForeground` style attribute to control the way the GMA forces Android™ to keep your app alive. Set this attribute to "no" if your app can be stopped by Android™, when it is in background state. When this style attribute is set to "no", GMA will not display a notification, when the app switches to background mode.

**Important:** When using `androidKeepForeground=no`, Android™ may stop the app at any time. Make sure that the code is ready for this case.

For more details, see UserInterface style attributes on page 1116.

App user interface

This section includes topics about user interface programming for mobile.

In general, the user interface of a mobile app written in Genero displays and reacts as a desktop or web application, while simultaneously respecting the device operating system look-and-feel. There are parts of the interface, however, that display and react in a specific way.

Take a look at each of the user interface items in this chapter, to understand how they are portrayed in a mobile app. A user interface feature not listed means there is nothing mobile-specific to its display or behavior.

- Images and icons on page 3301
- Action rendering on page 3301
- Toolbar rendering on page 3302
- Topmenu rendering on page 3303
- Keyboard type on page 3305
- List views on page 3305
- Split views on page 3305
- Front call support on page 3307
- Color and theming on page 3307
Images and icons

For this topic, an image can refer to the IMAGE item type or the icons used in the app.

Image format support

Mobile apps written in Genero supports all image formats supported by the device OS. However, each platform has its own restrictions on which image formats it supports:

- Android image format support
- iOS image format support

Mobile devices have a much higher pixel density (a higher resolution) than classic desktop monitors. An image which looks nice on a desktop can appear small or as an upscaled image on a mobile device.

Providing the image resource

Genero supports different solutions to provide the image data in a mobile app, depending on the need (button icon, application picture, etc). To understand how to get image resource on mobile apps with Genero, see Providing the image resource on page 1049.

Image sizing on mobile devices

The IMAGE item type defines an area for the display of an image on a form.

Image layout and sizing can be controlled with form item attributes to adapt to the type of mobile device.

For more details, see Controlling the image layout on page 1047.

Default action icons

In general, you want the icons used for your mobile app to be the standard icons used by all apps for the mobile platform. Genero is set up to use such icons by default. For more details, see Action views on mobile devices on page 1678.

Genero also supports icon centralization based on TTF icons, to get a global consistent look and feel for all your mobile apps. For more details, see Providing the image resource on page 1049.

Action rendering

Actions are rendered with default action views following mobile platforms standards.

The top and/or bottom parts of the mobile app screen is dedicated to displaying default action views to the user.

A default action view is an implicit graphical item that can be tapped to fire the corresponding action.

The default action views are rendered on the mobile device using platform-specific standards, which are covered in Action views on mobile devices on page 1678.

<table>
<thead>
<tr>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
</table>

Figure 129: Action rendering example on an Android™ device

Figure 130: Action rendering example on an iOS device

**Toolbar rendering**

Toolbars allow control over where actions display (and in what order).

For desktop applications, the toolbar is a series of buttons typically contained in a toolbar object, located at the top of the form.

On Genero mobile apps, toolbars are rendered to the mobile platform standards.
Table 689: Mobile platform differences for toolbars

<table>
<thead>
<tr>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genero toolbar items appear in the Android™ <strong>action bar</strong>.</td>
<td>Genero toolbar items appear in the iOS <strong>toolbar pane</strong>.</td>

</table>

Related concepts

- Toolbars on mobile devices on page 1331
  Toolbars can be used to control action view rendering on mobile devices.

- Action views on mobile devices on page 1678
  Action views are rendered following mobile specific standards.

Topmenu rendering

Topmenus provide a hierarchical menu in the app.

The rendering of a tomenu depends on the mobile operating system.
Table 690: Genero Mobile and topmenus

<table>
<thead>
<tr>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>

</tbody>
</table>

**Figure 131: Navigation drawer for Android**

A navigation drawer is visible in the action bar if a topmenu is available to the displayed form. The navigation drawer is a panel to the left of the app icon (seen as three bars).

**Figure 132: Menu button for iOS**

A menu icon is visible in the navigation bar if a topmenu is available to the displayed form.

Related concepts

- Topmenus on mobile devices on page 1339
- Topmenus can be used to implement a general options menu in mobile apps.
- Action views on mobile devices on page 1678
Action views are rendered following mobile specific standards.

**Keyboard type**

Depending on the data being entered, a mobile device is expected to display the keyboard that is appropriate for the data.

There are a variety of keyboard types for mobile devices. A field dedicated to phone number input is expected to display a keyboard specifically for phone number input.

The `KEYBOARDHINT` form field attribute provides a hint regarding the kind of data the form field contains. Valid values include `DEFAULT`, `EMAIL`, `NUMBER`, and `PHONE`:

```
ATTRIBUTES
EDIT f01 = customer.cust_phone, KEYBOARDHINT = PHONE;
...
```

Although Genero mostly respects the provided hint, the variable data type that is bound to the form field is also examined, to determine what keyboard to display:

- If the field is defined as a `DATE` or `DATETIME` field, the date picker displays regardless of the `KEYBOARDHINT` setting.
- If the field is a `TEXT` data, a text keyboard displays regardless of the `KEYBOARDHINT` setting.

For more details, see `KEYBOARDHINT` attribute on page 1270.

**List views**

Form tables in a mobile app render as list views.

List views are commonly used in mobile apps to present an indexed list of items or selectable list of options. They are also used to let users navigate through hierarchically structured data.

List views are displayed as either full list views or embedded list views.

The list view only displays the first two columns’ content and any associated row image, regardless of the number of columns defined.

No column header/title is displayed in mobile list views. Thus the mobile user cannot manipulate columns (hide, reorder, resize, or sort).

With full list views, the built-in reduce filter allows the user to filter the rows displayed.

The `JUSTIFY` attribute of the second column can influence how the rows are displayed.

Various options affect the rendering and behavior, by defining `TABLE` container attributes, `DISPLAY ARRAY` dialog attributes and `ON ACTION` handler attributes.

For complete details on implementing table views in a mobile app, see Using tables on mobile devices on page 1768.

**Split views**

Split views refer to the ability to access two forms side by side on a mobile device.

**Side by side views on mobile apps**

Many mobile apps offer a specific form layout, splitting the screen in two in order to show a list of the left side and a detail form on the right side. Such kind of layout can be implemented in Genero with the *Split views* on page 1802.

**Differences in how split views are handled by the clients**

There are differences between the Genero Mobile for iOS (GMI) and Genero Mobile for Android (GMA) implementations of split views and parallel dialogs, to include:
• When the application displays in a single pane or in two panes.
• How a user switches between the two panes.

There are also differences in how the split view renders between GMA and GMI.

Figure 133: The stores2 demo rendered on an Android device

With Genero Mobile for Android:
• The navigator pane renders as a menu in the left-hand side of the title bar.
• All buttons are merged.
• The title is not displayed when there is a navigator pane. If there is no navigator pane, the title of the current window is displayed.
With Genero Mobile for iOS:

- The navigator pane renders along the bottom of the app.
- Each window has its own title and its own buttons.

Figure 134: The stores2 demo rendered on an iOS device

Front call support

Genero Mobile provides front calls to interface with the device capabilities.

Use front calls to access mobile devices capabilities. For example, with the mobile/takePhoto front call, you can open the camera app of the device to take a picture.

Note: In a classical Genero client/server configuration, a front call is a remote procedure call that involves a round-trip between the front-end and the server where the application executes. For a standalone mobile app, this does not cause any latency. For a server-side app (using the runOnServer front call), however, latency can result.

The details for each front call can be found in Built-in front calls summary on page 2486.

Color and theming

Mobile applications must follow the platform colors and theming.

User interface design on mobile devices

Genero BDL provides several ways to define colors and styles for a mobile app. This section introduces features that can be used to customize your mobile app and adapt to the target platform user interface design. As a general rule, avoid using non-standard ergonomics and decorations, use defaults to let Genero render your forms depending on the platform standards. For example, the GMA front-end will use Google material design on Android™ devices.

Defining TTF icon colors

By default, TTF icons get the color of the platform theme. A default color can be defined for all TTF icons of a window with the defaultTTFColor style attribute. In order to define a color for a specific icon, add an #RGB color specification in your image to font glyph mapping file.

For more details, see Using a simple image name (centralized icons) on page 1050

App color theme on Android

Android™ apps can be created with a specific color theme following the Google material design.

When building the APK with the gmabuildtool, you can specify the general app colors with the --build-app-colors option.

For more details, see Define app's color theme on page 3323.

iOS specific UI elements

On iOS devices, some UI elements are specific to the platform and are not represented in the Abstract User Interface tree. In order to define the decoration of these elements, specific style attributes have been defined. For more details, see Decorate iOS UI elements on page 3308.

Screen orientation

Detecting screen orientation changes with the mobile device.

Detecting screen orientation changes

Mobile apps can adapt to the device orientation, when switching between portrait and landscape mode.
Screen orientation changes can be detected with the `windowresized` predefined action:

```plaintext
ON ACTION windowresized
...
```

For more details, see [Adapting to viewport changes](#) on page 1308.

**Controlling screen orientation on GMA / Android**

Use the `allowedOrientations` Window style attribute, to control screen orientation options on Android devices:

```xml
<Style name="Window.main">
  <StyleAttribute name="allowedOrientations" value="portrait_reverse" />
</Style>
```

For the complete list of possible values, see [Window style attributes](#) on page 1117.

**Controlling screen orientation on GMI / iOS**

On iOS devices using GMI, the screen orientation possibilities must be defined in the `Info.plist` resource file. Keys such as `UISupportedInterfaceOrientations` must be defined in the file, for example:

```xml
<?xml version="1.0" encoding= "UTF-8"?>
<!DOCTYPE plist PUBLIC  
  "-//Apple//DTD PLIST 1.0//EN" 
  "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version= "1.0">
  <dict>
    <key>UISupportedInterfaceOrientations</key>
    <array>
      <string>UIInterfaceOrientationPortrait</string>
      <string>UIInterfaceOrientationPortraitUpsideDown</string>
    </array>
    <key>UISupportedInterfaceOrientations~ipad</key>
    <array>
      <string>UIInterfaceOrientationPortrait</string>
      <string>UIInterfaceOrientationPortraitUpsideDown</string>
    </array>
  </dict>
</plist>
```

For more details about `Info.plist` usage, see the section about defining iOS app properties in `Info.plist`.

**Decorate iOS UI elements**

This section describes the presentation style attributes that are supported for iOS devices.

**Foreground colors**

In order to define the foreground color for items used in the iOS navigation bar, toolbar, and some items in the forms (Buttons, SpinEdit, Radiogroups, and row checkmark and disclosure indicators in list views), the `iosTintColor` style attribute can be used at Window level:

```xml
<StyleList>
  <Style name="Window">
    <StyleAttribute name="iosTintColor" value="white" />
  </Style>
</StyleList>
```
Background colors

Background color of iOS specific elements can be defined with the following style attributes at the Window level:

- `iosTabBarTintColor`
- `iosToolbarTintColor`
- `iosNavigationBarTintColor`

For example:

```xml
<StyleList>
  <Style name="Window">
    <StyleAttribute name="iosTintColor" value="white" />
    <StyleAttribute name="iosNavigationBarTintColor" value="blue" />
    <StyleAttribute name="iosToolBarTintColor" value="blue" />
  </Style>
</StyleList>
```

**iosTintColor** inheritance

The `iosTintColor` style attribute can be used at Window level to defined the text color for Tabbar and Toolbar elements.

However, when defining the text color at Window level, it has an impact on the form elements such as Folder, Button, SpinEdit and RadioGroup too. For example, if you set `iosTintColor` to white at the window level, Folder, Button, SpinEdit and RadioGroup element will appear as if they were hidden.

To avoid this, set another text color at the Form element level, as shown in the next .4st style file:

```xml
<StyleList>
  <Style name="Window">
    <StyleAttribute name="iosTintColor" value="white" />
    <StyleAttribute name="iosNavigationBarTintColor" value="blue" />
    <StyleAttribute name="iosToolBarTintColor" value="blue" />
  </Style>
  <Style name="Form">
    <StyleAttribute name="iosTintColor" value="blue" />
  </Style>
</StyleList>
```

**Important:** Note that in the above example, the `iosToolBarTintColor` and `iosNavigationBarTintColor` define respectively the background color for the iOS navigation bar and the iOS toolbar.

For a complete description of these attributes, see Style attributes reference on page 1082.

Database support on mobile devices

On the device, a Genero app can use SQL for data management.

**Databases supported on mobile devices**

Only SQLite can be used on mobile devices. SQLite has a small footprint, is free and readily available.

The database driver (dbmsqt) and the SQLite library are built into the runtime system for mobile Genero apps. No database driver specification is required when running on mobile.

To read more about SQLite programming, see Using SQLite database in mobile apps on page 3310.
Synchronizing data with a central database

When local mobile app data needs to be synchronized with a central database, you must write your own synchronization routines using Web Services. You must implement a back-end service to collect mobile database updates and to send central database changes back to the mobile app.

**Important:** If you are using GMI, and the device goes into standby mode, the application does not run in the background and activities with the network are suspended. If you are synchronizing data with the server, and the device goes into standby, the synchronization is suspended until the device resumes from standby. If you have a long synchronization, you need to either disable the sleep to allow the synchronization to complete, or accept that the synchronization will suspend when the device goes into standby mode.

**Related concepts**
- SQLite on page 922

Using SQLite database in mobile apps

On the device, Genero Mobile uses the SQLite database only.

Running an app in development mode

When running an app in development mode (where the app runs on a computer), you can use any database server that Genero supports for the operating system of the server-side app.

Running an app on a mobile device

When running the application on the device, only SQLite can be used. The database must be created at the first application execution, or it must be delivered as the default database in the .ipa or .apk package.

Locale character set and length semantics

SQLite stores data in UTF-8 codeset, mobile apps will by default run in UTF-8 and with character length semantics (FGL_LENGTH_SEMANTICS=CHAR).

Creating the database

Mobile applications usually create their database at first execution. The SQLite database file must be created in the application sandbox, in a writable directory. If the database file does not exist in the current working directory (os.Path.pwd()), create an empty file and then perform a CONNECT TO instruction.

For more details, see Creating a database from programs on page 548.

Providing a default database

SQLite database file format is cross-platform. Instead of creating the database the first time the application starts, you might want to prepare a default database file in your development environment, and include it in the .ipa/.apk package.

Data types with SQLite

SQLite does not have strict data type checking as traditional databases. If you define a table column as a DECIMAL, you can still store character values in that column. Pay attention to this SQLite specific feature, to avoid invalid storage and type conversion errors in your application.

Consider using the following data types for maximum portability, especially when data needs to be synchronized with a central database server, where the data types must match to the types used in the mobile application: CHAR, VARCHAR, DATE, DATETIME YEAR TO MINUTE, DATETIME YEAR TO FRACTION(3), DECIMAL, SMALLINT, INTEGER, BIGINT, BYTE, TEXT.
Optimizing data changes

SQLite can be slow at doing commits, due to the data integrity technique used for transactions. Since each INSERT / UPDATE / DELETE statements acts as an individual transaction (i.e., auto-commit), there will be as many transactions/commits as data manipulation statements. For example, it takes about 10 seconds to insert 1000 rows on an Intel core i7 2.60GHz CPU / 5400.0 RPM HDD computer.

When executing code that modifies a lot of rows (for example, when inserting default data at first application execution, or when doing synchronization with a central database), enclose the SQL statements within a BEGIN WORK / COMMIT WORK transaction block to speed up the process:

```
BEGIN WORK
FOR i=1 TO mylog.getLength()
    -- INSERT / UPDATE / DELETE statements
END FOR
COMMIT WORK
```

Enforcing foreign key constraints

SQLite 3.6.19 and + support foreign key constraints, with ON DELETE CASCADE and ON UPDATE CASCADE options. By default, however, foreign key constraints are not enforced. Each application must explicitly turn on the feature with a PRAGMA command. Immediately after the database connection, you can perform the PRAGMA command in an EXECUTE IMMEDIATE statement:

```
CONNECT TO connstr AS "c1"
EXECUTE IMMEDIATE "PRAGMA foreign_keys = ON"
```

Truncating the SQLite database file

By default, when deleting rows, SQLite keeps the unused database file pages for future storage. As result, when deleting a large amount of data, the database file might be larger than necessary. Consider truncating the database file with the VACUUM SQL command (in an EXECUTE IMMEDIATE statement), if disk space is limited and when a lot of database rows were deleted.

Depending on the application, the VACUUM command can be executed:

- when starting the application, just after connecting to the database,
- after doing a large database operation (such as a synchronization with a central database),
- as a manual option that the user can trigger.

For example, after connecting to the database:

```
CONNECT TO connstr AS "c1"
EXECUTE IMMEDIATE "VACUUM"
```

Sharing database files between Android apps

Two different Android™ apps (each packaged as a separate .apk) execute in their own sandbox, but have access to the storage area (SD-CARD) and therefore can share a common database file.

