<tr>
<td>NUMBER(*) (s)</td>
<td>Fixed point decimal numbers with a precision of 38 digits.</td>
</tr>
<tr>
<td>NUMBER</td>
<td>Floating point decimals with a precision of 38 digits.</td>
</tr>
<tr>
<td>FLOAT(b) (1&lt;=b&lt;= 126)</td>
<td>Floating point numbers with a binary precision b. This is a sub-type of NUMBER.</td>
</tr>
<tr>
<td>BINARY_FLOAT (since Oracle® 10g)</td>
<td>32-bit floating point number.</td>
</tr>
<tr>
<td>BINARY_DOUBLE (since Oracle® 10g)</td>
<td>64-bit floating point number.</td>
</tr>
</tbody>
</table>

ANSI types like SMALLINT, INTEGER are supported by Oracle® but will be converted to the native NUMBER type.

When dividing INTEGER or SMALLINT types, Informix® rounds the result (7 / 2 = 3), while Oracle® doesn't, because it does not have a native integer data type (7 / 2 = 3.5)

Solution

Use the following conversion rules to map Informix® numeric types to Oracle® numeric types:
Table 237: Informix® numeric types and Oracle® equivalents

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Oracle® data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>NUMBER(5,0)</td>
</tr>
<tr>
<td>INTEGER</td>
<td>NUMBER(10,0)</td>
</tr>
<tr>
<td>BIGINT</td>
<td>NUMBER(20,0)</td>
</tr>
<tr>
<td>INT8</td>
<td>NUMBER(20,0)</td>
</tr>
<tr>
<td>DECIMAL(p,s)</td>
<td>NUMBER(p,s)</td>
</tr>
<tr>
<td>DECIMAL(p)</td>
<td>FLOAT(p * 3.32193)</td>
</tr>
<tr>
<td>DECIMAL (not recommended)</td>
<td>FLOAT</td>
</tr>
<tr>
<td>MONEY(p,s)</td>
<td>NUMBER(p,s)</td>
</tr>
<tr>
<td>MONEY(p)</td>
<td>NUMBER(p,2)</td>
</tr>
<tr>
<td>MONEY</td>
<td>NUMBER(16,2)</td>
</tr>
<tr>
<td>SMALLFLOAT</td>
<td>BINARY_FLOAT</td>
</tr>
<tr>
<td>FLOAT[(p)]</td>
<td>BINARY_DOUBLE</td>
</tr>
</tbody>
</table>

Avoid dividing integers in SQL statements. If you do divide an integer, use the TRUNC() function with Oracle®.

When creating a table directly in Oracle's sqlplus, using ANSI data types INTEGER, SMALLINT, you do actually create columns with the NUMBER type, which has a precision of 38 digits. As result, it is not possible to distinguish the original types used in CREATE TABLE, nor can it be possible to distinguish the columns created explicitly with the native NUMBER type, in the next example, all columns will be of type NUMBER:

```
$ sqlplus ...
sql> CREATE TABLE mytab (  
co11 INTEGER,  
co12 SMALLINT,  
co13 NUMBER,  
...  
)
```

When extracting the database schema with fgldbsch, NUMBER, NUMBER(p>32) and NUMBER(p>32,s) types will by default give an extraction error. However, these types can be converted to DECIMAL(32) and DECIMAL(32,s) with the -cv option, by using the "B" character at positions 22 (for NUMBER) and 23 (for NUMBER(p>32,[s])).

**Note:** When fetching a NUMBER(p>32,[s]) into a BDL DECIMAL(32,[s]) type, if the value stored in the NUMBER column has more than 32 digits, it will be rounded to fit into a DECIMAL(32), or the overflow error -1226 will occur when fetching into a DECIMAL(32,s). Note that it must be allowed to fetch numeric expressions such as 1/3 (=0.333333333333....) into a DECIMAL(p,s), even if such expression will produce more than 32 digits with Oracle.

When creating a table in a BDL program with DECIMAL(p), this type is converted to native Oracle® FLOAT(p*3.32193). When creating a table in a BDL program with DECIMAL (without precision) this type is converted to native Oracle® FLOAT. The native Oracle® FLOAT[(p)] type can be extracted by fgldbsch, but Oracle's FLOAT has a higher precision than the BDL DECIMAL type, which can lead to value rounding when fetching rows.

With Oracle® versions older than 10g, when creating tables in a BDL program with SMALLFLOAT or FLOAT types, these types are mapped to NUMBER (The native Oracle® FLOAT(b) type could have been used, but this type is reserved to map DECIMAL(p) types). Starting with Oracle® 10g, SMALLFLOAT or FLOAT types will respectively be converted to BINARY_FLOAT and BINARY_DOUBLE native Oracle® types, which can be extracted by fgldbsch and mapped back to BDL SMALLFLOAT and FLOAT respectively in the .sch file.
Note: As a general recommendation, do not use DECIMAL\((p)\) or SMALLFLOAT/FLOAT floating point types in business applications. These types should only be used for scientific data storage.

The numeric types translation can be controlled with the following FGLPROFILE entries:

```
<table>
<thead>
<tr>
<th>Entry</th>
<th>True</th>
<th>False</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbi.database.dsnname.ifxemul.datatype.smallint</td>
<td></td>
<td></td>
</tr>
<tr>
<td>dbi.database.dsnname.ifxemul.datatype.integer</td>
<td></td>
<td></td>
</tr>
<tr>
<td>dbi.database.dsnname.ifxemul.datatype.bigint</td>
<td></td>
<td></td>
</tr>
<tr>
<td>dbi.database.dsnname.ifxemul.datatype.int8</td>
<td></td>
<td></td>
</tr>
<tr>
<td>dbi.database.dsnname.ifxemul.datatype.decimal</td>
<td></td>
<td></td>
</tr>
<tr>
<td>dbi.database.dsnname.ifxemul.datatype.money</td>
<td></td>
<td></td>
</tr>
<tr>
<td>dbi.database.dsnname.ifxemul.datatype.float</td>
<td></td>
<td></td>
</tr>
<tr>
<td>dbi.database.dsnname.ifxemul.datatype.smallfloat</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

**fgldbsch** on page 1978

The **fgldbsch** tool generates the database schema files from an existing database.

**DATE and DATETIME data types**

**Informix®**

Informix® provides two data types to store date and time information:

- **DATE** = for year, month and day storage.
- **DATETIME** = for year to fraction (1-5) storage.

The **DATE** type is stored as an **INTEGER** with the number of days since 1899/12/31.

The **DATETIME** type can be defined with various time units, by specifying a start and end qualifier. For example, you can define a datetime to store an hour-to-second time value with **DATETIME HOUR TO SECOND**.

The values of Informix® **DATETIME** can be represented with a character string literal, or as **DATETIME()** literals:

```
'2017-12-24 15:45:12.345' -- a DATETIME YEAR TO FRACTION(3)
'15:45' -- a DATETIME HOUR TO MINUTE
DATETIME(2017-12-24 12:45) YEAR TO MINUTE
DATETIME(12:45:56.333) HOUR TO FRACTION(3)
```

Informix® is able to convert quoted strings to **DATE** / **DATETIME** data, if the string contains matching environment parameters. The string to date conversion rules for **DATE** is defined by the DBDATE environment variable. The string to datetime format for **DATETIME** is defined by the GL_DATETIME environment variable.

Note: Within Genero programs, the string representation for **DATETIME** values is always ISO (**YYYY-MM-DD hh:mm:ss.fffff**)

Informix® supports date arithmetic on **DATE** and **DATETIME** values. The result of an arithmetic expression involving dates/times is an **INTEGER** number of days when only **DATE** values are used, and an **INTERVAL** value if a **DATETIME** is used in the expression.

Informix® automatically converts an **INTEGER** to a **DATE** when the integer is used to set a value of a date column.

**ORACLE**

Oracle® provides the following data types to store date and time data:

- **DATE** = for year, month, day, hour, min, second storage.
- **TIMESTAMP** = for year, month, day, hour, min, second, fraction storage.
As in Informix®, Oracle® can convert quoted strings to DATE or TIMESTAMP data if the contents of the string matches the NLS date format parameters (NLS_DATE_FORMAT, NLS_TIMESTAMP_FORMAT).

The TO_DATE() and TO_TIMESTAMP() SQL functions convert strings to dates or timestamps, based on a given format. The TO_CHAR() SQL function allows you to convert dates or timestamps to strings, according to a given format.

In Oracle® the result of an arithmetic expression involving DATE values is a number of days as NUMBER type; the decimal part is the fraction of the day ( 0.5 = 12H00, 2.00694444 = (2 + (10/1440)) = 2 days and 10 minutes ). The result of an expression involving Oracle® TIMESTAMP data is of type INTERVAL.

To compare dates that have time data in Oracle®, you can use the ROUND() or TRUNC() SQL functions.

See the Oracle® documentation for more details.

Solution

Use the following conversion rules to map Informix® date/time types to Oracle® date/time types:

**Table 238: Informix® data types and Oracle® equivalents**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Oracle®</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME YEAR TO YEAR</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME YEAR TO MONTH</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME YEAR TO DAY</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME YEAR TO HOUR</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME YEAR TO MINUTE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME YEAR TO SECOND</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME YEAR TO FRACTION(n)</td>
<td>TIMESTAMP(n)</td>
</tr>
<tr>
<td>DATETIME MONTH TO MONTH</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME MONTH TO DAY</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME MONTH TO HOUR</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME MONTH TO MINUTE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME MONTH TO SECOND</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME MONTH TO FRACTION(n)</td>
<td>TIMESTAMP(n)</td>
</tr>
<tr>
<td>DATETIME DAY TO DAY</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME DAY TO HOUR</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME DAY TO MINUTE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME DAY TO SECOND</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME DAY TO FRACTION(n)</td>
<td>TIMESTAMP(n)</td>
</tr>
<tr>
<td>DATETIME HOUR TO HOUR</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME HOUR TO MINUTE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME HOUR TO SECOND</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME HOUR TO FRACTION(n)</td>
<td>TIMESTAMP(n)</td>
</tr>
<tr>
<td>DATETIME MINUTE TO MINUTE</td>
<td>DATE</td>
</tr>
<tr>
<td>Informix® data type</td>
<td>Oracle®</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------</td>
</tr>
<tr>
<td>DATETIME MINUTE TO SECOND</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME MINUTE TO FRACTION(n)</td>
<td>TIMESTAMP(n)</td>
</tr>
<tr>
<td>DATETIME SECOND TO SECOND</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME SECOND TO FRACTION(n)</td>
<td>TIMESTAMP(n)</td>
</tr>
<tr>
<td>DATETIME FRACTION TO FRACTION(n)</td>
<td>TIMESTAMP(n)</td>
</tr>
</tbody>
</table>

The DATE and DATETIME types translation can be controlled with the following FGLPROFILE entries:

```plaintext
dbi.database.schema.ifxemul.datatype.date = { true | false }
dbi.database.schema.ifxemul.datatype.datetime = { true | false }
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Storing BDL DATE values**

The Oracle® DATE type is used to store Genero BDL DATE values. However, keep in mind that the Oracle® DATE type stores also time (hh:mm:ss) information. The database interface automatically sets the time part to midnight (00:00:00) during input/output operations.

You must be very careful since manual modifications of the database might set the time part, for example:

```plaintext
UPDATE table SET date_col = SYSDATE
```
(SYSDATE is equivalent to CURRENT YEAR TO SECOND in Informix®).

After this type of update, when columns have date values with a time part different from midnight, some SELECT statements might not return all the expected rows.

When fetching Oracle® DATE values into Genero BDL DATE or DATETIME variables, the date and time information is directly set for the individual date/time parts and the conversion is straight forward. But when fetching an Oracle® DATE into a CHAR or VARCHAR variable, date to string conversion occurs. Since Oracle® dates are equivalent of Informix® DATETIME YEAR TO SECOND, the values are by default converted with the ISO format (YYYY-MM-DD hh:mm:ss), which is not the typical Informix® behavior where dates are formatted from the DBDATE environment variable. If your application fetches DATE values into CHAR/VARCHAR and you want to get the DBDATE conversion, you must set the following FGLPROFILE entry:

```plaintext
dbi.database.dbname.ora.date.ifxfetch = true
```

**Note:** Oracle® does not support INTEGER to DATE automatic conversion.

**Storing BDL DATETIME values**

Informix® DATETIME data with any precision from YEAR to SECOND is stored in Oracle® DATE columns. The database interface makes the conversion automatically. Missing date or time parts default to 1900-01-01 00:00:00. For example, when using a DATETIME HOUR TO MINUTE with the value of "11:45", the Oracle® DATE value will be "1900-01-01 11:45:00".

Informix® DATETIME YEAR TO FRACTION(n) data is stored in Oracle® TIMESTAMP columns. The TIMESTAMP data type can store up to 9 digits in the fractional part, and therefore can store all precisions of Informix® DATETIME.

**Important:**

- Most arithmetic expressions involving dates (for example, to add or remove a number of days from a date) will produce the same result with Oracle®. But keep in mind that Oracle® evaluates date arithmetic expressions
to \texttt{NUMBER ( days.fraction )} while Informix® evaluates to \texttt{INTEGER} when only \texttt{DATE} values are used in the expression, or to \texttt{INTERVAL} values if at least one \texttt{DATETIME} is used in the expression.

- Even if a configuration parameter exists to get the Informix® behavior, avoid fetching date values into \texttt{CHAR} or \texttt{VARCHAR}, to bypass the DBDATE / ISO format conversion difference with Oracle®.

### Date/time SQL functions

**Table 239: Informix® and Oracle® date/time SQL functions**

<table>
<thead>
<tr>
<th>Informix®</th>
<th>Oracle®</th>
</tr>
</thead>
<tbody>
<tr>
<td>today</td>
<td>\texttt{trunc( sysdate )}</td>

<td>day( value )</td>
<td>\texttt{to_number( to_char( value, 'dd' ) )}</td>
</tr>
<tr>
<td>extend( dtvalue, first to last )</td>
<td>\texttt{to_date( nvl( to_char( dtvalue, 'fmt-mask' ), '19000101000000' ), 'fmt-mask' )}</td>
</tr>
<tr>
<td>mdy(m,d,y)</td>
<td>\texttt{to_date( to_char(m,'09')</td>
</tr>
<tr>
<td>month( date )</td>
<td>\texttt{to_number( to_char( date, 'mm' ) )}</td>
</tr>
<tr>
<td>weekday( date )</td>
<td>\texttt{to_number( to_char( date, 'd' ) ) -1}</td>
</tr>
<tr>
<td>year( date )</td>
<td>\texttt{to_number( to_char( date, 'yyyy' ) )}</td>
</tr>
<tr>
<td>date( &quot;string&quot;</td>
<td>integer )</td>
</tr>
</tbody>
</table>

**Related concepts**

- [Date/time literals in SQL statements](page 571)
- Good practices for date and time handling in SQL.

### INTERVAL data type

**Informix®**

Informix® provides the \texttt{INTERVAL} data type to store a value that represents a span of time.

\texttt{INTERVAL} types are divided into two classes:

- \textit{year-month} intervals. For example: \texttt{INTERVAL YEAR(5) TO MONTH}
- \textit{day-time} intervals. For example: \texttt{INTERVAL DAY(9) TO SECOND}

\texttt{INTERVAL} columns can be defined with various time units, by specifying a start and end qualifier. For example, you can define an interval to store a number of hours and minutes with \texttt{INTERVAL HOUR(n) TO MINUTE}, where \texttt{n} defines the maximum number of digits for the hours unit.

The values of Informix® \texttt{INTERVAL} can be represented with a character string literal, or as \texttt{INTERVAL()} literals:

- \texttt{'-9834 15:45:12.345'} -- an \texttt{INTERVAL DAY(6) TO FRACTION(3)}
- \texttt{'7623-11'} -- an \texttt{INTERVAL YEAR(9) TO MONTH}
- \texttt{INTERVAL(18734:45) HOUR(5) TO MINUTE}
- \texttt{INTERVAL(-7634-11) YEAR(5) TO MONTH}
**ORACLE**

ORACLE provides an INTERVAL data type similar to Informix®, implementing two classes (YEAR TO MONTH and DAY TO SECOND).

However, Oracle’s intervals cannot be defined with a time units different from the two interval classes. For example, you cannot define an INTERVAL HOUR TO MINUTE in Oracle.

**Note:** The ORACLE INTERVAL DAY TO SECOND (n) contains the fractional part of seconds and therefore is equivalent to the Informix® INTERVAL DAY TO FRACTION (n) type.

**Solution**

Informix® INTERVAL YEAR (n) TO MONTH data is stored in Oracle INTERVAL YEAR(n) TO MONTH columns. These data types are equivalent.

Informix® INTERVAL DAY (n) TO FRACTION (p) data is stored in Oracle INTERVAL DAY(n) TO SECOND (p) columns. These data types are equivalent.

Other Informix® INTERVAL types must be stored in CHAR() columns, because the high qualifier precision cannot be specified with Oracle INTERVALS. For example, Informix® INTERVAL HOUR (5) TO MINUTE has no native equivalent in Oracle.

The INTERVAL types translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemul.datatype.interval = \true \false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

*Using portable data types* on page 553

Only a limited set of data types are really portable across several database engines.

**SERIAL data types**

**Informix®**

Informix® supports the SERIAL, BIGSERIAL data types to produce automatic integer sequences:

- SERIAL can produce 32 bit integers (INTEGER)
- BIGSERIAL can produced 64 bit integers (BIGINT)
- SERIAL8 is a synonym for BIGSERIAL

Steps to use serials with Informix®:

1. Create the table with a column using SERIAL, or BIGSERIAL.
2. To generate a new serial, no value or a zero value is specified in the INSERT statement:

   ```sql
   INSERT INTO tab1 ( c ) VALUES ( 'aa' )
   INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
   ```

3. After INSERT, the new value of a SERIAL column is provided in SQLCA.SQLERRD[2], while the new value of a BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```sql
CREATE TABLE tab ( k SERIAL ); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
```
---

**ORACLE**

Oracle® provides several solutions to implement auto-incremented columns:

1. Sequence objects can be created to generate numbers (CREATE SEQUENCE, `seqname.currval`).
2. Since Oracle® 12c, it is possible to reference a sequence in DEFAULT ON NULL column clauses.
3. Since Oracle® 12c, you can define columns with the GENERATE ... AS IDENTITY clause.

Details about Oracle® sequences:

- Sequences are totally detached from tables.
- The purpose of sequences is to provide unique integer numbers.
- Sequences are identified by a sequence name.
- To create a sequence, you must use the CREATE SEQUENCE statement. Once a sequence is created, it is permanent (like a table).
- To get a new sequence value, you must use the `nextval` keyword, preceded by the name of the sequence. The `seqname.nextval` expression can be used in INSERT statements:

```sql
INSERT INTO tab1 VALUES ( tab1_seq.nextval, ... )
```

- To get the last generated number, Oracle® provides the `currval` keyword:

```sql
SELECT seqname.currval FROM DUAL
```

- In order to improve performance, Oracle® can handle a set of sequences in the cache (See CREATE SEQUENCE syntax in the Oracle® documentation).

**Solution**

**Note:** For best SQL portability when using different type of databases, consider using sequences as described in **Solution 3: Use native SEQUENCE database objects** on page 565.

The SERIAL data type can be emulated with sequences used in INSERT triggers or with the DEFAULT ON NULL clause.

The method used to emulate SERIAL types is defined by the `ifxemul.datatype.serial.emulation` FGLPROFILE parameter:

```sql
dbi.database.dbname.ifxemul.datatype.serial.emulation = {"native","native2","regtable"}
```

- **native**: uses insert triggers with sequences.
- **native2**: uses DEFAULT ON NULL column clause with sequences.
- **regtable**: uses insert triggers with the SERIALREG table.

The default emulation technique is "native".

The serial types emulation can be enabled or disabled with the following FGLPROFILE entries:

```sql
dbi.database.dbname.ifxemul.datatype.serial = [true|false]
dbi.database.dbname.ifxemul.datatype.serial8 = [true|false]
dbi.database.dbname.ifxemul.datatype.bigserial = [true|false]
```

**Important:** The "regtable" emulation based on the SERIALREG table is provided to simplify the migration from Informix. We strongly recommend that you use the native or native2 method instead. The "native2" method is the fastest solution when inserting a large number of rows in the database.
Notes common to all serial emulation modes

When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the Oracle® interface automatically creates the additional SQL objects (column clauses, sequences or triggers) to generate numbers when an INSERT statement is performed.

Users executing programs which create tables with SERIAL columns must have the CONNECT and RESOURCE roles assigned to create triggers and sequences.

SERIAL[(n)] data types are converted to NUMBER(10,0), while BIGSERIAL[(n)] is replaced by NUMBER(20,0).

For SERIAL types, the SQLCA.SQLERRD[2] register is filled as expected with the last generated serial value. However, since SQLCA.SQLERRD[2] is defined as an INTEGER, it cannot hold values from BIGSERIAL (NUMBER(20,0)) auto-incremented columns. If you are using BIGSERIAL columns, you must fetch the sequence pseudo-column CURR_VAL or fetch the LASTSERIAL column from the SERIALREG table, if used.

Check whether your application uses tables with a SERIAL column that can contain a NULL value: INSERT statements using NULL for the SERIAL column will produce a new serial value:

```sql
INSERT INTO tab ( col1, col2 ) VALUES ( NULL, 'data' )
```

This behavior is mandatory in order to support INSERT statements that do not use the serial column:

```sql
INSERT INTO tab (col2) VALUES ('data')
```

For SQL portability, it is recommended to review INSERT statements to remove the SERIAL column from the list. For example, the following statement:

```sql
INSERT INTO tab (col1,col2) VALUES (0, p_value)
```

can be converted to:

```sql
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```sql
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES (rec.*) -- will use the serial column
```

can be converted to:

```sql
INSERT INTO tab VALUES rec.* -- without parentheses, serial column is removed
```

When using the Static SQL INSERT or UPDATE syntax using record.* without parentheses, make sure that your database schema files contain information about serials. This information can be lost when extracting the schema from an Oracle® database. See Database Schema for more details about the serial flag in column type encoding (data type code must be 6).

If the "native" or "regtable" emulation is used, inserting rows with Oracle® tools like SQL*Plus or SQL*Loader will execute the INSERT triggers. When loading big tables, you can disable triggers with ALTER TRIGGER [ENABLE | DISABLE] (see Oracle® documentation for more details). After reactivation of the serial triggers, the SERIAL sequences must be re-initialized (use serialpkg.create_sequence('tab','col')) or re-execute the PL/SQL script containing the sequence and trigger creation.

Using the native serial emulation

Each table having a SERIAL column needs an INSERT TRIGGER and a SEQUENCE dedicated to SERIAL generation.
To know how to write those sequences and triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native SQL commands to create the sequence and the trigger.

For temporary tables, the trigger and the sequence are dropped automatically after a "DROP TABLE temptab" or when the program disconnects from the database.

**Using the native2 serial emulation**

With this emulation, a SERIAL type is converted to a DEFAULT ON NULL clause using a sequence is created automatically by the database driver, for example:

```sql
CREATE TABLE t1 ( mykey SERIAL(100), .... )
```

is converted to:

```sql
CREATE SEQUENCE t1_srl INCREMENT BY 1 START WITH 100
CREATE TABLE t1 (mykey NUMBER(10,0) DEFAULT ON NULL t1_srl.nextval , ...
```

For temporary tables, the sequence is dropped automatically after a "DROP TABLE temptab" or when the program disconnects from the database.

**Note:** The native2 serial emulation uses the DEFAULT ON NULL clause, supported by Oracle, starting from version 12.1.

**Using the regtable serial emulation**

Each table having a SERIAL column needs an INSERT TRIGGER which uses the SERIALREG table dedicated to SERIAL registration.

First, you must prepare the database and create the SERIALREG table as follows:

```sql
CREATE TABLE serialreg (  
    tablename VARCHAR2(50) NOT NULL,  
    lastserial NUMBER(20,0) NOT NULL,  
    PRIMARY KEY ( tablename )  
)
```

**Important:** This table must exist in the database before creating the serial triggers.

In database creation scripts, all SERIAL\[(n)\] data types must be converted to INTEGER data types and you must create one trigger for each table. SERIAL8/BIGSERIAL columns must be converted to NUMBER(20,0). To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command.

The serial production is based on the SERIALREG table which registers the last generated number for each table. If you delete rows of this table, sequences will restart at start values and you might get duplicated values.

For temporary tables, the trigger is dropped automatically after a "DROP TABLE temptab" or when the program disconnects from the database.

Set the FGLSQLDEBUG environment variable to print SQL debug info.

**ROWID columns**

**Informix®**

When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only).

The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

**Note:** Informix® ROWID usage was a common practice in the early days of Informix® 4GL programming. Today it is recommended to define all your database tables with a PRIMARY KEY to uniquely identify rows.

With Informix®, the SQLCA.SQLERRD[6] register contains the ROWID of the last modified row.

**ORACLE**

Oracle® supports ROWIDs, but the data type is different from Informix® ROWIDs: Oracle® rowids are CHAR(18).

For example:

```
AAAA8mAALAAAAQkAAA
```

Since Oracle® rowids are physical addresses, they cannot be used as permanent row identifiers (After a DELETE, an INSERT statement might reuse the physical place of the deleted row, to store the new row).

**Solution**

If the BDL application uses Informix® ROWIDs, it is recommended that the program logic is reviewed in order to use the real primary keys instead (usually, serials which can be supported), or Oracle® rowids as CHAR(18) (Informix® rowids will fit in this char data type).

If you cannot avoid using rowids, you must change the type of variables which hold ROWID values. Instead of using INTEGER, you must use CHAR(18). Informix® rowids (integers) will automatically fit into a CHAR(18) variable.

All references to SQLCA.SQLERRD[6] must be removed because this variable will not contain the ROWID of the last modified row when using the Oracle® interface.

The ROWID keyword translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemul.rowid = {true | false}
```

For more details see [IBM Informix emulation parameters in FGLPROFILE](#) on page 614.

**Related concepts**

- Using ROWID columns on page 578
- Automatic ROWID columns is not a common database feature.

**The RAW data type**

ORACLE supports the RAW data type to hold binary data. This data type is for example used to return values from the SYS_GUID() SQL function.

**Solution**

The ORACLE RAW values can be converted to a character string in the hexadecimal notation.

When fetching rows from the database, the database driver will automatically convert ORACLE RAW values to hexadecimal. On the other hand, when using SQL parameters, the database driver will convert hexadecimal VARCHAR strings to binary data.
Since each byte is represented with two characters in the hexadecimal notation, you must define a VARCHAR(N*2) variable to hold the values of a native RAW(N) column.

When extracting a database schema with the fgl dbsch tool, the ORACLE RAW(N) type is converted to VARCHAR2(N*2).

**TEXT and BYTE (LOB) types**

**Informix**

Informix® provides the TEXT, BYTE, CLOB and BLOB data types to store very large texts or binary data.

Legacy Informix® 4GL applications typically use the TEXT and BYTE types.

Genero BDL does not support the Informix® CLOB and BLOB types.

**ORACLE**

ORACLE provides CLOB, BLOB, and BFILE data types to store large text and binary data.

The ORACLE large object types are similar to Informix® LOB types.

**Solution**

The ORACLE database interface can convert BDL TEXT data to ORACLE CLOB and BYTE data to ORACLE BLOB.

Genero TEXT/BYTE program variables have a limit of 2 gigabytes. Make sure that the large object data does not exceed this limit.

The ORACLE BFILE type is not supported by Genero BDL.

The TEXT and BYTE types translation can be controlled with the following FGLPROFILE entries:

```plaintext
  dbi.database.dsnname.ifxemul.text = [true | false ]
  dbi.database.dsnname.ifxemul.byte = [true | false ]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

**Table constraints**

**Informix**

Informix® supports primary key, unique, foreign key, default and check constraints.

The constraint naming syntax is different in Informix® and most other databases: Informix expects the "CONSTRAINT" keyword after the constraint specification:

```sql
CREATE TABLE emp (  
  ...  
  emp_code CHAR(10) UNIQUE CONSTRAINT pk_emp,  
  ...  
)
```

While other databases it before:

```sql
CREATE TABLE emp (  
  ...  
  emp_code CHAR(10) CONSTRAINT pk_emp UNIQUE,  
  ...  
)```
ORACLE supports primary key, unique, foreign key, default and check constraints. The constraint naming clause must be placed before the constraint specification.

**Primary keys**
Like Informix®, ORACLE creates an index to enforce PRIMARY KEY constraints (some RDBMS do not create indexes for constraints). Using CREATE UNIQUE INDEX to define unique constraints is obsolete (use primary keys or a secondary key instead).

**Unique constraints**
Like Informix®, ORACLE creates an index to enforce UNIQUE constraints (some RDBMS do not create indexes for constraints).

When using a unique constraint, Informix® allows only one row with a NULL value, while ORACLE allows several rows with NULL! Using CREATE UNIQUE INDEX is obsolete.

**Foreign keys**
Both Informix® and ORACLE support the ON DELETE CASCADE option. To defer constraint checking, Informix® provides the SET CONSTRAINT command while ORACLE provides the ENABLE and DISABLE clauses.

**Check constraints**
The check condition may be any valid expression that can be evaluated to TRUE or FALSE, including functions and literals. You must verify that the expression is not Informix® specific.

**Null constraints**
Informix® and ORACLE support not null constraints, but Informix® does not allow you to give a name to NOT NULL constraints.

**Constraint naming syntax**
The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for ORACLE.

**Related concepts**
- **Data definition statements** on page 552
  It is recommended to avoid use of DDL in programs.

**Name resolution of SQL objects**

**Informix®**
Informix® uses the following form to identify an SQL object:

```
database[@dbservername]:[|{owner|"owner"}.]identifier
```

The ANSI convention is to use double quotes for identifier delimiters (For example: "customer". "cust_name").

Informix® database object names are not case-sensitive in non-ANSI databases. When using double-quoted identifiers, Informix® becomes case sensitive.
With non-ANSI Informix® databases, you do not have to give a schema name before the tables when executing an SQL statement:

```
SELECT ... FROM customer WHERE ...
```

In Informix® ANSI compliant databases:

- The table name must include "owner", unless the connected user is the owner of the database object.
- The database server shifts the owner name to uppercase letters before the statement executes, unless the owner name is enclosed in double quotes.

**ORACLE**

With Oracle®, an object name takes the following form:

```
[(schema|"schema")\.](identifier|"identifier")[@database-link]
```

Oracle® has separate namespaces for different classes of objects (tables, views, triggers, indexes, clusters).

Object names are limited to 30 chars in ORACLE.

Unlike Informix®, Oracle® database object names are stored in UPPERCASE in system catalogs. That means that `SELECT "col1" FROM "tab1"` will produce an error because those objects are identified by "COL1" and "TAB1" in Oracle® system catalogs.

An Oracle® database schema is owned by a user (usually, the application administrator) and this user must create PUBLIC SYNONYMS to provide a global scope for his table names. PUBLIC SYNONYMS can have the same name as the schema objects they point to.

**Solution**

As a general rule, to write portable SQL, it is recommended that you only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

Check that you do not use single-quoted or double-quoted table names or column names in your source. Those quotes must be removed because the database interface automatically converts double quotes to single quotes, and Oracle® does not allow single quotes as database object name delimiters.

See also the issue Database Concepts

**NULLs in indexed columns**

Oracle btree indexes do not store null values, while Informix® btree indexes do. This means that if you index a single column and select all the rows where that column is null, Informix® will do an indexed read to fetch just those rows, but Oracle will do a sequential scan of all rows to find them. Having an index unusable for "is null" criteria can also completely change the behavior and performance of more complicated selects without causing a sequential scan.

**Solution**

Declare the indexed columns as NOT NULL with a default value and change the program logic. If you do not want to change the programs, partitioning the table so that the nulls have a partition of their own will reduce the sequential scan to just the nulls (un-indexed) partition, which is relatively fast.

**Data manipulation**

Oracle Database related data manipulation topics.

**Reserved words**

**Informix®**

With Informix®, it is possible to create database objects with reserved words.
For example:

```sql
CREATE TABLE table ( char CHAR(10) );
```

Indeed this is not good practice, but Informix® SQL allows this to be backward compatible when introducing a new keyword in the SQL syntax.

Most other database systems do not allow reserved words as database identifiers. If your legacy code is using SQL reserved words of the target database SQL syntax, an error will be thrown at CREATE TABLE execution.

**ORACLE**

SQL object names like table and column names cannot be SQL reserved words in ORACLE.

An example of a common word which is part of the ORACLE SQL grammar is 'level'.

**Solution**

Table or column names which are ORACLE reserved words must be renamed.

ORACLE reserved keywords are listed in the ORACLE documentation, or Oracle 8i provides the V $RESERVED_WORDS view to track Oracle reserved words. All BDL application sources must be verified. To check if a given keyword is used in a source, you can use UNIX™' 'grep' or 'awk' tools. Most modifications can be done automatically with UNIX™ tools like 'sed' or 'awk'.

**Outer joins**

**Informix® OUTER() syntax**

In Informix® SQL, outer joins can be defined in the FROM clause with the OUTER keyword:

```sql
SELECT ... FROM a, OUTER (b)  
WHERE a.key = b.akey
```

```sql
SELECT ... FROM a, OUTER(b,OUTER(c))  
WHERE a.key = b.akey  
AND b.key1 = c.bkey1 AND b.key2 = c.bkey2
```

Informix® also supports the ANSI OUTER join syntax, which is the recommended way to specify outer joins with recent SQL database engines:

```sql
SELECT ... FROM cust LEFT OUTER JOIN order  
LEFT OUTER JOIN item  
ON cust.key = order.custno  
ON order.key = item.ordno  
WHERE order.cdate > current date
```

**ORACLE**

Oracle supports the ANSI outer join syntax:

```sql
SELECT ...  
FROM cust LEFT OUTER JOIN order  
LEFT OUTER JOIN item  
ON order.key = item.ordno  
ON cust.key = order.custno  
WHERE order.cdate > current date
```

The ORACLE legacy outer join specification uses the (+) notation.
The (+) symbol must be placed after columns of the tables which must have NULL values when no record matches the condition:

```
SELECT ... FROM a, b WHERE a.key = b.key (+)
```

```
SELECT ... FROM a, b, c WHERE a.key = b.akey (+)
  AND b.key1 = c.bkey1 (+)
  AND b.key2 = c.bkey2 (+)
```

When using additional conditions on outer tables, the (+) operator also has to be used. For example:

```
SELECT ... FROM a, OUTER(b) WHERE a.key = b.akey AND b.colx > 10
```

Must be converted to:

```
SELECT ... FROM a, b WHERE a.key = b.akey (+)
  AND b.colx (+) > 10
```

The ORACLE outer joins restriction:

In a query that performs outer joins of more than two pairs of tables, a single table can only be the NULL generated table for one other table. The following case is not allowed: WHERE a.col = b.col (+) AND b.col (+) = c.col

**Solution**

The Genero database drivers can convert Informix® OUTER specifications to ANSI outer joins.

**Note:** For better SQL portability, use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The outer join translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemul.outers =  
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**• Prerequisites:**

1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.

   Example which does not work:

   ```
   ... FROM OUTER(tab2), tab1
   ```

2. The outer join in the WHERE clause must use the table name as prefix:

   ```
   ... WHERE tab1.col1 = tab2.col2
   ```

**• Restrictions:**

1. Statements composed by 2 or more SELECT instructions are not supported:

   ```
   SELECT ... UNION SELECT ...
   ```

   or:

   ```
   SELECT ... WHERE col IN (SELECT...)
   ```

2. Additional conditions on outer table columns cannot be detected and therefore are not supported:

   ```
   ... FROM tab1, OUTER(tab2)
   WHERE tab1.col1 = tab2.col2
   ```
AND tab2.colx > 10

• **Notes:**

1. Table aliases are detected in OUTER expressions.

   OUTER example with table alias:

   ```
   ... OUTER(tab1 alias1) ...
   ```

2. In the outer join, `outertab.col` can be placed on both right or left sides of the equal sign:

   ```
   ... WHERE outertab.col1 = maintab.col2
   ```

3. Table names detection is not case-sensitive:

   ```
   SELECT ... FROM tab1, TAB2
   WHERE tab1.col1 = tab2.col2
   ```

4. **Temporary tables** are supported in OUTER specifications:

   ```
   CREATE TEMP TABLE tt1 ( ... )
   SELECT ... FROM tab1, OUTER(tt1) ...
   ```

**Related concepts**

**Outer joins** on page 577
Use standard ISO outer join syntax instead of the old IBM® Informix® OUTER() syntax.

**Transactions handling**

**Informix®**

With the Informix® native mode (non ANSI):

- Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```
UPDATE tab1 SET ... -- auto-committed
BEGIN WORK -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK -- end of TX block
```

Informix® version 11.50 introduces savepoints:

```
SAVEPOINT name [UNIQUE]
ROLLBACK WORK TO SAVEPOINT name
RELEASE SAVEPOINT name
```

**ORACLE**

With ORACLE transactions:

- Beginnings of transactions are implicit.
- A transaction ends with a COMMIT or ROLLBACK statement.
- The current transaction is automatically committed when a DDL statement is executed.

```
UPDATE tab1 SET ... -- start of TX block
UPDATE tab2 SET ...
```
ORACLE supports savepoints too. However, there are differences:

- Savepoints cannot be declared as UNIQUE
- Rollback must always specify the savepoint name
- You cannot release savepoints (RELEASE SAVEPOINT)

**Solution**

Regarding transaction control instructions, BDL applications do not have to be modified in order to work with ORACLE. The Informix® behavior is simulated with an autocommit mode in the ORACLE interface. A switch to the explicit commit mode is done when a BEGIN WORK is performed by the BDL program.

When executing a DDL statement inside a transaction, ORACLE automatically commits the transaction. Therefore, you must extract the DDL statements from transaction blocks.

If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

See also SELECT FOR UPDATE

**Related concepts**

Database transactions on page 538

Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Temporary tables**

**Informix®**

Informix® temporary tables are created with the CREATE TEMP TABLE DDL instruction or with SELECT ... INTO TEMP statement:

```sql
CREATE TEMP TABLE tt1 ( pkey INT, name VARCHAR(50) )
CREATE TEMP TABLE tt2 ( pkey INT, name VARCHAR(50) ) WITH NO LOG
SELECT * FROM tab1 WHERE pkey > 100 INTO TEMP tt2
```

Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the DROP TABLE command. There is no name conflict when several users create temporary tables with the same name.

BDL REPORTs can create a temporary table when the rows are not sorted externally (by the source SQL statement).

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

When creating temporary tables in Informix®, the WITH NO LOG clause can be used to avoid the overhead of recording DML operations in transaction logs.

**Oracle**

Oracle® does not support temporary tables as Informix®.

Oracle® provides GLOBAL TEMPORARY TABLE command to create tables shared among several processes (only data is temporary and local to an SQL process).

**Solution**

In accordance with some prerequisites, temporary table creation in BDL programs can be supported by the database interface.
**Important:** When creating a temporary table, you perform a Data Definition Language statement. Oracle® automatically commits the current transaction when executing a DDL statement. Therefore, you must avoid temp table creation/destruction in transactions.

The general FGLPROFILE entry to control temporary table emulation is:

```sql
dbi.database.dsnname.ifxemul.temptables = { true | false }
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

The temporary table emulation can use regular tables or GLOBAL TEMPORARY tables. The way the driver converts Informix® temp table statements to Oracle® regular tables or global temporary tables is driven by the following FGLPROFILE entry:

```sql
dbi.database.dbname.ifxemul.temptables.emulation = { "default" | "global" }
```

By default, the database driver uses regular tables (the "default" emulation). This default emulation provides maximum compatibility with Informix® temporary tables, but requires real table creation which can be a significant overhead with Oracle®.

The "global" emulation uses native Oracle® Global Temporary Tables, requiring only one initial table creation and thus making programs run faster. However, the global emulation mode has to be used carefully because of some limitations and constraints.

With both emulation methods, you can control the schema and the tablespace used to create the Oracle® tables with the following FGLPROFILE parameters:

```sql
# Define the tablespace for Oracle tables:
#dbi.database.dbname.ora.temptables.tablespace = "mytemptabs"

# Get the schema from the current user name specified in connection command:
#dbi.database.dbname.ora.temptables.schema.source = "login"

# or, get the schema from a SELECT statement:
dbi.database.dbname.ora.temptables.schema.command = "SELECT SYS_CONTEXT('USERENV', 'SESSION_USER') FROM DUAL"
```

**Related concepts**

- Temporary tables on page 575
- Syntax for temporary table creation is not unique across all database engines.
- Oracle DB specific FGLPROFILE parameters on page 617

**Using the default temporary table emulation**

The default temporary table emulation is provided to achieve a high level of Informix® compatibility, when minimal code change is required.

**How does the default emulation work?**

- Informix® CREATE TEMP TABLE and SELECT INTO TEMP statements are automatically converted to ORACLE "CREATE TABLE". The name of the temporary table is converted to a unique table name.
- By default, Oracle tables are created in the current schema (i.e. no schema prefix is added to the generated table name). In order to control the schema where the Oracle tables are created, use the following FGLPROFILE parameters:
When specifying "login" in the ora.temptables.schema.source parameter, the user name passed to the connection instruction will be used as schema name. When specifying "command" as schema source, the schema name will be produced by the SELECT statement defined in the ora.temptables.schema.command parameter.

Schema specification for temporary table emulations is mandatory when you have created a DB user for each end user, and you force common schema usage with the ora.schema parameter:

```java
dbi.database.dsnname.ora.schema = "app_owner"
```

In such case, it is better to add the current user as schema name for temporary tables, to get Oracle tables created in the current user schema, instead of creating table in the common schema: Creating tables in another schema requires CREATE ANY TABLE / DROP ANY TABLE privileges for each DB user, which is not possible in an organization using strong security policy.

- By default, temporary tables are created in a dedicated tablespace named "TEMPTABS". Of course the TEMPTABS tablespace must exist before running programs, otherwise temporary table creation will fail. Using a specific tablespace for temporary tables allows you to specify storage options, for example to use a physical device which can be different from the disk drive used for real data storage. Additionally, backups of permanent application tables can be performed without the data of temporary tables.

If required, you can specify another tablespace name for Oracle tables with the following FGLPROFILE entry:

```java
dbi.database.dsnname.ora.temptables.tablespace = "mytemptabs"
```

- Starting with Oracle 10g, dropped tables are saved in the recycle bin by default. You may want to avoid the recycle bin feature at the database level or session level with:

  ```sql
  ALTER SYSTEM SET recyclebin = OFF scope=spfile
  ```
  
or, at current session level only:

  ```sql
  ALTER SESSION SET recyclebin = OFF
  ```

- Once the temporary table has been created, all other SQL statements performed in the current SQL session are parsed to convert the original table name to the corresponding unique table name.

- When the BDL program disconnects from the database (for example, when it ends or when a CLOSE DATABASE instruction is executed), the tables which have not been removed with an explicit "DROP TABLE" are automatically removed by the database interface. However, if the program crashes, the tables will remain in the database, so you may need to cleanup the database from time to time.

**Prerequisites when using the default emulation**

- Application users must have sufficient privileges to create database tables in the schema used to create the Oracle table (usually, "CONNECT" and "RESOURCE" roles).

- Create a dedicated tablespace for Oracle tables created. The default tablespace is named "TEMPTABS", but it can be another tablespace defined by the ora.temptables.tablespace FGLPROFILE entry as described before.

  The tablespace must be of type "permanent", as it will hold permanent tables used to emulate Informix® temp tables.

  Make sure the tablespace is big enough to hold all the data, and check for automatic extension.

  When using a PDB, the tablespace must be created in the context of the PDB.

```sql
CREATE TABLESPACE temptabs
  DATAFILE 'file-path' SIZE 1M AUTOEXTEND ON;
-- Give privileges on temptabs tablespace to other users
ALTER USER dbuser QUOTA UNLIMITED ON TEMPTABS;
```
For more details, see "CREATE TABLESPACE" in the Oracle documentation.

**Limitations of the default emulation**

- When using the default emulation, the real name of an emulated temporary table will have the following format:

  tt$number$_original_name

  Where *number* is the Oracle AUDSID session id returned by:

  ```sql
  SELECT USERENV('SESSIONID') FROM DUAL
  ```

  As Oracle 9i and 10g table names cannot exceed 30 characters in length, and since session ids are persistent over server shutdown, you must pay attention to the names of your temporary tables. For example, if you create a temp table with the name TEMP_CUSTOMER_INVOICES (22c) it leaves 30 - (3 + 22) = 5 characters left for the session id, which gives a limit of 99999 sessions.

  To workaround this limitation, you can provide your own SQL command to generate a unique session id with the following FGLPROFILE entry:

  ```sql
  dbi.database.dbname.ora.sid.command = "select ...
  ```

  As an example, you can use the SID column value from V$SESSION:

  ```sql
  SELECT SID FROM V$SESSION WHERE AUDSID = USERENV('SESSIONID')
  ```

- Application tables and columns cannot use the same table name as the name generated for temporary tables. Make sure you are not using table or column names with the format:

  tt$number$_name

- Tokens matching the original table names are converted to unique names in all SQL statements. Make sure you are not using the temp table name for other database objects, like columns. The following example illustrates this limitation:

  ```sql
  CREATE TABLE tab1 ( key INTEGER, tmp1 CHAR(20) )
  CREATE TEMP TABLE tmp1 ( col1 INTEGER, col2 CHAR(20) )
  SELECT tmp1 FROM tab1 WHERE ...
  ```

**Maintenance of default emulation**

- If you want to list the tables created by a specific user, do this:

  ```sql
  SELECT * FROM ALL_TABLES WHERE OWNER = 'user_name'
  ```

  As with other database object names, the user name is stored in uppercase letters if it has been created without using double quotes (create user scott ... = stored name is "SCOTT").

**Creating indexes on temporary tables with default emulation**

- Indexes created on temporary tables must have unique names also. The database interface detects CREATE INDEX statements which are using temporary tables and converts the index name to unique names. Indexes created on temporary tables follow the same storage and schema settings as for the CREATE TABLE statements: Schema and tablespace specification of FGLPROFILE will also be applied to CREATE INDEX commands.

  - DROP INDEX statements are also detected to replace the original index name by the real name.
SERIALs in temporary table creation with default emulation

- You can use the SERIAL data type when creating a temporary table.
  Sequences and triggers will be created in the current schema.
  See issue about SERIALs for more details.

Using the global temporary table emulation

The global temporary table emulation is provided to get benefit of the Oracle® GLOBAL TEMPORARY TABLES, by sharing the same table structure with multiple SQL sessions, reducing the cost of the CREATE TABLE statement execution. However, this emulation does not provide the same level of Informix® compatibility as the default emulation, and must be used carefully.

How does the global emulation work?

- Informix® CREATE TEMP TABLE and SELECT INTO TEMP statements are automatically converted to Oracle® "CREATE GLOBAL TEMPORARY TABLE" statements. The original table name is kept, but it gets by default a "TEMPTABS" schema prefix, to share the underlying table structure with other database users.

In order to control the schema where the Oracle® global temporary tables are created, use the following FGLPROFILE parameters:

```plaintext
dbi.database.dsname.ora.temptables.schema.source = "$login" "$command" $schema
```

Note: The purpose of global temporary tables is to create the table once in Oracle® and have all users share the same table structure. Therefore the default "TEMPTABS" schema is considered sufficient for this emulation method.

- The Global Temporary Tables are created with the "ON COMMIT PRESERVE ROWS" option, to keep the rows in the table when a transaction ends.
- If the global temporary table to be created exists already, error ORA-00955 will be ignored by the database driver. This allows to do several CREATE TEMP TABLE statements in your programs with no SQL error, to emulate the Informix® behavior. This works fine as long as the table name is unique for a given structure (column count and data types must match).

Note: Since DROP TABLE statements are converted to DELETE statements, you might want to use Oracle® sqlplus to issue a real DROP TABLE of global temporary tables, to make a real cleanup from time to time.

- By default, global temporary table is created without any tablespace option, and thus will be created in the default tablespace assigned to the current user.

If required, you can specify another tablespace name for Oracle® tables with the following FGLPROFILE entry:

```plaintext
dbi.database.dsname.ora.temptables.tablespace = "mytemptabs"
```

- Once the Global Temporary Table has been created, all other SQL statements performed in the current SQL session are parsed to convert the original table name to schema.original-tablename.
- When doing a DROP TABLE temp-table statement in the program, the database driver converts it to a DELETE statement, to remove all data added by the current session. A next CREATE TEMP TABLE or SELECT INTO TEMP will fail with error ORA-00955 but since this error is ignored, it will be transparent for the program. We cannot use TRUNCATE TABLE because that would require at least DROP ANY TABLE privileges for all users.
- When the BDL program disconnects from the database (for example, when it ends or when a CLOSE DATABASE instruction is executed), the tables that have not been dropped by the program with an explicit DROP TABLE statement will be automatically cleaned by Oracle.
Prerequisites when using the global emulation

- You must create a database user (schema) dedicated to this emulation, the default name is "TEMPTABS":

```
CREATE USER temptabs IDENTIFIED BY pswd;
```

- If your programs need to create temporary tables on the fly with this method, you must grant CREATE ANY TABLE + CREATE ANY INDEX system privilege to all DB users. This is not a good practice for security reasons. You better "prepare" the database by creating the Global Temporary Table (when using the default schema, create it with the TEMPTABS user). Do not forget to specify ON COMMIT PRESERVE ROWS option. Then grant INSERT, UPDATE, DELETE and SELECT object privileges to PUBLIC, for example:

```
CREATE GLOBAL TEMPORARY TABLE temptabs.mytable
  ( k INT PRIMARY KEY, c CHAR(10) ) ON COMMIT PRESERVE ROWS;
CREATE UNIQUE INDEX temptabs.ix1 ON temptabs.mytable ( c );
GRANT SELECT, UPDATE, INSERT, DELETE ON temptabs.mytable TO PUBLIC;
```

For testing purpose, consider using a user with DBA privileges, to simplify the configuration.

Limitations of the global emulation

- Global Temporary Tables are shared by multiple users/sessions. In order to have the global emulation working properly, each temporary table name must be unique for a given table structure, for all programs. Avoid using temp tables names such as "tmp1". It is recommended to use table names as follows:

```
CREATE TEMP TABLE custinfo_1 
  ( cust_id INTEGER, 
    cust_name VARCHAR(50) 
  );
CREATE TEMP TABLE custinfo_2 
  ( cust_id INTEGER, 
    cust_name VARCHAR(50),
    cust_addr VARCHAR(200) 
  );
```

- Tokens matching the original table names are converted to unique names in all SQL statements. Make sure you are not using the temp table name for other database objects, like columns. The following example illustrates this limitation:

```
CREATE TABLE tab1 ( key INTEGER, tmp1 CHAR(20) );
CREATE TEMP TABLE tmp1 ( col1 INTEGER, col2 CHAR(20) );
SELECT tmp1 FROM tab1 WHERE ...  
```

Creating indexes on temporary tables with global emulation

- Indexes created on temporary tables get also the TEMPTABS schema prefix by default. Indexes created on temporary tables follow the same storage and schema settings as for the CREATE GLOBAL TEMPORARY TABLE statements: Schema and tablespace specification of FGLPROFILE will also be applied to CREATE INDEX commands.

- When executing a DROP INDEX statement on a temporary table in a program, the database driver just ignores the statement.

SERIALs in temporary table creation with global emulation

- You can use the SERIAL data type when creating a temporary table.

  Sequences and triggers will be created in the TEMPTABS schema too.

  See issue about SERIALs for more details.
Substrings in SQL

Informix®

Informix® SQL statements can use subscripts on columns defined with the character data type:

```
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R'  -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ... 
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

**Important:** With other database servers as Informix®, when the subscript notation is used to modify column values in UPDATE statement, or as ORDER BY element, you will get an SQL error:

```
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

**ORACLE**

ORACLE provides the `SUBSTR()` function, to extract a substring from a string expression:

```
SELECT .... FROM tab1 WHERE SUBSTR(col1,2,2) = 'RO'
SELECT SUBSTR('Some text',6,3)FROM DUAL  -- Gives 'tex'
```

**Solution**

Replace all Informix® `col[x,y]` right-value expressions by `SUBSTR(col,x,y-x+1)`.

Rewrite UPDATE and ORDER BY clauses using `col[x,y]` expressions.

The translation of `col[x,y]` expressions can be controlled with the following FGLPROFILE entry:

```
  dbi.database.dsnname.ifxemul.colsubs = [ true | false ]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Substring expressions on page 577

Handle substrings expressions with different database engines.

**The LENGTH() function**

**Informix®**

Informix® provides the `LENGTH()` function to count the number of bytes of a character string expression:

```
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```

Informix® `LENGTH()` does not count the trailing blanks for CHAR or VARCHAR expressions, while Oracle counts the trailing blanks.

Informix® `LENGTH()` returns 0 when the given string is empty. That means, `LENGTH('') = 0`.

**ORACLE**

Oracle supports the `LENGTH()` function, but there are some differences with Informix® `LENGTH()`.

The Oracle `LENGTH()` function counts trailing blanks. When using a CHAR column, values are blank padded, and the function returns the size of the CHAR column. When using a VARCHAR column, trailing blanks are significant, and the function returns the number of characters, including trailing blanks.
Because ORACLE handles empty strings (""") as NULL values, writing LENGTH ("") is equivalent to LENGTH (NULL). In this case, the function returns NULL.

Solution

Check if the trailing blanks are significant when using the LENGTH() SQL function in your application.

To count the number of character by ignoring the trailing blanks, use the RTRIM() function:

```
SELECT LENGTH(RTRIM(col)) FROM table
```

SQL conditions which verify that the result of LENGTH() is greater that a given number do not have to be changed, because the expression evaluates to false if the given string is empty (NULL>n):

```
SELECT * FROM x WHERE LENGTH(col)>0
```

Only SQL conditions that compare the result of LENGTH() to zero will not work if the column is NULL. You must check your BDL code for such conditions:

```
SELECT * FROM x WHERE LENGTH(col)=0
```

In this case, you must add a test to verify if the column is null:

```
SELECT * FROM x WHERE (LENGTH(col)=0 OR col IS NULL)
```

In addition, when retrieving the result of a LENGTH() expression into a BDL variable, you must check that the variable is not NULL.

In ORACLE, you can use the NVL() function in order to get a non-null value:

```
SELECT * FROM x WHERE NVL(LENGTH(c),0)=0
```

Since Informix® supports the NVL() function, you can write the same SQL for both Informix® and ORACLE, as shown in this example.

The translation of LENGTH() expressions can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemul.length = { true | false }
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

The LENGTH() function in SQL on page 581

The semantics of the LENGTH() SQL function differs according to the database engine.

Empty character strings

Informix®

Informix® SQL considers empty strings ("" or "") as a non-NULL string with a length of zero.

Note:

In Genero BDL, when setting a variable with an empty string constant, it is automatically set to a NULL value:

```
DEFINE x char(10)
LET x = ""
IF x IS NULL THEN -- evaluates to TRUE
  ...
END IF
```
ORACLE

Oracle® SQL considers empty strings ('') as NULL.

Using literal string values that are empty ('') for INSERT or UPDATE statements will result in the storage of NULL values with Oracle®, while Informix® stores the value as a string with a length of zero:

```sql
INSERT INTO tab1 ( col1, col2 ) VALUES ( NULL, '' )
```

Using comparison operators (col='') with Oracle® makes no sense, because an empty string is equivalent to NULL: The correct SQL expression is (col IS NULL).

```sql
SELECT * FROM tab1 WHERE col2 IS NULL
```

Solution

To increase portability, it is recommended that you avoid the usage of literal string values with a length of zero in SQL statements. Instead, use the NULL constant, or program variables.

String delimiters

Informix®

The ANSI SQL string delimiter character is the single quote ('string'), while double quotes are used to delimit database object names:

```sql
SELECT ... WHERE "tabname"."colname" = 'a string value'
```

In Informix® databases created in native mode (non-ANSI), you can use double quotes as string delimiters:

```sql
SELECT ... WHERE tabname.colname = 'a string value'
```

This is important, since many BDL programs use that character to delimit the strings in SQL commands.

Note: This problem concerns only double quotes within SQL statements. Double quotes used in pure BDL string expressions are not subject to SQL compatibility problems.

ORACLE

ORACLE follows the ANSI SQL specification, using single quotes for string delimiters and double quotes for database object names.

Solution

When using Static SQL statements, the fglcomp compiler converts string literals using double quotes to string literals with single quotes:

```
$ cat s.4gl
MAIN
   DEFINE n INT
   SELECT COUNT(*) INTO n FROM tab1 WHERE col1 = "abc"
END MAIN
```

```
$ fglcomp -S s.4gl
s.4gl^3^SELECT COUNT(*) FROM tab1 WHERE col1 = 'abc'
```

However, SQL statements created dynamically are not modified by the Genero compiler.

The Genero database interface can automatically replace all double quotes by single quotes in SQL statements. This applies to static and dynamic SQL statements.
The translation of double quoted expression to single quoted expressions can be controlled with the following FGLPROFILE entry:

```
dbi.database.dbname.ifxemul.dblquotes = [ true | false ]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

However, database object names must not be delimited by double quotes, because the database interface cannot determine the difference between a database object name and a quoted string! For example, if the program executes the SQL statement:

```
... WHERE "tabname"."colname" = "a string value"
```

replacing all double quotes by single quotes would produce:

```
... WHERE 'tabname'.'colname' = 'a string value'
```

This would produce an error since 'tabname'.colname' is not allowed by ORACLE.

Escaped string delimiters can be used inside strings like the following:

```
'This is a single quote: ''
'This is a single quote: \'
"This is a double quote: '"
"This is a double quote: \
```

Although double quotes are replaced automatically in SQL statements, it is recommended that you use only single quotes to enforce portability.

**Related concepts**

String literals in SQL statements on page 570

Single quotes is the standard for delimiting string literals in SQL.

**Single row SELECT**

**Informix®**

With Informix®, you must use the system table with a condition on the table id:

```
SELECT user FROM systables WHERE tabid=1
```

**ORACLE**

Oracle provides the DUAL table to generate one row only:

```
SELECT user FROM DUAL
```

**Solution**

Check the BDL sources for "FROM systables WHERE tabid=1" and use dynamic SQL to resolve this problem.

Consider writing a FUNCTION which produces the FROM and WHERE part, depending on the target database type.

**MATCHES and LIKE**

**Informix®**

Informix® supports MATCHES and LIKE operators in SQL statements.
MATCHES expects * and ? wild-card characters, while LIKE uses the % and _ wild-cards as equivalents.

\[
\begin{align*}
& ( \text{col MATCHES 'Smi*' AND col NOT MATCHES 'R?x'} ) \\
& ( \text{col LIKE 'Smi%' AND col NOT LIKE 'R_x'} )
\end{align*}
\]

MATCHES accepts also brackets notation, to specify a set of matching characters at a given position:

\[
\begin{align*}
& ( \text{col MATCHES '[Pp]aris'} ) \\
& ( \text{col MATCHES '[0-9][a-z]*'} )
\end{align*}
\]

**ORACLE**

Oracle\textsuperscript{®} does not provide an equivalent of the Informix\textsuperscript{®} MATCHES operator.

The LIKE operator is supported.

**Important:** With Oracle\textsuperscript{®}, columns defined as \texttt{CHAR(N)} are blank padded, and trailing blanks are significant in LIKE expressions. As a result, with a \texttt{CHAR(5)} value such as 'abc ' (with 2 trailing blanks), the expression (colname LIKE 'ab_') will not match. To workaround this behavior, you can use \texttt{(RTRIM(colname) LIKE 'pattern')}. However, consider adding the condition \texttt{AND (colname LIKE 'pattern%')} to force the DB server to optimize the query of the column as indexed. The CONSTRUCT instruction uses this technique when the entered criteria does not end with a * star wildcard.

**Solution**

The database driver is able to translate Informix\textsuperscript{®} MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.

The MATCHES to LIKE expression translation is controlled by the following FGLPROFILE entry:

```
\begin{verbatim}
dbi.database.dbname.ifxemul.matches = true \| false 
\end{verbatim}
```

**Important:** Only [NOT] MATCHES followed by a search pattern provided as a string literal can be converted by ODI drivers. A [NOT] MATCHES followed by a ? question mark parameter place holder is not translated!

For maximum portability, consider replacing the MATCHES expressions with LIKE expressions in all SQL statements.

Avoid using \texttt{CHAR(N)} types for variable length character data (such as name, address).

**Related concepts**

- MATCHES and LIKE operators on page 579
- Use the standard LIKE operator instead of the MATCHES operator.
- Query by example (CONSTRUCT) on page 1461

**SELECT * (asterisk)**

Informix\textsuperscript{®}

Informix\textsuperscript{®} allows you to use the star character in the select list along with other expressions:

```
SELECT col1, * FROM tab1 ...
```

**ORACLE**

Oracle\textsuperscript{®} does not support the asterisk notation after another expression in the SELECT list.
Use the table name as a prefix to the star:

```
SELECT col1, tab1.* FROM tab1 ...
```

**Solution**

Always use the table name before the star.

**BDL programming**

Oracle Database related programming topics.

**SQL errors on PREPARE**

**Informix®**

With Informix®, a PREPARE instruction returns an SQL error in case of problem:

```
TRY
  PREPARE stmt FROM "SELECT * FROM WHERE pk=1" -- table is missing!
CATCH
  DISPLAY "SQL ERROR:", SQLCA.SQLCODE
END TRY
```

**ORACLE**

The Oracle® interface is implemented with the Oracle® Call Interface (OCI). This library does not provide a way to send SQL statements to the database server during the BDL PREPARE instruction, as in the Informix® interface.

When preparing an SQL statement with the BDL PREPARE or DECLARE instruction, no SQL error will be returned if the SQL statement is invalid. However, an SQL error will occur after the OPEN / FOREACH / EXECUTE instructions.

**Solution**

Make sure your BDL programs do not test the STATUS or SQLCA.SQLCODE variable just after PREPARE instructions.

Change the program logic in order to handle the SQL errors when opening the cursors (OPEN) or when executing SQL statements (EXECUTE).

**Related concepts**

The SQLCA diagnostic record on page 532

The SQLCA variable is a predefined record containing SQL statement execution information.

**INSERT cursors**

**Informix®**

Informix® provides insert cursors to optimize row creation in a database. An insert cursor is declared as a cursor, and rows as added with the PUT instruction. The rows are buffered and sent to the database server when executing a FLUSH instruction, or when the cursor is closed with CLOSE. When using transactions in Informix®, the OPEN, PUT and FLUSH instructions must be executed within a transaction block.

```
DECLARE c1 CURSOR FOR INSERT INTO tab1 ...
BEGIN WORK
  OPEN c1
  WHILE ...
    PUT c1 USING var-list
  END WHILE
CLOSE c1
```
ORACLE

ORACLE does not support insert cursors.

Solution

Insert cursors are emulated by the database interface, using basic INSERT SQL instructions. The performances might be not as good as with Informix®, but the feature is fully supported.

Related concepts

Insert cursors on page 569
Using insert cursors with non-Informix databases.

Cursors WITH HOLD

Informix®

Informix® closes opened cursors automatically when a transaction ends, unless the WITH HOLD option is used in the DECLARE instruction:

```
DECLARE c1 CURSOR WITH HOLD FOR SELECT ...  
OPEN c1  
BEGIN WORK  
FETCH c1 ...  
COMMIT WORK  
FETCH c1 ...  
CLOSE c1
```

ORACLE

With ORACLE, opened cursors using SELECT statements without a FOR UPDATE clause are not closed when a transaction ends: All ORACLE cursors are WITH HOLD cursors unless the FOR UPDATE clause is used in the SELECT statement.

Solution

BDL cursors that are not declared WITH HOLD are automatically closed by the database interface when a COMMIT WORK or ROLLBACK WORK is performed.

Since ORACLE automatically closes FOR UPDATE cursors when the transaction ends, opening cursors declared FOR UPDATE and WITH HOLD results in an SQL error that does not normally appear with Informix® under the same conditions.

Review the program logic in order to find another way to set locks.

Related concepts

WITH HOLD and FOR UPDATE on page 568
Hold cursors and not portable.

SELECT ... FOR UPDATE

Informix®

Legacy BDL programs typically use a cursor with SELECT FOR UPDATE to implement pessimistic locking and avoid several users editing the same rows:

```
DECLARE cc CURSOR FOR ...
```
```sql
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

The row must be fetched in order to set the lock.

If the cursor is local to a transaction, the lock is released when the transaction ends. If the cursor is declared WITH HOLD, the lock is released when the cursor is closed.

Informix® provides the `SET LOCK MODE` instruction to define the lock wait timeout:

```sql
SET LOCK MODE TO { WAIT | NOT WAIT | WAIT [seconds] }
```

The default mode is NOT WAIT.

**ORACLE**

ORACLE allows individual and exclusive row locking with:

```sql
SELECT ... FOR UPDATE [OF col-list]
```

A lock is acquired for each selected row when the cursor is opened, before the first fetch.

Cursors using `SELECT ... FOR UPDATE` are automatically closed when the transaction ends.

Locks are not released when a cursor is closed.

ORACLE's locking granularity is at the row level.

The `NOWAIT` keyword can be used in `SELECT ... FOR UPDATE` statement, the return immediately if the row is already locked by another user:

```sql
SELECT ... FOR UPDATE [OF col-list] NOWAIT
```

**Solution**

**Important:** Cursors declared with `SELECT ... FOR UPDATE` using the WITH HOLD clause cannot be supported with ORACLE.

The database interface is based on an emulation of an Informix® engine using transaction logging.

Opening a `SELECT ... FOR UPDATE` cursor declared outside a transaction will raise an SQL error -255 (not in transaction).

When using pessimistic locking with `DECLARE ... CURSOR FOR SELECT ... FOR UPDATE`, review the program logic to have `OPEN` and `CLOSE` instructions inside transactions (`BEGIN WORK + COMMIT WORK / ROLLBACK WORK`).

See also **Cursors with Hold** and **UPDATE/DELETE WHERE CURRENT OF** for more details.

**Related concepts**

**WITH HOLD and FOR UPDATE** on page 568

Hold cursors and not portable.

**UPDATE/DELETE ... WHERE CURRENT OF**

Informix®

Informix® allows positioned UPDATEs and DELETEs with the "WHERE CURRENT OF cursor" clause, if the cursor has been DECLARED with a `SELECT ... FOR UPDATE` statement.
**ORACLE**

The **UPDATE/DELETE ... WHERE CURRENT OF cursor** statements are not supported by the Oracle database API.

However, ROWIDs can be used for positioned updates and deletes.

**Solution**

**UPDATE/DELETE ... WHERE CURRENT OF** instructions are emulated by the ORACLE database interface by using ROWIDs:

The ORACLE database interface replaces **WHERE CURRENT OF cursor** by **WHERE ROWID=:rid** and sets the value of the ROWID returned by the last FETCH done with the given cursor.

**Related concepts**

- Positioned **UPDATE/DELETE** on page 567
- Using positioned updates/deletes with named database cursors.

**LOAD and UNLOAD**

**Informix®**

Informix® provides two SQL instructions to export / import data from / into a database table:

The **UNLOAD** instruction copies rows from a database table into a text file:

```
UNLOAD TO "filename.unl" SELECT * FROM tab1 WHERE ..
```

The **LOAD** instructions insert rows from a text file into a database table:

```
LOAD FROM "filename.unl" INSERT INTO tab1
```

**ORACLE**

ORACLE provides tools like SQL*Plus and SQL*Loader to load/unload data from a database.

**Solution**

**LOAD** and **UNLOAD** instruction are implemented in the Genero BDL runtime system with basic **INSERT** (for **LOAD**) or **SELECT** (for **UNLOAD**) SQL commands. The **LOAD** and **UNLOAD** instruction can be supported with various database servers.

However, **LOAD** and **UNLOAD** require the description of the column types in order to work, that can lead to some differences in the data formatting.

**Note:** If no transaction is started, the **LOAD** instruction will automatically execute a **BEGIN WORK** and **COMMIT WORK** when finished, or **ROLLBACK WORK** if a row insertion failed while loading. Terminating a transaction will automatically close cursors not defined **WITH HOLD** option. To workaround this situation, see more details in the **LOAD** on page 684 reference topic.

The **LOAD** and **UNLOAD** BDL instructions are supported with **ORACLE** with some limitations:

- There is a difference when using **ORACLE DATE** columns. **DATE** columns created in the ORACLE database are equivalent to Informix® **DATETIME YEAR TO SECOND** columns. In **LOAD** and **UNLOAD**, all **ORACLE DATE** columns are treated as Informix® **DATETIME YEAR TO SECOND** columns and thus will be unloaded with the "**YYYY-MM-DD hh:mm:ss**" format.
- Informix® **INTEGER** and **SMALLINT** are mapped to **ORACLE NUMBER(?)** columns. Those values will be unloaded as Informix® **DECIMAL(10)** and **DECIMAL(5)** values, that is, with a trailing dot-zero ".0".
- When using an Informix® database, simple dates are unloaded using the **DBDATE** format (ex: "23/12/1998"). Unloading from an Informix® database for loading into an ORACLE database is not supported.
Related concepts
LOAD and UNLOAD instructions on page 574
The LOAD and UNLOAD instructions can produce different data formats depending on the database server type.

SQL Interruption

Informix®
With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

ORACLE
Oracle supports SQL Interruption: The db client must issue an OCIBreak() OCI call to interrupt a query.

Solution
The ORACLE database driver supports SQL interruption and converts the native SQL error code -1013 to the Informix® error code -213.

Related concepts
Using SQL interruption on page 539
Interrupt long running SQL queries, or interrupt queries waiting for locked data.

Scrollable cursors

Informix®
Informix® SQL and Genero BDL support scrollable cursors when you specify the SCROLL clause in the DECLARE cursor instruction:

```
DECLARE c1 SCROLL CURSOR FOR SELECT ...
```

ORACLE
Oracle OCI supports native scrollable cursors with the OCI_STMT_SCROLLABLE_READONLY statement attribute.

Solution
The Oracle database driver uses native scrollable cursors by setting the OCI_STMT_SCROLLABLE_READONLY statement attribute.

Related concepts
Scrollable cursors on page 560
How scrollable cursors can be supported on different databases.

PostgreSQL

Supported versions
Genero BDL supports the following PostgreSQL versions:
- PostgreSQL 9.4 to 9.6
- PostgreSQL 10

Installation (Runtime Configuration)
PostgreSQL related installation topics.
Install PostgreSQL and create a database - database configuration/design tasks
If you are tasked with installing and configuring the database, here is a list of steps to be taken:
1. Compile and install the PostgreSQL Server on your computer. PostgreSQL is a free database, you can download the sources from [www.postgresql.org](http://www.postgresql.org).

2. Read PostgreSQL installation notes for details about the "data" directory creation with the initdb utility.

3. Set configuration parameters in postgresql.conf:
   a) PostgreSQL 9.1 and higher have by default the standard_conforming_strings parameter set to on. The ODI drivers for PostgreSQL 9.1 and + do no longer escape the backslash characters in string literals with a second backslash.
   b) If ROWIDs are used in the applications, these are converted to PostgreSQL OIDs. However, this feature is disabled by default.

   In order to get OIDs in PostgreSQL, set the default_with_oid server parameter to on.

   Start a postmaster process to listen to database client connections.

   **Important:** If you want to connect through TCP (for example from a Windows™ PostgreSQL client), you must start postmaster with the -i option and setup the "pg_hba.conf" file for security (trusted hosts and users).

4. Create a PostgreSQL database with the createdb utility, by specifying the character set of the database.

   ```
   $ createdb -h hostname dbname --encoding encoding --locale locale
   ```

5. If you plan to use SERIAL emulation, you need the plpgsql procedure language, because the database interface uses this language to create serial triggers.

   Make sure that the plpgsql language is supported by the PostgreSQL version you are using. Starting with PostgreSQL 9.0, this stored procedure language is available by default.

6. Connect to the database as the administrator user and create a database user dedicated to your application, the application administrator:

   ```
   dbname=# CREATE USER appadmin PASSWORD 'password';
   CREATE USER
   dbname=# GRANT ALL PRIVILEGES ON DATABASE dbname TO appadmin;
   GRANT
   dbname=# \q
   ```

7. Create the application tables.

   Convert Informix® data types to PostgreSQL data types. See Data type conversion table: Informix to PostgreSQL on page 894 for more details.

8. If you plan to use the SERIAL emulation, you must prepare the database.

   See SERIAL data types on page 903 for more details.

**Prepare the runtime environment - connecting to the database**

1. In order to connect to PostgreSQL, you must have a PostgreSQL database driver "dbmpgs" in FGLDIR/dbdrivers.

   On HP/UX LP64, the PostgreSQL database driver must be linked with the libxnet library if you want to use networking.

2. The PostgreSQL client software is required to connect to a database server.

   Check whether the PostgreSQL client library (libpq.*) is installed on the machine where the BDL programs run.

3. Make sure that the PostgreSQL client environment variables are properly set.

   Check, for example, PGDIR (the path to the installation directory), PGDATA (the path to the data files directory), etc. See the PostgreSQL documentation for more details.

4. Check the database client locale settings (for example, set the PGCLIENTENCODING environment variable).

   The database client locale must match the locale used by the runtime system (LC_ALL, LANG).

5. Verify the environment variable defining the search path for the PostgreSQL database client shared libraries (libpq.so on UNIX™, LIBPQ.DLL on Windows™).
Table 240: Shared library environment setting for PostgreSQL

<table>
<thead>
<tr>
<th>PostgreSQL version</th>
<th>Shared library environment setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>PostgreSQL 9.0 and higher</td>
<td><em>UNIX™</em>: Add $PGDIR/lib to LD_LIBRARY_PATH (or its equivalent).</td>
</tr>
<tr>
<td></td>
<td><em>Windows™</em>: Add %PGDIR%\bin to PATH.</td>
</tr>
</tbody>
</table>

6. To verify if the PostgreSQL client environment is correct, you can start the PostgreSQL command interpreter:

```bash
$ psql dbname -U appadmin -W
```

7. Set up the fglprofile entries for database connections.
   a) Define the PostgreSQL database driver:

   ```
   dbi.database.dbname.driver = "dbmpgs"
   ```

   b) The `source` parameter defines the name of the PostgreSQL database, as well as additional connection parameters if needed, such as the server host name, the TCP port and specific PostgreSQL connection options.

   ```
   dbi.database.dbname.source = "test1"
   ```

   The source parameter must have the following form:

   ```
   dbname[@host[:port]]?options]
   ```

   where:
   - `dbname` defines the name of the PostgreSQL database
   - `host` defines the server host name, or IP address (IPv6 host address needs to be enclosed in square brackets)
   - `port` defines the TCP port
   - `options` is a URI-style query string defining PostgreSQL connection parameters

   For example:

   ```
   mydb@orion:5433?connect_timeout=10&application_name=myapp
   ```

   c) Define pre-fetch rows.

   To improve performances, you can define the number of result set rows that the driver must prefetch:

   ```
   dbi.database.dbname.pgs.prefetch.rows = integer
   ```

   This will be applied to all application cursors.

   The default is 10 rows. Do not change the default, except if it gives really better performances: This can blow up memory usage for each DB client process.

   For more details, see PostgreSQL specific FGLPROFILE parameters on page 620.

**Database concepts**
PostgreSQL related database concepts topics.

**Database concepts**

Like Informix® servers, PostgreSQL can handle multiple database entities. Tables created by a user can be accessed without the owner prefix by other users as long as they have access privileges to these tables.
Solution
Create a PostgreSQL database for each Informix® database.

Data storage concepts
When converting from Informix® to PostgreSQL, the aim is to try to preserve as much of the data storage information as possible in the process. The most important storage decisions made for Informix® database objects (like initial sizes and physical placement) can be applied to the PostgreSQL database.

Storage concepts are quite similar in Informix® and in PostgreSQL, but the names are different.

Concurrency management

Data consistency and concurrency concepts
- Data Consistency applies to situations when readers want to access data currently being modified by writers.
- Concurrent Data Access applies to situations when several writers are accessing the same data for modification.
- Locking Granularity defines the amount of data concerned when a lock is set (for example, row, page, table).

Informix®
Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with UPDATE, INSERT or DELETE, an exclusive lock is set on the touched rows. The lock remains active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set shared locks, depending on isolation level. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification, or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the lock wait mode.

Control:
- Lock wait mode: SET LOCK MODE TO ...
- Isolation level: SET ISOLATION TO ...
- Locking granularity: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:
- The default isolation level is READ COMMITTED.
- The default lock wait mode is NOT WAIT.
- The default locking granularity is PAGE.

PostgreSQL
When data is modified, exclusive locks are set and held until the end of the transaction. For data consistency, PostgreSQL uses a multi-version consistency model: A copy of the original row is kept for readers before performing writer modifications. Readers do not have to wait for writers as in Informix®. The simplest way to think of the PostgreSQL implementation of read consistency is to imagine each user operating a private copy of the database, hence the multi-version consistency model. Since PostgreSQL 9.4, the lock wait mode for the current SQL session can be changed by updating the 'lock_timeout' parameter of the pg_settings system view. Locks are set at the row level in PostgreSQL and this cannot be changed.

Control:
- Lock wait mode: UPDATE pg_settings SET setting=ms WHERE name='lock_timeout'
- Isolation level: SET TRANSACTION ISOLATION LEVEL ...
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:
- The default isolation level is Read Committed.
The main difference between Informix® and PostgreSQL is that readers do not have to wait for writers in PostgreSQL.

**Solution**

The `SET ISOLATION TO` ... Informix® syntax is replaced by `SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL` ... in PostgreSQL. The next table shows the isolation level mappings done by the PostgreSQL database driver:

**Table 241: Isolation level mappings done by the PostgreSQL database driver**

<table>
<thead>
<tr>
<th>SET ISOLATION instruction in program</th>
<th>Native SQL command</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET ISOLATION TO DIRTY READ</td>
<td>SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL READ COMMITTED</td>
</tr>
<tr>
<td>SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]</td>
<td>SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL READ COMMITTED</td>
</tr>
<tr>
<td>SET ISOLATION TO CURSOR STABILITY</td>
<td>SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL READ COMMITTED</td>
</tr>
<tr>
<td>SET ISOLATION TO REPEATABLE READ</td>
<td>SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL SERIALIZABLE</td>
</tr>
</tbody>
</table>

For portability, it is recommended that you work with Informix® in the read committed isolation level, make processes wait for each other (lock mode wait), and create tables with the "lock mode row" option.

When using `SET LOCK MODE` ... in the programs, it will be converted to an `UPDATE pg_setting` instruction for PostgreSQL:

**Table 242: SET LOCK MODE as handled by the PostgreSQL database driver**

<table>
<thead>
<tr>
<th>SET LOCK MODE instruction in program</th>
<th>Native SQL command</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET LOCK MODE TO WAIT</td>
<td>UPDATE pg_settings SET setting=0 WHERE name='lock_timeout'</td>
</tr>
<tr>
<td>SET LOCK MODE TO WAIT seconds</td>
<td>UPDATE pg_settings SET setting= (seconds*1000) WHERE name='lock_timeout'</td>
</tr>
<tr>
<td>SET LOCK MODE TO NOT WAIT</td>
<td>UPDATE pg_settings SET setting=1 WHERE name='lock_timeout'</td>
</tr>
</tbody>
</table>

See the Informix® and PostgreSQL documentation for more details about data consistency, concurrency and locking mechanisms.

**Related concepts**

- **Concurrent data access** on page 537
  Understanding concurrent data access and data consistency.

- **Optimistic locking** on page 561
  Implementing optimistic locking to handle access concurrently to the same database records.

- **WITH HOLD and FOR UPDATE** on page 568
Transactions handling

Informix®

With the Informix® native mode (non ANSI):

- Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```
UPDATE tab1 SET ...   -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK           -- end of TX block
```

Informix® version 11.50 introduces savepoints:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT _name_  
RELEASE SAVEPOINT name
```

PostgreSQL

PostgreSQL supports transaction with savepoints:

- Transactions are started with `BEGIN WORK`.
- Transactions are validated with `COMMIT WORK`.
- Transactions are canceled with `ROLLBACK WORK`.
- Savepoints can be placed with `SAVEPOINT name`.
- Transactions can be rolled back to a savepoint with `ROLLBACK TO SAVEPOINT name`.
- Savepoints can be released with `RELEASE SAVEPOINT name`.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.
- If an SQL error occurs in a transaction, the whole transaction is aborted.

Transactions in stored procedures: avoid using transactions in stored procedures to allow the client applications to handle transactions, depending on the transaction model.

The main difference between Informix® and PostgreSQL resides in the fact that PostgreSQL cancels the entire transaction if an SQL error occurs in one of the statements executed inside the transaction. The following code example illustrates this difference:

```
CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
WHENEVER ERROR CONTINUE
BEGIN WORK
  INSERT INTO tab1 ( 1, 'abc' )
  INSERT INTO tab1 ( 1, 'abc' )
  -- PK constraint violation = SQL Error, whole TX is aborted
COMMIT WORK
```

With Informix®, this code will leave the table with one row inside, since the first INSERT statement succeeded. With PostgreSQL, the table will remain empty after executing this piece of code, because the server will rollback the whole transaction. To workaround this problem in PostgreSQL you can use `SAVEPOINT` as described in Solution on page 893.
Solution

Informix® transaction handling commands are automatically converted to PostgreSQL instructions to start, validate or cancel transactions.

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with PostgreSQL.

You must review the SQL statements inside BEGIN WORK / COMMIT WORK instruction and check if these can raise an SQL error. The SQL statements that can potentially raise an SQL error must be protected with a SAVEPOINT. If an error occurs, just rollback to the savepoint:

```
MAIN
  DATABASE test1
  CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
  WHENEVER ERROR CONTINUE
  BEGIN WORK
  INSERT INTO tab1 VALUES ( 1, 'abc' )
  CALL sql_protect()
  INSERT INTO tab1 VALUES ( 1, 'abc' )
  -- PK constraint violation = SQL Error
  CALL sql_unprotect()
  COMMIT WORK
END MAIN

FUNCTION sql_protect()
  IF fgl_db_driver_type()!='pgs' THEN
    RETURN
  END IF
  SAVEPOINT _sql_protect_
END FUNCTION

FUNCTION sql_unprotect()
  IF fgl_db_driver_type()!='pgs' THEN
    RETURN
  END IF
  IF SQLCA.SQLCODE < 0 THEN
    ROLLBACK WORK TO SAVEPOINT _sql_protect_
  ELSE
    RELEASE SAVEPOINT _sql_protect_
  END IF
END FUNCTION
```

Note: If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

Related concepts

Database transactions on page 538
Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

Database users

Informix®

Until version 11.70.xC2, Informix® database users must be created at the operating system level and must be members of the ‘informix’ group.

Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as in most other db servers.

Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.
PostgreSQL
PostgreSQL users must be registered in the database with the CREATE USER command:

```
dbname=# CREATE USER user-name PASSWORD 'password';
CREATE USER
dbname=# GRANT ALL PRIVILEGES ON DATABASE dbname TO user-name;
GRANT
```

**Solution**

Based on the application logic (if it is a multiuser application), you have to create one or several PostgreSQL users.

**Related concepts**

- Database users and security on page 547
  Properly identifying database users allows to use database security and audit features.

**Setting privileges**

**Informix®**

Informix® users must have at least the CONNECT privilege to access the database:

```
GRANT CONNECT TO username
```

Application administration users need the RESOURCE privilege to create tables:

```
GRANT RESOURCE TO username
```

Since version 7.20, Informix® supports database roles:

```
GRANT rolename TO username
```

**PostgreSQL**

PostgreSQL supports the concept of roles to grant or revoke permissions to a group of users.

See PostgreSQL documentation for more details.

**Solution**

Informix® and PostgreSQL user privileges management are quite similar.

**Data dictionary**

PostgreSQL related data dictionary topics.

TEXT | TEXT
BYTE | BYTEA

Notes:

1. For more details about serial emulation, see SERIAL data types on page 903.

**BOOLEAN data type**

**Informix®**

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values.

Genero BDL implements the BOOLEAN data type in a different way: A BOOLEAN variable stores integer values 1 or 0 (for TRUE or FALSE). This type is designed to hold the result of a boolean expression.

**PostgreSQL**

PostgreSQL supports the BOOLEAN data type and stores 't' or 'f' values for TRUE and FALSE representation.

**Note:** It is not possible to insert the integer values 1 or 0 into PostgreSQL BOOLEAN columns: Values must be true, false, 't', 'f', '1' or '0'.

**Solution**

The PostgreSQL database interface converts the BOOLEAN integer values to a CHAR\((1)\) values '1' or '0'.

The BOOLEAN type translation can be controlled with the following FGLPROFILE entry:

```
  dbi.database.dsnname.ifxemul.datatype.boolean = true | false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

**CHAR and VARCHAR data types**

**Informix®**

Informix® supports the following character data types:

**Table 244: Informix® character data types**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR ((n))</td>
<td>SBCS and MBCS character data (max is 32767 bytes)</td>
</tr>
</tbody>
</table>
Informix® data type | Description
--- | ---
VARCHAR \((n, m)\) | SBCS and MBCS character data (max is 255 bytes)
NCHAR \((n)\) | Same as CHAR, with specific collation order
NVARCHAR \((n, m)\) | Same as VARCHAR, with specific collation order
LVARCHAR \((n)\) | max size varies depending on the IDS version

With Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is in how they use sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order.

The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable.

The character set used by applications is defined by the CLIENT_LOCALE environment variable.

Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR \((N)\) is expressed in bytes, not characters as in some other databases)

**PostgreSQL**

PostgreSQL supports following data types to store character data:

**Table 245: PostgreSQL character data types**

<table>
<thead>
<tr>
<th>PostgreSQL data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR ((n))</td>
<td>SBCS or MBCS character data using the database character set, where (n) is specified in characters (max is 10485760 characters)</td>
</tr>
<tr>
<td>VARCHAR ((n))</td>
<td>SBCS or MBCS character data using the database character set, where (n) is specified in characters (max is 10485760 characters); The length specification is optional.</td>
</tr>
<tr>
<td>TEXT</td>
<td>SBCS or MBCS character data using the database character set (max is 1Gb)</td>
</tr>
</tbody>
</table>

In PostgreSQL, CHAR, VARCHAR and TEXT types store data in single byte or multibyte character sets. For CHAR and VARCHAR, the size is specified in a number of characters, not bytes. The character set used to store data for these types is defined by the database character set, which can be specified when you create the database with the `createdb` tool or the CREATE DATABASE SQL command.

**Note:** The VARCHAR type of PostgreSQL can be used without a length specification. If no size is specified, the column accepts strings of any size. However, as Genero BDL needs to know the size of CHAR and VARCHAR columns to define fields and program variables from a schema file, it is not recommended to create tables in PostgreSQL having VARCHAR columns without size specification. If you try to extract a schema with fgl dbsch, this tool will report that the VARCHAR column cannot be converted to a BDL type for the .sch file.

Automatic character set conversion between the PostgreSQL client and server is supported. You must properly specify the client character set for PostgreSQL. This can be done in different ways, with the SET CLIENT_ENCODING TO SQL command for example, or with configuration parameters. See the PostgreSQL documentation for more details.

**Solution**

Informix® CHAR \((N)\) types must be mapped to PostgreSQL CHAR \((N)\) types, and Informix® VARCHAR \((N)\) or LVARCHAR \((N)\) columns must be mapped to PostgreSQL VARCHAR \((N)\).

**Note:** When creating a table from the BDL program with NCHAR or NVARCHAR types, the type names will be left as is and produce an SQL error because these types are not supported by PostgreSQL.
You can store single-byte or multibyte character strings in PostgreSQL CHAR, VARCHAR and TEXT columns.

PostgreSQL uses character length semantics: When you define a CHAR(20) and the database character set is multibyte, the column can hold more bytes/characters than the Informix® CHAR(20) type, when using byte length semantics.

When using a multibyte character set (such as UTF-8), define database columns with the size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a PostgreSQL database, the fgl dbsch schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters) ) column a in PostgreSQL database using the UTF-8 character set, the .sch file will get a size of 10, that will be interpreted following FGL_LENGTH_SEMANTICS as a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

See also the section about Localization.

The CHAR/VARCHAR type translation can be controlled with the following FGLPROFILE entries:

```plaintext
dbi.database.dsname.ifxemul.datatype.char = □ true □ false □
dbi.database.dsname.ifxemul.datatype.varchar = □ true □ false □
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

CHAR and VARCHAR types on page 555

Using the CHAR and VARCHAR data types with different databases.

**NUMERIC data types**

Informix® supports several data types to store numbers:

**Table 246: Informix® numeric data types**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>16 bit signed integer</td>
</tr>
<tr>
<td>INTEGER</td>
<td>32 bit signed integer</td>
</tr>
<tr>
<td>BIGINT</td>
<td>64 bit signed integer</td>
</tr>
<tr>
<td>INT8</td>
<td>64 bit signed integer (replaced by BIGINT)</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>Equivalent to DECIMAL(16)</td>
</tr>
<tr>
<td>DECIMAL(p)</td>
<td>Floating-point decimal number (max precision is 32)</td>
</tr>
<tr>
<td>DECIMAL(p, s)</td>
<td>Fixed-point decimal number (max precision is 32)</td>
</tr>
<tr>
<td>MONEY</td>
<td>Equivalent to DECIMAL(16, 2)</td>
</tr>
<tr>
<td>MONEY(p)</td>
<td>Equivalent to DECIMAL(p, 2) (max precision is 32)</td>
</tr>
<tr>
<td>MONEY(p, s)</td>
<td>Equivalent to DECIMAL(p, s) (max precision is 32)</td>
</tr>
<tr>
<td>REAL / SMALLFLOAT</td>
<td>32-bit floating point decimal (C float)</td>
</tr>
<tr>
<td>DOUBLE PRECISION / FLOAT[(n)]</td>
<td>64-bit floating point decimal (C double)</td>
</tr>
</tbody>
</table>
PostgreSQL

PostgreSQL supports the following data types to store numbers:

Table 247: PostgreSQL numeric data types

<table>
<thead>
<tr>
<th>PostgreSQL data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT2 / SMALLINT</td>
<td>16 bit signed integer</td>
</tr>
<tr>
<td>INT4 / INTEGER</td>
<td>32 bit signed integer</td>
</tr>
<tr>
<td>INT8 / BIGINT</td>
<td>64 bit signed integer</td>
</tr>
<tr>
<td>DECIMAL(p, s)</td>
<td>Decimals with precision and scale (fractional part)</td>
</tr>
<tr>
<td>DECIMAL(p)</td>
<td>Integers with p digits (no fractional part)</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>Floating point numbers (no limit)</td>
</tr>
<tr>
<td>FLOAT4</td>
<td>16 bit variable precision</td>
</tr>
<tr>
<td>FLOAT8</td>
<td>32 bit variable precision</td>
</tr>
</tbody>
</table>

ANSI types like SMALLINT, INTEGER, FLOAT are supported by PostgreSQL as aliases to INT2, INT4 and FLOAT8 native types.

Informix® DECIMAL (p) floating point types are converted to DECIMAL without precision/scale, to store any floating point number in PostgreSQL.

Solution

Use the following conversion rules to map Informix numeric types to PostgreSQL numeric types:

Table 248: Informix® numeric data types and PostgreSQL equivalents

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>PostgreSQL equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>INT2</td>
</tr>
<tr>
<td>INTEGER</td>
<td>INT4</td>
</tr>
<tr>
<td>INT8 / BIGINT</td>
<td>INT8</td>
</tr>
<tr>
<td>DECIMAL(p, s)</td>
<td>DECIMAL(p, s)</td>
</tr>
<tr>
<td>DECIMAL(p)</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>DECIMAL</td>
</tr>
<tr>
<td>MONEY(p, s)</td>
<td>DECIMAL(p, s)</td>
</tr>
<tr>
<td>MONEY(p)</td>
<td>DECIMAL(p, 2)</td>
</tr>
<tr>
<td>MONEY</td>
<td>DECIMAL(16, 2)</td>
</tr>
<tr>
<td>SMALLFLOAT</td>
<td>FLOAT4</td>
</tr>
<tr>
<td>FLOAT[(n)]</td>
<td>FLOAT8</td>
</tr>
</tbody>
</table>

The numeric types translation can be controlled with the following FGLPROFILE entries:

```plaintext
dbi.database.dsname.ifxemul.datatype.smallint = {true | false}
dbi.database.dsname.ifxemul.datatype.integer = {true | false}
dbi.database.dsname.ifxemul.datatype.bigint = {true | false}
dbi.database.dsname.ifxemul.datatype.int8 = {true | false}
dbi.database.dsname.ifxemul.datatype.decimal = {true | false}
```
DATE and DATETIME data types

Informix® provides two data types to store date and time information:

- **DATE** = for year, month and day storage.
- **DATETIME** = for year to fraction (1-5) storage.

The **DATE** type is stored as an **INTEGER** with the number of days since 1899/12/31.

The **DATETIME** type can be defined with various time units, by specifying a start and end qualifier. For example, you can define a datetime to store an hour-to-second time value with `DATETIME HOUR TO SECOND`.

The values of Informix® **DATETIME** can be represented with a character string literal, or as **DATETIME()** literals:

- `'2017-12-24 15:45:12.345'` -- a **DATETIME YEAR TO FRACTION(3)**
- `'15:45'` -- a **DATETIME HOUR TO MINUTE**
- `DATETIME('2017-12-24 12:45') YEAR TO MINUTE`
- `DATETIME(12:45:56.333) HOUR TO FRACTION(3)`

Informix® is able to convert quoted strings to **DATE**/**DATETIME** data, if the string contains matching environment parameters. The string to date conversion rules for **DATE** is defined by the DBDATE environment variable. The string to datetime format for **DATETIME** is defined by the GL_DATETIME environment variable.

**Note:** Within Genero programs, the string representation for **DATETIME** values is always ISO (**YYYY-MM-DD** **hh:mm:ss.ffffff**)  

Informix® supports date arithmetic on **DATE** and **DATETIME** values. The result of an arithmetic expression involving dates/times is an **INTEGER** number of days when only **DATE** values are used, and an **INTERVAL** value if a **DATETIME** is used in the expression.

Informix® automatically converts an **INTEGER** to a **DATE** when the integer is used to set a value of a date column.

**PostgreSQL**

PostgreSQL supports the following data types to store date/time values:

**Table 249: PostgreSQL date/time data types**

<table>
<thead>
<tr>
<th>Netezza® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>for year, month, day storage</td>
</tr>
<tr>
<td>TIME (p) (p) (</td>
<td>\text{with}</td>
</tr>
<tr>
<td>TIMESTAMP (p) (p) (</td>
<td>\text{with}</td>
</tr>
<tr>
<td>Netezza® data type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>for year, month, day, hour, minute, second, fraction (with 6 decimal positions)</td>
</tr>
</tbody>
</table>

PostgreSQL can convert quoted strings to date time data depending on the `DateStyle` session parameter. PostgreSQL always accepts ISO date time strings.

With PostgreSQL, the date format can be defined with the `SET DATESTYLE` SQL command.

With PostgreSQL, the result of an arithmetic expression involving `DATE` values is an `INTEGER` representing a number of days.

**Solution**

Use the following conversion rules to map Informix® date/time types to PostgreSQL date/time types:

**Table 250: Informix® data types and PostgreSQL equivalents**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>PostgreSQL data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME HOUR TO MINUTE</td>
<td>TIME(0) WITHOUT TIME ZONE</td>
</tr>
<tr>
<td>DATETIME HOUR TO SECOND</td>
<td>TIME(0) WITHOUT TIME ZONE</td>
</tr>
<tr>
<td>DATETIME HOUR TO FRACTION(p)</td>
<td>TIME(p) WITHOUT TIME ZONE</td>
</tr>
<tr>
<td>DATETIME YEAR TO MINUTE</td>
<td>TIMESTAMP(0) WITHOUT TIME ZONE</td>
</tr>
<tr>
<td>DATETIME YEAR TO SECOND</td>
<td>TIMESTAMP(0) WITHOUT TIME ZONE</td>
</tr>
<tr>
<td>DATETIME YEAR TO FRACTION(p)</td>
<td>TIMESTAMP(p) WITHOUT TIME ZONE</td>
</tr>
<tr>
<td>DATETIME q1 TO q2 (other than above)</td>
<td>TIMESTAMP(p) WITHOUT TIME ZONE</td>
</tr>
</tbody>
</table>

The `DATE` and `DATETIME` types translation can be controlled with the following FGLPROFILE entries:

```plaintext
 dbi.database.dsnname.ifxemul.datatype.date = [ true | false ]
 dbi.database.dsnname.ifxemul.datatype.datetime = [ true | false ]
```

For more details see [IBM Informix emulation parameters in FGLPROFILE](#) on page 614.

The PostgreSQL and Informix® `DATE` types are equivalent and store year, month, day values.

**Important:** (FGL-4680): Starting with Genero 3.10.07, the PostgreSQL ODI driver can detect the current date format used in the SQL session, and you can safely use `SET DATESTYLE` if needed. Older versions of Genero PostgreSQL expect `DATE` values in ISO format. Do not change the `DATE` format with the `SET DATESTYLE` instruction with Genero versions before 3.10.07.

PostgreSQL `TIME(N) WITHOUT TIME ZONE` data type can be used to store `DATETIME HOUR TO ???` values.

PostgreSQL `TIMESTAMP(N) WITHOUT TIME ZONE` data type can be used to store `DATETIME YEAR TO ???` values.

The SQL Translator of the PostgreSQL driver makes the following conversions automatically for the `DATETIME` types:

- `DATETIME HOUR TO MINUTE` is converted to PostgreSQL `TIME(0) WITHOUT TIME ZONE` (seconds set to 00).
- `DATETIME HOUR TO SECOND` is converted to PostgreSQL `TIME(0) WITHOUT TIME ZONE`.
- `DATETIME HOUR TO FRACTION(n)` is converted to PostgreSQL `TIME(N) WITHOUT TIME ZONE`.
- DATETIME YEAR TO MINUTE is converted to PostgreSQL TIMESTAMP (0) WITHOUT TIME ZONE (seconds set to 00).
- DATETIME YEAR TO SECOND is converted to PostgreSQL TIMESTAMP (0) WITHOUT TIME ZONE.
- DATETIME YEAR TO FRACTION(n) is converted to PostgreSQL TIMESTAMP (N) WITHOUT TIME ZONE.

Other DATETIME types will be mapped to PostgreSQL TIMESTAMP (n) types. Missing date or time parts default to 1900-01-01 00:00:00.

Complex DATETIME expressions (involving INTERVAL values for example) are Informix-specific and have no equivalent in PostgreSQL.

Related concepts
Date/time literals in SQL statements on page 571
Good practices for date and time handling in SQL.

**INTERVAL data type**

**Informix**

Informix® provides the INTERVAL data type to store a value that represents a span of time.

INTERVAL types are divided into two classes:
- year-month intervals. For example: INTERVAL YEAR (5) TO MONTH
- day-time intervals. For example: INTERVAL DAY (9) TO SECOND

INTERVAL columns can be defined with various time units, by specifying a start and end qualifier. For example, you can define an interval to store a number of hours and minutes with INTERVAL HOUR (n) TO MINUTE, where n defines the maximum number of digits for the hours unit.

The values of Informix® INTERVAL can be represented with a character string literal, or as INTERVAL() literals:

```
'-9834 15:45:12.345'  -- an INTERVAL DAY (6) TO FRACTION (3)
'7623-11'              -- an INTERVAL YEAR (9) TO MONTH
INTERVAL (18734:45) HOUR (5) TO MINUTE
INTERVAL (-7634-11) YEAR (5) TO MONTH
```

**PostgreSQL**

PostgreSQL provides an INTERVAL data type which is equivalent to the Informix® INTERVAL:

- It is possible to specify the interval class / precision with YEAR, MONTH, DAY, HOUR, MINUTE and SECOND [(p)] fields.
- Fractional part of seconds can be defined with up to 6 digits.
- The interval value range is from -178000000 to +178000000 years.
- Input and output format can be controlled with the SET interval style command.

**Solution**

Use the following conversion rules to map Informix® numeric types to PostgreSQL numeric types:

**Table 251: Informix® numeric data types and PostgreSQL equivalents**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>PostgreSQL equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTERVAL YEAR [(p)] TO MONTH</td>
<td>INTERVAL YEAR TO MONTH</td>
</tr>
<tr>
<td>INTERVAL YEAR [(p)] TO YEAR</td>
<td>INTERVAL YEAR</td>
</tr>
<tr>
<td>INTERVAL MONTH [(p)] TO MONTH</td>
<td>INTERVAL MONTH</td>
</tr>
</tbody>
</table>
The PostgreSQL database interface converts the Informix-style `INTERVAL` type to the native PostgreSQL `INTERVAL` type.

**Important:** The PostgreSQL database driver forces the interval style session parameter to ‘iso_8601’, this is required to insert and fetch interval database with the libpq CAPI functions. You must not change this setting during program execution.

While PostgreSQL intervals support up to 9 digits for the higher unit like Informix®, year values range from -178000000 to +178000000 only. This limitation exists in PostgreSQL 8.4 and maybe solved in future versions.

The `INTERVAL` types translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsnname.ifxemul.datatype.interval = ↓ true ↓ false ↓
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

**Using portable data types** on page 553

Only a limited set of data types are really portable across several database engines.

**SERIAL data types**

**Informix®**

Informix® supports the `SERIAL`, `BIGSERIAL` data types to produce automatic integer sequences:

- `SERIAL` can produce 32 bit integers (`INTEGER`)
- `BIGSERIAL` can produced 64 bit integers (`BIGINT`)
- `SERIAL8` is a synonym for `BIGSERIAL`

Steps to use serials with Informix®:

1. Create the table with a column using `SERIAL`, or `BIGSERIAL`.  

<table>

<tr>
<td><code>INTERVAL FRACTION[(p)] TO FRACTION(n)</code></td>
<td><code>INTERVAL SECOND(n)</code></td>
</tr>
</tbody>
</table>
2. To generate a new serial, no value or a zero value is specified in the INSERT statement:

```sql
INSERT INTO tab1 ( c ) VALUES ( 'aa' )
INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
```

3. After INSERT, the new value of a SERIAL column is provided in SQLCA.SQLERRD[2], while the new value of a BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```sql
CREATE TABLE tab ( k SERIAL ); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

**PostgreSQL**

PostgreSQL SERIAL data type:

- PostgreSQL's SERIAL data type has the same name as in Informix®, but it behaves differently.
- You cannot define a start value (SERIAL(100)).
- You cannot specify zero as serial value to get a new serial, the PostgreSQL serial is based on default values, thus you must omit the serial column in the INSERT statement.
- When you INSERT a row with a specific value for the serial column, the underlying sequence will not be incremented. As result, the next INSERT that does not specify the serial column may get a new sequence that was already inserted explicitly.
- With some old versions of PostgreSQL, when you drop the table you must drop the sequence too.

PostgreSQL sequences:

- The purpose of sequences is to provide unique integer numbers.
- To create a sequence, you must use the CREATE SEQUENCE statement.
- To get a new sequence value, you must use the nextval() function:

```sql
INSERT INTO tab1 VALUES ( nextval('tab1_seq'), ... )
```

- To get the last generated number, PostgreSQL provides the currval() function:

```sql
SELECT currval('tab1_seq')
```

**Solution**

**Note:** For best SQL portability when using different type of databases, consider using sequences as described in Solution 3: Use native SEQUENCE database objects on page 565.

The Informix® SERIAL data type can be emulated with three different methods.

The method used to emulate SERIAL types is defined by the ifxemul.datatype.serial.emulation FGLPROFILE parameter:

```sql
dbi.database.dbname.ifxemul.datatype.serial.emulation = { "native" | "regtable" | "trigseq" }
```

- **native**: uses the native PostgreSQL serial data type.
- **regtable**: uses insert triggers with the SERIALREG table.
- **trigseq**: uses insert triggers with sequences.
The default emulation technique is "native".

The serial types emulation can be enabled or disabled with the following FGLPROFILE entries:

```sql
  dbi.database.dbname.ifxemul.datatype.serial = [true|false]
  dbi.database.dbname.ifxemul.datatype.serial8 = [true|false]
  dbi.database.dbname.ifxemul.datatype.bigserial = [true|false]
```

**Using the native serial emulation**

The "native" mode is the default serial emulation mode, using the native PostgreSQL SERIAL data type. In this mode, the original type name will be left untouched by the SQL Translator and you will get the behavior of the PostgreSQL SERIAL column type, based on sequences.

**Note:** INSERT statements cannot use the serial column, even with a value zero. When using a NULL value, PostgreSQL will report a non-null constraint error. Therefore, the serial column must be omitted from the INSERT statement.

See also the PostgreSQL documentation for more details about the native SERIAL type.

**Using the regtable serial emulation**

With the "regtable" mode, the SERIAL data type is emulated with a PostgreSQL INTEGER data type and INSERT triggers using the table SERIALREG which is dedicated to sequence production. After an insert, `sqlca.sqlerrd[2]` register holds the last generated serial value. BIGSERIAL and SERIAL8 types can be converted to BIGINT in PostgreSQL, but the `sqlca.sqlerrd[2]` register cannot be used since it is defined as an INTEGER type.

The triggers can be created manually during the application database installation procedure, or automatically from a BDL program: When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the SERIAL data type to INTEGER and dynamically creates the triggers.

You must create the SERIALREG table as follows:

```sql
CREATE TABLE SERIALREG (
  TABLENAME VARCHAR(50) NOT NULL,
  LASTSERIAL DECIMAL(20,0) NOT NULL,
  PRIMARY KEY ( TABLENAME )
)
```

**Important:** The SERIALREG table must be created before the triggers. The serial production is based on the SERIALREG table which registers the last generated number for each table. If you delete rows of this table, sequences will restart at 1 and you will get unexpected data.

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types and you must create one trigger for each table. To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command.

With this emulation mode, INSERT statements using NULL for the SERIAL column will produce a new serial value:

```sql
  INSERT INTO tab ( col1, col2 ) VALUES ( NULL, 'data' )
```

This behavior is mandatory in order to support INSERT statements that do not use the serial column:

```sql
  INSERT INTO tab (col2) VALUES ('data')
```

Check if your application uses tables with a SERIAL column that can contain a NULL value. Consider removing the serial column from the INSERT statements.
**Using the trigseq serial emulation**

With "trigseq", the SERIAL data type is emulated with a PostgreSQL INTEGER data type and INSERT triggers using a sequence `tablename_seq`. After an insert, `sqlca.sqlerrd[2]` register holds the last generated serial value.

The triggers can be created manually during the application database installation procedure, or automatically from a BDL program: When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the SERIAL data type to INTEGER and dynamically creates the triggers.

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types and you must create one trigger for each table. To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command.

With this emulation mode, INSERT statements using NULL for the SERIAL column will produce a new serial value:

```
INSERT INTO tab ( col1, col2 ) VALUES ( NULL, 'data' )
```

This behavior is mandatory in order to support INSERT statements which do not use the serial column:

```
INSERT INTO tab (col2) VALUES ('data')
```

Check if your application uses tables with a SERIAL column that can contain a NULL value. Consider removing the serial column from the INSERT statements.

**Notes common to all serial emulation modes**

Since `sqlca.sqlerrd[2]` is defined as an INTEGER, it cannot hold values from BIGSERIAL (BIGINT) auto incremented columns. If you are using BIGSERIAL columns, you must query the sequence pseudo-column CURRVAL() or fetch the LASTSERIAL column from the SERIALREG table if used.

For SQL portability, it is recommended to review INSERT statements to remove the SERIAL column from the list. For example, the following statement:

```
INSERT INTO tab (col1,col2) VALUES ( 0 , p_value )
```

can be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES ( rec.*) -- will use the serial column
```

can be converted to:

```
INSERT INTO tab VALUES rec.* -- without parentheses, serial column is removed
```

**Important:** When using the Static SQL INSERT and UPDATE syntax using record.* without parentheses, make sure that your database schema files contain information about serials: This information can be lost when extracting the schema from a PostgreSQL database which does not use native serial emulation. See Database Schema for more details about the serial flag in column type encoding (data type code must be 6)

**Related concepts**

Auto-incremented columns (serials) on page 562
How to implement automatic record keys.

**ROWID columns**

**Informix®**

When creating a table, Informix® automatically adds a **ROWID** integer column (applies to non-fragmented tables only).

The **ROWID** column is auto-filled with a unique number and can be used like a primary key to access a given row.

**Note:** Informix® **ROWID** usage was a common practice in the early days of Informix® 4GL programming. Today it is recommended to define all your database tables with a **PRIMARY KEY** to uniquely identify rows.

With Informix®, the SQLCA.SQLERRD[6] register contains the **ROWID** of the last modified row.

**PostgreSQL**

PostgreSQL tables can be created with an **OID** (Object Identifier) column, that is similar to Informix® **ROWID** columns.

The type of PostgreSQL **OID** columns is **INTEGER**.

**Important:** Starting with PostgreSQL version 8.1, **OID** columns are no longer enabled by default. To have **OID** columns created for tables, you need to set the `default_with_oid` parameter to "on" in the `postgresql.conf` file.

The PostgreSQL C API provides the `PQoidValue()` function, to get the **OID** of the last inserted row. Unlike Informix® SQLCA.SQLERRD[6], PostgreSQL does not return the **OID** of the last row modified by an **UPDATE**, or removed by a **DELETE**.

**Solution**

The database automatically converts **ROWID** keywords to **OID** for PostgreSQL.

If PostgreSQL **OID** columns are enabled in the database, SQL statements such as "SELECT **ROWID** FROM" and "UPDATE .. WHERE **ROWID** = ?" will work as with Informix®.

To enable **OID** columns, the `default_with_oid` PostgreSQL server parameter must be set to "on". See Database configuration and design tasks for more details.

**Note:** SQLCA.SQLERRD[6] is partly supported: It works only for **INSERT** statements. As PostgreSQL does not return the **OID** of the last row modified by an **UPDATE**, or removed by a **DELETE**, this register will not contain the **OID** of the last modified or deleted row. All references to SQLCA.SQLERRD[6] should be reviewed.

As a general programming pattern, consider using **PRIMARY KEY** columns to identify database table rows.

The **ROWID** keyword translation can be controlled with the following FGLPROFILE entry:

```
  dbi.database.dsnname.ifxemul.rowid = { \true \false }
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Using **ROWID** columns on page 578

Automatic **ROWID** columns is not a common database feature.

**TEXT and BYTE (LOB) types**

**Informix®**

Informix® provides the **TEXT**, **BYTE**, **CLOB** and **BLOB** data types to store very large texts or binary data.

Legacy Informix® 4GL applications typically use the **TEXT** and **BYTE** types.
Genero BDL does not support the Informix® CLOB and BLOB types.

**PostgreSQL**

PostgreSQL provides the **TEXT** and **BYTEA** data types for large objects storage. With these data types, large objects are handled as a whole.

PostgreSQL also supports LOB storage through the large objects facility based on stream-style access. The large object facility is provided as a set of C and SQL API functions to create / delete / modify large objects identified by a unique object id (OID). For example, the `lo_create(-1)` SQL function will create a new large object and return a new object id that will be used to handle the LOB. See PostgreSQL documentation for more details.

**Solution**

**TEXT** and **BYTE** data can be stored in PostgreSQL **TEXT** and **BYTEA** columns.

The **TEXT** and **BYTE** types translation can be controlled with the following FGLPROFILE entries:

```
<table>
<thead>
<tr>
<th>Entry</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbi.database.dsname.ifxemul.text</td>
<td>true</td>
</tr>
<tr>
<td>dbi.database.dsname.ifxemul.byte</td>
<td>false</td>
</tr>
</tbody>
</table>
```

For more details see [IBM Informix emulation parameters in FGLPROFILE](#) on page 614.

Genero BDL does not interface automatically with the PostgreSQL Large Object facility. However, the **OID** values can be stored in **BIGINT** variables, and you can use server-side LOB functions to convert large objects to **BYTEA** data, that can be fetched into **BYTE** variables. The next code example creates a table with an **OID** column, imports a LOB from an image file, and then fetches the LOB back into a **BYTE**:

```sql
MAIN

DEFINE img BYTE, obj_id BIGINT

CONNECT TO "test1+driver='dbmpgs'" USER "postgres" USING "fourjs"

# Need superuser privileges to create the LOB....
WHENEVER ERROR CONTINUE
DROP TABLE t1
WHENEVER ERROR STOP
EXECUTE IMMEDIATE "create table t1 ( k int, image oid )"
GRANT SELECT ON t1 TO PUBLIC
INSERT INTO t1 VALUES ( 1, lo_import("/var/images/landscape.png") )
SELECT image INTO obj_id FROM t1 WHERE k=1
DISPLAY "obj_id = ", obj_id
EXECUTE IMMEDIATE "grant select on large object "||obj_id||" to public"

# Next block can be executed by any user:
LOCATE img IN FILE -- a temp file will be used
SELECT loread(lo_open(image, 262144), 1000000) INTO img FROM t1 WHERE k=1
DISPLAY length(img)

# Delete the object
SELECT lo_unlink(obj_id) FROM t1 WHERE k=1
DROP TABLE t1
END MAIN

**Related concepts**

[Using portable data types](#) on page 553
Only a limited set of data types are really portable across several database engines.

**Table constraints**

**Informix®**

Informix® supports primary key, unique, foreign key, default and check constraints.

The constraint naming syntax is different in Informix® and most other databases: Informix expects the "CONSTRAINT" keyword after the constraint specification:

```sql
CREATE TABLE emp (
    ...
    emp_code CHAR(10) UNIQUE CONSTRAINT pk_emp,
    ...
)
```

While other databases it before:

```sql
CREATE TABLE emp (
    ...
    emp_code CHAR(10) CONSTRAINT pk_emp UNIQUE,
    ...
)
```

**PostgreSQL**

PostgreSQL support primary key, unique, foreign key, default and check constraints.

**Constraint naming syntax**

The constraint naming clause must be placed before the constraint specification.

**Unique constraints**

**Note:** When using a unique constraint, Informix® allows only one row with a NULL value, while PostgreSQL allows several rows with NULL!

**Solution**

The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for PostgreSQL.

**Related concepts**

Data definition statements on page 552

It is recommended to avoid use of DDL in programs.

**Name resolution of SQL objects**

**Informix®**

Informix® uses the following form to identify an SQL object:

```
database[@dbservername]:][{owner|"owner"}.]identifier
```

The ANSI convention is to use double quotes for identifier delimiters (For example: "customer"."cust_name").

Informix® database object names are not case-sensitive in non-ANSI databases. When using double-quoted identifiers, Informix® becomes case sensitive.
With non-ANSI Informix® databases, you do not have to give a schema name before the tables when executing an SQL statement:

```
SELECT ... FROM customer WHERE ...
```

In Informix® ANSI compliant databases:

- The table name must include "owner", unless the connected user is the owner of the database object.
- The database server shifts the owner name to uppercase letters before the statement executes, unless the owner name is enclosed in double quotes.

**PostgreSQL**

With PostgreSQL, an object name takes the following form:

```
[owner.]identifier
```

**Solution**

As a general rule, to write portable SQL, it is recommended that you only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

**Data manipulation**

PostgreSQL related data manipulation topics.

**Reserved words**

**Informix®**

With Informix®, it is possible to create database objects with reserved words.

For example:

```
CREATE TABLE table ( char CHAR(10) );
```

Indeed this is not good practice, but Informix® SQL allows this to be backward compatible when introducing a new keyword in the SQL syntax.

Most other database systems do not allow reserved words as database identifiers. If your legacy code is using SQL reserved words of the target database SQL syntax, an error will be thrown at `CREATE TABLE` execution.

**PostgreSQL**

SQL object names like table and column names cannot be SQL reserved words in PostgreSQL.

**Solution**

Table or column names which are PostgreSQL reserved words must be renamed.

**Outer joins**

**Informix® OUTER() syntax**

In Informix® SQL, outer joins can be defined in the `FROM` clause with the `OUTER` keyword:

```
SELECT ... FROM a, OUTER (b)
WHERE a.key = b.akey

SELECT ... FROM a, OUTER (b, OUTER (c))
WHERE a.key = b.akey
AND b.key1 = c.bkey1 AND b.key2 = c.bkey2
```
Informix® also supports the ANSI OUTER join syntax, which is the recommended way to specify outer joins with recent SQL database engines:

```
SELECT ... FROM cust LEFT OUTER JOIN order
    ON cust.key = order.custno
WHERE ...
```

**PostgreSQL**

PostgreSQL supports the ANSI outer join syntax:

```
SELECT ...
FROM cust LEFT OUTER JOIN order
    LEFT OUTER JOIN item
    ON order.key = item.ordno
    ON cust.key = order.custno
WHERE order.cdate > current date
```

**Solution**

The Genero database drivers can convert Informix Informix® OUTER specifications to ANSI outer joins.

**Note:** For better SQL portability, use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The outer join translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsnname.ifxemulouters = \true \false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

- **Prerequisites:**
  1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.

     Example which does not work:

     ```
     ... FROM OUTER(tab2), tab1
     ```

  2. The outer join in the WHERE clause must use the table name as prefix:

     ```
     ... WHERE tab1.col1 = tab2.col2
     ```

- **Restrictions:**
  1. Statements composed by 2 or more SELECT instructions are not supported:

     ```
     SELECT ... UNION SELECT ...
     ```

     or:

     ```
     SELECT ... WHERE col IN (SELECT...)
     ```

  2. Additional conditions on outer table columns cannot be detected and therefore are not supported:

     ```
     ... FROM tab1, OUTER(tab2)
     WHERE tab1.col1 = tab2.col2
     AND tab2.colx > 10
     ```

- **Notes:**
  1. Table aliases are detected in OUTER expressions.
OUTER example with table alias:

```
... OUTER(tab1 alias1) ...
```

2. In the outer join, `outertab.col` can be placed on both right or left sides of the equal sign:

```
... WHERE outertab.col1 = maintab.col2
```

3. Table names detection is not case-sensitive:

```
SELECT ... FROM tab1, TAB2
WHERE tab1.col1 = tab2.col2
```

4. Temporary tables are supported in OUTER specifications:

```
CREATE TEMP TABLE tt1 ( ... )
SELECT ... FROM tab1, OUTER(tt1) ...
```

**Related concepts**

*Outer joins* on page 577
Use standard ISO outer join syntax instead of the old IBM® Informix® OUTER () syntax.

**Transactions handling**

*Informix®*

With the Informix® native mode (non ANSI):

- Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```
UPDATE tab1 SET ... -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...                    -- end of TX block
COMMIT WORK
```

*Informix®* version 11.50 introduces savepoints:

```
SAVEPOINT name [UNIQUE]  
ROLLBACK [WORK] TO SAVEPOINT _name_  
RELEASE SAVEPOINT name
```

*PostgreSQL*

PostgreSQL supports transaction with savepoints:

- Transactions are started with `BEGIN WORK`.
- Transactions are validated with `COMMIT WORK`.
- Transactions are canceled with `ROLLBACK WORK`.
- Savepoints can be placed with `SAVEPOINT name`.
- Transactions can be rolled back to a savepoint with `ROLLBACK TO SAVEPOINT name`.
- Savepoints can be released with `RELEASE SAVEPOINT name`.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.
- If an SQL error occurs in a transaction, the whole transaction is aborted.
Transactions in stored procedures: avoid using transactions in stored procedures to allow the client applications to handle transactions, depending on the transaction model.

The main difference between Informix® and PostgreSQL resides in the fact that PostgreSQL cancels the entire transaction if an SQL error occurs in one of the statements executed inside the transaction. The following code example illustrates this difference:

```sql
CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
WHENEVER ERROR CONTINUE
BEGIN WORK
INSERT INTO tab1 ( 1, 'abc' )
INSERT INTO tab1 ( 1, 'abc' )
-- PK constraint violation = SQL Error, whole TX is aborted
COMMIT WORK
```

With Informix®, this code will leave the table with one row inside, since the first INSERT statement succeeded. With PostgreSQL, the table will remain empty after executing this piece of code, because the server will rollback the whole transaction. To workaround this problem in PostgreSQL you can use SAVEPOINT as described in Solution on page 913.

**Solution**

Informix® transaction handling commands are automatically converted to PostgreSQL instructions to start, validate or cancel transactions.

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with PostgreSQL.

You must review the SQL statements inside `BEGIN WORK / COMMIT WORK` instruction and check if these can raise an SQL error. The SQL statements that can potentially raise an SQL error must be protected with a `SAVEPOINT`. If an error occurs, just rollback to the savepoint:

```sql
MAIN
  DATABASE test1
  CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
  WHENEVER ERROR CONTINUE
  BEGIN WORK
  INSERT INTO tab1 VALUES ( 1, 'abc' )
  CALL sql_protect()
  INSERT INTO tab1 VALUES ( 1, 'abc' )
  -- PK constraint violation = SQL Error
  CALL sql_unprotect()
  COMMIT WORK
END MAIN

FUNCTION sql_protect()
  IF fgl_db_driver_type()!="pgs" THEN
    RETURN
  END IF
  SAVEPOINT _sql_protect_
END FUNCTION

FUNCTION sql_unprotect()
  IF fgl_db_driver_type()!="pgs" THEN
    RETURN
  END IF
  IF SQLCA.SQLCODE < 0 THEN
    ROLLBACK WORK TO SAVEPOINT _sql_protect_
  ELSE
    RELEASE SAVEPOINT _sql_protect_
  END IF
END FUNCTION
```
**Note:** If you want to use savepoints, do not use the `UNIQUE` keyword in the savepoint declaration, always specify the savepoint name in `ROLLBACK TO SAVEPOINT`, and do not drop savepoints with `RELEASE SAVEPOINT`.

**Related concepts**

Database transactions on page 538

Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Temporary tables**

**Informix®**

Informix® temporary tables are created with the `CREATE TEMP TABLE` DDL instruction or with `SELECT ... INTO TEMP` statement:

```sql
CREATE TEMP TABLE tt1 ( pkey INT, name VARCHAR(50) )
CREATE TEMP TABLE tt2 ( pkey INT, name VARCHAR(50) ) WITH NO LOG
SELECT * FROM tab1 WHERE pkey > 100 INTO TEMP tt2
```

Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the `DROP TABLE` command. There is no name conflict when several users create temporary tables with the same name.

BDL REPORTs can create a temporary table when the rows are not sorted externally (by the source SQL statement).

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

When creating temporary tables in Informix®, the `WITH NO LOG` clause can be used to avoid the overhead of recording DML operations in transaction logs.

**PostgreSQL**

PostgreSQL support temporary tables as Informix® does, with a little syntax difference in the `SELECT INTO TEMP` instruction:

```sql
SELECT * INTO TEMP temptab FROM source
```

**Solution**

Temporary tables are well supported with native PostgreSQL temp tables.

The general FGLPROFILE entry to control temporary table emulation is:

```
dbi.database.dsnname.ifxemul.temptables = [true | false]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Temporary tables on page 575

Syntax for temporary table creation is not unique across all database engines.

**Substrings in SQL**

**Informix®**

Informix® SQL statements can use subscripts on columns defined with the character data type:

```sql
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R' -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```
**Important:** With other database servers as Informix®, when the subscript notation is used to modify column values in UPDATE statement, or as ORDER BY element, you will get and SQL error:

<table>
<thead>
<tr>
<th>SQL support</th>
<th>915</th>
</tr>
</thead>
</table>

```
UPDATE tab1 SET col[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col[1,3]
```

**PostgreSQL**

provides the `SUBSTRING( ... from ... to ... )` function, to extract a substring from a string expression:

<table>
<thead>
<tr>
<th>SQL support</th>
<th>915</th>
</tr>
</thead>
</table>

```
SELECT .... FROM tab1 WHERE SUBSTRING(col1 from 2 for 2) = 'RO'
SELECT SUBSTRING('Some text' from 6 for 3) ... -- Gives 'tex'
```

**Solution**

Replace all Informix® `col[x,y]` right-value expressions by `SUBSTRING( col from x for (y-x+1) )`. Rewrite UPDATE and ORDER BY clauses using `col[x,y]` expressions.

The translation of `col[x,y]` expressions can be controlled with the following FGLPROFILE entry:

```
<table>
<thead>
<tr>
<th>SQL support</th>
<th>915</th>
</tr>
</thead>
</table>
```

```
<table>
<thead>
<tr>
<th>SQL support</th>
<th>915</th>
</tr>
</thead>
</table>
```

```
<table>
<thead>
<tr>
<th>SQL support</th>
<th>915</th>
</tr>
</thead>
</table>
```

```
<table>
<thead>
<tr>
<th>SQL support</th>
<th>915</th>
</tr>
</thead>
</table>
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Substring expressions on page 577
Handle substrings expressions with different database engines.

**String delimiters**

**Informix®**

The ANSI SQL string delimiter character is the single quote (`'string'`), while double quotes are used to delimit database object names:

```
SELECT ... WHERE "tabname"."colname" = 'a string value'
```

In Informix® databases created in native mode (non-ANSI), you can use double quotes as string delimiters:

```
SELECT ... WHERE tabname.colname = 'a string value'
```

This is important, since many BDL programs use that character to delimit the strings in SQL commands.

**Note:** This problem concerns only double quotes within SQL statements. Double quotes used in pure BDL string expressions are not subject to SQL compatibility problems.

**PostgreSQL**

PostgreSQL follows the ANSI SQL specification, using single quotes for string delimiters and double quotes for database object names.

**Solution**

When using Static SQL statements, the `fglcomp` compiler converts string literals using double quotes to string literals with single quotes:

```
$ cat s.4gl
MAIN
```

DEFINE n INT
    SELECT COUNT(*) INTO n FROM tab1 WHERE col1 = "abc"
END MAIN

$ fglcomp -S s.4gl
s.4gl^3^SELECT COUNT(*) FROM tab1 WHERE col1 = 'abc'

However, SQL statements created dynamically are not modified by the Genero compiler.

The Genero database interface can automatically replace all double quotes by single quotes in SQL statements. This applies to static and dynamic SQL statements.

The translation of double quoted expression to single quoted expressions can be controlled with the following FGLPROFILE entry:

    dbi.database.dbname.ifxemul.dblquotes = | true | false |

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

However, database object names must not be delimited by double quotes, because the database interface cannot determine the difference between a database object name and a quoted string! For example, if the program executes the SQL statement:

    ... WHERE "tabname"."colname" = "a string value"

replacing all double quotes by single quotes would produce:

    ... WHERE 'tabname'.'colname' = 'a string value'

This would produce an error since 'tabname'.colname' is not allowed by ORACLE.

Escaped string delimiters can be used inside strings like the following:

    'This is a single quote: '''
    'This is a single quote: \\
    "This is a double quote: ""
    "This is a double quote: \"

Although double quotes are replaced automatically in SQL statements, it is recommended that you use only single quotes to enforce portability.

**Related concepts**

*String literals in SQL statements* on page 570
Single quotes is the standard for delimiting string literals in SQL.

**MATCHES and LIKE**

*Informix*

Informix® supports MATCHES and LIKE operators in SQL statements.

MATCHES expects * and ? wild-card characters, while LIKE uses the % and _ wild-cards as equivalents.

( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x' )

MATCHES accepts also brackets notation, to specify a set of matching characters at a given position:

( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-zA-Z]*' )
**PostgreSQL**

PostgreSQL supports the `LIKE` operator, and the `~` operator which expects regular expressions as follows:

```
( col ~ 'a.*' )
```

PostgreSQL provides the `SIMILAR TO` operator, allowing character range specification as the Informix `MATCHES` operator:

```
( col SIMILAR TO '[Pp]ar%' )
```

**Important:** With PostgreSQL, columns defined as `CHAR(N)` are blank padded, and trailing blanks are significant in the `LIKE` expressions. As a result, with a `CHAR(5)` value such as `'abc '` (with 2 trailing blanks), the expression `(colname LIKE 'ab_')` will not match. To workaround this behavior, you can do `(RTRIM(colname) LIKE 'pattern')`. However, consider adding the condition `AND (colname LIKE 'pattern')` to force the DB server to optimize the query of the column is indexed. The `CONSTRUCT` instruction uses this technique when the entered criteria does not end with a * star wildcard.

**Solution**

The database driver converts Informix® `MATCHES` expressions to `LIKE` expressions, when no `[ ]` bracket character ranges are used in the `MATCHES` operand. When character ranges are used, the driver converts to a PostgreSQL `SIMILAR TO` expression, to find the same values as with the Informix `MATCHES` operator.

**Important:** Only `[NOT] MATCHES` followed by a search pattern provided as a string literal can be converted by ODI drivers. A `[NOT] MATCHES` followed by a ? question mark parameter place holder is not translated!

For maximum portability, consider replacing the `MATCHES` expressions to `LIKE` expressions in all SQL statements of your programs.

With PostgreSQL, trailing blanks are significant when comparing `CHAR()` columns with `LIKE` or `SIMILAR TO` expressions. Consider adding an ending * when comparing with `CHAR()` columns. This is not needs for `VARCHAR()` columns.

Avoid using `CHAR(N)` types for variable length character data (such as name, address).

**Related concepts**

- [MATCHES and LIKE operators](#) on page 579
- Use the standard `LIKE` operator instead of the `MATCHES` operator.

**The LENGTH() function**

**Informix®**

Informix® provides the `LENGTH()` function to count the number of bytes of a character string expression:

```
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```

Informix® `LENGTH()` does not count the trailing blanks for `CHAR` or `VARCHAR` expressions, while Oracle counts the trailing blanks.

Informix® `LENGTH()` returns 0 when the given string is empty. That means, `LENGTH('')`=0.

**PostgreSQL**

PostgreSQL supports the `LENGTH()` function, which is similar to Informix® `LENGTH()`.

The PostgreSQL `LENGTH()` function ignores trailing blanks.

When passing `NULL` as parameter, the PostgreSQL `LENGTH()` function returns `NULL`. 
**Solution**

The SQL `LENGTH()` function name can be used with PostgreSQL.

**Related concepts**

The `LENGTH()` function in SQL on page 581

The semantics of the `LENGTH()` SQL function differs according to the database engine.

**BDL programming**

PostgreSQL related programming topics.

**SQL errors on PREPARE**

**Informix®**

With Informix®, a `PREPARE` instruction returns an SQL error in case of problem:

```sql
TRY
  PREPARE stmt FROM "SELECT * FROM WHERE pk=1" -- table is missing!
CATCH
  DISPLAY "SQL ERROR:", SQLCA.SQLCODE
END TRY
```

**PostgreSQL**

The PostgreSQL database driver is implemented with the PostgreSQL libpq API. This library does not provide a way to send SQL statements to the database server during the BDL `PREPARE` instruction, like the Informix® interface does.

When preparing an SQL statement with the BDL `PREPARE` or `DECLARE` instruction, no SQL error will be returned if the SQL statement is invalid. However, an SQL error will occur after the `OPEN` / `FOREACH` / `EXECUTE` instructions.

**Solution**

Make sure your BDL programs do not test the `STATUS` or `SQLCA.SQLCODE` variable just after `PREPARE` instructions.

Change the program logic in order to handle the SQL errors when opening the cursors (`OPEN`) or when executing SQL statements (`EXECUTE`).

**INSERT cursors**

**Informix®**

Informix® provides *insert cursors* to optimize row creation in a database. An insert cursor is declared as a cursor, and rows as added with the `PUT` instruction. The rows are buffered and sent to the database server when executing a `FLUSH` instruction, or when the cursor is closed with `CLOSE`. When using transactions in Informix®, the `OPEN`, `PUT` and `FLUSH` instructions must be executed within a transaction block.

```xml
DECLARE c1 CURSOR FOR INSERT INTO tab1 ...
BEGIN WORK
  OPEN c1
  WHILE ...
    PUT c1 USING var-list
  END WHILE
  CLOSE c1
  COMMIT WORK
```
**PostgreSQL**

PostgreSQL does not support insert cursors.

**Solution**

Insert cursors are emulated by the database interface, using basic `INSERT` SQL instructions.

The performances might be not as good as with Informix®, but the feature is fully supported.

**Related concepts**

- Insert cursors on page 569
- Using insert cursors with non-Informix databases.

**Cursors WITH HOLD**

**Informix®**

Informix® closes opened cursors automatically when a transaction ends, unless the `WITH HOLD` option is used in the `DECLARE` instruction:

```sql
DECLARE c1 CURSOR WITH HOLD FOR SELECT ...;
OPEN c1;
BEGIN WORK;
FETCH c1 ...;
COMMIT WORK;
FETCH c1 ...;
CLOSE c1;
```

**PostgreSQL**

With PostgreSQL, opened cursors using `SELECT` statements without a `FOR UPDATE` clause are not closed when a transaction ends. All PostgreSQL cursors are `WITH HOLD` cursors, unless the `FOR UPDATE` clause issued in the `SELECT` statement.

Cursors declared `FOR UPDATE` and using the `WITH HOLD` option cannot be supported with PostgreSQL because `FOR UPDATE` cursors are automatically closed by PostgreSQL when the transaction ends.

**Solution**

BDL cursors that are not declared `WITH HOLD` are automatically closed by the database interface when a `COMMIT WORK` or `ROLLBACK WORK` is performed.

Since PostgreSQL automatically closes `FOR UPDATE` cursors when the transaction ends, opening cursors declared `FOR UPDATE` and the `WITH HOLD` option results in an SQL error that does not normally appear with Informix® under the same conditions.

Review the program logic in order to find another way to set locks.

**Related concepts**

- WITH HOLD and FOR UPDATE on page 568
- Hold cursors and not portable.

**SELECT ... FOR UPDATE**

**Informix®**

Legacy BDL programs typically use a cursor with `SELECT FOR UPDATE` to implement pessimistic locking and avoid several users editing the same rows:

```sql
DECLARE cc CURSOR FOR
```
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released

The row must be fetched in order to set the lock.

If the cursor is local to a transaction, the lock is released when the transaction ends. If the cursor is declared WITH HOLD, the lock is released when the cursor is closed.

Informix® provides the SET LOCK MODE instruction to define the lock wait timeout:

SET LOCK MODE TO { WAIT | NOT WAIT | WAIT seconds }

The default mode is NOT WAIT.

**PostgreSQL**

With PostgreSQL, locks are released when closing the cursor or when the transaction ends.

PostgreSQL locking granularity is at the row level.

PostgreSQL has no equivalent for SET LOCK MODE TO NOT WAIT.

**Solution**

The database interface is based on an emulation of an Informix® engine using transaction logging. Therefore, opening a SELECT ... FOR UPDATE cursor declared outside a transaction will raise an SQL error -255 (not in transaction).

You must review the program logic if you use pessimistic locking because it is based on the NOT WAIT mode which is not supported by PostgreSQL.

**Related concepts**

*WITH HOLD and FOR UPDATE* on page 568

Hold cursors and not portable.

**UPDATE/DELETE ... WHERE CURRENT OF**

**Informix®**

Informix® allows positioned UPDATEs and DELETEs with the "WHERE CURRENT OF cursor" clause, if the cursor has been DECLARED with a SELECT ... FOR UPDATE statement.

**PostgreSQL**

UPDATE/DELETE ... WHERE CURRENT OF is supported by PostgreSQL with server-side cursors created by a DECLARE statement.

**Solution**

With PostgreSQL, UPDATE/DELETE ... WHERE CURRENT OF instructions are executed as is without translation: Since SELECT FOR UPDATE statements are implemented with a DECLARE statement to get a server cursor, native positioned update/delete can take place in PostgreSQL.

**Related concepts**

*Positioned UPDATE/DELETE* on page 567
Using positioned updates/deletes with named database cursors.

**LOAD and UNLOAD**

**Informix®**
Informix® provides two SQL instructions to export / import data from / into a database table:

The **UNLOAD** instruction copies rows from a database table into a text file:

```
UNLOAD TO "filename.unl" SELECT * FROM tab1 WHERE ..
```

The **LOAD** instructions insert rows from a text file into a database table:

```
LOAD FROM "filename.unl" INSERT INTO tab1
```

**PostgreSQL**
PostgreSQL does not provide **LOAD** and **UNLOAD** instructions.

**Solution**

**LOAD** and **UNLOAD** instruction are implemented in the Genero BDL runtime system with basic **INSERT** (for **LOAD**) or **SELECT** (for **UNLOAD**) SQL commands. The **LOAD** and **UNLOAD** instruction can be supported with various database servers.

However, **LOAD** and **UNLOAD** require the description of the column types in order to work, that can lead to some differences in the data formatting.

**Note:** If no transaction is started, the **LOAD** instruction will automatically execute a **BEGIN WORK** and **COMMIT WORK** when finished, or **ROLLBACK WORK** if a row insertion failed while loading. Terminating a transaction will automatically close cursors not defined **WITH HOLD** option. To workaround this situation, see more details in the **LOAD** on page 684 reference topic.

The **LOAD** and **UNLOAD** BDL instructions are supported with PostgreSQL.

**Related concepts**

**LOAD and UNLOAD instructions** on page 574

The **LOAD** and **UNLOAD** instructions can produce different data formats depending on the database server type.

**SQL Interruption**

**Informix®**
With Informix®, it is possible to interrupt a long running query if the **SQL INTERRUPT ON** option.

**PostgreSQL**
PostgreSQL supports SQL Interruption: The db client must issue an **PQcancel()** libPQ call to interrupt a query.

**Solution**

The PostgreSQL database driver supports SQL interruption and converts the SQLSTATE code 57014 to the Informix® error code -213.

**Related concepts**

**Using SQL interruption** on page 539
Interrupt long running SQL queries, or interrupt queries waiting for locked data.

**Scrollable cursors**

**Informix®**

Informix® SQL and Genero BDL support scrollable cursors when you specify the SCROLL clause in the DECLARE cursor instruction:

```
DECLARE c1 SCROLL CURSOR FOR SELECT ... 
```

**PostgreSQL**

PostgreSQL supports native scrollable cursors: The client application must use the SCROLL option when declaring a server cursor.

**Solution**

The PostgreSQL database driver uses native scrollable cursors by declaring server cursors with the SCROLL option.

**Related concepts**

Scrollable cursors on page 560

How scrollable cursors can be supported on different databases.

**SQLite**

**Supported versions**

Genero BDL supports the following SQLite versions:

- SQLite 3.x

**Installation (Runtime Configuration)**

SQLite related installation topics.

**Install SQLite and create a database - database configuration/design tasks**

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. If the dbmsqt database driver is linked dynamically with the SQLite library, you must install the SQLite software on your computer. However, on most platforms, the driver has an embedded version of the SQLite library, and on platforms such as Linux® and Mac OS X™, the SQLite library is usually present. The minimum required version is SQLite 3.6.

2. Create a new SQLite database.

   To create a new database with tables, start the sqlite3 command line tool and execute SQL statements:

   ```
   $ sqlite3 /var/data/stores.db
   sqlite> CREATE TABLE customer ( cust_id INT PRIMARY KEY, ... );
   $ .exit
   ```

   To create an empty database, you can also issue the following command:

   ```
   $ sqlite3 /var/data/stores.db ""
   ```

   or create an empty file with operating system command:

   ```
   $ touch /var/data/stores.db
   ```
And empty file can also be created from a program by using a `base.Channel` object:

```sql
DEFINE ch base.Channel
LET ch = base.Channel.create()
CALL ch.openFile("/var/data/stores.db","w")
CALL ch.close
```

**Related concepts**

SQL programming on page 528
Covers topics about interacting with a database server using SQL.

**Prepare the runtime environment - connecting to the database**

1. In order to connect to SQLite, you must have a database driver "dbmsqt" in FGLDIR/dbdrivers. On most platforms, the SQLite driver is linked statically with the SQLite library, in other word SQLite is embedded in the ODI driver. However, on some platforms such as Linux® and Max OS X, where the SQLite library is usually present.

2. Make sure that the SQLite environment variables are properly set. You may want to define an environment variable such as SQLITEDIR to hold the installation directory of SQLite, which can then be used to set PATH and LD_LIBRARY_PATH. See SQLite documentation for more details.

3. If the SQLite library is not embedded in the dbmsqt* driver, the environment must be set to find the SQLite library. Verify the environment variable defining the search path for the SQLite shared library.

**Table 252: Shared library environment setting for SQLite**

<table>
<thead>
<tr>
<th>SQLite version</th>
<th>Shared library environment setting (if SQLite lib not built-in driver)</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLite 3.6 and higher</td>
<td>UNIX®: Add $SQLITEDIR/lib to LD_LIBRARY_PATH (or its equivalent).</td>
</tr>
<tr>
<td></td>
<td>Windows®: Add %SQLITEDIR%\bin to PATH.</td>
</tr>
</tbody>
</table>

4. Make sure that all operating system users running the application have read/write access to the database file.

5. SQLite uses UTF-8 encoding. If the locale used by the runtime system (LANG/LC_ALL) is not compatible to UTF-8 (for example, fr_FR.iso88591), Genero will do the appropriate character set conversions.