SQLite handles concurrent access to the same database file by setting a lock on the entire db file when modifying data (INSERT/UPDATE/DELETE). By default, if a writer process locks the file, other processes must wait until the lock owner process completes its transaction and releases the lock.

Because of Informix® compatibility, Genero BDL uses a default lock timeout or zero (i.e., not waiting for locks to be released). As result, when writing to a database file that is locked by another process, if the isolation level is SERIALIZATION (the default with SQLite), an application will get the SQL error -244.
To avoid this problem, you must change the default lock timeout with the `SET LOCK MODE` instruction, after starting the database session:

```
CONNECT TO connstr AS "c1"
SET LOCK MODE TO 5 -- seconds
```

The second process will then wait until the first process releases the lock. If transactions are short (milliseconds), having processes waiting for each other is transparent to the user.

## Accessing device functions

Mobile apps can access device functions by using front calls.

### Accessing device functions using frontcalls

Mobile applications typically want to access device functions such as geolocation, multi-media content (photos, videos), messaging (contacts database, email, sms).

This can be easily achieved by using front calls dedicated to mobile features. Note that some functions are platform specific, for example to launch an Android activity, or access to iOS device settings.

As a general rule, execute your front call in a `TRY / CATCH` block to catch errors:

```
DEFINE status STRING,
               latitude, longitude FLOAT
TRY
   CALL ui.Interface.frontCall("mobile", "getGeolocation",
                                [], [status, latitude, longitude] )
CATCH
   ERROR "Could not get coordinates..."
END TRY
```

For more details, see [Genero Mobile common front calls](#) on page 2546, [Genero Mobile Android front calls](#) on page 2562, [Genero Mobile iOS front calls](#) on page 2566.

### Accessing Android™ device functions using the Java Interface

**Note:** On Android™ devices, some system functions can only be accessed in the context of a JVM. Use the `Java Interface` with the `com.fourjs.gma.vm.FglRun` class to access such system specifics.

## Web Services on mobile devices

Web Services can be used within mobile applications.

### Web Services and Genero Mobile for Android

Points to consider when using Web Services on Android™ platforms:

- V3 SSL Certificates are required.

For complete details about Web Services on GMA, see [Web Services on GMA (Android)](#) on page 3107
Web Services and Genero Mobile for iOS

Points to consider when using Web Services on iOS platforms:

- GWS configuration FGLPROFILE entries related to SSL/TLS keys (security.*) are not supported (uses iOS native SSL/TLS).
- When executing a long-running HTTP request, the app may go into background mode, and raise the runtime error -15553 when switching back to foreground mode.

For complete details about Web Services on GMI, see Web Services on GMI (iOS) on page 3107.

Debugging a mobile app

Different solutions are available to debug a mobile app.

Debugging a mobile app in development mode

When executing a mobile app program on a server, displaying the user interface on a mobile front-end defined by FGLSERVER, it is possible to debug the BDL code with the fglrun -d option:

```
$ export FGLSERVER=device-ip-address
$ fglrun -d main.42m
```

For more details, see Starting fglrun in debug mode on page 2031.

AUI protocol debugging

With an app running on a server or on the device, it is possible to show AUI protocol exchanges in the console running the program on the server, by setting the FGLGUIDEBUG environment variable to 1. When this variable is set, you can watch user interface events that occur during program execution and how they are treated by the runtime system.

To set the FGLGUIDEBUG environment variable for an app running on the device, use an FGLPROFILE fglrun.environment entry. The output can be inspected with the program logs as described later in this section.

For more details, see FGLGUIDEBUG on page 240.

AUI protocol logging in development mode

With an app running on a server, it can be useful to log AUI protocol exchanges between the runtime system and the mobile front-end, to inspect the content, or replay a scenario. This is possible with the --start-guilog and --run-guilog options of fglrun:

```
$ fglrun --start-guilog=casel.log
```

The AUI protocol log file produced by the --start-guilog option can then be shared for analysis.

For more details, see Front-end protocol logging on page 1021.

Debugging a mobile app running on the device

When executing the mobile app on a device, and if the app has been created with debug mode, it is possible to establish a connection to the runtime system executing on the mobile device, by using the fgldb command line tool.

Important: On iOS devices, after installing the app, you need to enable the debug port in the app settings, otherwise the app will not listen to the debug port.

For example:

```
$ fgldb -m 192.168.1.23:6400
108 DISPLAY ARRAY contlist TO sr.*
```
This way you can debug an app running on a device, by using the source code located on the server where the \texttt{fgldb} command is executed.

For more details, see \textit{Debugging on a mobile device} on page 2032.

\textbf{Building mobile apps in debug mode}

In order to enable debug features of an app running on a mobile device, you need to build the app in debug mode:

- For Android:
  The \texttt{gmabuildtool} provides the \texttt{--mode debug} option, to create a debug version of the APK.
  For more details, see \textit{Building Android apps with Genero} on page 3317.

- For iOS:
  The \texttt{gmibuildtool} provides the \texttt{--mode debug} option, to create a debug version of the IPA. The certificate defined in the provisioning profile must be a development certificate.
  \textbf{Note:} After installing the debug version of the app on your iOS device, you need to enable the debug port in the app settings.
  For more details, see \textit{Building iOS apps with Genero} on page 3332.

\textbf{Browse the AUI tree created on the mobile front-end side}

The content of the \textit{Abstract User Interface tree} created on the mobile front-end side can be inspected from a web browser, when the app has been created with debug mode, or in development mode by executing the app on a server and displaying on the device.

To inspect AUI tree, open a web browser and enter the following URL:

\begin{center}
\url{http://device-ip-address:6480 (or 6400)}
\end{center}

For more details, see \textit{Inspecting the AUI tree of a front end} on page 1012.

\textbf{Viewing embedded app program logs}

The program logs of an app running on a device can be viewed in a browser, if the app was created in debug mode. VM messages (runtime errors, standard output and standard error) are available. This feature is not available if the app is built in release mode.

To inspect program logs, open a web browser and enter the following URL:

\begin{center}
\url{http://device-ip-address:6480 (or 6400)}
\end{center}

A menu will then appear in the web page, where you can choose the VM output to be inspected.

\textbf{Debugging a WEBCOMPONENT HTML/JavaScript}

The HTML content and JavaScript code can be debugged on GMA and GMI mobile devices.

For more details, see \textit{Debugging a web component} on page 1830.

\textbf{Related concepts}

Mobile apps are started and stopped, and can switch between foreground and background states when running.

App localization on page 3298
Mobile apps can be designed to display localized texts based on the language selected on the device.

Environment variables on page 3297
You may need to set environment variables for your app.

Database support on mobile devices on page 3309
On the device, a Genero app can use SQL for data management.

Deploying mobile apps on Android™ devices

This section contains information to create a mobile application to be deployed on Android™ devices.

Directory structure for GMA apps
Platform-specific rules need to be considered when deploying on Android™ devices (GMA).

The application sandbox

On Android™ devices, applications are deployed in an application sandbox. The application can access and store data outside of its space, but then the data is also accessible by the other applications.

Directory structure for a GMA application

Inside its application sandbox, an Android™ app uses the following directory structure:

```
appdir/
  -- main.42m
  -- *.42m
  -- *.42f
  -- fglprofile
  ...:
  -- defaults/*.42s
  -- de/
    | -- *.42s
  -- fr/
    | -- *.42s
  -- zh/
    | -- *.42s
  ...
```

Program files
Program files directory (**appdir**)

Application program files (.42m, .42r, and so on) need to be deployed in the **appdir** application base directory.

The program files directory can be found in programs with the `base.Application.getProgramDir` on page 2270 method.

**Important:** On Android™, the program files directory returned by the `base.Application.getProgramDir()` method is the same directory as the default working directory, returned by `os.Path.pwd()`.

The **FGLAPPDIR** environment variable is automatically set to the **appdir** directory.

Program name (MAIN)

When deploying on mobile devices, the name of the program file must be `main.42m` or `main.42r`.

**Note:** When using the command-line app build scripts, the name of the program file must be `main.42?`. When using Genero Studio, the packaging script takes care of renaming this file, if you have not named it `main`.

As with other program files, the "MAIN" module must be located under the **appdir** application program directory.

Working directory

On Android™ devices, the default current working directory is the **appdir** directory, and can be used for writable files.

The current working directory can be found in programs with the `os.Path.pwd` on page 2653 method.

Files that need to be writable (such as SQLite database files) can be created directly under the **appdir** directory. However, to better organize application files, create sub-directories such as `appdir/appdata`, keeping original files directly under the **appdir** directory. For example, create the application database under `os.Path.pwd() || "/database"`.

Temporary directory (**tmpdir**)

A temporary directory is available for the application.

In order to find the temporary directory for the app, use the `standard.feInfo` front call, with the "dataDirectory" parameter.

To create a temporary file name, use the `os.Path.makeTempName()` method.
**Language directories for localized strings**

When the app starts, the appropriate .42s string files will be loaded from the directory corresponding to the current language settings of the mobile device. String files to be loaded can be defined in the app's fglprofile, or you can use the main program name to avoid fglprofile settings.

For each language supported by your application, a directory must exist under `appdir`, with a name including the locale codes. Default string files (in English for example) can be provided under `appdir/defaults`, in case the regional settings of the device do not match one of the locale directories of the app, otherwise the application will stop with error -8006.

For example:

```
appdir/defaults/mystings.42s
appdir/fr/mystings.42s
appdir/de/mystings.42s
```

For more details, see [Localized string files on mobile devices](#) on page 438.

**Deploying a custom fglprofile file**

If you need to set fglprofile entries for your mobile application, create a file with the name fglprofile, and deploy it under the `appdir` directory, along with the other program files.

See [Understanding FGLPROFILE](#) on page 221 for more details about fglprofile settings.

**Creating the initial database file**

When a mobile application starts for the first time, it typically creates a new database, or copies an existing database template file from the file directory (`base.Application.getProgramDir` on page 2270) to the working directory (`os.Path.pwd` on page 2653).

**Note:** It is recommended that different database file names are used for the original and final application database, as folders pointed to by `base.Application.getProgramDir()` and `os.Path.pwd()` can be the same on Android™ devices.

For more details about database creation on mobile devices, see [Creating a database from programs](#) on page 548.

**Building Android™ apps with Genero**

Genero provides a command-line tool to create applications for Android™ devices.

**Basics**

Genero mobile apps for Android™ are distributed as APK packages like any other Android™ app.

Genero provides the `gmabuildtool` command line tool, to build the APK package for your mobile application.

For testing purposes, the tool can deploying and automatically launch the app on a specific device or simulator.

The tool has also an option to update the Android™ SDK and an option to manage scaffold archives.

**Note:** This documentation section implies that you are familiar with Android™ app programming concepts and requirements. For example, you will need the Android™ SDK tools to be installed (and up to date) to build your Android™ apps. For more details, visit the [Android SDK tools download page](#).

**Prerequisites**

Before starting the command line tool to build or deploy the app, fulfill the following prerequisites:

1. The Genero BDL development environment (FGLDIR) must be installed to compile your program files.
2. The Java JDK must be installed. The minimum required version is 1.8.
3. The Android™ SDK must be installed (the buildtool uses the "Gradle" utility).
Note: The first time the Android™ tools are called, they automatically check for updates. An internet connection is required.

4. Install the GMA software components.

The GMA buildtool and GMA binary archive are provided in the GMA distribution archive (fjs-gma-*.zip).

To set up the GMA installation directory, perform the following steps:

   a. Create a dedicated directory (gma-install-dir)
   b. Extract the content of the fjs-gma-*.zip.
   c. Add the gma-install-dir directory to your PATH environment variable, in order to find the gmabuildtool command.

The gma-install-dir will contain the gmabuildtool command, and the original GMA scaffold archive (gma-install-dir/artifacts).

5. All required Android™ SDK packages must be downloaded. To download the required Android™ SDK packages, execute the gmabuildtool updatesdk command.

   Note: Execute the gmabuildtool updatesdk command every time a new version of the GMA buildtool and GMA binary archive is installed.

6. Android™-specific app resources such as icons (in all required sizes) are required, along with the application program files.

7. If you plan to publish your app on Google Play, register to Google Play as a developer and create a Google Play project.

Environment settings

Define the following environment variables before starting the command-line buildtool:

- Android™ SDK environment settings (ANDROID_SDK_ROOT, PATH)
- Java JDK environment settings (JAVA_HOME, PATH)

Update the Android™ SDK with the GMA buildtool

After a fresh installation of the GMA buildtool and GMA binary archive, upgrade the Android™ SDK, to download all required Android™ SDK packages, with the gmabuildtool updatesdk command.

   Important: When using gmabuildtool updatesdk on Microsoft™ Windows® platforms, the "tools" package of Android™ SDK cannot be updated due to an SDK manager bug. The workaround is to download and install a new Android™ SDK. This problem exists for example with Android™ SDK 26.0.2, and may be solved in higher SDK versions.

The Android™ SDK installation directory is required for the SDK update, and is found in ANDROID_SDK_ROOT environment variable, or with the --android-sdk option:

\[ gmabuildtool updatesdk --android-sdk /use/local/32bits/android-sdk/r22.6.2 \]

Use the --accept-licenses option to silently accept all Android™ SDK licenses.

\[ gmabuildtool updatesdk --accept-licenses ... \]

If you need to specify a proxy to download the Android™ SDK, use the --proxy-host and --proxy-port options:

\[ gmabuildtool updatesdk --proxy-host amadeus --proxy-port 3232 ... \]
Use the `--no-install-extras` option to skip the installation of extra SDK modules such as Google's driver for Windows® and the HAXM for Windows® and OS X:

```
gmabuildtool updatesdk
   --no-install-extras
   ...
```

### Manage GMA scaffold archives

The GMA scaffold archives can be managed by the `gmabuildtool scaffold` command.

In order to get the list of plugins installed in the GMA development environment, use the `--list-plugins` option:

```
$ gmabuildtool scaffold --list-plugins
   ...
   cordova-plugin-device-motion.aar
   cordova-plugin-media.aar
   ...
```

To install additional plugins in the GMA installation directory, use the `--install-plugins` option, for example:

```
$ gmabuildtool scaffold --install-plugins path-to-plugin-sources
```

For more usage examples, see Cordova plugins on page 3370.

### Building your APK with the GMA buildtool

The `gmabuildtool build` command creates the APK from a set of files, and following the options passed as parameter.

```
gmabuildtool build
   ... build options ...
```

The process will be explained in details in the next sections of this topic.

For a complete description of the `build` command options, see `gmabuildtool` on page 1989.

### Gradle build cache

To build Android apps, the GMA buildtool uses the Gradle toolkit.

Gradle can speed up APK creation time, by reusing outputs saved in a cache produced from previous builds. The `gmabuildtool` command uses the Gradle build cache.

On Unix-like platforms, the `gmabuildtool` Gradle build cache is in the `/tmp/gma` directory. On Windows®, it is in `C:\tmp\gma`.

**Important:** The Gradle build cache directory used by `gmabuildtool` can grow to a significant size and consequently fill the disk. Take care to monitor the size of this cache and manually clean out the cache files, to ensure that it does not become too large in size.

### Cleaning intermediate build files

The build process is optimized to avoid a complete APK rebuild every time you invoke the GMA buildtool.

The GMA buildtool creates intermediate archive files, that can be reused in the next build, if no changes are detected in application program files. However, these files might be corrupted, in case of user interruption or gradle build failure.
In this situation, you can use the `--clean` option of the `gmabuildtool build ...` command, to clean up the scaffold build directory, and restart with a fresh build:

```
 gmabuildtool build --clean ...
```

**Force scaffold update during build**

During the build process, if not yet done, the GMA buildtool will automatically unzip the original GMA scaffold archive (`gma-install-dir/artifacts`) into the `--build-project` directory. During next builds, the scaffold files present in the project build directory will be reused.

If needed (especially, when upgrading GMA), you can force an update of these scaffold files with the `--build-force-scaffold-update` option of the `gmabuildtool build` command:

```
 gmabuildtool build --build-force-scaffold-update ...
```

**Note:** When using the `--build-force-scaffold-update` option, the GMA buildtool will ask for a confirmation to remove the scaffold files in your project directory. In order to build silently and answer yes to all questions asked during the build process, use the `--build-quietly` option:

```
 gmabuildtool build --build-force-scaffold-update --build-quietly ...
```

**Using an options file**

To simplify option specification, create a file with the list of options to be passed to the `gmabuildtool` with the `--input-options` argument. Each option must be specified in a dedicated line (note that the main command argument appears in the first line):

```
$ cat myoptions.txt
build
  --build-output-apk-name MyApp
  --build-app-name MyApp
  --build-app-package-name com.example.myapp
 ...
$ gmabuildtool --input-options ./myoptions.txt
```

**Elements used in building the Android™ app**

The `gmabuildtool build` command builds the Android™ APK package from the following:

- The GMA binary archive, containing the GMA front-end and the FGLGWS runtime system. The original scaffold is provided in `gma-install-dir/artifacts` and unzipped/copied for APK builds into a directory defined by the `--build-project` option.
- The compiled application program and resource files (.42m, .42f, etc) (`--build-app-genero-program* options),
- The prefix for the APK file name to be generated (`--build-output-apk-name` option),
- The name of the app (`--build-app-name` option),
- The version code of the app (`--build-app-version-code` option),
- The version name of the app (`--build-app-version-name` option),
- Android™ app specific resources:
  - Android™ app icons (all sizes) (`--build-app-icon*` and `--build-status-icon-*` options).
- Android™ app specifics (to sign the app, not required in development mode):
• The keystore alias, used with the keytool to generate the keystore file (\texttt{--build-jarsigner-alias} option).
• The keystore file, generated from keytool (for the \texttt{--build-jarsigner-keystore} option).