6. Set up the fglprofile entries for database connections.
   a) Define the SQLite database driver:
      ```bash
dbi.database.dbname.driver = "dbmsqt"
```
   b) The "source" parameter defines the path to the SQLite database file. Note that the database file must reside on the local disk (SQLite does not support network file systems). SQLite also supports in-memory database creation with the :memory: db specification. See SQLite documentation (sqlite3_open) for more details.
      ```bash
dbi.database.dbname.source = "/opt/myapp/stock.dbs"
```
   c) If the "source" parameter defines a relative path or a simple file name and the SQLite database file does not reside in that location based on the current directory of the fglrun process, define the DBPATH environment variable to find the database file. See DBPATH documentation for more details about this environment variable.
      ```bash
DBPATH="/opt/myapp"
```

**Related concepts**
The FGLPROFILE file(s) on page 220
FGLPROFILE environment variable defines Genero BDL configuration files

**Database concepts**
SQLite related database concepts topics.

**Database concepts**
Informix® servers can handle multiple database entities, while SQLite can manage several database files.

**Solution**
Map each Informix® database to a SQLite database file.

Consider creating the SQLite database file before using the connection instruction. The database file can be created as an empty file, with a OS shell command (touch) or by program by using the file utility classes.

It is possible to specify an SQLite database file name in the database specification in `CONNECT TO` or `DATABASE` instructions:

```plaintext
DATABASE "/opt/myapp/database/stock1.dbs"
```

However, it is recommended to use an indirection by providing an abstract name identifier in the program, and by defining the real database file with the "source" connection parameter. The file defined by "source" is then found directly (can be a relative or absolute path), or by using `DBPATH` settings, if not found from the current directory of fglrun (when it's not an absolute path).

In the program:

```plaintext
DATABASE stock
```

In the FGLPROFILE configuration file, define the SQLite driver and the database file:

```plaintext
dbi.database.stock.driver = "dbmsqt"
dbi.database.stock.source = "/opt/myapp/database/stock1.dbf"
```

Or if in FGLPROFILE, you define the file name only:

```plaintext
dbi.database.stock.source = "stock1.dbf"
```

The file is found by using `DBPATH`:

```plaintext
DBPATH="/opt/myapp/database"
```

When specifying `:memory:` as database file name, an empty SQLite database is created in memory. This can be useful if the persistence of the data is not required after the program has terminated:

```plaintext
DATABASE ":memory:"
```

**Concurrency management**
Informix® is a multiusers database engine, while SQLite is typically used for a single-user application. SQLite 3 supports multiusers access to the same database file, but it is not designed for large multiusers applications.

SQLite 3 supports two isolation levels: `SERIALIZABLE` (the default), and `READ UNCOMMITTED`. The isolation level can be changed with the `PRAGMA` command.

By default in the `SERIALIZABLE` isolation level, SQLite will raise an SQL error if a program tries to access a database resource in use by another program. To avoid the SQL error and force programs to wait for each other, programs define the behavior when the SQLite database is busy (SQLITE_BUSY), with a specific API call. No SQL command exists for this.
**Solution**

We recommend that you use SQLite for single-user DB applications. If several programs must access the same SQLite database, each program must perform a `SET LOCK MODE TO WAIT` instruction after the connection: `SET LOCK MODE` will be mapped to a call to the sqlite3_busy_timeout() SQLite API function to get the same behavior as Informix®, while `SET ISOLATION` instructions will be ignored.

**Related concepts**

- **Concurrent data access** on page 537
  Understanding concurrent data access and data consistency.

- **Optimistic locking** on page 561
  Implementing optimistic locking to handle access concurrently to the same database records.

- **WITH HOLD and FOR UPDATE** on page 568
  Hold cursors and not portable.

**Transactions handling**

**Informix®**

With the Informix® native mode (non ANSI):

- Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```
UPDATE tab1 SET ...   -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK           -- end of TX block
```

Informix® version 11.50 introduces savepoints:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [TRANSACTION] TO SAVEPOINT [name] 
RELEASE SAVEPOINT name
```

**SQLite**

With SQLite:

- Individual SQL statements are auto-committed.
- Transactions start with `BEGIN TRANSACTION` and end with `COMMIT TRANSACTION` or `ROLLBACK TRANSACTION`.
- DDL statements can be executed (and canceled) in transaction blocks.

SQLite supports savepoints with some differences compared to Informix®:

- `SAVEPOINT` can be used instead of `BEGIN TRANSACTION`. In this case, `RELEASE` is like a `COMMIT`.
- The syntax of a rollback to the savepoint is `ROLLBACK [TRANSACTION] TO [SAVEPOINT] name`.
- The syntax of a release of the savepoint is `RELEASE [SAVEPOINT] name`.
- Rollback must always specify the savepoint name.
- You cannot rollback to a savepoint if cursors are opened.
- In SQLite versions prior to 3.7, you cannot rollback are transaction if a cursor is open.
Solution

Regarding transaction control instructions, BDL applications do not have to be modified in order to work with SQLite. The BEGIN WORK, COMMIT WORK and ROLLBACK WORK commands are translated the native commands of SQLite.

Note: If you want to use savepoints, always specify the savepoint name in ROLLBACK TO SAVEPOINT and do not open cursors during transactions using savepoints. If you are using an SQLite versions prior to 3.7, it is not possible to perform a ROLLBACK WORK if a cursor (with hold) is currently open.

See also SELECT FOR UPDATE

Related concepts

Database transactions on page 538

Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

Database users

Informix®

Until version 11.70.xC2, Informix® database users must be created at the operating system level and must be members of the 'informix' group.

Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as in most other db servers.

Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.

SQLite

SQLite does not have the database users concept.

However, the operating system user must have read/write access to the database file.

Solution

SQLite is mainly designed for single-user applications.

Related concepts

Database users and security on page 547

Properly identifying database users allows to use database security and audit features.

Notes:

1. For more details about serial emulation, see SERIAL data types on page 933.

**BOOLEAN data type**

**Informix®**

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values.

Genero BDL implements the BOOLEAN data type in a different way: A BOOLEAN variable stores integer values 1 or 0 (for TRUE or FALSE). This type is designed to hold the result of a boolean expression.
SQLite

SQLite does not implement a native BOOLEAN type, but accepts BOOLEAN in the SQL syntax and uses integer values 1/0 for true/false booleans.

Solution

The SQLite database interface supports the BOOLEAN data type and stores 1 or 0 values in the column.

The BOOLEAN type translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsnname.ifxemul.datatype.boolean = { true | false }
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

CHAR and VARCHAR data types

Informix®

Informix® supports the following character data types:

**Table 254: Informix® character data types**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>SBCS and MBCS character data (max is 32767 bytes)</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>SBCS and MBCS character data (max is 255 bytes)</td>
</tr>
<tr>
<td>NCHAR (n)</td>
<td>Same as CHAR, with specific collation order</td>
</tr>
<tr>
<td>NVARCHAR (n)</td>
<td>Same as VARCHAR, with specific collation order</td>
</tr>
<tr>
<td>LVARCHAR (n)</td>
<td>max size varies depending on the IDS version</td>
</tr>
</tbody>
</table>

With Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is in how they use sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order.

The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the **DB_LOCALE** environment variable.

The character set used by applications is defined by the **CLIENT_LOCALE** environment variable.

Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR (N) is expressed in bytes, not characters as in some other databases)

SQLite

SQLite 3 provides the TEXT native data type with no strict size limitation. SQLite allows the CHAR (n), VARCHAR (n), NCHAR (n) and NVARCHAR (n) type names to be used, but actually stores the data in a TEXT native type.

SQLite treats empty strings as NOT NULL values like Informix®.

**Note:** With the default BINARY collation, SQLite compares VARCHAR and CHAR values by taking trailing blanks into account. Informix® always ignores trailing blanks when comparing CHAR/VARCHAR values.

SQLite supports only the UTF-8 character encoding. Thus, client applications must provide UTF-8 encoded strings.
Solution

The database interface supports character string variables in SQL statements for input (BDL USING) and output (BDL INTO).

Important: With the default BINARY collation, CHAR and VARCHAR comparison in SQLite takes trailing blanks into account. As result, some queries returning rows with Informix® may not return the same result set with SQLite. When creating a table in SQLite, you can change the default collation rule to force the database engine to trim trailing blanks before comparing CHAR/VARCHAR values, by specifying COLLATION RTRIM in the column definitions. When creating a table from a Genero program, if Informix® emulation is enabled for the CHAR/VARCHAR types, the SQLite database driver adds automatically COLLATE RTRIM after the CHAR(N) or VARCHAR(N) type, to get the same comparison semantics as Informix®.

Regarding character sets, the SQLite database driver automatically converts character strings used in the programs to/from UTF-8 for SQLite.

SQLite uses character length semantics: When you define a CHAR(20) and the database character set is multibyte, the column can hold more bytes/characters than the Informix® CHAR(20) type, when using byte length semantics. When using a multibyte character set (such as UTF-8), define database columns with the size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a SQLite database, the fgldbch schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters) ) column a in SQLite database using the UTF-8 character set, the .sch file will get a size of 10, that will be interpreted following FGL_LENGTH_SEMANTICS, as a number of bytes or characters.

See also the section about Localization.

The CHAR/VARCHAR type translation can be controlled with the following FGLPROFILE entries:

```
dbi.database.dsnname.ifxemul.datatype.char = true | false
begin
  $dbi.database.dsnname.ifxemul.datatype.varchar = true | false
end
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

</tr>
</tbody>
</table>
Informix® data type | Description
--- | ---
MONEY(p) | Equivalent to DECIMAL(p, 2) (max precision is 32)
MONEY(p,s) | Equivalent to DECIMAL(p, s) (max precision is 32)
REAL / SMALLFLOAT | 32-bit floating point decimal (C float)
DOUBLE PRECISION / FLOAT[(n)] | 64-bit floating point decimal (C double)

SQLite

SQLite 3 supports INTEGER (8 byte integer) and REAL (8 byte floating point) as native types to store numbers, but allows also synonyms:

Table 256: SQLite numeric data types and supported synonyms

<table>
<thead>
<tr>
<th>Supported synonyms</th>
<th>SQLite type affinity</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT, INTEGER, TINYINT, SMALLINT, MEDIUMINT, BIGINT, UNSIGNED BIG INT, INT2, INT8</td>
<td>INTEGER (8 bytes!)</td>
</tr>
<tr>
<td>REAL, DOUBLE, DOUBLE PRECISION, FLOAT</td>
<td>REAL (8 bytes!)</td>
</tr>
<tr>
<td>DECIMAL(p,s), NUMERIC</td>
<td>NUMERIC (based on REAL)</td>
</tr>
</tbody>
</table>

Important: Exact decimal types like DECIMAL(p,s) may be stored as floating point numbers (REAL), INTEGER or TEXT types, according to the type affinity selected by SQLite. When converted to floating point type, data loss and rounding rule differences are possible with SQLite.

Solution

Informix® numeric types are not translated by the SQLite database driver: The numeric types are used as is when creating tables, since SQLite supports a wide range of type synonyms.

Since SQLite 3 does not have exact decimal types like DECIMAL(p,s), you must pay attention to the rounding rules and data loss when using numbers with many significant digits. Arithmetic operations like division have different results than with Informix®. It is better to fetch the original column value into a DECIMAL variable, and do arithmetic operations in the application program.

The numeric types translation can be controlled with the following FGLPROFILE entries:

```
dbi.database.dsname.ifxemul.datatype.smallint = true
dbi.database.dsname.ifxemul.datatype.integer = true
dbi.database.dsname.ifxemul.datatype.bigint = true
dbi.database.dsname.ifxemul.datatype.int8 = true
dbi.database.dsname.ifxemul.datatype.decimal = true
dbi.database.dsname.ifxemul.datatype.money = true
dbi.database.dsname.ifxemul.datatype.float = true
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

**DATE and DATETIME data types**

**Informix®**

Informix® provides two data types to store date and time information:

- **DATE** = for year, month and day storage.
- **DATETIME** = for year to fraction (1-5) storage.

The **DATE** type is stored as an **INTEGER** with the number of days since 1899/12/31.

The **DATETIME** type can be defined with various time units, by specifying a start and end qualifier. For example, you can define a datetime to store an hour-to-second time value with **DATETIME HOUR TO SECOND**.

The values of Informix® **DATETIME** can be represented with a character string literal, or as **DATETIME()** literals:

- `'2017-12-24 15:45:12.345'` -- a **DATETIME YEAR TO FRACTION(3)**
- `'15:45'` -- a **DATETIME HOUR TO MINUTE**
- **DATETIME**(2017-12-24 12:45) **YEAR TO MINUTE**
- **DATETIME**(12:45:56.333) **HOUR TO FRACTION(3)**

Informix® is able to convert quoted strings to **DATE**/**DATETIME** data, if the string contains matching environment parameters. The string to date conversion rules for **DATE** is defined by the DBDATE environment variable. The string to datetime format for **DATETIME** is defined by the GL_DATETIME environment variable.

**Note:** Within Genero programs, the string representation for **DATETIME** values is always ISO (**YYYY-MM-DD hh:mm:ss.ffffff**)  

Informix® supports date arithmetic on **DATE** and **DATETIME** values. The result of an arithmetic expression involving dates/times is an **INTEGER** number of days when only **DATE** values are used, and an **INTERVAL** value if a **DATETIME** is used in the expression.

Informix® automatically converts an **INTEGER** to a **DATE** when the integer is used to set a value of a date column.

**SQLite**

SQLite 3 does not have a native type for date/time storage, but you can use data/time type names and functions based on the string representation of dates and times. The date/time values are stored in the **TEXT** native type.

The date/time functions of SQLite are based on standard **DATE** (**YYYY-MM-DD**), **TIME** (**hh:mm:ss**) and **TIMESTAMP** (**YYYY-MM-DD hh:mm:ss**) concepts.

For maximum flexibility with other RDBMS SQL languages, SQLite allows you to define table columns with your own type names. You can for example use the **SMALLDATETIME**, **SMALLTIME**, **TIME(N)**, **DATETIME(N)** type names.

**Solution**

**Note:** Since SQLite allows various data type names, the conversion rules define specific data/time type names such as **SMALLTIME**, **TINYDATETIME**, to map original Informix® date/time types. This allows the SQLite ODI driver and the fgldbsch tool detect the exact date/time type of a column. When a **CREATE TABLE** statement in a **BDL** program uses **DATETIME HOUR TO MINUTE**, it is mapped to a **SMALLTIME** by the ODI driver, and when extracting the database schema, fgldbsch can recognized **SMALLTIME** as a **BDL**/Informix® **DATETIME HOUR TO MINUTE** column.

Use the following conversion rules to map Informix® date/time types to SQLite date/time (pseudo) types:
Table 257: Informix® data types and SQLite equivalents

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>SQLite (pseudo data type)</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME HOUR TO MINUTE</td>
<td>SMALLTIME</td>
</tr>
<tr>
<td>DATETIME HOUR TO SECOND</td>
<td>TIME</td>
</tr>
<tr>
<td>DATETIME HOUR TO FRACTION(n)</td>
<td>TIME(n)</td>
</tr>
<tr>
<td>DATETIME YEAR TO DAY</td>
<td>TINYDATETIME</td>
</tr>
<tr>
<td>DATETIME YEAR TO MINUTE</td>
<td>SMALLDATETIME</td>
</tr>
<tr>
<td>DATETIME YEAR TO SECOND</td>
<td>DATETIME</td>
</tr>
<tr>
<td>DATETIME YEAR TO FRACTION(n)</td>
<td>DATETIME(n)</td>
</tr>
<tr>
<td>DATETIME q1 TO q2 (different from above)</td>
<td>TIMESTAMP</td>
</tr>
</tbody>
</table>

The DATE and DATETIME types translation can be controlled with the following FGLPROFILE entries:

```
dbi.database.dsname.ifxemul.datatype.date = {true | false}
dbi.database.dsname.ifxemul.datatype.datetime = {true | false}
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

In SQL statements, CURRENT expressions are converted to SQLite `strftime('%Y-%m-%d %H:%M:%S','now')`. The SQLite 'now' option returns the current date/time in UTC, while the FGL runtime system CURRENT instruction returns the current local time. Both values can differ. Always consider using SQL parameters with program variables assigned by the CURRENT instruction of Genero BDL, instead of using CURRENT instructions in SQL statements.

**Related concepts**

- Date/time literals in SQL statements on page 571
- Good practices for date and time handling in SQL.
- SQL LOAD and UNLOAD on page 683
- Describes the instructions to export/import information from/to a database.

**INTERVAL data type**

**Informix®**

Informix® provides the INTERVAL data type to store a value that represents a span of time.

INTERVAL types are divided into two classes:

- **year-month** intervals. For example: `INTERVAL YEAR(5) TO MONTH`
- **day-time** intervals. For example: `INTERVAL DAY(9) TO SECOND`

INTERVAL columns can be defined with various time units, by specifying a start and end qualifier. For example, you can define an interval to store a number of hours and minutes with `INTERVAL HOUR(n) TO MINUTE`, where `n` defines the maximum number of digits for the hours unit.

The values of Informix® INTERVAL can be represented with a character string literal, or as INTERVAL() literals:

```
'9834 15:45:12.345' -- an INTERVAL DAY(6) TO FRACTION(3)
'7623-11' -- an INTERVAL YEAR(9) TO MONTH
INTERVAL(18734:45) HOUR(5) TO MINUTE
INTERVAL(-7634-11) YEAR(5) TO MONTH
```
SQLite

SQLite 3 does not provide a data type similar to Informix® INTERVAL.

Solution

The INTERVAL data type and values are converted CHAR(50) column with SQLite.

INTERVAL values can be stored and retrieved from the database. However, since SQLite does not support a native interval type, arithmetics cannot be performed on the database side in SQL statements.

Related concepts

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

SERIAL data types

Informix®

Informix® supports the SERIAL, BIGSERIAL data types to produce automatic integer sequences:

- SERIAL can produce 32 bit integers (INTEGER)
- BIGSERIAL can produced 64 bit integers (BIGINT)
- SERIAL8 is a synonym for BIGSERIAL

Steps to use serials with Informix®:

1. Create the table with a column using SERIAL, or BIGSERIAL.
2. To generate a new serial, no value or a zero value is specified in the INSERT statement:

   ```sql
   INSERT INTO tabl ( c ) VALUES ( 'aa' )
   INSERT INTO tabl ( k, c ) VALUES ( 0, 'aa' )
   ```

3. After INSERT, the new value of a SERIAL column is provided in SQLCA.SQLERRD[2], while the new value of a BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```sql
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

SQLite

SQLite supports the AUTOINCREMENT attribute for columns:

- Only one column must be declared as INTEGER PRIMARY KEY AUTOINCREMENT.
- To get the last generated number, SQLite provides the sqlite_sequence table:

  ```sql
  SELECT seq FROM sqlite_sequence WHERE name='table_name'
  ```

- When inserting a zero in the auto-increment column, SQLite will not generate a new sequence like Informix® does.
- When inserting a NULL in the auto-increment column, SQLite generates a new sequence; Informix® denies NULLs in SERIALs.
**Solution**

**Note:** For best SQL portability when using different type of databases, consider using sequences as described in Solution 3: Use native SEQUENCE database objects on page 565.

When using SQLite, the SERIAL data type is converted to INTEGER PRIMARY KEY AUTOINCREMENT.

The serial types emulation can be enabled or disabled with the following FGLPROFILE entries:

```sql
dbi.database.dbname.ifxemul.datatype.serial = [true|false]
dbi.database.dbname.ifxemul.datatype.serial8 = [true|false]
dbi.database.dbname.ifxemul.datatype.bigs Serial = [true|false]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

The SQLCA.SQLERRD[2] register is filled automatically after each INSERT with the last generated number, by fetching the value from the `sqlite_sequence` table.

SQLite (V 3.6) does not support auto-incremented BIGINTs. Therefore, BIGSERIAL or SERIAL8 cannot be converted.

Because SQLite does not behave like Informix® regarding zero and NULL value specification for auto-incremented columns, all INSERT statements must be reviewed to remove the SERIAL column from the list.

For example, the following statement:

```sql
INSERT INTO tab (col1,col2) VALUES ( 0 , p_value)
```

Can be converted to:

```sql
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```sql
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES ( rec.*) -- will use the serial column
```

Can be converted to:

```sql
INSERT INTO tab VALUES rec.* -- without parentheses, serial column is removed
```

**Related concepts**

Auto-incremented columns (serials) on page 562

How to implement automatic record keys.

**ROWID columns**

**Informix®**

When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only).

The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

**Note:** Informix® ROWID usage was a common practice in the early days of Informix® 4GL programming. Today it is recommended to define all your database tables with a PRIMARY KEY to uniquely identify rows.

With Informix®, the SQLCA.SQLERRD[6] register contains the ROWID of the last modified row.

**SQLite**

SQLite supports ROWID columns as 64-bit integers. Informix® rowids are 16-bit integers.
Solution

If the BDL application uses ROWIDs, it is recommended that the program logic is reviewed in order to use the real primary keys instead (usually serials, which can be supported). All references to SQLCA.SQLERRD[6] must be removed because this variable will not hold the ROWID of the last modified row.

If you cannot avoid the use of rowids, you must change the type of the variables which hold ROWID values. Instead of using INTEGER, use DECIMAL(20).

The ROWID keyword translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsnname.ifxemul.rowid = 'true' 'false'
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Using ROWID columns on page 578

Automatic ROWID columns is not a common database feature.

Foreign key support

Foreign keys are an important feature in modern database design, to enforce database integrity:

```sql
CREATE TABLE orders ( ... ,
    FOREIGN KEY(ord_customer) REFERENCES customer(cust_num) )
```

SQLite (3.6.19 and +) implements foreign key support, but this feature is not enabled by default. In fact, it is possible to define foreign keys on tables, but when doing database operations, the constraints are not enforced until you enable it explicitly with a PRAGMA command.

Solution

In order to turn on foreign key constraint checking, you must issue a PRAGMA command, which can for example be executed with a EXECUTE IMMEDIATE instruction:

```
EXECUTE IMMEDIATE "PRAGMA foreign_keys = ON"
```

Future releases of SQLite might change this, so that foreign key constraints enabled by default.

Related concepts

Data definition statements on page 552

It is recommended to avoid use of DDL in programs.

TEXT and BYTE (LOB) types

Informix®

Informix® provides the TEXT, BYTE, CLOB and BLOB data types to store very large texts or binary data.

Legacy Informix® 4GL applications typically use the TEXT and BYTE types.

Genero BDL does not support the Informix® CLOB and BLOB types.

SQLite

SQLite 3 provides the TEXT and BLOB native data types for large objects storage.

Solution

The SQLite database interface can convert BDL TEXT data to SQLite TEXT and BYTE data to SQLite BLOB.
The **TEXT** and **BYTE** types translation can be controlled with the following FGLPROFILE entries:

```plaintext
dbi.database dsname.ifxemul.text = \{true \ false\}
dbi.database dsname.ifxemul.byte = \{true \ false\}
```

For more details see [IBM Informix emulation parameters in FGLPROFILE](#) on page 614.

**Related concepts**

**Using portable data types** on page 553

Only a limited set of data types are really portable across several database engines.

**Data manipulation**

SQLite related data manipulation topics.

**Outer joins**

**Informix® OUTER() syntax**

In Informix® SQL, outer joins can be defined in the FROM clause with the OUTER keyword:

```sql
SELECT ... FROM a, OUTER (b) 
  WHERE a.key = b.akey

SELECT ... FROM a, OUTER(b,OUTER(c)) 
  WHERE a.key = b.akey
  AND b.key1 = c.bkey1 AND b.key2 = c.bkey2
```

Informix® also supports the ANSI OUTER join syntax, which is the recommended way to specify outer joins with recent SQL database engines:

```sql
SELECT ... FROM cust LEFT OUTER JOIN order 
  ON cust.key = order.custno 
  WHERE ...
```

**SQLite**

SQLite supports the ANSI outer join syntax:

```sql
SELECT ... 
  FROM cust LEFT OUTER JOIN order 
  LEFT OUTER JOIN item 
  ON order.key = item.ordno 
  ON cust.key = order.custno 
  WHERE order.cdate > current date
```

**Solution**

The Genero database drivers can convert Informix Informix® OUTER specifications to ANSI outer joins.

**Note:** For better SQL portability, use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The outer join translation can be controlled with the following FGLPROFILE entry:

```plaintext
dbi.database dsname.ifxemul.outers = \{true \ false\}
```

For more details see [IBM Informix emulation parameters in FGLPROFILE](#) on page 614.

- **Prerequisites:**
  1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.
Example which does not work:

... FROM OUTER(tab2), tab1

2. The outer join in the WHERE clause must use the table name as prefix:

... WHERE tab1.col1 = tab2.col2

- Restrictions:
  1. Statements composed by 2 or more SELECT instructions are not supported:

      SELECT ... UNION SELECT ...

      or:

      SELECT ... WHERE col IN (SELECT...)

  2. Additional conditions on outer table columns cannot be detected and therefore are not supported:

      ... FROM tab1, OUTER(tab2)
      WHERE tab1.col1 = tab2.col2
      AND tab2.colx > 10

- Notes:
  1. Table aliases are detected in OUTER expressions.

      OUTER example with table alias:

      ... OUTER(tab1 alias1) ...

  2. In the outer join, outertab.col can be placed on both right or left sides of the equal sign:

      ... WHERE outertab.col1 = maintab.col2

  3. Table names detection is not case-sensitive:

      SELECT ... FROM tab1, TAB2
      WHERE tab1.col1 = tab2.col2

  4. Temporary tables are supported in OUTER specifications:

      CREATE TEMP TABLE tt1 ( ... )
      SELECT ... FROM tab1, OUTER(tt1) ...

Transactions handling

Informix®

With the Informix® native mode (non ANSI):

- Transactions blocks start with BEGIN WORK and terminate with COMMIT WORK or ROLLBACK WORK.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

UPDATE tab1 SET ... -- auto-committed
BEGIN WORK -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK -- end of TX block
Informix® version 11.50 introduces savepoints:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name] ]
RELEASE SAVEPOINT name
```

**SQLite**

With SQLite:

- Individual SQL statements are auto-committed.
- Transactions start with `BEGIN TRANSACTION` and end with `COMMIT TRANSACTION` or `ROLLBACK TRANSACTION`.
- DDL statements can be executed (and canceled) in transaction blocks.

SQLite supports savepoints with some differences compared to Informix®:

- `SAVEPOINT` can be used instead of `BEGIN TRANSACTION`. In this case, `RELEASE` is like a `COMMIT`.
- The syntax of a rollback to the savepoint is `ROLLBACK [TRANSACTION] TO [SAVEPOINT] name.`
- The syntax of a release of the savepoint is `RELEASE [SAVEPOINT] name.`
- Rollback must always specify the savepoint name.
- You cannot rollback to a savepoint if cursors are opened.
- In SQLite versions prior to 3.7, you cannot rollback a transaction if a cursor is open.

**Solution**

Regarding transaction control instructions, BDL applications do not have to be modified in order to work with SQLite. The `BEGIN WORK`, `COMMIT WORK` and `ROLLBACK WORK` commands are translated the native commands of SQLite.

**Note:** If you want to use savepoints, always specify the savepoint name in `ROLLBACK TO SAVEPOINT` and do not open cursors during transactions using savepoints. If you are using an SQLite versions prior to 3.7, it is not possible to perform a `ROLLBACK WORK` if a cursor (with hold) is currently open.

See also `SELECT FOR UPDATE`

**Related concepts**

- Database transactions on page 538
- Temporary tables

**Temporary tables**

Informix®

Informix® temporary tables are created with the `CREATE TEMP TABLE` DDL instruction or with `SELECT ... INTO TEMP` statement:

```
CREATE TEMP TABLE tt1 ( pkey INT, name VARCHAR(50) )
CREATE TEMP TABLE tt2 ( pkey INT, name VARCHAR(50) ) WITH NO LOG
SELECT * FROM tab1 WHERE pkey > 100 INTO TEMP tt2
```

Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the `DROP TABLE` command. There is no name conflict when several users create temporary tables with the same name.

BDL REPORTs can create a temporary table when the rows are not sorted externally (by the source SQL statement).

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

When creating temporary tables in Informix®, the `WITH NO LOG` clause can be used to avoid the overhead of recording DML operations in transaction logs.
SQLite

SQLite supports temporary tables with the `CREATE TEMP TABLE` statement:

```sql
CREATE TEMP TABLE mytt1 ( pkey INT, name VARCHAR(50) )
CREATE TEMP TABLE mytt2 AS SELECT * FROM source
```

Solution

Informix® `CREATE TEMP TABLE` statements are kept as is, while `SELECT INTO TEMP` statements are converted to SQLite native SQL `CREATE TEMP TABLE AS SELECT ...`

The general FGLPROFILE entry to control temporary table emulation is:

```ini
dbi.database.dsname.ifxemul.temptables = \[ true \| false \]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Temporary tables on page 575
Syntax for temporary table creation is not unique across all database engines.

Substrings in SQL

Informix®

Informix® SQL statements can use subscripts on columns defined with the character data type:

```sql
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R' -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ... 
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

Important: With other database servers as Informix®, when the subscript notation is used to modify column values in UPDATE statement, or as ORDER BY element, you will get an SQL error:

```sql
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

SQLite

SQLite provides the `SUBSTR(expr, start, length)` function, to extract a substring from a string expression:

```sql
SELECT SUBSTR(col,10,5) ...
```

Solution

Replace all Informix® `col[x,y]` right-value expressions by `SUBSTR(col,x,y-x+1)`.

Rewrite UPDATE and ORDER BY clauses using `col[x,y]` expressions.

The translation of `col[x,y]` expressions can be controlled with the following FGLPROFILE entry:

```ini
dbi.database.dsname.ifxemul.colsubs = \[ true \| false \]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Substring expressions on page 577
Handle substrings expressions with different database engines.

**MATCHES and LIKE**

**Informix®**

Informix® supports MATCHES and LIKE operators in SQL statements.

MATCHES expects * and ? wild-card characters, while LIKE uses the % and _ wild-cards as equivalents.

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Sm1%' AND col NOT LIKE 'R_x' )
```

MATCHES accepts also brackets notation, to specify a set of matching characters at a given position:

```
( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )
```

**SQLite**

The SQLite does not provide an equivalent of the Informix® MATCHES operator.

The LIKE operator is supported.

**Solution**

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.

The MATCHES to LIKE expression translation is controlled by the following FGLPROFILE entry:

```
  dbi.database.dbname.ifxemul.matches = [true | false]
```

**Important:** Only [NOT] MATCHES followed by a search pattern provided as a string literal can be converted by ODI drivers. A [NOT] MATCHES followed by a ? question mark parameter place holder is not translated!

For maximum portability, consider replacing the MATCHES expressions with LIKE expressions in all SQL statements.

Avoid using CHAR(N) types for variable length character data (such as name, address).

**Related concepts**

- MATCHES and LIKE operators on page 579
- Use the standard LIKE operator instead of the MATCHES operator.

**The LENGTH() function**

**Informix®**

Informix® provides the LENGTH() function to count the number of bytes of a character string expression:

```
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```

Informix® LENGTH() does not count the trailing blanks for CHAR or VARCHAR expressions, while SQLite counts the trailing blanks.

Informix® LENGTH() returns 0 when the given string is empty. That means, LENGTH("")=0.

**SQLite**

SQLite supports the LENGTH() function, but there are some differences with Informix® LENGTH().
The SQLite `LENGTH()` function counts trailing blanks. When using a `CHAR` column, values are blank padded, and the function returns the size of the `CHAR` column. When using a `VARCHAR` column, trailing blanks are significant, and the function returns the number of characters, including trailing blanks.

When passing `NULL` as parameter, the SQLite `LENGTH()` function returns `NULL`.

**Solution**

The SQL `LENGTH()` function name can be used with SQLite.

Check if the trailing blanks are significant when using the `LENGTH()` SQL function in your application.

To count the number of characters by ignoring the trailing blanks, you must use the `RTRIM()` function:

```sql
SELECT LENGTH(RTRIM(col1)) FROM table
```

**Related concepts**

The `LENGTH()` function in SQL on page 581

The semantics of the `LENGTH()` SQL function differs according to the database engine.

**BDL programming**

SQLite related programming topics.

**INSERT cursors**

**Informix®**

Informix® provides *insert cursors* to optimize row creation in a database. An insert cursor is declared as a cursor, and rows as added with the `PUT` instruction. The rows are buffered and sent to the database server when executing a `FLUSH` instruction, or when the cursor is closed with `CLOSE`. When using transactions in Informix®, the `OPEN`, `PUT` and `FLUSH` instructions must be executed within a transaction block.

```sql
DECLARE c1 CURSOR FOR INSERT INTO tab1 ...
BEGIN WORK
OPEN c1
WHILE ...
  PUT c1 USING var-list
END WHILE
CLOSE c1
COMMIT WORK
```

**SQLite**

SQLite does not support insert cursors.

**Solution**

Insert cursors are emulated by the database interface, using basic `INSERT` SQL instructions.

The performances might be not as good as with Informix®, but the feature is fully supported.

**Related concepts**

*Insert cursors* on page 569
Using insert cursors with non-Informix databases.

**SELECT ... FOR UPDATE**

**Informix®**

Legacy BDL programs typically use a cursor with `SELECT FOR UPDATE` to implement pessimistic locking and avoid several users editing the same rows:

```sql
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

The row must be fetched in order to set the lock.

If the cursor is local to a transaction, the lock is released when the transaction ends. If the cursor is declared WITH HOLD, the lock is released when the cursor is closed.

**Informix®** provides the `SET LOCK MODE` instruction to define the lock wait timeout:

```sql
SET LOCK MODE TO { WAIT | NOT WAIT | WAIT seconds }
```

The default mode is NOT WAIT.

**SQLite**

SQLite does not support the `FOR UPDATE` close in `SELECT` syntax.

**Solution**

Review the program logic when using `SELECT ... FOR UPDATE` statements.

**Related concepts**

- [WITH HOLD and FOR UPDATE](#) on page 568
- [Hold cursors and not portable.](#)

**Cursors WITH HOLD**

**Informix®**

Informix® closes opened cursors automatically when a transaction ends, unless the WITH HOLD option is used in the `DECLARE` instruction:

```sql
DECLARE c1 CURSOR WITH HOLD FOR SELECT ... 
OPEN c1 
BEGIN WORK 
FETCH c1 ... 
COMMIT WORK 
FETCH c1 ... 
CLOSE c1 
```

**SQLite**

With SQLite, opened cursors using `SELECT` statements without a `FOR UPDATE` clause are not closed when a transaction ends: All SQLite cursors are WITH HOLD cursors unless the `FOR UPDATE` clause is used in the `SELECT` statement.
Solution

BDL cursors that are not declared WITH HOLD are automatically closed by the database interface when a COMMIT WORK or ROLLBACK WORK is performed.

Since SQLite automatically closes FOR UPDATE cursors when the transaction ends, opening cursors declared FOR UPDATE and WITH HOLD results in an SQL error that does not normally appear with Informix® under the same conditions.

Review the program logic in order to find another way to set locks.

Related concepts
WITH HOLD and FOR UPDATE on page 568
Hold cursors and not portable.

UPDATE/DELETE ... WHERE CURRENT OF

Informix®

Informix® allows positioned UPDATEs and DELETEs with the "WHERE CURRENT OF cursor" clause, if the cursor has been DECLARED with a SELECT ... FOR UPDATE statement.

SQLite

SQLite does not support the SELECT ... FOR UPDATE and UPDATE/DELETE WHERE CURRENT OF SQL instruction.

Solution

Review the program logic and use primary keys to update the rows.

Related concepts
Positioned UPDATE/DELETE on page 567
Using positioned updates/deletes with named database cursors.

LOAD and UNLOAD

Informix®

Informix® provides two SQL instructions to export / import data from / into a database table:

The UNLOAD instruction copies rows from a database table into a text file:

```
UNLOAD TO "filename.unl" SELECT * FROM tab1 WHERE ..
```

The LOAD instructions insert rows from a text file into a database table:

```
LOAD FROM "filename.unl" INSERT INTO tab1
```

SQLite

SQLite does not natively provide LOAD and UNLOAD instructions.

Solution

LOAD and UNLOAD instruction are implemented in the Genero BDL runtime system with basic INSERT (for LOAD) or SELECT (for UNLOAD) SQL commands. The LOAD and UNLOAD instruction can be supported with various database servers.

However, LOAD and UNLOAD require the description of the column types in order to work, that can lead to some differences in the data formatting.
**Note:** If no transaction is started, the LOAD instruction will automatically execute a `BEGIN WORK` and `COMMIT WORK` when finished, or `ROLLBACK WORK` if a row insertion failed while loading. Terminating a transaction will automatically close cursors not defined with `WITH HOLD` option. To workaround this situation, see more details in the LOAD on page 684 reference topic.

The LOAD and UNLOAD BDL instructions are supported with SQLite.

**Related concepts**

LOAD and UNLOAD instructions on page 574

The LOAD and UNLOAD instructions can produce different data formats depending on the database server type.

**SQL Interruption**

**Informix®**

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

**SQLite**

SQLite supports SQL Interruption: The db client must issue an `sqlite3_interrupt()` ODBC call to interrupt a query.

**Solution**

The SQLite database driver supports SQL interruption and converts the native SQL execution status `SQLITE_ABORT` to the Informix® error code -213.

**Related concepts**

Using SQL interruption on page 539

Interrupt long running SQL queries, or interrupt queries waiting for locked data.

**Scrollable cursors**

**Informix®**

Informix® SQL and Genero BDL support scrollable cursors when you specify the SCROLL clause in the DECLARE cursor instruction:

```sql
DECLARE c1 SCROLL CURSOR FOR SELECT ... 
```

**SQLite**

SQLite does not support scrollable cursors.

**Solution**

The SQLite database driver emulates scrollable cursors by fetching rows in a temporary file.

See Scrollable cursors on page 560 for more details about scroll cursor emulation.

**Modifying many rows in a table**

**SQLite**

SQLite is very slow when doing commits, because of the technique used to ensure data integrity (see SQLite documentation for details).

When a program executes a DML statement like INSERT, it will be automatically committed by SQLite. As result, if you do not enclose the SQL instruction between `BEGIN WORK / COMMIT WORK`, there will be as many commits as data manipulation statements.
For example, it takes about 10 seconds to insert 1000 rows on an Intel core i7 2.60GHz CPU / 5400.0 RPM HDD computer.

Solution
If a program must modify many rows in a table, execute the SQL statement within a transaction block delimited by BEGIN WORK / COMMIT WORK instructions. This will dramatically speed up the program with SQLite, and even with other non-Informix database servers.

See Performance with transactions on page 596.

Optimizing database file usage

SQLite
By default, when deleting a large amount of data in an SQLite database, it leaves behind empty space, causing the database file to be larger than strictly necessary.

This might be an issue with some mobile applications, when the disk space of the mobile device is limited.

Solution
Execute the VACUUM SQL command, to truncate the database file and reduce the disk usage.

According to the application, the VACUUM command can be executed:
- when starting the application,
- after doing a large db operation (like a synchronization with a central db),
- as a manual option that the user can trigger.

Note that SQLite also supports "PRAGMA auto_vacuum", but it appears that it's not as efficient as the VACUUM command, regarding page fragmentation.

Pay attention to the fact that VACUUM needs twice the disk space of the actual database file, because it rebuilds totally the db file.

VACUUM is not Informix SQL syntax, use EXECUTE IMMEDIATE to perform this SQL statement:

```sql
EXECUTE IMMEDIATE "VACUUM"
```

SAP® ASE

Supported versions
Genero BDL supports the following SAP® Adaptive Server® Enterprise (ASE) database version:
- SAP® ASE 16.x

Note: SAP® ASE was originally known as Sybase ASE and references to its original title may still be found in this documentation.

Installation (Runtime Configuration)
SAP® ASE related installation topics.

Install SAP ASE and create a database - database configuration/design tasks
If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. Install SAP® ASE software on your computer, with the SAP® client software.
   Make sure that the server is started and environment variables are properly set (On UNIX™, you will find SYBASE.* shell scripts to source in the installation directory).
2. Try to connect to the server with the isql command line tool.
If needed, change the password of the "sa" database administrator:

```bash
$ isql -S server_name -U sa
1> sp_password old_password, new_password
2> go
Password correctly set.
```

Starting with SAP® ASE 15.7, the password of the sa user is defined at installation time.

3. Define server's default character set: You must identify what server character set you want to use (typically, utf8) and re-configure the server if needed.

With SAP® ASE, the db character set cannot be specified at the database level, it is defined at the server level, typically during the installation. It is also possible to change the server character set with the `charset` utility and with the `sp_configure` stored procedure. You have to shutdown the server, start a first time to have the server take the new character set into account and then restart a second time for use. See SAP® documentation for more details or more recent versions of SAP® ASE.

Make sure that you select a case-sensitive character set / sort order.

**Note:** Check the `$SYBROOT/locales/locales.dat` file, to make sure that your current locale (LANG/LC_ALL) is listed in the file. You may want to add the following lines for UTF-8 support, under the section of your operating system:

```plaintext
locale = POSIX, us_english, utf8
locale = en_US.utf8, us_english, utf8
; Windows only:
locale = .fglutf8, us_english, utf8
```

Example:

```bash
$ export DSQUERY=servername
$ charset -U sa -P binary.srt utf8
Please enter sa's Password:
Loading file 'binary.srt'.
Found a [sortorder] section.
This is Class-1 sort order.
Finished loading the Character Set Definition.
Finished loading file 'binary.srt'.
1 sort order loaded successfully
$ isql -U sa -P
1> sp_configure 'default sortorder id', 50, 'utf8'
2> go
3> shutdown
4> go
Server SHUTDOWN by request.
ASE is terminating this process.
........
$ $SYBROOT/ASE_*/install/RUN_servername
... (server makes some initialization / setup and stops) ...
$ $SYBROOT/ASE_*/install/RUN_servername
...
```

4. Create a new SAP® ASE database entity, with sufficient storage devices for data and transaction log.
Use either the SAP® Central, the SAP® Control Center GUI tool or use isql with SQL commands.

Connect to the server with the sa user.

First create database devices for data and transaction log. Define a transaction that can hold the biggest transaction your application can do to avoid administrative tasks to dump the log when the server hangs. When creating the database, use the new created database devices as database segments:

```sql
use master
go
disk init
    name = "devname",
    physname = "filename",
    size = devsize ...
go
create database dbname
    on devname
    with ...
go
```

5. Leave the default transaction mode ("unchained" mode), to force explicit transaction start and end commands. See the set chained command for more details.

6. The database allows NULLs by default when creating columns.
   This is controlled by the 'allow nulls by default' option. If this option is set to OFF, columns created without NULL or NOT NULL keywords are NOT NULL by default:

```sql
master..sp_dboption dbname, 'allow nulls by default', true
```

7. The database must allow Data Definition Language (DDL) statements in transaction blocks.
   To turn this on, use following commands:

```sql
master..sp_dboption dbname, 'ddl in tran', true
go
checkpoint
```

8. For development purpose, consider setting the database option to truncate the transaction log when a checkpoint occurs, otherwise you will have to dump the transaction log when it is full.
   Command to automatically truncate the transaction log on checkpoint:

```sql
master..sp_dboption dbname, 'trunc log on chkpt', true
```

9. Create a new login dedicated to your application: the application administrator.
   Assign the new created database as default database for this user:

```sql
use dbname
    go
    sp_addlogin 'username', 'password', dbname, ... options ...
go
```

10. Create a new database user linked to the new application administrator login:
    In SAP ASE Central, open to the "Databases" node, select "Users" and right-click "New" ...

```sql
use dbname
    go
    sp_adduser 'username', 'group', ... options ...
go
```
See documentation for more details about database users and privileges. You must create groups to make tables visible to all users.

11. If you plan to use SERIAL emulation based on triggers using a registration table, create the SERIALREG table.

Create the triggers for each table using a SERIAL. See issue SERIAL data types for more details.

12. Create the application tables.

Convert Informix® data types to SAP® ASE data types. See topic data type Conversion Table for more details. In order to make application tables visible to all users, make sure that all users are members of the group of the owner of the application tables. For more details, see SAP® ASE documentation ("Database object names and prefixes").

**Prepare the runtime environment - connecting to the database**

1. In order to connect to SAP® ASE, you must have a SAP® ASE database driver "dbmase" in FGLDIR/dbdrivers.

2. If you want to connect to a remote database server, you must have the SAP® ASE Client Software installed on the computer running BDL applications.

   The SAP® Open Client Library is required.

3. Make sure that the SAP ASE client environment variables are properly set.

   Check for example SYBASE (the path to the installation directory), SYBASE_ASE (the name of the server sub-directory), SYBASE_OCS (the name of the client sub-directory), etc. See SAP® ASE documentation for more details.

4. Verify the environment variable defining the search path for SAP® ASE OCS database client shared libraries (libsybct[64].so, libsybcs[64].so UNIX™, LIBSYBCT[64].DLL and LIBSYBCS[64].DLL on Windows®).

**Table 258: Shared library environment setting for SAP ASE**

<table>
<thead>
<tr>
<th>SAP® ASE version</th>
<th>Shared library environment setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAP® ASE 16.0 and higher</td>
<td>UNIX: Add $SYBASE_OCS/lib to</td>
</tr>
<tr>
<td></td>
<td>LD_LIBRARY_PATH (or its equivalent).</td>
</tr>
<tr>
<td></td>
<td>Windows: Add %SYBASE_OCS\dll to PATH.</td>
</tr>
<tr>
<td></td>
<td>Where SYBASE_OCS is the directory of the SAP ASE Open Client Software.</td>
</tr>
</tbody>
</table>

5. The name of the SAP® ASE server must be registered in a configuration file.

   On UNIX™, the server name must be defined in the "interfaces" file located in $SYBASE. On Windows®, the server name must be defined in the "sql.ini" file located in %SYBASE%\ini. You may want to define the DSQUERY environment variable to the name of the server. See SAP® ASE documentation for more details.

   When connecting from a Genero program, both database and server names can be specified with:

   `database@server`

   For more details see the description for the connection data source parameter in DATABASE and CONNECT instructions.

6. Check the SAP® ASE database client locale settings.

   The SAP® ASE client locale must match the locale used by the runtime system (LC_ALL, LANG on UNIX™, ANSI code page on Windows®).

   By default, SAP® ASE OCS uses the character set defined by the operating system. On Windows®, this is the ANSI code page, on UNIX™ it is defined by LC_CTYPE, LC_ALL or LANG environment variables. Note that Genero BDL allows your to define the LANG environment variable also on Windows®. The value of the LANG environment variable must be listed in the "locales.dat" file under the %SYBASE/locales directory, otherwise you will get an error when connecting to the database.
Note: Check the $SYBROOT/locales/locales.dat file, to make sure that your current locale (LANG/ LC_ALL) is listed in the file. You may want to add the following lines for UTF-8 support, under the section of your operating system:

```plaintext
locale = POSIX, us_english, utf8
locale = en_US.utf8, us_english, utf8
; Windows only:
locale = .fglutf8, us_english, utf8
```

See also SAP ASE OCS documentation regarding localization and character set definition.

7. Test the SAP ASE Client Software: Make sure the server is started and try to connect to a database by using the SAP ASE command interpreter:

```bash
$ isql -S server -U appadmin -P password
```

8. Set up the fglprofile entries for database connections:
   a) Define the SAP ASE database driver:

   ```plaintext
dbi.database.dbname.driver = "dbmase"
```

   b) Define the connection timeout with the following fglprofile entry:

   ```plaintext
dbi.database.dbname.ase.logintime = integer
```

   This entry defines the number of seconds to wait for a connection.
   Default is 5 seconds.

   c) Define the number of rows to be pre-fetched for result sets:

   ```plaintext
dbi.database.dbname.ase.prefetch.rows = integer
```

   Default is 10 rows.

Database concepts
SAP® ASE related database concepts topics.

Database concepts
As in Informix®, a SAP® ASE engine can manage multiple database entities. When creating a database object such as a table, SAP® ASE allows you to use the same object name in different databases.

Concurrency management

Data consistency and concurrency concepts

- Data Consistency applies to situations when readers want to access data currently being modified by writers.
- Concurrent Data Access applies to situations when several writers are accessing the same data for modification.
- Locking Granularity defines the amount of data concerned when a lock is set (for example, row, page, table).

Informix®
Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with UPDATE, INSERT or DELETE, an exclusive lock is set on the touched rows. The lock remains active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set shared locks, depending on isolation level. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification, or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the lock wait mode.

Control:
• Lock wait mode: SET LOCK MODE TO ...
• Isolation level: SET ISOLATION TO ...
• Locking granularity: CREATE TABLE ... LOCK MODE {PAGE | ROW}
• Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:
• The default isolation level is READ COMMITTED.
• The default lock wait mode is NOT WAIT.
• The default locking granularity is PAGE.

SAP ASE

As in Informix®, SAP® ASE uses locks to manage data consistency and concurrency. The database manager sets exclusive locks on the modified rows and shared locks when data is read, based on the isolation level. The locks are held until the end of the transaction. When multiple processes want to access the same data, the latest processes must wait until the first finishes its transaction or the lock timeout occurred. The lock granularity is at the row, page or table level. For more details, see SAP® ASE's Documentation.

Control:
• The lock wait mode can be controlled with: SET LOCK {WAIT seconds | NOWAIT}
• Isolation level: Can be set with: SET TRANSACTION ISOLATION LEVEL = {0 | 1 | 2 | 3}
• Locking granularity: Row, page or table level (depends on locking scheme).
• Explicit locking: SELECT ... FOR UPDATE

Defaults:
• The default isolation level is Read Committed (readers cannot see uncommitted data; no shared lock is set when reading data).

Solution

The SET ISOLATION TO ... Informix® syntax is replaced by SET TRANSACTION ISOLATION LEVEL ... in SAP® ASE. The following table shows the isolation level mappings done by the SAP® ASE database driver:

Table 259: Isolation level mappings done by the SAP ASE database driver

<table>
<thead>
<tr>
<th>SET ISOLATION instruction in program</th>
<th>Native SQL command</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET ISOLATION TO DIRTY READ</td>
<td>SET TRANSACTION ISOLATION LEVEL = 0</td>
</tr>
<tr>
<td>SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]</td>
<td>SET TRANSACTION ISOLATION LEVEL = 1</td>
</tr>
<tr>
<td>SET ISOLATION TO CURSOR STABILITY</td>
<td>SET TRANSACTION ISOLATION LEVEL = 2</td>
</tr>
<tr>
<td>SET ISOLATION TO REPEATABLE READ</td>
<td>SET TRANSACTION ISOLATION LEVEL = 3</td>
</tr>
</tbody>
</table>

For portability, it is recommended that you work with Informix® in the read committed isolation level, to make processes wait for each other (lock mode wait) and to create tables with the "lock mode row" option.

The SET LOCK MODE TO ... Informix® syntax is replaced by SET LOCK ... in SAP® ASE. If SET LOCK MODE TO WAIT is used in programs (i.e. wait forever), the driver will simulate this with a SET LOCK WAIT 5000 in SAP® ASE:
### Table 260: SET LOCK MODE instruction for SAP ASE

<table>
<thead>
<tr>
<th>SET LOCK MODE instruction in program</th>
<th>Native SQL command</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET LOCK MODE TO NOT WAIT</td>
<td>SET LOCK NOWAIT</td>
</tr>
<tr>
<td>SET LOCK MODE TO WAIT n</td>
<td>SET LOCK WAIT n</td>
</tr>
<tr>
<td>SET LOCK MODE TO WAIT</td>
<td>SET LOCK WAIT 5000</td>
</tr>
</tbody>
</table>

See the Informix® and SAP® ASE documentation for more details about data consistency, concurrency and locking mechanisms.

**Related concepts**

- **Concurrent data access** on page 537
  Understanding concurrent data access and data consistency.

- **Optimistic locking** on page 561
  Implementing optimistic locking to handle access concurrently to the same database records.

- **WITH HOLD and FOR UPDATE** on page 568
  Hold cursors and not portable.

**Transactions handling**

**Informix®**

With the Informix® native mode (non ANSI):

- Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```sql
UPDATE tab1 SET ...   -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK           -- end of TX block
```

Informix® version 11.50 introduces savepoints:

```sql
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name] 
RELEASE SAVEPOINT name
```

**SAP ASE**

- SAP® ASE supports two transaction modes:
  1. The SQL standards-compatible mode, called *chained* mode, to get implicit transaction.
  2. The default mode, called *unchained* mode, where transactions have to be started/ended explicitly.
- Transactions are started with "BEGIN TRANSACTION [name]."
- Transactions are validated with "COMMIT TRANSACTION [name]."
- Transactions are canceled with "ROLLBACK TRANSACTION [name]."
- Transactions save points can be placed with "SAVEPOINT [name]."
- SAP® ASE supports named and nested transactions.
- DDL statements can be executed in transactions blocks when the 'ddl in tran' option is set to true with:

```sql
master..sp_dboption dbname, 'ddl in tran', true
```
**Solution**
Informix® transaction handling commands are automatically converted to SAP® ASE instructions to start, commit or rollback transactions.

Make sure that the database uses the default *unchained* mode (set chained off) and allows DDLs in transactions (`ddl in tran` option is true).

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with SAP® ASE.

**Related concepts**
- Database transactions on page 538
  Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Database users**

**Informix®**
Until version 11.70.xC2, Informix® database users must be created at the operating system level and must be members of the 'informix' group.

Starting with 11.70.xC2, Informix® supports database-only users with the `CREATE USER` instruction, as in most other db servers.

Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the `GRANT` command.

**SAP ASE**
The system administrator (DBA) must declare the application users in the database with the `GRANT` statement.

You may also need to define groups in order to make tables visible to other users.

**Solution**
See SAP® ASE documentation for more details on database logins and users.

**Related concepts**
- Database users and security on page 547
  Properly identifying database users allows to use database security and audit features.

**Setting privileges**

**Informix®**
Informix® users must have at least the `CONNECT` privilege to access the database:

```
GRANT CONNECT TO username
```

Application administration users need the `RESOURCE` privilege to create tables:

```
GRANT RESOURCE TO username
```

Since version 7.20, Informix® supports database roles:

```
GRANT rolename TO username
```
SAP ASE

SAP® ASE supports the concept of roles to grant or revoke permissions to a group of users. See SAP® ASE documentation for more details.

Solution

Informix® and SAP® ASE user privileges management are quite similar.

</tbody>
</table>
Informix® data types | SAP® ASE data types
---|---
TEXT | TEXT
BYTE | IMAGE

Notes:

1. For more details about serial emulation, see SERIAL data type on page 961.

**BOOLEAN data type**

**Informix®**

Informix® supports the BOOLEAN data type, which can store ‘t’ or ‘f’ values.

Genero BDL implements the BOOLEAN data type in a different way: A BOOLEAN variable stores integer values 1 or 0 (for TRUE or FALSE). This type is designed to hold the result of a boolean expression.

**SAP ASE**

SAP® ASE provides the BIT data type to store boolean values.

However, unlike Informix® types, BIT columns cannot be NULL and thus you must specify the NOT NULL constraint when creating the table.

**Solution**

The SAP® ASE database interface converts BOOLEAN type to BIT columns and stores 1 or 0 values in the column.

You must explicitly specify the NOT NULL constraint in the CREATE TABLE statement.

The BOOLEAN type translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemul.datatype.boolean = \[ true \ | false \]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

**CHAR and VARCHAR data types**

**Informix®**

Informix® supports the following character data types:

**Table 262: Informix® character data types**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>SBCS and MBCS character data (max is 32767 bytes)</td>
</tr>
<tr>
<td>VARCHAR(nL, mL)</td>
<td>SBCS and MBCS character data (max is 255 bytes)</td>
</tr>
<tr>
<td>NCHAR (n)</td>
<td>Same as CHAR, with specific collation order</td>
</tr>
<tr>
<td>NVARCHAR(nL, mL)</td>
<td>Same as VARCHAR, with specific collation order</td>
</tr>
<tr>
<td>LVARCHAR (n)</td>
<td>max size varies depending on the IDS version</td>
</tr>
</tbody>
</table>
With Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is in how they use sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order.

The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable.

The character set used by applications is defined by the CLIENT_LOCALE environment variable.

Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR(N) is expressed in bytes, not characters as in some other databases)

**SAP ASE**

SAP® ASE supports following data types to store character data:

**Table 263: SAP ASE character data types**

<table>
<thead>
<tr>
<th>SAP® ASE data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>SBCS or MBCS character data using the database character set, where n is specified in bytes (max is 16384 bytes)</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>SBCS or MBCS character data using the database character set, where n is specified in bytes (max is 16384 bytes)</td>
</tr>
<tr>
<td>NCHAR (n)</td>
<td>MBCS character data using the database character set, where n is specified in characters (max is 16384 bytes)</td>
</tr>
<tr>
<td>NVARCHAR (n)</td>
<td>MBCS character data using the database character set, where n is specified in characters (max is 16384 bytes)</td>
</tr>
<tr>
<td>UNICHAR (n)</td>
<td>UNICODE/UCS-2 character data, where n is specified in characters (max is 16384 characters)</td>
</tr>
<tr>
<td>UNIVARCHAR (n)</td>
<td>UNICODE/UCS-2 character data, where n is specified in characters (max is 16384 characters)</td>
</tr>
</tbody>
</table>

SAP® ASE implements the following character data types:

- CHAR (N) with N <= 16384 bytes
- VARCHAR (N) with N <= 16384 bytes
- NCHAR (N) with N <= 16384 characters
- NVARCHAR (N) with N <= 16384 characters
- UNICHAR (N) with N <= 16384 characters
- UNIVARCHAR (N) with N <= 16384 characters

Like Informix®, SAP® ASE can store multibyte characters in CHAR/VARCHAR columns, depending on the database character set. For example, SAP® can store UTF-8 strings in CHAR/VARCHAR columns. For multibyte character sets, you could also use the NCHAR/NVARCHAR or UNICHAR/UNIVARCHAR SAP® ASE types, the only difference with CHAR/VARCHAR is that the length is specified in characters instead of bytes. The UNICHAR/UNIVARCHAR types store characters in 16 bit UCS-2 charset only, but this is transparent to the database client.

SAP® ASE supports automatic character set conversion between the client application and the server. By default, the SAP® ASE database client character set is defined by the operating system locale where the database client runs. On Windows®, it is the ANSI code page of the login session (can be overwritten by setting the LANG environment variable), on UNIX™ it is defined by the LC_CTYPE, LC_ALL or LANG environment variable. You may need to edit the $SYBASE/locales/locales.dat file to map the OS locale name to a known SAP® ASE character set.

Unlike most other database engines, SAP® ASE trims trailing blanks when inserting character strings in a VARCHAR column.
For example:

```
CREATE TABLE t1 ( k INT, vc VARCHAR(5))
INSERT INTO t1 VALUES ( 1, 'abc ' )
SELECT '"'||vc||'"' FROM t1 WHERE k = 1
------------------------------------------------
[abc]
```

With other database servers you would get 1 blank after abc:

```
[abc ]
```

**Solution**

If your application must support multibyte character sets like BIG5 or UTF-8, it is recommended that you use CHAR/VARCHAR SAP® ASE data types, where the length is specified in bytes like with Informix®.

Check that your database schema does not use CHAR, VARCHAR or LVARCHAR types with a length exceeding the SAP® ASE limit.

If your application creates tables with NCHAR/NVARCHAR types, the same type name will be used in SAP® ASE. Keep in mind that the size of NCHAR/NVARCHAR in SAP® is specified in characters, while Informix® uses a number of bytes.

When using a multibyte character set (such as UTF-8), define database columns with the size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a SAP® ASE database, the fgldbsch schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters) ) column in a SAP® ASE database using the UTF-8 character set, the .sch file will get a size of 10, that will be interpreted by FGL_LENGTH_SEMANTICS as a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

Since trailing blanks are trimmed for VARCHAR columns, make sure that your application does not rely on this non-standard behavior.

See also the section about Localization

The CHAR/VARCHAR type translation can be controlled with the following FGLPROFILE entries:

```
    dbi.database.dsnname.ifxemul.datatype.char = { true | false }
    dbi.database.dsnname.ifxemul.datatype.varchar = { true | false }
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

CHAR and VARCHAR types on page 555

Using the CHAR and VARCHAR data types with different databases.

**NUMERIC data types**

**Informix®**

Informix® supports several data types to store numbers:

**Table 264: Informix® numeric data types**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>16 bit signed integer</td>
</tr>
<tr>
<td>Informix® data type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>------------------------------------</td>
</tr>
<tr>
<td>INTEGER</td>
<td>32 bit signed integer</td>
</tr>
<tr>

<td>32-bit floating point decimal (C float)</td>
</tr>
<tr>
<td>DOUBLE PRECISION / FLOAT[(n)]</td>
<td>64-bit floating point decimal (C double)</td>
</tr>
</tbody>
</table>

**SAP ASE**

SAP® ASE supports the following numeric data types:

Table 265: SAP ASE numeric data types

<table>
<thead>
<tr>
<th>SAP® ASE data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>16 bit signed integer</td>
</tr>
<tr>
<td>INTEGER</td>
<td>32 bit signed integer</td>
</tr>
<tr>
<td>BIGINT</td>
<td>64 bit signed integer</td>
</tr>
<tr>
<td>DECIMAL(p,s)</td>
<td>Fixed point decimal.</td>
</tr>
<tr>
<td>SMALLMONEY</td>
<td>32-bit floating point decimal with currency</td>
</tr>
<tr>
<td>MONEY</td>
<td>64-bit floating point decimal with currency</td>
</tr>
<tr>
<td>REAL</td>
<td>32-bit floating point decimal (C float)</td>
</tr>
<tr>
<td>FLOAT[(n)] (DOUBLE)</td>
<td>64-bit floating point decimal (C double)</td>
</tr>
</tbody>
</table>

Notes about SAP® ASE DECIMAL type:

- Without any decimal storage specification, the precision defaults to 18 and the scale defaults to zero:
  - DECIMAL in SAP ASE = DECIMAL(18, 0) in Genero BDL.
  - DECIMAL(p) in SAP ASE = DECIMAL(p, 0) in Genero BDL.
- The maximum precision is 38.

Notes about the SAP® ASE MONEY and SMALLMONEY types:

- SAP® ASE provides the MONEY and SMALLMONEY data types, but the currency symbol handling is quite different. Therefore, it is recommended to implement Informix® MONEY columns as DECIMAL columns in SAP® ASE.

**Solution**

Use the following conversion rules to map Informix® numeric types to SAP® ASE numeric types:
<table>
<thead>
<tr>
<th>Informix®</th>
<th>SAP® ASE</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>INTEGER</td>
<td>INTEGER</td>
</tr>
<tr>

<td>DECIMAL(16,2)</td>
</tr>
<tr>
<td>REAL / SMALLFLOAT</td>
<td>REAL</td>
</tr>
<tr>
<td>FLOAT[(n)] / DOUBLE PRECISION</td>
<td>FLOAT(n) (Where n must be from 1 to 15)</td>
</tr>
</tbody>
</table>

When creating tables from BDL programs, the database interface automatically converts Informix® numeric data types to corresponding SAP® ASE data types. In database creation scripts, apply the conversion rules as described in the above table.

**Important:** There is no SAP ASE equivalent for the Informix® DECIMAL(p) floating point decimal (i.e. without a scale). If your application is using such data types, you must review the database schema in order to use SQL Server compatible types. To workaround the SAP ASE limitation, the SAP ASE database driver converts DECIMAL(p) types to a DECIMAL(2*p, p), to store all possible numbers an Informix® DECIMAL(p) can store. However, the original Informix® precision cannot exceed 19, since SAP® ASE maximum DECIMAL precision is 38 (2*19). If the original precision is bigger than 19, a CREATE TABLE statement executed from a Genero program will fail with an SAP ASE error 2756.

SAP® ASE does not support implicit character string to numeric conversions. For example, if you compare an integer column to ‘123’ in a WHERE clause, SAP® ASE will raise a conversion error. The problem exists also when using CHAR or VARCHAR SQL parameters. Check that your programs do not use string literals or CHAR/VARCHAR SQL parameters in integer expressions, as in this example:

```sql
DEFINE pv CHAR(1)
CREATE TABLE mytable ( v1 INT, v2 INT )
LET pv = '1'
SELECT * FROM mytable WHERE v1 = '1' AND v2 = pv
```

The numeric types translation can be controlled with the following FGLPROFILE entries:

```sql
dbi.database.dsnname.ifxemul.datatype.smallint = { true  ▼ false }
dbi.database.dsnname.ifxemul.datatype.integer = { true  ▼ false }
dbi.database.dsnname.ifxemul.datatype.bigint = { true  ▼ false }
dbi.database.dsnname.ifxemul.datatype.int8 = { true  ▼ false }
dbi.database.dsnname.ifxemul.datatype.decimal = { true  ▼ false }
dbi.database.dsnname.ifxemul.datatype.money = { true  ▼ false }
dbi.database.dsnname.ifxemul.datatype.float = { true  ▼ false }
dbi.database.dsnname.ifxemul.datatype.smallfloat = { true  ▼ false }
```

For more details see [IBM Informix emulation parameters in FGLPROFILE](#) on page 614.
Related concepts
Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

DATE and DATETIME data types

Informix®

Informix® provides two data types to store date and time information:

- **DATE** = for year, month and day storage.
- **DATETIME** = for year to fraction (1-5) storage.

The **DATE** type is stored as an **INTEGER** with the number of days since 1899/12/31.

The **DATETIME** type can be defined with various time units, by specifying a start and end qualifier. For example, you can define a datet ime to store an hour-to-second time value with **DATETIME HOUR TO SECOND**.

The values of Informix® **DATETIME** can be represented with a character string literal, or as **DATETIME()** literals:

<table>
<thead>
<tr>
<th>Character string literal</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'2017-12-24 15:45:12.345'</td>
<td><strong>DATETIME YEAR TO FRACTION(3)</strong></td>
</tr>
<tr>
<td>'15:45'</td>
<td><strong>DATETIME HOUR TO MINUTE</strong></td>
</tr>
<tr>
<td><strong>DATETIME(2017-12-24 12:45)</strong> YEAR TO MINUTE</td>
<td></td>
</tr>
<tr>
<td><strong>DATETIME(12:45:56.333) HOUR TO FRACTION(3)</strong></td>
<td></td>
</tr>
</tbody>
</table>

Informix® is able to convert quoted strings to **DATE / DATETIME** data, if the string contains matching environment parameters. The string to date conversion rules for **DATE** is defined by the DBDATE environment variable. The string to datetime format for **DATETIME** is defined by the GL_DATETIME environment variable.

**Note:** Within Genero programs, the string representation for **DATETIME** values is always ISO (YYYY-MM-DD hh:mm:ss.fffffff)

Informix® supports date arithmetic on **DATE** and **DATETIME** values. The result of an arithmetic expression involving dates/times is an **INTEGER** number of days when only **DATE** values are used, and an **INTERVAL** value if a **DATETIME** is used in the expression.

Informix® automatically converts an **INTEGER** to a **DATE** when the integer is used to set a value of a date column.

SAP ASE

SAP® ASE provides the following data type to store date and time data:

**Table 267: SAP ASE date/time data types**

<table>
<thead>
<tr>
<th>SAP® ASE SERVER data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DATE</strong></td>
<td>for year, month, day storage</td>
</tr>
<tr>
<td><strong>TIME</strong></td>
<td>for hour, minutes, seconds, fraction(3) storage</td>
</tr>
<tr>
<td><strong>SMALLDATETIME</strong></td>
<td>for hour, minutes, seconds, fraction(3) storage</td>
</tr>
<tr>
<td><strong>DATETIME</strong></td>
<td>for hour, minutes, seconds, fraction(3) storage</td>
</tr>
<tr>
<td><strong>BIGTIME</strong></td>
<td>for hour, minutes, seconds, fraction(6) storage</td>
</tr>
<tr>
<td><strong>BIGDATETIME</strong></td>
<td>for year, month, day, hour, minutes, seconds, fraction(6) storage</td>
</tr>
</tbody>
</table>

SAP® ASE can convert quoted strings representing datetime data in the ANSI format. The **CONVERT()** SQL function allows you to convert strings to dates.

With SAP® ASE, you must use built-in functions to do date/time computing (for example, see **dateadd()** function).
Solution

Use the following conversion rules to map Informix® date/time types to SAP® ASE date/time types:

Table 268: Informix® data types and SAP ASE equivalents

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>SAP ASE data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>DATE (yyyy-mm-dd)</td>
</tr>
<tr>
<td>DATETIME HOUR TO FRACTION(n)</td>
<td>BIGTIME (hh:mm:ss.ffffff)</td>
</tr>
<tr>
<td>DATETIME HOUR TO SECOND</td>
<td>BIGTIME (hh:mm:ss.ffffff)</td>
</tr>
<tr>
<td>DATETIME q1 TO q2 (different from above)</td>
<td>BIGDATETIME(yyyy-mm-dd hh:mm:ss.ffffff)</td>
</tr>
</tbody>
</table>

The DATE and DATETIME types translation can be controlled with the following FGLPROFILE entries:

```sql
  dbi.database.dsnname.ifxemul.datatype.date = {true | false}
  dbi.database.dsnname.ifxemul.datatype.datetime = {true | false}
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

SAP ASE has the same DATE data type as Informix® (year, month, day). So you can use SAP ASE DATE data type for Informix® DATE columns.

SAP ASE BIGTIME data type can be used to store Informix® DATETIME HOUR TO SECOND and DATETIME HOUR TO FRACTION(5) values. The database interface makes the conversion automatically.

Informix® DATETIME values with any precision from YEAR to FRACTION(5) can be stored in SAP ASE BIGDATETIME columns. The database interface makes the conversion automatically. Missing date or time parts default to 1900-01-01 00:00:00.0. For example, when using a DATETIME HOUR TO MINUTE with the value of "11:45", the ASE TIMESTAMP value will be "1900-01-01 11:45:00.0".

Note: SAP ASE does not support INTEGER to DATE automatic conversion.

Related concepts

- Date/time literals in SQL statements on page 571
- Good practices for date and time handling in SQL.

**INTERVAL data type**

**Informix®**

Informix® provides the INTERVAL data type to store a value that represents a span of time.

INTERVAL types are divided into two classes:

- *year-month* intervals. For example: INTERVAL YEAR(5) TO MONTH
- *day-time* intervals. For example: INTERVAL DAY(9) TO SECOND

INTERVAL columns can be defined with various time units, by specifying a start and end qualifier. For example, you can define an interval to store a number of hours and minutes with INTERVAL HOUR(n) TO MINUTE, where n defines the maximum number of digits for the hours unit.

The values of Informix® INTERVAL can be represented with a character string literal, or as INTERVAL() literals:

- '9834 15:45:12.345' -- an INTERVAL DAY(6) TO FRACTION(3)
- '7623-11' -- an INTERVAL YEAR(9) TO MONTH
- INTERVAL(18734:45) HOUR(5) TO MINUTE
- INTERVAL(-7634-11) YEAR(5) TO MONTH
SAP ASE

SAP® ASE does not provide a data type corresponding to the Informix® INTERVAL data type.

Solution

The INTERVAL data type and values are converted CHAR(50) column with SAP® ASE. INTERVAL values can be stored and retrieved from the database. However, since SAP® ASE does not support a native interval type, arithmetics cannot be performed on the database side in SQL statements.

The INTERVAL types translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemul.datatype.interval = {true | false}
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

SERIAL data type

Informix®

Informix® supports the SERIAL, BIGSERIAL data types to produce automatic integer sequences:

- SERIAL can produce 32 bit integers (INTEGER)
- BIGSERIAL can produce 64 bit integers (BIGINT)
- SERIAL8 is a synonym for BIGSERIAL

Steps to use serials with Informix®:

1. Create the table with a column using SERIAL, or BIGSERIAL.
2. To generate a new serial, no value or a zero value is specified in the INSERT statement:

   ```
   INSERT INTO tab1 ( c ) VALUES ( 'aa' )
   INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
   ```

3. After INSERT, the new value of a SERIAL column is provided in SQLCA.SQLERRD[2], while the new value of a BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

SAP ASE

SAP® ASE IDENTITY columns:

- When creating a table, the IDENTITY keyword must be specified after the column data type:

  ```
  CREATE TABLE tab1 ( k integer identity, c char(10) )
  ```

- You cannot specify a start value
• A new number is automatically created when inserting a new row:

```sql
INSERT INTO tab1 ( c ) VALUES ( 'aaa' )
```

• To get the last generated number, SAP® ASE provides a global variable:

```
SELECT @@IDENTITY
```

• When `IDENTITY_INSERT=ON`, you can set a specific value into a `IDENTITY` column, but zero does not generate a new serial:

```sql
SET IDENTITY_INSERT tab1 ON
INSERT INTO tab1 ( k, c ) VALUES ( 100, 'aaa' )
```

Informix® SERIALs and SAP® ASE `IDENTITY` columns are quite similar; the main difference is that SAP® ASE does not generate a new serial when you specify a zero value for the identity column.

**Solution**

**Note:** For best SQL portability when using different type of databases, consider using sequences as described in [Solution 3: Use native SEQUENCE database objects](#) on page 565.

With SAP® ASE, the `SERIAL` emulation can use `IDENTITY` columns (1) or insert triggers based on the `SERIALREG` table (2). The first solution is faster, but does not allow explicit serial value specification in insert statements; the second solution is slower but allows explicit serial value specification. You can initially use the second solution to have unmodified BDL programs working on SAP® ASE, but it is recommended that you update your code to use native `IDENTITY` columns for performance.

The method used to emulate `SERIAL` types is defined by the `ifxemul.datatype.serial.emulation` FGLPROFILE parameter:

```sql
dbi.database.dbname.ifxemul.datatype.serial.emulation = {"native","regtable"}
```

- `native`: uses `IDENTITY` columns.
- `regtable`: uses insert triggers with the `SERIALREG` table.

The default emulation technique is "native".

The serial types emulation can be enabled or disabled with the following FGLPROFILE entries:

```sql
dbi.database.dbname.ifxemul.datatype.serial = {true,false}
dbi.database.dbname.ifxemul.datatype.serial8 = {true,false}
dbi.database.dbname.ifxemul.datatype.bigserial = {true,false}
```

**Using the native serial emulation**

In database creation scripts, all `SERIAL` data types must be converted by hand to `INTEGER IDENTITY` data types, while `BIGSERIAL` must be converted to `BIGINT IDENTITY`.

Start values `SERIAL(n) / BIGSERIAL(n)` cannot be converted, there is no `INTEGER IDENTITY(n)` in SAP® ASE.

Tables created from the BDL programs can use the `SERIAL` data type: When a BDL program executes a `CREATE [TEMP] TABLE` with a `SERIAL` column, the database interface automatically converts the "`SERIAL[(n)]" data type to "`INTEGER IDENTITY[(n,1)]"."

In BDL, the new generated `SERIAL` value is available from the `SQLCA.SQLERRD[2]` variable. This is supported by the database interface which performs a "`SELECT @@IDENTITY". However, `SQLCA.SQLERRD[2]` is defined as an `INTEGER`, it cannot hold values from `BIGINT identity columns. If you are using `BIGINT IDENTITY` columns, you must use `@@IDENTITY`.}
When you insert a row with zero as serial value, the serial column gets the value zero. You must review all INSERT statements using zero for the serial column. For example, the following statement:

```
INSERT INTO tab (col1, col2)VALUES (0, p_value)
```

must be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES (rec.*) -- will use the serial column
```

can be converted to:

```
INSERT INTO tab VALUES rec.* -- without parentheses, serial column is removed
```

**Using the regtable serial emulation**

First, you must prepare the database and create the SERIALREG table as follows:

```
CREATE TABLE serialreg  
  (tablename VARCHAR(50) NOT NULL,
   lastserial BIGINT NOT NULL,
   PRIMARY KEY ( tablename )
  )
```

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types, BIGSERIAL column types must be changed to BIGINT, and you must create one trigger for each table. To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command.

Tables created from the BDL programs can use the SERIAL data type. When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the "SERIAL[(n)]" data type to "INTEGER" and creates the insert triggers.

SAP® ASE does not allow you to create triggers on temporary tables. Therefore, you cannot create temp tables with a SERIAL column when using this solution.

**Note:**

- SELECT ... INTO TEMP statements using a table created with a SERIAL column do not automatically create the SERIAL triggers in the temporary table. The type of the column in the new table is INTEGER.
- SAP® ASE triggers are not automatically dropped when the corresponding table is dropped. Database administrators must be aware of this behavior when managing schemas.
- INSERT statements using NULL for the SERIAL column will produce a new serial value:

```
INSERT INTO tab ( coll1, col2 ) VALUES ( NULL, 'data' )
```

This behavior is mandatory in order to support INSERT statements which do not use the serial column:

```
INSERT INTO tab (col2) VALUES('data')
```

Check if your application uses tables with a SERIAL column that can contain a NULL value.
- The serial production is based on the SERIALREG table which registers the last generated number for each table. If you delete rows of this table, sequences will restart at 1 and you will get unexpected data.
Related concepts
Auto-incremented columns (serials) on page 562
How to implement automatic record keys.
The SQLCA diagnostic record on page 532
The SQLCA variable is a predefined record containing SQL statement execution information.

ROWID columns

Informix®
When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only).
The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.
Note: Informix® ROWID usage was a common practice in the early days of Informix® 4GL programming. Today it is recommended to define all your database tables with a PRIMARY KEY to uniquely identify rows.
With Informix®, the SQLCA.SQLERRD[6] register contains the ROWID of the last modified row.

SAP ASE
SAP® ASE does not support ROWIDs.

Solution
If the BDL application uses ROWIDs, it is recommended that the program logic is reviewed in order to use the real primary keys instead (usually serials, which can be supported). All references to SQLCA.SQLERRD[6] must be removed because this variable will not hold the ROWID of the last modified row.
The ROWID keyword translation can be controlled with the following FGLPROFILE entry:
```
dbi.database.dsnname.ifxemul.rowid = 1 true 1 false
```
For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts
Using ROWID columns on page 578
Automatic ROWID columns is not a common database feature.

Case sensitivity

Informix®
With Informix®, database object names like table and column names are not case sensitive:
```
CREATE TABLE Customer ( Custno INTEGER, ... )
SELECT CustNo FROM cuStomer ...
```

SAP ASE
With SAP® ASE, database object names and character data are case-insensitive by default:
```
CREATE TABLE Customer ( Custno INTEGER, CustName CHAR(20) )
INSERT INTO CUSTOMER VALUES ( 1, 'TECHNOSOFT' )
SELECT CustNo FROM cuSTomer WHERE custname = 'techNOSoft'
```
Solution

When you create a SAP® ASE database with dbinit, you can use the -c option to make the database case-sensitive.

**TEXT and BYTE (LOB) types**

**Informix®**

Informix® provides the TEXT, BYTE, CLOB and BLOB data types to store very large texts or binary data.

Legacy Informix® 4GL applications typically use the TEXT and BYTE types.

Genero BDL does not support the Informix® CLOB and BLOB types.

**SAP ASE**

SAP® ASE provides the TEXT and IMAGE data types for large objects storage.

SAP® ASE 16.0 does not support TEXT/IMAGE expressions in WHERE clauses.

Solution

TEXT and BYTE data types are supported by the SAP® ASE database interface, with some limitation.

**Important:** The SAP® ASE ODI driver is implemented with the SAP Open Client Library C API. In SAP® ASE version 16.0, this API has limited support for LOBs, especially when it comes to update LOB data in the database. You cannot directly INSERT large LOB data, you must first INSERT nulls and then UPDATE the row with the real data. Additionally, UPDATE can only take one LOB parameter at a time. Fetching LOB data is supported, with the following limitation: LOB columns must appear at the end of the SELECT list.

When inserting TEXT/BYTE data in a table, you must first insert with nulls, the update the new row, and only with one TEXT/BYTE parameter at a time:

```sql
DEFINE ptext TEXT, pbyte BYTE
...
LOCATE ptext IN ...
LOCATE pbyte IN ...
CREATE TABLE tab (k INT, t TEXT, b BYTE)
-- First INSERT a new row with NULLs
INSERT INTO tab VALUES (123,null,null)
-- Then UPDATE first TEXT column
UPDATE tab SET t = ptext WHERE k = 123
-- Then UPDATE second BYTE column
UPDATE tab SET b = pbyte WHERE k = 123
```

Fetching TEXT/BYTE columns is possible as long as the columns appear at the end of the SELECT list. For example, if you have a statement such as (where pdata is a TEXT or BYTE column):

```sql
SELECT pid, pdata, ptimestamp FROM pic WHERE ...
```

Put the TEXT/BYTE column at the end of the SELECT list:

```sql
SELECT pid, ptimestamp, pdata FROM pic WHERE ...
```

The TEXT and BYTE types translation can be controlled with the following FGLPROFILE entries:

```sql
dbi.database.dsname.ifxemul.text =  |
false |
true |
false |
dbi.database.dsname.ifxemul.byte =  |
false |
true |
false |
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.
Related concepts
Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

Table constraints

Informix®

Informix® supports primary key, unique, foreign key, default and check constraints.
The constraint naming syntax is different in Informix® and most other databases: Informix expects the "CONSTRAINT" keyword after the constraint specification:

```sql
CREATE TABLE emp (
    ... 
    emp_code CHAR(10) UNIQUE CONSTRAINT pk_emp,
    ... 
)
```

While other databases it before:

```sql
CREATE TABLE emp (
    ... 
    emp_code CHAR(10) CONSTRAINT pk_emp UNIQUE,
    ... 
)
```

SAP ASE

SAP® ASE supports primary key, unique, foreign key, default and check constraints.

Constraint naming

However, SAP® ASE does not support a constraint naming clause.

Solution

The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for SAP® ASE.

Related concepts

Data definition statements on page 552
It is recommended to avoid use of DDL in programs.

Name resolution of SQL objects

Informix®

Informix® uses the following form to identify an SQL object:

```
database[@dbservername]::[owner|"owner"][identifier]
```

The ANSI convention is to use double quotes for identifier delimiters (For example: "customer"."cust_name").

Informix® database object names are not case-sensitive in non-ANSI databases. When using double-quoted identifiers, Informix® becomes case sensitive.
With non-ANSI Informix® databases, you do not have to give a schema name before the tables when executing an SQL statement:

```
SELECT ... FROM customer WHERE ...
```

In Informix® ANSI compliant databases:

- The table name must include "owner", unless the connected user is the owner of the database object.
- The database server shifts the owner name to uppercase letters before the statement executes, unless the owner name is enclosed in double quotes.

**SAP ASE**

With SAP® ASE, an object name takes the following form:

```
[{database| [database]}][{owner | [owner]}].{identifier | [identifier]}
```

Informix® database object names are not case sensitive in non-ANSI databases.

SAP® ASE database objects names are case sensitive by default.

**Solution**

As a general rule, to write portable SQL, it is recommended that you only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

Always create and use tables and columns names in lower case.

**Data manipulation**

SAP® ASE related data manipulation topics.

**Reserved words**

**Informix®**

With Informix®, it is possible to create database objects with reserved words.

For example:

```
CREATE TABLE table ( char CHAR(10) );
```

Indeed this is not good practice, but Informix® SQL allows this to be backward compatible when introducing a new keyword in the SQL syntax.

Most other database systems do not allow reserved words as database identifiers. If your legacy code is using SQL reserved words of the target database SQL syntax, an error will be thrown at CREATE TABLE execution.

**SAP ASE**

Even if SAP® ASE allows SQL reserved keywords as SQL object names even if enclosed in square brackets (create table [table] ( col1 int )), verify this with your existing database schema and make sure that you do not use SAP® ASE SQL words.

**Solution**

Database objects having names which are SAP® ASE SQL reserved words must be renamed.

All BDL application sources must be verified. To check if a given keyword is used in a source, you can use UNIX™ grep or awk tools. Most modifications can be automatically done with UNIX™ tools like sed or awk.
Outer joins

Informix® OUTER() syntax

In Informix® SQL, outer joins can be defined in the FROM clause with the OUTER keyword:

```
SELECT ... FROM a, OUTER (b)
    WHERE a.key = b.akey
```

```
SELECT ... FROM a, OUTER(b,OUTER(c))
    WHERE a.key = b.akey
    AND b.key1 = c.bkey1 AND b.key2 = c.bkey2
```

Informix® also supports the ANSI OUTER join syntax, which is the recommended way to specify outer joins with recent SQL database engines:

```
SELECT ... FROM cust LEFT OUTER JOIN order
    ON cust.key = order.custno
```

SAP ASE

SAP® ASE supports the ANSI outer join syntax:

```
SELECT ...
    FROM cust LEFT OUTER JOIN order
    LEFT OUTER JOIN item
    ON order.key = item.ordno
    ON cust.key = order.custno
    WHERE order.cdate > current date
```

Note:

The legacy syntax to specify outer join in SAP® ASE uses the *= notation:

```
SELECT ... FROM a, b WHERE a.key *= b.key
```

Solution

The Genero database drivers can convert Informix Informix® OUTER specifications to ANSI outer joins.

**Note:** For better SQL portability, use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The outer join translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemulouters = true false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

- **Prerequisites:**
  1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.

      Example which does not work:

      ```
      ... FROM OUTER(tab2), tab1
      ```

  2. The outer join in the WHERE clause must use the table name as prefix:

      ```
      ... WHERE tab1.col1 = tab2.col2
      ```
• **Restrictions:**
  1. Statements composed by 2 or more SELECT instructions are not supported:

```
SELECT ... UNION SELECT ...
```

or:

```
SELECT ... WHERE col IN (SELECT...)
```

2. Additional conditions on outer table columns cannot be detected and therefore are not supported:

```
... FROM tab1, OUTER(tab2)
  WHERE tab1.col1 = tab2.col2
  AND tab2.colx > 10
```

• **Notes:**
  1. Table aliases are detected in OUTER expressions.

  OUTER example with table alias:

```
... OUTER(tab alias1) ...
```

2. In the outer join, `outertab.col` can be placed on both right or left sides of the equal sign:

```
... WHERE outertab.col1 = maintab.col2
```

3. Table names detection is not case-sensitive:

```
SELECT ... FROM tab1, TAB2
  WHERE tab1.col1 = tab2.col2
```

4. **Temporary tables** are supported in OUTER specifications:

```
CREATE TEMP TABLE tt1 ( ... )
SELECT ... FROM tab1, OUTER(tt1) ...
```

**Related concepts**

*Outer joins* on page 577

Use standard ISO outer join syntax instead of the old IBM® Informix® OUTER() syntax.

**Transactions handling**

**Informix®**

With the Informix® native mode (non ANSI):

- Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```
UPDATE tab1 SET ...   -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK           -- end of TX block
```

Informix® version 11.50 introduces savepoints:

```
SAVEPOINT name [UNIQUE]
```
**SAP ASE**

- SAP® ASE supports two transaction modes:
  1. The SQL standards-compatible mode, called *chained* mode, to get implicit transaction.
  2. The default mode, called *unchained* mode, where transactions have to be started/ended explicitly.
- Transactions are started with "BEGIN TRANSACTION [name]".
- Transactions are validated with "COMMIT TRANSACTION [name]".
- Transactions are canceled with "ROLLBACK TRANSACTION [name]".
- Transactions save points can be placed with "SAVEPOINT [name]".
- SAP® ASE supports named and nested transactions.
- DDL statements can be executed in transactions blocks when the 'ddl in tran' option is set to true with:

  ```
  master..sp_dboption dbname, 'ddl in tran', true
  go
  checkpoint
  go
  ```

**Solution**

Informix® transaction handling commands are automatically converted to SAP® ASE instructions to start, commit or rollback transactions.

Make sure that the database uses the default *unchained* mode (set chained off) and allows DDLs in transactions ('ddl in tran' option is true).

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with SAP® ASE.

**Related concepts**

- [Database transactions](#) on page 538
  
  Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Temporary tables**

- **Informix®**

  Informix® temporary tables are created with the `CREATE TEMP TABLE` DDL instruction or with `SELECT ... INTO TEMP` statement:

  ```
  CREATE TEMP TABLE tt1 ( pkey INT, name VARCHAR(50) )
  CREATE TEMP TABLE tt2 ( pkey INT, name VARCHAR(50) ) WITH NO LOG
  SELECT * FROM tab1 WHERE pkey > 100 INTO TEMP tt2
  ```

  Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the `DROP TABLE` command. There is no name conflict when several users create temporary tables with the same name.

  BDL REPORTs can create a temporary table when the rows are not sorted externally (by the source SQL statement).

  Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

  When creating temporary tables in Informix®, the `WITH NO LOG` clause can be used to avoid the overhead of recording DML operations in transaction logs.
SAP ASE

SAP® ASE supports temporary tables by using the # pound sign before the table name:

```sql
CREATE TABL #temp1 ( kcol INTEGER, .... )
SELECT * INTO #temp2 FROM customers WHERE ...
```

Solution

In BDL, Informix® temporary tables instructions are converted to generate native SAP® ASE temporary tables.

SELECT INTO TEMP statements cannot be converted, because SAP® ASE does not provide a way to create a temporary table from a result set, such as CREATE TABLE xx AS (SELECT ... ).

The general FGLPROFILE entry to control temporary table emulation is:

```sql
dbi.database.dsname.ifxemul.temptables = true | false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Temporary tables on page 575
Syntax for temporary table creation is not unique across all database engines.

Substrings in SQL

Informix®

Informix® SQL statements can use subscripts on columns defined with the character data type:

```sql
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R' -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

Important: With other database servers as Informix®, when the subscript notation is used to modify column values in UPDATE statement, or as ORDER BY element, you will get and SQL error:

```sql
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

SAP ASE

SAP® ASE provides the SUBSTRING() function, to extract a substring from a string expression:

```sql
SELECT .... FROM tab1 WHERE SUBSTRING(col1,2,2) = 'RO'
SELECT SUBSTRING('Some text',6,3 ) FROM DUAL -- Gives 'tex'
```

Solution

Replace all Informix® col[x,y] right-value expressions by SUBSTRING( col from x for (y-x+1) ).

Rewrite UPDATE and ORDER BY clauses using col[x,y] expressions.

The translation of col[x,y] expressions can be controlled with the following FGLPROFILE entry:

```sql
dbi.database.dsname.ifxemul.colsubs = true | false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.
Related concepts

Substring expressions on page 577
Handle substrings expressions with different database engines.

String delimiters

Informix®

The ANSI SQL string delimiter character is the single quote (‘string’), while double quotes are used to delimit database object names:

```
SELECT ... WHERE "tabname"."colname" = 'a string value'
```

In Informix® databases created in native mode (non-ANSI), you can use double quotes as string delimiters:

```
SELECT ... WHERE tabname.colname = 'a string value'
```

This is important, since many BDL programs use that character to delimit the strings in SQL commands.

Note: This problem concerns only double quotes within SQL statements. Double quotes used in pure BDL string expressions are not subject to SQL compatibility problems.

SAP ASE

SAP® ASE allows to use double quotes as string delimiters, if the QUOTED_IDENTIFIER session option is OFF (the default):

```
SET QUOTED_IDENTIFIER OFF
```

Solution

When using Static SQL statements, the fglcomp compiler converts string literals using double quotes to string literals with single quotes:

```
$ cat s.4gl
MAIN
   DEFINE n INT
   SELECT COUNT(*) INTO n FROM tab1 WHERE col1 = "abc"
END MAIN

$ fglcomp -S s.4gl
s.4gl^3^SELECT COUNT(*) FROM tab1 WHERE col1 = 'abc'
```

However, SQL statements created dynamically are not modified by the Genero compiler.

The Genero database interface can automatically replace all double quotes by single quotes in SQL statements. This applies to static and dynamic SQL statements.

The translation of double quoted expression to single quoted expressions can be controlled with the following FGLPROFILE entry:

```
dbi.database.dbname.ifxemul.dblquotes = \true \false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.
However, database object names must not be delimited by double quotes, because the database interface cannot
determine the difference between a database object name and a quoted string! For example, if the program executes
the SQL statement:

```
... WHERE "tabname"."colname" = "a string value"
```

replacing all double quotes by single quotes would produce:

```
... WHERE 'tabname'.'colname' = 'a string value'
```

This would produce an error since 'tabname'.colname' is not allowed by ORACLE.

Escaped string delimiters can be used inside strings like the following:

```
'This is a single quote: ''
'This is a single quote: \\
"This is a double quote: ""
"This is a double quote: \\
```

Although double quotes are replaced automatically in SQL statements, it is recommended that you use only single
quotes to enforce portability.

**Related concepts**

[String literals in SQL statements](#) on page 570

Single quotes is the standard for delimiting string literals in SQL.

**Single row SELECT**

**Informix®**

With Informix®, you must use the system table with a condition on the table id:

```
SELECT user FROM systables WHERE tabid=1
```

**SAP ASE**

With SAP® ASE, you can omit the FROM clause to generate one row only:

```
SELECT user
```

**Solution**

Check the BDL sources for "FROM systables WHERE tabid=1" and use dynamic SQL to resolve this problem.

Consider writing a FUNCTION which produces the FROM and WHERE part, depending on the target database type.

**MATCHES and LIKE**

**Informix®**

Informix® supports MATCHES and LIKE operators in SQL statements.

MATCHES expects * and ? wild-card characters, while LIKE uses the % and _ wild-cards as equivalents.

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x' )
```
MATCHES accepts also brackets notation, to specify a set of matching characters at a given position:

```
( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )
```

**SAP ASE**

SAP® ASE does not provide an equivalent of the Informix® MATCHES operator. The **LIKE** operator is supported.

**Solution**

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.

The MATCHES to LIKE expression translation is controlled by the following FGLPROFILE entry:

```
dbi.database dbname.ifxemul.matches = \true \false
```

**Important**: Only [NOT] MATCHES followed by a search pattern provided as a string literal can be converted by ODI drivers. A [NOT] MATCHES followed by a ? question mark parameter place holder is not translated!

For maximum portability, consider replacing the MATCHES expressions with LIKE expressions in all SQL statements.

Avoid using CHAR(N) types for variable length character data (such as name, address).

**Related concepts**

MATCHES and LIKE operators on page 579

Use the standard LIKE operator instead of the MATCHES operator.

**The LENGTH() function**

**Informix®**

Informix® provides the LENGTH() function to count the number of bytes of a character string expression:

```
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```

Informix® LENGTH() does not count the trailing blanks for CHAR or VARCHAR expressions, while Oracle counts the trailing blanks.

Informix® LENGTH() returns 0 when the given string is empty. That means, LENGTH('') = 0.

**SAP ASE**

SAP® ASE supports the LEN() function, which is similar to Informix® LENGTH(). The SAP ASE LEN() function ignores trailing blanks.

When passing NULL as parameter, the SAP ASE LEN() function returns NULL.

**Solution**

The database driver is able to replace LENGTH() by the LEN() function name.

The translation of LENGTH() expressions can be controlled with the following FGLPROFILE entry:

```
dbi.database dsname.ifxemul.length = \true \false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.
Related concepts
The LENGTH() function in SQL on page 581
The semantics of the LENGTH() SQL function differs according to the database engine.

BDL programming
SAP® ASE related programming topics.

INSERT cursors

Informix®
Informix® provides insert cursors to optimize row creation in a database. An insert cursor is declared as a cursor, and rows as added with the PUT instruction. The rows are buffered and sent to the database server when executing a FLUSH instruction, or when the cursor is closed with CLOSE. When using transactions in Informix®, the OPEN, PUT and FLUSH instructions must be executed within a transaction block.

```sql
DECLARE c1 CURSOR FOR INSERT INTO tab1 ...
BEGIN WORK
OPEN c1
WHILE ...
  PUT c1 USING var-list
END WHILE
CLOSE c1
COMMIT WORK
```

SAP ASE
SAP® ASE does not support insert cursors.

Solution
Insert cursors are emulated by the database interface, using basic INSERT SQL instructions.

The performances might be not as good as with Informix®, but the feature is fully supported.

Related concepts
Insert cursors on page 569
Using insert cursors with non-Informix databases.

Cursors WITH HOLD

Informix®
Informix® closes opened cursors automatically when a transaction ends, unless the WITH HOLD option is used in the DECLARE instruction:

```sql
DECLARE c1 CURSOR WITH HOLD FOR SELECT ...
BEGIN WORK
OPEN c1
FETCH c1 ...
COMMIT WORK
FETCH c1 ...
CLOSE c1
```

SAP ASE
By default, SAP® ASE does not close cursors when a transaction ends.

See the SAP ASE manual for more details about cursor behaviors and configuration settings to control the behavior of cursors.
**Solution**

BDL cursors declared WITH HOLD remain open even after terminating a transaction with a COMMIT WORK or ROLLBACK WORK.

For consistency with other database brands, database cursors that are not declared WITH HOLD are automatically closed, when a COMMIT WORK or ROLLBACK WORK is performed.

**Important:** Opening a WITH HOLD cursor declared with a SELECT FOR UPDATE results in an SQL error; in the same conditions, this does not normally appear with Informix®. Review the program logic in order to find another way to set locks.

**Related concepts**

WITH HOLD and FOR UPDATE on page 568

Hold cursors and not portable.

**SELECT ... FOR UPDATE**

**Informix®**

Legacy BDL programs typically use a cursor with SELECT FOR UPDATE to implement pessimistic locking and avoid several users editing the same rows:

```sql
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

The row must be fetched in order to set the lock.

If the cursor is local to a transaction, the lock is released when the transaction ends. If the cursor is declared WITH HOLD, the lock is released when the cursor is closed.

Informix® provides the SET LOCK MODE instruction to define the lock wait timeout:

```
SET LOCK MODE TO { WAIT | NOT WAIT | WAIT seconds }
```

The default mode is NOT WAIT.

**SAP ASE**

SAP® ASE supports SELECT ... FOR UPDATE clause in the context of a cursor. This can be achieved by using the CS_FOR_UPDATE option in ct-lib Client-Library ct_cursor() function.

**Note:** The "select for update" database configuration parameter is by default set to zero. This parameter defines if a single SELECT ... FOR UPDATE (at the SQL language level) must set locks. This parameter does not need to be 1 when executing SELECT ... FOR UPDATE in the context of a SAP ASE ct-lib cursor (ct_cursor() + CS_FOR_UPDATE).

Rows selected with SELECT ... FOR UPDATE, within or outside of a cursor context, retain an exclusive lock until the transaction is complete.

SAP® ASE's locking granularity is at the row level, page level or table level (the level is automatically selected by the engine for optimization, depending on the locking scheme).

**Solution**

SELECT FOR UPDATE statements are supported with SAP® ASE under some conditions:

SAP® ASE requires a PRIMARY KEY or UNIQUE INDEX on the table using in the SELECT ... FOR UPDATE statement.
When the SAP® ASE database driver must execute a SELECT FOR UPDATE, the ct-lib ct_cursor() function is called with the CS_FOR_UPDATE option.

Locks are acquired when fetching rows with the cursor. Locks are released when the transaction ends or when the cursor is closed.

The database interface is based on an emulation of an Informix® engine using transaction logging. Therefore, opening a SELECT ... FOR UPDATE cursor declared outside a transaction will raise an SQL error -255 (not in transaction).

**Related concepts**

WITH HOLD and FOR UPDATE on page 568
Hold cursors and not portable.

**LOAD and UNLOAD**

**Informix®**

Informix® provides two SQL instructions to export / import data from / into a database table:

The UNLOAD instruction copies rows from a database table into a text file:

```sql
UNLOAD TO "filename.unl" SELECT * FROM tab1 WHERE ..
```

The LOAD instructions insert rows from a text file into a database table:

```sql
LOAD FROM "filename.unl" INSERT INTO tab1
```

**SAP ASE**

SAP® ASE has LOAD and UNLOAD instructions, but those commands are related to database backup and recovery. Do not confuse with Informix® commands.

**Solution**

LOAD and UNLOAD instruction are implemented in the Genero BDL runtime system with basic INSERT (for LOAD) or SELECT (for UNLOAD) SQL commands. The LOAD and UNLOAD instruction can be supported with various database servers.

However, LOAD and UNLOAD require the description of the column types in order to work, that can lead to some differences in the data formatting.

**Note:** If no transaction is started, the LOAD instruction will automatically execute a BEGIN WORK and COMMIT WORK when finished, or ROLLBACK WORK if a row insertion failed while loading. Terminating a transaction will automatically close cursors not defined WITH HOLD option. To workaround this situation, see more details in the LOAD on page 684 reference topic.

The LOAD and UNLOAD BDL instructions are supported with SAP® ASE with some limitations:

- The LOAD instruction does not work with tables using emulated SERIAL columns because the generated INSERT statement holds the SERIAL column which is actually a IDENTITY column in SAP® ASE. See the limitations of INSERT statements when using SERIAL types.
- With SAP® ASE, Informix® DATETIME data is stored in BIGDATETIME columns, but BIGDATETIME columns are similar to Informix® DATETIME YEAR TO FRACTION(5) columns. Therefore, when using LOAD and UNLOAD, those column values are converted to text data with the format "YYYY-MM-DD hh:mm:ss.ffffff".

**Related concepts**

LOAD and UNLOAD instructions on page 574
The LOAD and UNLOAD instructions can produce different data formats depending on the database server type.

**SQL Interruption**

**Informix®**

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

**SAP ASE**

SAP® ASE supports SQL Interruption: The db client must issue an `ct_cancel()` call to interrupt a query.

**Solution**

The SAP® ASE database driver supports SQL interruption and raises error code -213 if the statement is interrupted.

**Related concepts**

Using SQL interruption on page 539

Interrupt long running SQL queries, or interrupt queries waiting for locked data.

**Scrollable cursors**

**Informix®**

Informix® SQL and Genero BDL support scrollable cursors when you specify the `SCROLL` clause in the `DECLARE` cursor instruction:

```sql
DECLARE c1 SCROLL CURSOR FOR SELECT ...
```

**SAP ASE**

SAP® ASE supports native scrollable cursors.

**Solution**

The SAP® ASE database driver uses the native SAP® ASE Open Client Library scrollable cursors.

**Related concepts**

Scrollable cursors on page 560

How scrollable cursors can be supported on different databases.

**SAP HANA®**

**Supported versions**

Genero BDL supports the following SAP HANA® versions:

- SAP HANA 2.0

**Installation (Runtime Configuration)**

SAP HANA® related installation topics.

**Install SAP HANA® and create a database - database configuration/design tasks**

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. Install the SAP HANA® database server on your computer.

   The installation program requires you to provide a strong password for system users. Keep this password in mind for future usage.

2. Understand basic SAP HANA® server administration tasks (command line).
• The configuration files nameserver.ini and the indexserver.ini can be edited by the OS administrator user (root).
• The default SAP HANA® admin OS user is <sid>adm. For example, with SAP HANA express edition it is hxeadm.
• To check if the SAP HANA® server is up, use: the HDB info command.
• To start/stop the SAP HANA® server, use HDB start/HDB stop commands.
• If needed, configure the host firewall for remote connections. For example, on UNIX/Linux, check TCP ports to be opened with the netstat -tnlp command.

3. Create a SAP HANA® database entity: dbname

Connect as the SYSTEM user to the SystemDB database and create the application database:

Note: In next examples the SAP HANA instance number is 90.

```bash
$ hdbsql -i 90 -d SystemDB -u SYSTEM -p system-password
...> CREATE DATABASE dbname SYSTEM USER PASSWORD password;
...> \q
```

4. Create the DB user to be the owner of application database tables.

Connect to the new created database with the SYSTEM user, and create the application user, and grant the required privileges to create tables:

```bash
$ hdbsql -i 90 -d dbname -u SYSTEM -p system-password
...> CREATE USER appadmin PASSWORD password;
...> GRANT USER ADMIN TO appadmin WITH ADMIN OPTION;
...> \q
```

5. Create the application tables with CREATE TABLE statements.

Connect to the application database as the application administrator and create the tables:

```bash
$ hdbsql -i 90 -d dbname -u appadmin -p password
...> CREATE TABLE customer ( ... ) ;
...```

Convert Informix® data types to SAP HANA® data types. See issue Data Type Conversion Table for more details.

6. If you plan to use SERIAL column emulation, you must prepare the database.

See SERIAL data types on page 991.

**Prepare the runtime environment - connecting to the database**

1. In order to connect to SAP HANA®, you must have the database driver "dbmhdb" in FGLDIR/dbdrivers.
2. Make sure that the SAP HANA® client software is installed and check that SAP HANA environment variables are properly set.
   
   See SAP HANA® documentation for more details.
3. The database client locale does not need to be defined with the SAP HANA® ODI driver: The driver will automatically do the required code set conversions from/to the application client locale and UTF-16LE, with the wide char (SQL_C_WCHAR) ODBC APIs.
   
   Only define the application locale for the runtime system (LC_ALL, LANG).
4. Verify the environment variable defining the search path for the SAP HANA® database client shared library (libodbcHDB.so on UNIX™, libodbcHDB.DLL on Windows™).
5. To verify if the SAP HANA® client environment is correct, you can start the hdbsql command interpreter and connect to the server:

```bash
$ hdbsql -i 90 -d SystemDB -u SYSTEM -p password
```

6. Setup the fglprofile entries for database connections.
   a) Define the SAP HANA database driver:
      ```
dbi.database.dbname.driver = "dbmhdb"
```
   b) The "source" parameter defines the name of the SAP HANA® ODBC data source.
      ```
dbi.database.dbname.source = "test1"
```
   c) Define the database schema selection if needed:
      Use the following entry to define the database schema to be used by the application. The database interface will automatically perform a SET SCHEMA name instruction to switch to a specific schema:
      ```
dbi.database.dbname.hdb.schema = 'name'
```

Here dbname identifies the database name used in the BDL program (DATABASE dbname) and name is the schema name to be used in the SET SCHEMA instruction. If this entry is not defined, no "SET SCHEMA" instruction is executed and the current schema defaults to the user's name.

### Database concepts
SAP HANA® related database concept topics.

#### Database concepts
As with Informix®, one SAP HANA® database server can handle more than one database entity, with multitenant database containers. The multitenant database feature has been introduced in SAP HANA SPS09. In a given tenant database, you can create several schemas, owned by database users.

Informix® servers have an ID (INFORMIXSERVER) and databases are identified by name.

#### Data storage concepts
Because SAP HANA® is an in-memory database engine, the Informix® storage concepts and options cannot be applied with this database.

#### Concurrency management

#### Data consistency and concurrency concepts
- **Data Consistency** applies to situations when readers want to access data currently being modified by writers.
- **Concurrent Data Access** applies to situations when several writers are accessing the same data for modification.
- **Locking Granularity** defines the amount of data concerned when a lock is set (for example, row, page, table).

### Informix®
Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with UPDATE, INSERT or DELETE, an exclusive lock is set on the touched rows. The lock remains
active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set shared locks, depending on isolation level. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification, or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the lock wait mode.

Control:
- Lock wait mode: SET LOCK MODE TO ...
- Isolation level: SET ISOLATION TO ...
- Locking granularity: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:
- The default isolation level is READ COMMITTED.
- The default lock wait mode is NOT WAIT.
- The default locking granularity is PAGE.

**SAP HANA®**

SAP HANA® uses multi-version row and exclusive locks to manage data consistency and concurrency. Concurrent readers will see a consistent view of the database data without blocking concurrent write operations. Updates are implemented by inserting new versions of data and not by overwriting existing records. The database engine sets exclusive locks on the modified rows and shared locks when data is read, based on the isolation level. The locks are held until the end of the transaction. When multiple processes want to access the same data, the latest processes must wait until the first finishes its transaction. The lock granularity is at the row. For more details, see SAP HANA® documentation.

Control:
- Lock wait mode: SET TRANSACTION LOCK WAIT TIMEOUT milliseconds. Default is defined by server settings.
- Isolation level: SET TRANSACTION ISOLATION LEVEL {READ COMMITTED | REPEATABLE READ | SERIALIZABLE}.
- Locking granularity: row (or table level, if demanded by the SQL command semantics).
- Explicit locking: SELECT ... FOR UPDATE

Defaults:
- The default isolation level is READ COMMITTED.

**Important:** With SAP HANA, when a lock timeout occurs, the complete SQL transaction is rolled back: SAP HANA will cancel the SQL statements executed in the transaction before the SQL statement which produced the lock timeout.

**Solution**

The SET ISOLATION TO ... Informix® syntax is converted to SET TRANSACTION ISOLATION LEVEL ... for SAP HANA®. The table shows the isolation level mappings applied by the database driver:

**Table 270: Isolation level mappings done by the SAP HANA® database driver**

<table>
<thead>
<tr>
<th>SET ISOLATION instruction in program</th>
<th>Native SQL command</th>
</tr>

</tbody>
</table>

When using the `SET LOCK MODE` instruction in your Genero programs, the SAP HANA® driver will execute the equivalent `SET TRANSACTION LOCK WAIT TIMEOUT` instruction, by converting the number of seconds to milliseconds.

For portability, it is recommended that you work with Informix® in the read committed isolation level, to make processes wait for each other (lock mode wait) and to create tables with the “lock mode row” option.

See Informix® and SAP HANA® documentation for more details about data consistency, concurrency and locking mechanisms.

Regarding transaction rollback when a lock timeout occurs, you may need to review your code, to handle the SAP HANA® behavior, where all SQL statements in the transaction are canceled. However, lock timeouts should not occur, if transactions are quick, and each process uses read committed isolation level, and define a lock timeout that is sufficient to let other processes terminate their transactions.

**Related concepts**

- **Concurrent data access** on page 537
  Understanding concurrent data access and data consistency.

- **Optimistic locking** on page 561
  Implementing optimistic locking to handle access concurrently to the same database records.

- **WITH HOLD and FOR UPDATE** on page 568
  Hold cursors and not portable.

### Transactions handling

**Informix®**

With the Informix® native mode (non ANSI):

- Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```sql
UPDATE tab1 SET ...   -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK           -- end of TX block
```

Informix® version 11.50 introduces savepoints:

```sql
SAVEPOINT name [UNIQUE] 
ROLLBACK [WORK] TO SAVEPOINT name 
RELEASE SAVEPOINT name
```

**SAP HANA®**

Transactions in SAP HANA®:

- Beginning of transactions are implicit; two transactions are delimited by `COMMIT` or `ROLLBACK`.
• DDL statements can be executed in transactions, but these will persist on rollback. Savepoints are NOT supported in SAP HANA®.

Solution
The Informix® behavior is simulated with an autocommit mode in the SAP HANA® database interface. A switch to the explicit commit mode is done when a BEGIN WORK is performed by the BDL program. Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with SAP HANA®.

Note: Savepoints are not supported.

See also SELECT FOR UPDATE

Related concepts
Database transactions on page 538
Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

Database users

Informix®
Until version 11.70.xC2, Informix® database users must be created at the operating system level and must be members of the 'informix' group.
Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as in most other db servers.

Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.

SAP HANA®

SAP HANA® users are created for each database tenant with the CREATE USER instruction. Users can be authenticated with a password that must be provided at each connection (CREATE USER name PASSWORD password), or can be identified with an external authentication mechanism (CREATE USER name IDENTIFIED EXTERNALLY AS ...).

For each database user a schema with the user's name is automatically created, owned by this user and becomes the default schema.

Solution
Create your database users with the CREATE USER SQL instruction.

Related concepts
Database users and security on page 547
Properly identifying database users allows to use database security and audit features.

Setting privileges

Informix®

Informix® users must have at least the CONNECT privilege to access the database:

```sql
GRANT CONNECT TO username
```

Application administration users need the RESOURCE privilege to create tables:

```sql
GRANT RESOURCE TO username
```
Since version 7.20, Informix® supports database roles:

```
GRANT rolename TO username
```

**SAP HANA®**

Typically, SAP HANA® users must have *schema privileges* to access the database table of a schema created by the application administrator.

SAP HANA® supports concept of *roles*, to define common user privileges.

**Solution**

Informix® and SAP HANA® user privileges management is quite similar.

**Data dictionary**

SAP HANA® related data dictionary topics.

### BOOLEAN data type

**Informix**

Informix® supports the BOOLEAN data type, which can store ‘t’ or ‘f’ values.

Genero BDL implements the BOOLEAN data type in a different way: A BOOLEAN variable stores integer values 1 or 0 (for TRUE or FALSE). This type is designed to hold the result of a boolean expression.

**SAP HANA**

SAP HANA® provides a BOOLEAN SQL type, similar to the Genero BDL BOOLEAN type, which is able to store TRUE/FALSE values.

**Solution**

The SAP HANA® database interface supports the BOOLEAN SQL type.

The BOOLEAN type translation can be controlled with the following FGLPROFILE entry:

```
    dbi.database.dsnname.ifxemul.datatype:boolean = ▼ true ▼ false ▼
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

- Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

### CHAR and VARCHAR data types

**Informix**

Informix® supports the following character data types:

**Table 272: Informix® character data types**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>SBCS and MBCS character data (max is 32767 bytes)</td>
</tr>
<tr>
<td>Informix® data type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>VARCHAR(n, m)</td>
<td>SBCS and MBCS character data (max is 255 bytes)</td>
</tr>
<tr>
<td>NCHAR(n)</td>
<td>Same as CHAR, with specific collation order</td>
</tr>
<tr>
<td>NVARCHAR(n)</td>
<td>Same as VARCHAR, with specific collation order</td>
</tr>
<tr>
<td>LVARCHAR(n)</td>
<td>max size varies depending on the IDS version</td>
</tr>
</tbody>
</table>

With Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is in how they use sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order.

The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable.

The character set used by applications is defined by the CLIENT_LOCALE environment variable.

Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR(N) is expressed in bytes, not characters as in some other databases)

**SAP HANA®**

SAP HANA® provides the following character data types:

- **VARCHAR(N)** with N <= 5000 bytes, to store ASCII-7 character strings.
- **NVARCHAR(N)** with N <= 5000 characters, to store UNICODE character strings.
- **ALPHANUM(N)** with N <= 127 bytes, to store ASCII-7 alpha-numeric character strings.
- **SHORTTEXT(N)**, supporting text and string search features.
- **CHAR(N) / NCHAR(N)**: Not officially supported!

The SAP HANA® VARCHAR data type must only be used to store ASCII-7 character strings. To store non-ASCII / locale dependent character strings (such as the UTF-8 codeset), you must use the NVARCHAR data type.

**Note:** The SAP HANA® database does not officially support the CHAR and NCHAR datatypes. See SAP HANA® documentation for more details.

**Solution**

Because SAP HANA® VARCHAR(N) can only store ASCII-7 characters and does not recommend to use CHAR/NCHAR types, Informix® CHAR(N), VARCHAR(N) or LVARCHAR(N) types must be mapped to SAP HANA® NVARCHAR(N) when using UTF-8, or a single-byte encoding like ISO-8859-15. In some rare cases where the application character set is ASCII-7 or when only ASCII-7 data is stored in the column, you can eventually use SAP HANA® VARCHAR(N) type.

**Important:** Since SAP HANA® does not officially support the CHAR/NCHAR types, all character columns must be SAP HANA® VARCHAR (if ASCII-7) or NVARCHAR (if non-ASCII). As the semantics of VARCHAR types are different regarding blanc padding, you will get different behavior, when comparing with string values containing trailing blanks.

When extracting a database schema from a SAP HANA® database, the fglodbshc schema extractor uses the size of the column in characters, not the octet length. If you have created a NVARCHAR(10 (characters) ) column a in SAP HANA® database using the UTF-8 character set, the .sch file will get a size of 10, that will be interpreted depending on FGL_LENGTH_SEMANTICS as a number of bytes or characters.

Check that your database schema does not use CHAR or VARCHAR types with a length exceeding the SAP HANA® limits especially as the Informix® CHAR type has a very long size limit compared to SAP HANA® NVARCHAR.

The SAP HANA® database interface of Genero automatically converts from/to the application locale to the database locale. Therefore, no database client locale configuration is required with SAP HANA®.

See also the section about Localization.

<td>DOUBLE</td>
</tr>
</tbody>
</table>

SQL scripts to create databases must be converted manually. Tables created from BDL programs do not have to be converted; the database interface detects the MONEY data type and uses the DECIMAL type for SAP HANA®.

Important: There is no SAP HANA® equivalent for the Informix® DECIMAL (p) floating point decimal (i.e. without a scale). If your application is using such data types, you must review the database schema in order to use SAP HANA® compatible types. To workaround the SAP HANA® limitation, the SAP HANA® database driver converts DECIMAL (p) types to a DECIMAL( 2*p, p ), to store all possible numbers an Informix® DECIMAL (p) can store. However, the original Informix® precision cannot exceed 19, because SAP HANA® supports a maximum DECIMAL precision of 38 (2*19). If the original precision is bigger than 19, a CREATE TABLE statement executed from a Genero program will fail with an SQL error.

The numeric types translation can be controlled with the following FGLPROFILE entries:

```plaintext
dbi.database.dsnname.ifxemul.datatype.smallint = true | false
dbi.database.dsnname.ifxemul.datatype.integer = true | false
dbi.database.dsnname.ifxemul.datatype.bigint = true | false
dbi.database.dsnname.ifxemul.datatype.int8 = true | false
dbi.database.dsnname.ifxemul.datatype.decimal = true | false
dbi.database.dsnname.ifxemul.datatype.money = true | false
dbi.database.dsnname.ifxemul.datatype.float = true | false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

DATE and DATETIME data types

Informix®

Informix® provides two data types to store date and time information:

- DATE = for year, month and day storage.
• **DATETIME** = for year to fraction (1-5) storage.

The **DATE** type is stored as an **INTEGER** with the number of days since 1899/12/31.

The **DATETIME** type can be defined with various time units, by specifying a start and end qualifier. For example, you can define a datetime to store an hour-to-second time value with **DATETIME HOUR TO SECOND**.

The values of Informix® **DATETIME** can be represented with a character string literal, or as **DATETIME()** literals:

- `'2017-12-24 15:45:12.345'` -- a **DATETIME YEAR TO FRACTION(3)**
- `'15:45'` -- a **DATETIME HOUR TO MINUTE**
- **DATETIME(2017-12-24 12:45)** **YEAR TO MINUTE**
- **DATETIME(12:45:56.333)** **HOUR TO FRACTION(3)**

Informix® is able to convert quoted strings to **DATE / DATETIME** data, if the string contains matching environment parameters. The string to date conversion rules for **DATE** is defined by the DBDATE environment variable. The string to datetime format for **DATETIME** is defined by the GL_DATETIME environment variable.

**Note:** Within Genero programs, the string representation for **DATETIME** values is always ISO (YYYY-MM-DD hh:mm:ss.ffffff)

Informix® supports date arithmetic on **DATE** and **DATETIME** values. The result of an arithmetic expression involving dates/times is an **INTEGER** number of days when only **DATE** values are used, and an **INTERVAL** value if a **DATETIME** is used in the expression.

Informix® automatically converts an **INTEGER** to a **DATE** when the integer is used to set a value of a date column.

**SAP HANA®**

SAP HANA® provides following data type to store dates:

**Table 276: SAP HANA® date/time data types**

<table>
<thead>
<tr>
<th>SAP HANA® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>for year, month, day storage</td>
</tr>
<tr>
<td>SECONDDATE</td>
<td>for year, month, day, hour, minutes, seconds storage</td>
</tr>
<tr>
<td>TIME</td>
<td>for hour, minutes, seconds storage</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>for year, month, day, hour, minutes, seconds, fraction(7) storage</td>
</tr>
</tbody>
</table>

As Informix®, SAP HANA® can convert quoted strings to date-time values. Only one format is possible: 'yyyy-mm-dd' for **DATE**, 'hh:mm:ss' for **TIME**, 'yyyy-mm-dd hh:mm:ss' for **SECONDDATE** and 'yyyy-mm-dd hh:mm:ss:ffffffff' for **TIMESTAMP**.

In SAP HANA® (2.x), does not support date/time computation.

**Solution**

Use the following conversion rules to map Informix date/time types to SAP HANA® date/time types:

**Table 277: Informix® data types and SAP HANA® equivalents**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>SAP HANA® data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME HOUR TO MINUTE</td>
<td>TIME</td>
</tr>
<tr>
<td>DATETIME HOUR TO SECOND</td>
<td>TIME</td>
</tr>
<tr>
<td>DATETIME YEAR TO MINUTE</td>
<td>SECONDDATE</td>
</tr>
</tbody>
</table>
Informix® data type | SAP HANA® data type
---|---
DATETIME YEAR TO SECOND | SECONDDATE
DATETIME YEAR TO FRACTION(n) | TIMESTAMP
DATETIME q1 TO q2 (different from above) | TIMESTAMP

The `DATE` and `DATETIME` types translation can be controlled with the following FGLPROFILE entries:

dbi.database.dsnname.ifxemul.datatype.date = true | false
dbi.database.dsnname.ifxemul.datatype.datetime = true | false

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Informix® `DATETIME` that are not with a precision of `YEAR TO MINUTE`, `YEAR TO SECOND` or `YEAR TO FRACTION()` can be stored in SAP HANA® `TIMESTAMP` columns. Missing date or time parts default to 1900-01-01 00:00:00.0. For example, when using a `DATETIME MONTH TO MINUTE` with the value of "04-23 11:45", the SAP HANA® `TIMESTAMP` value will be "1900-04-23 11:45:00.0".

**Date/time SQL functions**

**Table 278: Informix® and SAP HANA® date/time SQL functions**

<table>
<thead>
<tr>
<th>Informix®</th>
<th>SAP HANA®</th>
</tr>
</thead>
<tbody>
<tr>
<td>today</td>
<td>current_date</td>
</tr>
<tr>
<td>current hour to second</td>
<td>current_time</td>
</tr>
<tr>
<td>current year to fraction(5)</td>
<td>current_timestamp</td>
</tr>
</tbody>
</table>

**Related concepts**

[Date/time literals in SQL statements](#) on page 571

Good practices for date and time handling in SQL.

**INTERVAL data type**

**Informix®**

Informix® provides the `INTERVAL` data type to store a value that represents a span of time.

`INTERVAL` types are divided into two classes:

- `year-month` intervals. For example: `INTERVAL YEAR(5) TO MONTH`
- `day-time` intervals. For example: `INTERVAL DAY(9) TO SECOND`

`INTERVAL` columns can be defined with various time units, by specifying a start and end qualifier. For example, you can define an interval to store a number of hours and minutes with `INTERVAL HOUR(n) TO MINUTE`, where `n` defines the maximum number of digits for the hours unit.

The values of Informix® `INTERVAL` can be represented with a character string literal, or as `INTERVAL()` literals:

- `'9834 15:45:12.345'` -- an `INTERVAL DAY(6) TO FRACTION(3)`
- `'7623-11'` -- an `INTERVAL YEAR(9) TO MONTH`
- `INTERVAL(18734:45) HOUR(5) TO MINUTE`
- `INTERVAL(-7634-11) YEAR(5) TO MONTH`

**SAP HANA®**

SAP HANA® does not provide a data type corresponding the Informix® `INTERVAL` data type.
Solution

The INTERVAL data type and values are converted CHAR(50) column with SAP HANA®.

INTERVAL values can be stored and retrieved from the database. However, since SAP HANA® does not support a native interval type, arithmetics cannot be performed on the database side in SQL statements.

The INTERVAL types translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemul.datatype.interval = ↓ true ↓ false ↓
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

SERIAL data types

Informix®

Informix® supports the SERIAL, BIGSERIAL data types to produce automatic integer sequences:

- SERIAL can produce 32 bit integers (INTEGER)
- BIGSERIAL can produced 64 bit integers (BIGINT)
- SERIAL8 is a synonym for BIGSERIAL

Steps to use serials with Informix®:

1. Create the table with a column using SERIAL, or BIGSERIAL.
2. To generate a new serial, no value or a zero value is specified in the INSERT statement:

   ```
   INSERT INTO tab1 ( c ) VALUES ( 'aa' )
   INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
   ```

3. After INSERT, the new value of a SERIAL column is provided in SQLCA.SQLERRD[2], while the new value of a BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

SAP HANA®

SAP HANA® supports IDENTITY columns:

```
CREATE TABLE tab ( k BIGINT GENERATED BY DEFAULT AS IDENTITY
    (START WITH 101 INCREMENT BY 1) NOT NULL,
    ... )
```

To get the last generated IDENTITY value after an INSERT, SAP HANA® provides the CURRENT_IDENTITY_VALUE() function:

```
INSERT INTO table_with_identity_column VALUES (...)
SELECT CURRENT_IDENTITY_VALUE() FROM DUMMY
```
SAP HANA® supports SEQUENCES:

```
CREATE SEQUENCE seq1 START WITH 100
```

To create a new sequence number, you must use the "sequence-name.NEXTVAL" expression:

```
INSERT INTO table VALUES ( seq1.NEXTVAL, ... )
```

To get the last generated sequence number, you must use the "sequence-name.CURRVAL" expression:

```
SELECT seq1.CURRVAL FROM DUMMY
```

**Solution**

*Note:* For best SQL portability when using different type of databases, consider using sequences as described in Solution 3: Use native SEQUENCE database objects on page 565.

To emulate Informix® serials with SAP HANA®, you can use IDENTIFY columns (1), or insert triggers using sequences (2). The first solution is faster, but does not allow explicit serial value specification in insert statements; the second solution is slower but allows explicit serial value specification.

**Important:** The trigger-based solution is provided to simplify the conversion from Informix, but is slower as the solution using identity columns. We strongly recommend that you use native IDENTIFY columns instead to get best performances.

The method used to emulate SERIAL types is defined by the `dbi.database.dbname.ifxemul.datatype.serial.emulation` FGLPROFILE parameter:

```
dbi.database.dbname.ifxemul.datatype.serial.emulation = {"native" | "trigseq"}
```

- native: uses IDENTIFY columns.
- trigseq: uses insert triggers with sequences.

The default emulation technique is "native".

The serial types emulation can be enabled or disabled with the following FGLPROFILE entries:

```
dbi.database.dbname.ifxemul.datatype.serial = {true | false}
dbi.database.dbname.ifxemul.datatype.serial8 = {true | false}
dbi.database.dbname.ifxemul.datatype.bigserial = {true | false}
```

**Using the native serial emulation**

In database creation scripts, all `SERIAL[n]` data types must be converted by hand to:

```
INTEGER GENERATED ALWAYS AS IDENTITY[( START WITH n INCREMENT BY 1)]
```

while the `SERIAL8` and `BIGSERIAL[n]` types must be converted to:

```
BIGINT GENERATED ALWAYS AS IDENTITY[( START WITH n INCREMENT BY 1)]
```

*Note:* Unlike other database types, the syntax of SAP HANA® IDENTIFY options does not use the comma.

Tables created from the BDL programs can use the `SERIAL` data type: When a BDL program executes a `CREATE [TEMP] TABLE` with a `SERIAL` column, the database interface automatically converts the `SERIAL[n]` data type to an IDENTIFY specification.

In BDL, the new generated `SERIAL` value is available from the `SQLCA.SQLERRD[2]` variable: The database interface which performs a call to the `CURRENT_IDENTITY_VALUE()` function. However,
SQLCA.SQLERRD[2] is defined as an INTEGER, it cannot hold values from BIGINT identity columns. If you are using BIGINT IDENTITY columns, you must use the IDENTITY_VAL_LOCAL() function.

The SAP HANA® GENERATED ALWAYS AS IDENTITY feature does not allow you to specify the value of IDENTITY columns, it is mandatory to convert all INSERT statements to remove the SERIAL column from the list. For example, the following statement:

```sql
INSERT INTO tab (col1,col2) VALUES (0, p_value)
```

must be converted to:

```sql
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```sql
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES ( rec.* ) -- will use the serial column
```

must be converted to:

```sql
INSERT INTO tab VALUES rec.* -- without parentheses, serial column is removed
```

### Using the trigseq serial emulation

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER DEFAULT 0 data types, SERIAL8/BIGSERIAL must be converted to BIGINT DEFAULT 0, and you must create a sequence and a trigger for each table using a SERIAL.

To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native SQL commands to create the sequence and the trigger.

Tables created from the BDL programs can use the SERIAL data type: When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the SERIAL[(n)] data type to INTEGER and creates the sequence and the insert trigger.

**Important:**
- With SAP HANA®, trigger creation is not allowed on temporary tables. Therefore, the "trigseq" method cannot work with temporary tables using serials.

**Related concepts**
- Auto-incremented columns (serials) on page 562
- How to implement automatic record keys.

### ROWID columns

**Informix®**

When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only).

The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

**Note:** Informix® ROWID usage was a common practice in the early days of Informix® 4GL programming. Today it is recommended to define all your database tables with a PRIMARY KEY to uniquely identify rows.

With Informix®, the SQLCA.SQLERRD[6] register contains the ROWID of the last modified row.
**SAP HANA®**

SAP HANA® has an internal rowid column ($rowid$) but this feature is internal and not documented.

**Solution**

If the BDL application uses ROWIDs, it is recommended that the program logic is reviewed in order to use the real primary keys instead (usually serials, which can be supported). All references to SQLCA.SQLERRD[6] must be removed because this variable will not hold the ROWID of the last modified row.

The ROWID keyword translation can be controlled with the following FGLPROFILE entry:

```plaintext
dbi.database.dsnma.ifxemul.rowid = [true | false]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

- Using ROWID columns on page 578
  
Automatic ROWID columns is not a common database feature.

**TEXT and BYTE (LOB) types**

**Informix®**

Informix® provides the TEXT, BYTE, CLOB and BLOB data types to store very large texts or binary data.

Legacy Informix® 4GL applications typically use the TEXT and BYTE types.

Genero BDL does not support the Informix® CLOB and BLOB types.

**SAP HANA®**

SAP HANA® supports several data types for large objects storage:

**Table 279: SAP HANA® LOB data types**

<table>
<thead>
<tr>
<th>SAP HANA® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOB</td>
<td>To store large binary data like images</td>
</tr>
<tr>
<td>CLOB</td>
<td>To store large ASCII text data</td>
</tr>
<tr>
<td>NCLOB</td>
<td>To store large UNICODE text data</td>
</tr>
<tr>
<td>TEXT</td>
<td>Similar to NCLOB, but supports textsearch-features and is only for column-tables</td>
</tr>
</tbody>
</table>

In SAP HANA®, The maximum size of an LOB is 2 GB.

**Solution**

The SAP HANA® database interface can convert BDL TEXT data to SAP HANA NCLOB and BYTE data to SAP HANA BLOB.

If you want to use the TEXT type for SAP HANA® column-tables, the tables must be created outside Genero BDL programs, or the TEXT data type emulation flag must be set to false when creating tables in BDL programs:

```plaintext
dbi.database.dbname.ifxemul.datatype.text = false
```

The TEXT and BYTE types translation can be controlled with the following FGLPROFILE entries:

```plaintext
dbi.database.dsnma.ifxemul.text = [true | false]
```
For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts
Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

Table constraints

Informix®
Informix® supports primary key, unique, foreign key, default and check constraints.
The constraint naming syntax is different in Informix® and most other databases: Informix expects the "CONSTRAINT" keyword after the constraint specification:

```
CREATE TABLE emp (
    ...
    emp_code CHAR(10) UNIQUE CONSTRAINT pk_emp,
    ...
)
```

While other databases it before:

```
CREATE TABLE emp (
    ...
    emp_code CHAR(10) CONSTRAINT pk_emp UNIQUE,
    ...
)
```

SAP HANA®
SAP HANA® supports primary key, unique, foreign key, default and check constraints.

Constraint naming
The constraint naming clause must be placed before the constraint specification.

Primary keys
Like Informix®, SAP HANA® creates an index to enforce PRIMARY KEY constraints (some RDBMS do not create indexes for constraints). Using CREATE UNIQUE INDEX to define unique constraints is obsolete (use primary keys or a secondary key instead).

Note: SAP HANA® primary key constraints do not allow NULLs; make sure your tables do not contain NULLs in the primary key columns.

Unique constraints
Like Informix®, SAP HANA® creates an index to enforce UNIQUE constraints (some RDBMS do not create indexes for constraints).

Note: SAP HANA® unique constraints do allow NULLs; this can be forced with NOT NULL.

Foreign keys
Both Informix® and SAP HANA® support the ON DELETE CASCADE option.
Check constraints
Informix® supports CHECK constraints, but this feature is not available in SAP HANA®.

Null constraints
Informix® and SAP HANA® support NOT NULL constraints.

Solution
Constraint naming syntax: The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for SAP HANA®.

Related concepts
Data definition statements on page 552
It is recommended to avoid use of DDL in programs.

Name resolution of SQL objects

Informix®
Informix® uses the following form to identify an SQL object:

database[@dbservername]:

The ANSI convention is to use double quotes for identifier delimiters (For example: "customer"."cust_name").
Informix® database object names are not case-sensitive in non-ANSI databases. When using double-quoted identifiers, Informix® becomes case sensitive.

With non-ANSI Informix® databases, you do not have to give a schema name before the tables when executing an SQL statement:

SELECT ... FROM customer WHERE ...

In Informix® ANSI compliant databases:
• The table name must include "owner", unless the connected user is the owner of the database object.
• The database server shifts the owner name to uppercase letters before the statement executes, unless the owner name is enclosed in double quotes.

SAP HANA®
SAP HANA® database object names are case-sensitive. When a name is used without double quotes, it is automatically converted to uppercase letters. When using double quotes, the names are not converted:

CREATE TABLE tab1 ( Key INT, Col1 CHAR(20) )
-- Table name is "TAB1", column names are "KEY" and "COL1"
CREATE TABLE "Tab1" ( "Key" INT, "Col1" CHAR(20) )
-- Table name is "Tab1", column names are "Key" and "Col1"

In an SAP HANA®, tables always belong to a database schema. When executing a SQL statement, a schema name must be used as the high-order part of a two-part object name, unless the current schema corresponds to the table's schema.

The default (implicit) schema is the current user's name but it can be changed with the SET SCHEMA instruction.
**Solution**

Case sensitivity in object names:

Avoid the usage of double quotes around the database object names. All names will be converted to uppercase letters.

The SAP HANA® schema concept:

After a connection, the database interface can automatically execute a `SET SCHEMA name` instruction if the following FGLPROFILE entry is defined:

```sql
dbi.database.dbname.hdb.schema= "name"
```

Here `dbname` identifies the database name used in the BDL program (DATABASE `dbname`) and `name` is the schema name to be used in the SET SCHEMA instruction. If this entry is not defined, no "SET SCHEMA" instruction is executed and the current schema defaults to the user's name.

Examples:

```sql
dbi.database.stores.hdb.schema= "STORES1"
dbi.database.accnts.hdb.schema= "ACCSCH"
```

**Data manipulation**

SAP HANA® related data manipulation topics.

**Reserved words**

**Informix®**

With Informix®, it is possible to create database objects with reserved words.

For example:

```sql
CREATE TABLE table ( char CHAR(10) );
```

Indeed this is not good practice, but Informix® SQL allows this to be backward compatible when introducing a new keyword in the SQL syntax.

Most other database systems do not allow reserved words as database identifiers. If your legacy code is using SQL reserved words of the target database SQL syntax, an error will be thrown at CREATE TABLE execution.

**SAP HANA®**

Even if SAP HANA® allows SQL reserved keywords as SQL object names when using double-quotation marks, it is still recommended that you check your existing database schema for use of SAP HANA® reserved words.

**Solution**

See SAP HANA® documentation for reserved keywords.

**Outer joins**

**Informix® OUTER() syntax**

In Informix® SQL, outer joins can be defined in the FROM clause with the OUTER keyword:

```sql
SELECT ... FROM a, OUTER (b)
WHERE a.key = b.akey

SELECT ... FROM a, OUTER(b, OUTER(c))
WHERE a.key = b.akey
    AND b.key1 = c.bkey1 AND b.key2 = c.bkey2
```
Informix® also supports the ANSI OUTER join syntax, which is the recommended way to specify outer joins with recent SQL database engines:

```
SELECT ... FROM cust LEFT OUTER JOIN order
    ON cust.key = order.custno
WHERE ...  
```

**SAP HANA®**

SAP HANA® supports the ANSI outer join syntax:

```
SELECT ...
FROM cust LEFT OUTER JOIN order
    LEFT OUTER JOIN item
    ON order.key = item.ordno
    ON cust.key = order.custno
WHERE order.cdate > current date
```

**Solution**

The Genero database drivers can convert Informix Informix® OUTER specifications to ANSI outer joins.

**Note:** For better SQL portability, use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The outer join translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsnname.ifxemul.outers = \{|true|false|\}  
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

- **Prerequisites:**
  1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.

    Example which does not work:
    
    ```
    ... FROM OUTER(tab2), tab1  
    ```

  2. The outer join in the WHERE clause must use the table name as prefix:

    ```
    ... WHERE tab1.col1 = tab2.col2  
    ```

- **Restrictions:**

  1. Statements composed by 2 or more SELECT instructions are not supported:

    ```
    SELECT ... UNION SELECT ...  
    ```

    or:

    ```
    SELECT ... WHERE col IN (SELECT...)  
    ```

  2. Additional conditions on outer table columns cannot be detected and therefore are not supported:

    ```
    ... FROM tab1, OUTER(tab2)
    WHERE tab1.col1 = tab2.col2
    AND tab2.col1x > 10  
    ```

- **Notes:**

  1. Table aliases are detected in OUTER expressions.
OUTER example with table alias:

```sql
... OUTER(tab1 alias1) ...
```

2. In the outer join, `outertab.col` can be placed on both right or left sides of the equal sign:

```sql
... WHERE outertab.col1 = maintab.col2
```

3. Table names detection is not case-sensitive:

```sql
SELECT ... FROM tab1, TAB2
    WHERE tab1.col1 = tab2.col2
```

4. Temporary tables are supported in OUTER specifications:

```sql
CREATE TEMP TABLE tt1 ( ... )
SELECT ... FROM tab1, OUTER(tt1) ...
```

Related concepts

- **Outer joins** on page 577
- Use standard ISO outer join syntax instead of the old IBM® Informix® `OUTER()` syntax.

### Transactions handling

**Informix®**

With the Informix® native mode (non ANSI):

- Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```sql
UPDATE tab1 SET ...  -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK           -- end of TX block
```

**Informix®** version 11.50 introduces savepoints:

```sql
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name] 
RELEASE SAVEPOINT name
```

**SAP HANA®**

Transactions in SAP HANA®:

- Beginning of transactions are implicit; two transactions are delimited by `COMMIT` or `ROLLBACK`.
- DDL statements can be executed in transactions, but these will persist on rollback.

Savepoints are NOT supported in SAP HANA®.

**Solution**

The Informix® behavior is simulated with an autocommit mode in the SAP HANA® database interface. A switch to the explicit commit mode is done when a `BEGIN WORK` is performed by the BDL program. Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with SAP HANA®.
**Note:** Savepoints are not supported.
See also SELECT FOR UPDATE

**Related concepts**

Database transactions on page 538
Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Temporary tables**

**Informix®**
Informix® temporary tables are created with the CREATE TEMP TABLE DDL instruction or with SELECT ... INTO TEMP statement:

```
CREATE TEMP TABLE tt1 ( pkey INT, name VARCHAR(50) )
CREATE TEMP TABLE tt2 ( pkey INT, name VARCHAR(50) ) WITH NO LOG
SELECT * FROM tab1 WHERE pkey > 100 INTO TEMP tt2
```

Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the DROP TABLE command. There is no name conflict when several users create temporary tables with the same name.

BDL REPORTs can create a temporary table when the rows are not sorted externally (by the source SQL statement).

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

When creating temporary tables in Informix®, the WITH NO LOG clause can be used to avoid the overhead of recording DML operations in transaction logs.

**SAP HANA®**
SAP HANA® supports several types of temporary tables (local/global).

Then equivalent of Informix® temporary tables are session temporary tables created with CREATE LOCAL TEMPORARY TABLE instruction:

```
CREATE LOCAL TEMPORARY TABLE #tt1 ( pk INT, name NVARCHAR(50) )
```

**Note:** SAP HANA® temporary tables must be specified with a # number sign prefix.
For more details, see the SAP HANA® documentation.

**Solution**
In accordance with some prerequisites, temporary tables creation in BDL programs can be supported with SAP HANA®.

The general FGLPROFILE entry to control temporary table emulation is:

```
dbi.database.dsname.ifxemul.temptables = true false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**How does it work ?**
Informix-specific statements involving temporary table creation are automatically converted to SAP HANA® CREATE LOCAL TEMPORARY TABLE statements.

The database interface automatically adds a # number sign prefix before the table name. When used in other SQL statement the temporary table name is also prefixed with a # character.
Limitations

- Tokens matching the original table names all get a # number sign prefix in all SQL statements. Make sure you are not using a temp table name for other database objects, like columns. The following example illustrates this limitation:

  ```sql
  CREATE TEMP TABLE tmp1 ( col1 INTEGER, col2 CHAR(20) )
  SELECT tmp1 FROM table_x WHERE ...
  ```

- Only the 'native' serial emulation mode is supported with temporary tables. The serial emulation based on triggers is not supported, because triggers cannot be created on temporary tables.

  For more details see SERIAL data types on page 991.

- SAP HANA® does not support index creation on temporary tables.

Substrings in SQL

Informix®

Informix® SQL statements can use subscripts on columns defined with the character data type:

  ```sql
  SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
  SELECT ... FROM tab1 WHERE col1[10] = 'R' -- Same as col1[10,10]
  UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
  SELECT ... FROM tab1 ORDER BY col1[1,3]
  ```

**Important:** With other database servers as Informix®, when the subscript notation is used to modify column values in UPDATE statement, or as ORDER BY element, you will get and SQL error:

  ```sql
  UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
  SELECT ... FROM tab1 ORDER BY col1[1,3]
  ```

SAP HANA®

SAP HANA® provides the SUBSTRING(expr, start, length) function, to extract a substring from a string expression:

  ```sql
  SELECT SUBSTRING(col,10,5) ...
  ```

Solution

Replace all Informix® col[x,y] right-value expressions by SUBSTRING(col, x, y-x+1).

Rewrite UPDATE and ORDER BY clauses using col[x,y] expressions.

The translation of col[x,y] expressions can be controlled with the following FGLPROFILE entry:

  ```sql
  dbi.database.dsname.ifxemul.colsubs = \true \false
  ```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Substring expressions on page 577
Handle substrings expressions with different database engines.

**String delimiters**

**Informix®**

The ANSI SQL string delimiter character is the single quote ('string'), while double quotes are used to delimit database object names:

```
SELECT ... WHERE "tabname"."colname" = 'a string value'
```

In Informix® databases created in native mode (non-ANSI), you can use double quotes as string delimiters:

```
SELECT ... WHERE tabname.colname = 'a string value'
```

This is important, since many BDL programs use that character to delimit the strings in SQL commands.

**Note:** This problem concerns only double quotes within SQL statements. Double quotes used in pure BDL string expressions are not subject to SQL compatibility problems.

**SAP HANA®**

SAP HANA® follows the ANSI SQL specification, using single quotes for string delimiters and double quotes for database object names.

**Solution**

When using Static SQL statements, the fglcomp compiler converts string literals using double quotes to string literals with single quotes:

```
$ cat s.4gl
MAIN
   DEFINE n INT
   SELECT COUNT(*) INTO n FROM tab1 WHERE coll = "abc"
END MAIN
```

```
$ fglcomp -S s.4gl
s.4gl^3^SELECT COUNT(*) FROM tab1 WHERE coll = 'abc'
```

However, SQL statements created dynamically are not modified by the Genero compiler. The Genero database interface can automatically replace all double quotes by single quotes in SQL statements. This applies to static and dynamic SQL statements.

The translation of double quoted expression to single quoted expressions can be controlled with the following FGLPROFILE entry:

```
 dbi.database.dbname.ifxemul.dblquotes = {true | false }
```

For more details see **IBM Informix emulation parameters in FGLPROFILE** on page 614.

However, database object names must not be delimited by double quotes, because the database interface cannot determine the difference between a database object name and a quoted string! For example, if the program executes the SQL statement:

```
... WHERE "tabname"."colname" = "a string value"
```

replacing all double quotes by single quotes would produce:

```
... WHERE 'tabname'.'colname' = 'a string value'
```
This would produce an error since 'tabname'.colname' is not allowed by ORACLE.

Escaped string delimiters can be used inside strings like the following:

| 'This is a single quote: '''  
| 'This is a single quote: \''  
| "This is a double quote: """  
| "This is a double quote: \"" |

Although double quotes are replaced automatically in SQL statements, it is recommended that you use only single quotes to enforce portability.

**Single row SELECT**

**Informix**

With Informix®, you must use the system table with a condition on the table id:

```sql
SELECT user FROM systables WHERE tabid=1
```

**SAP HANA**

To retrieve a single row with SAP HANA®, use DUMMY table:

```sql
SELECT user FROM DUMMY
```

**Solution**

Check the BDL sources for "FROM systables WHERE tabid=1" and use dynamic SQL to resolve this problem.

Consider writing a FUNCTION which produces the FROM and WHERE part, depending on the target database type.

**MATCHES and LIKE**

**Informix**

Informix® supports MATCHES and LIKE operators in SQL statements.

MATCHES expects * and ? wild-card characters, while LIKE uses the % and _ wild-cards as equivalents.

```sql
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x' )
```

MATCHES accepts also brackets notation, to specify a set of matching characters at a given position:

```sql
( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )
```

**SAP HANA**

SAP HANA® does not provide an equivalent of the Informix® MATCHES operator.

The LIKE operator is supported.