**Generate the keystore file to sign your app**

In order to build an APK that can be deployed on the market (Google Play), you need to sign your Android™ app.

First, you need to generate a keystore file with the keytool Android™ utility.

The keystore file and keystore alias will be used by the gmabuildtool to sign the APK with the jarsigner utility. These signing credentials are passed to the buildtool with the \texttt{--build-jarsigner-keystore} and \texttt{--build-jarsigner-alias} options.

For more details, see manual Android application signing.

**Generated APK file name**

The file name of the APK package is formed from:

1. The APK file name prefix defined by the \texttt{--build-output-apk-name} option (by default, "app"),
2. When building a debug version, the \texttt{-debug} suffix,
3. The .apk file extension.

For example, if the APK file name prefix is MyApp and is a debug package, the resulting APK file name will be: MyApp-debug.apk.

**Default build directory structure**

For convenience, the buildtool supports a default directory structure to find all files required to build the APK:

```
top-dir
|-- main.42m and other program files, as described in Directory structure for GMA apps on page 3315
|-- gma
  |-- project
  |   ...
  |   |-- ic_app_hdpi.png
  |   |-- ic_app_mdpi.png
  |   |-- ic_app_xhdpi.png
  |   |-- ic_app_xxhdpi.png
  |   |   ...
```

In the above directory structure:

1. \texttt{top-dir} is the top directory of the default structure. It typically holds your application program files. The program files directory can be specified with the \texttt{--build-app-genero-program} option.
2. \texttt{top-dir/gma} is the default directory containing the GMA binary archive and the app icons.
3. \texttt{top-dir/gma/project} contains the scaffold files copied automatically by gmabuildtool from \texttt{gma-install-dir/artifacts}. This directory can be specified with the \texttt{--build-project} option.

**Android™ permissions**

To use a mobile device feature such as the camera, an Android™ app must be created with the corresponding Android™ permission.

Android™ distinguishes "Normal Permissions" and "Dangerous Permissions": Dangerous Permissions require a user validation at runtime, the first time the device feature is used.
**Note:** Before Android™ 6, Dangerous Permissions defined by the app were set at app installation. Starting with version 6, Dangerous Permissions must be requested by the app code on demand.

Android™ permissions can be specified with the `--build-app-permissions` option of the gmabuildtool. Define the list of permissions as a single argument, by using the comma as separator.

For example:

```
  gmabuildtool build \
  ... \
  --build-app-permissions android.permission.READ_CALENDAR,... \ 
  ... 
```

Assuming that the permission was specified when building the APK, a Dangerous Permission required for a core GMA feature (like internet access), or a built-in front call, will make the GMA automatically ask for user confirmation. For example, if the app code makes a `chooseContact` front call, the GMA will automatically request the user to access the contacts database.

Other permissions (not related to core GMA features or built-in front calls) need to be specified when building the app.

**Note:** Dangerous Permissions not related to core GMA features or built-in front calls, need to be enabled by the app code. To request the user for a specific permission, perform a `askForPermission` front call, before using the feature.

The permissions listed below show Android™ "Normal Permissions", required for core GMA app features and built-in mobile front calls.

**Note:** Normal Permissions listed below are set by default. They do not need to be specified when building the APK.

- `android.permissionINTERNET`
- `android.permissionACCESS_NETWORK_STATE`
- `android.permissionCHANGE_NETWORK_STATE`
- `android.permissionACCESS_WIFI_STATE`
- `android.permissionREORDER_TASKS`
- `android.permissionKILL_BACKGROUND_PROCESSES`
- `android.permissionMOUNT_FORMAT_FILESYSTEMS`
- `android.permissionREAD_LOGS`
- `android.permissionWAKE_LOCK`
- `com.google.android.c2dm.permission.RECEIVE`
- `packageName.permission.C2D_MESSAGE`

The following list shows the Android™ "Dangerous Permissions", required for core GMA app features and built-in mobile front calls.

**Important:** Dangerous Permissions listed below are not set by default: They must be specified explicitly with the `--build-app-permissions` option, when building the APK.

- `android.permission.ACCESS_FINE_LOCATION`: For `getGeolocation` on page 2551 front call.
- `android.permission.ACCESS_COARSE_LOCATION`: For `getGeolocation` on page 2551 front call.
- `android.permission.READ_CONTACTS`: For `chooseContact` on page 2548 front call.
- `android.permission.GET_ACCOUNTS`: Only on Android™ 5.1 and lower (< API 23), for `chooseContact` on page 2548 front call.
- `android.permission.READ_PHONE_STATE`: For `feInfo (deviceid, iccid, imei)` front calls.
- `android.permission.WRITE_EXTERNAL_STORAGE`: For `importContact` on page 2555, `takeVideo` on page 2561, `takePhoto` on page 2560 front calls.
- `android.permission.READ_EXTERNAL_STORAGE`: For `chooseVideo` on page 2549, `takeVideo` on page 2561, `choosePhoto` on page 2548, `takePhoto` on page 2560 front calls.

For a complete list of Android™ permissions, see Android's Manifest permissions.
Define app’s color theme

To customize your Android™ app, it can be created with a color theme defined by a list of colors. The colors are specified as a comma-separated list of RGB colors with the `--build-app-colors` option.

**Note:** This feature is only available with Android™ 5.0 / SDK 21 and higher. With older versions of Android™, the colors specified with the `--build-app-colors` option will not take effect.

The value provided to the `--build-app-colors` option must be a comma-separated list of four hexadecimal RGB colors.

The position of the RGB value in the color list defines its purpose:

1. `colorPrimary`: The main color used in the app.
2. `primaryDark`: The color used for the status bar and the navigation bar.
3. `accent`: The accent color used for widgets and table lines.
4. `actionBarText`: The foreground color for the texts in the action bar.
5. `primaryText`: The text color for items in the whole application.
6. `windowBackground`: The window background color.
7. `navigationBarBackground`: The background color of the bottom bar.

By default, the color theme is the Genero purple color.

For example, to define a red color theme, use the following combination:

```
 gmabuildtool build \
   ... \
   --build-app-colors \
   "#F44336,#B71C1C,#EF9A9A,#FFFFFF,#FF0000,#00AA00,#DDAA00" \
   ...
```

For more details, see [Android material theme](#) and [Android color palette](#)

Debug and release versions

Android™ apps can be generated in a debug or release version. Release version are prepared for distribution on Google Play, while debug versions are used in development. In debug mode, the app installed on the device will listen on the debug TCP port to allow `fgldb -m` connections.

Debug or release mode can be controlled with the `--build-mode` option of the `gmabuildtool` command:

```
 gmabuildtool build \ 
   --build-mode debug \ 
   ...
```

By default the app is built in release mode.

Building an Android™ app with gmabuildtool

Follow the next steps to setup a GMA app build directory in order to create an Android™ app, based on the default directory structure:

1. Create the root distribution directory (`top-dir`)
2. Copy compiled program files (.42m, .42f, fglprofile, application images, web component files, etc) under `top-dir`.
3. Copy the default English .42s compiled string resource file under `top-dir`.
4. Create non-English language directories (fr, ge, ...) under `top-dir` and copie the corresponding .42s files.
5. Copy default application data files (database file for ex) under `top-dir`.
6. Create the `top-dir/gma` directory.
7. Copy Android™ app resources (icons) under `top-dir/gma`. 
Once the build directory is prepared, issue the following commands to build the APK:

```
$ cd top-dir
$ gmabuildtool build \
   --android-sdk /home/mike/android/sdk \
   --build-force-scaffold-update \
   --build-apk-outputs /home/mike/work/example/outputs \
   --build-output-apk-name MyApp \
   --build-app-name MyApp \
   --build-app-package-name com.example.myapp \
   --build-app-version-code 1002 \
   --build-app-version-name "10.02" \
   --build-jarsigner-alias android_alias \
   --build-jarsigner-keystore /home/mike/work/example/sign/android.keystore \
   --build-mode release \
   --build-app-permissions android.permission.ACCESS_WIFI_STATE,android.permission.CALL_PHONE
```

Building an app with GMA custom extensions

The `gmabuildtool build` command supports APK creation for applications using GMA custom extensions written in Java.

Before building the APK package, create the custom GMA binary archive with your extensions, as described in Packaging custom Java extensions for GMA on page 2102.

When your custom GMA binary archive is complete, build the APK package with the `gmabuildtool build` command. Use the `--build-project` option to specify the path to the Android™ Studio project that was used to build your custom GMA binary archive:

```
$ gmabuildtool build \
   ... \
   --build-project /home/mike/android_project/mycustgma \
   ...
```

**Note:** Other options have to be specified as for a regular build using the original standard GMI binary archive.

Deploy and launch the app

After building the APK package, for testing purposes, you can deploy and launch your app from the command line with the `gmabuildtool test` command.

**Note:** The `test` command is provided for development only. To deploy your app in production for several devices, use the regular publication channel of Android™ apps.

In order to deploy and launch the app, you must provide:

1. the path to the APK file

There must be only one Android™ device connected or running Android™ emulator.

```
$ gmabuildtool test \
   --test-apk /home/mike/work/example/outputs/MyApp-arm-debug.apk
```

**Related concepts**

- **Genero Mobile common front calls** on page 2546
  This section describes common front calls provided by all mobile front-ends.
- **Color and theming** on page 3307
Mobile applications must follow the platform colors and theming.

**gmbuildtool**
The *gmbuildtool* is a utility to create and test applications for an Android™ device.

**Syntax**

```
gmbuildtool command [option [...]]
```

1. *command* can be one of the following:
   - `updatesdk`: updates the Android™ SDK, to download packages required by GMA.
   - `scaffold`: manages scaffold archives.
   - `build`: builds an APK package.
   - `test`: deploys and launches an app on the device or emulator.
2. *option* can be a general or command-specific option, as described in **Options** on page 3325.

**Known issues**

**Important**: When using *gmbuildtool updatesdk* on Microsoft™ Windows® platforms, the "tools" package of Android™ SDK cannot be updated due to an SDK manager bug. The workaround is to download and install a new Android™ SDK. This problem exists for example with Android™ SDK 26.0.2, and may be solved in higher SDK versions.

| --build-app-colors color-list | -bc          | Define the Android™ color theme for the app (Android™ 5.0+ / SDK 21+)

The value must be a comma-separated list of four hexadecimal RGB colors: #F44336, #B71C1C, #EF9A9A,...

The position of the RGB value in the color list defines its purpose:

1. **colorPrimary**: The main color used in the app.
2. **primaryDark**: The color used for the status bar and the navigation bar.
3. **accent**: The accent color used for widgets and table lines.
4. **actionBarText**: The foreground color for the texts in the action bar.
5. **primaryText**: The text color for items in the whole application.
6. **windowBackground**: The window background color.
7. **navigationBarBackground**: The background color of the bottom bar.

By default, the color theme is the Genero purple color.

Relative path to the main module of the application (can be .xcf, .42m or .42r).

Defaults to main.42m

Defines the path to the application program files (.42m, .42f, etc)

The contents of this directory will be zipped and bundled inside APKs. This option can handle an already zipped Genero program archive.

If not specified, defaults to the current working directory.

**Note**: The path defined by this option is used as base directory for other options such as --build-project and application icon resources options.

Defines the path to application icon in hdpi.

Default is top-dir/gma/ic_app_hdpi.png, where top-dir is defined by the --build-app-genero-program option.

Defines the path to application icon in mdpi.

Default is top-dir/gma/ic_app_mdpi.png, where top-dir is defined by the --build-app-genero-program option.

Defines the path to application icon in xhdpi.

Default is top-dir/gma/ic_app_xhdpi.png, where top-dir is defined by the --build-app-genero-program option.
<table>
<thead>
<tr>
<th>Option</th>
<th>Short option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--build-app-icon-xxhdpi path</td>
<td>-bixxh</td>
<td>Defines the path to application icon in xxhdpi. Default is top-dir/gma/ic_app_xxhdpi.png, where top-dir is defined by the --build-app-genero-program option.</td>
</tr>
<tr>
<td>--build-app-name app-name</td>
<td>-bn</td>
<td>Application name. If not specified, the application name defaults to the current working directory.</td>
</tr>
<tr>
<td>--build-app-package-name name</td>
<td>-bpn</td>
<td>APK package name. It is recommended to format the package name as &quot;com.organization-name.app-name&quot;. If not specified, the application package name defaults to com.example.current-working-directory.</td>
</tr>
<tr>
<td>--build-app-permissions</td>
<td>-ba</td>
<td>Android™ application permissions. The list of permissions is provided as a comma separated list of android.permission.* identifiers. For more details, see Android permissions on page 3321.</td>
</tr>
<tr>
<td>--build-app-version-code</td>
<td>-bvc</td>
<td>Application version code. For example: 100915 The value of this option must be an integer (do not use decimal numbers).</td>
</tr>
<tr>
<td>--build-app-version-name</td>
<td>-bvn</td>
<td>Application version name. For example: 10.09.15 This will be the actual app version visible on devices.</td>
</tr>
<tr>
<td>--build-apk-outputs path</td>
<td>-bo</td>
<td>Defines the destination folder where the APK packages must be created.</td>
</tr>
<tr>
<td>--build-cordova cordova-plugin-names</td>
<td>-bco</td>
<td>Defines Cordova plugins to be embedded in the app package. When specifying multiple cordova plugins, use the comma (,) as separator. The name of the plugin must match the Git repository name. It is case-sensitive. Note: To get the list of available Cordova plugins, use the gmbuildtool scaffold --list-plugins command. For further information, see Cordova plugins on page 3370.</td>
</tr>
<tr>
<td>--build-force-scaffold-update</td>
<td>-bfsu</td>
<td>Forces to re-create the app project directory with the original GMA scaffold directory (defined by --build-project)</td>
</tr>
<tr>
<td>Option</td>
<td>Short option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>--build-jarsigner-alias alias</td>
<td>-bja</td>
<td>Jarsigner alias. This is the alias provided to the keystore utility to build the keystore file to sign the app. Used when APK artifacts are signed.</td>
</tr>
<tr>
<td>--build-jarsigner-keypass keypass</td>
<td>-bjk</td>
<td>Jarsigner keypass. Specifies the password used to protect the private key of the keystore entry addressed by the alias specified in the --build-jarsigner-alias option. The password is required when using jarsigner to sign a JAR file. Used when APK artifacts are signed.</td>
</tr>
<tr>
<td>--build-jarsigner-keystore path</td>
<td>-bjks</td>
<td>Jarsigner keystore path. This is the path to the keystore file generated by the keystore utility to sign the app. Used when APK artifacts are signed.</td>
</tr>
<tr>
<td>--build-jarsigner-storepass storepass</td>
<td>-bjs</td>
<td>Jarsigner storepass. Specifies the password that is required to access the keystore. Used when APK artifacts are signed.</td>
</tr>
<tr>
<td>--build-mode {release</td>
<td>debug}</td>
<td>-bm</td>
</tr>
<tr>
<td>--build-output-apk-name name</td>
<td>-ban</td>
<td>Defines the prefix for the APK packages names. By default, this prefix is &quot;app&quot;. The file name of the APK package is formed from: 1. The APK file name prefix defined by the --build-output-apk-name option (by default, &quot;app&quot;), 2. When building a debug version, the -debug suffix, 3. The .apk file extension. For example, if the APK file name prefix is MyApp and is a debug package, the resulting APK file name will be: MyApp-debug.apk. Defines the path to the directory containing the original GMA binary archive files (i.e. scaffolding), or the directory containing the Android™ Studio project, when building a customized GMA. Default is top-dir/gma/project, where top-dir is defined by the --build-app-genero-program option. Forces a silent build, by answering yes to all questions asked during the build process. By default, the user must answer to the build questions by yes/no.</td>
</tr>
</tbody>
</table>

**Related concepts**

**Building Android apps with Genero** on page 3317

Genero provides a command-line tool to create applications for Android™ devices.

**Deploying mobile apps on iOS devices**

This section contains information to create a mobile application to be deployed on iOS devices.

**Directory structure for GMI apps**

Platform-specific rules need to be considered when deploying on iOS devices (GMI).