**Solution**

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.
The MATCHES to LIKE expression translation is controlled by the following FGLPROFILE entry:

```
  dbi.database.dbname.ifxemul.matches = \ downarrow true \ downarrow false \ downarrow
```

**Important:** Only [NOT] MATCHES followed by a search pattern provided as a string literal can be converted by ODI drivers. A [NOT] MATCHES followed by a ? question mark parameter place holder is not translated!

For maximum portability, consider replacing the MATCHES expressions with LIKE expressions in all SQL statements.

Avoid using CHAR(N) types for variable length character data (such as name, address).

**Related concepts**
MATCHES and LIKE operators on page 579
Use the standard LIKE operator instead of the MATCHES operator.

**The LENGTH() function**

**Informix®**

Informix® provides the `LENGTH()` function to count the number of bytes of a character string expression:

```
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```

Informix® `LENGTH()` does not count the trailing blanks for CHAR or VARCHAR expressions, while Oracle counts the trailing blanks.

Informix® `LENGTH()` returns 0 when the given string is empty. That means, `LENGTH('') = 0`.

**SAP HANA®**

SAP HANA® supports the `LENGTH()` function, but there are some differences with Informix® `LENGTH()`.

The SAP HANA® `LENGTH()` function counts trailing blanks. When using a NCHAR column, values are blank padded, and the function returns the size of the NCHAR column. When using a NVARCHAR column, trailing blanks are significant, and the function returns the number of characters, including trailing blanks.

When passing NULL as parameter, the SAP HANA `LENGTH()` function returns NULL.

**Solution**

Check if the trailing blanks are significant when using the `LENGTH()` SQL function in your application.

To count the number of characters by ignoring the trailing blanks, you must use the `RTRIM()` function:

```
SELECT LENGTH(RTRIM(col1)) FROM table
```

The translation of `LENGTH()` expressions can be controlled with the following FGLPROFILE entry:

```
  dbi.database.dsname.ifxemul.length = \ downarrow true \ downarrow false \ downarrow
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**
The `LENGTH()` function in SQL on page 581
The semantics of the `LENGTH()` SQL function differs according to the database engine.

**BDL programming**

SAP HANA® related programming topics.
**INSERT cursors**

**Informix**

Informix® provides *insert cursors* to optimize row creation in a database. An insert cursor is declared as a cursor, and rows as added with the `PUT` instruction. The rows are buffered and sent to the database server when executing an `FLUSH` instruction, or when the cursor is closed with `CLOSE`. When using transactions in Informix®, the OPEN, PUT and FLUSH instructions must be executed within a transaction block.

```sql
DECLARE c1 CURSOR FOR INSERT INTO tab1 ...
BEGIN WORK
OPEN c1
WHILE ...
  PUT c1 USING var-list
END WHILE
CLOSE c1
COMMIT WORK
```

**SAP HANA**

SAP HANA® does not support insert cursors.

**Solution**

Insert cursors are emulated by the database interface, using basic `INSERT` SQL instructions.

The performances might be not as good as with Informix®, but the feature is fully supported.

**Related concepts**

- [Insert cursors](#) on page 569
- Using insert cursors with non-Informix databases.

**Cursors WITH HOLD**

**Informix**

Informix® closes opened cursors automatically when a transaction ends, unless the **WITH HOLD** option is used in the DECLARE instruction:

```sql
DECLARE c1 CURSOR WITH HOLD FOR SELECT ...
OPEN c1
BEGIN WORK
FETCH c1 ...
COMMIT WORK
FETCH c1 ...
CLOSE c1
```

**HANA DB**

HANA DB® does not close cursors when a transaction ends.

**Solution**

Even if HANA DB® supports cursors across transactions, for consistency with other ODI drivers, BDL cursors that are not declared **WITH HOLD** are automatically closed, when a `COMMIT WORK` or `ROLLBACK WORK` is performed.
**SELECT ... FOR UPDATE**

**Informix®**

Legacy BDL programs typically use a cursor with `SELECT FOR UPDATE` to implement pessimistic locking and avoid several users editing the same rows:

```sql
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

The row must be fetched in order to set the lock.

If the cursor is local to a transaction, the lock is released when the transaction ends. If the cursor is declared WITH HOLD, the lock is released when the cursor is closed.

Informix® provides the `SET LOCK MODE` instruction to define the lock wait timeout:

```sql
SET LOCK MODE TO \{ WAIT | NOT WAIT | \WAIT seconds \}
```

The default mode is `NOT WAIT`.

**SAP HANA®**

SAP HANA® supports `SELECT FOR UPDATE`.

SAP HANA® releases locks when the transaction ends (at `COMMIT WORK` or `ROLLBACK WORK`).

SAP HANA®'s locking granularity is at the row level.

**Note:** When using a cursor declared with a `SELECT FOR UPDATE`, all rows of the result set will get an exclusive lock when the cursor is opened.

SAP HANA® has an equivalent for Informix®'s `SET LOCK MODE TO NOT WAIT`:

```sql
SET TRANSACTION LOCK WAIT TIMEOUT milliseconds
```

**Solution**

The database interface is based on an emulation of an Informix® engine using transaction logging. Therefore, opening a `SELECT ... FOR UPDATE` cursor declared outside a transaction will raise an SQL error -255 (not in transaction).

If the program is doing a `SET LOCK MODE` instruction, it will be converted to a `SET TRANSACTION LOCK WAIT TIMEOUT` command by the database interface.

**Important:** Since SAP HANA® sets locks when the cursor is opened, it is not possible to get the Informix® behavior, where locks are set at `FETCH` time.

**LOAD and UNLOAD**

**Informix®**

Informix® provides two SQL instructions to export / import data from / into a database table:

The `UNLOAD` instruction copies rows from a database table into a text file:

```sql
UNLOAD TO "filename.unl" SELECT * FROM tab1 WHERE ..
```
The LOAD instructions insert rows from a text file into a database table:

```
LOAD FROM "filename.unl" INSERT INTO tab1
```

**SQLite**

SAP HANA® does not provide LOAD and UNLOAD instructions.

**Solution**

LOAD and UNLOAD instruction are implemented in the Genero BDL runtime system with basic INSERT (for LOAD) or SELECT (for UNLOAD) SQL commands. The LOAD and UNLOAD instruction can be supported with various database servers.

However, LOAD and UNLOAD require the description of the column types in order to work, that can lead to some differences in the data formatting.

**Note:** If no transaction is started, the LOAD instruction will automatically execute a BEGIN WORK and COMMIT WORK when finished, or ROLLBACK WORK if a row insertion failed while loading. Terminating a transaction will automatically close cursors not defined WITH HOLD option. To workaround this situation, see more details in the LOAD on page 684 reference topic.

The LOAD and UNLOAD BDL instructions are supported with SAP HANA®.

**Related concepts**

LOAD and UNLOAD instructions on page 574

The LOAD and UNLOAD instructions can produce different data formats depending on the database server type.

**UPDATE/DELETE ... WHERE CURRENT OF**

**Informix®**

Informix® allows positioned UPDATEs and DELETEs with the "WHERE CURRENT OF cursor" clause, if the cursor has been DECLARED with a SELECT ... FOR UPDATE statement.

**SAP HANA®**

SAP HANA® do not support UPDATE/DELETE with the WHERE CURRENT OF cursor clause.

**Solution**

UPDATE/DELETE ... WHERE CURRENT OF is not supported by SAP HANA®; review your code for occurrences.

**Related concepts**

Positioned UPDATE/DELETE on page 567

Using positioned updates/deletes with named database cursors.

**SQL Interruption**

**Informix®**

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

**SAP HANA®**

SAP HANA® supports SQL Interruption: The db client must issue an SQLCancel () ODBC call to interrupt a query.
**Important:** With SAP HANA, when an SQL statement is interrupted, the complete SQL transaction is rolled back: SAP HANA will cancel the SQL statements executed in the transaction before the interrupted SQL statement.

**Solution**
The SAP HANA® database driver supports SQL interruption and converts the native SQL error code -139 to the Informix® error code -213.

If your application allows SQL interruption in transaction blocks delimited by `BEGIN WORK / COMMIT WORK`, the code needs to be reviewed, because SQL statements prior to the interrupted SQL statement will be rolled back.

**Related concepts**
Using SQL interruption on page 539
Interrupt long running SQL queries, or interrupt queries waiting for locked data.

**Scrollable Cursors**

**Informix®**
Informix® SQL and Genero BDL support scrollable cursors when you specify the `SCROLL` clause in the `DECLARE` cursor instruction:

```
DECLARE c1 SCROLL CURSOR FOR SELECT ...  
```

**SAP HANA®**
SAP HANA® does not support scrollable cursors.

**Solution**
The SAP HANA® database driver emulates scrollable cursors by fetching rows in a temporary file.

See Scrollable cursors on page 560 for more details about scroll cursor emulation.

**User interface**

These topics cover programming the user interface (UI) with the Genero Business Development Language.

The dynamic user interface

The dynamic user interface is the base concept of the Genero user interaction components.

The dynamic user interface (DUI) concept implements a flexible graphical user interface programming toolkit, based on the usage of XML standards to define an abstract representation of the application forms, that can be displayed by different types of display devices called front-ends, which execute on the user workstation or on the same platform as the runtime system.

By using the same program source code, the abstract definition of the user interface that can be manipulated at runtime as a tree of interface objects. This tree is called the abstract user interface tree.

The runtime system is in charge of the abstract user interface tree and the front end is in charge of rendering this abstract tree visible on the screen. The front-end gets a copy of that tree which is automatically synchronized by the runtime system by using the front-end protocol.

In development, application screens are defined by form specification files. These files are compiled by the fglform form compiler to produce the runtime form files that can be deployed in production environments.

The following schema describes the dynamic user interface concept, showing how the abstract user Interface tree is shared by the runtime system and the front end.

![Figure 35: AUI tree shared between the runtime system and front end](image)

The abstract user interface tree (AUI tree) on the front-end is synchronized with the runtime system AUI tree when a user interaction instruction takes the control. This means that the user will not see any display as long as the program is doing batch processing, until an interactive statement is reached.

If you want to show something on the screen while the program is running in a batch procedure, you can force synchronization with the front-end, by calling the `ui.Interface.refresh()` method.

Note that the `refresh()` method must only be called when really needed: By default, the AUI tree will be automatically synchronized when the control goes back to the runtime system dialog instruction.

Keep in mind that when the AUI trees are synchronized, only the changes are sent to the front-end. If a modification has been made that does not result in a change in the values of the attributes of a node of the tree (for example, you change the contents of an image file but keep the same name), that modification will not be sent to the front-end.

Note that when running on a mobile device, both front-end and runtime system execute on the same platform. Still the AUI tree protocol takes place, and both component perform the tasks they are dedicated to.

**Related concepts**
The abstract user interface tree on page 1010
The abstract user interface tree is the XML representation of the application forms displayed to the end user.

Form specification files on page 1132
Form specification files are the source files defining the layout and content of application forms.

The abstract user interface tree

The abstract user interface tree is the XML representation of the application forms displayed to the end user.

The abstract user interface tree (AUI tree) is a DOM tree describing the objects of the user interface elements of a program at a given time.

A copy of the AUI tree is held by both the front-end and the runtime system.

AUI tree synchronization is automatically done by the runtime system using the front-end protocol.

The programs can manipulate the AUI tree element by using XML utility classes or high-level built-in classes such as `ui.Dialog` and `ui.Form`.

What does the abstract user interface tree contain?

The abstract user interface defines a tree of objects organized by parent/child relationship. The different kinds of user interface objects are defined by attributes. The AUI tree can be serialized as text based on the XML standard notation.

The following example shows a part of an AUI tree defining a toolbar serialized with the XML notation:

```xml
<ToolBar>
  <ToolBarItem name="f5" text="List" image="list" />
  <ToolBarSeparator/>
  <ToolBarItem name="Query" text="Query" image="search" />
  <ToolBarItem name="Add" text="Append" image="add" />
  ...
</ToolBar>
```

Related concepts

Toolbars on page 1327
Toolbars define a bar of buttons that appears at the top of application forms.

Manipulating the abstract user interface tree

Modifying the AUI tree with user interface specific built-in classes

The objects of the abstract user interface tree can be queried and modified at runtime with specific built-in classes like `ui.Form`, provided to manipulate form elements.

The code in the example gets the current window object, then gets the current form in that window, and hides a group-box form element identified by the name "gb1":

```gen
DEFINE w ui.Window
DEFINE f ui.Form
LET w = ui.Window.getCurrent()
LET f = w.getForm()
CALL f.setElementHidden("gb1",1)
```

Using the user interface specific built-in classes is the recommended way to modify the AUI tree in your programs.

Using low-level APIs to modify the AUI tree

In very special cases, you can also directly access the nodes of the AUI tree by using DOM built-in classes like `om.DomDocument` and `om.DomNode`.

Important: As FOUR Js continues to add new features to Genero, we encounter situations that forces us to modify the AUI Tree to add new element types and attributes. If you are using the low level API to directly modify user
interface elements, your code may be impacted when changes are made in the AUI tree definition. To minimize the impact, consider the following course of action with regards to use of the DOM/SAX API:

1. During a dialog instruction, do not create or delete AUI tree nodes, or change attributes that are not for decoration only (text, color and styles can be changed during dialog). When possible, consider using `ui.Dialog` and `ui.Form` built-in class methods instead of the low-level DOM/SAX API.

2. Place all custom changes to the DOM/SAX API within centralized library functions that are accessible to all modules, as opposed to scattering DOM/SAX calls throughout your code base.

3. Do not create nodes or change attributes that are not explicitly documented as modifiable. For example, `TopMenu` or `ToolBar` nodes can be created and configured dynamically, but it is not recommended to add `FormField` nodes to existing forms, or modify the `active` attribute of fields or actions. Do not create AUI nodes, that would not be created by a `.42f` file produced by the `fglform` compiler from a `.per` source file.

4. AUI tree nodes that have already been sent to the front end can only be modified by updating, appending or deleting children nodes. Inserting nodes with the `om.DomNode.insertBefore()` method is not supported in the AUI tree synchronization protocol, once the parent node has been sent.

To get the user interface nodes at runtime, the language provides different kinds of API functions or methods, depending on the context. For example, to get the root of the AUI tree, call the `ui.Interface.getRootNode()` method. You can also get the current form node with `ui.Form.getNode()` or search for an element by name with the `ui.Form.findNode()` method.

**Related concepts**

- **The abstract user interface tree** on page 1010
  The abstract user interface tree is the XML representation of the application forms displayed to the end user.

- **Dialog instructions** on page 1342
  This section describes the dialog instructions to control application forms and the concepts related to dialog implementation.

**XML node types and attribute names**

By tradition the language uses uppercase keywords, such as `LABEL` in form files, and the examples in this documentation reflect that convention. The language itself is not case-sensitive. However, XML is case-sensitive, and by convention node types use uppercase/lowercase combinations to indicate word boundaries. Therefore, the nodes and attributes of an abstract user interface tree are handled as follows:

- **Node types** - the first letter of the node type is always capitalized. Subsequent letters are lowercase, unless the type consists of multiple words joined together. In that case, the first letter of each of the multiple words is capitalized (the camel-case convention). Examples: `Label`, `FormField`, `DateEdit`, `Edit`.

- **Attribute names** - the first letter of the name is always lowercase; subsequent letters are also lowercase, unless the name consists of multiple words joined together. In that case, the first letter of each subsequent word is capitalized (the Lower camel-case convention). Examples: `text`, `colName`, `width`, `tabIndex`.

- **Attribute values** - the values are enclosed in quotes, and the runtime system does not convert them.

If you reference AUI tree XML nodes or attributes in your code, you must always respect the naming conventions.

**Actions in the abstract user interface tree**

The abstract user interface identifies all possible actions that can be received by the current interactive instruction with a list of `Action` nodes. The list of possible actions are held by a `Dialog` node. An `Action` node is identified by the 'name' attribute and defines common properties such as the accelerator key, default image, and default text.

Interactive elements are bound to `Action` nodes by the 'name' attribute. For example, a toolbar button (a.k.a toolbar item) with the name 'cancel' is bound to the `Action` node having the name 'cancel', which in turn defines the accelerator key, the default text, and the default image for the button.
Figure 36: AUI Tree binding

When an interactive element is used (such as a form field input, toolbar button click, or menu option selection), an `ActionEvent` node is sent to the runtime system. The name of the `ActionEvent` node identifies what action occurred and the 'idRef' attribute indicates the source element of the action.

Inspecting the AUI tree of a front end

When executing a program displaying on a front-end, it is possible to inspect the content of the abstract user interface built on the front-end side. The way to show the AUI tree depends on the type of front-end.

Genero Desktop Client

The GDC must have been started in debug mode (`-aD` option).

In the current window of the running program, do a control-right-click with the mouse. This opens the AUI tree debug window.

You can then browse the AUI tree created on the GDC side.

Genero Browser Client

The GAS / GBC must have been started with debug option. In the `as.xcf` configuration file, add the following line:

```xml
<CONFIGURATION ...>
  <APPLICATION_SERVER>
    ...
    <RESOURCE Id="res.uaproxy.param" Source="INTERNAL">--development</RESOURCE>
    ...
  </APPLICATION_SERVER>
</CONFIGURATION>
```

Start your application in a web browser; a debug icon appears on the right of the window. Click the icon to display the AUI debug tree.

You can then browse the AUI tree created on the GBC side.
Genero Mobile for Android™

The GMA must execute with debug mode enabled in the settings panel.

Open a web browser and enter the following URL:

```
http://device-ip-address:6480
```

You can then browse the AUI tree created on the GMA side.

Genero Mobile for iOS

The GMI must have been started in debug mode: the debug option needs to be enabled in GMI app settings on the device.

Open a web browser and enter the following URL:

```
http://device-ip-address:6480 (or 6400)
```

You can then browse the AUI tree created on the GMI side.

Genero user interface modes

User interface modes allow you to adapt the application form rendering to different types of displays.

There supported user interface modes are:

- Text mode rendering on page 1013
- Graphical mode rendering on page 1014
- Traditional GUI mode on page 1015

Text mode rendering

The text user interface (TUI) has been designed for character-based terminals. This mode can be used to run your application on a text terminal hardware or in a terminal emulator.

In order to run a Genero program on text mode, set the FGLGUI environment variable to 0 (zero).

In TUI mode, the application windows/forms will display within the current console/terminal window as shown.
On UNIX™ platforms, you need to configure your terminal capabilities with the TERM, TERMINFO or TERMCAP environment variables.

**Related concepts**
- [Graphical mode rendering](#) on page 1014
- **FGLGUI** on page 240
  Defines the user interface mode to be used by the program.
- [Using a text terminal](#) on page 1024
  This section covers topics about text terminal configuration when using the TUI mode (when the FGLGUI environment variable is set to zero).

**Graphical mode rendering**

Genero supports the graphical user interface (GUI) to provide a real graphical look and feel, for desktop workstation, web browsers and mobile front-end platforms.

When set to 1, the FGLGUI environment variable defines the graphical mode usage. This is the default. In graphical mode, the application forms are displayed on the front-end workstation identified with the FGLSERVER environment variable. Application forms will be rendered with real graphical widgets providing a nice look-and-feel as shown.
To simplify migration from text mode to graphical mode with legacy applications, you can use the traditional GUI mode option to render application windows in a single front-end GUI window.

Related concepts

Traditional GUI mode on page 1015

Traditional GUI mode

What is the Traditional GUI mode designed for?

With the graphical mode, you immediately get the benefit of standard GUI widgets and windows. Forms are rendered as real movable and resizable windows, form labels and fields become widgets using variable fonts, toolbars and pull-down menus are displayed, and error messages are displayed in the status bar. However, that can be annoying if you have to migrate from a project that was developed for dumb terminals (TUI mode).

You can use the traditional GUI mode to ease migration from TUI based applications to GUI mode.

With the traditional mode, application windows bound to forms using a SCREEN section will be displayed as simple boxes in a main front end window. Other windows bound to forms defined with the LAYOUT section will be displayed as new GUI windows.
Enabling the traditional GUI mode

The traditional GUI mode can be enabled with the following FGLPROFILE entry:

```plaintext
gui.uiMode = "traditional"
```

By default, the traditional GUI mode is off.

Window rendering rules

If the traditional GUI mode is enabled, the OPEN WINDOW statement works differently depending on the layout type of bound forms.

On the front-end side, there is one unique main graphical window (a top-level widget called "compatibility window container") created to host all the windows created by a program. Traditional forms are form files which have a SCREEN section instead of the LAYOUT section. When migrating from a TUI mode project, all forms initially contain a SCREEN section; hence all windows opened in traditional mode will appear in the compatibility window container.

To rebuild a form file with graphical items such as group boxes, buttons and tables, use a LAYOUT section. If the rebuilt form file is loaded via OPEN WINDOW ... WITH FORM form-file then, even in traditional mode, the newly created window will appear as a new top-level widget on the front end side. This opens a smooth migration path using the traditional mode; as a first step, it is possible to migrate and enhance some application forms like typical search lists, while keeping the rest of the application forms running in the traditional rendering.

Note, however, that following instructions do not work in traditional GUI mode:

1. OPEN WINDOW window_id AT line, column WITH height ROWS, width COLUMNS
2. OPEN FORM form_id FROM "form_file"
   (where form_file is defined with a LAYOUT section)
3. DISPLAY FORM form_id

A runtime error results, because you cannot display a form with dynamic geometry in a fixed geometry container. Only forms with a SCREEN section can be displayed at a later stage in a window that was initially opened inside the compatibility window container.
**Function key shifting**

When the traditional mode is enabled, you can map Shift-Fx and Ctrl-Fx key strokes to F(x+offset) actions. The offset is defined with the `gui.key.add_function` entry:

```
 gui.key.add_function = 12
```

This entry defines the number of function keys of the keyboard (default is 12). When defined as 12, a Shift-F1 will be received as an F13 (12+1) action event by the program, and a Control-F1 will be F25 (12*2+1).

**GUI front-end connection**

This section explains runtime to front-end connection in its simplest form.

**Connecting with a front-end**

In graphical mode, depending on the front-end technology that is used (desktop client, mobile client, web server client), there are different solutions to establish the connection between the runtime system and the front-end.

This topic describes the development context case, where programs are executed directly with `fglrn`. In a production environment, programs will typically be started with another technology, since the execution of programs will be triggered by the end user interacting with the front-end. Read front-end specific documentation for more details.

From the point of view of the runtime system, the front-end acts as a graphical server and thus the programs must connect to that GUI server in order to display forms and get user input.

The runtime system will try to connect to the front-end only when the first interactive instruction like `MENU` or `INPUT` is reached.

For the runtime system, the front-end is identified by the `FGLSERVER` environment variable. This variable defines the host name of the machine where the front-end resides, and the number of the front-end instances to be used.

The syntax for FGLSERVER is:

```
{hostname|ip-address}[[:servername]]
```

For example:

```
$ FGLSERVER=fox:1
$ fglrun myprog
```

The `servername` parameter is a whole number that defines the instance of the front-end. It is actually defining a TCP port number the front-end is listening to, starting from 6400. For example, if `servername` equals 2, the TCP port number used is 6402 (6400+2).

This is the standard/basic connection technique, but you can set up different types of configurations. For example, you can have the front-end connect to an application server via ssh, to pass through firewalls over the internet. Refer to the front-end documentation for more details.

There is an exception to the standard FGLSERVER specification, if the front-end is denied permission to listen to a TCP port (this is the case with the Genero Mobile Development Client). If you need to revert the connection principle in this particular case, use the `--gui-listen` option of `fglrn`. With this option, the runtime system will listen
to the specified port, so the front-end can bind to the program and start to use the GUI protocol. The procedure to work in such configuration is the following:

1. Start the program with:

   ```
   fglrun --gui-listen=tcp-port prog-name
   ```

2. Connect from the front-end, for example, with an URL using the following format:

   ```
   fgl://dev-server-hostname:tcp-port
   ```

**Related concepts**

  The `fglrn` tool is the runtime system program that executes p-code programs.

- **Graphical mode rendering** on page 1014

**The front-end protocol**

The front end protocol (FEP) is an internal protocol used by the runtime system to synchronize the abstract user interface (AUI) representation on the front-end side. This protocol defines a simple set of operations to modify the AUI tree. This protocol is based on a command processing principle (send command, receive answer) that can be serialized for transport over any network protocol, like HTTP for example.

![Figure 40: Typical communication between the Runtime System and the Front End](image)

1. Initialization phase: The runtime system sends the initial AUI tree.
2. The front-end builds the graphical user interface based on the AUI tree.
3. The front-end waits for a user interaction (mouse click, keyboard typing).
4. When the user performs some interaction, the front-end sends front-end events corresponding to the modifications made by the user.
5. Front-end events are analyzed and validated by the runtime system.
6. The runtime system sends back the result of the front-end requests, by way of AUI tree modification commands.
7. When receiving these commands, the front-end modifies its version of the AUI tree and updates the graphical user interface. It then waits for new user interactions (step 3).
Front-end identification

To start a program from the front-end platform, the front-end can open a terminal session on the application server. This is done for example by using a ssh, rlogin, or telnet terminal session. When the terminal session is open, the front end sends some shell commands to set environment variables, like FGLSERVER, before starting the program to display the application forms on the front-end where the terminal session was initiated.

In this configuration, front-end identification takes place. The front-end identification prevents the display of application forms on a front-end that did not start the program on the server. If the front-end is not identified, a serious security issue can arise, as anyone could run a fake program to display on any front-end and ask for a password.

Important: Front-end identification is achieved automatically by an initial protocol handshake. However, there can be a security hole if regular operating system users on the application server can overwrite the program or the shell script started by the front-end terminal session. Malicious programs can try to display the application on another workstation to read confidential data. As long as basic application users do not have read and write privileges on the program files, there is no risk. To make sure that program files on the server side are protected from basic users, create a special user on the server to manage the application program files, and give other users only read access to those files. As long as basic users cannot modify programs on the server side, there is no security issue.

FGLSERVER on page 245
Defines the graphical front-end form the application.

Configure the GUI connection timeout

When initiating the connection to the front-end, if the front-end software is stopped, the host machine is down, or a firewall drops connections for the TCP port used for the GUI connection, the program will stop with an error after a given timeout.

This timeout can be specified with the following FGLPROFILE entry:

```
gui.connection.timeout = seconds
```

The default timeout is 30 seconds.

Related concepts
The FGLPROFILE file(s) on page 220
FGLPROFILE environment variable defines Genero BDL configuration files

Wait for front-end ping timeout

Define the wait-for-ping timeout of the runtime system to control the built-in "keep alive" solution provided by Genero.

Important: This feature is not supported when running on mobile devices, or when displaying applications on mobile devices.

It can happen that the user leaves the program for a while without using it. The network policy (firewall) might force a close of the TCP connection after a given period of inactivity. To avoid such connection shutdown when there is no GUI exchange, the front-end sends successive ping events after a timeout period of inactivity, to keep the TCP connection alive. The inactivity timeout can be configured in front-ends. The front-end ping is normal behavior and part of the GUI client/server protocol.

Important: With this keep alive technique, a front-end connection always remains open, even if the user leaves the workstation for several hours. If your network connection comes at a cost to support this type of connection, it is recommended that you consider configuring the front-end to turn off the ping event or stop it after a given number of pings. Check the front-end configuration documentation for more details.

If the front-end program is not stopped properly as happens when, for example, it is killed by a system reboot, or when there is network failure, the TCP connection is lost and the runtime system no longer receives ping events. In
this case, the runtime system waits for a specified time, before it raises the error -8063. By default (when no exception handler is defined), the runtime system just stops. However, the error -8063 can be trapped with a WHENEVER ERROR or TRY/CATCH block, to perform some finalization tasks. The program should then immediately stop with EXIT PROGRAM n (where n > 0).

The wait-for-ping timeout period of the runtime system can be configured with the gui.protocol.pingTimeout fglprofile entry. By default, the runtime system waits for 600 seconds (10 minutes):

```
gui.protocol.pingTimeout = 800
```

**Important**: If you set the wait-for-ping timeout to a value lower than the ping delay of the front-end, the program will stop with the -8063 error after that timeout, even if the TCP connection is still alive. For example, when a front-end has a ping delay of 5 minutes, the recommended minimum value for this parameter is about 330 seconds (5 minutes + 30 seconds to make sure the client ping arrives).

**Related concepts**
The FGLPROFILE file(s) on page 220
FGLPROFILE environment variable defines Genero BDL configuration files

**GUI protocol compression**

*GUI protocol compression* might be used to reduce the amount of data exchanged between the front-end and the runtime system. Compression is typically useful on slow networks. The compression algorithm is provided by the standard ZLIB library of the system.

When using the Genero Browser Client (GBC), compression is not useful and is automatically disabled.

Compression makes sense on slow networks (for example, with a phone-line dialup modem, or broadband modem based networks); On fast networks, compression is not required and will in fact use unnecessary processor time.

Compression is disabled by default, and can be enabled with this FGLPROFILE entry:

```
gui.protocol.format = "zlib"
```

If this parameter is defined, but the ZLIB library is not installed on your system or if the ZLIB version is not compatible with the version needed by the runtime system, compression cannot be supported, and the program will stop with error -6317. The ZLIB version must be 1.2.5 (or compatible with version 1.2.5). On Microsoft™ Windows® platforms, the name of the library must be ZLIB1.DLL. Precompiled binary packages can easily be found on the internet. On UNIX™ platforms, the name of the shared library must be libz.so (normally located in /usr/lib). Note that on Linux® distributions, you typically have to install the zlib (or zlib1g) package and create a symbolic link for libz.so. The libz.so file is part of zlib-devel package, though.

**Related concepts**
The FGLPROFILE file(s) on page 220
FGLPROFILE environment variable defines Genero BDL configuration files

**Front-end protocol errors**

When the front-end receives an invalid instruction from the runtime system, it stops the application connection.

The runtime system then stops and displays error -6313 with an additional message, for example:

```
Program stopped at 'myprog.4gl', line number 675.
FORMS statement error number -6313.
The User Interface has been destroyed: Unexpected interface version sent by the runtime system.
```

When the runtime system receives an invalid AUI event from a front-end, it will raise a C assertion and produce a core file on UNIX® systems.
Related concepts
Exceptions on page 451
Describes exception (error) handling in the programs.

Debugging the front-end protocol

When setting the FGLGUIDEBUG environment variable to 1, information about GUI communication will be printed to stderr by the runtime system, and the GUI protocol exchange will be indented for a better readability in the front-end log window.

Important: Sensitive and personal data may be written to the output. Make sure that the log output is written to files that can only be read by application administrators.

UNIX™ (shell) example:

```
$ FGLGUIDEBUG=1
$ export FGLGUIDEBUG
$ fglrun myprog 2>guidbg.txt
```

Note: The output format of FGLGUIDEBUG is for debug purpose only and can change in next product releases.

Note that in TUI mode, displayed screens can be dumped by setting the DBSCREENDUMP or DBSCREENOUT environment variables. This can be used to take a snapshot of the current TUI screen, for debugging or testing purpose.

Related concepts
FGLGUIDEBUG on page 240
Defines the debug level in GUI mode.

Front-end protocol logging

GUI protocol exchanges can be logged to a file with the --start-guilog=filename option of fglrun, and replayed with the --run-guilog=filename option.

Important: Sensitive and personal data may be written to the output. Make sure that the log output is written to files that can only be read by application administrators.

The --start-guilog/--run-guilog options are used to simulate a program execution by connecting with a front-end, without the program files. Basically, the runtime system connects with the front-end and replays the abstract user interface exchanges.

The --start-guilog=filename instructs fglrun to start the program and log into filename, all user interface exchanges with the front-end. This option is typically used on site, with the program files.

With the --run-guilog=filename option, the runtime system replays abstract user interface exchanges, as when the program was executed with the --start-guilog option. This step can be done without the program files.

This feature can be used to set up non-regression tests for front-ends, and to provide a log file to your support center in order to replay a specific application issue.

The options take the log file as parameter:

UNIX™ (shell) example:

```
$ fglrun --start-guilog=mylog.txt myprogram
```

All user interaction and AUI tree updates will be logged into the mylog.txt file.

The log file can then be replayed with the --run-guilog option, to mimic the user interaction and program, to reproduce potential issues in front-ends:

```
$ fglrun --run-guilog=mylog.txt myprogram
```
Note: If the parent program starts other child programs with `RUN cmd [WITHOUT WAITING]`, the parent program and each child program will write into the same log file. When replaying the GUI log file, the runtime system is able to identify parent and child program logs in order to restart individual processes.

When replaying the GUI log file, the runtime system prompts you for each user interaction. Type `ENTER` to replay each event step by step, or type `c` to continue by playing the full log:

```
$ fglrun --run-guilog=mylog.txt myprogram
enter: one step; c: continue

`fglrun` on page 1968

The `fglrun` tool is the runtime system program that executes p-code programs.

**Automatic front-end startup**

This section describes how to start a graphical front-end automatically when the runtime system and the front-end reside on the same computer.

When a program starts in graphical mode, the runtime system tries to open a connection to the graphical front-end set by the `FGLSERVER` on page 245 environment variable. This requires having the front-end already started and listening to the TCP port specified by `FGLSERVER`.

In some configurations, such as X11 workstations or METAFRAME/Citrix Winframe or Microsoft™ Windows® Terminal Server, each user may want to start his own front-end to have a dedicated process. This can be done by starting the front-end automatically when the program executes, based on settings in the DISPLAY (X11) or SESSIONNAME/CLIENTNAME (WTSE) environment variables.

Automatic front-end startup settings are defined with `gui.server.autostart.*` entries in FGLPROFILE. In these FGLPROFILE entries, the term "GUI server" refers to the graphical front end.
In a first time, the runtime system tries to establish the connection without starting the front-end (in a normal usage, it is already started). The front-end is identified by the FGLSERVER environment variable. If FGLSERVER is not defined, it defaults to localhost:0, except if gui.server.autostart.wsmap entries are defined in FGLPROFILE. When wsmap entries are defined, workstation id to GUI server id mapping takes place and FGLSERVER defaults to localhost:n, where n is the GUI server number found from wsmap entries.

If this first connection fails and the gui.server.autostart.cmd entry is defined, the runtime system executes the command to start the GUI server, then waits for n seconds as defined by gui.server.autostart.wait entry, and after this delay tries to connect to the front-end. If the connection fails, it tries again for a number of attempts defined by the gui.server.autostart.repeat entry. Finally, if the last attempt fails, the runtime system stops with a GUI connection error -6300.

If the gui.server.autostart.cmd entry is not defined, neither workstation id to GUI id mapping, nor automatic front-end startup is done.

Here is a detailed description of each gui.server.autostart FGLPROFILE entry:

The cmd entry is used to define the command to be executed to start the front-end:

```
gui.server.autostart.cmd = "/opt/app/gdc-2.30/bin/gdc -p %d -q -M"
```

Here, %d will be replaced by the TCP port the front-end must listen to.

By default the runtime system waits for two seconds before it tries to connect to the front-end. You can change this delay with the wait entry:

```
gui.server.autostart.wait = 5   -- wait five seconds
```

The runtime system tries to connect to the front-end ten times. You can change this with the repeat entry:

```
gui.server.autostart.repeat = 3 -- repeat three times
```

The following FGLPROFILE entries can be used to define workstation id to front-end id mapping:

```
gui.server.autostart.wsmap.max = 3
gui.server.autostart.wsmap.0.names = "fox:1.0,fox.sxb.4js.com:1.0"
gui.server.autostart.wsmap.1.names = "wolf:1.0,wolf.sxb.4js.com:1.0"
gui.server.autostart.wsmap.2.names = "wolf:2.0,wolf.sxb.4js.com:2.0"
```

The first wsmap.max entry defines the maximum number of front-end identifiers to look for. The wsmap.N.names entries define a mapping for each GUI server, where N is the front-end identifier. The value of those entries defines a comma-separated list of workstation names to match. If no wsmap entries are defined, the GUI server number will default to zero.

For gui.server.autostart.wsmap entries, the first GUI server number starts at zero.

On X11 configurations, a workstation is identified by the DISPLAY environment variable. In this example, fox:1.0 identifies a workstation that will make the runtime start a front end with the number 1.

On Windows® Terminal Server, the CLIENTNAME environment variable identifies the workstation. If no corresponding front-end id can be found in the wsmap entries, the front-end number defaults to the id of the session defined by the SESSIONNAME environment variable, plus one. The value of this variable has the form protocol#id; for example, RDP-Tcp#4 would automatically define a front-end id of 5 (4+1).

If the front-end processes are started on the same machine as the runtime system, you do not need to set the FGLSERVER environment variable. This will then default to localhost:id, where id will be detected from the wsmap workstation mapping entries.

If the front-end is executed on a middle-tier machine that is different from the application server, MIDHOST for example, you can set FGLSERVER to MIDHOST without a GUI server id. The workstation mapping will automatically find the id from the wsmap settings.
**Note:** The Genero Desktop Client (GDC), raise the control panel to the top of the window stack when you try to restart it. In this case the program window might be hidden by the GDC control panel. To avoid this problem, you can use the -M option to start the GDC in minimized mode.

### Using a text terminal

This section covers topics about text terminal configuration when using the TUI mode (when the FGLGUI environment variable is set to zero).

Terminal type and terminal capabilities definition is not a Genero-specific configuration: TERM, TERMCAP and TERMIINFO are also used by other UNIX™ applications and commands.

On UNIX™ platforms, the TERM environment variable must be set to define the terminal type/name. For example, if you execute the application in an xterm X11 window, set TERM=xterm.

On Windows® platforms, you can run applications in text mode inside a CMD console window. You must not set the TERM environment variable in this case.

Genero supports both termcap and terminfo implementations of text terminal capabilities. The INFORMIXTERM environment variable defines the type of library used to interact with the terminal. When INFORMIXTERM is set to termcap (the default), the runtime system reads terminal capabilities from the file defined by the TERMCAP environment variable. When INFORMIXTERM is set to terminfo, the runtime system uses the ncurses library of the operating system to interact with the terminal. We strongly recommend you to use the terminfo solution.

**Related concepts**
- Text mode rendering on page 1013
- FGLGUI on page 240
  - Defines the user interface mode to be used by the program.

### TERMIINFO terminal capabilities

When the INFORMIXTERM environment variable is set to terminfo, the runtime system will use the ncurses or curses library of the UNIX™ system to display and interact with the terminal device defined by the TERM environment variable.

Make sure that the Curses library is installed on your UNIX™ operating system. Check operating system installation requirements for more details.

The TERMIINFO environment variable can be used to define a different terminal capabilities database as the default. If your UNIX™ system is properly configured, there is no need to set the TERMIINFO environment variable.

**Related concepts**
- INFORMIXTERM on page 248
  - Defines terminal control library to be used.
- TERM on page 229
  - Defines the type of terminal on UNIX™ platforms.

### TERMCAP terminal capabilities

When the INFORMIXTERM environment variable is set to termcap or when this variable is undefined, the runtime system will use the termcap terminal capabilities database.

The termcap solution is provided for backward compatibility. You should use terminfo instead, by setting the INFORMIXTERM variable to terminfo.

The default termcap database is in the /etc/termcap file. If this file is not found, the runtime system will use its default file $FGLDIR/etc/termcap. Use the TERMCAP environment variable to specify a different termcap
file as the defaults. If you plan to modify the default termcap file, we strongly recommend that you make a copy of the original file and point to the new file with the TERMCAP variable.

In this section we will briefly describe the syntax of the termcap file. For a complete definition please refer to your operating system documentation (see man pages describing the termcap file syntax).

Related concepts
INFORMIXTERM on page 248
Defines terminal control library to be used.

TERM on page 229
Defines the type of terminal on UNIX™ platforms.

TERMCAP on page 229
Defines the termcap terminal capabilities database on UNIX™ platforms.

Termcap syntax
All termcap entries contain a list of terminal names, followed by a list of terminal capabilities, in the following format:

- Each capability, including the last one in the entry, is followed by a colon (:).
- ESCAPE is specified as a backslash (\) followed by the letter E. CTRL is specified as a caret (^). Do not use the ESCAPE or CTRL keys to indicate escape sequences or control characters in a termcap entry.
- Entries must be defined on a single logical line; a backslash (\) appears at the end of each line that wraps to the next line.
- Comment lines begin with a hash sign (#).

Example: xterm terminal definition:

```
xterm|xterm terminal emulator:\
:km:mi:ms:xn:pt:\
:co#80:li#24:\
:is=\E[r\E[m\E[2J\E[H\E?[7h\E]?1;3;4;6l:\
...
```

Terminal Names
Termcap entries begin with one or more names for the terminal, each separated by a vertical (|) bar. Any one of these names can be used for access to the termcap entry.

Boolean capabilities
Boolean capabilities are two-character codes indicating whether a terminal has a specific feature. If the boolean capability exists in the termcap entry, the terminal has that particular feature.

For example:

```
:bs:am:
# bs backspace with CTRL-H
# am automatic margins
```

Numeric Capabilities
Numeric capabilities are two-character codes followed by a hash symbol (#) and a value.

For example:

```
:co#80:li#24:
# co number of columns in a line
# li number of lines on the screen
```
The runtime system assumes that the value is zero for any numeric capabilities that are not listed.

**String Capabilities**

String capabilities specify a sequence that can be used to perform a terminal operation. A string capability is a two-character code, followed by an equal sign (=) and a string ending at the next delimiter (:).

Most termcap entries include string capabilities for clearing the screen, arrow keys, cursor movement, underscore, function keys, etc.

For example, this shows some string capabilities for a Wyse 50 terminal:

```
:ce=\Et:cl=\E*:\
:nd=^L:up=^K:\
:so=\EG4:se=\EG0:
# ce=\Et clear to end of line
# cl=\E* clear the screen
# nd=^L non-destructive cursor right
# up=^K up one line
# so=\EG4 start stand-out
# se=\EG0 end stand-out
```

**Genero-specific termcap definitions**

**Controlling the delay for ESC key**

When using termcap, the ESCDELAY environment variable can be set to mimic the feature of the terminfo implementation: ESCDELAY specifies the delay (in milliseconds) before returning the ESC as a single key. Otherwise, ESC is the leading key of a control character sequence. The granularity of the delay value is 100 milliseconds. If ESCDELAY is not set (or set to 0), a default value of 500 milliseconds is used.

```
$ export ESCDELAY=600
```

**Extending Function Key Definitions**

In TUI mode, the runtime system recognizes function keys F1 through F36. These keys correspond to the termcap capabilities k0 through k9, followed by kA through kZ.

The termcap entry for these capabilities is the sequence of ASCII characters your terminal sends when you press the function keys (or any other keys you choose to use as function keys).

This example shows some function key definitions for the xterm terminal:

```
k0=\E[11~:k1=\E[12~:k2=\E[13~:k3=\E[14~:\n...k9=\E[21~:kA=\E[23~:kB=\E[24~:\n```

**Defining dialog action keys**

Dialog action keys for insert, delete and list navigation can be defined with the following capabilities:

- **ki**: Insert line (default is CTRL-J)
- **kj**: Delete line (default is CTRL-K)
- **kf**: Next page (default is CTRL-M)
- **kg**: Previous page (default is CTRL-N)

**Note**: You can also use the OPTIONS statement to name other function keys or CTRL keys for these operations.
Specifying Characters for Window Borders

The runtime system uses the graphics characters in the `termcap` file when you specify a window border in an `OPEN WINDOW` statement.

The runtime system uses characters defined in the `termcap` file to draw the border of a window. If no characters are defined in this file, the runtime system uses the hyphen ( - ) for horizontal lines, the vertical bar ( | ) for vertical lines, and the plus sign ( + ) for corners.

Steps to define the graphical characters for window borders for your terminal type:

1. Determine the escape sequences for turning the terminal graphics mode ON and OFF (Refer to the manual of your terminal). For example, on Wyse 50 terminals, the escape sequence for entering graphics mode is `ESC H^B`, and the escape sequence for leaving graphics mode is `ESC H^C`.

2. Identify the ASCII equivalents for the six graphics characters that Genero requires to draw the window borders. The ASCII equivalent of a graphics character is the key you would press in graphics mode to obtain the indicated character. The six graphical characters needed by Genero are:
   a. The upper left corner
   b. The lower left corner
   c. The upper right corner
   d. The lower right corner
   e. The horizontal line
   f. The vertical line

3. Edit the `termcap` entry for your terminal, and define the following string capabilities:
   a. `gs`: The escape sequence for entering graphics mode. In the `termcap` file, `ESCAPE` is represented as a backslash ( \ ) followed by the letter E; `CTRL` is represented as a caret ( ^ ). For example, the Wyse 50 escape sequence `ESC-H CTRL-B` is represented as `\EH^B`.
   b. `ge`: The escape sequence for leaving graphics mode. For example, the Wyse 50 escape sequence `ESC-H CTRL-C` is represented as `\EH^C`.
   c. `gb`: The concatenated, ordered list of ASCII equivalents for the six graphics characters used to draw the border. Using the order as listed in (2).

For example, if you are using a Wyse 50 terminal, you would add the following, in a linear sequence:
```
:gs=\EH^B:ge=\EH^C:gb=2135z6:\
```

For terminals without graphics capabilities, you must enter a blank value for the `gs` and `ge` capabilities. For `gb`, enter the characters you want Genero to use for the window border. The following example shows possible values for `gs`, `ge`, and `gb` in an entry for a terminal without graphics capabilities:
```
:gs=:ge=:gb=..|.|_:\n```

With these settings, window borders would be drawn using underscores ( _ ) for horizontal lines, vertical bars ( | ) for vertical lines, periods ( . ) for the top corners, and vertical bars ( | ) for the lower corners.

Adding Color and Intensity

In TUI mode, a Genero program can be written either for a monochrome or a color terminal, and then you can run the program on either type of terminal. If you set up the `termcap` files as described, the color attributes and the intensity attributes are related.

Table 280: Relationship between color attributes and intensity attributes

<table>
<thead>
<tr>
<th>Number</th>
<th>Color</th>
<th>Intensity</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>WHITE</td>
<td>NORMAL</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>YELLOW</td>
<td>BOLD</td>
<td></td>
</tr>
</tbody>
</table>
The background for colors is BLACK in all cases. In either color or monochrome mode, you can add the REVERSE, BLINK, or UNDERLINE attributes if your terminal supports them.

**The ZA String Capability**

Genero uses a parameterized string capability named ZA in the termcap file to determine color assignments. Unlike other termcap string capabilities that you set to a literal sequence of ASCII characters, ZA is a function string that depends on the following four parameters:

**Table 281: ZA function parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>p1</td>
<td>Color number between 0 and 7 (see <a href="#">Table 280: Relationship between color attributes and intensity attributes</a> on page 1027).</td>
</tr>
<tr>
<td>2</td>
<td>p2</td>
<td>0 = Normal; 1 = Reverse.</td>
</tr>
<tr>
<td>3</td>
<td>p3</td>
<td>0 = No-Blink; 1 = Blink.</td>
</tr>
<tr>
<td>4</td>
<td>p3</td>
<td>0 = No-underscore; 1 = Underscore.</td>
</tr>
</tbody>
</table>

ZA uses the values of these four parameters and a stack machine to determine which characters to send to the terminal. The ZA function is called, and these parameters are evaluated, when a color or intensity attribute is encountered in a Genero program. Use the information in your terminal manual to set the ZA parameters to the correct values for your terminal.

The ZA string uses stack operations to push values onto the stack or to pop values off the stack. Typically, the instructions in the ZA string push a parameter onto the stack, compare it to one or more constants, and then send an appropriate sequence of characters to the terminal. More complex operations are often necessary; by storing the display attributes in static stack machine registers (named a through z), you can have terminal-specific optimizations.

The different stack operators that you can use to write the descriptions are summarized here. For a complete discussion of stack operators, see your operating system documentation.

**Operators that Send Characters to the Terminal**

- `%d` pops a numeric value from the stack and sends a maximum of three digits to the terminal. For example, if the value 145 is at the top of the stack, `%d` pops the value off the stack and sends the ASCII representations of 1, 4, and 5 to the terminal. If the value 2005 is at the top of the stack, `%d` pops the value off the stack and sends the ASCII representation of 5 to the terminal.
• \texttt{%2d} pops a numeric value from the stack and sends a maximum of two digits to the terminal, padding to two places. For example, if the value 145 is at the top of the stack, \texttt{%2d} pops the value off the stack and sends the ASCII representations of 4 and 5 to the terminal. If the value 5 is at the top of the stack, \texttt{%2d} pops the value off the stack and sends the ASCII representations of 0 and 5 to the terminal.

• \texttt{%3d} pops a numeric value from the stack and sends a maximum of three digits to the terminal, padding to three places. For example, if the value 7 is at the top of the stack, \texttt{%3d} pops the value off the stack and sends the ASCII representations of 0, 0, and 7 to the terminal.

• \texttt{%c} pops a single character from the stack and sends it to the terminal.

Operators that Manipulate the Stack

• \texttt{%p[1-9]} pushes the value of the specified parameter on the stack. The notation for parameters is p1, p2, ... p9. For example, if the value of p1 is 3, \texttt{%p1} pushes 3 on the stack.

• \texttt{%P[a-z]} pops a value from the stack and stores it in the specified variable. The notation for variables is Pa, Pb, ... Pz. For example, if the value 45 is on top of the stack, \texttt{%Pb} pops 45 from the stack and stores it in the variable Pb.

• \texttt{%g[a-z]} gets the value stored in the corresponding variable (P[a-z]) and pushes it on the stack. For example, if the value 45 is stored in the variable Pb, \texttt{%gb} gets 45 from Pb and pushes it on the stack.

• \texttt{%’c’} pushes a single character on the stack. For example, \texttt{%’k’} pushes k on the stack.

• \texttt{%{n}} pushes an integer constant on the stack. The integer can be any length and can be either positive or negative. For example, \texttt{%{0}} pushes the value 0 on the stack.

• \texttt{%S[a-z]} pops a value from the stack and stores it in the specified static variable. (Static storage is nonvolatile since the stored value remains from one attribute evaluation to the next.) The notation for static variables is Sa, Sb, ... Sz. For example, if the value 45 is on top of the stack, \texttt{%Sb} pops 45 from the stack and stores it in the static variable Sb. This value is accessible for the duration of the Genero program.

• \texttt{%G[a-z]} gets the value stored in the corresponding static variable (S[a-z]) and pushes it on the stack. For example, if the value 45 is stored in the variable Sb, \texttt{%Gb} gets 45 from Sb and pushes it on the stack.

Arithmetic Operators

Each arithmetic operator pops the top two values from the stack, performs an operation, and pushes the result on the stack.

• \texttt{%+} Addition.
  For example, \texttt{%{2}%{3}%+} is equivalent to 2+3.

• \texttt{%-} Subtraction.
  For example, \texttt{%{7}%{3}%–} is equivalent to 7-3.

• \texttt{%*} Multiplication.
  For example, \texttt{%{6}%{3}%*} is equivalent to 6*3.

• \texttt{%/} Integer division.
  For example, \texttt{%{7}%{3}%/} is equivalent to 7/3 and produces a result of 2.

• \texttt{%m} Modulus (or remainder).
  For example, \texttt{%{7}%{3}%m} is equivalent to (7 mod 3) and produces a result of 1.

Bit Operators

The following bit operators pop the top two values from the stack, perform an operation, and push the result on the stack:

• \texttt{%&} Bit-and.
  For example, \texttt{%{12}%{21}%&} is equivalent to (12 and 21) and produces a result of 4.

• \texttt{%|} Bit-or.
  For example, \texttt{%{12}%{21}%|} is equivalent to (12 or 21) and produces a result of 29.
• %^ Exclusive-or.
  For example, %\{12\}%\{21\}%^ is equivalent to (12 exclusive-or 21) and produces a result of 25.

The following unary operator pops the top value from the stack, performs an operation, and pushes the result on the stack:
• %~ Bitwise complement.
  For example, %\{25\}%~ results in a value of -26.

Logical Operators
The following logical operators pop the top two values from the stack, perform an operation, and push the logical result (0 for false or 1 for true) on the stack:
• %= Equal to.
  For example, if the parameter p1 has the value 3, the expression %p1%\{2\}%= is equivalent to 3=2 and produces a result of 0 (false).
• %> Greater than.
  For example, if the parameter p1 has the value 3, the expression %p1%\{0\}%> is equivalent to 3>0 and produces a result of 1 (true).
• %< Less than.
  For example, if the parameter p1 has the value 3, the expression %p1%\{4\}%< is equivalent to 3<4 and produces a result of 1 (true).

The following unary operator pops the top value from the stack, performs an operation, and pushes the logical result (0 or 1) on the stack.
• %! Logical negation.
  This operator produces a value of zero for all nonzero numbers and a value of 1 for zero. For example, %\{2\}%! results in a value of 0, and %\{0\}%! results in a value of 1.

Conditional Statements
The conditional statement has the following format:

```%
? expr %t thenpart %e elsepart %;
%
```

The %e elsepart is optional. You can nest conditional statements in the thenpart or the elsepart.

When Genero evaluates a conditional statement, it pops the top value from the stack and evaluates it as either true or false. If the value is true, the runtime performs the operations after the %t; otherwise it performs the operations after the %e (if any).

For example, the expression:

```%
??p1%\{3\}%=%t;31%
%
```

is equivalent to:

```python
if p1 = 3 then print ",;31"
```

Assuming that p1 in the example has the value 3, Genero would perform the following steps:
• %? does not perform an operation but is included to make the conditional statement easier to read.
• %p1 pushes the value of p1 on the stack.
• %\{3\} pushes the value 3 on the stack.
• `%=` pops the value of p1 and the value 3 from the stack, evaluates the boolean expression p1=3, and pushes the resulting value 1 (true) on the stack.
• `%t` pops the value from the stack, evaluates 1 as true, and executes the operations after `%t`. (Since ";31" is not a stack machine operation, Genero prints ";31" to the terminal.)
• `%;` terminates the conditional statement.

**ZA example**

The ZA sequence for the ID Systems Corporation ID231 (color terminal) is:

```
ZA =
\E[0; # Print lead-in
%?=p1{%0}%=t{%7} # Encode color number (translate color number
to number for the ID231 term)
%e%p1{%1}=t{%3} #
%e%p1{%2}=t{%5} #
%e%p1{%3}=t{%1} #
%e%p1{%4}=t{%6} #
%e%p1{%5}=t{%2} #
%e%p1{%6}=t{%4} #
%e%p1{%7}=t{%0}%; #
%?=p2{%30};%({40})%+%2d # if p2 is set, print '30' and '40' + color number
(reverse)
%e40;{%30}+%2d%; # else print '40' and '30' + color number (normal)
%?=p3{%5}; # if p3 is set, print 5 (blink)
%?=p4{%4}; # if p4 is set, print 4 (underline)
m # print 'm' to end character sequence
```

**Text mode screen dump**

For compatibility with IBM® Informix® 4GL, Genero supports the DBSCREENDUMP and DBSCREENOUT environment variables for debugging purpose, which allows you to take a screenshot when running in TUI mode and save the result in a file.

To enable TUI screenshot, set either DBSCREENDUMP or DBSCREENOUT to the name of the output file, then run your Genero program with FGLGUI=0 set and press the Ctrl-P key to dump the current screen. Each time you press Ctrl-P, the output file will be overwritten.

The DBSCREENDUMP variable writes the screen with escape sequences of TTY attributes, while DBSCREENOUT writes only the characters displayed on the screen, which makes the output more readable.

If both variables are set, the runtime will generate both output files. However use different file names, otherwise the output is undefined.

**Related concepts**

- [DBSCREENDUMP on page 237](#)
  Defines the output file name for text screen shots.
- [DBSCREENOUT on page 238](#)
  Defines the output file name for text screen shots.

---

**Form definitions**

This section describes how to define application forms and program resources related to the presentation layer.

- [Windows and forms on page 1032](#)
- [Using images on page 1046](#)
- [Accessibility guidelines on page 1056](#)
- [Message files on page 1059](#)
- [Action defaults files on page 1061](#)
Windows and forms

The section describes the concept of windows and forms in the language.

Understanding windows and forms

This is an introduction to Genero windows and forms.

Programs manipulate windows and forms, to define display and input areas controlled by interactive instructions such as the \texttt{INPUT} dialog. When a dialog is started, it uses the form associated with the current window. Forms are defined in \texttt{.42f} compiled form files and are loaded and displayed in windows.

Window objects

The windows are created from programs; they define a display context for sub-elements like forms, menus, message and error lines. A window can contain only one form at a time, but you can display different forms successively in the same window.

When using the text mode (FGLGUI=0), windows are displayed in the character terminal as fixed-size boxes, at a given line/column position, width and height. When using a graphical desktop front-end (FGLGUI=1), windows are displayed as independent resizable windows by default. Note that a GUI application can run in traditional mode (\texttt{gui.uiMode="traditional"} FGLPROFILE setting), displaying windows as simple static areas inside a real graphical parent window. When using a mobile device front-end, only one window is visible at the time, because of device platform GUI standards and the limited screen sizes (smartphones). Split views are the exception, as they allow for the display of two windows side by side in a typical list-detail display on tablets.

A program creates a new window with the \texttt{OPEN WINDOW} instruction, which also defines the window identifier. A window is destroyed with the \texttt{CLOSE WINDOW} instruction:

\begin{verbatim}
OPEN WINDOW mywindow WITH FORM "myform"
...
CLOSE WINDOW mywindow
\end{verbatim}

If there is a current window, it is possible to display several forms successively in that same window. The previous form is removed automatically by the runtime system when displaying a new form to the window:

\begin{verbatim}
OPEN WINDOW mywindow WITH FORM "form1"
INPUT BY NAME ... -- uses form1 elements
...
OPEN FORM f1 FROM "form2"
DISPLAY FORM f1 -- removes "form1" from the window
INPUT BY NAME ... -- uses form2 elements
\end{verbatim}
When a program starts, the runtime system creates a default window named SCREEN. This default window can be used as a regular window: it can hold a menu and a form. If needed, it can be closed with CLOSE WINDOW SCREEN. You typically display the main form of your program in the SCREEN window, by using OPEN FORM + DISPLAY FORM:

```plaintext
MAIN
    -- The SCREEN window exists by default
    ...
    OPEN FORM f_main FROM "customers"
    DISPLAY FORM f_main -- displays in SCREEN
    ...
END MAIN
```

Several windows can be created, but there can be only one current window when using modal dialogs (only one dialog is active at the time, thus only the current window can be active). By using parallel dialogs, several windows can be active concurrently. Parallel dialogs were introduced to implement split views, for mobile devices.

There is always a current window. The last created window becomes the current window. When the last created window is closed, the previous window in the window stack becomes the current window. Use the CURRENT WINDOW instruction to make a specific window current before executing the corresponding dialog that is controlling the window content:

```plaintext
OPEN WINDOW w_customers ...
OPEN WINDOW w_orders ...
...
CURRENT WINDOW IS w_customers
...
CLOSE WINDOW w_customers
CURRENT WINDOW IS w_orders
...
```

By default, a window has no particular type and displays as a modal window on the front-end, to be controlled by a modal dialog instruction. In some situations, you must specify the type of the window to get a specific rendering and behavior. This is achieved by defining the TYPE attribute in the ATTRIBUTES clause of the OPEN WINDOW instruction:

```plaintext
OPEN WINDOW w_cust WITH FORM "f_cust" ATTRIBUTES(TYPE=LEFT)
...
OPEN WINDOW w_pref WITH FORM "f_pref" ATTRIBUTES(TYPE=POPUP)
...
```

Specify decoration options with a presentation style for the window, identified the STYLE attribute of the ATTRIBUTES section of OPEN WINDOW. Window styles can also be specified at form level, with the WINDOWSTYLE form attribute in the LAYOUT of the form definition:

```plaintext
OPEN WINDOW w_cust WITH FORM "f_cust" ATTRIBUTES(STYLE="dialog2")
```

The ui.Window built-in class can be used to manipulate windows as objects. The common practice is to get the current form of the window and use it as ui.Form object to manipulate its content.

The windows can be displayed in an WCI container application, by using the ui.Interface methods to define parent / child relationship.

**Form objects**

Forms define the layout and presentation of areas used by the dialogs (INPUT), to display or input data. Forms are loaded by programs from external files with the .42f extension, the compiled version of .per form specification files.
Forms can be stamped with the \texttt{VERSION} attribute. The form version attribute is used to indicate that the form content has changed. The front-end is then able to distinguish different form versions and avoid saved settings being applied for new form versions.

Forms can be loaded with the \texttt{OPEN FORM} instruction followed by a \texttt{DISPLAY FORM}, to display the form into the current window, or forms can be used directly as window creation argument with the \texttt{OPEN WINDOW ... WITH FORM} instruction:

\begin{verbatim}
OPEN FORM f_cust FROM "f_cust"
DISPLAY FORM f_cust -- into current window
...
OPEN WINDOW w_cust WITH FORM "f_cust"
\end{verbatim}

The form that is used by interactive instructions like \texttt{INPUT} is defined by the current window containing the form. Switching between existing windows (and thus, between forms associated with the windows) is done with the \texttt{CURRENT WINDOW} instruction.

Several forms can be successively displayed in the same (current) window. The last displayed form will be used by the next dialog, while the form displayed before will be automatically removed from the window:

\begin{verbatim}
OPEN WINDOW w_common WITH 20 ROWS, 60 COLUMNS
...
OPEN FORM f1 FROM "f_cust"
DISPLAY FORM f1 -- f_cust is shown
INPUT BY NAME rec_cust.* ...
...
OPEN FORM f2 FROM "f_ord"
DISPLAY FORM f2 -- f_ord is shown (f_cust is removed)
INPUT BY NAME rec_ord.* ...
\end{verbatim}

The \texttt{ui.Form} built-in class is provided to handle form elements. You can, for example, hide some parts of a form with the \texttt{setElementHidden()} method. Get a \texttt{ui.Form} object with the \texttt{ui.Window.getForm()} method.

\section*{Related concepts}

\textbf{What are dialog controllers?} on page 1608
Application forms are controlled by interactive instruction blocks called dialogs. These blocks perform the common tasks associated with the form, such as field input and action handling.

\textbf{Parallel dialogs (START DIALOG)} on page 1600
The \texttt{START DIALOG} and \texttt{TERMINATE DIALOG} instructions provide dialogs functionality executing concurrently in different application forms.

\textbf{The INPUT sub-dialog} on page 1491
The \texttt{INPUT} sub-dialog implements single record input in fields of the current form.

\section*{OPEN WINDOW}
Creates and displays a new window.

\section*{Syntax}

\begin{verbatim}
OPEN WINDOW identifier
  ↓ AT line, column ↓
  WITH ↓ FORM form-file
        ↓ height ROWS, width COLUMNS
        ↓ ATTRIBUTES ( window-attributes ) ↓
\end{verbatim}

where \texttt{display-attribute} is:

\begin{verbatim}
↓ BLACK ↓ BLUE ↓ CYAN ↓ GREEN
↓ MAGENTA ↓ RED ↓ WHITE ↓ YELLOW
\end{verbatim}
**User interface**

1. **identifier** is the name of the window. It is always converted to lowercase by the compiler.
2. **line** is the integer defining the top position of the window. The first line in the screen is 1, while the relative line number inside the window is zero.
3. **column** is the integer defining the position of the left margin. The first column in the screen is 1, while the relative column number inside the window is zero.
4. **form-file** defines the name of the compiled form file, without .42f extension.
5. **height** defines the number of lines of the window in character units; includes the borders in character mode.
6. **width** defines the number of lines of the window in character units; includes the borders in character mode.

**Usage**

An **OPEN WINDOW** statement can have the following effects:

- Declares a name (the **identifier**) for the window.
- Indicates which form has to be used in that window.
- Specifies the display attributes of the window.
- When using character mode, specifies the position and dimensions of the window, in character units.

For graphical applications, use this instruction without the **AT** clause, and with the **WITH FORM** clause.

The window identifier must follow the rules for identifiers and be unique among all windows defined in the program. Its scope is the entire program. You can use this identifier to reference the same Window in other modules with other statements (for example, **CURRENT WINDOW** on page 1042 and **CLOSE WINDOW** on page 1041).

The compiler converts the window identifier to lowercase for internal storage. When using functions or methods receiving the window identifier as a string parameter, the window name is case sensitive. We recommend that you always specify the window identifier in lowercase letters.

The runtime system maintains a stack of all open windows. If you execute **OPEN WINDOW** to open a new window, it is added to the window stack and becomes the current window. Other statements that can modify the window stack are **CURRENT WINDOW** and **CLOSE WINDOW**.

**Example**

```plaintext
MAIN
  OPEN WINDOW w1 WITH FORM "customer"
  MENU "Test"
    COMMAND KEY(INTERRUPT) "exit" EXIT MENU
  END MENU
  CLOSE WINDOW w1
END MAIN
```

**Related concepts**

Form specification files are the source files defining the layout and content of application forms.

The Window class on page 2347
The ui.Window class provides an interface to the window objects create with the OPEN WINDOW instruction.

The Form class on page 2353
The ui.Form class provides an interface to form objects created by an OPEN WINDOW WITH FORM or DISPLAY FORM instruction.

Window containers (WCI) on page 1922
WCI containers define window containers to group several programs in a parent multiple document interface presentation.

Window position and size
Window objects can be created with a position and size for the TUI mode.

A typical OPEN WINDOW instruction for TUI mode specifies the position on the screen:

```
OPEN WINDOW w1 AT 10,5 WITH FORM "custlist"
```

When using the TUI mode (or traditional GUI mode), the AT line, column clause defines the position of the top-left corner of the window on the terminal screen and WITH lines ROWS, characters COLUMNS clause specifies explicit vertical and horizontal dimensions for the window. The expression at the left of the ROWS keyword specifies the height of the window, in character unit lines. This must be an integer between 1 and max, where max is the maximum number of lines that the screen can display. The integer expression after the comma at the left of the COLUMNS keyword specifies the width of the window, in character unit columns. This must return a whole number between 1 and length, where length is the number of characters that your monitor can display on one line. In addition to the lines needed for a form, allow room for the COMMENT line, the MENU line, the MENU comment line and the ERROR line. The runtime system issues a runtime error if the window does not include sufficient lines to display both the form and these additional reserved lines. The minimum number of lines required to display a form in a window is the number of lines in the form, plus an additional line below the form for prompts, messages, and comments.

When using the full GUI mode (without the traditional mode), the AT line, column clause is optional and if used, the WITH lines ROWS, characters COLUMNS clause is ignored, because the size of the window is automatically calculated based on its contents.

OPEN WINDOW attributes
List of attributes for the OPEN WINDOW instruction.

Table 282: Window-attributes supported by the OPEN WINDOW statement

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEXT = string</td>
<td>Defines the default title of the window. When a form is displayed, the form title (LAYOUT(TEXT=&quot;mytitle&quot;)) will be used as window title.</td>
</tr>
<tr>
<td></td>
<td><strong>Tip:</strong> We recommend that you define the window title in the form file.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>STYLE = string</td>
<td>Defines the default style of the window. If the form defines a window style, (LAYOUT(WINDOWSTYLE=&quot;mystyle&quot;)), it overwrites the default window style.</td>
</tr>
<tr>
<td>Tip:</td>
<td>We recommend that you define the window style in the form file.</td>
</tr>
<tr>
<td>TYPE = [LEFT</td>
<td>RIGHT</td>
</tr>
<tr>
<td>BLACK, BLUE, CYAN, GREEN, MAGENTA, RED, WHITE, YELLOW</td>
<td>Default TTY color of the data displayed in the window.</td>
</tr>
<tr>
<td>BOLD, DIM, INVISIBLE, NORMAL</td>
<td>Default TTY font attribute of the data displayed in the window.</td>
</tr>
<tr>
<td>REVERSE, BLINK, UNDERLINE</td>
<td>Default TTY video attribute of the data displayed in the window.</td>
</tr>
<tr>
<td>PROMPT LINE integer</td>
<td>In character mode, indicates the position of the prompt line for this window. The position can be specified with FIRST and LAST predefined line positions.</td>
</tr>
<tr>
<td>FORM LINE integer</td>
<td>In character mode, indicates the position of the form line for this window. The position can be specified with FIRST and LAST predefined line positions.</td>
</tr>
<tr>
<td>MENU LINE integer</td>
<td>In character mode, indicates the position of the ring menu line for this window. The position can be specified with FIRST and LAST predefined line positions.</td>
</tr>
<tr>
<td>MESSAGE LINE integer</td>
<td>In character mode, indicates the position of the message line for this window. The position can be specified with FIRST and LAST predefined line positions.</td>
</tr>
<tr>
<td>ERROR LINE integer</td>
<td>In character mode, indicates the position of the error line for this window. The position can be specified with FIRST and LAST predefined line positions.</td>
</tr>
<tr>
<td>COMMENT LINE [OFF</td>
<td>integer]</td>
</tr>
<tr>
<td>BORDER</td>
<td>Indicates if the window must be created with a border in character mode. A border frame is drawn outside the specified window. This means, that the window needs 2 additional lines and columns on the screen.</td>
</tr>
</tbody>
</table>

The following list describes the default line positions in character mode:
• First line: Prompt line (output from PROMPT statement) and Menu line (command value from MENU statement).
• Second line: Message line (output from MESSAGE statement; also the descriptions of MENU options).
• Third line: Form line (output from DISPLAY FORM statement).
• Last line: Error line (output from ERROR statement). Also comment line in any window except SCREEN.

Related concepts

The MENU instruction implements a list of options the end user can choose from.

Prompt for values (PROMPT) on page 1353
The PROMPT instruction provides unique field input in an automatic pop-up window.

Static display (DISPLAY/ERROR/MESSAGE/CLEAR) on page 1343
This section explains the instructions displaying static information to application forms, such as DISPLAY, ERROR, MESSAGE, CLEAR.

DISPLAY FORM on page 1044
Displays and associates a form with the current window.

The WITH FORM clause
Creating a window object with a form.

The WITH FORM clause can be used to specify the name of a compiled form file to be used to create a window. A window object is automatically opened and sized to the screen layout of the form.

```
OPEN WINDOW w1 WITH FORM "custlist"
```

Note: When using the TUI mode, the width of the window is from the left-most character on the screen form (including leading blank spaces) to the right-most character on the screen form (truncating trailing blank spaces). The length of the window is calculated as (form line) + (form length).

It is recommended that you use the WITH FORM clause, especially in the default GUI mode, because the window is created in accordance with the form. If you use this clause, you do not need the OPEN FORM, DISPLAY FORM, or CLOSE FORM statement to open and close the form. The CLOSE WINDOW on page 1041 statement closes the window and the form.

Important:
The form file name identifies the compiled .42f file to be loaded. The file name may use a .42f extension, but this is not recommended.

The file name can be a simple file name, a relative file path, or an absolute file path.

- When using a simple file name or a relative path, form files are found relative to several directories in a given order, as described in the FGLRESOURCEPATH reference topic.
- When specifying an absolute path, FGLRESOURCEPATH (or DBPATH) is not used. On Windows®, an absolute file name must start with a drive letter (C:), a backslash (\) or a slash (/). If FGLRESOURCEPATH contains a driver letter (C:), a form file specified as "/foo/bar" will only be found in "C:/foo/bar", if C: is the current drive.

Related concepts
Genero user interface modes on page 1013
User interface modes allow you to adapt the application form rendering to different types of displays.

Form specification files on page 1132
Form specification files are the source files defining the layout and content of application forms.

Text mode rendering on page 1013
**Window styles**

Use the `STYLE` attribute to set a style for a window.

By default, windows are displayed as normal application windows, but you can use the `WINDOWSTYLE` attribute on page 1303 to show a window in front of other windows, as a "modal window".

The window style defines the type of the window (normal, modal) and its decoration, via a presentation style. The presentation style specifies a set of attributes in an external file (`.4st`).