**The application sandbox**

On iOS devices, program interactions with the file system are limited to the directories inside the app's sandbox.
Directory structure for a GMI application

Inside its application sandbox, an iOS app uses the following directory structure:

```
appdir/
|-- main.42m
|-- *.42m
|-- *.42f
|-- fglprofile
    ...
|-- defaults/*.42s
|-- de/
    |-- *.42s
|-- fr/
    |-- *.42s
|-- zh/
    |-- *.42s
|-- ... other resource files/dirs ...
    ...
|-- webcomponents
    |-- component-type
        |-- component-type.html
        |-- other-web-comp-resource
    ...

Documents/
|-- ... writable app files ...

tmpdir/
|-- ... temporary files ...
```

Program files directory (appdir)

Application program files (.42m, .42f, as well as other program resources) need to be deployed in the appdir directory.

**Important:** On iOS, the application program directory is read-only. Only the "Documents" directory is writable.

The program files directory can be found in programs with the `base.Application.getProgramDir` on page 2270 method.

The FGLAPPPDIR environment variable is automatically set to the appdir directory.

Program name (MAIN)

When deploying on mobile devices, the name of the program file must be main.42m or main.42r.

**Note:** When using the command-line app build scripts, the name of the program file must be main.42?. When using Genero Studio, the packaging script takes care of renaming this file, if you have not named it main.

As with other program files, the "MAIN" module must be located under the appdir application program directory.

Working directory

The current working directory for an iOS application is typically a writable "Documents" directory, in the private folder of the app. For example, the path to the working directory can be "/private/var/mobile/.../Documents".

The current working directory can be found in program with the `os.Path.pwd` on page 2653 method.

**Note:** Any file access without an absolute path will be relative to the current working directory.
Files that need to be writable (such as SQLite database files) must be created or copied from the program files directory into the working directory. Copy must be done by the app at first execution, by using `base.Application.getProgramDir` on page 2270, to find the program files directory, and `os.Path.pwd()` to find the working directory.

**Temporary directory (** `tmpdir` **)**

A temporary directory is available for the application.

In order to find the temporary directory for the app, use the `standard.feInfo` front call, with the "dataDirectory" parameter.

To create a temporary file name, use the `os.Path.makeTempName()` method.

**Language directories for localized strings**

When the app starts, the appropriate `.42s` string files will be loaded from the directory corresponding to the current language settings of the mobile device. String files to be loaded can be defined in the app's `fglprofile`, or you can use the main program name to avoid `fglprofile` settings.

For each language supported by your application, a directory must exist under `appdir`, with a name including the locale codes. Default string files (in English for example) can be provided under `appdir/defaults`, in case the regional settings of the device do not match one of the locale directories of the app, otherwise the application will stop with error -8006.

For example:

```plaintext
appdir/defaults/mystrings.42s
appdir/fr/mystrings.42s
appdir/de/mystrings.42s
```

For more details, see [Localized string files on mobile devices](#) on page 438.

**Deploying a custom fglprofile file**

If you need to set `fglprofile` entries for your mobile application, create a file with the name `fglprofile`, and deploy it under the `appdir` directory, along with the other program files.

See [Understanding FGLPROFILE](#) on page 221 for more details about `fglprofile` settings.

**Creating the initial database file**

When a mobile application starts for the first time, it typically creates a new database, or copies a existing database template file from the `appdir` program file directory (`base.Application.getProgramDir` on page 2270) to the working directory (`os.Path.pwd` on page 2653).

For more details about database creation on mobile devices, see [Creating a database from programs](#) on page 548.

**Building iOS apps with Genero**

Genero provides a command-line tool to build applications for iOS devices.

**Basics**

Genero mobile apps for iOS are distributed as IPA packages, like any other iOS app. Genero provides a command line tool to build the .ipa package for your mobile application, or the .app directory for simulators.

**Note:** This documentation section implies that you are familiar with iOS app programming concepts and requirements. In order to build your apps, you must have an Apple® developer account, as well as certificates and provisioning profiles to deploy your apps. For more details, visit the [Apple developer site](#).
Prerequisites

Before starting the command line tool to build or deploy the app, fulfill the following prerequisites:

1. The Genero BDL development environment (FGLDIR) must be installed on the Mac computer to compile your program files.

2. The GMI archive (and gmibuildtool) must be installed and available.

   The GMI archive is provided as a ZIP archive (fjs-fqlgmi-*.*.zip). Extract the archive into FGLDIR.

   **Warning:** If the GMI archive is not extracted into FGLDIR, the Xcode® project of the FGLDIR/demo/ MobileDemo/userfrontcall demo does not work.

   For test purposes, the GMI zip archive can be installed elsewhere in a location of your choice. You may choose to do this to resolve problems resulting from several GMI versions. If you install elsewhere, define an environment variable GMIDIR on page 248 with the install location and add $GMIDIR/bin to the path.

   **Note:** The GMI buildtool does not need GMIDIR. However, all the supplied GMI demos need GMIDIR in the Makefiles.

   Check that the gmibuildtool command is available (add GMI-install-dir/bin to PATH for convenience).

   **Important:** When re-installing a new GMI archive, remove all "build" directories created by the gmibuildtool.

3. Get an Apple® developer account, device identifiers (UDID) and corresponding identifiers to sign your iOS app (certificate, bundle id, provisioning profile).

   **Important:** The UDID is the identifier of your physical device, it can be found with the instruments -s command when the device is plugged to the Mac. When deploying on a physical device, make sure that the UDID of the device is listed in the Apple® Developer account that is used to generate the provisioning profiles.

4. Xcode® must be installed on your Mac® OS X computer (utilities from Xcode® toolchain are required).

   **Note:** Make sure that the installed Xcode® version supports the iOS versions of your mobile devices. As a general rule, update the Xcode® and iOS to the latest versions.

5. iOS app resources such as icons and launch images (in all required sizes).

Finding the UDID of the plugged device

In order to find the UDID of the device plugged to your Mac, execute the instruments -s command, and identify the line describing your physical device:

```
$ instruments -s
Known Devices:
fraise [55D66C1-DE87-52F0-86E-3C6DC79F13D7]
Fourjs2 iPod touch (9.1) [78b7452fa9462c98c3bc7047da344314fd032004]
iPad 2 (9.0) [19CDA827-CA55-46F1-9376-BF61E2ECFDBB]
iPad Air (9.0) [F55E1207-C42B-472E-BD76-5B5AE46DE77A]
iPad Air 2 (9.0) [A0E8C4CD-67CD-42CB-84DF-9C75AC773293]
...
Known Templates:
"Activity Monitor"
"Allocations"
...
```

In the above output, the UDID of the iPod® is 78b7452fa9462c98c3bc7047da344314fd032004.

Environment settings

Before starting the command-line buildtool, make sure that Xcode® tools are available. Try xcodebuild from the command line.
The gmibuildtool

The gmibuildtool command line tool can build IPA packages of iOS apps written in Genero.

In order to identify the exact product version number of each GMI component, use the `--version` option of the gmibuildtool:

```bash
$ gmibuildtool --version
GMI version:1.30.12
VM version:3.10.05
GWS version:3.10.06
```

Manage GMI plugins

In order to get the list of plugins installed in the GMI environment, use the `--list-plugins` option:

```bash
$ gmibuildtool --list-plugins
...
cordova-plugin-device-motion
cordova-plugin-media
...
```

To install additional plugins in the GMI installation directory, use the `--install-plugins` option, for example:

```bash
gmibuildtool --install-plugins path-to-plugin-sources
```

For more usage examples, see Cordova plugins on page 3370.

Creating the GMI front-end for development purpose

A self-made GMI front-end can be created with the gmibuildtool command. For more details, see Mobile development mode on page 3294.

Specifying the target to build and deploy the iOS app

The gmibuildtool command can build and install iOS apps for the simulator or for physical devices.

The build and/or install action is controlled by the `--device` option:

- By default, when not specifying the `--device` option, a GMI.app directory is created for the simulator.
- When specifying the `--device booted` option, the GMI.app directory is created and the app is installed on the booted simulator.
- When specifying the `--device phone` option, the GMI.app directory and .ipa file are created.
- When specifying the `--device physical-device-name` option (with a real physical device name plugged on your Mac), the GMI.app directory and .ipa file are created and the app is installed on the device.

By default, the generated GMI.app directory and .ipa archive can be found in $PWD/build sub-directories. However you can specify the destination IPA file with the `--output` option.

Elements used to build the iOS app

The gmibuildtool command builds the iOS app package from the following:

- The GMI binary archive, containing the GMI front end and the FGL runtime system library.
  
  **Note:** These files are provided in the fjs-fglgmi-*.zip archive.
  
  **Important:** When re-installing a new GMI archive, remove all "build" directories created by the gmibuildtool.

- The compiled application program and resource files (.42m, .42f, etc).
  
  **Note:** The application program files must include a main.42m or main.42r module.
• The display name of the app (--app-name parameter),
• The version of the app (--app-version parameter),
• The debug or release mode (--mode parameter),
• The certificate (to sign the app) (--certificate parameter),
• The bundle Identifier (--bundle-id parameter),
• The app provisioning profile (.mobileprovision file) (--provisioning parameter),
• iOS app specific resources:
  • App icons (--icons parameter),
  • Launch images (--launch-images parameter) or launch storyboard file (--storyboard parameter).

For a complete description of command options, see gmibuildtool on page 1994.

**Default build directory structure**

For convenience, the buildtool supports a default directory structure to find all files required to build the app:

```
| --- top-dir
| --- -- main.42m and other program files, as described in Directory structure for GMI apps on page 3330
| --- -- gmi
| | --- -- Info.plist
| | --- -- LaunchScreen.storyboard or (default launch images)
| | | --- -- Default@2x.png
| | | --- -- Default-568h@2x.png
| | | --- -- Default-Landscape.png
| | | --- -- Default-Landscape-667h@2x.png
| | | --- -- Default-Landscape-736h@3x.png
| | | --- -- Default-Landscape@2x.png
| | | --- -- Default-Portrait.png
| | | --- -- Default-Portrait-736h@3x.png
| | | --- -- Default-Portrait-667h@2x.png
| | | --- -- Default-Portrait@2x.png
| | | ...+
| | --- -- icon_29x29.png
| | --- -- icon_40x40.png
| | --- -- icon_57x57.png
| | --- -- icon_58x58.png
| | --- -- icon_72x72.png
| | --- -- icon_76x76.png
| | --- -- icon_80x80.png
| | --- -- icon_120x120.png
| | --- -- icon_152x152.png
| | | ...
```

In the above directory structure:

1. **top-dir** is the top directory of the default structure. It will typically hold your application program files. A different program files directory can be specified with the --program-files option.

2. **top-dir/gmi** is the default directory containing the app resource files such as icons:
   a. **Info.plist** is the Information Property List File that will be used to build the app. Some properties will be overwritten by gmibuildtool options like --app-name and --app-version.
   b. Provide either a launch screen storyboard or default launch images:
      - **LaunchScreen.storyboard** is the default storyboard file for the app launch screen. This file can be specified with the gmibuildtool --storyboard option.
• Default-*.png are the app launch image files. The directory to find launch images can be specified with the gmibuildtool --launch-images option.

c. icon_*.png are the app icon files. The directory to find icons can be specified with the gmibuildtool --icons option.

Debug and release versions

iOS apps can be generated in a debug or release version. Release version are prepared for distribution on the App Store, while debug versions are used in development.

In debug mode, the app installed on the device can listen on the debug TCP port to allow fgldb -m connections, after enabling the debug port in the app settings.

Debug or release mode must be specified in the command line with the --mode debug or --mode release option. Additionally, if you want to deploy on a physical device, you need to use a provisioning profile corresponding to the debug or release mode:

• In debug mode, the certificate must be a development certificate.
• In release mode, the certificate must be a distribution certificate.

Defining the app version and build number

Apple distinguishes the app version number of a bundle (visible to the end user), from the build version number of a bundle (called a release version number in Apple docs).

You specify the app version number with the --app-version option of the gmibuildtool command. This option sets the CFBundleVersion property of the Info.plist file, and must match the version specified in iTunes® Connect.

In order to distinguish multiple builds (Apple's term is "releases") of the same app version number, define the build version number of your app with the --build-number option. This option sets the CFBundleShortVersionString property of the Info.plist file. For a given app version, you need to increase this build number, to be able to upload a new binary on iTunes® Connect.

Note: If you do not specify the --build-number option, the build version number defaults to the app version specified with the --app-version option.

Defining app properties in the ./gmi/Info.plist file

iOS app are created with a set of properties that are essential configuration information for a bundled executable. These properties are defined in the "Information Property List File", an XML formatted file named Info.plist by convention.

Most important Info.plist properties are defined with gmibuildtool options such as --app-name and --app-version. However, you may need to define other properties that are out of the scope of the buildtool. For example: background modes, device capabilities, screen orientations, permanent wifi, and so on.

In order to define specific app properties, create an Info.plist file in the top-dir/gmi directory before executing the gmibuildtool. Properties covered by the buildtool will be overwritten, while any other property defined in the top-dir/gmi/Info.plist file will be left untouched.

For more details about the Info.plist file structure, see Apple developer site page about Information Property List File.

Building an iOS app with gmibuildtool

Follow the next steps to setup a GMI app build directory in order to create an iOS app, based on the default directory structure:

1. Create the root distribution directory (top-dir)
2. Copy compiled program files (.42m, .42f, fglprofile, application images, web component files, etc) under top-dir.
3. Copy the default English .42s compiled string resource file under `top-dir`.
4. Create non-English language directories (fr, ge, ...) under `top-dir` and copy the corresponding .42s files.
5. Copy default application data files (database file for ex) under `top-dir`.
6. Create the `top-dir/gmi` directory.
7. Copy iOS app resources (icons, launch screen, storyboard) under `top-dir/gmi`.
8. If needed, create an `top-dir/gmi/info.plist` file, to define specific iOS app properties.

Once the build directory is prepared, issue the following commands:

```
$ cd top-dir
$ gmibuildtool \
   --output myapp.ipa \
   --app-name "My App" \
   --app-version "v3.1.6" \
   --bundle-id "com.example.mycompany.myapp" \
   --mode release \ 
   --certificate "iPhone Developer" \
   --provisioning "/Library/MobileDevice/Provisioning Profiles/myapp.mobileprovision" \
   --device phone
```

**Building a GMI app with C extensions or custom front calls**

In order to create an iOS app using C extensions written in Objective-C as in Implementing C-Extensions for GMI on page 2127, proceed as follows (the same technique can be used to build apps that include custom front calls):

1. Build a static library from your Objective-C sources, by using the `staticlib` target of the `GMIDIR/lib/Makefile-gmi` generic makefile (specify the library file name with the `USER_LIBNAME` variable). The `staticlib` makefile target will produce a `.a` library file, by using all `.m` and `.c` files found in the current directory. For example:

```
$ make -f $GMIDIR/lib/Makefile-gmi USER_LIBNAME=mylib.a staticlib
```

2. When building the app, specify the additional libraries with the `--extension-libs` option. For example:

```
$ gmibuildtool ... --extension-libs "-lz libBPush.a mylib.a" ...
```

Regardless of whether the `--extension-libs` parameter is set, the `gmibuildtool` looks to see if `./gmi/*.a` exists. If they exist, it adds these static libs to the link list.

If a file called `./gmi/link_flags.sh` exists, this file is read by `gmibuildtool` to set additional link flags. For example:

```
#set LINK_FLAGS to add additional system libs or frameworks
LINK_FLAGS="-bz2 -framework MapKit"
```

In most cases the `.a` files will be sufficient, for system frameworks like MapKit, as long as the following hint is specified in your `.m` source file:

```
/*@ this avoids using -framework MapKit and instructs the linker to link with MapKit*/
@ import MapKit;
```

Only pure C libs such as `libbz2.a` actually need the `link_flags.sh` file, if no `--extension-libs` option is used and one of the static extension libs needs a system C library.

For complete examples, see `GMIDIR/demo/MobileDemo/userextension` and `GMIDIR/demo/MobileDemo/userfrontcall`
Mobile applications

Related concepts
Mobile development mode on page 3294
Set up a development environment to display app forms on a mobile front-end.

gmibuildtool
The gmibuildtool is a utility to create and test applications for an iOS devices.

Syntax

```
gmibuildtool [options]
```

1. options are described in Options on page 3338.

Options

Table 696: gmibuildtool options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--app-name application-name</code></td>
<td>Display name of the mobile app. This option can be specified to define the display name of the app, it sets the CFBundleDisplayName property in the Info.plist file. If not specified, the name defaults to &quot;Noname&quot;.</td>
</tr>
<tr>
<td><code>--app-version application-version</code></td>
<td>Defines app version visible to the users on the App Store. This option is mandatory and sets CFBundleVersion properties in the Info.plist file. Note: If the <code>--build-number</code> option is not used, <code>--app-version</code> will also set the both the CFBundleShortVersionString property.</td>
</tr>
<tr>
<td></td>
<td>In iTunes® Connect, you define the version of your app, that must match the CFBundleVersion property in the Info.plist file of the app. If these versions do not match, the app cannot be published. Once the app is visible on App Store, the version specified in iTunes® Connect shows up in the &quot;Version&quot; section of the application page. The recommendation for the app version number is that it is a string comprised of three period-separated integers. For example: &quot;1.4.2&quot;</td>
</tr>
<tr>
<td><code>--bundle-id bundle-identifier</code></td>
<td>Defines the Bundle Identifier (a.k.a. App Id) for the app. This option is mandatory and sets the CFBundleIdentifier property in the Info.plist file. A bundle identifier is the unique identifier of your app, to let iOS recognize new app versions. When developing for the simulator, you can choose your own identifier. When creating an application for the App Store, the bundle identifier must be registered with Apple. If not specified, the name defaults to &quot;noname&quot; (for prototyping).</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| `--build-cordova cordova-plugin-names` | Defines Cordova plugins to be embedded in the app package.  
When specifying multiple cordova plugins, use the comma (,) as separator.  
The name of the plugin must match the Git repository name. It is case-sensitive.  
**Note:** To get the list of available Cordova plugins, use the `gmibuildtool --list-plugins` command. |
| `--build-number build-number` | Defines the build number used to upload a new binary of the same app version.  
This option must be used to distinguish different builds for the same app version. It sets the `CFBundleShortVersionString` property in the `Info.plist` file.  
The build number needs to be incremented in order to upload a new binary version of the same app version in iTunes® Connect.  
If this option is not used, the build number defaults to the version specified with the `--app-version` option.  
The build number is a string comprised of three period-separated integers. For example: "1.4.2" |
| `--certificate identity` | Name of a certificate to sign the app.  
This option is mandatory to build apps for a physical device or for the app store.  
The certificate can be found in the Keychain® access program, in the "Common Name" field of the certificate panel.  
The command `security find-identity -v` can be used to list all available certificates. |
| `--crypto {yes|no}` | Enables GWS cryptographic APIs based on the OpenSSL library. When using this option, the OpenSSL library is embedded into the resulting `.ipa` file.  
The default is `yes`. |
| `--device device-name` | Defines the name of a device or simulator.  
- By default, when not specifying the `--device` option, a `GMI.app` directory is created for the simulator.  
- When specifying the `--device booted` option, the `GMI.app` directory is created and the app is installed on the booted simulator.  
- When specifying the `--device phone` option, the `GMI.app` directory and `.ipa` file are created.  
- When specifying the `--device physical-device-name` option (with a real physical device name plugged on your Mac), the `GMI.app` directory and `.ipa` file are created and the app is installed on the device.  
**Note:** Use the `instruments -s Xcode®` command to find the list of available devices (simulators or connected devices). |
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--extension-libs</td>
<td>Specify the libraries to use when compiling and linking the app. This option is used when you want to provide your own C extension or custom front calls.</td>
</tr>
<tr>
<td>--help</td>
<td>Display the help of the command tool.</td>
</tr>
<tr>
<td>--icons icons-dir</td>
<td>Provides the directory where the application icons are located. By default, the application icons directory is <code>current-working-dir/gmi</code>. The name of the app icon files must be: <code>icon_57x57.png</code>, <code>icon_72x72.png</code>, <code>icon_29x29.png</code>, <code>icon_40x40.png</code>, <code>icon_120x120.png</code>, <code>icon_152x152.png</code>, <code>icon_58x58.png</code>, <code>icon_76x76.png</code>, <code>icon_80x80.png</code>.</td>
</tr>
<tr>
<td>--install [yes</td>
<td>no]</td>
</tr>
<tr>
<td>--install-plugins github-url</td>
<td>This option installs additional plugins in the GMI installation directory.</td>
</tr>
<tr>
<td>--launch-images launch-images-dir</td>
<td>The directory where launch images are located. By default, the launch images directory is <code>current-working-dir/gmi</code>. Note: This option is ignored if the <code>--storyboard</code> option is provided. The name of the image files must be: <code>Default.png</code>, <code>Default@2x.png</code>, <code>Default-568h@2x.png</code>, <code>Default-Portrait-667h@2x.png</code>, <code>Default-Landscape-667h@2x.png</code>, <code>Default-Portrait-736h@3x.png</code>, <code>Default-Landscape-736h@3x.png</code>, <code>Default-Landscape.png</code>, <code>Default-Portrait@2x.png</code>, <code>Default-Landscape@2x.png</code>. Each file name corresponds to a device type (you may not need to provide all files if you target only recent iOS devices), see Apple® Developer documentation for more details about launch images.</td>
</tr>
<tr>
<td>--list-plugins</td>
<td>This option lists the shipped plugins and additional plugins installed in the GMI installation directory.</td>
</tr>
</tbody>
</table>

<table>

<td>--verbose yes</td>
<td>no</td>
</tr>
<tr>
<td>--version</td>
<td>Provides product version numbers of GMI components.</td>
</tr>
</tbody>
</table>

**Related concepts**

Building iOS apps with Genero on page 3332
Genero provides a command-line tool to build applications for iOS devices.

**Running mobile apps on an application server**
From the mobile device, programs can be started remotely on an application server, and displayed on the device.

**Purpose of remote application execution for mobile devices**
Remote applications displayed on a mobile device allow the use of the processor, memory, storage and software resources available on a server, for mobile users.

**Note:** Executing remote/server applications for display on a mobile device requires a reliable and constant network connection. If the network connection fails, the application will stop, as with other client/server Genero front-ends.

Server applications can only be started through the Genero Application Server (GAS), by using the UA protocol available since version 3.00. You must set up and configure the GAS for the programs you want to start remotely. See the GAS documentation for more details.

**Note:** Applications executed on the GAS server must use the UTF-8 encoding. Mobile front-ends will reject any attempt to display forms of an application using an encoding other than UTF-8.

**Implementing the embedded mobile app**
Create a small application to be deployed on the mobile device, which then starts the application(s) on an GAS server.

The server application is started from the embedded application through the `runOnServer` front call. The embedded mobile application can be a very simple `MAIN / END MAIN` program, only performing the "runOnServer" front call.

For example, this is the very minimal embedded application, starting a program on the GAS:

```
MAIN
    CALL ui.interface.frontcall("mobile","runOnServer",
        ["http://myappserver:6394/ua/r/myapp"],[])
END MAIN
```

When the remote application starts, the graphical user interface displays on the mobile device.

The `runOnServer` front call returns when the called application ends, control goes back to the initial application executing on the mobile device.

**Note:** In development context, it is possible to execute the parent starter app on a server, display on a mobile device with `FGLSERVER` on page 245 set properly, and use the `runOnServer` front call. Because starting remote GAS applications is done with a front call, this configuration mimics an embedded starter app running on the device.

**Using the runOnServer front call**
The application executed on the server-side is identified by the first parameter of the `runOnServer` front call. This application must be delivered by the Genero Application Server. The parameter must contain an "ua/r" URL syntax (the UA protocol introduced with the GAS 3.00).

For example: `http://myappserver:6394/ua/r/myapp`

The URL may contain a query string, with parameters for the application to be executed by the GAS.

If needed, you can add a second argument to define a timeout as a number of seconds. The embedded application will wait for the remote application to start, until the timeout expired. If no timeout parameter is specified, or when zero is passed, the timeout is infinite.

In case of failure (application not found, timeout expired), the front call raises the runtime error -6333 and the HTTP status code of the request can be found in the error message details. Use a `TRY/CATCH` block to check if the execution the server application was successful:

```
MAIN
```
Subsequent server-side application runs are allowed; the last active application will display on the device. However, it is not possible to navigate between started applications. Therefore, an application started with the `runOnServer` front call must only use the `RUN` instruction to start sub-programs. `RUN WITHOUT WAITING` is not supported.

**Passing parameters to the server application**

If needed, the embedded app can pass arguments to the server application by using parameter specification in the URL string, with the `?Arg=value1&Arg=value1&...` notation:

```gas
DEFINE params, base, complete_url STRING
LET params = "Arg=verbose&Arg=5677"
LET url = "http://myappserver:6394/ua/r/myapp"
LET complete_url = base || "?" || params
```

The remote program can retrieve the parameters with the `arg_val()` built-in function.

**Note:** It is not needed to URL-encode the string passed to the `runOnServer` front call.

See the GAS documentation (AllowUrlParameters attribute) about passing parameters in the application URL.

This is an example of an embedded application to be deployed on the mobile device, which passes parameters to a server-side application:

```gas
IMPORT util
MAIN
DEFINE arr DYNAMIC ARRAY OF STRING, x INT
MENU "test"
  COMMAND "runOnServer"
  CALL arr.clear()
  LET arr[1] = "first argument"
  LET arr[2] = "second argument"
  LET x = do_run("http://10.0.40.29:6394/ua/r/test1", 10, arr)
  COMMAND "exit"
EXIT MENU
END MENU
END MAIN

FUNCTION do_run(url,timeout,params)
DEFINE url STRING,
  timeout SMALLINT,
  params DYNAMIC ARRAY OF STRING
DEFINE i, r INTEGER, tmp STRING
LET r = 0
LET tmp = url
FOR i=1 TO params.getLength()
  LET tmp = tmp || IIF(i==1,"?","&") || "Arg=" || params[i]
END FOR
TRY
  CALL ui.interface.frontcall("mobile","runOnServer",[tmp,timeout],[])
CATCH
  ERROR err_get(STATUS)
  LET r = -1
END TRY
RETURN r
```

```
A sample server-side application:

```plaintext
MAIN
  MENU "Prog1"
    COMMAND "arg1" MESSAGE "Arg 1 = ", arg_val(1)
    COMMAND "arg2" MESSAGE "Arg 2 = ", arg_val(2)
    COMMAND "arg3" MESSAGE "Arg 3 = ", arg_val(3)
    COMMAND "Quit" EXIT MENU
END MENU
END MAIN
```

Sharing files between embedded and server app

If files need to be shared between the embedded application and the server application, the application running on the GAS can only access the `data-directory` directory, in the sandbox of the embedded application that executes the "runOnServer" front call.

This matters when using file handling APIs such as `fgl_putfile()` and `fgl_getfile()` or front calls like `takePhoto` and `launchURL`.

The `data-directory` on the mobile device can be found with the `feInfo/dataDirectory` front call. In both the embedded app and the app running on the server, this front call will return the same directory.

The following workflow can be used:

1. Before starting the server application with a `runOnServer` front call, the embedded app must copy files to the `data-directory`.
2. While executing, the server application can retrieve files from the `data-directory` with `fgl_getfile()`, and send its own files to the `data-directory` with `fgl_putfile()`.
3. When the server application terminates, the embedded app can read files the server application left in the `data-directory`.

**Note:** If several remote applications are started successively on the server with a `RUN` instruction, make sure to not overwrite files written by other server programs.

In order to write code for the embedded app, that can be executed in development mode (running on a server) and on the mobile device, you can adapt to the execution context: Make a simple file copy when executing on the mobile device, or do an `fgl_putfile()` call, when running on the development server. Check the execution context with the `base.Application.isMobile()` method.

This example, in the embedded app on the mobile device, copies a file from the device private directory to the `data-directory`:

```plaintext
IMPORT os
...
  CALL mobile_copy_to_data_dir("myfile.txt")
...
FUNCTION mobile_copy_to_data_dir(fn)
  DEFINE fn, dd, dst STRING, r INT
  CALL ui.interface.frontcall("standard","feInfo",["dataDirectory"],[dd])
  -- Always use / as path sep for Android/iOS dirs.
  LET dst = dd || "/" || os.Path.basename(fn)
  IF base.Application.isMobile() THEN
    -- Executing on device: make a simple copy to data-dir
    LET r = os.Path.copy(fn, dst)
    MESSAGE SFMT("COPY status = %1", r)
  ELSE
    -- Executing on dev server: make a file transfer to data-dir
    CALL fgl_putfile(fn, dst)
  END IF
```
Note: We do not use the `os.Path.join()` method here because it would add the path separator for the operating system where the application is executed. This would not be a problem when executing on the mobile device or Unix-like platforms. However, when running on a Windows® platform, the `os.Path.join()` method would join the directory and the file name with a backslash, and the resulting path would not fit Android™ or iOS directory path specification for the `data-directory`.

In the server application, use the `fgl_getfile()` function, to transfer a file from the mobile device `data-directory` to the local server disk:

```
IMPORT os
...
    CALL server_get_from_data_dir("myfile.txt", "/tmp/server_file.txt")
...
FUNCTION server_get_from_data_dir(fn, dst)
    DEFINE fn, dst, dd, src STRING
    CALL ui.interface.frontcall("standard","feInfo",["dataDirectory"],[dd])
    -- Use / as path sep for Android/iOS dirs!
    LET src = dd || "/" || fn
    CALL fgl_getfile(src, dst)
END FUNCTION
```

Similarly, in the server application, use the `fgl_putfile()` function, to copy a file from the server application to the `data-directory` of the embedded app:

```
IMPORT os
...
    CALL server_put_to_data_dir("/tmp/server_file.txt", "myfile.txt")
...
FUNCTION server_put_to_data_dir(src, fn)
    DEFINE src, fn, dd, dst STRING
    CALL ui.interface.frontcall("standard","feInfo",["dataDirectory"],[dd])
    -- Use / as path sep for Android/iOS dirs!
    LET dst = dd || "/" || fn
    CALL fgl_putfile(src, dst)
END FUNCTION
```

**Push notifications**

This section describes how to implement push notification with Genero.

A push notification is a short message sent by a central server entity to an app installed on a mobile device. In order to be notified, the app+device must register itself to a push service (a global service such as Firebase Cloud Messaging), and register also to a push provider (part of the custom application). To indicate that fresh information is available, notifications are sent by push providers to the push service, which broadcasts notifications to registered devices. The apps can then get details about the notification and display a little hint to the end user. Enterprise mobile applications can use push notifications to produce urgent and important updates for users.
Figure 135: This figure describes the workflow for a push notification (items in yellow are the components that can be implemented with Genero BDL)

Workflow:

1. The app registers to the push service.
2. The push service generates a unique token to identify the device+app and returns this token to the app.
3. The app transmits the token to the token maintainer.
4. The token maintainer stores the new token in a database.
5. Some event occurs in the global application workflow that requires a push notification to warn all registered devices/apps.
6. The push provider reads the database for registered tokens.
7. The push provider sends push notification requests to the push service.
8. The push service broadcasts the notification messages to all registered devices.

There are several push notification mechanisms available. This chapter covers the Firebase Cloud Messaging (FCM) and Apple Push Notification Services (APNs).

Common components can be implemented on the same code base for both FCM and APNs push notification mechanisms: The mobile app and the token maintainer.

- Firebase Cloud Messaging (FCM) on page 3347
- Apple Push Notification Service (APNs) on page 3351
- Implementing a token maintainer on page 3357
- Handling notifications in the mobile app on page 3363

The complete source code is available of the FourJSGenero GitHub: https://github.com/FourjsGenero/ex_push_notification
**Firebase Cloud Messaging (FCM)**

Follow this procedure to implement push notification with FCM.

**Introduction to FCM push notification**

The push notification solution described in this section is based on the Firebase Cloud Messaging service. Familiarize yourself with FCM by visiting the Firebase Cloud Messaging web site.

Firebase Cloud Messaging services allow push servers to send notification message data to registered Android™ or iOS devices.

The system involves the following actors:

- **The Firebase Cloud Messaging service (FCM):**
  FCM provides push server and client identification. It also handles all aspects of queuing of messages and delivery to the target application running on registered devices.

- **The registration tokens maintainer:**
  A Web services server program maintaining the database of registration tokens with application user information. This program must listen to new device registration events and store them in a database. The push server program can then query this database to build the list of registration tokens to identify the devices to be notified.

- **The push server program:**
  Implemented by a third-party service or as a Genero BDL program using the Web services API. This push server program will send notification messages to FCM with two connection servers (HTTP and XMPP).

- **Devices running the Genero app registered to the push notification server:**
  Registered devices use the push notification client API to register, get notifications data and unregister from the service.

**Note:** The database used to store registration tokens must be a multi-user database (do not use SQLite for example), since two distinct programs will use the database.

**Creating a FCM project**

To initiate a push notification service dedicated to your applications, you must first create a Firebase Cloud Messaging project in the FCM console. Creating an FCM project will provide you:

- The `google-services.json` configuration file, to be bundled with your app.
- The "Server Key" is the authentication key to access Google services.

Steps to setup your FCM projet:

1. Go to the FCM console and login with your Google developer account.
2. Add a new FCM project.
3. Add an (Android) app to your FCM project: Specify the same package name specified when building your app with the `--build-app-package-name` option of `gmabuildtool`.
4. Download the `google-services.json` configuration file. This file needs to be added to the `appdir`, beside other program files.
5. Skip other FCM project creation steps.
6. In the project overview page, go to the settings of the new created project.
7. Select the "Cloud Messaging" panel.
8. Copy the "Server Key" and save it to a file. This is the key to be send with the "Authorization:key=server-key" HTTP header when posting a message to the FCM server endpoint `fcm.googleapis.com/fcm/send`.

For more details about FCM project creation, visit the Firebase Cloud Messaging web site.
Implementing the registration tokens maintainer

To handle device registrations on the server side of your application, the same code base can be used for FCM and other token-based frameworks.

For more details, see Implementing a token maintainer on page 3357.

Implementing the push server

The push server will produce application notification messages that will be transmitted to the FCM service. The FCM service will then spread them to all mobile devices registered to the service with the Sender ID.

Important: The size of an FCM notification content cannot exceed 4 Kilobytes. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The push server will use RESTFul HTTP POST requests to send notifications through the FCM service to the following URL:

"https://fcm.googleapis.com/fcm/send".

The HTTP POST header must contain the following attributes:

| Content-Type:application/json |
| Authorization:key=server-key |

where server-key is the Server Key obtained from the FCM project settings.

The push server program can be implemented with the Web Services API to make RESTFul requests as follows:

```java
IMPORT com
IMPORT util

FUNCTION fcm_send_notif_http(server_key, notif_obj)
    DEFINE server_key STRING,
            notif_obj util.JSONObject
    DEFINE req com.HTTPRequest,
            resp com.HTTPResponse,
            req_msg, res STRING
    TRY
        LET req = com.HTTPRequest.Create("https://fcm.googleapis.com/fcm/send")
        CALL req.setHeader("Content-Type", "application/json")
        CALL req.setHeader("Authorization", SFMT("key=%1", server_key))
        CALL req.setMethod("POST")
        LET req_msg = notif_obj.toString()
        IF req_msg.getLength() > 4096 THEN
            LET res = "ERROR : GCM message cannot exceed 4 kilobytes"
            RETURN res
        END IF
        CALL req.doTextRequest(req_msg)
        LET resp = req.getResponse()
        IF resp.getStatusCode() != 200 THEN
            LET res = SFMT("HTTP Error (%1) %2",
                            resp.getStatusCode(),
                            resp.getStatusDescription())
            ELSE
                LET res = "Push notification sent!"
            END IF
        END IF
    CATCH
        LET res = SFMT("ERROR : %1 (%2)", STATUS, SQLCA.SQLERRM)
    END TRY
    RETURN res
END FUNCTION
```
The body of the HTTP POST request must be a JSON formatted record using a structure similar to the following example:

```
{
    "collapse_key": "stock_update",
    "time_to_live": 108,
    "delay_while_idle": true,
    "data":
    {
        "stock_change":
        {
            "stock_id": "STK-034",
            "timestamp": "2015-02-24 15:10:34.18345",
            "item_count": 15023
        },
    },
    "registration_ids": [ "APA91b...", "Hun4MxP...", "5ego..." ]
}
```

**Note:** This notification message uses the "registration_ids" attribute to provide a list of devices to be notified. If you want to notify a single device, use the "to" attribute instead of "registration_ids", and pass a single registration token instead of a JSON array.

For more details about the JSON request structure in a FCM HTTP POST, visit the Firebase Cloud Messaging web site.

By convention, if the "data" member of the JSON request defines a "genero_notification" member, the front-end will show graphical notification (pop-up hint) with the "title", "content" and the "icon" values.

**Note:** The recommendation for GMA is that the icon is packaged in the APK and is accessible by name (as the gma_ic_genero.png in the drawable folders).

For example:

```
...
"data":
{
    "genero_notification":
    {
        "title": "Stock has changed",
        "content": "New stock information will be retrieved from the backend server...",
        "icon": "stock_update"
    },
    ...
},
"registration_ids": [ "APA91b...", "Hun4MxP...", "5ego..." ]
}
```

The next code example implements a function that creates the JSON object, which can be passed to the fcm_send_notif_http() function described above. The only purpose of this notification message is to test the "genero_notification" pop-up hint. The function takes an array of registration tokens as a parameter, which will be used to set the "registration_ids" attribute:

```python
FUNCTION fcm_simple_popup_notif(reg_ids, notif_obj, popup_msg, user_data)
  DEFINE reg_ids DYNAMIC ARRAY OF STRING,
              notif_obj util.JSONObject,
              popup_msg, user_data STRING
  DEFINE data_obj, popup_obj util.JSONObject
  CALL notif_obj.put("registration_ids", reg_ids)
```
LET data_obj = util.JSONObject.create()
LET popup_obj = util.JSONObject.create()
CALL popup_obj.put("title", "Push demo")
CALL popup_obj.put("content", popup_msg)
CALL popup_obj.put("icon", "genero")
CALL data_obj.put("genero_notification", popup_obj)
CALL data_obj.put("other_info", user_data)
CALL notif_obj.put("data", data_obj)
END FUNCTION

The `fcm_simple_popup_notif()` and `fcm_send_notif_http()` functions can then be used as follows:

```java
IMPORT com
IMPORT util

MAIN
CONSTANT server_key = "xyz..."
DEFINE reg_ids DYNAMIC ARRAY OF STRING,
notif_obj util.JSONObject

LET reg_ids[1] = "APA91bHun..."
LET reg_ids[2] = "B4AA2q7xa..."

LET notif_obj = util.JSONObject.create()
CALL fcm_simple_popup_notif(reg_ids, notif_obj, "This is my message!")
CALL fcm_send_notif_http(server_key, notif_obj)

END MAIN
```

In order to use the tokens database maintained by a token maintainer program, your FCM push server can collect registration tokens as shown in the following example:

```java
FUNCTION fcm_collect_tokens(reg_ids)
DEFINE reg_ids DYNAMIC ARRAY OF STRING
DEFINE rec RECORD
id INTEGER,
notification_type VARCHAR(10),
registration_token VARCHAR(250),
badge_number INTEGER,
app_user VARCHAR(50),
reg_date DATETIME YEAR TO FRACTION(3)
END RECORD
DECLARE c1 CURSOR FOR
SELECT * FROM tokens
WHERE notification_type = "FCM"
CALL reg_ids.clear()
FOREACH c1 INTO rec.*
    CALL reg_ids.appendElement()
    LET reg_ids[reg_ids.getLength()] = rec.registration_token
END FOREACH
END FUNCTION
```

The above function can then be used by another function to send the push message to all registered devices:

```java
FUNCTION fcm_send_text(server_key, msg_title, user_data)
DEFINE server_key, msg_title, user_data STRING
DEFINE reg_ids DYNAMIC ARRAY OF STRING,
notif_obj util.JSONObject,
```
info_msg STRING
CALL fcm_collect_tokens(reg_ids)
IF reg_ids.getLength() == 0 THEN
    RETURN "No registered devices..."
END IF
LET notif_obj = util.JSONObject.create()
CALL fcm_simple_popup_notif(reg_ids, notif_obj, msg_title, user_data)
LET info_msg = fcm_send_notif_http(server_key, notif_obj)
RETURN info_msg
END FUNCTION

Handle push notifications in mobile apps

To handle push notifications in mobile apps, the same code base can be used for FCM and other token-based frameworks.

For more details see Handling notifications in the mobile app on page 3363.

Related concepts
Apple Push Notification Service (APNs) on page 3351

Follow this procedure to implement push notification with APNs.

Apple Push Notification Service (APNs)

Follow this procedure to implement push notification with APNs.

Introduction to APNs push notification

The push notification solution described in this section is based on the Apple Push Notification Service. Familiarize yourself with APNs by visiting the Apple Push Notification Service web site.

Apple Push Notification service allows push servers to send notification message data to registered iOS (and OS X) devices.

The APNs service transports and routes a remote notification from a given provider to a given device. A notification is a short message built from two pieces of data: the device token and the payload.

Note: Each device needs to be identified by its device token, and the provider must send individual notification messages for each registered device.

The system involves the following actors:

- The Apple Push Notification Service (APNs):
  APNs provides push server and client identification. It also handles all aspects of message queuing and delivery to the target applications running on registered devices. The APNs system includes a feedback service that can be queried to check for devices that have unregistered and no longer need to be notified.
- The device tokens maintainer:
  A Web Services server program maintaining the database of device tokens, with application user information. This program must listen to new device registration events, store them in a database, and from time to time query the APNs feedback service to check for unregistrations.
- The push provider:
  This program will send notification messages to the APNs server by using the com.APNS class and TCP request API. The push provider program will query the device token database to know which devices need to be notified.
- Devices running the Genero app registered to the push notification server:
  Registered devices use the push notification client API to register, get notifications data and unregister from the service.

Note: The database used to store device tokens must be a multi-user database (do not use SQLite for example), since two distinct programs will use the database.
**APNs push notification security**

iOS apps must be created with an Apple certificate for development or distribution, linked to an App ID (or Bundle ID) with push notification enabled. The provisioning profile used when building the IPA must be linked to the App ID with push enabled. Certificate, provisioning and bundle id must be specified to the GMI buildtool.

To create the push provider linked to your app, usually you need to create two Apple Push Notification certificates linked to your App ID (you select the App ID when you create a push certificate in the Apple member center): One certification for development and another for distribution. For more details about the push provider certificates, see APNs SSL/TLS certificate on page 2766.

Check also Apple Push Notification documentation for more details about certificate requirements for push notifications.

**Identifying target devices**

Each APNs client device is identified by a *device token*. A device token is an opaque identifier of a device that APNs gives to the device when an app registers itself for push notification. It enables APNs to locate in a unique manner the device on which the client app is installed. The device shares the device token with the push provider. The push provider must produce notification messages for each device by including the device token in the message structure.

**Important:** The mobile app obtains its device token by registering to the APNs service with the registerForRemoteNotifications on page 2556 front call. It is then in charge of sending its device token to the push provider; typically through a RESTFul request. The push provider must collect and store the device tokens, as they need to be specified in a push notification message send by the push provided.

**Notification content (payload)**

In a notification message, the *payload* is a JSON-defined property list that specifies how the user of an app on a device is to be alerted.

**Important:** The size of an APNs notification payload cannot exceed 2 Kilobytes. Make sure that the resulting BYTE variable does not exceed this size limitation. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The payload must contain a list of "aps" records. Each "aps" record represents a notification message to be displayed as a hint on the device (for example, by adding a badge number to the app icon). The "aps" records can also contain custom data in a separate set of JSON attributes.

In the Genero mobile app, the notification messages are obtained by using the getRemoteNotifications on page 2552 front call, after a notificationpushed action was detected with an ON ACTION handler.

**Important:** When an iOS app is in background, silent push notifications can occur, but notification message data (i.e. the payload) may not be available. In such case, GMI is able to detect that a notification arrived (i.e. when the app badge number is greater than zero) and raise the notificationpushed action, but the getRemoteNotifications front call will return no message data (data return param is NULL). If such case, implement a fallback mechanism (based on RESTFul web services for example), to contact the push notification provider and retrieve the message information.

Example of notification record list (JSON array) returned by the getRemoteNotifications front call:

```
[
  {
   "aps" : {
    "alert" : "My first push",
    "badge" : 1,
    "sound" : "default",
    "content-available" : 1
   }
  }
]```
Badge number handling

With APNs, badge number handling is in charge of the application code: The push provider sends a badge number in the payload records, the app can check the message content, and must communicate with a server component, to indicate that the notification message has been consumed. The server program can then maintain a badge number for each registered device, decrementing the badge number.

In order to set or query the badge number for your app, use the following front calls:

- `setBadgeNumber (iOS)` on page 2568
- `getBadgeNumber (iOS)` on page 2567

In this tutorial, badge numbers are stored on the server database. The token maintainer handlers requests from apps to sync the badge number for a given device token, and the push provider program reads the database to set the badge number in the notification payload. When the app consumes messages, it queries and resets the app badge number with the `getBadgeNumber/setBadgeNumber` front calls, and informs the token maintainer to sync the badge number in the central database.

Communication channels

A provider communicates with Apple Push Notification service over a binary network interface, using a streaming TCP socket design in conjunction with binary content:

- The binary interface of the APNs development environment is available through the URL `gateway.sandbox.push.apple.com` on port 2195.
- The binary interface of the APNs production environment is available through the URL `gateway.push.apple.com` on port 2195.
- The binary interface of the APNs feedback service is available through the URL `feedback.push.apple.com` on port 2196.

For each interface, use TLS (or SSL) to establish a secured communication channel. The SSL/TLS certificate required for these connections is obtained from Apple's Member Center.

To establish a TLS session with APNs, an Entrust Secure CA root certificate must be installed on the provider's server. If the server is running OS X, this root certificate is already in the keychain. On other systems the certificate might not be available.

Creating an APNs certificate for the app

The Apple Push Notification Certificate identifies the push notification service for a given mobile app. This certificate will be created from an App ID (a.k.a. Bundle ID) and is used by the APNs system to dispatch the notification message to the registered devices.

For more details, see APNs SSL/TLS certificate on page 2766.
Implementing the device tokens maintainer

To handle device registrations on the server side of your application, the same code base can be used for APNs and other token-based frameworks.

For more details, see Implementing a token maintainer on page 3357.

Implementing the push provider

The push provider will produce application notification messages that will be transmitted to the APNs service. The APNs service will then spread them to all registered mobile devices, identified by their device token.

To send notification messages, the push provider must build binary messages by using the `com.APNS` API, provided by the Web Services library, and send TCP message requests over SSL/TLS to the following URLs:

- "tcps://gateway.sandbox.apple.com:2195" (for development)
- "tcps://gateway.push.apple.com:2195" (for production)

**Note:** In order to establish a secure connection to the APNs framework an SSL/TLS certificate needs to be defined in `FGLPROFILE`, as described in APNs SSL/TLS certificate on page 2766.

To send a notification message, the push provider must know the device tokens of the registered devices / applications.

**Note:** A distinct notification message must be sent for each registered device.

The following example demonstrates how to implement a function to send an APNs notification message. The function takes a device token and a JSON object as parameters. First, build the binary data with the `com.APNS.EncodeMessage()` method, then POST the data with a `com.TCPRequest.doDataRequest()` method. In case of success, the TCP request timeout will occur (APNs service only responds immediately in case of error), then use the `com.TCPResponse.getDataResponse()` method, to get status information. See `com.APNS.EncodeMessage()` for more details about notification message creation.

```java
IMPORT com
IMPORT security
IMPORT util
FUNCTION apns_send_notif_http(deviceTokenHexa, notif_obj)
  DEFINE deviceTokenHexa STRING,
      notif_obj util.JSONObject
  DEFINE req com.TCPRequest,
      resp com.TCPResponse,
      uuid STRING,
      ecode INTEGER,
      dt DATETIME YEAR TO SECOND,
      exp INTEGER,
      data, err BYTE,
      res STRING
  LOCATE data IN MEMORY
  LOCATE err IN MEMORY

  LET dt = CURRENT + INTERVAL(10) MINUTE TO MINUTE
  LET exp = util.Datetime.toSecondsSinceEpoch(dt)

  TRY

  --LET req = com.TCPRequest.create( "tcps://
      gateway.push.apple.com:2195" )
  LET req = com.TCPRequest.create( "tcps://
      gateway.sandbox.push.apple.com:2195" )
  CALL req.setKeepConnection(true)
  CALL req.setTimeout(2) # Wait 2 seconds for APNs to return error
  code

  LET uuid = security.RandomGenerator.createRandomString(4)
  ```
DISPLAY "PUSH MESSAGE: ", deviceTokenHexa, "/", notif_obj.toString() CALL com.APNS.EncodeMessage(
data,
security.HexBinary.ToBase64(deviceTokenHexa),
notif_obj.toString(),
uuid,
exp,
10
)
IF LENGTH(data) > 2000 THEN
    LET res = "ERROR : APNS payload cannot exceed 2 kilobytes"
    RETURN res
END IF
CALL req.doDataRequest(data)
TRY
    LET resp = req.getResponse()
    CALL resp.getDataResponse(err)
    CALL com.APNS.DecodeError(err) RETURNING uuid, ecode
    LET res = SFMT("APNS result: UUID: %1, Error code: %2",uuid,ecode)
    CATCH
        CASE STATUS
            WHEN -15553 LET res = "Timeout Push sent without error"
            WHEN -15566 LET res = "Operation failed ":, SQLCA.SQLERRM
            WHEN -15564 LET res = "Server has shutdown"
            OTHERWISE LET res = "ERROR :",STATUS
        END CASE
    END CATCH
END TRY
RETURN res
END FUNCTION

The next code example implements a function that creates the JSON object defining notification content (payload). That object can be passed to the apns_send_notif_http() function described above:

FUNCTION apns_simple_popup_notif(notif_obj, msg_title, user_data,
    badge_number)
    DEFINE notif_obj util.JSONObject,
        msg_title, user_data STRING,
        badge_number INTEGER
    DEFINE aps_obj, data_obj util.JSONObject
    LET aps_obj = util.JSONObject.create()
    CALL aps_obj.put("alert", msg_title)
    CALL aps_obj.put("sound", "default")
    CALL aps_obj.put("badge", badge_number)
    CALL aps_obj.put("content-available", 1)
    CALL notif_obj.put("aps", aps_obj)
    LET data_obj = util.JSONObject.create()
    CALL data_obj.put("other_info", user_data)
    CALL notif_obj.put("custom_data", data_obj)
END FUNCTION

The apns_simple_popup_notif() and apns_send_notif_http() functions can then be used as follows:

IMPORT com
IMPORT util

MAIN

DEFINE reg_ids DYNAMIC ARRAY OF STRING,
    notif_obj util.JSONObject,
    i INTEGER

LET notif_obj = util.JSONObject.create()
CALL gcm_simple_popup_notif(notif_obj, "This is my message!", 1)

LET reg_ids[1] = "APA91bHun..."
LET reg_ids[2] = "B4AA2q7xa..."
...
FOR i=1 TO reg_ids.getLength()
    DISPLAY gcm_send_notif_http(reg_ids[i], notif_obj)
END FOR

END MAIN

In order to use the tokens database maintained by a token maintainer program, your APNs push provider can collect device tokens as shown in the example below. Note that the dynamic array contains token ids and badge numbers:

FUNCTION apns_collect_tokens(reg_ids)

DEFINE reg_ids DYNAMIC ARRAY OF RECORD
    token STRING,
    badge INTEGER
END RECORD

DEFINE rec RECORD
    id INTEGER,
    notification_type VARCHAR(10),
    registration_token VARCHAR(250),
    badge_number INTEGER,
    app_user VARCHAR(50),
    reg_date DATETIME YEAR TO FRACTION(3)
END RECORD,

x INTEGER

DECLARE c1 CURSOR FOR
    SELECT * FROM tokens
    WHERE notification_type = "APNS"
CALL reg_ids.clear()
FOREACH c1 INTO rec.*
    LET x = reg_ids.getLength() + 1
    LET reg_ids[x].token = rec.registration_token
    LET reg_ids[x].badge = rec.badge_number
END FOREACH

END FUNCTION

In order to handle badge numbers for each registered device, implement a function to update badge numbers in database:

FUNCTION save_badge_number(token, badge)

DEFINE token STRING,
    badge INT

UPDATE tokens SET
    badge_number = badge
WHERE registration_token = token

END FUNCTION

The above functions can then be used to send a push message to all registered devices:

FUNCTION apns_send_message(msg_title, user_data)

DEFINE msg_title, user_data STRING
DEFINE reg_ids DYNAMIC ARRAY OF RECORD
  token STRING,
  badge INTEGER
END RECORD,
notif_obj util.JSONObject,
info_msg STRING,
new_badge, i INTEGER
CALL apns_collect_tokens(reg_ids)
IF reg_ids.getLength() == 0 THEN
  RETURN "No registered devices..."
END IF
LET info_msg = "Send:
FOR i=1 TO reg_ids.getLength()
  LET new_badge = reg_ids[i].badge + 1
  CALL save_badge_number(reg_ids[i].token, new_badge)
  LET notif_obj = util.JSONObject.create()
  CALL apns_simple_popup_notif(notif_obj, msg_title, user_data, new_badge)
  LET info_msg = info_msg, \"\n\",
      apns_send_notif_http(reg_ids[i].token, notif_obj)
END FOR
RETURN info_msg
END FUNCTION

Handle push notifications in mobile apps
To handle push notifications in mobile apps, the same code base can be used for APNs and other token-based frameworks.

For more details see Handling notifications in the mobile app on page 3363.

Follow this procedure to implement push notification with FCM.

Implementing a token maintainer
The token maintainer is a BDL Web Services server program that handles push token registration from mobile apps.

Basics
In order to implement a push notification mechanism, you need to set up a server part (token maintainer and push notification server), based on a push notification framework such as Firebase Cloud Messaging (FCM) or Apple Push Notification service (APNs). In addition, you need to handle notification events in your mobile app. This section describes how to implement the token maintainer, the server program that maintains the list of registered devices (i.e. registration tokens for FCM or device tokens for APNs).

Note: The max length of a push client token can vary depending on the push framework provider. If you need to store registration tokens in a database, check the max size for a token and consider using a large column type such as VARCHAR(250).

The same code base can be used for Android™ (using FCM) and iOS (using APNs) applications: The token maintainer will basically handle RESTful HTTP requests coming from the internet for token registration and token unregistration. For each of these requests, the program will insert a new record or delete an existing record in a dedicated database table.

Note: The database used to store tokens must be created before starting the token maintainer program. By default, the push demo program uses SQLite (dbmsqt) and the name of the database is "tokendb". To create this SQLite database, simply create an empty file with this name.

The push provider/server program can then query the tokens table to build the list of target devices for push notifications.
In the context of APNs, the token maintainer must also handle badge numbers for each registered device: When consuming notification messages, the iOS app must inform the token maintainer that the badge number has changed. This function is implemented with the "badge_number" command.

The token maintainer is a Web Services server program which must be deployed behind a GAS to handle load balancing. You can, however, write code to test your program in development without a GAS.

The act of registering/unregistering push tokens is application specific: When registering tokens, you typically want to add application user information. Genero BDL allows you to implement a token maintainer in a simple way.

**Note:** When executing this token maintainer program with APNs, you must pass the "APNS" command line argument to execute APNs feedback queries.

### MAIN block and database creation

Start with the MAIN block, and the connection to a database. In this tutorial, we use SQLite as the database. The program will automatically create the database file and the tokens table if it does not yet exist.

```plaintext
IMPORT util
IMPORT com
IMPORT os

CONSTANT DEFAULT_PORT = 9999

MAIN
    CALL open_create_db()
    CALL handle_registrations()
END MAIN

FUNCTION open_create_db()
    DEFINE dbsrc VARCHAR(100),
            x INTEGER
    IF NOT os.Path.exists("tokendb") THEN
        CALL create_empty_file("tokendb")
    END IF
    LET dbsrc = "tokendb+driver='dbmsqt'"
    CONNECT TO dbsrc
    WHENEVER ERROR CONTINUE
    SELECT COUNT(*) INTO x FROM tokens
    WHENEVER ERROR STOP
    IF SQLCA.SQLCODE<0 THEN
        CREATE TABLE tokens (  
            id INTEGER NOT NULL PRIMARY KEY,  
            notification_type VARCHAR(10) NOT NULL,  
            registration_token VARCHAR(250) NOT NULL UNIQUE,  
            badge_number INTEGER NOT NULL,  
            app_user VARCHAR(50) NOT NULL, -- UNIQUE  
            reg_date DATETIME YEAR TO FRACTION(3) NOT NULL  
        )
    END IF
END FUNCTION

FUNCTION create_empty_file(fn)
    DEFINE fn STRING, c base.Channel
    LET c = base.Channel.create()
    CALL c.openFile(fn, "w")
    CALL c.close()
END FUNCTION
```
Handling registration and unregistration requests

The next function is typical Web Service server code using the Web Services API to handle RESTful requests. Note that the TCP port is defined as a constant that is used to set FGLAPPSERVER automatically when not running behind the GAS:

```
IMPORT util
IMPORT com

CONSTANT DEFAULT_PORT = 9999

MAIN
...
   CALL handle_registrations()
END MAIN

FUNCTION handle_registrations()
   DEFINE req com.HTTPServiceRequest,
        url, method, version, content_type STRING,
        reg_data, reg_result STRING
   IF LENGTH(fgl_getenv("FGLAPPSERVER"))==0 THEN
      -- Normally, FGLAPPSERVER is set by the GAS
      DISPLAY SFMT("Setting FGLAPPSERVER to %1", DEFAULT_PORT)
      CALL fgl_setenv("FGLAPPSERVER", DEFAULT_PORT)
   END IF
   CALL com.WebServiceEngine.Start()
   WHILE TRUE
      TRY
         LET req = com.WebServiceEngine.getHTTPServiceRequest(20)
         CATCH
            IF STATUS==-15565 THEN
               DISPLAY "TCP socket probably closed by GAS, stopping process...
               EXIT PROGRAM 0
            ELSE
               DISPLAY "Unexpected getHTTPServiceRequest() exception: ",
               STATUS
               DISPLAY "Reason: ", SQLCA.SQLERRM
               EXIT PROGRAM 1
            END IF
         END TRY
         IF req IS NULL THEN -- timeout
            DISPLAY SFMT("HTTP request timeout...: %1", CURRENT YEAR TO FRACTION)
            CALL check_apns_feedback()
            CALL show_tokens()
            CONTINUE WHILE
         END IF
         LET url = req.getURL()
         LET method = req.getMethod()
         IF method IS NULL OR method != "POST" THEN
            IF method == "GET" THEN
               CALL req.sendTextResponse(200,NULL,"Hello from token maintainer..."
            ELSE
               DISPLAY SFMT("Unexpected HTTP request: %1", method)
               CALL req.sendTextResponse(400,NULL,"Only POST requests supported"
            END IF
         END IF
         LET version = req.getRequestVersion()
         IF version IS NULL OR version != "1.1" THEN
```

```
DISPLAY SFMT("Unexpected HTTP request version: %1", version)
CONTINUE WHILE
END IF
LET content_type = req.getHeader("Content-Type")
IF content_type IS NULL
OR content_type NOT MATCHES "application/json*" -- ;Charset=UTF-8 THEN
DISPLAY SFMT("Unexpected HTTP request header Content-Type: %1", content_type)
CALL req.sendTextResponse(400,NULL,"Bad request")
CONTINUE WHILE
END IF
TRY
CALL req.readTextRequest() RETURNING reg_data
CATCH
DISPLAY SFMT("Unexpected HTTP request read exception: %1", STATUS)
END TRY
LET reg_result = process_command(url, reg_data)
CALL req.setContentType("application/json")
CALL req.setHeader("Content-Type","application/json")
CALL req.sendTextResponse(200,NULL,reg_result)
END WHILE
END FUNCTION

Processing registration and unregistration commands

The next function is called when a RESTful request is to be processed. The URL will define the type of command to be executed by the server:

• If the URL contains "/token_maintainer/register", a new token must be inserted in the database.
• If the URL contains "/token_maintainer/unregister", an existing token must be deleted from the database.

FUNCTION process_command(url, data)
DEFINE url, data STRING
DEFINE data_rec RECORD
notification_type VARCHAR(10),

  data_rec.registration_token)
END IF
END CASE
CATCH
  LET result_rec.status = -1
  LET result_rec.message = SFMT("Failed to register token:
  [%1]",
  data_rec.registration_token)
END TRY
LABEL pc_end:
  DISPLAY result_rec.message
  LET result = util.JSON.stringify(result_rec)
  RETURN result
END FUNCTION
Showing the current registered tokens

The following function is called after a WebServiceEngine timeout, when no request is to be processed. Its purpose is just to show the current list of registered tokens in a server log (stdout):

```plaintext
FUNCTION show_tokens()
    DEFINE rec RECORD -- Use CHAR to format
                         id INTEGER,
                         notification_type CHAR(10),
                         registration_token CHAR(250),
                         badge_number INTEGER,
                         app_user CHAR(50),
                         reg_date DATETIME YEAR TO FRACTION(3)
                     END RECORD
    DECLARE c1 CURSOR FOR SELECT * FROM tokens ORDER BY id
    FOREACH c1 INTO rec.*
        DISPLAY "   ", rec.id, ": ",
               rec.notification_type, ": ",
               rec.app_user[1,10], " / ",
               "(" , rec.badge_number USING "<<<<&", " ) ",
               rec.registration_token[1,20], "..."
    END FOREACH
    IF rec.id == 0 THEN
        DISPLAY "No tokens registered yet..."
    END IF
END FUNCTION
```

APNs feedback checking

When using Apple Push Notification service, the device token maintainer can also handle device unregistration by querying the APNs feedback service. The APNs feedback service will provide the list of device tokens that are no longer valid because the app on the devices has unregistered.

The token maintainer can use this service to clean up the token database.

**Note:** When using the APNs feedback service, an SSL/TLS certificate needs to be defined in FGLPROFILE as described in APNs SSL/TLS certificate on page 2766.

To get the list of unregistered devices, send an HTTP POST to the following URL:

tcps://feedback.push.apple.com:2196

The next function is called after a timeout when no request needs to be processed by the token maintainer:

```plaintext
FUNCTION check_apns_feedback()
    DEFINE req com.TCPRequest,
             resp com.TCPResponse,
             feedback DYNAMIC ARRAY OF RECORD
                         timestamp INTEGER,
                         deviceToken STRING
                     END RECORD,
    IF arg_val(1)!="APNS" THEN RETURN END IF
    DISPLAY "Checking APNs feedback service..."
    LOCATE data IN MEMORY
    TRY
        LET req = com.TCPRequest.create( "tcps://
                                         feedback.push.apple.com:2196" )
        TRY
            LET resp = req.send()
            LET feedback = resp.get_data()
            IF feedback IS NULL THEN
                DISPLAY "No feedback received"
            ELSE
```
CALL req.setKeepConnection(true)
CALL req.setTimeout(2)
CALL req.doRequest()
LET resp = req.getResponse()
CALL resp.getDataResponse(data)
CALL com.APNS.DecodeFeedback(data,feedback)
FOR i=1 TO feedback.getLength()
  LET timestamp = util.Datetime.fromSecondsSinceEpoch(feedback[i].timestamp)
  LET timestamp = util.Datetime.toUTC(timestamp)
  LET token = feedback[i].deviceToken
  DELETE FROM tokens
  WHERE registration_token = token
  AND reg_date < timestamp
END FOR
CATCH
  CASE STATUS
    WHEN -15553 DISPLAY "APNS feedback: Timeout: No feedback message"
    WHEN -15566 DISPLAY "APNS feedback: Operation failed :",
        SQLCA.SQLERRM
    WHEN -15564 DISPLAY "APNS feedback: Server has shutdown"
    OTHERWISE DISPLAY "APNS feedback: ERROR :",STATUS
END CASE
END TRY
END FUNCTION

For more details about APNs feedback service, see the Apple Push Notification Service documentation.

Follow this procedure to implement push notification with APNs.

Handling notifications in the mobile app
This topic describes how to handle push notification in the app running on mobile devices.

Basics
In order to implement a push notification mechanism, you need to set up a server part (token maintainer and push notification server), based on a push notification framework such as Firebase Cloud Messaging (FCM) or Apple® Push Notification service (APNs). In Addition, you need to handle notification events in your mobile app. This section describes how to implement push notification in the app with the push notification API available in Genero BDL.

The same code base can be used to handle push notifications for Android”™ (using FCM) and iOS (using APNs) devices. Only the content of the notification message will have to be processed with specific code, as the structure of the message differs depending on standards defined by the push notification framework.

Genero API for push notifications
Genero BDL provides an API to handle push notification on mobile apps. Dedicated front calls are available to register to a push server, fetch push notification data, and unregister:

- registerForRemoteNotifications on page 2556
- getRemoteNotifications on page 2552
- unregisterFromRemoteNotifications on page 2561
To detect when a notification message arrives from the push server, a specific action called `notificationpushed` must be used by app code on a `ON ACTION` handler. This special action is referenced as a predefined action.

**Android™ app permissions for FCM push notifications**

Android apps using push notification services need specific permissions (Android manifest), such as:

- `android.permission.INTERNET`
- `android.permission.GET_ACCOUNTS`
- `android.permission.WAVE_LOCK`
- `com.google.android.c2dm.permission.RECEIVE`
- `application-package-name.permission.C2D_MESSAGE` where `application-package-name` is the Android™ package name of your app (for example, `com.mycompany.pushclient`)

Permissions are automatically set for Android™ APK packages by the GMA buildtool. As some permissions need to be prefixed with the package name, they are applied with the `--build-app-package-name` option.

See the FCM documentation for more details about required permissions for push notifications.

**iOS app certificates for APNs push notifications**

iOS apps must be created with an Apple® certificate for development or distribution, linked to an App ID (or Bundle ID) with push notification enabled. The provisioning profile used when building the IPA must be linked to the App ID with push enabled. Certificate, provisioning and bundle id must be specified to the GMI buildtool.

**Handling push notification in the app**

To handle push notifications in your mobile app, perform the following steps:

1. **Register to the push service and get the registration token**
2. **Send the push notification token to your token maintainer**
3. **Handle notification events with the `notificationpushed` action**
4. **Eventually un-register from the push servers**

**1 - Registering to the push service and to the push provider**

Register the app to the push notification service with the "registerForRemoteNotifications" front call.

- When using FCM, you must provide Sender ID to identify the FCM project.
- When using APNs, you can set the Sender ID to NULL.

**Note:** The app does not need to register for notification each time it is restarted. Even if the app is closed, the registration is still active until the `unregisterFromRemoteNotifications` front call is performed. At first execution, an app will typically ask if the user wants to get push notifications and register to the push service if needed. To disable push notification, apps usually implement an option that can be disabled (to unregister) and re-enabled (to register again) by the user. On Android™, the app must register for notification each time it is upgraded.

**Important:**

When an app restarts, if notifications are pending and the app has already registered for push notification in a previous execution, the `notificationpushed` action will be raised as soon as a dialog with the corresponding `ON ACTION` handler activates. The app then performs a `getRemoteNotifications` on page 2552 front call as in the usual way, to get the pending notifications pushed to the device while the app was off.

However, special consideration needs to be given to iOS devices. When push notification arrives for an iOS app that has not started, there is no mechanism to wake up the app and get the push data. Therefore, when the user starts the app from the springboard, there will never be any push data available. Depending on the context, implement the following programming patterns to solve this problem:
1. If the push notification contains a badge number, the app can verify if the badge is greater than 0 (with the `getBadgeNumber` front call) in order to perform a `getRemoteNotifications` front call. Even if there is no data available with the front call, it is recommended that the app sends a request directly to the server push provider to get last push data.

2. If the push notification does not contain badge numbers, it is still recommended that the app performs a `getRemoteNotification` front call when it starts. If there is no push data available from the front call, the recommendation is that the app sends a request to the server push provider to see if there is push data available. This is by the way also recommended when receiving a `notificationpushed` action during application life time.

3. If the user starts the app from the Notification Center, the app is launched with push data transmitted from the system, and the `notificationpushed` action is sent. It is recommended that the app perform a `getRemoteNotifications` front call and get the push data.

The `registerForRemoveNotifications` front call will return a registration token for the app which will be used by the push server (a.k.a push provider).

- When using FCM, the returned identifier is the FCM "registration token".
- When using APNs, the returned identifier is the APNs "device token".