There are different ways to define the style of a window: The `STYLE` attribute on page 1287 can be used in the `OPEN WINDOW` on page 1034 instruction to define the default style for a window, but it is better to specify the window style in the form file, with the `WINDOWSTYLE` attribute of the `LAYOUT section` on page 1194. This avoids decoration-specific code in the programs.

<table>
<thead>
<tr>
<th>Style name in 4st file</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Window</td>
<td>Defines presentation attributes for common application windows. When using MDI containers, normal windows are displayed as MDI children.</td>
</tr>
<tr>
<td>Window.main, Window.main2</td>
<td>Defines presentation attributes for starter applications, where the main window shows a start menu if one is defined by the application.</td>
</tr>
<tr>
<td>Window.dialog, Window.dialog2, Window.dialog3, Window.dialog4</td>
<td>Defines presentation attributes for typical OK/Cancel modal windows. On iOS mobile devices, opening a new window with the predefined style 'dialog' causes the window to slide up from the bottom:</td>
</tr>
<tr>
<td>Window.naked</td>
<td>Defines presentation attributes for windows that do not show the default view for ring menus and action buttons (OK/Cancel).</td>
</tr>
<tr>
<td>Window.viewer</td>
<td>Defines presentation attributes for viewers as the report pager (fglreport.per).</td>
</tr>
</tbody>
</table>

It is recommended that you **not** change the default settings of windows styles in the `FGLDIR/lib/default.4st` file. If you create your own style file, copy the default styles into your own file in a different directory.

It is not possible to change the presentation style attributes of windows dynamically in the AUI tree. The style is applied when the window and form are loaded.

If you open and display a second form in an existing window, the window style of the second form is not applied.

**Related concepts**

Start menus on page 1918

Start menus define a tree of application programs that can be started.

The abstract user interface tree on page 1010

The abstract user interface tree is the XML representation of the application forms displayed to the end user.

Understanding presentation styles on page 1065

*Presentation styles* centralize the attributes related to the decoration of the graphical user interface elements.

**Related reference**

Window style attributes on page 1117
Window style presentation attributes apply to a window element.

**Window titles**

Use the TEXT attribute to define a title for a window.

The TEXT attribute in the ATTRIBUTE clause of OPEN WINDOW on page 1034 defines the default title of the window. If the window is opened with a form (WITH FORM clause) that defines a TEXT attribute in the LAYOUT section, the default is ignored. Subsequent OPEN FORM/DISPLAY FORM instructions may change the window title if the new form defines a different title in the LAYOUT section.

It is recommended that you specify the window title in the form file, instead of using the TEXT attribute of the OPEN WINDOW instruction.

If you want to set a window title dynamically, you can use the setText () method of the ui.Window built-in class.

**Related concepts**

LAYOUT section  on page 1194  
The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

The Window class  on page 2347  
The ui.Window class provides an interface to the window objects create with the OPEN WINDOW instruction.

**Window icons**

Use a IMAGE attribute to define the icon for a window.

If the window is opened with OPEN WINDOW WITH FORM, by using a form file that defines an IMAGE attribute in the LAYOUT section, the window will use this image as icon. Subsequent OPEN FORM/DISPLAY FORM instructions may change the window icon if the new form defines a different image in the LAYOUT section.

If you want to set a window icon dynamically, you can use the setImage () method of the ui.Window built-in class.

**Related concepts**

LAYOUT section  on page 1194  
The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

The Window class  on page 2347  
The ui.Window class provides an interface to the window objects create with the OPEN WINDOW instruction.

**Window types**

Use the TYPE attribute to define the type of a window.

**Important:** This feature is only for mobile platforms.

The type of a window can be specified with the TYPE attribute in the OPEN WINDOW instruction:

```
OPEN WINDOW w_main WITH FORM "navi"
ATTRIBUTES( TYPE = NAVIGATOR )
```

This attribute was introduced to implement split-views on mobile front-ends.

Possible values for the TYPE attribute are described in the following table:

**Table 284: Supported window types**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| LEFT | Defines the window as the left pane when implementing split views.  
The window will be the parent window of a window cascade displayed on the left-hand side. |
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAVIGATOR</td>
<td>Defines the window as the action pane (i.e. iOS Tab bar) or drop down menu (Android) when implementing split views. This type of window will be used as top-level navigator window, showing the options to switch between different windows controlled by parallel dialogs.</td>
</tr>
<tr>
<td>POPUP</td>
<td>Defines the window as pop-up (modal) window, to open on the top of other windows. <strong>Note:</strong> The POPUP window type is ignored by GMA on Android™.</td>
</tr>
<tr>
<td>RIGHT</td>
<td>Defines the window as the right pane when implementing split views. The window will be the parent window of a window cascade displayed on the right-hand side.</td>
</tr>
</tbody>
</table>

**Related concepts**

Split views on page 1802
These topics describe split view programming in the language.

Windows and forms on page 1032
The section describes the concept of windows and forms in the language.

**CLOSE WINDOW**
Closes and destroys a window.

**Syntax**

```
CLOSE WINDOW ↓ identifier ↓ SCREEN ↓
```

1. **identifier** is the name of the window.

**Usage**
If the OPEN WINDOW statement includes the WITH FORM clause, it closes both the form and the window.

Closing a window has no effect on variables that were set while the window was open.

Closing the current window makes the next window on the stack the new current window. If you close any other window, the runtime system deletes it from the stack, leaving the current window unchanged.

If the window is currently being used for input, CLOSE WINDOW generates a runtime error.

You can close the default screen window with the CLOSE WINDOW SCREEN instruction.

**Example**

```
MAIN
  OPEN WINDOW w1 WITH FORM "customer"
  MENU "Test"
    COMMAND KEY(INTERRUPT) "exit" EXIT MENU
  END MENU
  CLOSE WINDOW w1
END MAIN
```

**Related concepts**

OPEN WINDOW on page 1034
CURRENT WINDOW
Makes a specified window the current window.

Syntax

```
CURRENT WINDOW IS { identifier | SCREEN }
```

1. `identifier` is the name of the window.

Usage

Programs with multiple windows might need to switch to a different open window so that input and output occur in the appropriate window. To make a window the current window, use the `CURRENT WINDOW` statement.

When a program starts, the screen is the current window. Its name is `SCREEN`. To make this the current window, specify the keyword `SCREEN` instead of a window identifier.

If the window contains a form, that form becomes the current form when a `CURRENT WINDOW` statement specifies the name of that window. All interactive instruction such as `CONSTRUCT`, `INPUT` use only the current window for input and output. If the user displays another form (for example, through an `ON KEY` clause) in one of these statements, the window containing the new form becomes the current window. When an interactive instruction resumes, its original window becomes the current window.

The `CURRENT WINDOW` instruction is typically used in text user interface (TUI) based applications, when distinct areas of the screen are reserved for different usage. In a GUI application, windows are typically opened and closed sequentially or on a stack of windows.

Example

```
MAIN
  OPEN WINDOW w1 WITH FORM "customer"
  ...
  OPEN WINDOW w2 WITH FORM "custlist"
  ...
  CURRENT WINDOW IS w1
  ...
  CURRENT WINDOW IS w2
  ...
  CLOSE WINDOW w1
  CLOSE WINDOW w2
END MAIN
```

Related concepts

- `OPEN WINDOW` on page 1034
  Creates and displays a new window.
- `Text mode rendering` on page 1013

CLEAR WINDOW
Clears the contents of a window.

Syntax

```
CLEAR WINDOW { identifier | SCREEN }
```

1. `identifier` is the name of the window.
Usage

The **CLEAR WINDOW** instruction clears the content of the specified window that was declared in an **OPEN WINDOW**. If the window was created with borders, these are left untouched (only the content of the window is cleared).

If you specify **CLEAR WINDOW SCREEN**, the root screen will be cleared, except areas occupied by an existing window. **CLEAR WINDOW SCREEN** will not change the current window setting.

The **CLEAR WINDOW** instruction is typically used in text user interface (TUI) based applications, as it clears the whole content of the window, including static labels and messages.

Related concepts

- **OPEN WINDOW** on page 1034
  Creates and displays a new window.
- **Text mode rendering** on page 1013

**OPEN FORM**

Declares a compiled form in the program.

Syntax

```
OPEN FORM identifier FROM form-file
```

1. `identifier` is an identifier that defines the name of the form object.
2. `form-file` defines the name of the compiled form file, without `.42f` extension.

Usage

In order to use a `.42f` compiled version of a form specification file, the programs must declare the form with the **OPEN FORM** instruction and then display the form in the current window by using the **DISPLAY FORM** on page 1044 instruction.

**OPEN FORM**/**DISPLAY FORM** are typically used at the beginning of programs to display the main form in the default **SCREEN** window:

```
OPEN FORM custform FROM "customer"
DISPLAY FORM custform
```

The form identifier does not need to match the name of the form specification files, but it must be unique among form names in the program. Its scope of reference is the entire program.

**Important:**

The form file name identifies the compiled `.42f` file to be loaded. The file name may use a `.42f` extension, but this is not recommended.

The file name can be a simple file name, a relative file path, or an absolute file path.

- When using a simple file name or a relative path, form files are found relative to several directories in a given order, as described in the **FGLRESOURCEPATH** reference topic.
- When specifying an absolute path, **FGLRESOURCEPATH** (or **DBPATH**) is not used. On Windows®, an absolute file name must start with a drive letter (`C:`), a backslash (`\`) or a slash (`/`). If **FGLRESOURCEPATH** contains a driver letter (`C:`), a form file specified as `'"/foo/bar"` will only be found in `"C:/foo/bar"`, if `C:` is the current drive.

If you execute an **OPEN FORM** with the name of an open form, the runtime system first closes the existing form before opening the new form.

The scope of reference of form identifier is the entire program.

When the window is dedicated to the form, use the **OPEN WINDOW WITH FORM** instruction to create the window and the form object in one statement.
In TUI mode, the form is displayed in the current window at the position defined by the FORM_LINE attribute that can be specified in the ATTRIBUTE clause of OPEN_WINDOW on page 1034 or as default with the OPTIONS instruction.

After the form is loaded, you can activate the form by executing a CONSTRUCT, DISPLAY_ARRAY, INPUT, INPUT_ARRAY, or DIALOG statement. When the runtime system executes the OPEN FORM instruction, it allocates resources and loads the form into memory. To release the allocated resources when the form is no longer needed, the program must execute the CLOSE_FORM on page 1045 instruction. This is a memory-management feature to recover memory from forms that the program no longer displays on the screen. If the form was loaded with a window by using the WITH FORM clause, it is automatically closed when the window is closed with a CLOSE_WINDOW instruction.

Example

```main
OPEN_FORM f1 FROM "customer"
DISPLAY FORM f1
CALL input_customer()
CLOSE FORM f1
OPEN_FORM f2 FROM "custlist"
DISPLAY FORM f2
CALL input_custlist()
CLOSE FORM f2
END MAIN
```

Related concepts

Form specification files on page 1132
Form specification files are the source files defining the layout and content of application forms.

Defining the position of reserved lines on page 506
The OPTIONS element LINE defines position of dedicated screen lines.

DISPLAY FORM
Displays and associates a form with the current window.

Syntax

```display_form
DISPLAY FORM identifier
\ ATTRIBUTES (display-attributes) \n```

1. **identifier** is the name of the form.
2. **window-attributes** defines the display attributes of the form.

where **display-attribute** is:

```display-attribute
BLACK | BLUE | CYAN | GREEN
MAGENTA | RED | WHITE | YELLOW
BOLD | DIM | INVISIBLE | NORMAL
REVERSE | BLINK | UNDERLINE
```

Usage

The DISPLAY FORM instruction creates a form element in the current window, from a form resource loaded by the OPEN FORM instruction.

**Important:** The INVISIBLE display attribute is ignored.

The runtime system applies display attributes that you specify in the ATTRIBUTES clause to any fields that have not been assigned attributes by the ATTRIBUTES section of the form specification file, or by the database schema.
files, or by the OPTIONS runtime configuration statement. If the form is displayed in a window, color attributes from the DISPLAY FORM statement supersede any from the OPEN WINDOW on page 1034 statement. If however subsequent CONSTRUCT, DISPLAY, or DISPLAY ARRAY statements that include an ATTRIBUTES clause reference the form, their attributes take precedence over those specified in the DISPLAY FORM instruction.

In graphical mode, by default, the parent window adapts its size to the content of the form displayed with DISPLAY FORM. When successive DISPLAY FORM instructions use different forms (with different content), it is possible to control the parent window resizing with the resetFormSize style attribute. Note that this style attribute is to be used in the form element, not in the window element.

**Related concepts**

- OPEN FORM on page 1043
  Declares a compiled form in the program.
- CLOSE FORM on page 1045
  Closes the resources allocated by OPEN FORM.
- ATTRIBUTES section on page 1221
  The ATTRIBUTES section describes properties of grid-based layout elements used in the form.
- Form specification files on page 1132
  Form specification files are the source files defining the layout and content of application forms.
- Defining the position of reserved lines on page 506
  The OPTIONS element LINE defines position of dedicated screen lines.

**CLOSE FORM**

Closes the resources allocated by OPEN FORM.

**Syntax**

```
CLOSE FORM identifier
```

1. `identifier` is the name of the form.

**Usage**

The CLOSE FORM instruction releases the memory allocated to the form.

A form associated with a window by the OPEN WINDOW WITH FORM instruction is automatically closed when the program closes the window with a CLOSE WINDOW instruction.

**Related concepts**

- CLOSE WINDOW on page 1041
  Closes and destroys a window.
- OPEN FORM on page 1043
  Declares a compiled form in the program.

**CLEAR SCREEN**

Clears the complete application screen.

**Syntax**

```
CLEAR SCREEN
```

**Usage**

The CLEAR SCREEN instruction is typically used in TUI mode to clear the complete screen and make the root screen window the current window on the stack.
The whole screen will be cleared, including prompt, error and message lines (the menu line is not cleared).

**Related concepts**
- **Text mode rendering** on page 1013
- **CLEAR WINDOW** on page 1042
  CLEARS the contents of a window.

**DISPLAY AT**
Displays text at a given line/column position in the current window.

**Syntax**

```
DISPLAY text AT line, column [ATTRIBUTES (display-attributes)]
```

1. `text` is any expression to be evaluated and displayed at the given position in the current window.
2. `line` is an integer expression defining the line position in the current window.
3. `column` is an integer expression defining the column position on the screen.
4. `display-attributes` defines the display attributes for the `text`.

**Usage**

The `DISPLAY AT` instruction evaluates a string expression and displays the result at a given line and column in the current window. This instruction is typically used in text user interface (TUI) text-based applications to display static text on the screen such as messages or decoration lines with – (dash) or _ (underscore) characters.

Use of the `DISPLAY AT` instruction is recommended only in TUI mode. To display data at a given place in a graphical form, use form fields and the `DISPLAY BY NAME` or `DISPLAY TO` instructions, or use interactive instructions with the UNBUFFERED mode to automatically display program variable data to form fields.

When using `DISPLAY AT` in GUI mode, the text will only be displayed if the current window contains no form, or contains a form defined with the SCREEN layout.

**Table 285: Display-attributes supported by the DISPLAY AT statement**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>

Image handling basics
This is an introduction to image handling in Genero.

Purpose of images in applications
Graphical applications typically use images for various purposes:

- Application icon for the operating system taskbar / window manager.
- Icons in pop-up messages, menu options, form buttons, toolbars, list elements, treeview nodes.
- Decoration pictures in forms like background images, company logo, etc.
- Application photos, to get a visual identification for objects or people.

Images can be static (like toolbar icons, logos), or can change during the program execution (images related to application data).

In .per form definition files, specify static or dynamic image form items, with the IMAGE item type on page 1174.

Sources for image data
An image can come from different sources:

- An image file located on the system where the program executes (available on the platform, or from your own application).
- An URL (or URI) resource: the image file is located on a Web server and can be downloaded from the internet.
- Image data stored in a database within Binary Large Object (BLOB) typed columns.
- Pictures coming from a mobile device photo gallery, or camera.

In all cases, the image data must be available locally on the front-end platform to be displayed. Since the program can run on a different platform as the front-end, Genero provides several solutions to transmit the image data to the front-end, when the image is not available as a local file. For more details, see Providing the image resource on page 1049.

Image triggering actions
If needed, it is possible to associate an action to an image by defining the ACTION attribute. The associated action handler will then be executed in the program code, for example to react to mouse clicks on the image for desktop front-ends:

```
IMAGE i1: logo,
   IMAGE = "genero_logo",
   ACTION = show_about_box;
```

For more details about action handling, see Dialog actions on page 1640.

Controlling the image layout
Explains how image form items can be sized in different front-end layout systems.

Image sizing basics
It is important to differentiate the image and the image container (the widget): when designing a form, you're defining the image container. The actual image that will be displayed in this container can be smaller or larger. Genero provides several form file attributes, to control how the image and its container are sized.

How an IMAGE item renders on the front-end screen depends on these factors:

- The type of layout used (grid-based or stack-based layout).
• The size of the form item tag in the LAYOUT section, or the WIDTH and HEIGHT attributes defined for the IMAGE item.
• The combination of image item attributes (SIZEPOLICY, AUTOSCALE, STRETCH). These attributes may have a limited effect depending on the front-end platform.
• The image resource (actual picture file) size when displayed (especially when SIZEPOLICY=DYNAMIC/INITIAL).
• The scaleIcon presentation style attribute, for elements using icons such as BUTTON or TOOLBAR items.

**Note:** The typical layout settings of an IMAGE item is a combination of SIZEPOLICY=FIXED, AUTOSCALE and eventually a WIDTH/HEIGHT: The fixed size policy is to get an image size that corresponds the rest of the form layout, while auto-scaling will make the image fit to its container and avoid scrollbars with large images. The WIDTH/HEIGHT attributes may be used to specify the size of the image container. However, the preferred way to define the size of an image container is the item tag dimensions, in the layout section of the form.

**Image size in grid-based layout**

The AUTOSCALE attribute indicates if the picture must be scaled to the available space in the image item. The space is defined by the SIZEPOLICY attribute, the STRETCH attribute, and the form item size (the form item tag in the layout or the WIDTH and HEIGHT attributes).

AUTOSCALE is only useful if the size of the image differs from the size of the container. AUTOSCALE is useless with SIZEPOLICY=DYNAMIC, as the container always fits to the image size.

The STRETCH attribute defines how the image item adapts to the parent container when it is re-sized. The default is NONE.

SIZEPOLICY and the WIDTH/HEIGHT attributes define the size of the container, not the size of the image.

The SIZEPOLICY attribute defines how the image widget gets its size, depending on the context:

• When SIZEPOLICY is INITIAL (the default) and AUTOSCALE is not used, the size of the widget is defined by the first picture displayed in the form element. The size will not change if other pictures with different sizes display in the widget. If no initial image is displayed (the image field value is NULL), the form item does not take up space in the layout (and also does not adapt the size if an image is displayed later on).
• When SIZEPOLICY is DYNAMIC, the size of the widget is automatically adapted to the size of the pictures displayed in the image form item. The AUTOSCALE attribute has no effect.
• If SIZEPOLICY attribute is set to FIXED, the size of the widget is defined by the form specification file, either by the size of the item-tag in the layout, or by the WIDTH and HEIGHT attributes. With a fixed image widget size, if AUTOSCALE is not used, scrollbars may appear if the picture is greater than the widget.

By default, the size of the image widget defaults to the relative width and height defined by the item-tag in the form layout section. The size of an image widget can also be specified in the WIDTH and HEIGHT attributes, but these attributes only have an effect when SIZEPOLICY=FIXED.

The WIDTH and HEIGHT attributes define the size of the container, but they are dependent on the SIZEPOLICY. It means the image container may grow or shrink even if WIDTH and HEIGHT are specified. If you really want to have a container with a fixed size, you have to use WIDTH and HEIGHT in combination with SIZEPOLICY=FIXED.

All image layout attributes (except AUTOSCALE) only have an impact on the container size, not on the image size. If AUTOSCALE is defined, the image fits to the container size, but without losing its initial proportionality. If STRETCH allows the container to grow/reduce in the X or Y direction, the image will grow with the container, but the original proportionality is always kept.

**Note:** On some platforms, the image widgets automatically add a border to the source picture. For these platforms, if the image form item is the same size as the image, you may need to increase the size of the image form item to avoid automatic scrollbars. For example, if your image source has a size of 500x500 pixels and the widget displays a border with a size of 1 pixel, you will have to set WIDTH and HEIGHT to 502 pixels. If you do not, scrollbars will appear or the image will shrink if AUTOSCALE is used. Alternatively, you can avoid the image border with the border presentation style attribute.
Image size in stack-based layout

With a stacked layout, where form items display vertically on each other, by default the image is auto-scaled with the correct aspect/ratio in the available form space.

The image size can be controlled by the `HEIGHT` attribute of the image container.

If the `HEIGHT` attribute is set, it is expressed in `CHARACTERS` as for grid-based layout, and the width is determined by the correct aspect/ratio.

Providing the image resource

There are several things you need to know about providing an image resource in a Genero program.

Supported image formats

Genero supports various image data formats, typically PNG, JPEG and SVG. However, the supported image formats depend on the type of front-end used. Check the front-end platform documentation for supported image formats.

True Type Font (TTF) files are also supported. The TTF format is used when image-to-font-glyph mapping is enabled by specifying a mapping file in the `FGLIMAGEPATH` environment variable.

Image resolution

Consider using the appropriate image resolution for the target front-end platform. For example, mobile devices have a much higher pixel density (a higher resolution) than desktop monitors. An image which looks nice on a desktop can appear small or as an unscaled image on a mobile device.

Static versus dynamic images

The image resource specification is different for static and dynamic images:

- For static images (such as button icons), set the image resource in the image attribute (`IMAGE, IMAGELEAF, and so on`). See Static images on page 1051.
- For dynamic images (such as image fields displaying photos from a database), the image resource is specified with the field/variable value, to be rendered in a form field. The form field is typically defined as an `IMAGE` item, or an `IMAGECOLUMN` in a table view. For more details, see Runtime images on page 1052.

Image resource lookup

The image data can be provided in different ways, depending on the image resource specification:

1. As a Uniform Resource Locator (URL).
2. As a simple image name (typical for icons).
3. As a simple file name, typically with a `.png` or `.jpg` extension, or a relative or absolute file path.

Using an URL image resource

If the image specification starts with a URL prefix, the front-end will try to download the image from the location specified by the URL.

The network access to the Web server must exist and network bandwidth must be sufficient to rapidly download the images.
### Table 286: Supported image resource locations (URLs)

<table>
<thead>
<tr>
<th>Image resource location (URL)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://location-specification">http://location-specification</a></td>
<td>HTTP server</td>
</tr>
<tr>
<td><a href="https://location-specification">https://location-specification</a></td>
<td>HTTPS server (HTTP over SSL/TLS)</td>
</tr>
</tbody>
</table>

### Using a simple image name (centralized icons)

If the image specification is a simple name (without a file extension), and the FGLIMAGEPATH environment variable defines an icon mapping file for the runtime system, the image name is converted to a font file and font glyph, based on the mapping file entries, and the image form item displays the glyph/icon found in the font definition file. The mapping file and the font definition file are centralized on the application server.

A line in the image-to-font-glyph mapping file must have the following format:

```
image-name=font-file:hexa-ordinal[:color-spec]
```

For example, if the image mapping file defines the following lines:

```
smiley=FontAwesome.ttf:f118
red_smiley=FontAwesome.ttf:f118:#8B0000
```

An image resource (IMAGE attribute, IMAGECOLUMN value, and so on) with the name "smiley" will be mapped to the glyph with ordinal position 0xf118 in the FontAwesome.ttf font file, and the image resources using "red_smiley" will use the same glyph, but will get a red color.

**Important:** The directory to the font file must be specified in FGLIMAGEPATH, except if the font file is located in the same directory as the mapping file.

A default color can be defined for all TTF icons of a window, by using the `defaultTTFColor` style attribute:

```xml
<StyleList>
  <Style name="Window.important">
    <StyleAttribute name="defaultTTFColor" value="red" />
  </Style>
  ...
</StyleList>
```

A default mapping file named "image2font.txt" and the "FontAwesome.ttf" font file are provided in FGLDIR/lib. If FGLIMAGEPATH is not defined, the runtime system will use these files to make the image to font glyph mapping.

**Important:** When providing your own customized font file, it must be a valid TTF file. For example, changing the file name is not sufficient to turn it into a different font: In order to produce a valid TTF file, use font management tools such as FontForge (http://fontforge.github.io/en-US/) or Fontello (http://fontello.com). Furthermore, to target Microsoft® Internet Explorer (version 11), you will need to patch the generated TTF file to remove embedding limitations from TrueType fonts, by setting the fsType field in the OS/2 table to zero. This modification can be done with freeware tools like ttembed.

It is possible to mix several plain image file directories with several image-to-font glyph mapping files in FGLIMAGEPATH. The list of mapping files and directories defines the order of precedence, for example:

```sh
cat FGLIMAGEPATH="/var/myapp/myimages:\n/var/myapp/myicons.txt:/var/myapp/fontfiles:\n$FGLDIR/lib/image2font.txt:$FGLDIR/lib"
```

In the above FGLIMAGEPATH configuration:

- `/var/myapp/myimages`: Directory where plain image files can be found
- `/var/myapp/myicons.txt`: Custom image-to-font-glyph mapping file (icons)
• /var/myapp/fontfiles: Font files used by the myicons.txt mapping file
• $FGLDIR/lib/image2font.txt: Default icon mapping files (using FontAwesome.ttf)
• $FGLDIR/lib: Location of the default FontAwesome.ttf file

Consider defining your own image mapping file and make FGLIMAGEPATH point to your own files.

**Note:** When executing the application on a mobile device, you must define the FGLIMAGEPATH environment variable with the mobile.environment.FGLIMAGEPATH entry in FGLPROFILE. Use $FGLAPPDIR and $FGLDIR placeholders to include the current appdir (program file directory) and the FGL runtime system directory, respectively.

See FGLIMAGEPATH on page 241 for more details about this environment variable.

**Using file names or paths**
If the image specification is a simple file path (without an URL prefix, and typically with an image file extension), the front-end gets the image file from the runtime system.

**Note:** When specifying a file name as an image resource, consider using the extension (.png, .jpg), to avoid unnecessary file searching, trying different combinations with all supported formats. The file extension will also be used by the front-end to easily identify the compression format (for example, to define the Content-Type in an HTML entity).

The image file is searched on the platform where the program executes. The runtime system uses the FGLIMAGEPATH environment variable when searching for the images. If FGLIMAGEPATH is not set, the current working directory is searched for the image files.

**Note:** If FGLIMAGEPATH is defined, the current working directory is not searched. If you want to look for image files in the current working directory and in other directories, add "." to the FGLIMAGEPATH path list.

If the image file is specified without a file extension, Genero will try to find the file with a predefined list of extensions (.png, .jpg, etc). The search depends on the name of the image file, the list of directories defined in FGLIMAGEPATH, and the predefined list of file extensions. This search procedure was implemented to allow different types of front-ends to pass the preferred image compression formats, and to allow you to define the image name in your forms without any extension. However, it is much more efficient to specify the image file with a portable extension. Using image files with extensions is strongly recommended.

**Application images in Web Components**
Web Components can display static images (part of the Web Component assets), and application images provided at runtime (for example, a photo gallery web component). In order to provide application images to a Web Component, the program must use the `ui.Interface.filenameToURI()` method to convert the local file name to a URI that can be accessed by the front-end.

For more details, see Using image resources with the gICAPI web component on page 1855.

**Static images**
Describes how to decorate forms with icons.

**Static image usage context**
Static images are application pictures that do not change during program executing, like icons in toolbar buttons and window icons.

Static images can be defined in different contexts withing form definition, or configuration files:

- Global application icon for platform window managers (taskbars), by using the `ui.Interface.setImage` method. The recommendation for mobile devices is that the application icon is provided in the installation package (.apk for Android™, .ipa for iOS).
- Window specific icons, with the `IMAGE` attribute in the `LAYOUT definition` of a form (recommended) or at runtime, with the `ui.Window.setImage` method (if it must be changed during program execution).
• As default icon for action views, with the `IMAGE` action configuration attribute (in action defaults for example).
• As specific action view icons, directly in the form item definition with the `IMAGE` attribute (for toolbars, menu items, buttons, buttonedits, etc).
• Image form items (logos), defined by the `IMAGE item-tag : item-name` syntax, using the `IMAGE` attribute.
• Default treeview node icons, with the `IMAGEEXPANDED, IMAGECOLLAPSED, IMAGELEAF` attributes of a `TREE` container.

### Static image examples

The following code example, defines an `ITEM` toolbar element using an icon, that is specified with the `IMAGE` attribute:

```plaintext
TOOLBAR
  ITEM print ( TEXT="Print", IMAGE="printer" )
```

Next example defines a `BUTTONEDIT` form field with an icon named "listchoice":

```plaintext
ATTRIBUTES
  BUTTONEDIT f05 = customer.cust_city,
  ACTION=get_city,
  IMAGE="listchoice",
...
```

### Related concepts

**Configuring actions** on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with `action attributes`.

**Providing the image resource** on page 1049
There are several things you need to know about providing an image resource in a Genero program.

### Runtime images

Explains how to display pictures at runtime.

### Dynamic image usage context

Application images like photos or variable icons (in list views) are only known at runtime, and are displayed during program execution. Such images are typically centralized on a server, as BLOBs in a database, or on the file system, as regular files.

For simple files (not URLs), images to be displayed are automatically handled by Genero; the program just needs to specify the name of the file to be displayed.

This section describes programming patterns to handle application images. For a complete description of the mechanisms to provide images to front-ends, see **Providing the image resource** on page 1049.

### IMAGE form fields

To display a picture dynamically in a form area, you must define a form field with the `IMAGE` item type:
The program can then display an image dynamically by assigning the image resource to the form field, for example, with a `DISPLAY TO` instruction:

```plaintext
DEFINE image_field STRING
LET image_field = "local_image_file.png"
DISPLAY BY NAME image_field
```

It is also possible to use the program variable containing the image resource in a dialog using the `UNBUFFERED` option:

```plaintext
DEFINE rec RECORD
    pk INT,
    name VARCHAR(30),
    image_field VARCHAR(50)
END RECORD
INPUT BY NAME rec.* ATTRIBUTES(UNBUFFERED)
ON ACTION set_picture
    LET rec.image_field = "local_image_file.png"
```

**IMAGECOLUMN attribute of TABLE/TREE**

The `IMAGECOLUMN` attribute can be used to define a PHANTOM field that will hold the image resource for a TABLE or TREE column:

```plaintext
... ATTRIBUTES
    PHANTOM FORMONLY.item_icon;
    EDIT FORMONLY.item_desc, IMAGECOLUMN=item_icon;
... END INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.item_icon, FORMONLY.item_desc, ...);
...
```

In the program code, the image resource is specified in the array member attached to the icon field. Each row can define a different image for the cell:

```plaintext
LET arr[1].item_icon = "honda_logo.png"
LET arr[1].item_desc = "Honda CB600 Hornet (red)"
LET arr[2].item_icon = "honda_logo.png"
LET arr[2].item_desc = "Honda CB1000r (black)"
LET arr[3].item_icon = "ducati_logo.png"
LET arr[3].item_desc = "Ducati Diavel Carbon"
DISPLAY ARRAY arr TO sr.*
...
```

**Displaying images contained in BYTE variables**

Application images managed by a program can be held in a `BYTE` on page 255 variable. You need to use this data type to interface with databases storing images in Binary Large OBject (BLOB) columns.

When using an `IMAGE` field, if the `BYTE` variable holding the image data is located in a file (`LOCATE IN FILE`), the runtime system can automatically send the content of the `BYTE` file to the front-end when doing a `DISPLAY BY NAME`, `DISPLAY TO` field, or if the `BYTE` variable is controlled by a dialog using the `UNBUFFERED` option.

```plaintext
DEFINE pb BYTE
LOCATE pb IN FILE -- temp file used
```
... 
OPEN FORM f1 FROM "myform"
DISPLAY FORM f1
...
SELECT image_col INTO pb FROM mytable WHERE pk = ... 
DISPLAY pb TO image_field
...

Furthermore, if the image data is modified, without changing the name of the file (i.e., without a new LOCATE IN FILE instruction), the runtime system detects the file modification time, and if needed, re-sends the image data to the front-end. For example, consider the following program flow:

DEFINE pb BYTE
LOCATE pb IN FILE -- temp file used
...
-- A first SELECT fetches image data from row 345 into the BYTE
SELECT image_col INTO pb FROM mytable WHERE pk = 345
-- And displays the BYTE image to a field
DISPLAY pb TO image_field
-- A second SELECT fetches new image data from row 672 into the BYTE
SELECT image_col INTO pb FROM mytable WHERE pk = 672
-- And displays the BYTE image to a field
DISPLAY pb TO image_field
-- The BYTE file name has not changed, only the image data has changed
...

Images on mobile devices

When executing the application on a mobile device, it is possible to use a front call to choose or take a photo. Those front calls return an opaque file identifier referencing an image in the device photo gallery (or database).

On all mobile platforms, you can directly display the returned opaque file path to an IMAGE form field:

DEFINE path STRING
-- Here we use "choosePhoto" front call, could be "takePhoto"
CALL ui.Interface.frontCall("mobile", "choosePhoto", [], [path])
DISPLAY path TO ff_image

Consider the path returned by such a front call as an opaque local file identifier, and do not use it as a persistent file name for the picture. For example, if you store such a path name in a database, and if the mobile photo gallery storage technology changes, the stored file names will no longer be valid.

If you need to keep the image data in the application (to store it in a local file or in the database), grab the image data into the runtime system context with a fgl_getfile() call. The mobile picture path can be used in a fgl_getfile() call to the photo from the mobile device into the file storage context where the runtime system executes. When the runtime system executes on the mobile device, the fgl_getfile() call will copy the picture to the application sandbox. If the program executes on an application server, the call will transfer the picture to the application server file system. It is possible to load the picture data into a BYTE variable, by transferring the image data directly into the file used by the BYTE variable located in byte_file, by doing a fgl_getfile(mobile_path, byte_file). It is also possible to keep the transferred files on the file system where the VM executes, if you do not want to use BYTE variables to store images in your database.

CONSTANT vm_fn = "mypic.tmp"
DEFINE md_fn STRING, image BYTE
CALL ui.Interface.frontCall("mobile", "choosePhoto", [], [md_fn])
CALL fgl_getfile(md_fn,vm_fn)
LOCATE image IN FILE vm_fn
DISPLAY image TO ff_image
UPDATE mytab SET pic = image WHERE ...

**Note:** When using `fgl_getfile()` with BYTE variables located in files, pay attention to the fact that `INITIALIZE byte_var TO NULL` will set the internal null indicator of the BYTE variable, and a subsequent `fgl_getfile(mobile_path, byte_file)` will only modify the file without touching the null flag. The recommended pattern is to re-locate the BYTE variable after the `fgl_getfile()` call:

```plaintext
CALL fgl_getfile(mobile_path, byte_file)
LOCATE byte_var IN FILE byte_file
```

**Videos on mobile devices**

Let the user take videos or choose videos from the gallery with the `takeVideo` on page 2561 and `chooseVideo` on page 2549 front calls.

Similar to photo front calls, the video front calls return an opaque path to the video file, which can then be used in the `fgl_getfile()` function to transfer the video file from the device context to the runtime system context in a BYTE variable for persistent storage.

**Note:** The opaque path can, however, be used to show the video with the "`launchURL`" front call.

For example:

```plaintext
IMPORT os
CONSTANT VM_MOVIES = "./movies"

MAIN
  DEFINE r INTEGER,
    mb_path STRING,
    vm_path STRING
  LET r = os.Path.delete(VM_MOVIES)
  LET r = os.Path.mkDir(VM_MOVIES)
  MENU
    COMMAND "take_video"
      CALL ui.Interface.Frontcall("mobile", "takeVideo", [], [mb_path])
      IF mb_path IS NOT NULL THEN
        LET vm_path = SFMT("%1/%2", VM_MOVIES, os.Path.baseName(mb_path) )
        CALL fgl_getfile(mb_path, vm_path)
      END IF
    COMMAND "choose_video"
      CALL ui.Interface.Frontcall("mobile", "chooseVideo", [], [mb_path])
      IF mb_path IS NOT NULL THEN
        LET vm_path = SFMT("%1/%2", VM_MOVIES, os.Path.baseName(mb_path) )
        CALL fgl_getfile(mb_path, vm_path)
      END IF
    COMMAND "show_video"
      IF mb_path IS NOT NULL THEN
        CALL ui.Interface.Frontcall("standard", "launchURL", [mb_path], [])
      END IF
    COMMAND "quit"
      EXIT MENU
  END MENU
END MAIN
```

### Accessibility guidelines

This section describes the best practices to make your application accessible to disabled people.

- **Keyboard access** on page 1056
- **Form description for screen readers** on page 1057
- **Usability and ergonomics** on page 1058

#### Keyboard access

How to implement keyboard usage to follow accessibility standard?

**Defining keyboard accelerators for every action**

Since a mouse or other pointing devices may not be used by people with reduced vision, an accessible application must be usable with the keyboard alone. Therefore, all the possible actions that could be triggered by a user must have a keyboard shortcut.

We strongly suggest that you define consistent keyboard shortcuts for all actions through the use of action defaults. Developers can avoid overriding the system default shortcuts by checking the target platform guidelines, especially for system shortcuts that trigger accessible actions (for example, Ctrl-Shift-Enter, which triggers spoken information about the currently selected item). Overriding system shortcuts is generally a bad practice, even for non-accessible applications, although overriding may be unavoidable due to compatibility issues.

**Keyboard focus and action views**

Generally, keyboard navigation in an application may be easier if you keep the **MENU** actions in the menu frame; the actions can have the keyboard focus and the user can navigate through them using the up and down arrows.

You can also use a **TOPMENU**, because you can pull it down with the keyboard (for example, the Alt key on Windows®) and then navigate using arrow keys, but it may be less accessible than the menu panel. To ensure that every item of the menu can be activated by a keyboard shortcut, use the & (ampersand) before a character in menu items to indicate the keyboard shortcut that triggers the menu action with that letter.

Avoid using toolbars alone in accessible applications, because toolbars by default are not accessible using the keyboard. Toolbars cannot have the keyboard focus, and there is no way to navigate through all toolbar items or to activate one of them using the keyboard. If you do use toolbars, provide keyboard shortcuts and duplicate them in a **topmenu**.

The TOOLBAR section defines a toolbar with buttons that are bound to actions.

**Form description for screen readers**

How to integrate with platform screen readers?

**Understanding screen readers**

Screen readers are special system applications that transform the application's graphical user interface into speech. The behavior may change between screen reader implementations, but, basically, each widget is named and described by speech. On some workstation operating systems, special keyboard shortcuts are available to trigger the complete enumeration of all the components of a window, or to describe only the component having the current focus.

**Providing form item descriptions to screen readers**

Screen readers use special bindings to get the information that they need (name, full description, hierarchy, triggered actions, and so on) about each graphical component of the entire graphical user interface. It is up to the programmer to provide these bindings to the screen reader, but most of the work is already done by the front-end.

Programmers can provide two things for each widget to provide speech information to screen readers:

- an accessible **name**, using the TEXT form attribute if available, otherwise with the COMMENT form attribute.
- an accessible **description**, with the COMMENT form attribute.

This can be tedious, but it absolutely must be done carefully, keeping in mind that the text will be spoken. As such, *customer's name* is preferable to *cust_name_str*.

Spaces and punctuation are allowed.

Most of the form items are supported: All kind of form field, static labels, static images, and action-based items (such as buttons); some containers (GROUP and FOLDER) work out of the box as soon as their TEXT attributes are set.

**Examples**

In an action defaults file (mydefaults.4ad)

```xml
<ActionDefaultList>
  <ActionDefault name="new" text="New..." image="new.svg"
    comment="Create a new database"
    acceleratorName="Control-N" />
  <ActionDefault name="open" text="Open...
    comment="Open an existing database"
    acceleratorName="Control-O" />
  <ActionDefault name="save" text="Save"
    comment="Save the current database"
    acceleratorName="Control-S" />
...
</ActionDefaultList>
```

In field definitions on a form specification file (myform.per)

```xml
<ATTRIBUTES>
  EDIT login_name = formonly.login_name, NOT NULL,
    COMMENT="Login name of the current user";
  EDIT password = formonly.password, NOT NULL, INVISIBLE, VERIFY,
    COMMENT="Password of the current user";
  EDIT first_name = formonly.first_name, NOT NULL,
    COMMENT="First name of the current user";
  EDIT last_name = formonly.last_name, NOT NULL,
    COMMENT="Last name of the current user";
  DATEEDIT birthdate = formonly.birthdate, FORMAT="mm/dd/yyyy",
    COMMENT="Date of birth of the current user";
  EDIT email = formonly.email,
    COMMENT="E-mail of the current user";
END -- ATTRIBUTES
```
In this form specification file, the COMMENT attribute is used for both the accessible name and the accessible description.

**Related concepts**

- **TEXT attribute** on page 1288
  
  The TEXT attribute defines the label associated with a form item.

- **COMMENT attribute** on page 1250
  
  The COMMENT attribute defines a hint for the user about the form element.

**Usability and ergonomics**

How to adapt application forms to disabled users?

**Design simple application forms**

Keep your forms as simple as possible. Because everything will be described by the screen reader software, it is preferable to have a lot of small and concise forms with a few fields. With forms containing a lot of labels and fields, the screen reader will take a long time to enumerate every name and description. The end user must be able to create an image of the form in his mind, based on the form description.

**Make form content bigger**

Consider using a special .4st presentation styles file defining big fonts, big icons, and high contrast color themes; this will make your application a lot more efficient for users who are partially sighted. Forms will take more space on the screen, assuming that the forms have a limited number of fields to have sufficient room for large widgets.

Use large icons (such as 64x64 pixel icons), for people with impaired vision. Do not forget that most of the default sizes (font, icons, GUI components, and so on) were set when the default resolution was 640*640 pixels in 16 colors. Now, even if the user has very good sight, with the screen resolution available today, old-style icons look small.

Use a high contrast color theme. Although support of the system high contrast theme is only partial, nothing prevents you from setting up the correct theme using a specific presentation style attributes.

**Example**

Presentation styles file defining larger, bolder fonts and larger icons:

```xml
<StyleList>
  <Style name="*" >
    <StyleAttribute name="fontSize" value="10" />
  </Style>
  
  <Style name="Action">
    <StyleAttribute name="scaleIcon" value="28px"/>
    <StyleAttribute name="fontSize" value="12" />
  </Style>
  
  <Style name="Window">
    <StyleAttribute name="actionPanelPosition" value="bottom"/>
    <StyleAttribute name="actionPanelButtonSpace" value="huge"/>
    <StyleAttribute name="actionPanelHAlign" value="center"/>
    <StyleAttribute name="ringMenuPosition" value="bottom"/>
    <StyleAttribute name="ringMenuButtonSpace" value="huge"/>
    <StyleAttribute name="ringMenuHAlign" value="center"/>
  </Style>
  
  <Style name="ToolBar">
    <StyleAttribute name="scaleIcon" value="32px"/>
  </Style>
  
  <Style name="Edit:focus">
    <StyleAttribute name="fontWeight" value="bold" />
  </Style>
</StyleList>
```
Message files
Message files centralize strings and larger texts identified by a number, that can be used in programs.

- Understanding message files on page 1059
- Syntax of message files (.msg) on page 1059
- Compiling message files on page 1060
- Using message files at runtime on page 1060
- Examples on page 1061

Understanding message files
This is an introduction to message files.

Message files define text messages with a unique integer identifier.

Several message files can be created and loaded by the same program.

Message files are typically used to implement application help system, and are especially designed for the TUI mode.

In order to use a message file, do the following:

1. Create the .msg source message file with a text editor.
2. Compile the source message file with fglmkmsg to create the .iem binary format.
3. Copy the binary file to a distribution directory.
4. In programs, specify the message file with the OPTIONS HELP FILE instruction.
5. Use a specific message with the HELP clause of dialogs, or load a given message with the SHOWHELP() function.

Message files provide a simple way to implement a help system in your application.

For other application messages and texts, consider using localized strings instead of message files.

Related concepts
Localization on page 405
Localization support allows you to implement programs that follow specific language and cultural rules.

Localized strings on page 430
Localized strings provide a means of writing applications in which the text of strings can be customized on site.

Syntax of message files (.msg)
A message file contains a set of messages identified by an integer number.

```
filename.msg
```

1. `filename` is the name of the message source file.

Syntax of a message file
```
message-definition
```
```
include-directive
```
where message-definition is:

```
.message-number
message-line  \ new-page
 [...]```

where include-directive is:

```
.include filename```

And where new-page is:

```
^L (Control-L, ASCII 12)```

1. message-number is an integer in the range -2147483648 to 2147483647.
2. You can split the message into pages by adding the ^L (Control-L / ASCII 12) in a line.
3. Note that multi-line messages will include the newline (ASCII 10) characters.

**Compiling message files**
The .msg message files must be compiled to .iem binary files, in order to be loaded by the runtime system.

In order to use message files in a program, the message source files (with .msg extension) must be compiled with the fglmkmsg on page 1976 utility to produce compiled message files (with .iem extension).

The following command line compiles the message source file mess01.msg:

```
fglmkmsg mess01.msg```

This creates the compiled message file mess01.iem.

For backward compatibility, you can specify the output file as second argument:

```
fglmkmsg mess01.msg mess01.iem```

The .iem compiled version of the message file must be distributed on the machine where the programs are executed.

**Related concepts**

**Compiling program code files (.4gl)** on page 2001
The .4gl source files must be compiled to .42m p-code files, in order to be loaded by the runtime system.

**Compiling form specification files (.per)** on page 1999
The .per form definition files must be compiled to .42f XML files, in order to be loaded by the runtime system.

**Importing modules** on page 2003
Describes how to define modules interdependence with IMPORT FGL.

**Using message files at runtime**

In order to use compiled message files (.iem) in programs, specify the current message file with the OPTIONS HELP FILE command:

```
OPTIONS HELP FILE "mymessages.iem"```

The message file provided in the OPTIONS HELP FILE command is searched for in several directories, as described in the FGLRESOURCEPATH reference topic.

After the message file is defined, you can start the help viewer by calling the SHOWHELP () function:

```
CALL showhelp(1242)```
Use the HELP clause in a dialog instruction such as INPUT to define particular message number for that the dialog:

```plaintext
INPUT BY NAME ... HELP 455
```

The help viewer will automatically display the message text corresponding to the number when the user presses the help key. By default, the help key is Ctrl-W in TUI mode and F1 in GUI mode.

Note that you can implement your own help viewer by overloading the SHOWHELP() function defined in FGLDIR/src/fglhelp.4gl. This allows you to customize the help system for your application.

**Related concepts**
- Defining the message file on page 512
- The OPTIONS HELP FILE instruction defines the name of the message file.
- showhelp() on page 2179
  - Displays a runtime help text.

**Examples**

Message files (.msg) usage examples.

**Example 1: Help message file used in a MENU**

The message source file `help.msg`:

```plaintext
.101
This is help about option 1
.102
This is help about help
.103
This is help about My Menu
```

Compiling the message file:

```plaintext
$ fglmkmsg help.msg
```

Program using the .iem compiled message file.

```plaintext
MAIN
  OPTIONS
    HELP FILE "help.iem"
  MENU "Sample"
    COMMAND "Option 1" HELP 101
    DISPLAY "Option 1 chosen"
    COMMAND "Help"
    CALL showhelp(103)
END MENU
END MAIN
```

**Action defaults files**

Action defaults files allow to centralize action configuration parameters such as text, icon, accelerators and behavior options in XML format.

- Understanding action defaults files on page 1062
- Syntax of action defaults files (.4ad) on page 1062
- Action default attributes reference (.4ad) on page 1062
- Using action defaults files on page 1064
- Examples on page 1064
**Understanding action defaults files**

This is an introduction to action default files.

Action defaults files define the defaults for action attributes in an XML file. These defaults can be overwritten with form item attributes, or with dialog action handler attributes, when using default action views.

This section describes only the .4ad action defaults file reference, for more details see Configuring actions on page 1646.

**Syntax of action defaults files (.4ad)**

A .4ad action default file is an XML file defining default attributes for actions.

Action defaults are defined in the .4ad file with this syntax:

```xml
<ActionDefaultList>
  <ActionDefault name="action-name" attribute=value [...]
  ...]
</ActionDefaultList>
```

1. `action-name` identifies the action.
2. `attribute` is the name of an attribute.
3. `value` defines the value to be assigned to `attribute`.

**Action default attributes reference (.4ad)**

This topic contains all attributes you can define in a .4ad action defaults file.

**Table 287: Action default attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name = &quot;action-name&quot;</td>
<td>This attribute identifies the action.</td>
</tr>
<tr>
<td>text = &quot;action-label&quot;</td>
<td>The default label to be displayed in action views (typically, the text of buttons).</td>
</tr>
<tr>
<td>comment = &quot;action-comment&quot;</td>
<td>The default help text for this action (typically, displayed as bubble help).</td>
</tr>
<tr>
<td>image = &quot;action-icon&quot;</td>
<td>The default image file to be displayed in the action view.</td>
</tr>
<tr>
<td>acceleratorName = &quot;key-name&quot;</td>
<td>The default accelerator key that can trigger the action, as defined in Keyboard accelerator names on page 1673.</td>
</tr>
<tr>
<td>acceleratorName2 = &quot;key-name&quot;</td>
<td>The second default accelerator key that can trigger the action, as defined in Keyboard accelerator names on page 1673.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>

<tr>
<td></td>
<td>Values can be:</td>
</tr>
<tr>
<td></td>
<td>• &quot;no&quot; the default action view is never visible.</td>
</tr>
<tr>
<td></td>
<td>• &quot;yes&quot; the default action view is always visible, if the action is visible (ui.Dialog.setActionHidden).</td>
</tr>
<tr>
<td></td>
<td>• &quot;auto&quot; the default action view is visible if no other action view is explicitly defined and the action is visible (ui.Dialog.setActionHidden).</td>
</tr>
<tr>
<td></td>
<td>The default is &quot;auto&quot;.</td>
</tr>
<tr>
<td></td>
<td>See also: DEFAULTVIEW attribute on page 1253</td>
</tr>
<tr>
<td>contextMenu = {&quot;yes&quot;</td>
<td>&quot;no&quot;</td>
</tr>
<tr>
<td></td>
<td>Values can be:</td>
</tr>
<tr>
<td></td>
<td>• &quot;no&quot; the context menu option is never visible.</td>
</tr>
<tr>
<td></td>
<td>• &quot;yes&quot; the context menu option is always visible, if the action is visible (ui.Dialog.setActionHidden).</td>
</tr>
<tr>
<td></td>
<td>• &quot;auto&quot; the context menu option is visible if no other action view is explicitly defined and the action is visible (ui(Dialog.setActionHidden).</td>
</tr>
<tr>
<td></td>
<td>The default is &quot;yes&quot;.</td>
</tr>
<tr>
<td></td>
<td>See also: CONTEXTMENU attribute on page 1250</td>
</tr>
</tbody>
</table>
### Attribute | Description
---|---
validate = "no" | Defines the behavior of data validation when the action is invoked.

Values can be:

- "no" no data validation is done (field text only available in input buffer).

By default, data validation is driven by the dialog mode (UNBUFFERED or default mode).

For more details, see Data validation at action invocation on page 1665.

See also: VALIDATE attribute on page 1294

**Related concepts**

Configuring actions on page 1646

Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

ON ACTION block on page 1369

**Using action defaults files**

To use action default files, you must understand how they work and how to structure the code.

Global action defaults are defined in an XML file with the .4ad extension. By default, the runtime system searches for a file named default.4ad in several directories as described in the FGLRESOURCEPATH reference topic. If no file was found, standard action default settings are loaded from the FGLDIR/lib/default.4ad file.

Action defaults files usage is related to action configuration concepts. For more details, see Configuring actions on page 1646.

**Related concepts**

FGLRESOURCEPATH on page 244

Defines search path for resource files.

**Examples**

Action defaults files (.4ad) usage examples.

**Example 1: Loading a global action defaults file**

Some action defaults in XML format (exit action has Localized Strings):

```xml
<ActionDefaultList>
  <ActionDefault name="print" text="Print" image="printer"
    comment="Print report" />
  <ActionDefault name="modify" text="Update"
    comment="Update the record" />
  <ActionDefault name="exit" text="Quit" image="byebye"
    comment="Exit the program" validate="no">
    <LStr text="common.exit.text" />
  </ActionDefault>
</ActionDefaultList>
```

The program loading the action defaults file:

```plaintext
MAIN
  CALL ui.Interface.loadActionDefaults("mydefaults")
  OPEN FORM f FROM "myform"
  DISPLAY FORM f
  ...
```
Presentation styles

Use presentation styles to specify decoration attributes for window and form elements.

- Understanding presentation styles on page 1065
- Syntax of presentation styles file (.4st) on page 1067
- Using presentation styles on page 1067
- Predefined attribute values on page 1074
- Style attributes reference on page 1082
- Examples on page 1129

Understanding presentation styles

*Presentation styles* centralize the attributes related to the decoration of the graphical user interface elements.

The decoration attributes are defined in a separate file, which can be easily modified to customize the application. Presentation styles are only supported for the GUI front-ends. If you design an application for the TUI mode, you can use TTY attributes.

Styles are applied implicitly by using global styles, or explicitly by naming a specific style in the *style* attribute of the element.

Common presentation attributes define font properties, foreground colors and background colors. Some presentation attributes are specific to a given class of widgets (like the first day of the week in a `DATEEDIT` item type on page 1168).

Presentation styles are defined in a resource file having an extension of `.4st`. The `.4st` file must be distributed with the other runtime files.

Presentation styles are inspired by the *cascading style sheets* (CSS) used in HTML, with the following deviations:

1. The elements using style definitions are AUI tree elements; CSS styles apply to HTML elements.
2. To specify a style for an AUI tree element, you must use the "style" attribute; HTML/CSS use the "class" attribute.
3. Inline-style definition is not supported in the AUI tree.
4. Some pseudo selectors, such as "query," are specific to Genero.

*Figure 41: Form without presentation styles (GDC)* on page 1066 shows a desktop application without presentation styles:
Figure 41: Form without presentation styles (GDC)

Figure 42: Form using presentation styles (GDC) on page 1066 shows a desktop application with presentation styles:
Syntax of presentation styles file (.4st)

A .4st presentation styles file is an XML file defining style attributes to be applied by front-ends.

Syntax (.4st)

```xml
<StyleList>
  <Style name="style-identifier">
    <StyleAttribute name="attribute-name" value="attribute-value" />
  </Style>
  [...]
</StyleList>
```

where style-identifier is:

```plaintext
+ element-type . style-name :pseudo-selector
```

1. `element-type` is a type of AUI tree element, such as Edit, Window.
2. `style-name` is an explicit style name, that can be referenced in `STYLE` attributes of form items.
3. `pseudo-selector` indicates in what context the style should apply.
4. `attribute-name` defines the name of the style attribute.
5. `attribute-value` defines the value to be assigned to `attribute-name`.

Syntax of attribute values

Presentation style attribute values are always specified as strings, for example:

```xml
<StyleAttribute name="fontFamily" value="Serif" />
```

Numeric values must be specified in quotes:

```xml
<StyleAttribute name="completionTimeout" value="60" />
```

Boolean values must be specified with the values "yes" or "no":

```xml
<StyleAttribute name="forceDefaultSettings" value="yes" />
```

**Note:** For backward compatibility, the values 0/1 and true/false are supported by some front-ends. Use exclusively the yes/no values.

Related concepts

*Understanding presentation styles* on page 1065

*Presentation styles* centralize the attributes related to the decoration of the graphical user interface elements.

*Pseudo selectors* on page 1068

Pseudo selectors can be used to apply style only when some conditions are fulfilled.

Using presentation styles

Use presentation styles to centralize the decoration of your user interface.

**Defining a style**

Styles can be defined to be global (for all elements), for an element in general, or for specific types of an element.

The style is identified by the `name` attribute, that can be a combination of element type, style name and pseudo selector, or the star character. See *Syntax of presentation styles file (.4st)* on page 1067 for a complete description of the presentation style definition syntax.

In the definition of a style, the `name` attribute is used as a selector to apply style attributes to graphical elements.
You can define a style as global or specific to a class of graphical object:

- A style identified by a star (*) is a global style that is automatically applied to all elements:
  
  ```xml
  <Style name="*"/>
  ```

- A style identified by an *element-type* is a global style that is automatically applied to all objects of this type:
  
  ```xml
  <Style name="ComboBox"/>
  ```

- A style identified by a *style-name* is a specific style that can be applied to any element types using that style name in a *STYLE* attribute:
  
  ```xml
  <Style name=".important"/>
  ```

- A style identified by an *element-type* followed by a dot and a *style-name* is a specific style that will only be applied to elements of the given type using the style name in a *STYLE* attribute:
  
  ```xml
  <Style name="Window.main"/>
  ```

- A style identified by an *element-type* followed by a colon and a *pseudo-selector* is a style that will only be applied to elements of the given type, if the condition defined by the pseudo-selector is satisfied:
  
  ```xml
  <Style name="Edit:focus"/>
  ```

- A style identified by an *element-type* followed by a dot and a *style-name*, and a colon with a *pseudo-selector*, is a specific style that will only be applied to elements of the given type, using the style name in a *STYLE* attribute, if the condition defined by the pseudo-selector is satisfied:
  
  ```xml
  <Style name="Edit.important:focus"/>
  ```

- It is possible to combine pseudo-selectors:
  
  ```xml
  <Style name="Edit:query:focus"/>
  ```

**Pseudo selectors**

Pseudo selectors can be used to apply style only when some conditions are fulfilled.

Pseudo selectors are preceded by a colon and can be combined:

```xml
<Style name="Table:even:input"/>
<Style name="Edit:focus"/>
<Style name="Edit.important:focus"/>
```

When combining several pseudo selectors, the style will be applied if all pseudo selector conditions are fulfilled.

**Note:** Depending on the type of the front-end, some pseudo selectors are meaningless, or unsupported. See the table below to check which pseudo selectors are supported on your front-end platform.

Pseudo selectors have different priorities; the style with the most important pseudo selector will be used when several styles match.

**Table 288: Pseudo selectors for presentation styles**

<table>
<thead>
<tr>
<th>Priority</th>
<th>Pseudo selectors</th>
<th>Condition</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>focus</td>
<td>The widget has the focus</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>2</td>
<td>query</td>
<td>The widget is in construct mode</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>3</td>
<td>display</td>
<td>The widget is in a display array</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Pseudo selectors also define the priority of your styles. A more generic style will be used when the pseudo-selector has a higher priority.

For instance: you want all important edits to have red text, but you want the current field to be displayed in blue:

```html
<Style name="Edit.important" >
<Style name=":focus" >
```

The style ":focus" is more generic than "Edit.important"; therefore, it will be used for the focused item, as the pseudo selector is more precise.

**Related concepts**

- MESSAGE on page 1344
  The MESSAGE instruction displays a message to the user.

- ERROR on page 1345
  The ERROR instruction displays an error message to the user.

- AGGREGATE item definition on page 1223
  Defines screen-record fields that hold computed values to be displayed as footer cells in a TABLE container.

- Summary lines in tables on page 1767
  Table views can display a summary line, to show aggregate values for columns.

**Related reference**

- Message style attributes on page 1097
  Message style presentation attributes apply to an ERROR or MESSAGE instruction.

**Using a style**

To apply a specific style, set the *style-name* in the *style* attribute of the node representing the graphical element in the abstract user interface tree.

There are different ways to set the *style* attribute of an element:

- As a form element attribute, with a *STYLE* attribute in the form specification file.
- In the *ATTRIBUTES* clause of instructions such as OPEN WINDOW, MESSAGE, ERROR.
- Dynamically by a program, using the `ui.Form.setElementStyle()` method.

<table>
<thead>
<tr>
<th>Priority</th>
<th>Pseudo selectors</th>
<th>Condition</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>input</td>
<td>The widget is in an input array, input or construct</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>5</td>
<td>even</td>
<td>This widget is on an even row if in a list (Table or Tree)</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>6</td>
<td>odd</td>
<td>This widget is on an odd row if in a list (Table or Tree)</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>7</td>
<td>inactive</td>
<td>The widget is inactive</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>8</td>
<td>active</td>
<td>The widget is active</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>9</td>
<td>message</td>
<td>Applies only to text displayed with the MESSAGE instruction</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>10</td>
<td>error</td>
<td>Applies only to text displayed with the ERROR instruction</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>11</td>
<td>summaryLine</td>
<td>Applies only to text displayed in AGGREGATE fields of tables</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
For example, to define a style in a form file for an input field:

```
EDIT f001 = customer.fname, STYLE = "info";
```

**Note:** The string used to define the STYLE attribute must be a *style-name* only, it must not contain the *element-type* that is typically used to define the style in a .4st file (as CheckBox.important for example)

**Related concepts**
- [ATTRIBUTES section](#) on page 1221
  
  The ATTRIBUTES section describes properties of grid-based layout elements used in the form.

**Order of precedence**

Style definitions are applied following and order of precedence.

If different styles can be applied to an element, the following priority is used to determine the style definition to be applied:

1. `element-type.style-name: pseudo-selector`
2. `.:style-name: pseudo-selector`
3. `element-type.style-name`
4. `element-type: pseudo-selector`
5. `:pseudo-selector`
6. `.:style-name`
7. `element-type`
8. `*`

**Note:** The precedence rules to apply styles can be specific to a front-end type. As a general rule, Genero presentation styles precedence rules are similar to HTML/CSS precedence rules.

For example, consider an Edit element with the style attribute set to 'mandatory':

```
EDIT f1 = FORMONLY.cust_name, STYLE="mandatory"
```

With the following style definitions (mystyles.4st):

```xml
<?xml version="1.0" encoding="ANSI_X3.4-1968"?>
<StyleList>
    <Style name="Edit.mandatory:focus">
        <StyleAttribute name="backgroundColor" value="yellow" />
    </Style>
    <Style name=".:mandatory:focus">
        <StyleAttribute name="backgroundColor" value="blue" />
    </Style>
    <Style name="Edit.mandatory">
        <StyleAttribute name="backgroundColor" value="green" />
    </Style>
    <Style name="Edit:focus">
        <StyleAttribute name="backgroundColor" value="red" />
    </Style>
    <Style name=":focus">
        <StyleAttribute name="backgroundColor" value="cyan" />
    </Style>
    <Style name=".:mandatory">
        <StyleAttribute name="backgroundColor" value="magenta" />
    </Style>
    <Style name="*">
        <StyleAttribute name="backgroundColor" value="orange" />
    </Style>
</StyleList>
```

The style definitions are scanned in the following order:
1. Edit.mandatory:focus
2. .mandatory:focus
3. Edit.mandatory
4. Edit:focus
5. :focus
6. .mandatory
7. Edit
8. *

If the Edit field f1 has the focus, with the mystyles.4st definition file, the field background color will be yellow. If the Edit field f1 does not have the focus, the field background color will be green.

**Combining styles**

You can combine several styles, by using the space character as a separator in the STYLE attribute.

In the following example, the STYLE attribute defines three different style names:

```
EDIT f001 = customer.fname, STYLE = "info highlight mandatory";
```

When several styles are combined, the same presentation attribute might be defined by different styles. In this case, the first style listed that defines the attribute takes precedence over the other styles.

For example, if the textColor presentation attribute is defined as follows by the info, highlight and mandatory styles:

- info style does not define textColor.
- highlight style defines textColor as blue.
- mandatory style defines textColor as red.

The widgets having a style set to "info highlight mandatory" will get a blue text color, because highlight is listed before mandatory.

**Related concepts**

- **STYLE attribute** on page 1287
- The STYLE attribute specifies a presentation style for a form element.

**Style attribute inheritance**

A style attribute may be inherited by the descendants of a given node in the abstract user interface tree.

The style inheritance is implicitly defined by the attribute. Common font and color related style attributes are typically inherited.

For example, when defining a style using the fontFamily in a window or group container, all the children of this container will get the same font family. However, most style attributes (such as "border" for the Window element type) are specific to a type of element, and are not inherited.

Style attribute inheritance can be overwritten by defining the same attribute for the type of elements that are used inside the parent container. In the example, the .4st style file defines a text color for groups and all its descendant nodes. The same attribute is then redefined explicitly for labels and edit nodes:

```
<StyleList>
  <Style name="Group">
    <StyleAttribute name="textColor" value="red" />
  </Style>
  <Style name="Label">
    <StyleAttribute name="textColor" value="windowText" />
  </Style>
  <Style name="Edit">
    <StyleAttribute name="textColor" value="windowText" />
  </Style>
</StyleList>
```
For more details, see Style attributes reference on page 1082.

Presentation styles in the AUI tree
Presentation styles are loaded in the abstract user interface tree, under the UserInterface node, in a StyleList node following the presentation style syntax.

The StyleList node holds a list of Style nodes that define a set of attribute values. Attribute values are defined in StyleAttribute nodes, with a name and a value attribute.

Related concepts

The abstract user interface tree is the XML representation of the application forms displayed to the end user.

Syntax of presentation styles file (.4st) on page 1067
A .4st presentation styles file is an XML file defining style attributes to be applied by front-ends.

Loading presentation styles
Presentation styles are defined in an XML file with a 4st extension. In order to load the presentation styles, the engine needs to locate the appropriate style file.

By default, the runtime system searches for a file named default.4st in several directories, as described in the FGLRESOURCEPATH reference topic. If the file is not found using the FGLRESOURCEPATH/DBPATH environment variables, default presentation styles are loaded from the FGLDIR/lib/default.4st file.

Overwrite the default search by loading a specific presentation style file with the ui.Interface.loadStyles() method:

```
MAIN
    CALL ui.Interface.loadStyles("mystyles")
... END MAIN
```

This method accepts an absolute path with the 4st extension, or a simple file name without the 4st extension. If you give a simple file name, for example "mystyles", the runtime system searches for the mystyles.4st file in the current directory or in the application directory. If the file does not exist, it searches in the directories defined by the FGLRESOURCEPATH environment variable. If FGLRESOURCEPATH is not defined, it searches in the directories defined by the DBPATH environment variable.

The presentation styles must be defined in a unique 4st file. When loading a styles file with the ui.Interface.loadStyles() method, current styles created from the default file or from a prior load will be replaced. The styles will not be combined when loading several files.

The default styles file located in FGLDIR/lib should not be modified directly: your changes would be lost if you upgrade the product. Make a copy of the original file into the program directory of your application, then modify the copied file.

Related concepts
ui.Interface.loadStyles on page 2339
Load the presentation styles file.

Combining TTY and style attributes
TTY attributes can be specific to a form element or can be inherited by an element from a parent node (such as the form or window).

Specific element TTY attributes are directly set in the element node in the AUI tree; they can, for example, be defined with the COLOR attribute of form items. Inherited TTY attributes are taken from the parent nodes of the leaf element to be displayed. For example, when a form is displayed with DISPLAY FORM followed by an ATTRIBUTE clause containing TTY color, font option and/or video attributes, all static labels will be displayed with the TTY attributes of the form. Note that the form elements controlled by interactive instructions (i.e. form fields) will explicitly get the TTY attributes defined by the ATTRIBUTE clause of OPEN WINDOW, OPEN FORM, DISPLAY TO / BY NAME or the current dialog statement, and must be considered specific TTY attributes for the element.
Specific TTY attributes defined for a form element have a higher priority than style attributes, while inherited TTY attributes (set on one of the parent elements) have a lower priority than style attributes defined for the element.

To illustrate this rule, imagine a form defining two static labels and two fields, with all items using the mystyle presentation style, and one of the labels and fields defining a specific TTY attribute with COLOR=BLUE:

```
LABEL lab01: TEXT="Field 1:", COLOR = BLUE, STYLE = "mystyle";
EDIT fld01 = FORMONLY.field01, COLOR = BLUE, STYLE = "mystyle";
LABEL lab02: TEXT="Field 2:", STYLE = "mystyle";
EDIT fld02 = FORMONLY.field02, STYLE = "mystyle";
```

The program displays the form (or window) with an ATTRIBUTES clause using a red color, and the fields are used by an INPUT dialog, with no ATTRIBUTES clause, so the default TTY attributes are gotten from the OPEN FORM instruction:

```
OPEN FORM f FROM "ttyform"
DISPLAY FORM f ATTRIBUTES(RED)
INPUT BY NAME field01, field02 WITHOUT DEFAULTS
```

The .4st styles file defines the mystyle attributes as follows:

```
<StyleList>
  <Style name="Edit.mystyle">
    <StyleAttribute name="textColor" value="green" />
  </Style>
  <Style name="Label.mystyle">
    <StyleAttribute name="textColor" value="magenta" />
  </Style>
</StyleList>
```

The text in the form field fld01 is displayed in blue (from the specific COLOR attribute), while fld02 is displayed in red (the TTY attribute of the form, the style Edit.mystyle being ignored).

Since labels are not used by the interactive instructions, lab01 is displayed in blue (from the specific COLOR attribute), while lab02 is displayed in magenta (from the style Label.mystyle, the form TTY attribute red being ignored).

**Related concepts**

COLOR attribute on page 1248
The COLOR attribute defines the foreground color of the text displayed by a form element.

DISPLAY FORM on page 1044
Displays and associates a form with the current window.

OPEN WINDOW on page 1034
Creates and displays a new window.

DISPLAY TO on page 1346
The DISPLAY TO instruction displays data to form fields explicitly.

**Element types**

Styles may apply to any graphical elements of the user interface, such as Button, Edit, ComboBox, ButtonEdit, Table, and Window.

The name of the element when used in a style file is case sensitive (use CheckBox, not checkbox).

For example, the following style definition uses the "Window" element type in the style name:

```
<Style name="Window.dialog">
  <StyleAttribute name="position" value="center" />
</Style>
```
The supported element types is defined by the style attributes, for more details, see Style attributes reference on page 1082.

**Predefined attribute values**
This section describes the values that must be used for some style attributes.

**Colors**
When providing a value for style attributes that define color, you can specify a generic color name or its RGB value.

This section describes how to specify a value for style attributes defining colors, such as `textColor`.

**Syntax**

```
  \{ generic-color \} | \#rrggbb 
```

1. `generic-color` is any of the predefined colors supported by the language.
2. `#rrggbb` is a numerical color defined by a red/green/blue specification.

**Usage**
In most cases it is not possible to know what a potential end-user might expect regarding the font family. Therefore, avoid using explicit font families in your application and use only the `fontWeight/fontStyle(fontSize` properties. A specific font family is used only if the client cannot determine a proper default font family for the desired platform.

The language defines a set of generic color names, interpreted by the front end depending on the graphical capability of the workstation.

**RGB notation**
When a predefined color is not what you require, you can specify the exact color with the RGB notation, starting with a # hash character:

```
<Style name="Edit.mandatory">
  <StyleAttribute name="textColor" value="#50AEFF" />
</Style>
```

Each value of the RGB color specification must be provided in hexadecimal, in the range [00-FF].

**Generic color names**
Use generic color names, to keep your style definitions portable across several front-end types.

**Note:** The exact rendered color depends on front-end type.
### Table 289: Generic color names

<table>
<thead>
<tr>
<th>Generic color name</th>
<th>Visual result</th>
<th>RGB value</th>
</tr>
</thead>
<tbody>
<tr>
<td>black</td>
<td><img src="#000000" alt="Visual result" /></td>

</tbody>
</table>
Example

```
<StyleAttribute name="textColor" value="blue" />
<StyleAttribute name="textColor" value="#00FF45" />
```

Related concepts

Font families on page 1077

Use the fontFamily style attribute to define a generic or specific font family.

**GDC System Colors**

System color names can be used to get a color from the current theme of the workstation windowing system where the GDC executes.

**Important:** While system color names have meaning for both the GDC and GBC front-end clients, the mapping of the system color name to its meaning in this topic is relevant for GDC applications only.

**Table 290: System color names**

<table>
<thead>
<tr>
<th>System color name</th>

<td>gbc-primary-text-color</td>
</tr>
</tbody>
</table>

**Fonts**
A graphical application defaults to using the front-end platform theme. The front-end tries to determine the default font for the application screens.

**Font families**
Use the `fontFamily` style attribute to define a generic or specific font family.

This section describes the possible values of the `fontFamily` style attribute.

**Syntax**

`font-family [, . . . ]`

1. `font-family` defines a generic or a native font family.

**Usage**
Sets of generic font families are supported. These are interpreted by the front-end depending on the graphical capability of the platform.

If the `fontFamily` is not a generic font family, it is interpreted as a native font family, which identifies a local font supported by the front-end. Usually, it is one of the fonts installed on the platform operating system. See front-end documentation for a list of supported native fonts.

**Tip:** It is recommended to use a generic font family instead of a native font family.

A native font family is used only if the front-end cannot determine a proper default font family for the desired platform.

**Important:** A font family containing white-spaces must be single quoted. In the XML definition of the style, this leads to a single quoted string that is, in turn, enclosed in double quotes:

```xml
<StyleAttribute name="fontFamily" value="'Courier New'" />`
When specifying a comma-separated list of font families, the front-end uses the best matching font available on the platform. You can mix generic and native font families:

```xml
<StyleAttribute name="fontFamily" value="'Times New Roman',Times,serif" />
```

### Table 292: Generic font families to front-end platform fonts

<table>
<thead>
<tr>
<th>Generic font family name</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>serif</td>
<td>Times</td>
<td>serif (CSS)</td>
<td>Serif</td>
<td>Times New Roman</td>
</tr>
<tr>
<td>sans-serif</td>
<td>Arial</td>
<td>sans-serif (CSS)</td>
<td>Sans-Serif</td>
<td>Helvetica Neue</td>
</tr>
<tr>
<td>cursive</td>
<td>Comic Sans Ms</td>
<td>cursive (CSS)</td>
<td>N/A (keeps default font)</td>
<td>Marker Felt</td>
</tr>
<tr>
<td>fantasy</td>
<td>Algerian</td>
<td>fantasy (CSS)</td>
<td>N/A (keeps default font)</td>
<td>Papyrus</td>
</tr>
<tr>
<td>monospace</td>
<td>Courier New</td>
<td>monospace (CSS)</td>
<td>Monospace</td>
<td>Courier</td>
</tr>
</tbody>
</table>

**Note:**

- The GBC front-end uses the font family as `font-family` property in a CSS style. For more details, see [CSS generic-font-families](#).
- The GMI front-end tries to find a font family in the available fonts of the application (this means the iOS built-in fonts and any application-specific fonts) which matches the `fontFamily` given in the styles. If none is found, the fallback is "Helvetica Neue".
- The GMA front-end maps generic font family names to Android™ generic font names (Serif, Monospace), these are then mapped to real font names. The real font name depends on the Android™ brand. For example sans-serif is usually implemented with the "Roboto" font.

**Example**

```xml
<StyleAttribute name="fontFamily" value="sans-serif" />
<StyleAttribute name="fontFamily" value=""'Courier New"" />
<StyleAttribute name="fontFamily" value="'Times New Roman',Times,serif" />
```

**Related concepts**

**Syntax of presentation styles file (.4st) on page 1067**

A .4st presentation styles file is an XML file defining style attributes to be applied by front-ends.

**Font sizes**

Use the `fontSize` style attribute to influence the size of a font.

**Syntax**

```xml
\l generic-size \l points \l size \l
```

1. `generic-size` is one of the generic font size names (such as 'small' or 'xx-large') listed in Table 293: Generic font sizes on page 1079.
2. `points` defines an absolute size in points. Specify a number followed immediately by `pt`, for example, 3pt.
3. `size` defines relative size. Specify a number followed immediately by `em`, for example, 3em.
Usage
Specify either a generic font size, an absolute size in points with the "pt" unit, or a relative size with the "em" unit.

Absolute sizes (using the "pt" suffix) define a font size in physical points. Physical points are much like pixels, in that they are fixed-size units and cannot scale in size. For example, on HTML pages using CSS styles, one point is equal to 1/72 of an inch.

Relative sizes (using the "em" suffix) define a font size in a scalable size unit that adapts to the front-end platform, where one "em" unit results in the same size as the size of the default font on the platform. For example, if the size of the platform default font is 16 points, \(1em = 16pt\), \(2em = 32pt\), etc.

Generic font sizes are interpreted by the front end depending on the graphical capability of the platform.

Note: Use generic font sizes such as medium, large, small, or sizes relative to the user-chosen font (using em units), rather than absolute point values. In an HTML browser you can choose two fonts (proportional/fixed), and a well-designed document does not use more than 2 fonts. This is also valid for applications.

Table 293: Generic font sizes

<table>
<thead>
<tr>
<th>Generic font size name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>xx-small</td>
<td>Tiny font size</td>
</tr>
<tr>
<td>x-small</td>
<td>Extra-small font size</td>
</tr>
<tr>
<td>small</td>
<td>Small font size</td>
</tr>
<tr>
<td>medium</td>
<td>Medium font size</td>
</tr>
<tr>
<td>large</td>
<td>Large font size</td>
</tr>
<tr>
<td>x-large</td>
<td>Extra-large font size</td>
</tr>
<tr>
<td>xx-large</td>
<td>Huge font size</td>
</tr>
</tbody>
</table>

You can also specify an absolute font size, by giving a numeric value followed by the units such as pt or em:

Example

```xml
<StyleAttribute name="fontSize" value="medium" />
<StyleAttribute name="fontSize" value="xx-large" />
<StyleAttribute name="fontSize" value="12pt" />
<StyleAttribute name="fontSize" value="1em" />
```

Related concepts
Font families on page 1077
Use the `fontFamily` style attribute to define a generic or specific font family.

**Font styles**
Use the `fontStyle` style attribute to define the style of a font.

**Syntax**

```
italic | roman | oblique
```

**Usage**
The style of a font can be specified with a generic name, that is interpreted by the front end depending on the graphical capabilities of the platform. For example, on "Android™" devices, `italic` and `oblique` result in the same font aspect.

**Table 294: Generic font style**

<table>
<thead>
<tr>
<th>Generic font style name</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>italic</td>
<td>Specifies an italic font style, using a typeface that slants slightly to the right. Uses a different glyph as the roman style.</td>
</tr>
<tr>
<td>oblique</td>
<td>Specifies an oblique font style. This style is similar to italic, except that it uses the same glyphs as the roman type, but distorted.</td>
</tr>
<tr>
<td>roman</td>
<td>Specifies a roman font style. This is the typical default font style in Latin-script typography.</td>
</tr>
</tbody>
</table>

**Example**

```xml
<StyleAttribute name="fontStyle" value="italic" />
```

**Font weights**
Use the `fontWeight` style attribute to define the aspect of a font.

**Syntax**

```
black | bold | book | condensed | condensedbold | condensedlight | demibold | extrablack | heavy | light | medium | normal | regular | semibold | thin
```

**Usage**
The availability of the weight depends on the chosen font family. For example, if the font family is defined as `AmericanTypewriter`, and the front-end platform supports the following set of font names (for this font family):
AmericanTypewriter, AmericanTypewriter-Light, AmericanTypewriter-Bold, AmericanTypewriter-CondensedLight, AmericanTypewriter-CondensedBold, AmericanTypewriter-Condensed, you can only use the condensed, light and bold font weights.

Before using a font weight, make sure that the target platform supports the value. For example, on "Android™" devices, only normal and bold are supported.

**Example**

```xml
<StyleAttribute name="fontWeight" value="bold" />  
```

**StatusBar types**

Possible values for Window status bar type.

This section describes how to specify a value for the `Window.statusBarType` style attribute.

**Syntax**

```xml
<statusbar-type />  
```

1. `statusbar-type` is a predefined status bar type name.

**Usage**

The `statusBarType` style attribute can get one of the values listed in the following table, to customize the rendering of error and message texts.

**Important:** This style attribute is mainly used for desktop application using the GDC front-end.

**Table 295: Possible status bar types for the statusBarType attribute**

<table>
<thead>
<tr>

- ToolBarSeparator style attributes on page 1115
- UserInterface style attributes on page 1116
- Window style attributes on page 1117
**Common style attributes**
Common style presentation attributes apply to any graphical element, such as windows, layout containers, or form items.

**Important:** Common style attribute apply to basic layout elements such as containers (Group) and form widgets (Label, Button, Edit, CheckBox). Depending on the front-end platform, common style attributes typically do not apply to advanced graphical elements such as TopMenu or ToolBar, especially when such widgets can be configured with the user interface theme of the front-end platform. Consider using common style attribute only for elements inside the form layout.

**Table 296: Common style attributes**

<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Defines the color to be used to paint the text of the object.
For possible values, see Colors on page 1074.
Default is no value (default object color or inherited color).

**Note:** In GMI, `textColor` affects the widgets they are defined on, not the labels in the form used to display the widgets. It is also used to set the tint of checkbox, radio group (horizontal), and spin edit.

<table>
<thead>
<tr>
<th><strong>textDecoration</strong></th>
<th>Yes</th>
<th>Yes</th>
<th>No</th>
<th>No</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>
Defines the decoration for the text.

Values can be "overline", "underline" or "line-through".
Default is no value (default object font or inherited font).

**Related concepts**

STYLE attribute on page 1287
The STYLE attribute specifies a presentation style for a form element.

**Button style attributes**

Button style presentation attributes apply to BUTTON elements.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

**Table 297: Button style attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>alignment</strong></td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Defines the position of the image and/or text inside a button, when the button is bigger than the content.

The value can be a combination of a vertical and horizontal alignment hints, separated by a space.

The value can also be "center", which is equivalent to "verticalCenter horizontalCenter".

**Vertical alignment hints:**
- "top": anchor to the top edge.
- "verticalCenter": center in middle.
- "bottom": anchor to the bottom edge.

**Horizontal alignment hints:**
- "left": anchor to the left edge.
- "horizontalCenter": center in middle.
- "right": anchor to the right edge.

The default is "center".
### buttonType

Defines the rendering of a button.

Values can be:

- "normal" (default): The button is rendered as a regular push button.
- "link": the button is rendered as an HTML hyper-link. In contrast to the label hyper-link support, clicking on a "link" button does not start the default browser, but triggers the corresponding action, like a normal button.
- "commandLink": the button is rendered as a "Command Link" button on Microsoft® Windows® Vista and Windows® 7.

**Important:** The buttonType Button style attribute cannot be changed dynamically, once the widget has been displayed.

### scaleIcon

Defines the scaling behaviors of the associated icon, if the source image size is bigger than the place reserved for it in the widget.

**Note:** On GDC and GBC, if the scaleIcon attribute is undefined, the behavior depends on the type of action view: toolbar button icons and action panel button icons are scaled down to match the size of the widget. For other widgets, by default no scaling occurs, as for scaleIcon="no".

Values can be:

- "no": No scaling occurs and the image is taken as-is. It is up to the developer to resize the source image to avoid misalignment. This is the default on GDC/GBC.
- "yes": Images are scaled down following the height of the widget (button or edit field). Setting a big font can result in a big icon. This is the default on GMA/GMI.
- "nnnpx": Images are scaled down based on the specified size. For example, scaleIcon="128px" will make every icon a maximum of 128*128 pixels. At least one side equal to 128 pixels, depending if the source image is square or not.

Independently of the style value, the source image is never upscaled to avoid pixelization or blurring of the image. The exception is for SVG images, which can be upscaled without any penalty. If the icon must be enlarged, the image is centered and a transparent border is added to "fill" the empty space. This allows a mix of larger and smaller icons while keeping widget alignment.

If scaling takes place, the aspect ratio of the original image is kept. A non-square source image displays as a non-square scaled icon.

### Related concepts

**BUTTON item type** on page 1163
Defines a push-button that can trigger an action.

**ButtonEdit style attributes**

ButtonEdit style presentation attributes apply to BUTTONEDIT elements.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

**Note:** On GDC and GBC, if the `scaleIcon` attribute is undefined, the behavior depends on the type of action view: toolbar button icons and action panel button icons are scaled down to match the size of the widget. For other widgets, by default no scaling occurs, as for `scaleIcon="no"`. Values can be:

- "no": No scaling occurs and the image is taken as-is. It is up to the developer to resize the source image to avoid misalignment. This is the default on GDC/GBC.
- "yes": Images are scaled down following the height of the widget (button or edit field). Setting a big font can result in a big icon. This is the default on GMA/GMI.
- "nnnpx": Images are scaled down based on the specified size. For example, `scaleIcon="128px"` will make every icon a maximum of 128*128 pixels. At least one side equal to 128 pixels, depending if the source image is square or not.

Independently of the style value, the source image is never upscaled to avoid pixelization or blurring of the image. The exception is for SVG images, which can be upscaled without any penalty. If the icon must be enlarged, the image is centered and a transparent border is added to "fill" the empty space. This allows a mix of larger and smaller icons while keeping widget alignment.

If scaling takes place, the aspect ratio of the original image is kept. A non-square source image displays as a non-square scaled icon.

**Related concepts**

BUTTONEDIT item type on page 1164

Defines a line-edit with a push-button that can trigger an action.

**CheckBox style attributes**

CheckBox style presentation attributes apply to CHECKBOX elements.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.
**Table 299: CheckBox style attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>customWidget</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Defines the type of widget to be used to render the CHECKBOX.

Values can be:

- "toggleButton": The checkbox is rendered as a toggle button (also known as "toggle switch" in HTML/CSS).

  **Important:** NULL values cannot be managed with the toggleButton widget type.

Default is to render the checkbox with a classical box using a check mark when set.

  **Important:** The customWidget CheckBox style cannot be changed dynamically, once the widget has been displayed.

| iosCheckBoxOnTintColor     | N/A | N/A | N/A | Yes |

On iOS devices, defines the color for the checkbox marker when on. This is different from backgroundColor, which is used for the tint of the whole switch.

**Related concepts**

CHECKBOX item type on page 1165

Defines a boolean or three-state checkbox field.

**ComboBox style attributes**

ComboBox style presentation attributes apply to COMBOBOX elements.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

**Table 300: ComboBox style attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>autoSelectionStart</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Defines the item from which the auto-selection will start, when pressing keys.

Valid can be:

- "current": (default) the auto-selection looks for the first corresponding item after the current item of the object.
- "first": the auto-selection looks for the first corresponding item after the first item of the object.
ComboboxCompleter

**Important**: This feature is deprecated, and may be removed in a future version.

Activate the ComboBox completer mode.

Possible values are "yes" and "no" (default).

When this attribute is set to yes, the ComboBox will have the following behavior:

- The ComboBox is editable, but only characters that match an item in the list are allowed (if the list contains the item "aa" and the item "ab", you can type "a", "aa", "ab", but nothing else. If you paste text in the field, it will be truncated until the rule is fulfilled.
- The drop-down list will only display item which starts with the same characters as the edit field. It is dynamically updated as you type (if the list contains the item "aa" and the item "ab" and you type "a", you will see both items displayed, but if you continue to type another "a", you will only see "aa" in the list.
- The best match is automatically selected when leaving the field (thus performing an "on change") as soon as you hit "TAB" key, even if the input is not complete.

CompletionTimeout

Defines the timeout (in milliseconds) to build the character sequence for item lookup when the user presses several keys successively. When pressing multiple keys, a character sequence is built for item lookup. After the timeout delay has expired, the character sequence is reset.

### Related concepts

**COMBOBOX item type** on page 1166

Defines a line-edit with a drop-down list of values.

**DateEdit style attributes**

DateEdit style presentation attributes apply to DATEEDIT elements.

**Note**: This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

### Table 301: DateEdit style attributes

<table>
<thead>
<tr>

</tbody>
</table>
| **Note:** If the device orientation is in portrait mode, Android™ may not display the text, even if you force it with this attribute.
### scaleIcon

Defines the scaling behaviors of the associated icon, if the source image size is bigger than the place reserved for it in the widget.

**Note:** On GDC and GBC, if the `scaleIcon` attribute is undefined, the behavior depends on the type of action view: toolbar button icons and action panel button icons are scaled down to match the size of the widget. For other widgets, by default no scaling occurs, as for `scaleIcon="no"`.

Values can be:

- "no": No scaling occurs and the image is taken as-is. It is up to the developer to resize the source image to avoid misalignment. This is the default on GDC/GBC.
- "yes": Images are scaled down following the height of the widget (button or edit field). Setting a big font can result in a big icon. This is the default on GMA/GMI.
- "nnnpx": Images are scaled down based on the specified size. For example, `scaleIcon="128px"` will make every icon a maximum of 128*128 pixels. At least one side equal to 128 pixels, depending if the source image is square or not.

Independent of the style value, the source image is never upscaled to avoid pixelization or blurring of the image. The exception is for SVG images, which can be upscaled without any penalty. If the icon must be enlarged, the image is centered and a transparent border is added to "fill" the empty space. This allows a mix of larger and smaller icons while keeping widget alignment.

If scaling takes place, the aspect ratio of the original image is kept. A non-square source image displays as a non-square scaled icon.

<table>

</thead>
<tbody>
<tr>
<td>scaleIcon</td>
<td>Yes (see note)</td>
<td>Yes (see note)</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

### Edit style attributes

Edit style presentation attributes apply to an EDIT element.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.
Table 303: Edit style attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>dataTypeHint</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

**Important:** This feature is deprecated, and may be removed in a future version.

**Important:** Consider using the KEYBOARDHINT form attribute instead of the dataTypeHint style attribute.

Defines the type of the input, to let the front-end render a field behavior suitable for the particular data type.

Values can be:
- "email" (for email addresses)
- "url" (for URLs)
- "tel" (for telephone numbers)
- "search" (for search box fields)

spellCheck           | No  | No (see note) | No  | Yes (see note) |

Defines if the edit field includes a spelling checker.

**Note:**
- With GBC, the attribute is not applicable: Input fields use the web browser spellchecker.
- With GMI, available values are "yes" or "no". If this attribute is not set, iOS will decide if spell checking is enabled, depending on the global auto-correction setting on the device.

Related concepts

EDIT item type on page 1170
Defines a simple line-edit field.

Folder style attributes

Folder style presentation attributes apply to FOLDER tab elements.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 304: Folder style attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>position</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Defines the position and type of the folder tabs.

Values can be "top" (default), "left", "right", "bottom" and "accordion".

**Note:** The "accordion" position is only supported by the GBC front-end.

Related concepts

FOLDER item type on page 1171
Defines a layout area to hold folder pages.

**Form style attributes**
Form style presentation attributes apply to a form element.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

**Table 305: Folder style attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>resetFormSize</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

This style attribute controls the resizing of the parent window, depending on the form content, when using successive OPEN FORM/DISPLAY FORM instructions (within the same current window)

Values can be "no" (default), "yes".

**Note:** The resetFormSize style attribute applies only to GDC front-end

**Related concepts**

DISPLAY FORM on page 1044
Displays and associates a form with the current window.

**Group style attributes**
Group presentation style attributes apply to a GROUP element.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

**Table 306: Group style attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>collapsible</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Defines if the group element can be collapsed and expanded.

By default groups are not collapsible.

Values can be "yes", "no" (default).

**initiallyCollapsed**

Defines if a collapsible group is in collapsed state when the form is displayed for the first time.

This style attribute is ignored if the collapsible attribute is not defined to "yes" for this group.

Values can be "yes", "no" (default).

**Related concepts**

GROUP item type on page 1172
Defines a layout area to group other layout elements together.

**HBox style attributes**

HBox style presentation attributes apply to an HBox element.

**Note:** This topic lists presentation style attributes for a specific class of form element, *common presentation style attributes* can also be used for this type of element.

**Table 307: HBox style attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>splitViewRendering</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Indicates if the HBox must be displayed as a split view.

- in landscape mode, panes are side by side and scroll independently
- in portrait mode, user navigates between the panes by swiping left or right

Values can be "yes" or "no" (default).

**Related concepts**

[HBOX container](#) on page 1197

Packs child layout elements horizontally.

[Rendering an HBox as a split view](#) on page 1809

Achieve a split view display with HBOX container and style attribute.

**Image style attributes**

Image style presentation attributes apply to an IMAGE element.

**Note:** This topic lists presentation style attributes for a specific class of form element, *common presentation style attributes* can also be used for this type of element.

**Table 308: Image style attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>alignment</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Defines the image alignment when the container is bigger than the image itself.

Possible values are a pair of horizontal ("left", "horizontalCenter", "right") and vertical alignments ("top", "verticalCenter", "bottom"). To combine alignment options, use a space as separator.

Value can also be "center", which is equivalent to "horizontalCenter verticalCenter".

The default value is "top left".
**Important:** This feature is deprecated, and may be removed in a future version.

**Important:** Instead of IMAGE fields with the `imageContainerType` style attribute, use URL-based Web Components: URL Web Components are much easier to use and more powerful.

When set to "browser", defines an image container as a browser. To use the image field as a browser, set a URL instead of an image name.

**Note:** This feature uses the WebKit Open Source project as provided with Qt, and has limitations such as no Java support. It will display HTML / rich text, but may encounter difficulties with more complex Web pages.

### Related concepts

**IMAGE item type** on page 1174
Defines an area that can display an image resource.

**Label style attributes**
Label style presentation attributes apply to `LABEL` elements.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

#### Table 309: Label style attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>textFormat</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Defines the rendering of the content of the label widget.

Possible values are:

- "plain" (default): the value assigned to this widget is interpreted as plain text.
- "html": it is interpreted as HTML (with hyperlinks).

**Important:** The HTML content displayed inside a form element using the `textFormat:html` style must not be a complete HTML document (using CSS styles for example). The content must be simple HTML, with basic tags such as text decoration like `<b/>` for bold, `<ul/>+<li/>` for bullet lists, and inline styles.

**Related concepts**

**LABEL item type** on page 1175
Defines a simple text area to display a read-only value.

**Menu style attributes**
Menu style presentation attributes apply to a `MENU` dialog.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.
This table shows the presentation attributes for Menu:

### Table 310: Menu style attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>position</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Defines the position of the automatic menu for "popup" menus.

Values can be:

- "cursor" (default): the pop-up menu appears at the cursor position.
- "field", the pop-up menu appears below the current field.
- "center", the pop-up menu appears at the center of the screen.
- "center2", the pop-up menu appears at the center of the current window.

**Related concepts**

[Ring menus (MENU) on page 1358](#)

The MENU instruction implements a list of options the end user can choose from.

### Message style attributes

Message style presentation attributes apply to an ERROR or MESSAGE instruction.

The element type for both ERROR and MESSAGE is Message. To distinguish ERROR from MESSAGE, the ":error" or ":message" pseudo-selectors can be used to specify a different style for the rendering of each instruction: "Message:error" corresponds to the ERROR instruction, and "Message:message" corresponds to the MESSAGE instruction.

The ERROR and MESSAGE instructions can get a STYLE attribute in the ATTRIBUTES clause, to specify a particular style name:

```
MESSAGE "No rows have been found." ATTRIBUTES(STYLE="info")
```

A limited set of common style attributes are supported for error/message display. In addition to the attributes described in the section, you can only define font style attributes for messages.

Like simple form fields, TTY attributes have a higher priority than style attributes. By default, ERROR has the TTY attribute REVERSE, which explains why ERROR messages have a reverse background, even when you use a backgroundColor style attribute. Use the NORMAL attribute in ERROR, to avoid the default REVERSE TTY attribute and define your own background color with a style.

Consider centralizing your ERROR and MESSAGE instruction calls in a function, to simplify global modifications:

```
FUNCTION my_error(m, s)
    DEFINE m, s STRING
    IF s IS NULL THEN
        ERROR m ATTRIBUTES(NORMAL)
    ELSE
        ERROR m ATTRIBUTES(NORMAL, STYLE=s)
    END IF
END FUNCTION
```

This table shows the presentation attributes for ERROR and MESSAGE instructions:
### Table 311: Presentation attributes for ERROR and MESSAGE instructions

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>position</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Defines the output type of the status bar message field.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Values can be:</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• &quot;statusbar&quot; (default): will display the text in the regular statusbar of the window.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• &quot;popup&quot;: will bring a pop-up window to the front; it is recommended to use this with care, as overuse can annoy the user.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• &quot;statustip&quot;: will add a small &quot;down&quot; arrow button that will show the pop-up once the user clicks on it. This can be useful to display very long text.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• &quot;both&quot;: will display the text in a pop-up window and then in the status bar.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>textFormat</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Defines the rendering of the content of the widget.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Possible values are:</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• &quot;plain&quot; (default): the value assigned to this widget is interpreted as plain text.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• &quot;html&quot;, it is interpreted as HTML (with hyperlinks).</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Important:** The HTML content displayed inside a form element using the `textFormat:html` style must not be a complete HTML document (using CSS styles for example). The content must be simple HTML, with basic tags such as text decoration like `<b/>` for bold, `<ul/>`+<li/> for bullet lists, and inline styles.

### Related concepts

**Pseudo selectors** on page 1068

Pseudo selectors can be used to apply style only when some conditions are fulfilled.

**ProgressBar style attributes**

ProgressBar style presentation attributes apply to PROGRESSBAR elements.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.
Table 312: ProgressBar style attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>percentageVisible</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Defines whether the current progress value is displayed.

Values can be:

- "no" (default): no progress value is displayed.
- "center": the progress will be displayed in the middle of the progressbar.
- "system": it will follow the system theme.

Related concepts

PROGRESSBAR item type on page 1177
Defines a progress indicator field.

RadioGroup style attributes

RadioGroup style presentation attributes apply to RADIOGROUP elements.

Note: This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 313: RadioGroup style attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>autoSelectionStart</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Defines the item from which the auto-selection will start, when pressing keys.

Values can be:

- "current" (default): it will look for the first corresponding item after the current item of the object.
- "first": the auto-selection will look for the first corresponding item after the first item of the object.

completionTimeout

Defines the timeout (in milliseconds) to build the character sequence for item lookup when the user presses several keys successively. When pressing multiple keys, a character sequence is built for item lookup. After the timeout delay has expired, the character sequence is reset.

Related concepts

RADIOGROUP item type on page 1178
Defines a mutual exclusive set of options field.

ScrollGrid style attributes

ScrollGrid style presentation attributes apply to SCROLLGRID container.

Note: This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.
Table 314: ScrollGrid style attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>customWidget</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
| Defines the display mode to be used for the SCROLLGRID. Values can be:  
  • "pagedScrollGrid": Stretchable scrollgrids (defined with WANTFIXEDPAGESIZE=NO) will be rendered as a responsive tile list. Each row is rendered as a tile. The page size of the scrollgrid defines the number of tiles in each page. Default is to render the scrollgrid as a vertical list. **Important:** The customWidget ScrollGrid style attribute cannot be changed dynamically, once the widget has been displayed. |
| rowActionTrigger   | Yes | Yes | No  | No  |
| Defines the physical event that will fire the row selection action (DOUBLECLICK) in a scrollgrid. Values can be "singleClick" or "doubleClick". Default is "doubleClick": a left-double-click triggers the action. |
| highlightColor     | Yes | Yes | Yes | No  |
| Defines the highlight color of rows for the SCROLLGRID, used for selected rows. For possible values, see Colors. For more details see Row and cell highlighting in SCROLLGRID on page 1101. |
| highlightCurrentCell | Yes | Yes | Yes | Yes |
| Indicates if the current cell is highlighted in a SCROLLGRID, with the system default highlight colors, or the colors defined by the highlightColor/highlightTextColor style attributes. Values can be "yes","no" (default depends on front-end and dialog type) For more details see Row and cell highlighting in SCROLLGRID on page 1101. |
**Attribute**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>highlightCurrentRow</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Indicates if the current row is highlighted in a SCROLLGRID, with system default highlight colors, or the colors defined by the `highlightColor/highlightTextColor` style attributes.

Values can be "yes" or "no" (default depends on front-end and dialog type)

For more details see Row and cell highlighting in SCROLLGRID on page 1101.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>highlightTextColor</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

Defines the highlighted text color of rows for the SCROLLGRID, used for selected rows.

For possible values, see Colors.

For more details see Row and cell highlighting in SCROLLGRID on page 1101.

**Related concepts**

**SCROLLGRID item definition** on page 1234
Defines a scrollgrid layout tag in a grid-based layout.

**Row and cell highlighting in SCROLLGRID**
SCROLLGRID containers can be configured with presentation styles, to control row and cell highlighting, using specific foreground and background colors.

**Row/cell highlighting with SCROLLGRID**
When using a SCROLLGRID, the same row/cell highlighting style attributes can be used as for TABLE containers, with some exceptions, as described in this topic.

**DISPLAY ARRAY using FOCUSONFIELD attribute**

- With GDC:
  - If `highlightCurrentRow=yes`, the current row is highlighted.
  - If `highlightCurrentRow=no`, the current row is not highlighted (same as default).

**Table style attributes**
Table style presentation attributes apply to a TABLE container.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.
Table 315: Table style attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>allowWebSelection</td>
<td>No</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Users need to select items from a table. Once selected, the keyboard shortcut for copying data can be used to copy the selection. Values can be &quot;yes&quot; or &quot;no&quot; (default). When allowWebSelection=&quot;no&quot;, item selection requires the user to hold down the CTRL key while dragging over the selection with the mouse. When allowWebSelection=&quot;yes&quot;, item selection requires a mouse drag only. There is no need to press the CTRL key. However, the ability to drag-and-drop data is disabled.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>forceDefaultSettings</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Values can be &quot;yes&quot; or &quot;no&quot; (default). By default, tables are reopened with column positions, visibility and sizes they had when the window was closed. By setting this attribute to true, the saved settings are ignored and the table gets the initial column layout. Note that the saved settings include also the sort columns, that will impact on the order of the rows in the table.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>headerAlignment</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
| Defines the column header alignment in a table. Values can be:
  • "default" (default): will use the system default. In most case it is left aligned.
  • "left" will force all column headers to be left aligned.
  • "center" will force all column headers to be centered.
  • "right" will force all column headers to be right aligned.
  • "auto" will first try to align each column header following the "justify" attribute of the column. If no "justify" attribute is set, the column header will be aligned based on the type of data: right for numeric data, left for text data. |
<p>| headerHidden                | Yes | Yes | No  | No  |
| Defines if the horizontal header must be visible in a table. Values can be &quot;yes&quot; or &quot;no&quot; (default). |
| highlightColor              | Yes | Yes | Yes | No  |
| Defines the highlight color of rows for the TABLE, used for selected rows. For possible values, see Colors. For more details see Row and cell highlighting in TABLE on page 1105. |</p>

<td>Yes (see note)</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Defines the rendering type of the table.

**Important:** The `tableType` style attribute cannot be changed dynamically, once the widget has been displayed.

Values can be:

- "normal" (default): Regular table rendering.
- "pictureFlow": The first column of the table is used to define the list of images to be used in the picture flow.
  
  **Note:** `pictureFlow` is only supported by GDC.
- "frozenTable": Users can "freeze" some columns when scrolling, so that they always remain visible. Default frozen columns can be defined with "leftFrozenColumns" and "rightFrozenColumns" attributes.
- "listView": The table is rendered as a mobile list view.
  
  **Note:** `listView` is only supported by GBC.

**Related concepts**

TABLE item definition on page 1236
Defines attributes for a table layout tag, in a grid-based layout.

STYLE attribute on page 1287
The STYLE attribute specifies a presentation style for a form element.

Summary lines in tables on page 1767
Table views can display a summary line, to show aggregate values for columns.

Row and cell highlighting in TABLE
TABLE containers can be configured with presentation styles, to control row and cell highlighting, using specific foreground and background colors.

**Purpose of row/cell highlighting style attributes**

Depending on the type of front-end, TABLE containers controlled by DISPLAY ARRAY dialog use a default rendering for the current row, and a default rendering for the current cell, when using INPUT ARRAY, INPUT or CONSTRUCT.

The following style attributes can be combined to change the rendering of the current row or current cell:

- `highlightCurrentRow` (yes/no): Controls current row highlighting.
- `highlightCurrentCell` (yes/no): Controls current cell highlighting.
- `highlightColor`: Defines the background color.
- `highlightTextColor`: Defines the text/foreground color.

The `highlightColor`/`highlightTextColor` can get color values. If these attributes are not specified and highlighting is required for the row or the cell, the front-end will use platform default highlighting colors.

**Note:** When using a dialog allowing user input such as INPUT ARRAY, cells can be edited and text can be selected in editor-based field types. When a highlight colors are used at the cell level, the front-ends will render the selected text accordingly.

A TABLE style can for example be defined as follows:

```xml
<Style name="Table.custom_style">
  <StyleAttribute name="highlightCurrentRow" value="no"/>
</Style>
```
<StyleAttribute name="highlightCurrentCell" value="yes"/>
<StyleAttribute name="highlightColor" value="red"/>
<StyleAttribute name="highlightTextColor" value="yellow"/>
</Style>

Note: Depending on the front-end platform, some widgets may support different highlight colors to the system defaults. If your application is intended for several types of front-ends, consider testing the style attributes with all of them.

Regular DISPLAY ARRAY (no FOCUSONFIELD attribute)
When using a regular DISPLAY ARRAY with row-level focus granularity, the rendering of the current row is as follows:
• By default:
  • On GBC and GDC, the current row is highlighted.
  • On GMA and GMI, the current row is not highlighted.
• If highlightCurrentRow=yes, the current row is highlighted (default with GDC and GBC).
• If highlightCurrentRow=no, the current row is not highlighted (default with GMA and GMI).
• The attribute highlightCurrentCell is ignored.

DISPLAY ARRAY using FOCUSONFIELD attribute
When using a DISPLAY ARRAY with FOCUSONFIELD attribute:
• By default, the current cell is highlighted
• If highlightCurrentRow=yes, the current row is highlighted.
• If highlightCurrentRow=no, the current row is not highlighted (default).
• If highlightCurrentCell=yes, the current cell is highlighted (default).
• If highlightCurrentCell=no, the current cell is not highlighted.

Note: Exception on GDC:
• The highlightCurrentRow attribute is ignored (due to platform limitations).

INPUT ARRAY
When using an INPUT ARRAY (and INPUT, CONSTRUCT):
• By default, the current cell is not highlighted.
• If highlightCurrentRow=yes, the current row is highlighted.
• If highlightCurrentRow=no, the current row is not highlighted (default).
• If highlightCurrentCell=yes, the current cell is highlighted.
• If highlightCurrentCell=no, the current cell is not highlighted (default).

Note: Exception on GMA and GMI:
• INPUT ARRAY is not yet supported.

Related concepts
Row and cell highlighting in SCROLLGRID on page 1101
SCROLLGRID containers can be configured with presentation styles, to control row and cell highlighting, using specific foreground and background colors.

Tree style attributes
Tree style presentation attributes apply to the TREE container.

Note: This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.
Note: In the .4st file, the style attribute for TREE containers must be specified with the "Table" class (in the AUI tree, TREE containers are represented with Table nodes)

**Table 316: Tree style attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>allowWebSelection</td>
<td>No</td>
<td>Yes</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Users need to select items from a treeview. Once selected, the keyboard shortcut for copying data can be used to copy the selection.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Values can be "yes" or "no" (default).

When allowWebSelection="no", item selection requires the user to hold down the CTRL key while dragging over the selection with the mouse.

When allowWebSelection="yes", item selection requires a mouse drag only. There is no need to press the CTRL key. However, the ability to drag-and-drop data is disabled.

<table>
<thead>
<tr>
<th>forceDefaultSettings</th>
<th>Yes</th>
<th>Yes</th>
<th>N/A</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>By default, tables are reopened with column positions, visibility and sizes they had when the window was closed. By setting this attribute to true, the saved settings are ignored and the table gets the initial column layout. Note that the saved settings include also the sort columns, that will impact on the order of the rows in the table.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Values can be "yes" or "no" (default).

<table>
<thead>
<tr>
<th>headerAlignment</th>
<th>Yes</th>
<th>Yes</th>
<th>N/A</th>
<th>N/A</th>
</tr>
</thead>
<tbody>
<tr>
<td>Defines the column header alignment in a table.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Values can be:

- "default" (default): will use the system default. In most case it is left aligned.
- "left" will force all column headers to be left aligned.
- "center" will force all column headers to be centered.
- "right" will force all column headers to be right aligned.
- "auto" will first try to align each column header following the "justify" attribute of the column. If no "justify" attribute is set, the column header will be aligned based on the type of data: right for numeric data, left for text data.

**Related concepts**

TREE item definition on page 1238
Defines attributes for a tree layout tag, in a grid-based layout.

*Row highlighting in TREE*
TREE containers can be configured with presentation styles, to control row highlighting, using specific foreground and background colors.

*Row highlighting with TREE*
When using a TREE, the same row highlighting style attributes can be used as for TABLE containers.

**Note:** Only row highlighting is supported, because DISPLAY ARRAY + FOCUSONFIELD and INPUT ARRAY dialogs are not supported with TREE containers.

TextEdit style attributes
TextEdit style presentation attributes apply to the TEXTEDIT element.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

**Table 317: TextEdit style attributes**

<table>
<thead>
<tr>

</tr>
<tr>
<td>Defines if the textedit field includes a spelling checker. Note:</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- With GDC, the possible values are the two dictionary files needed for each language (one .aff and one .dic). These files can be downloaded here. Only the files available for OpenOffice.org 2.x are working (files for OpenOffice.org 3.x are not supported yet):

  Supported file formats are:
  
  - Simple relative locale files like "my_affix_file.aff|my_dictionnary_file.dic"
  - Absolute paths such as "file:///c:/dics/my_dictionnary_file.aff|file:///c:/dics/my_dictionnary_file.dic"
  - URLs such as http://mywebserver.com/my_affix_file.aff
    http://mywebserver.com/my_dictionnary_file.dic

  The local directory of dictionary files can be queried in the GDC with the standard.feInfo frontcall using the dictionariesDirectory parameter

- With GBC, the attribute is not applicable: Input fields use the web browser spellchecker.

- With GMI, available values are "yes" or "no". If this attribute is not set, iOS will decide if spell checking is enabled, depending on the global auto-correction setting on the device.
### Attribute: textFormat

Defines the rendering of the content of the widget.

Values can be:

- "plain" (default): the value assigned to this widget is interpreted as plain text.
- "html", the value is interpreted as HTML (with hyperlinks), with rich text input feature enabled.

**Important:** The HTML content displayed inside a form element using the `textFormat:html` style must not be a complete HTML document (using CSS styles for example). The content must be simple HTML, with basic tags such as text decoration like `<b/>` for bold, `<ul/>+<li/>` for bullet lists, and inline styles.

**Note:** Consider using the `fglrichtext` web component, instead of the rich text option in TEXTEDIT fields. For more details, see Rich Text Editing in TEXTEDIT on page 1111.

<table>
<thead>
<tr>

<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>textFormat</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

### Attribute: wrapPolicy

Defines where the text can be wrapped in word wrap mode.

Values can be:

- "atWordBoundary" (default): the text will wrap at word boundaries.
- "anywhere": the text breaks anywhere, splitting words if needed.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>wrapPolicy</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

**Related concepts**

**TEXTEDIT item type** on page 1184

Defines a multi-line edit field.

**Rich Text Editing in TEXTEDIT**

The GDC and GBC front-ends support a rich text editing interface with TEXTEDIT fields.

**Note:** Consider using the `fglrichtext` web component, instead of richtext option in TEXTEDIT fields.

**Important:** The HTML content displayed inside a form element using the `textFormat:html` style must not be a complete HTML document (using CSS styles for example). The content must be simple HTML, with basic tags such as text decoration like `<b/>` for bold, `<ul/>+<li/>` for bullet lists, and inline styles.
Rich text editing provides:

- Text format: bold, italic, underline
- Paragraph alignment: left, center, right, justify
- Lists: bullet, decimal
- Paragraph indentation
- Font size

To enable rich text editing, set the `textFormat` styleAttribute to `html`:

```xml
<Style name="TextEdit.richText">
  <StyleAttribute name="textFormat" value="html" />
</Style>
```

**Richtext toolbox**

By default, when the mouse reaches the top border of the textedit field where rich text editing has been enabled, a toolbox appears. The toolbox disappears when the mouse leaves the top border area. This implementation is useful if you only use the textedit field to display rich text, as the toolbox is only visible in input.

If you want to always display the toolbox, you can set the `showEditToolBox` styleAttribute.

```xml
<Style name="TextEdit.richText">
  <StyleAttribute name="textFormat" value="html" />
  <StyleAttribute name="showEditToolBox" value="yes" />
</Style>
```
Figure 44: Rich text editing interface with toolbox always displayed.

**Tip:** The textedit field will be wide enough to display the toolbox in its entirety, even if you define a small width in your form definition file. Take this into account when designing your form.

**Tip:** The textedit field will be high enough to display the number of lines defined in the form definition file (using the textedit font) and the toolbox when required. A textedit with a height of 1 will display the toolbox and one line, which is much higher than without the toolbox.

**Important:** The behavior of the attribute showEditToolBox with the value auto differs between the Genero Desktop Client and the Genero Browser Client. With the Genero Desktop Client, 'auto' is interpreted as 'no'. With the Genero Browser Client, 'auto' is interpreted as 'yes'.

**Rich text local actions**

When using the TEXTEDIT rich text capability, a set of local actions are automatically created. These local actions can be configured like regular actions, to change the accelerator and decoration.

**Table 318: Local action names, accelerators, and icons**

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Accelerator</th>
<th>Icon Name</th>
<th>Icon</th>
</tr>
</thead>
<tbody>
<tr>
<td>richtextbold</td>
<td>Ctrl-b</td>
<td>textbold</td>
<td>B</td>

<td>None</td>
<td>textfontsizendown</td>
<td>A^*</td>
</tr>
<tr>
<td>richtextincreasefontsize</td>
<td>None</td>
<td>textfontsizeup</td>
<td>A^*</td>
</tr>
</tbody>
</table>

You can hide the toolbox using the `showEditToolBox` style attribute.

```
<StyleAttribute name="textFormat" value="html" />  
<StyleAttribute name="showEditToolBox" value="no" />  
```

TextEdit style attributes on page 1109
Textedit style presentation attributes apply to the TEXTEDIT element.

ToolBar style attributes
ToolBar style presentation attributes apply to the TOOLBAR element.

Note: This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.
Table 319: ToolBar style attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>scaleIcon</td>
<td>Yes (see note)</td>
<td>Yes (see note)</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Defines the scaling behaviors of the associated icon, if the source image size is bigger than the place reserved for it in the widget.

**Note:** On GDC and GBC, if the scaleIcon attribute is undefined, the behavior depends on the type of action view: toolbar button icons and action panel button icons are scaled down to match the size of the widget. For other widgets, by default no scaling occurs, as for scaleIcon="no".

Values can be:

- "no": No scaling occurs and the image is taken as-is. It is up to the developer to resize the source image to avoid misalignment. This is the default on GDC/GBC.
- "yes": Images are scaled down following the height of the widget (button or edit field). Setting a big font can result in a big icon. This is the default on GMA/GMI.
- "nnnpx": Images are scaled down based on the specified size. For example, scaleIcon="128px" will make every icon a maximum of 128*128 pixels. At least one side equal to 128 pixels, depending if the source image is square or not.

Independently of the style value, the source image is never upscaled to avoid pixelization or blurring of the image. The exception is for SVG images, which can be upscaled without any penalty. If the icon must be enlarged, the image is centered and a transparent border is added to "fill" the empty space. This allows a mix of larger and smaller icons while keeping widget alignment.

If scaling takes place, the aspect ratio of the original image is kept. A non-square source image displays as a non-square scaled icon.

| toolBarTextPosition | Yes | Yes | No | No |

Defines the text position of a ToolBarItem.

Values can be:

- "textBesideIcon"
- "textUnderIcon" (default)

**Related concepts**

**TOOLBAR section** on page 1192
The TOOLBAR section defines a toolbar with buttons that are bound to actions.

**ToolBarSeparator style attributes**

ToolBarSeparator style presentation attributes apply to the toolbar SEPARATOR element.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.
Table 320: ToolBarSeparator style attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>iosSeparatorStretch</td>
<td>N/A</td>
<td>N/A</td>
<td>N/A</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Stretches the SEPARATORS between toolbar items on iOS devices. When this attribute is set to `yes`, separators act like springs between the individual toolbar items.

Values can be:
- "no" (default): do not stretch toolbar item separators.
- "yes": stretch toolbar item separators.

Related concepts

**TOOLBAR section** on page 1192

The TOOLBAR section defines a toolbar with buttons that are bound to actions.

**UserInterface style attributes**

UserInterface style presentation attributes define general options related to the application user interface.

**Note:** This topic lists presentation style attributes for a specific class of form element, common presentation style attributes can also be used for this type of element.

Table 321: UserInterface style attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>androidKeepForeground</td>
<td>N/A</td>
<td>N/A</td>
<td>Yes (see note)</td>
<td>N/A</td>
</tr>
</tbody>
</table>

An Android™ app can switch between foreground to background states.

By default, when the app goes to background state, a notification is shown by GMA to give a higher priority to the app, and to prevent Android™ stopping the app if resources are required for other apps. The notification disappears, when the app returns to foreground state.

Use the `androidKeepForeground` style attribute to control the way the GMA forces Android™ to keep your app alive.

Values can be:
- "yes" (default): The app remains in foreground state: to keep it in foreground state, a notification is displayed when the app goes background.
- "no": The app can switch between foreground and background state (no notification is displayed to force the app to remain in foreground state)

**Important:** When using `androidKeepForeground=no`, GMA will no longer use a notification to keep the app in foreground, and Android™ may stop the app at any time.
### browserMultiPage

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>browserMultiPage</td>
<td>N/A</td>
<td>Yes</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Defines whether subsequent RUN and RUN WITHOUT WAITING instructions will be executed in the current browser tab or in a new browser tab.

This style only works if the application having this style is the first of the session.

This style requires the Genero Application Server 3.00.22 or greater.

Values can be:

- "no" (default): Subsequent RUN and RUN WITHOUT WAITING instructions are executed in the current browser tab.
- "yes": Subsequent RUN and RUN WITHOUT WAITING instructions are executed in a new browser tab.

### reverse

<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>reverse</td>
<td>N/A</td>
<td>Yes</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Global configuration option to display forms in reverse mode and enable right to left input, for right-to-left language support.

Values can be:

- "no" (default): Display forms for left-to-right languages.
- "yes": Display mirrored forms for right-to-left languages.

<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• &quot;portrait_all&quot;: Normal and reverse portrait orientation are allowed.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** This attribute is supported at the Window level only by GMA.
<table>
<thead>
<tr>
<th>Attribute</th>
<th>GDC</th>
<th>GBC</th>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>border</td>
<td>Yes</td>
<td>No</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>
| Defines the border type of the window. Values can be:  
  • "normal" (default): the border is standard, with a normal window header with a caption.  
  • "frame": only a frame appears, typically without a window header.  
  • "tool": a small window header is used.  
  • "none": the window gets no border.  
|                           |     |     |     |     |
| defaultTTFColor           | Yes | Yes | Yes | Yes |
| Defines the default color used for TTF icons. All icons displayed in the window using this style default get the color specified in the defaultTTFColor attribute. The value for this attribute must be an RGB specification or a named color as listed in Colors on page 1074. For more details about TTF icon usage see Using a simple image name (centralized icons) on page 1050. |
| errorMessagePosition      | Yes | No  | No  | No  |
| Defines the rendering of program errors displayed with the ERROR instruction. Values can be:  
  • "statusbar" (default): displays the comment in the window status bar.  
  • "popup" will bring a pop-up window to the front; to be used with care, as it can annoy the end user.  
  • "statustip" adds a small "down" arrow button that shows the pop-up once the user clicks on it; useful to display very long text.  
  • "both" will display the comment text in a pop-up window and then in the status bar. |
<p>| forceDefaultSettings      | Yes | Yes | No  | No  |
| Indicates if the window content must be initialized with the saved positions and sizes. By default, windows are reopened at the position and with the size they had when they were closed. You can force the use of the initial settings with this attribute. This applies also to column position and width in tables. Values can be &quot;yes&quot; or &quot;no&quot; (default). |</p>

<td>On iOS devices, indicates if default action views must be rendered with iOS standard icons and labels (yes, the default), or must use the text and image attributes of the corresponding action (no). Values can be &quot;yes&quot; (default) or &quot;no&quot;. The <code>iosRenderSystemActions</code> is taken into account depending on the image action attribute usage:  • If no image and no text attribute is used, GMI always uses the system action rendering, no matter what the value of <code>iosRenderSystemActions</code> is.  • If an image attribute is used, the image is always used to render the default action view, no matter what the value of <code>iosRenderSystemActions</code> is.  • If only a text attribute is used (no image attribute), <code>iosRenderSystemActions</code> defines if the iOS system action rendering is used (yes, the default) or if the text attribute is used (no) See also <a href="#">iOS default action views decoration</a> on page 1684.</td>

</tbody>
</table>
| Defines the rendering for program messages displayed with the MESSAGE instruction.
| Values can be:
| • "statusbar" (default): displays the comment in the window status bar.
| • "popup" brings a pop-up window to the front; to be used with care, as it can annoy the end user.
| • "statustip" adds a small "down" arrow button that will show the pop-up once the user clicks on it; useful to display very long text.
| • "both" will display the comment text in a pop-up window and then in the status bar.
| position          | Yes | Yes (see notes) | No | No |
| Indicates the initial position of the window.
| Values can be:
| • "default" (default): the windows are displayed depending on the window manager or browser rules.
| • "field": the window is displayed below the current field (works as "default", when current field does not exist). The windowType style attribute must be "modal".
| • "previous" the window is displayed at the same position (top left corner) as the previous window. (works as "default" when there is no previous window).
|  Note: "previous" is not supported by GBC.
| • "center": the window is displayed in the center of the screen.
| • "center2": the window is displayed in the center of the current window.
|  Note: "center2" is not supported by GBC.
| For front-ends using stored settings, "field" and "previous" have higher priority than the stored settings.

<td>Yes (see note)</td>
<td>Yes (see note)</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Values can be &quot;yes&quot; or &quot;no&quot; (default). Note: For the GDC, tabbedContainer=yes indicates that the WCI container must display the child application windows in a folder tab.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Note: For the GBC (WCI is not supported), if a window of an application uses tabbedContainer=yes, every application except the one hosting the tabbed container is embedded in a tab container generated by GBC. When using this style attribute, the GBC side bar is replaced by the StartMenu, which is mandatory when tabbedContainer=yes.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Attribute | GDC | GBC | GMA | GMI
--- | --- | --- | --- | ---
tabbedContainerCloseMethod | Yes | No | No | No
Defines the folder tab method of the container when tabbedContainer is set to "yes".
Values can be:
- "container" (default): container gets a close button in the tab.
- "page": each page has its own close button.
- "both": each page and the container has its close button.
- "none": no close button is shown.

thinScrollbarDisplayTime | Yes | Yes | No | No
Defines the display time (in seconds) of the automatic scrollbar displayed when scrolling on fixed screen array (a.k.a. "Matrix") and SCROLLGRIDs. After the delay, the scrollbar disappears.
A value of zero specifies an infinite time: The thin scrollbar remains visible while the record list can be scrolled (during dialog execution).
A negative value specifies that the scrollbar must always be hidden.
Default is 1 second.
toolBarDocking | Yes | No | No | No
Defines if the toolbar is movable and floatable.
Values can be "yes" (default) or "no".
toolBarPosition | Yes | No | No | No
Indicates the position of the toolbar, when a toolbar is defined.
Values can be "none", "top" (default), "left", "bottom" or "right".
windowMenu | Yes | No | No | No
Defines if the WCI container is to display an automatic "Window" menu, with Cascade and Tile features, and list of child windows.
Values can be "yes" or "no" (default).
windowOptionClose | Yes | Yes | No | No
Defines if the window can be closed with a system menu option or window header button.
Values can be "yes", "no" or "auto" (default).
When value is "auto", the option is enabled depending on the window type.
This attribute may have different behavior depending on the front-end operating system. For example, when no system menu is used, it may not be possible to have this option enabled.
### User interface

**Attribute** | **GDC** | **GBC** | **GMA** | **GMI**
--- | --- | --- | --- | ---
windowOptionMaximize | Yes | No | No | No

Defines if the window can be maximized with a system menu option or window header button.

Values can be "yes", "no" or "auto" (default).

When value is "auto", the option is enabled depending on the window type.

This attribute may have different behavior depending on the front-end operating system. For example, when no system menu is used, it may not be possible to have this option enabled.

windowOptionMinimize | Yes | No | No | No

Defines if the window can be minimized with a system menu option or window header button.

Values can be "yes", "no" or "auto" (default).

When value is "auto", the option is enabled depending on the window type.

This attribute may have different behavior depending on the front-end operating system. For example, when no system menu is used, it may not be possible to have this option enabled.

windowState | Yes | No | No | No

Defines the initial state of a window.

Values can be "normal" (default), "maximized", "minimized" or "fullscreen".

windowSystemMenu | Yes | N/A | No | No

Defines if the window shows a system menu.

Values can be "yes", "no" or "auto" (default).

When value is "auto", the system menu is enabled depending on the window type.

windowType | Yes | Yes | No | No

Defines the basic type of the window.

Values can be:

- "normal" (default): Normal windows are displayed as typical application windows.
- "modal": Modal windows are displayed over all other windows, typically used for temporary dialogs.

Windows and forms on page 1032
The section describes the concept of windows and forms in the language.

**Examples**

Presentation style (*.4st) usage examples.

**Example 1: Defining styles for grid elements**

This example shows how to define styles for grid elements.

The presentation style definition file:

```xml
<?xml version="1.0" encoding="ANSI_X3.4-1968"?>
<StyleList>
  <!-- Applies to all type of elements -->
  <Style name=".bigfont">
    <StyleAttribute name="fontSize" value="large" />
  </Style>
  <!-- Default text color and font family for all labels -->
  <Style name="Label">
    <StyleAttribute name="textColor" value="blue" />
    <StyleAttribute name="fontFamily" value="sans-serif" />
  </Style>
  <!-- Background color for Edits having focus -->
  <Style name="Edit:focus">
    <StyleAttribute name="backgroundColor" value="yellow" />
  </Style>
  <!-- Text color for Edits with STYLE="mandatory" -->
  <Style name="Edit.mandatory">
    <StyleAttribute name="textColor" value="red" />
  </Style>
</StyleList>
```

The form definition file:

```
LAYOUT
GRID
{
  [l1    ][f1            ]
  [l2    ][f2            ]
  [l3    ][f3            ]
}
END
ATTRIBUTES
LABEL l1: TEXT="Label 1:"
EDIT  f1 = FORMONLY.field1;
LABEL l2: TEXT="Label 2:"
EDIT  f2 = FORMONLY.field2;
LABEL l3: TEXT="Label 3:", STYLE="bigfont"
EDIT  f3 = FORMONLY.field3, STYLE="bigfont mandatory"
END
```

Program source file:

```
MAIN
  DEFINE rec RECORD
    field1 STRING,
    field2 STRING,
    field3 STRING
  END RECORD
  LET rec.field1 = "Field 1"
  LET rec.field2 = "Field 2"
  LET rec.field3 = "Field 3"
```
CALL ui.Interface.loadStyles("styles")
OPEN FORM f1 FROM "form"
DISPLAY FORM f1
    INPUT BY NAME rec.* WITHOUT DEFAULTS
END MAIN

Graphical result:

Figure 45: Form displayed based on styles applied

How the styles were applied
1. All labels get a blue text color and sans-serif font family because of the name="Label" style.
2. Label 3 and Edit 3 defined with the bigfont style name get a large font because of the name=".bigfont" style.
3. The Edit field having the focus gets a yellow background color because of the name="Edit:focus" style (using the focus pseudo-selector).
4. Edit fields defined with the mandatory style name get a red text color because of the name="Edit.mandatory" style.

Related concepts
Syntax of presentation styles file (.4st) on page 1067
A .4st presentation styles file is an XML file defining style attributes to be applied by front-ends.

Example 2: Defining styles for table rows
This example shows how to define styles for tables and table rows.

The presentation style definition file:

```xml
<?xml version="1.0" encoding="ANSI_X3.4-1968"?>
<StyleList>
    <!-- Applies to all type of elements -->
    <Style name=".bigfont">
        <StyleAttribute name="fontSize" value="large" />
    </Style>
    <!-- Background color form odd rows in tables -->
    <Style name="Table:odd">
        <StyleAttribute name="backgroundColor" value="yellow" />
    </Style>
</StyleList>
```
The form definition file:

```
LAYOUT
TABLE
{(c1 | c2 | c3 )
  [c1 | c2 | c3 ]
  [c1 | c2 | c3 ]
  [c1 | c2 | c3 ]
  [c1 | c2 | c3 ]}
END
ATTRIBUTES
EDIT c1 = FORMONLY.col1, TITLE="C1";
EDIT c2 = FORMONLY.col2, TITLE="C2";
EDIT c3 = FORMONLY.col3, TITLE="C3", STYLE="bigfont";
END
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.*);
END
```

Program source file:

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF RECORD
      col1 INTEGER,
      col2 STRING,
      col3 STRING
  END RECORD,
  i INTEGER

  FOR i=1 TO 20
    LET arr[i].col1 = i
    LET arr[i].col2 = "Item #"||i
    LET arr[i].col3 = IIF(i MOD 2, "odd", "even")
  END FOR

  CALL ui.Interface.loadStyles("styles")

  OPEN FORM f1 FROM "form"
  DISPLAY FORM f1

  DISPLAY ARRAY arr TO sr.*
END MAIN
```

Graphical result:
How the styles were applied

1. The odd rows get a yellow background because of the name="Table:odd" style (using the odd pseudo-selector).

2. Column 3 defined with the bigfont style name gets a large font because of the name=".bigfont" style.

Understanding form files

A form specification file is a source file that defines an application form providing for end user interaction with a program.

The form file defines the disposition, presentation (in other words the decoration), and behavior of screen elements called form items.
The source file must have the .per file extension: myform.per. Programs load the .42f compiled version of the form files, and use interactive instructions (dialogs) to control the form.

To compile a .per source file to a .42f format, use the fglform form compiler. When a SCHEMA is specified in the form file, fglform requires that the database schema file already exist. Compiled form files depend on both the source files and the database schema files.

Compiled forms will be loaded by the programs with the OPEN FORM or the OPEN WINDOW WITH FORM instructions. The .42f form file is searched for in several directories, as described in the FGLRESOURCEPATH reference topic.

Once a form is loaded, the program can manipulate forms to display or let the user edit data, with interactive instructions such as INPUT or DISPLAY ARRAY. Program variables are used as display and/or input buffers.

The content of a .per form file must follow a specific syntax as described in Form file structure on page 1188.

Form file concepts
To write a form specification file, you need to understand the concepts described in this section.

• Form items on page 1133
• External form inclusion on page 1161
• Boolean expressions in forms on page 1162

Form items
The concept of form item includes all elements used in the definition of a form.

Definition
A form item can be an input field such as an EDIT field, a push BUTTON, a GROUPBOX, or a TABLE container. A form item can also be an element of a TOOLBAR, TOPMENU, and ACTION DEFAULTS definition.

A form item can be:
• A satellite item
• A static item
• A layout item
• A stack item
• An action view
• A form field

Form item types
A form item is defined by its type, called a form item type. For example, a form field can be an EDIT, or a COMBOBOX. A form layout container can be a GROUP, or a GRID. A toolbar item can be an ITEM or a SEPARATOR.

For a detailed description, see Form item types on page 1163.
Form items in grid-based containers

In a grid-based container such as GRID, form items (typically, form fields) must be defined with a form tag in the LAYOUT section, bound by the tag name to a definition in the ATTRIBUTES section.

The form tag defines the position and length of the form item, while the appearance and the behavior of the form item is defined by a set of attributes in the ATTRIBUTES section:

```
LAYOUT
GRID
{
   [f1   ]
   ...  
}
END
END
...
ATTRIBUTES
EDIT f1 = customer.cust_name, ... ;
END
```

Form items in stack-based forms

In a stack-based container (STACK), form items (typically, form fields), are grouped and arranged in a given order, that will define their position in the stacked layout. The appearance and the behavior of the form item is defined by a list of attributes in the stack item definition:

```
LAYOUT
STACK
GROUP
   EDIT customer.cust_name, ... ;
END
END
END
```

Satellite form items

Other kinds of form items are defined in the section it belongs to (for example, an ITEM element of a TOOLBAR definition).

Related concepts

ATTRIBUTES section on page 1221
The ATTRIBUTES section describes properties of grid-based layout elements used in the form.

Stack-based layout on page 1322
A form file can define a stack-based layout within a tree of stack items.

Satellite items

Satellite items are display elements defined outside the LAYOUT section.

Satellite items like the TOOLBAR section are form elements independent from the main form layout, and are defined in addition to the LAYOUT section.

```
TOOLBAR -- Toolbar section
...
END
LAYOUT -- Main layout section
...
END
```
Related concepts

**ACTION DEFAULTS** section on page 1189
The **ACTION DEFAULTS** section defines local action view default attributes for the form elements.

**TOOLBAR** section on page 1192
The **TOOLBAR** section defines a toolbar with buttons that are bound to actions.

**TOPMENU** section on page 1190
The **TOPMENU** section defines a pull-down menu with options that are bound to actions.

**Static items**

A static item defines a simple form item as a final grid element that does not change.

A static item is a form element, such as text (typically, a field label), that is defined directly in a grid of the form **LAYOUT** section.

Static items are identified by the *fglform* compiler and converted to an AUI tree node element in the resulting *42f* file.

**Simple texts**

It is possible to define simple texts and field labels in the form layout:

```
LAYOUT
GRID
{ A simple text
} END
END
```

**Note:** To simplify internationalization, consider using named static labels instead of hard-coded text in the form layout.

**Horizontal lines**

You define a horizontal line with a sequence of hyphen-minus (-) characters in a grid:

```
LAYOUT
GRID
{ This is a horizontal line: ------------
} END
END
```

**Note:** Horizontal lines are mainly provided for TUI mode applications. While horizontal lines will be represented by some GUI front-ends, it is not a typical practice in common graphical applications.

Related concepts

**GRID container** on page 1201
Defines a layout area based on a grid of cells.

**LAYOUT** section on page 1194
The **LAYOUT** section defines the graphical alignment of the form by using a tree of layout containers.

**Layout items**

Layout items are containers with a body that can hold other form items, in a grid-based layout form.

Layout items can be specified as a tree of nested containers, or as layout tags within a single **GRID** container.
The example shows a tree of nested containers, where a GRID and TABLE are included in a VBOX:

```
LAYOUT
  VBOX
    GRID ...
    { }
    END
  TABLE ...
    { }
    END
END
```

The example shows a GRID container including layout tags. The layout tags group form fields in dedicated areas. This syntax is usually more convenient to describe application forms:

```
LAYOUT
  GRID
  {<g g1                     >
    Name: [f01              ]
    <                         >
    <t t1                     >
    [c1  |c2                  ]
    <                         >
  }
END
END
```

**Related concepts**

LAYOUT section on page 1194

The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

**Stack items**

*Stack items* are form elements used to define a stack-based layout in a STACK container.

To define a stacked layout within a STACK container, leaf stack items (typically, form fields, labels, buttons) are specified inside grouping stack items such as GROUP or TABLE.

The example shows a stack-based form definition with a GROUP stack item containing two EDIT stack items:

```
LAYOUT
  STACK
    GROUP g1
      EDIT customer.cust_num, NOENTRY;
      EDIT customer.cust_name, REQUIRED;
    END
END
```

**Related concepts**

STACK container on page 1202

The STACK container holds stack items defining a logical alignment of form items.

GRID container on page 1201
Defines a layout area based on a grid of cells.

**Action views**

An action view defines a form item that can trigger an action in the program.

**Action views as satellite items**

Below is TOOLBAR section defining a toolbar button using the close action name. Here no layout tag is used because the toolbar item is part of the toolbar graphical object (it will not appear in the form layout area):

```
TOOLBAR
  ITEM close (TEXT="Close")
END
```

**Action views in grid-based container**

The position and size of the element is defined with an item tag, while the rendering and behavior is defined in the ATTRIBUTES section. Both parts are bound by the name of the item tag. The item tag name is local to the .per file and is not available at runtime.

The example defines a BUTTON form item, where the item tag name is "b_close", and the button name (and the action name) is "close":

```
LAYOUT
GRID
{
  ...
  [b_close ]
}
END
END
... ATTRIBUTES
BUTTON b_close: close, TEXT="Close";
END
```

**Action views in stack-based layout**

In a stack-based container, action views are defined as stack items, with the attribute defining the rendering and behavior:

```
LAYOUT
STACK
  GROUP group1 ( TEXT="Customer" )
  ...
  BUTTON print, TEXT="Print Report", IMAGE="printer";
  ...
```

**Related concepts**

- **STACK container** on page 1202
  The STACK container holds stack items defining a logical alignment of form items.
- **GRID container** on page 1201
Defines a layout area based on a grid of cells.

Form fields

Form fields are form elements designed for data input and/or data display.

Purpose of form fields

A form field is a form item dedicated to data management. It associates a form item with a screen record field. The screen record field is used to bind program variables in interaction instructions (for example, dialogs). The program variables are the data models for the form fields.

There are different types of form fields:

- Database column fields on page 1139
- Formonly fields on page 1141
- Phantom fields on page 1142
- Aggregate fields on page 1144

Form fields can be used in a grid-based layout or in a stack-based layout.

Form fields are identified by the field name in programs, and are grouped in screen records (or screen arrays in the case of list containers). The interactive instruction must mediate between screen record fields and database columns by using program variables.

Form fields are usually related to database column, which types are defined in the database schema file.

Forms fields in grid-based containers

In a grid-based container, the position and size of a form field is defined with an item tag in the form layout, while the rendering and behavior is defined in the ATTRIBUTES section. Both parts are bound by the name of the item tag. The item tag name is local to the .per file and is not available at runtime: It is just the key to bind the item tag (position) with the item definition (attributes).

In the grid-based example, the "f1" item tag (in the LAYOUT section) is linked to the "vehicle.num" form field definition (in the ATTRIBUTES section), which references a column of the "vehicle" table, defined in the "carstore" database schema:

```
SCHEMA carstore
LAYOUT
GRID
{  
   Number:   [f1            ]
   Name:     [f2                        ]
  }
END
END
TABLES
   vehicle
END
ATTRIBUTES
   EDIT f1 = vehicle.num, STYLE="keycol";
   EDIT f2 = vehicle.name, UPSHIFT;
END
```

Forms fields in stack-based containers

In a stack-based container, the visual position of a form field is defined by the ordinal position of the stack item in the stack definition, while the rendering and behavior are defined with stack item attributes.
In the stack-based example, the "vehicle.num" form field definition references a column of the "vehicle" table, defined in the "carstore" database schema:

```
SCHEMA carstore
LAYOUT
  STACK
    GROUP
      EDIT vehicle.num, REQUIRED, STYLE="keycol";
    END
  END
END
TABLES
  vehicle
END
```

**Related concepts**

- **Grid-based layout** on page 1309
  A form file can define a grid-based layout within a tree of layout items.

- **Stack-based layout** on page 1322
  A form file can define a stack-based layout within a tree of stack items.

- **Variables** on page 366
  Explains how to define program variables.

- **Binding variables to form fields** on page 1620
  Some dialogs need program variables to store form field values.

**Database column fields**

Form fields defined with a table and column name get data type from the database schema file.

**Syntax 1: In grid-based container**

```
item-type item-tag = [table.]column
  ↓, attribute-list ↓;
```

**Syntax 2: In stack-based container**

```
item-type [table.]column
  ↓, attribute-list ↓;
```

1. `item-type` references an item type like `EDIT`.
2. `item-tag` identifies the layout location of the field.
3. `table` is the name or alias of a table, synonym, or view, as declared in the `TABLES` section.
4. `column` is the name of a database column.
5. `attribute-list` is a list of field attributes.

**Usage**

A form field is typically based on the definition of a database column found in the database schema specified with the `SCHEMA` clause at the beginning of the form file. The database column defines the data type of the form field.

**Important**: The data type of a form field is only used by the `CONSTRUCT` interactive statement to do database queries. When using the form field with an `INPUT`, `INPUT ARRAY` or `DISPLAY ARRAY` dialog, the type of the program variable defines the data type of the form field.

In order to reference database columns, the table name must be listed in the `TABLES` section of the form.

Fields are associated with database columns only during the compilation of the form specification file: The form compiler examines the database schema file to identify the data type of the column, and defines the form field with
this type. This technique allows form field data types in the schema files to be centralized. If the data type of a column changes, extract the schema again and recompile your forms to take the new type into account.

**Note:** The compilers also grab other field attributes like validation rules and video display attributes from .val and .att schema files. However, this is supported for backward compatibility only (formerly stored in syscolval and syscolatt database tables). Consider reviewing programs using this feature.

After the form compiler identifies data types from the schema file, the association between fields and database columns is broken, and the form cannot distinguish the name or synonym of a table or view from the name of a screen record.

The programs only have access to screen record fields, in order to display or input data using program variables. Regardless of how you define them, there is no implicit relationship between the values of program variables, form fields, and database columns. Even, for example, if you declare a variable `lname LIKE customer.lname`, the changes that you make to the variable do not imply any change in the column value. Functional relationships among these entities must be specified in the program code, through screen interaction statements, and through SQL statements. It is up to the programmer to determine what data a form displays and what to do with data values that the user enters into the fields of a form. You must indicate the binding explicitly in any statement that connects variables to forms or to database columns.

If a form field is declared with a table column using the SERIAL, SERIAL8 or BIGSERIAL SQL type, the field will automatically get the `NOENTRY` attribute, except if the field is defined with the `TYPE LIKE` syntax.

**Example**

Grid-based container database form field definition:

```plaintext```
SCHEMA stores  -- Database schema
LAYOUT
GRID
{
  [f001             ]
  ...
}
END
END
TABLES
  customer  -- Database table
END
ATTRIBUTES
  EDIT f001 = customer.fname,  -- DB-col form field
       REQUIRED, COMMENTS="Customer name";
...
```

Stack-based container database form field definition:

```plaintext```
SCHEMA stores  -- Database schema
TABLES
  customer  -- Database table
END
LAYOUT
  STACK
GROUP
    EDIT customer.fname, -- DB-col form field
    REQUIRED, COMMENTS="Customer name";
...
```

**Related concepts**

- **Variables** on page 366
  
  Explains how to define program variables.

- **Stack-based layout** on page 1322
A form file can define a stack-based layout within a tree of stack items.

**Grid-based layout** on page 1309
A form file can define a grid-based layout within a tree of layout items.

**Query by example (CONSTRUCT)** on page 1461
The CONSTRUCT instruction implements database query criteria input in an application form.

Form only fields
FORMONLY form fields define their data type explicitly, with or without referencing a database column.

**Syntax 1: In grid-based container**

```
item-type item-tag = FORMONLY.field-name
   ↓ TYPE
   ↓ LIKE [table.]column
   ↓ datatype NOT NULL
   ↓ , attribute-list
```

**Syntax 2: In stack-based container**

```
item-type FORMONLY.field-name
   ↓ TYPE
   ↓ LIKE [table.]column
   ↓ datatype NOT NULL
   ↓ , attribute-list
```

where `datatype` is one of:

```
| CHAR
| DECIMAL [(p[,s])] |
| SMALLFLOAT |
| REAL |
| FLOAT |
| MONEY [(p[,s])] |
| INTEGER |
| SMALLINT |
| DATE |
| VARCHAR |
| TEXT |
| BYTE |
| INTERVAL interval-qualifier |
| DATETIME datetime-qualifier |
| BIGINT |
| BOOLEAN |
```

1. `table` is the name or alias of a table, synonym, or view, as declared in the TABLES section.
2. `column` is the name of a database column.
3. `field-name` is the identifier that will be used in programs to handle the field.
4. `interval-qualifier` is an INTERVAL qualification clause such as `HOUR (5) TO SECOND`.
5. `datetime-qualifier` is a DATETIME qualification clause such as `DAY TO SECOND`.