```
DEFINE rec RECORD

      "mobile", "registerForRemoteNotifications",
        [], [ registration_token ])
    IF tm_command("register", notification_type,
      registration_token, app_user, 0 ) < 0 THEN
      RETURN NULL
    END IF
END FUNCTION
```
### 2 - Sending a push notification token to your token maintainer

Once registered to the FCM or APNs service, the app must also register to the push server or push provider by sending the token obtained in step 1.

This is typically done by using a RESTful HTTP POST, sending the token (along with additional application user information) to a dedicated server program that maintains the list of registered devices/tokens.

The device token maintainer can be implemented in BDL as a Web Service program, as described in Implementing a token maintainer on page 3337.

In this tutorial, the `tm_command()` function implements token registration (as well as badge number handling for APNs):

```bdl
IMPORT com
IMPORT util
...
LET rec.tm_host = "https://pushreg.example.orion"
LET rec.tm_port = 4930
...
FUNCTION tm_command( command, notification_type, registration_token, app_user, badge_number )
DEFINE command STRING,
    notification_type STRING,
    registration_token STRING,
    app_user STRING,
    badge_number INTEGER
DEFINE url STRING,
    json_obj util.JSONObject,
    req com.HTTPRequest,
    resp com.HTTPResponse,
    json_result STRING,
    result_rec RECORD
    status INTEGER,
    message STRING
END RECORD

END FUNCTION
```
When the app is declared as push notification client to the push server, continue with the normal program flow.

3 - Handling push notification events

To get and handle notification events, the current active dialog must implement the notificationpushed special action.

To control action view rendering defaults and current field validation behavior when the notificationpushed action is used, consider setting action default attributes for this action in your .4ad file as follows:

```xml
<ActionDefaultList>
  ...
  <ActionDefault name="notificationpushed" validate="no" defaultView="no" contextMenu="no"/>
  ...
</ActionDefaultList>
```

Another option is to define these action defaults attributes in the ON ACTION handler:

```
ON ACTION notificationpushed (VALIDATE=NO, DEFAULTVIEW=NO)
  ...
```

In the ON ACTION block for this action, query for notification messages by using the "getRemoteNotifications" front call, (passing the Sender ID as parameter when using FCM, for APNs the Sender ID must be NULL). This front call returns a JSON string containing a list of notification messages to be processed:

```plaintext
DEFINE notifs DYNAMIC ARRAY OF RECORD
    info STRING,
    ts DATETIME YEAR TO FRACTION(3)
END RECORD

... DEFINE x INTEGER

DIALOG ...
    DISPLAY ARRAY notifs TO sr.*
    END DISPLAY
...
ON ACTION notificationpushed
  LET x=handle_notification()
```
CALL DIALOG.setCurrentRow("sr",x)
...
END DIALOG
...

FUNCTION handle_notification()
DEFINE notif_list STRING,
notif_array util.JSONArray,
notif_item util.JSONObject,
notif_data util.JSONObject,
aps_record util.JSONObject,
gcm_data_s STRING,
gcm_genero_notification_s STRING,
gcm_genero_notification util.JSONObject,
info, other_info STRING,
i, x INTEGER
CALL ui.Interface.frontCall(
    "mobile", "getRemoteNotifications",
    [ ], [ notif_list ] )
TRY
    LET notif_array = util.JSONArray.parse(notif_list)
    IF notif_array.getLength() > 0 THEN
        CALL setup_badge_number(notif_array.getLength())
    END IF
    FOR i=1 TO notif_array.getLength()
        LET info = NULL
        LET other_info = NULL
        LET notif_item = notif_array.get(i)
        -- Try APNs msg format
        LET aps_record = notif_item.get("aps")
        IF aps_record IS NOT NULL THEN
            LET info = aps_record.get("alert")
            LET notif_data = notif_item.get("custom_data")
            IF notif_data IS NOT NULL THEN
                LET other_info = notif_data.get("other_info")
            END IF
        ELSE
            -- Try GCM msg format
            LET gcm_data_s = notif_item.get("data")
            IF gcm_data_s IS NOT NULL THEN
                LET notif_data = util.JSONObject.parse(gcm_data_s)
                IF notif_data IS NOT NULL THEN
                    LET gcm_genero_notification_s = notif_data.get("genero_notification")
                    LET gcm_genero_notification = util.JSONObject.parse(
                        gcm_genero_notification_s )
                    IF gcm_genero_notification IS NOT NULL THEN
                        LET info = gcm_genero_notification.get("content")
                    END IF
                    LET other_info = notif_data.get("other_info")
                END IF
            END IF
        END IF
        IF info IS NULL THEN
            LET info = "Unexpected message format"
        END IF
        MESSAGE SFMT("Notification message:
%1
%2", info, other_info)
        CALL notifs.appendElement()
        LET x = notifs.getLength()
        LET notifs[x].info = SFMT("%1 (%2)", info, other_info)
        LET notifs[x].ts = CURRENT
    END FOR
CATCH
When using APNs, the app must handle the badge numbers attached to the device token. The app must:

1. Query the current badge number with the `getBadgeNumber` front call.
2. Compute the new badge number based on the number of notifications consumed.
3. Reset the badge number with the `setBadgeNumber` front call.
4. Inform the token maintainer to sync the badge number in the central database.

The following function handles badge numbers for the app:

```plaintext
FUNCTION setup_badge_number(consumed)
DEFINE consumed INTEGER
DEFINE badge_number INTEGER
TRY -- If the front call fails, we are not on iOS...
   CALL ui.Interface.frontCall("ios", "getBadgeNumber", [], [badge_number])
   CATCH
   RETURN
   END TRY
IF badge_number>0 THEN
   LET badge_number = badge_number - consumed
   END IF
   CALL ui.Interface.frontCall("ios", "setBadgeNumber", [badge_number], [])
   IF tm_command( "badge_number", "APNS", rec.registration_token, rec.user_name, badge_number) < 0 THEN
       ERROR "Could not send new badge number to token maintainer."
       RETURN
   END IF
END FUNCTION
```

4 - Unregistering the app from push notification

If the app no longer wants to get push notifications, unregister from the push provider (using a RESTful POST, in the `regunreg_token()` function), and unregister from the push service by using the "unregisterFromRemoteNotifications" front call.

- When using FCM, you must pass the FCM Sender ID as parameter.
- When using APNs, the parameter must be NULL.

```plaintext
... 
LET rec.tm_host = "https://pushreg.example.orion"
LET rec.tm_port = 4930
CALL unregister(rec.registration_token, rec.app_user)
...
```

```plaintext
FUNCTION unregister(notification_type, registration_token, app_user)
DEFINE notification_type STRING,
registration_token STRING,
app_user STRING
IF tm_command( "unregister", notification_type, registration_token, app_user, 0 ) < 0 THEN
   RETURN
END IF
TRY
```
CALL ui.Interface.frontCall(  
  "mobile", "unregisterFromRemoteNotifications",  
  [ ], [ ] )
CATCH
  MESSAGE "Un-registration failed (broadcast service)."
RETURN
END TRY
MESSAGE "Un-registration succeeded"
END FUNCTION

Cordova plugins
This section describes how to use Cordova plugins.

- Understanding Cordova plugins on page 3370
- Installing Cordova plugins on page 3371
- Using a Cordova plugin API on page 3372
- Embed Cordova plugins in a GMA app on page 3374
- Embed Cordova plugins in a GMI app on page 3374

Understanding Cordova plugins
Cordova plugins allow you to access specific mobile device functionalities.

What are Cordova plugins in Genero?
Cordova plugins are based on the Apache Cordova cross-platform mobile development framework, to access mobile device functionality such as the accelerometer, the camera, the compass, the microphone, and more.

GMI and GMA act as a plugin container and provide a plugin API widely compatible with the original Cordova API. The implementation is Genero-specific and makes the native plugin interfaces available in Genero BDL.

Cordova plugins with device simulator or in client/server GUI mode
Depending on the configuration used when executing your app, some Cordova plugins or plugin APIs may not be available and may cause a malfunction.

- When using a device simulator, some Cordova plugin will not work because the feature is not available on the simulator.
- When executing the app on a server in development mode or in "runOnServer" mode, the front calls are slowed down by the network roundtrips.

Installing Cordova plugins into the development environment
In order to be used, Cordova plugins have to be downloaded from the FOURJS Cordova Github or from the Apache Cordova Github, and must be installed by using the --install-plugin option of GMA or GMI build tools.

For more details, see Installing Cordova plugins on page 3371.

Building apps with Cordova plugins
Installed Cordova plugins need to be specified in the build process when creating your app.
The Cordova plugins to be bundled with the app are specified with the `--cordova-plugin` option of GMA and GMI build tools:

- Embed Cordova plugins in a GMA app on page 3374
- Embed Cordova plugins in a GMI app on page 3374

**Using Cordova plugin APIs**

Access to the native code can be achieved using native Cordova APIs through Cordova plugin front calls. However, it is more convenient to have BDL wrappers on top of these front calls. Most Cordova plugins provided by FOURJS are shipped with a BDL wrapper library, available from the FOURJS Cordova Github.

**Installing Cordova plugins**

Before usage, Cordova plugins need to be installed in the GMA or GMI development environment.

**Using Cordova plugins from the GitHub**

GitHub contains a large number of Cordova plugins that can be used in your app, like those from the Apache Github for example, or the FOURJS Cordova Github.

To use a Cordova plugin:

1. Clone the git repository of the Cordova plugin on your local disk.
2. Install the plugin in your Genero GMA/GMI environment.
3. Identifying the native APIs of the Cordova plugin, to be called with Cordova front calls.
4. Implement BDL wrappers to encapsulate the Cordova front calls specific to this plugin, or use the BDL wrappers available with the plugins available on the FOURJS Cordova Github.

**Prerequisites**

Cordova plugins are available on a Github repository. The `git` command line tool is required to clone the repository on your local disk.

**Installing Cordova plugins**

To install a Cordova plugin from Github into your Genero environment, you must:

1. Clone the Github plugin sources from the Github.
2. Install the plugin in the Genero development environment with the `gmibuildtool` or `gmabuildtool --install-plugins` command line option.

For example, to install the Apache "cordova-plugin-network-information" plugin:

1. Clone the Git repository into a local directory:

```
$ cd /tmp
$ git clone https://github.com/apache/cordova-plugin-network-information.git
```

   The plugin is now in the `/tmp/cordova-plugin-network-information` directory.

2. Install the plugin with the GMA or GMI build tool:

   - For GMI / iOS:

   ```bash
   $ gmibuildtool --install-plugins=/tmp/cordova-plugin-network-information ...
   (wrapper and installation information is displayed)
   ```

   The `gmibuildtool --list-plugins` command now lists the new plugin in addition to the existing ones.
• For GMA / Android™ (note that you need to use the "scaffold" command!):

```bash
$ gmabuildtool scaffold --install-plugins /tmp/cordova-plugin-network-information
```

3. Check that the plugin is properly installed with the `--list-plugins` option of the build tool:

• For GMI / iOS:

```bash
$ gmibuildtool --list-plugins
...  
cordova-plugin-network-information
...
```

• For GMA / Android™:

```bash
$ gmabuildtool scaffold --list-plugins
...  
cordova-plugin-network-information
...
```

The `cordova-plugin-network-information` name can now be used for bundling an application using that plugin.

**Upgrading GMI (FGL) or GMA with installed Cordova plugins**

Cordova plugins need to be re-installed, after upgrading the GMI package (GMIDIR) or GMA package (GMADIR), or the FGL package if GMI is installed in FGLDIR.

• The GMI package can be installed into the FGLDIR installation directory, or in a separate GMIDIR installation directory.

• The GMA package is always installed in a GMADIR installation directory.

**Important**: In all cases, after upgrading an FGL, GMI or GMA environment where plugins have been installed, you need to re-execute the plugin installation with a `gmabuildtool cordova --install-plugin` or `gmibuildtool --install-plugin` command.

**Checking out a particular version from GitHub**

If you want to test a particular version of a plugin, you need to check out that version from GitHub before installing.

```bash
$ cd cordova-plugin-network-information
$ git checkout <superversion>
$ cd -
```

Then use the `gmibuildtool` or `gmabuildtool` to build with the super version.

**Note**: If a plugin with the same name is already installed, it is replaced by the new installation.

**Using a Cordova plugin API**

Cordova plugin features can be used by invoking cordova front calls.

**How to access Cordova plugin APIs**

Cordova plugin APIs are available to the front-end and therefore need to be called through Cordova plugin front calls.

Before calling a Cordova plugin function, you need to identify what native APIs are available. If provided, check the Cordova plugin API documentation for available functions.
Identifying Cordova plugin native APIs in JS sources

Cordova plugins are primarily targeted for JavaScript. Each plugin source directory has a www directory with JavaScript wrapper code calling into the native code.

For example, with the cordova-plugin-network-information plugin, the www/network.js file implements the following "getInfo" JavaScript function, that performs an exec() call of the "NetworkStatus.getConnectionInfo" native Cordova function:

```javascript
NetworkConnection.prototype.getInfo =
  function(successCallback, errorCallback) {
    exec(successCallback, errorCallback,
        "NetworkStatus", "getConnectionInfo", []);
  };
```

The BDL equivalent of the above exec() call is done with the generic Cordova front call "cordova.call":

```javascript
CALL ui.Interface.frontCall( "cordova", "call",
    ["NetworkStatus","getConnectionInfo"], [result] )
```

**Note:** In the README.md files of the plugins, the available methods for the plugins are documented for the JavaScript wrappers and not the underlying native calls.

In order to find available native Cordova APIs, such as getConnectionInfo, search for the exec() calls in the js files of the www directory. The native Cordova function name is the fourth parameter of the exec() function.

Implementing an app that uses the Cordova plugin

After installing a plugin, you can create a Genero program using a function of this plugin, by using the generic front call for Cordova APIs.

For example:

```genero
IMPORT FGL fgldialog
MAIN
DEFINE result STRING
MENU "network"
  COMMAND "Info"
    CALL ui.Interface.frontCall( "cordova", "call",
        ["NetworkStatus","getConnectionInfo"], [result] )
    CALL fgldialog.winMessage("Result",result,"info")
  COMMAND "Exit"
EXIT MENU
END MENU
END MAIN
```

Compile and build your app as usual (the installed Cordova plugins will be included).

Cordova plugin front calls overview

Cordova plugin front calls are generic functions that give access to the native Cordova APIs, in conjunction with the predefined cordovacallback action.

The `cordova.call` function issues a synchronous Cordova function call. In this case, the underlying native function is executed and the program waits until it returns. Results are provided in the front call output parameters.

The `cordova.callWithoutWaiting` function performs an asynchronous Cordova function call. The program continues while the Cordova function executes in parallel. The program can implement a trigger for the cordovacallback predefined action, to detect when results are available. To retrieve results of asynchronous calls, use the `cordova.getCallbackDataCount`, `cordova.getCallbackData` and `cordova.getAllCallbackData` front calls.

See these front calls in action in the demos provided on the FOURJS Cordova Github.
Implement BDL wrappers on top of Cordova front calls

For better code readability and maintenance, we strongly suggest you implement BDL functions that encapsulate Cordova front calls, as done with plugins available on the FOURJS Cordova Github.

Cordova plugin API internals

The IOS code is located in the src/ios directory of a plugin.

The Android™ code is located in the src/Android directory of a plugin.

The IOS code in src/ios/CDVConnection.m contains a method called

```(void)getConnectionInfo:(CDVInvokedUrlCommand*)command```

This is the native objective-C method called by the front call.

The Android™ code in src/android/NetworkManager.java contains an execute method for handling the getConnectionInfo string:

```public boolean execute(String action, JSONArray args, CallbackContext callbackContext) {
    if (action.equals("getConnectionInfo")) {
...```

The plugin.xml file

A plugin can contain several assets (images, sounds, native forms) which are listed in the plugin.xml file that is bundled by gmibuildtool.