**Usage**

Form fields can be specified with the FORMONLY prefix, when there is no corresponding database column, or when the field must be defined with another name to that of the database column.
**Important:** The data type of a form field is only used by the CONSTRUCT interactive statement to do database queries. When using the form field with an INPUT, INPUT ARRAY or DISPLAY ARRAY dialog, the type of the program variable defines the data type of the form field.

When using the LIKE 
{table columna} syntax, the form field gets the data type of the specific table column as defined in the database schema. The table name must be specified in the TABLES section.

When using the TYPE datatype clause, you explicitly specify the type of the field.

**Note:** For CHAR/VARCHAR data types, the size is defined by the item tag length in the layout.

If no data type is specified, and no database column is referenced, the default data type is CHAR.

Specifying a data type followed by the NOT NULL keyword is equivalent to the NOT NULL attribute.

The STRING data type is not supported in FORMONLY form field definitions.

The definition of FORMONLY fields can be completed by using the DISPLAY LIKE and VALIDATE LIKE attributes, to get the display and validation attributes from the .att and .val database schema files.

**Example**

Grid-based container FORMONLY form field definition (in the ATTRIBUTES section):

```plaintext
LAYOUT
GRID
{
  [f001             ]
  [f002             ]
  ...
}
END
END
ATTRIBUTES
EDIT f001 = FORMONLY.total TYPE DECIMAL(10,2), NOENTRY ;
EDIT f002 = FORMONLY.name TYPE LIKE customer.cust_name,
            VALIDATE LIKE customer.cust_name ;
```

Stack-based container FORMONLY form field definition:

```plaintext
LAYOUT
STACK
GROUP
  EDIT FORMONLY.total TYPE DECIMAL(10,2), NOENTRY ;
  EDIT FORMONLY.name TYPE LIKE customer.cust_name, REQUIRED;
```

**Related concepts**

**Variables** on page 366
Explains how to define program variables.

**Stack-based layout** on page 1322
A form file can define a stack-based layout within a tree of stack items.

**Grid-based layout** on page 1309
A form file can define a grid-based layout within a tree of layout items.

**Phantom fields**
A PHANTOM field defines a screen-record field which is not rendered in the layout (it acts as a hidden field).

**Syntax**

```
PHANTOM  \  [table columna]
         |  FORMONLY.field-name
         \  TYPE
```
\begin{verbatim}
\{ LIKE \{table.\column \n\{ data-type \{NOT NULL\} \n\} \};
\}
\end{verbatim}

where \textit{datatype} is one of:

\begin{verbatim}
\{ CHAR \n\{ DECIMAL \{p,s\}\} \n\{ SMALLFLOAT \n\{ REAL \n\{ FLOAT \n\{ MONEY \{p,s\}\} \n\{ INTEGER \n\{ SMALLINT \n\{ DATE \n\{ VARCHAR \n\{ TEXT \n\{ BYTE \n\{ INTERVAL \textit{interval-qualifier} \n\{ DATETIME \textit{datetime-qualifier} \n\{ BIGINT \n\{ BOOLEAN \n\}\end{verbatim}

1. \textit{table} is the name or alias of a table, synonym, or view, as declared in the TABLES section.
2. \textit{column} is the name of a database column.
3. \textit{field-name} is the identifier that will be used in programs to handle the field.
4. \textit{interval-qualifier} is an \texttt{INTERVAL} qualification clause such as \texttt{HOUR(5) TO SECOND}.
5. \textit{datetime-qualifier} is a \texttt{DATETIME} qualification clause such as \texttt{DAY TO SECOND}.

\textbf{Usage:}

A \texttt{PHANTOM} field defines a form field listed in a screen-record or screen-array, that has no corresponding layout element. It is only used for the screen-record (or screen-array) definition, to bind with program variables used by dialogs, typically to match a given database table definition.

Phantom fields are used by dialog instructions as regular form fields, but are not displayed to the end user, and the end user is not able to enter values for these fields. Data held by phantom fields is never send to the front-ends. They can be used to store critical data that must not go out of the application server.

Phantom fields can be based on columns defined in a database schema file, or as \texttt{FORMONLY} field.

For example, if you want to implement a screen-array with all the columns of a database table defined in the database schema file, but you don’t want to display all the columns in the \texttt{TABLE} container of the \texttt{LAYOUT} section, you must use \texttt{PHANTOM} fields. With the screen-array matching the database table, you can easily write program code to fetch all columns into an array defined with a \texttt{LIKE} clause.

\textbf{Example (grid-based layout)}

Form file:

\begin{verbatim}
SCHEMA carstore
LAYOUT( TEXT = "Vehicles" )
GRID
{<T t1                                  >}
| Num      Name            Price |
| c1 | c2 | c3    |
| c1 | c2 | c3    |
| c1 | c2 | c3    |
\}
\end{verbatim}
Program code:

```
SCHEMA carstore
...
DEFINE vl DYNAMIC ARRAY OF RECORD LIKE vehicle.*
...
DISPLAY ARRAY vl TO sr.*
...
```

Related concepts

- **Screen records / arrays** on page 1147
  Form fields can be grouped in a *screen record* or *screen array* definition.
- **Array binding in list controllers** on page 1731
  Program array elements are bound to screen arrays elements in the definition of the `DISPLAY ARRAY` or `INPUT ARRAY` list dialog.
- **GRID container** on page 1201
  Defines a layout area based on a grid of cells.

Aggregate fields

An **AGGREGATE** field defines a screen-record field to display summary information for a `TABLE` column.

**Syntax**

```
AGGREGATE item-tag = field-name [, attribute-list ] ;
```

1. `item-tag` is an identifier that defines the name of the item tag in the layout section.
2. `field-name` identifies the name of the screen record field.
3. `attribute-list` defines the aspect and behavior of the form item.

**Usage**

An **AGGREGATE** field defines a form field that is used to display a summary cell for a given column of a `TABLE` container. The aggregate fields are displayed after the last data line of the table. Such fields are typically used to show computed values for the corresponding column which appears above the aggregate cell.

**Important:** This feature is not supported on mobile platforms.

An aggregate field can be based on a database column defined in a schema file, or as `FORMONLY` field.

The **AGGREGATETYPE** attribute defines how the value of the field will be computed. For example, the **SUM** keyword (the default) can be used to instruct the runtime system to automatically compute the total of the associated column. By using the **PROGRAM** keyword, you indicate that the value of the aggregate field will be computed and displayed by program code. A simple `DISPLAY BY NAME` or `DISPLAY TO` can be used to show the summary value.
The value displayed in the AGGREGATE field follows the FORMAT attribute of the corresponding column, if defined. The FORMAT attribute is applied for automatically computed values, as well as for values displayed by user code with DISPLAY BY NAME or DISPLAY TO.

The label of an aggregate field can be specified with the AGGREGATETEXT attribute. The text defined with this attribute will be displayed on the left of the aggregate value (in the aggregate cell), except if there is no room to display the label (for example if the aggregate value is too large or if the column values are aligned to the left). An aggregate label can be a localized string with the "%"..." string syntax. You can also specify an AGGREGATETEXT attribute at the TABLE level, to get a global label for the summary line. If no text is defined for an aggregate field, the global aggregate text will appear on the left in the summary line.

Table aggregate decoration can be modified with a presentation style. Use the summaryLine pseudo-selector to change the font type and color, as well as the background of the summary line. Use the summaryLineAlwaysAtBottom table style attribute to force the summary line to stay on the bottom of the table.

**Aggregate fields in grid-based layout**

The item tag of an aggregate field must appear in the last line in the layout block of the TABLE container, and must be aligned vertically with a table column item tag. You can specify several aggregate item tags for the same table:

```plaintext
TABLE {
  [c1  | c2  | c3  | c4  | c5  ]
  [c1  | c2  | c3  | c4  | c5  ]
  [c1  | c2  | c3  | c4  | c5  ]
  [cnt ]
  [tot_c4 | tot_c5 ]
}
END

Aggregate fields in stack-based layout

**Important:** Aggregate fields are not supported in tables defined in a STACK container.

**Example (grid-based layout)**

```plaintext
SCHEMA stores
LAYOUT( TEXT = "Orders" )
GRID {
  <T t1>
    Num Date Order total
    [c1  | c2  | c3  | c4  | c5  ]
    [c1  | c2  | c3  | c4  | c5  ]
    [c1  | c2  | c3  | c4  | c5  ]
    [c1  | c2  | c3  | c4  | c5  ]
    [total ]
  }
END
END
TABLES
  orders
END
ATTRIBUTES
  TABLE t1: table1;
  EDIT c1 = orders.o_num;
  EDIT c2 = orders.o_date;
  EDIT c3 = orders.o_tot;
  AGGREGATE total = FORMONLY.o_total,
    AGGREGATETEXT = "Total:",
    AGGREGATETYPE = SUM;
END
```
INSTRUCTIONS
SCREEN RECORD sr(orders.*);
END

Related concepts
AGGREGATE item definition on page 1223
Defines screen-record fields that hold computed values to be displayed as footer cells in a TABLE container.

STACK container on page 1202
The STACK container holds stack items defining a logical alignment of form items.

GRID container on page 1201
Defines a layout area based on a grid of cells.

Pseudo selectors on page 1068
Pseudo selectors can be used to apply style only when some conditions are fulfilled.

Identifying form items
Elements defined in a form file can be identified with a name, to be used in programs.

Form fields are implicitly identified by the tabname.colname specification after the equal sign, while other (non-field) form items such as static labels and group boxes can get an optional item name.

The form item name defined in the form file will be copied to the name attribute of the corresponding node in the .42f file. It can then be used by programs to select a form element at runtime, to introspect or modify its attributes.

For example, specify the name for a GROUP container by writing an identifier after the layout container type:

```
GROUP group1 (TEXT="Customer")
```

Here the group name is 'group1', and it can be used in a program to identify the group element:

```
DEFINE w ui.Window
DEFINE g om.DomNode
LET w = ui.Window.getCurrent()
LET g = w.findNode("Group","group1")
CALL g.setAttribute("text","Another text")
```

Helper methods are provided for common tasks on form elements. For example, to hide a group with the identifier group1, you can use the setElementHidden() method on a ui.Form object:

```
DEFINE f ui.Form
...
LET f = DIALOG.getForm()
...
CALL f.setElementHidden("group1", TRUE)
```

Note: Consider defining unique names to identify form elements, and to simplify the search at runtime. A good practice is the use of a prefix based on the type of form element (g_ for groups, l_ for labels for example).

Static items in a grid-based layout container cannot get a name, because these are self-defined with the layout part of the item:

```
GRID
{
  Name: [f1 ]
  ...
}
END
```
In the above example, the label "Name:" cannot be identified. In order to give a name to such a label, use an item tag and add a LABEL line in the ATTRIBUTES section, and specify the name of the label after the colon:

```plaintext
GRID
{
  [l1] [f1]
  ...
}
END
ATRIBUTES
LABEL l1: l_name, TEXT="Name:";
...
```

**Related concepts**

**ATTRIBUTES section** on page 1221
The ATTRIBUTES section describes properties of grid-based layout elements used in the form.

**GRID container** on page 1201
Defines a layout area based on a grid of cells.

**STACK container** on page 1202
The STACK container holds stack items defining a logical alignment of form items.

**Screen records / arrays**

Form fields can be grouped in a screen record or screen array definition.

**Syntax**

```plaintext
SCREEN RECORD record-name [ size ] ( field-list )
```

where field-list is:

```plaintext
  | table.*
  | field-name
  | first-field | THROUGH | THRU | last-field |
  | ... |
```

1. `record-name` is the name of an explicit screen record or screen array.
2. `size` is an integer representing the number of records in the screen array. If the size is not specified in the SCREEN RECORD definition, it is deduced from the corresponding list container in the form layout.
3. `field-name` is a field identifier as defined in the right operand of a field definition in the ATTRIBUTES section.
4. `first-field` and `last-field` are field identifiers like `field-name`. This notation instructs the form compiler to take all the fields defined between the first and last field (inclusive).
5. `table` is the name or alias of a table, synonym, or view, as declared in the TABLES section. This notation instructs the form compiler to build the screen record with all fields declared in the ATTRIBUTES section for the given table.

**Usage**

Screen records and screen arrays are defined with the SCREEN RECORD keywords in the INSTRUCTIONS section of a form specification file to name a group of fields.

**Screen records**

A screen record is a named group of fields that screen interaction statements of the program can reference as a single object.

A screen record is the form-counterpart of a RECORD variable in your program.
By establishing a correspondence between a set of screen fields (the screen record) and a set of program variables (typically a program record), you can pass values between the program and the fields of the screen record.

In many applications, it is convenient to define a screen record that corresponds to a row of a database table.

The elements of a screen record are associated by name to a form field and the corresponding form item tag in the layout section, through its definition in the ATTRIBUTES section:

```
SCHEMA myshop
LAYOUT
  ...
  [f1] <--------+
  ...
END
TABLES
  customer
END
ATTRIBUTES
  ...
  f1 = customer.cust_name; ----+
  ...
  ^-----------------+
END
INSTRUCTIONS
  SCREEN RECORD sr_customer
    (...)
      customer.cust_name, ------------+
      ...
END
```

Like the name of a screen field, the identifier of a screen record must be unique within the form, and its scope is restricted to when its form is open. Interactive statements can reference `record-name` only when the screen form that includes it is being displayed. The form compiler returns an error if `record-name` is the same as the name or alias of a table in the TABLES section.

```
SCHEMA myshop
LAYOUT
  GRID
  {
    Customer id: [f1]
    Name: [f2]
    Create date: [f3]
  }
END
TABLES
  customer
END
ATTRIBUTES
  f1 = customer.cust_id;
  f2 = customer.cust_name;
  f3 = customer.cust_crea;
END
INSTRUCTIONS
  SCREEN RECORD sr_customer
    {
      customer.cust_id,
      customer.cust_name,
      customer.cust_crea
    );
```
Default screen records

The form compiler builds default screen records that consist of all the screen fields linked to the same database table within a given form. A default screen record is automatically created for each table that is used to reference a field in the ATTRIBUTES section.

The components of the default record correspond to the set of display fields that are linked to columns in that table. The name of the default screen record is the table name (or the alias, if you have declared an alias for that table in the TABLES section).

For example, all the fields linked to columns of the "customer" table constitute a default screen record whose name is "customer".

**Tip:** To find out what default screen records are created by the form compiler, check the RecordView nodes produced in the .42f file.

If a form includes one or more FORMONLY fields, those fields constitute a default screen record with the name "formonly".

Screen arrays

A screen array is a screen record with a dimension, to handle a list of records in layout containers such as TABLE, TREE, SCROLLGRID, or static field lists.

A screen array is the form-counterpart of a DYNAMIC ARRAY OF RECORD variable in your program.

**Note:** Screen arrays are associated with list containers, by comparing the fields and columns used in their definitions. Therefore, it is not possible to define multiple screen arrays for the same list container.

Each row of a screen array is a screen record. Each column of a screen array consists of fields with the same field tag ([f1 ]) in the LAYOUT section.

Screen arrays are typically defined with SCREEN RECORD using a [size] specification:

```
SCREEN RECORD sa_custlist[20]
(  
customer.cust_id,
  customer.cust_name,
  customer.cust_crea
);
```

The [size] can be omitted: When not specified, the screen array automatically gets the size of the corresponding list container (TABLE, TREE, SCROLLGRID or static field list), as defined in the form layout.

**Important:** If the screen array size is 1, it becomes a simple screen record.

If the size is specified, it must be equal to the number of lines of the list container in the layout of the form.

For resizable list containers, when the size is specified in the SCREEN RECORD definition, it can be considered as the default number of rows. At runtime, the list container may be resized, and the screen array can be used in the program with a screen row index that is greater than the default size specified in the form file. For example:

```
INPUT cust_record.* FROM sa_custlist[arr_curr()].*
```

In this example, a TABLE container represents a set of fields organized in columns:

```
LAYOUT
  TABLE
  {
    [f1] [f2] [f3]  
    [f1] [f2] [f3]  
  }
```
With the above TABLE container, when specified, the screen array size must be 4:

```plaintext
SCREEN RECORD sa_custlist[4]
(
  customer.cust_id,
  customer.cust_name,
  customer.cust_crea
);
```

Or, the screen array can be defined without a size:

```plaintext
SCREEN RECORD sa_custlist
(
  customer.cust_id,
  customer.cust_name,
  customer.cust_crea
);
```

**Using screen records and screen arrays in programs**

Screen records and screen arrays can display program records. If the fields in the screen record have the same sequence of data types as the columns in a database table, you can use the screen record to simplify operations that pass values between program variables and rows of the database.

Screen records are usually not referenced in programs within single record input statements, because program variable to form field binding is typically done by name with the `INPUT BY NAME` instruction:

```plaintext
DEFINE cust_rec RECORD LIKE customer.*
...
INPUT BY NAME cust_rec.*
...
```

Screen arrays are typically referenced in programs within interactive dialog controlling a list of records such as `DISPLAY ARRAY` and `INPUT ARRAY`. The current form must include that named screen array:

```plaintext
DEFINE cust_arr DYNAMIC ARRAY OF RECORD LIKE customer.*
...
DISPLAY ARRAY cust_arr TO sa_custlist.*
...
```

Form tags on page 1151

Form tags define layout elements inside a grid-based container.

Form tags define layout elements inside a grid-based container.

Form tags are place holders used inside a grid of the layout section, to define the position and the relation between form items.

The syntax and purpose of a form tag depends on the type of form tag.

The different sort of form tags are:

- Layout tags on page 1151
- Item tags on page 1155
- Hbox tags on page 1158

Layout tags

Layout tags define layout areas for containers inside the frame of a grid-based container.

Syntax

```
<type [identifier] >

1. <                        > (optional)

1. type defines the kind of layout tag to be inserted at this position.
2. identifier references a form item definition in the ATTRIBUTES section, it must be unique, but is optional.
3. content defines other form items inside the layout tag.
4. The (< >) ending the layout tag body is optional.

Usage

A layout tag defines a layout region of a container, in the body frame of a GRID container.

While complex layout with nested frames can be defined with HBOX and VBOX containers, it is sometimes more convenient to define a form with a complex layout by using layout tags within a GRID container.

A layout tag has a type that defines the kind of container generated in the compiled form.

A layout tag is delimited by angle brackets (<>, and contains the tag type (G/GROUP, T/TABLE, etc) and an optional identifier.

Table 323: Types of layout tags

<table>
<thead>
<tr>
<th>Tag Type</th>
<th>Abbr.</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GROUP</td>
<td>G</td>
<td>Defines a group box layout tag, resulting in the same presentation as the GROUP container.</td>
</tr>
<tr>
<td>TABLE</td>
<td>T</td>
<td>Defines a table view layout tag, resulting in the same presentation as the TABLE container.</td>
</tr>
<tr>
<td>TREE</td>
<td>N/A</td>
<td>Defines a tree-view list view layout tag, resulting in the same presentation as the TREE container.</td>
</tr>
<tr>
<td>SCROLLGRID</td>
<td>S</td>
<td>Defines a scrollable grid layout tag, resulting in the same presentation as the SCROLLGRID container.</td>
</tr>
</tbody>
</table>
The details of the layout tag definition are specified in the **ATTRIBUTE** section. Layout tags must be identified by an item tag name. In the example, the layout tag named "g1" is defined in the **ATTRIBUTE** section with the **GROUP** form item type to set the name and text of the element:

```
LAYOUT
GRID
{
  <GROUP g1        >
  [text1           ]
  [                ]
  [                ]
  <                >
END
END
ATTRIBUTES
GROUP g1:group1, TEXT="Description";
TEXTEDIT text1=FORMONLY.text1;
END
```

In the **ATTRIBUTES** section, the group element definition is bound to the layout item tag with the name "g1". The AUI element name will be "group1". This name can then be used in programs to manipulate the group element, for example with `ui.Form.setElementHidden("group1",1)`.

The layout region is a rectangle, in which the width is defined by the length of the layout tag, and the height by a closing tag (`< >`). In the example, the layout region is defined by the layout tag named "group1".

```
<GROUP group1            >
<                        >
```

Form items must be placed inside the layout region. The `[]` square brackets are not part of the form item's width and can be place at the same X position as the layout tag delimiters:

```
<GROUP group1            >
  Item:   [f001          ]
  Quantity: [f002       ]
  Date:   [f003          ]
<                        >
```

The `[]` square brace delimiters are not counted to define the width of an item tag. The width of the item is defined by the number of character between the square brackets. Thus, this layout is valid and can be compiled:

```
<GROUP group1            >
  [f001          ]
  [f002       ]
  Static labels must fit!!
<                        >
```

You can place several layout tags on the same layout line in order to split the frame horizontally. This example defines six layout regions (four group boxes and two tables):

```
<GROUP group1            ><GROUP group2               ><GROUP group4 >
  FName: [f001           ] Phone: [f004               ][f012   ]
  LName: [f002           ] EMail: [f005               ]
```

You can place several layout tags on the same layout line in order to split the frame horizontally. This example defines six layout regions (four group boxes and two tables):

```
<GROUP group1            ><GROUP group2               ><GROUP group4 >
  FName: [f001           ] Phone: [f004               ][f012   ]
  LName: [f002           ] EMail: [f005               ]
```
The `<` > closing layout tag is optional. When not specified, the end of the layout region is defined by the underlying layout tag or by the end of the current grid. However, the ending tag must be specified if the form compiler cannot detect the end of the layout region. This is usually the case with group layout tags.

In the example, the table does not need an ending layout tag because it is defined by the starting tag of the group, but the group needs an ending tag otherwise it would include the last field (`field3`). Additionally, if `field3` had a different size, the form compiler would raise an error because the group and the last field geometry would conflict.

It is possible to mix container layout tags with singular form items. You typically put form items using a large area of the form, such as `IMAGE` fields or `TEXTEDIT` fields. The `[ ]` square brace delimiters are not used to compute the size of the singular form items:

Table layout tags can be embedded inside group layout tags:

Hbox or vbox containers with splitter are automatically created by the form compiler in these conditions:

- Hbox is created when two or more stretchable elements are stacked side by side and touch each other (no space between).
- Vbox is created when two or more stretchable elements are stacked vertically and touch each other (no space between).
Stretchable elements are containers such as TABLE containers, or form items like IMAGE fields with the STRETCH attribute.

No hbox or vbox object will be created if the elements are in a SCROLLGRID container.

This example defines two tables stacked vertically, generating a VBox with splitter (note that ending tags are omitted):

```
<TABLE table1     >
[ colA | colB ]
[ colA | colB ]
[ colA | colB ]
[ colA | colB ]
<TABLE table2     >
[ colC | colD ]
[ colC | colD ]
```

In this example, the layout defines two stretchable TEXTEDIT fields placed side by side which would generate an automatic hbox with splitter. To make both textedits touch you need to use a pipe delimiter in between:

```
[ textedit1 | textedit2 ]
[          |          ]
[          |          ]
```

The next layout example would make the form compiler create an automatic vbox with splitter to hold table2 and textedit1, plus an hbox with splitter to hold table1 and the first VBox (We must use a pipe character to delimit the end of colB and textedit1 so that both tables can be placed side by side):

```
<TABLE table1     > <TABLE table2     >
[ colA | colB ] [ colC | colD ]
[ colA | colB ] [ colC | colD ]
[ colA | colB ] [ colC | colD ]
[ colA | colB ] | textedit1
[ colA | colB ] |
[ colA | colB ] |
```

If you want to avoid automatic hbox or vbox with splitter creation, you must add blanks between elements:

```
<TABLE table1     > <TABLE table2     >
[ colA | colB ] [ colC | colD ]
[ colA | colB ] [ colC | colD ]
[ colA | colB ] [ colC | colD ]
[ colA | colB ] [ textedit1 ]
[ colA | colB ] [            ]
[ colA | colB ] [            ]
```

Examples

The typical OK/Cancel window:

```
LAYOUT
GRID
{
<GROUP g1     >
[ com            ]
<             >
[ :bok | bno    ]
}
END
END
```
This example shows multiple uses of layout tags:

```xml
LAYOUT
  GRID
  {
    <GROUP g1                          ><GROUP g2         >
    Ident: [f001   ] [f002            ] [text1           ]
    Addr:  [f003                      ] [                ]
    <
    >
    <GROUP g3                                             >
    [text2                                                ]
    [                                                     ]
    [                                                     ]
    <                                                     >
    <TABLE t1                                             >
    Num      Name               State  Value
    |[col1    |col2              |col3  |col4              |
    |[col1    |col2              |col3  |col4              |
    |[col1    |col2              |col3  |col4              |
    |[col1    |col2              |col3  |col4              |
    <
  } END
END

ATTRIBUTES
GROUP g1:group1, TEXT="Customer";
GROUP g2:group2, TEXT="Comments";
TABLE t1:table1, UNSORTABLECOLUMNS;
```

Related concepts

Form rendering on page 1306
The section explains the layout rules to render forms on graphical front-ends.

Grid-based layout on page 1309
A form file can define a grid-based layout within a tree of layout items.

GRID item type on page 1172
Defines a layout area based on a grid of cells.

Automatic HBoxes and VBoxes on page 1312
Horizontal and vertical boxes are added automatically when stretchable elements are used.

Item tags

Item tags define the position and size in a grid-based container.

An item tag defines the position and size of a simple form item in a grid-area of a GRID or SCROLLGRID container. Form items defined with item tags are leaf nodes in the structure of a form definition, such as a form field (meaning that it is not a container form item).

Syntax

```
[identifier \-l i|...|]
```

1. identifier references a form item definition in the ATTRIBUTES section.
2. The optional – dash defines the real width of the element.
3. The pipe can be used as item tag separator (equivalent to \[\].

Usage

An item tag is delimited by square brackets (\[\]) or pipes (\|\) and contains an identifier used to reference the description of the form item in the ATTRIBUTES section. In this example, the identifier of the form item is "f01", and the form item type is BUTTONEDIT:

```
LAYOUT
GRID
{
    ...
    [f01]
    ...
}
END
...
ATTRIBUTES
BUTTONEDIT f01 = customer.cust_name, ACTION=zoom;
...
```

Each item tag must be indicated by left and right delimiters to show the length of the item and its position within the container layout. Both delimiters must appear on the same line. You must use square brackets (\[\]) to delimit item tags. The number of characters and the delimiters define the width of the region to be used by the item:

```
GRID
{
    Name: [f001]
}
END
```

The form item position starts after the open square brace and the length is defined by the number of characters between the square braces. The following example defines a form item starting at position 3, with a length of 2:

```
GRID
{
    1234567890
        [f1]
}
END
```

By default, the real width of the form item is defined by the number of characters used between the tag delimiters. For some special items like BUTTONEDIT, COMBOBOX and DATEEDIT, the width of the field is adjusted to include the button. The form compiler computes the width as: \( width = nbchars - 2 \) if \( nbchars \geq 2 \):

```
GRID
{
    1234567
        [f1]  -- this EDIT gets a width of 7
        [f2]  -- this BUTTONEDIT gets a width of 5 (7-2)
}
END
```

If the default width generated by the form compiler does not fit, the – dash symbol can be used to define the real width of the item. In this example, the form item occupies 7 grid cells, but gets a real width of 5 (this means for an EDIT field, you are able to enter 5 characters):

```
GRID
{
    1234567
```
To make two items appear directly next to each other, you can use the pipe symbol (|) to indicate the end of the first item and the beginning of the second item:

```
GRID
{  Info:   [f001   |f002       |f003   ]
}
END
```

If you need the form to support items with a specific height (more than one line), you can specify *multiple-segment* item tags that occupy several lines of a *grid-area*. To create a multiple-segment item, repeat the item tag delimiters without the item *identifier* on successive lines:

```
GRID
{  Multi-segment:   [f001
[  [  [  [  
]
]
]
]
}
END
```

The notation applies to the new *LAYOUT* section only. For backward compatibility (when using a *SCREEN* section), multiple-segment items can be specified by repeating the *identifier* in sub-lines.

If the same item tag (that is with the same *identifier*) appears more than once in the layout, it defines a column of a screen array (also known as "Matrix").

**Note:** While all repeated item-tags apply to a screen array definition, you must distinguish static screen array columns ("Matrix") defined in a GRID container, from *TABLE* (or *TREE*) column definitions and *SCROLLGRID* row templates.

Example:

```
GRID
{  Single-line static screen array:
    [f001   ] [f002   ] [f003   ]
    [f001   ] [f002   ] [f003   ]
    [f001   ] [f002   ] [f003   ]
    [f001   ] [f002   ] [f003   ]
}
END
...  
ATTRIBUTES
f001 = FORMONLY.field1;
f002 = FORMONLY.field2;
f003 = FORMONLY.field3;
END
INSTRUCTIONS
SCREEN RECORD my_screen_array (FORMONLY.*);
END
```

Multi-line list of fields can be defined as follows:

```
GRID
{  
```
The section explains the layout rules to render forms on graphical front-ends.

GRID container on page 1201
Defines a layout area based on a grid of cells.

ATTRIBUTES section on page 1221
The ATTRIBUTES section describes properties of grid-based layout elements used in the form.

Hbox tags
**Hbox tags** group several item tags within the same horizontal layout box, in a grid-based container.

An Hbox tag defines the position and size in a GRID container for an horizontal box containing several leaf form items. The elements in the Hbox tag can use additional alignment rules to get the required visual affect.

**Syntax**

```
[ element: [ ... ] ]
```

where **element** can be:

```
identifier [-1] \ string-list \n```

where **string-list** is:

```
\ string-literal \ spacer \ [ ... ]
```

1. **identifier** references a form item definition in the ATTRIBUTES section.
2. The optional – dash defines the real width of the element.
3. string-list is a combination of string-literals.
4. **string-literal** is a quoted text that defines a static label.
5. **spacer** is one or more blanks that define an invisible element that expands automatically.
6. The colon is the delimiter for Hbox tag elements.

**Usage**

Hbox tags are provided to control the alignment of form items in a grid. Hbox tags allow you to stack form items horizontally without the elements being influenced by elements above or below. In an Hbox, you can mix form fields, static labels and spacers. A typical use of the hbox is to have zip-code / city form fields side by side with predictable spacing in between.

An hbox tag is delimited by square brackets ([ ]) and must contain at least one **string-list** or an **identifier** preceded or followed by a colon (:). A **string-list** is a combination of **string-literals** (quoted text) and **spacers** (blank characters). The delimiter for hbox tag elements is the colon.
Hbbox tags are not allowed for fields of Screen records / arrays on page 1147; a form compiler error is generated. The client needs a matrix element directly in a grid or a scrollgrid to perform the necessary positioning calculations for the individual fields.

The following example shows simple hbox tags:

```plaintext
GRID
{
  ["Customer info":     ]
  [f001 :         ]
  [:f002              ]
  ["Name: " :f003      ]
}
END
```

In this example:
1. The first hbox tag contains two elements: a static label and a spacer.
2. The second hbox tag contains two elements: a form field and a spacer.
3. The third hbox tag contains two elements: a spacer and a form field.
4. The fourth hbox tag contains two elements: a static label and a form field.

An hbox tag defines the position and width (in grid cells) of several form items grouped inside an horizontal box. The position and width (in grid cells) of the horizontal box is defined by the square brackets ([]) delimiting the hbox tag.

When using an `identifier`, you define the position of a form item which is described in the `ATTRIBUTES` section. When using a `string-list`, you can define static labels and/or spacers. The following example defines an hbox tag generating 7 items (a static label, a spacer, a form item identified by `num`, a spacer, a static label, a spacer and a form item identified by `name`):

```plaintext
GRID
{
  ["Num:" :num : "Name:" :name        ]
}
END
```

A `spacer` is an invisible element that automatically expands. It can be used to align elements left, right or center in the hbox. The following example defines 3 hboxes with the same width. Each hbox contains one field. The first field is aligned to the left, the second is aligned to the right and third is centered:

```plaintext
GRID
{
  [left :              ]
  [         :right     ]
  [     :centered:     ]
}
END

ATTRIBUTES
  LABEL left: label1, TEXT="LEFT";
  LABEL right: label2, TEXT="RIGHT";
  LABEL centered: label3, TEXT="CENTER";
END
```

When you use string literals, the quotes define where the label starts and stops. If there is free space after the quote that ends the label, then it is filled by a spacer. Consider this example:

```plaintext
GRID
{
  [:"Labell1"
  [:"Label2"]
```
In this example:

1. The first line contains a spacer, followed by the static label, followed by another spacer. The quotation marks end the string literal; a colon is not required to delimit the label from the final spacer.
2. The second line contains a spacer, followed by the static label. Because there is no empty space between the end of the static label and the closing bracket of the hbox Tag ( ) .

A typical use of hbox tags is to vertically align some form items - that must appear on the same line - with one or more form items that appear on the other lines:

```
GRID
{ 
  Id:      [num :"Name: ":name ]
 Address: [street          ]
          [zip-code:city       ]
 Phones:  [phone           :fax ]
}
END
```

In this example, the form compiler will generate a grid containing 7 elements (3 labels and 4 hboxes):

1. The label "Id:",
2. A first hbox defines 3 cells, where:
   • The field 'num' will occupy the cell (1,1),
   • The label "Name:" will occupy the cell (2,1),
   • The field 'name' will occupy the cell (3,1).
3. The label "Address:" will occupy cell (1,2),
4. A second hbox defines 1 cell, where:
   • The field 'street' will occupy the cell (1,1).
5. A third hbox defines 2 cells, where:
   • The field 'zip-code' will occupy the cell (1,1),
   • The field 'city' will occupy the cell (2,1).
6. The label "Phones:" will occupy cell (1,4),
7. A fourth hbox defines 2 cells, where:
   • The field 'phone' will occupy the cell (1,1),
   • The field 'fax' will occupy the cell (2,1).

Inside an hbox tag, the positions and widths of elements are independent of other hboxes. It is not possible to align elements over hboxes. The position of items inside an hbox depends on the spacer and the real size of the elements. The following example does not align the items as you would expect, following the character positions in the layout definition:

```
GRID
{ 
  ["Num:   " :fnum :        ]
  ["Name:  " :fname         ]
}
END
```

A big advantage in using elements in an hbox is that the fields get their real sizes from the .per definition. The following example illustrates the case:
Here all items will occupy the same number of grid columns (5). The MMMMM static label will have the largest width and define the width of the 5 grid cells. The first field is defined with a normal item tag, and expands to the width of the 5 grid cells. The line 5 defines an hbox that will expand to the size of the 5 grid cells, according to the static label, but its child element - the field f2 - gets a size corresponding to the number of characters used before the ':' colon (that is 3 characters).

If the default width generated by the form compiler does not fit, the – dash symbol can be used to define the real width of the item. In this example, the hbox tag occupies 20 grid cells, the first form item gets a width of 5, and the second form item gets a width of 3:

```
GRID
{ 12345678901234567890
  [f1 - :f2 - : ]
}
END
```

The – dash size indicator is especially useful in BUTTONEDIT, DATEEDIT, and COMBOBOX form fields, for which the default width computed by the form compiler may not fit.

In this example, a static label is positioned above a TEXTEDIT field. The label will be centered over the TEXTEDIT field, and will remain centered as the field expands or contracts with the resizing of the window.

```
GRID
{ [ "label": ]
  [textedit ]
}
END

ATTRIBUTES
  TEXTEDIT textedit = formonly.textedit, STRETCH=BOTH;
END
```

**Related concepts**

  The ATTRIBUTES section describes properties of grid-based layout elements used in the form.

- Layout tags on page 1151
  Layout tags define layout areas for containers inside the frame of a grid-based container.

- Widget size within hbox tags on page 1321

**External form inclusion**

Form inclusion allows to reuse the same form part in different forms.

In some cases, application forms can become very complex, or can have a common layout part that repeats across forms. In such case, some parts of the form can be defined in an external .per file, that will be included in the final form by using the FORM clause inside the LAYOUT section.
Furthermore, the external form parts can be controlled by a declarative dialog instruction that can be attached to any procedural dialog instruction, with the SUBDIALOG clause of DIALOG.

```plaintext
LAYOUT
VBOX
GRID gl
{
    Customer information
    Name: [f001 ]
    ...
}
END
FORM "orders"
END
END
```

Related concepts

- **FORM clause** on page 1196
  Reuse the definition of a form in the current form.

- **The SUBDIALOG clause** on page 1496

**Boolean expressions in forms**

Some form item definitions can include boolean expressions with a form file specific syntax.

**Syntax**

```
[ ( ] bool-expr [AND|OR] bool-expr [ ) ]
```

where `bool-expr` is:

```
[ NOT ]
field-tag
  [ = ] expression
  [ <> ] expression
  [ != ] expression
  [ <= ] expression
  [ >= ] expression
  [ < ] expression
  [ > ] expression
  IS [ NOT ] NULL
  [ NOT ] BETWEEN expression AND expression
  [ NOT ] MATCHES "string"
  [ NOT ] LIKE "string"
```

1. `field-tag` is the name of the current field tag in form line with the attribute definition.
2. `expression` can be a character string, numeric or date-time literal.

**Usage**

Some form specification file attributes such as COLOR WHERE require a boolean expression. These boolean expressions are different from the language boolean expressions, and have a limited syntax which is specific to the form files.

When a `field-tag` is used in the boolean expression, the runtime system replaces `field-tag` at runtime with the current value in the screen field and evaluates the expression.
Example

```
EDIT f001 = item.price,
   COLOR=RED
   WHERE f001 >= 100 AND f001 < 1000;
```

Related concepts
COLOR WHERE Attribute on page 1249
The COLOR WHERE attribute defines a condition to set the foreground color dynamically.

Literals on page 288
Describes the syntax of literals (constant values) to be used in sources.

Form item types
The form item types defines the purpose of form elements.

BUTTON item type
Defines a push-button that can trigger an action.

BUTTON item basics
The BUTTON form item type defines a standard push button with a label and/or an icon.

Defining a BUTTON
The label of a BUTTON form item is defined with the TEXT attribute. The COMMENT attribute can be used to define a hint for the button. Consider using localized strings for these attributes.

The picture is defined by the IMAGE attribute. Consider using centralized icons for button images.

```plaintext
BUTTON ...
   TEXT = "%"common.button.text.ok",
   IMAGE = "accept",
   COMMENT = "%"common.button.hint.ok";
```

BUTTON form items can inherit action default attributes, to avoid having to specify the TEXT, COMMENT and IMAGE attributes in all elements bound to the same action. For more details, see Configuring actions on page 1646.

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083 and Button style attributes on page 1085.

Detecting BUTTON action
A BUTTON form item acts as an action view for a dialog action, and is bound to the ON ACTION handler by name. The action name can be prefixed with a sub-dialog identifier and/or a field name, to define a qualified action view:

```
-- Form file (grid layout)
BUTTON b1: print;

-- Program file:
ON ACTION print
   -- Execute code related to the print action
```

Note: When controlled by a COMMAND action handler in a DIALOG interactive instruction, form buttons can get the focus and thus be part of the tabbing list (TABINDEX attribute).

For more details, see Binding action views to action handlers on page 1664.

Where to use a BUTTON
A BUTTON form item can be defined in two different ways:
1. With an item tag and a **BUTTON item definition** on page 1224 in a grid-layout container (GRID, SCROLLGRID and TABLE).

2. As a **BUTTON stack item** on page 1203 in a STACK container.

**Related concepts**

- [Item tags](#) on page 1155
  - Item tags define the position and size in a grid-based container.

- [ATTRIBUTES section](#) on page 1221
  - The ATTRIBUTES section describes properties of grid-based layout elements used in the form.

**BUTTONEDIT item type**

Defines a line-edit with a push-button that can trigger an action.

**BUTTONEDIT item basics**

The BUTTONEDIT form item defines an edit field that gets user input, with an additional push button that can fire an action.

This type of form field is typically used to open a secondary window, to let the user choose from a large list of items and set the field value.

**Defining a BUTTONEDIT**

The IMAGE attribute of a BUTTONEDIT form item defines the picture to be displayed on the button.

By default, the text editor of a BUTTONEDIT allows the user to change the field value. Use the NOTEDITABLE attribute to deny text modification. The field still gets the focus, and the action button remains active, if there is a corresponding action handler in the current dialog.

```plaintext
BUTTONEDIT ...  
  IMAGE = "zoom",  
  NOTEDITABLE;
```

The button of BUTTONEDIT form items can inherit action default attributes, to avoid having to specify the IMAGE attributes in all elements bound to the same action. For more details, see [Configuring actions](#) on page 1646.

Most of the attributes described in the EDIT item type on page 1170 can also be used with the BUTTONEDIT.

Front-ends support different presentation and behavior options, which can be controlled by a **STYLE** attribute. For more details, see [Common style attributes](#) on page 1083 and [ButtonEdit style attributes](#) on page 1087.

**Detecting BUTTONEDIT button action**

The button of a BUTTONEDIT form element acts as an action view for a dialog action, and is bound to the ON ACTION handler by the ACTION attribute. The ACTION attribute defines the name of the action to be sent to the program when the user clicks on the button:

```plaintext
-- Form file
BUTTONEDIT ...  
  ACTION = open_city_list;

-- Program file:
ON ACTION open_city_list  
  -- Open the city pick-list
```

The button action can also be a common action name, prefixed with a sub-dialog identifier and/or field name, to define a qualified action view to be used in conjunction with ON ACTION action-name INFIELD field-name.
For more details, see Binding action views to action handlers on page 1664, Field-specific actions (INFIELD clause) on page 1669.

### Where to use a BUTTONEDIT

A BUTTONEDIT form item can be defined in two different ways:

1. With an item tag and a BUTTONEDIT item definition on page 1225 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a BUTTONEDIT stack item on page 1204 in a STACK container.

### Defining the widget size

In a grid-based layout, the size of a BUTTONEDIT widget is computed by the layout rules as described in Widget size within hbox tags on page 1321.

In a stack-based layout, the widget will take the full width available in the parent container.

### Field input length

In grid-based layout, the input length in a BUTTONEDIT fields is defined by the item tag and may need to get the SCROLL attribute. For more details, see Input length of form fields on page 1616.

### Related concepts

STACK container on page 1202
The STACK container holds stack items defining a logical alignment of form items.

GRID container on page 1201
Defines a layout area based on a grid of cells.

Defining action views in forms on page 1662
How to define action views that will fire action events.

CHECKBOX item type
Defines a boolean or three-state checkbox field.

### CHECKBOX item basics

The CHECKBOX form item defines a field with a check box and a text label.

### Defining a CHECKBOX

The TEXT attribute defines the label to be displayed near the check box. Consider using localized strings for this attribute.

The box shows a check mark when the form field contains the value defined in the VALUECHECKED attribute (for example: "y"), and shows no check mark if the field value is equal to the value defined by the VALUEUNCHECKED attribute (for example: "N"). If you do not specify the VALUECHECKED or VALUEUNCHECKED attributes, they respectively default to TRUE (integer 1) and FALSE (integer 0).

By default, during an INPUT dialog, a CHECKBOX field can have three states:

- Grayed ( NULL value )
- Checked ( VALUECHECKED value )
- Unchecked ( VALUEUNCHECKED value )

If the field is declared as NOT NULL, the initial state can be grayed if the default value is NULL; once the user has changed the state of the CHECKBOX field, it switches only between checked and unchecked states.

During a CONSTRUCT, a CHECKBOX field always has three possible states (even if the field is NOT NULL), to allow the end user to clear the search condition:

- Grayed (No search condition)
• Checked (Condition column = VALUECHECKED value)
• Unchecked (Condition column = VALUEUNCHECKED value)

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083 and CheckBox style attributes on page 1087.

Detecting CHECKBOX modification

To inform the dialog immediately when the value changes, define an ON CHANGE block for the CHECKBOX field. The program can then react immediately to user changes in the field:

```
-- Form file (grid layout)
CHECKBOX cb1 = order.ord_valid,
   ITEMS = ... ;

-- Program file:
ON CHANGE ord_valid
   -- The checkbox field has been modified
```

For more details, see Reacting to field value changes on page 1624.

Where to use a CHECKBOX

A CHECKBOX form item can be defined in two different ways:

1. With an item tag and a CHECKBOX item definition on page 1226 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a CHECKBOX stack item on page 1204 in a STACK container.

COMBOBOX item type

Defines a line-edit with a drop-down list of values.

COMBOBOX item basics

The COMBOBOX form item defines a field that can open a list of possible values the end user can choose from.

**Note:** The COMBOBOX is best used for a short list of possible values (10 to 50, maximum).

Defining a COMBOBOX

The values of the drop-down list are defined by the ITEMS attribute. Define a simple list of values like ("A", "B", "C", "D", ... ) or a list of key/value pairs like in ((1,"Paris"),(2,"Madrid"), (3,"London")). In the second case, the labels (city names) display depending on the key value (the city number) held by the field.

```
COMBOBOX ...
```

Consider using localized strings when defining key/value pairs in the combobox items:

```
COMBOBOX ...
   ITEMS=((1,%"cities.paris"),
          (2,%"cities.madrid"),
          (3,%"cities.london"));
```

The INITIALIZER attribute allows you to define an initialization function for the COMBOBOX. This function is invoked at runtime when the form is loaded, to fill the item list dynamically, for example with database records. It is
recommended that you use the TAG attribute, so you can identify in the program the kind of COMBOBOX form item to be initialized. The initialization function name is converted to lowercase by fglform.

```plaintext
COMBOBOX ...  
   TAG = "city", INITIALIZER=cmb_init;
```

If neither ITEMS nor INITIALIZER attributes are specified, the form compiler automatically fills the list of items with the values of the INCLUDE attribute, when specified. However, the item list will not automatically be populated with include range values (i.e. values defined using the TO keyword). The INCLUDE attribute can be specified directly in the form or indirectly in the schema files.

```plaintext
COMBOBOX ...  
   INCLUDE=("A","B","C","D","E");
```

During an input dialog, a COMBOBOX field value can only be one of the values specified in the ITEMS attribute. If the field allows NULL values, consider adding an item to reference the NULL value. However, the best practice is to deny nulls with the NOT NULL attribute, and add a special item such as (0,"<Undefined>") to identify a non-specified-value:

```plaintext
COMBOBOX ...  
   NOT NULL,  
   ITEMS=((0,"<Undefined>"),  
   (1,"Red"),  
   (2,"Yellow"),  
   (3,"Green");
```

**Note:** If one of the items is explicitly defined with NULL; in INPUT, selecting the corresponding combobox list item sets the field value to null. In CONSTRUCT, selecting the list item corresponding to null will be equivalent to the = query operator, which will generate a "colname is null" SQL condition. During a CONSTRUCT, a COMBOBOX field gets an additional 'empty' item (even if the field is NOT NULL), to let the user clear the search condition.

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083 and ComboBox style attributes on page 1088.

### Detecting COMBOBOX item selection

To inform the dialog when the value changes, define an ON CHANGE block for the COMBOBOX field. The program can then react immediately to user changes in the field:

```plaintext
-- Form file (grid layout)  
COMBOBOX cb1 = customer.cust_city,  
   ITEMS = ... ;

-- Program file:  
ON CHANGE cust_city  
   -- A new item was selected in the combobox list
```

For more details, see Reacting to field value changes on page 1624.

### Where to use a COMBOBOX

A COMBOBOX form item can be defined in two different ways:

1. With an item tag and a COMBOBOX item definition on page 1227 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a COMBOBOX stack item on page 1205 in a STACK container.
Defining the widget size

In a grid-based layout, the size of a COMBOBOX widget is computed from the SIZEPOLICY and SAMPLE attributes, and by following the layout rules as described in Widget size within hbox tags on page 1321.

In a stack-based layout, the widget will take the full width available in the parent container.

COMBOBOX on mobile devices

On mobile devices, COMBOBOX form items are best used for a short list of possible values that can be displayed on a single page; for example, 4 to 6 elements. When a list expands to more than one page, it is recommended that you use a BUTTONEDIT with a zoom, which you can improve with a search button to find an exact item or to reduce the list of items to scroll.

Related concepts

Filling a COMBOBOX item list on page 1635

The item list of COMBOBOX fields can be initialized at runtime.

DATEEDIT item type

Defines a line-edit with a calendar widget to pick a date.

DATEEDIT item basics

The DATEEDIT form item defines a field that can open a calendar to ease date input.

To store the field value, use a DATE program variable with this form item.

Important: DATEEDIT fields are dedicated for DATE value input. Some front-ends (especially on mobile devices) deny data types different from DATE. If the front-end does not support the data type used for the DATEEDIT field, the runtime system will raise an error and stop the program. Consider testing your application with all types of front-ends.

Defining a DATEEDIT

The DATEEDIT form item type allows the user to edit date values with a specific widget for date input. A DATEEDIT field typically provides a calendar widget, to let the end user pick a date from it.

When using a DATE variable as recommended, with desktop front-ends, the format of DATEEDIT fields is by default defined by the DBDATE environment variable as for other edit fields. Specific format can be defined with the FORMAT attribute, but it is recommended to use the default date formatting. On mobile platforms, the date format is defined by the device OS language settings.

Note: On some front-end platforms, native widgets used for DATEEDIT fields may allow only simple year/month/day value input, and therefore cannot be used with a CONSTRUCT instruction, where it must be possible to enter search filters like ">=24/03/2014".

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083 and DateEdit style attributes on page 1089.

Detecting DATEEDIT calendar selection

To inform the dialog when a date is picked from the calendar widget, define an ON CHANGE block for the DATEEDIT field. The program can then react immediately to user changes in the field:

```plaintext
-- Form file (grid layout)
DATEEDIT de1 = order.ord_shipdate,
   NOT NULL;

-- Program file:
ON CHANGE ord_shipdate
  -- A new date value was picked from the calendar
```
For more details, see Reacting to field value changes on page 1624.

**Where to use a DATEEDIT**

A DATEEDIT form item can be defined in two different ways:

1. With an item tag and a DATEEDIT item definition on page 1228 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a DATEEDIT stack item on page 1206 in a STACK container.

**Defining the widget size**

In a grid-based layout, the size of a DATEEDIT widget is computed by following the layout rules as described in Widget size within hbox tags on page 1321.

In a stack-based layout, the widget will take the full width available in the parent container.

**Field input length**

The input length in a DATEEDIT fields is defined by the (DATE) program variable. In a grid-based layout, define an item tag with 10 positions, to be able to display dates with 4 year digits. For more details, see Input length of form fields on page 1616.

**Calendar configuration**

A set of presentation style attributes for the DateEdit class can be used to customize the calendar. For example, you can define the icons of the button to open the calendar, the days off, the first day of the week, and the type of pop-up window for the calendar.

**Related concepts**

TIMEEDIT item type on page 1185
Defines a line-edit field with a clock widget to pick a time.

DATETIMEEDIT item type
Defines a line-edit with a calendar widget to pick a datetime.

**DATETIMEEDIT item basics**

The DATETIMEEDIT form item defines a field that can open a calendar to ease date-time input.

To store the field value, use a DATETIME YEAR TO MINUTE or DATETIME YEAR TO SECOND program variable with such form item.

**Important:** DATETIMEEDIT fields are dedicated for DATETIME value input. Some front-ends (especially on mobile devices) deny data types different from DATETIME. If the front-end does not support the data type used for the DATETIMEEDIT field, the runtime system raises an error and stops the program. Consider testing your application with all types of front-ends.

**Defining a DATETIMEEDIT**

The DATETIMEEDIT form item type allows the user to edit date-time values with a specific widget for date-time input. A DATETIMEEDIT field typically provides a calendar and clock widget, to let the end user pick a date and time from it.

The display and input precision (time part with or without seconds) of the DATETIMEEDIT widget depends on the front-end. On some platforms, native date-time editors do not handle the seconds. Furthermore, some front-ends (especially on mobile devices) do not allow data types different from DATETIME YEAR TO {MINUTE|SECOND}.

The native widget used for DATETIMEEDIT fields may allow only pure date-time value input, and therefore cannot be used with a CONSTRUCT instruction, where it must be possible to enter search filters like ">= 2014-01-23 11:00".
Front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see Common style attributes on page 1083.

**Detecting DATETIMEEDIT calendar selection**

To inform the dialog when a date-time is picked from the calendar widget, define an `ON CHANGE` block for the `DATETIMEEDIT` field. The program can then react immediately to user changes in the field:

```sql
-- Form file (grid layout)
DATETIMEEDIT dt1 = order.ord_shipdate,
   NOT NULL;

-- Program file:
ON CHANGE ord_shipdate
   -- A new date-time value was picked from the calendar
```

For more details, see Reacting to field value changes on page 1624.

**Where to use a DATETIMEEDIT**

A `DATETIMEEDIT` form item can be defined in two different ways:

1. With an item tag and a `DATETIMEEDIT` item definition on page 1228 in a grid-layout container (`GRID`, `SCROLLGRID` and `TABLE`).
2. As a `DATETIMEEDIT` stack item on page 1206 in a `STACK` container.

**Defining the widget size**

In a grid-based layout, the size of a `DATETIMEEDIT` widget is computed by following the layout rules as described in Widget size within hbox tags on page 1321.

In a stack-based layout, the widget will take the full width available in the parent container.

**Field input length**

The input length in a `DATETIMEEDIT` fields is defined by the `(DATETIME)` program variable. In a grid-based layout, define an item tag with enough positions to be able to display dates with 4 year digits. For more details, see Input length of form fields on page 1616.

**Related concepts**

- `TIMEEDIT` item type on page 1185
  Defines a line-edit field with a clock widget to pick a time.

- `EDIT` item type
  Defines a simple line-edit field.

**EDIT item basics**

The `EDIT` form item defines a field to enter a single-line of text, for any data type.

This item type is typically used to define character string and numeric form fields.

**Defining an EDIT**

The `EDIT` item type can be used for any data type that can be converted to editable text.

To show a hint to the user when the field has the focus, use the `COMMENT` attribute.

If the field is mandatory for input, combine the `NOT NULL` with the `REQUIRED` attribute.

The value accepted for the field can be limited with the `INCLUDE` attribute.
To provide a default value, define the `DEFAULT` attribute for the field.

Use the `DOWNSHIFT` or `UPSHIFT` attributes to force the letter case during input.

Input can be hidden (for example for password fields), with the `INVISIBLE` attribute.

Especially for mobile devices, use the `KEYBOARDHINT` attribute to get a specific keyboard when entering values into the field.

Input completion proposals can be implemented with the `COMPLETER` attribute.

Front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see `Common style attributes` on page 1083 and `Edit style attributes` on page 1092.

**Where to use an EDIT**

An `EDIT` form item can be defined in two different ways:

1. With an item tag and a `EDIT item definition` on page 1229 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a `EDIT stack item` on page 1206 in a `STACK` container.

**Field input length**

In grid-based layout, the input length in an `EDIT` fields is defined by the item tag and may need to get the `SCROLL` attribute. For more details, see `Input length of form fields` on page 1616.

**Related concepts**

- `BUTTONEDIT item type` on page 1164
  Defines a line-edit with a push-button that can trigger an action.

- `FOLDER item type` on page 1238
  Defines a layout area to hold folder pages.

**FOLDER item basics**

A `FOLDER` form item type groups folder pages together. Folder pages are defined with the `PAGE` form item.

**Defining an FOLDER**

The `FOLDER` form item is just a container for `PAGE` items.

```
FOLDER
  PAGE
  ...
  PAGE
  ...
```

**Where to use a FOLDER**

A `FOLDER` form item can be defined in two different ways:

1. In a `FOLDER container` in a `LAYOUT` tree, within a grid-based layout.
2. As a `FOLDER stack item`, inside a `STACK` container, within a stack-based layout.

**FOLDER rendering**

Front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. The rendering of the folder tabs can be controlled with the `position` style attribute.
When using the values "top", "left", "right" and "bottom", the folder is rendered as a classic folder/page view, with folder tabs at the required position.

When using the value "accordion", the folder pages are rendered as collapsible group boxes.

**Note:** The "accordion" position is only supported by the GBC front-end.

For more details, see Folder style attributes on page 1093.

**GRID item type**

Defines a layout area based on a grid of cells.

**GRID item basics**

A GRID form item defines an area in the layout section to place children form items by X,Y position in layout cells.

**Defining an GRID**

The GRID container declares a formatted text block defining the dimensions and the positions of the form items contained in the grid.

You can specify the position of labels, form fields for data entry or additional interactive objects such as buttons.

A GRID container can hold static text, item tags, field tags, hbox tags, and layout tags to define other containers such as TABLE, TREE and SCROLLGRID.

A GRID can hold form items such as labels, fields, or buttons at a specific position. Form items are located with item tags in the grid layout area. You can use layout tags to place some type of containers inside a grid.

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083.

**Where to use a GRID**

A GRID form item can only be defined as a GRID container in a LAYOUT tree.

**GRID layout definition**

For more details about grid layout concept, see Grid-based layout on page 1309.

**Related concepts**

- Layout items on page 1135

*Layout items* are containers with a body that can hold other form items, in a grid-based layout form.

**GROUP item type**

Defines a layout area to group other layout elements together.

**GROUP item basics**

A GROUP form item type groups other form items together, typically in a groupbox widget.

**Defining an GROUP**

The GROUP form item typically gets a TEXT attribute, to define the title of the group. Consider using localized strings for this attribute:

```plaintext
GROUP ...
   TEXT=%"customer.info";
```

**Note:** Depending on the front-end platform, a GROUP container may get a border, and a title. The border may also be rendered with a shadow effect.
Consider identifying group elements with a name, in order to manipulate the group during program execution. For example use the `ui.Form.setElementHidden()` method to hide or show groups in a form:

```plaintext
GROUP g1: g_cust_info, ... ;   -- grid-based layout
GROUP g_cust_info, ... ;       -- stack-based layout
```

Front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see Common style attributes on page 1083.

**Groups in grid-based layout**

In a `LAYOUT` tree with `GROUP` containers, if you want to include several children in a `GROUP`, you can add a `VBOX` or `HBOX` into the `GROUP`, to define how these form items are aligned.

**Note:** When defining a `GROUP` container, you cannot set the `GRIDCHILDRENINPARENT` attribute. This attribute makes sense only for a group item defined with a layout tag contained in a `GRID` area.

Consider using a group layout tag inside a `GRID` container, this layout specification technique is often more appropriate to define forms:

```plaintext
GRID
{
  <G g1             ><G g2        >
  [l1  :f1          ][f4          ]
  ...
  <G g3                            
  ...
}
```

**Groups in stack-based layout**

In a `STACK` container, `GROUP` form items are one of the base concepts used to put stack items together. For more details see Stacked group rendering on page 1324.

**Collapsible groups**

By default, groups are not collapsible.

Some front-ends (see Group presentation style attributes reference) support the `collapsible` presentation style attribute to let end users expand/collapse `GROUP` elements in your forms.

**Note:** This feature is only available with the GBC front-end.

In addition, the `initiallyCollapsed` style attribute can be used to force the initial state of a `GROUP`, when displayed for the first time:

```xml
<Style name="Group.mystyle">
  <StyleAttribute name="collapsible" value="yes" />
  <StyleAttribute name="initiallyCollapsed" value="yes" />
</Style>
```

These style attributes are supported in both stack and grid layout.

For more details, see Group style attributes on page 1094.

**Groups on mobile devices**

On mobile devices, groups render depending on the platform standards:

- With GMA/Android™, groups are visualized by a simple separator under the group title. Complex layout construction is supported: groups in groups, groups in a grid, and so on.
• With GMI/iOS, the layout is limited by the platform GUI standards. The only visible grouping container element is a group. Groups within groups are not allowed. GMI enforces each form item as a member in a group. There can be group headers and footers, but no elements in between groups.

**Where to use a GROUP**

A **GROUP** form item can be defined in three different ways:

1. As a **GROUP** container in a **LAYOUT** tree, within a grid-based layout.
2. As a `<GROUP>` layout tag with a **GROUP** item definition in the **ATTRIBUTES** section, within a grid-based layout.
3. As a **GROUP** stack item, inside a **STACK** container, within a stack-based layout.

**IMAGE** item type

Defines an area that can display an image resource.

**IMAGE** item basics

The **IMAGE** item type defines an area where a picture resource can be displayed.

**Defining an IMAGE**

An **IMAGE** form item can be defined as a form field image or as a static image. Use a form field image when the content of the image will change often during program execution (for example, to display images from the database). Use a static image if the image remains the same during program execution.

Front-ends support different presentation and behavior options, which can be controlled by a **STYLE** attribute. For more details, see Common style attributes on page 1083 and Image style attributes on page 1095.

**Form field IMAGE item**

Use a form field image item to display values that change often during program execution, for example if the image is stored in the database.

The picture resource is defined by the value of the field.

The value can be changed by the program using the `DISPLAY BY NAME / DISPLAY TO` instruction, or just by changing the value of the program variable bound to the image field when using the **UNBUFFERED** mode in an interactive instruction.

When defining the **IMAGE** item in the form, use a field name to identify the element in programs:

```
-- Grid-based layout (ATTRIBUTES item definition)
IMAGE f001 = cars.picture, SIZEPOLICY=FIXED, STRETCH=BOTH;

-- Stack-based layout (STACK item)
IMAGE cars.picture, SIZEPOLICY=FIXED, AUTOSCALE;
```

**Static IMAGE item**

Use a static image item to display an image that does not change during program execution, such as form decoration pictures and logos.

The resource of the image is defined by the **IMAGE** attribute; the item is not a form field. This kind of item is not affected by instructions such as **CLEAR FORM** or the `DISPLAY TO` instruction.

```
-- Grid-based layout (ATTRIBUTES item definition)
IMAGE img1: logo, IMAGE="fourjs.png", SIZEPOLICY=FIXED, STRETCH=BOTH;

-- Stack-based layout (STACK item)
IMAGE logo, IMAGE="fourjs.png", SIZEPOLICY=FIXED, AUTOSCALE;
```
Providing the image resource
To display an image, the front-end needs the image data, which can be provided in different ways.
For example, you can specify an URL, a mapped icon, or a plain image file (centralized on the application server).
For more details about image resource specification, see Providing the image resource on page 1049.

Detecting IMAGE clicks
To inform the dialog immediately when an image was clicked, define the ACTION attribute in the IMAGE item, and implement the corresponding ON ACTION handler in the dialog:

```
-- Form file (grid layout)
IMAGE : logo, IMAGE="fourjs.png", ACTION=show_about;

-- Program file:
ON ACTION show_about
    -- The image was clicked
```

The program can then react immediately when the user selects the image element.

Where to use IMAGE
An IMAGE form item can be defined in two different ways:
1. With an item tag and an IMAGE item definition on page 1231 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As an IMAGE stack item on page 1208 in a STACK container.

Defining the widget size
The size of an IMAGE widget can be controlled in grid-based or stack-based layout by several attributes such as SIZEPOLICY, AUTOSCALE and STRETCH.
For more details about image sizing, see Controlling the image layout on page 1047.

Related concepts
Using images on page 1046
Describes how to use pictures in the forms of your application.

LABEL item type
Defines a simple text area to display a read-only value.

LABEL item basics
The LABEL form item defines a read-only text area.

Defining a LABEL
A LABEL form item can be defined as a form field image or as a static label. Use a form field label when the text changes often during program execution (for example, to display text from the database). Use a static label if the text remains the same during program execution.
Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083 and Label style attributes on page 1096.

Form field LABEL item
Use a form field label item to display values that change often during program execution, for example if the text is stored in the database.
The label text is defined by the value of the field.

The value can be changed by the program using the `DISPLAY BY NAME / DISPLAY TO` instruction, or just by changing the value of the program variable bound to the label field when using the `UNBUFFERED` mode in an interactive instruction.

When defining the `LABEL` item in the form, use a field name to identify the element in programs:

```
-- Grid-based layout (ATTRIBUTES item definition)
LABEL f001 = cars.description;

-- Stack-based layout (STACK item)
LABEL cars.description;
```

**Static LABEL item**

Use a static label item to display text that does not change during program execution.

This kind of item is not affected by instructions such as `CLEAR FORM` or the `DISPLAY TO` instruction.

```
-- Grid-based layout (ATTRIBUTES item definition)
LABEL label1: label1, TEXT="Name:"

-- Stack-based layout (STACK item)
LABEL label1, TEXT="Name:"
```

Consider using localized strings to ease application internationalization:

```
LABEL ...
    TEXT = %"label.customer.name";
```

Static labels display only character text values, and therefore do not follow any justification rule as form field labels.

**Multi-line text in LABELs**

In order to display label text on several lines, the text must contain \n line-feed characters:

```
LABEL label1: label1,
    TEXT="First line.\nSecond line.";
```

**Where to use a LABEL**

A `LABEL` form item can be defined in two different ways:

1. With an item tag and a `LABEL` item definition on page 1232 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a `LABEL` stack item on page 1209 in a STACK container.

**Defining the widget size**

The size of a `LABEL` widget can be controlled in grid-based or stack-based layout by using the `SIZEPOLICY` attribute.

By default (`SIZEPOLICY=INITIAL`), labels adapt their width to the initial text displayed by the element.

With static labels, the initial text is usually defined in the form file, or with a localized string, and the size does not need to adapt once the label is displayed.

When using form field labels, the same default rule applies. However, if the initial text displayed in the form field is `NULL` or smaller than other texts that will be displayed, the size of the label element will not adapt after the initial text is displayed; the label stays at the size of the initial displayed text.
Important: When using a form field label, make sure that the size of the label will be large enough to display all possible values. To control the label size, use the SIZEPOLICY=DYNAMIC attribute, or use SIZEPOLICY=FIXED and define the form item with a sufficient size in the LAYOUT section.

PAGE item type
 Defines the content of a folder page.

PAGE item basics
A PAGE form item type groups other form elements together, to define a folder page of a parent FOLDER form item.

Defining an PAGE
A PAGE form item can only be a child of a FOLDER form item.

By default, PAGE form items are used to group elements for decoration only.

Note: Use the TABINDEX attribute of form fields inside the folder page, to define which field gets the focus when a folder page is selected.

The TEXT attributes defines the label of the folder page. Consider using localized strings for this attribute.

The IMAGE attribute can be used to specify which image to use as an icon.

Detecting folder page selection
If needed, you can use the ACTION attribute to bind an action to a folder page. When the page is selected, the program gets the corresponding action event.

Note: Use this feature with care; it is provided to implement different singular dialog statements (such as INPUT) in each folder page. It is recommended that you use a DIALOG statement to control all folder pages simultaneously.

Bring a folder page to the top
To bring a folder page to the top, use the NEXT FIELD program instruction to give the focus to one of the active fields of the page, or use the ui.Form.ensureFieldVisible() method if the fields are disabled/unused, or use the ui.Form.ensureElementVisible() method if the page does not contain focusable form items.

For more details, see Giving the focus to a form element on page 1631.

Where to use a PAGE
A PAGE form item can be defined in two different ways:

1. As a PAGE container in a LAYOUT tree, within a grid-based layout.
2. As a PAGE stack item, inside a STACK container, within a stack-based layout.

PROGRESSBAR item type
Defines a progress indicator field.

PROGRESSBAR item basics
The PROGRESSBAR form item defines a field that shows a progress indicator.

Note: Use a SMALLINT or INTEGER variable with a PROGRESSBAR form item. Larger types like BIGINT or DECIMAL are not supported.

Defining a PROGRESSBAR
The VALUEMIN and VALUEMAX attributes define respectively the lower and upper integer limit of the progress information. Any value outside this range will not be displayed. Default values are VALUEMIN=0 and VALUEMAX=100.
Front-ends support different presentation and behavior options, which can be controlled by a `STYLE` attribute. For more details, see `Common style attributes` on page 1083 and `ProgressBar style attributes` on page 1098.

**Displaying PROGRESSBAR values**

The position of the progress bar indicator is defined by the value of the corresponding form field. The value can be changed by the program using the `DISPLAY TO` instruction, to set the value of the field, or by changing the program variable bound to the field when using the `UNBUFFERED` dialog mode.

Progress information is typically displayed during non-interactive program code. To show changes to the end user in this context, you need to use the `ui.Interface.refresh()` method to force a refresh. To provide the best feedback to the user, consider calling the `refresh()` method regularly but not too often, otherwise you will overload the network traffic and bring down the front-end component.

For example, if you have to process 1000 rows, define `VALUemin=0` and `VALUemax=1000` in the `PROGRESSBAR` item, and perform a refresh every 50 rows:

```plaintext
FOR row=1 TO 1000
  ...
  IF (row MOD 50) == 0 THEN
    LET myprogbar = row
    CALL ui.Interface.refresh()
  END IF
END FOR
```

**Where to use a PROGRESSBAR**

A `PROGRESSBAR` form item can be defined in two different ways:

1. With an item tag and a `PROGRESSBAR` item definition on page 1232 in a grid-layout container (`GRID`, `SCROLLGRID` and `TABLE`).
2. As a `PROGRESSBAR` stack item on page 1211 in a `STACK` container.

**Related concepts**

- The buffered and unbuffered modes on page 1618
- The buffered and unbuffered mode control the synchronization of program variables and form fields.

**RADIOGROUP item type**

Defines a mutual exclusive set of options field.

**RADIOGROUP item basics**

The `RADIOGROUP` form item defines a field that provides several options that the user can make a selection from. Checking one radio button unchecks any previously checked button within the same group.

**Defining a RADIOGROUP**

A `RADIOGROUP` defines a set of radio buttons where each button is associated with a value defined in the `ITEMS` attribute.

The text associated with each item value will be used as the label of the corresponding radio button, for example: `ITEMS=((1,"Beginner"), (2,"Normal"), (3,"Expert"))` will create three radio buttons with the texts `Beginner`, `Normal` and `Expert`, respectively.

```plaintext
RADIOGROUP ...
  ITEMS=((1,"Beginner"), (2,"Normal"), (3,"Expert"));
```

Consider using localized strings when defining key/value pairs in the radio group items:

```plaintext
COMBOBOX ...
```
ITEMS=((1,"skills.beginner"),
(2,"skills.normal"),
(3,"skills.expert"));

If the ITEMS attribute is not specified, the form compiler automatically fills the list of items with the values of the INCLUDE attribute, when specified. However, the item list will not automatically be populated with include range values (that is values defined using the TO keyword). The INCLUDE attribute can be specified directly in the form or indirectly in the schema files.

During an INPUT, a RADIOGROUP field value can only be one of the values specified in the ITEMS attribute. During a CONSTRUCT, a RADIOGROUP field allows all items to be unchecked (even if the field is NOT NULL), to let the user clear the search condition.

If one of the items is explicitly defined with NULL and the NOT NULL attribute is omitted, in INPUT, selecting the corresponding radio button sets the field value to null. In CONSTRUCT, selecting the radio button corresponding to null will be equivalent to the equals (=) query operator, which will generate a "colname is null" SQL condition.

Use the ORIENTATION attribute to define if the radio group must be displayed vertically or horizontally:

COMBOBOX ...
   ITEMS=(...),
   ORIENTATION = HORIZONTAL;

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083 and RadioGroup style attributes on page 1099.

**Detecting RADIOGROUP item selection**

To inform the dialog when a value change, define an ON CHANGE block for the RADIOGROUP field. The program can then react immediately to user changes in the field:

```plaintext
-- Form file (grid layout)
RADIOGROUP rgl = user.user_skill,
   ITEMS = ... ;

-- Program file:
ON CHANGE user_skill
   -- An new item was selected in the radiogroup
```

For more details, see Reacting to field value changes on page 1624.

**Where to use a RADIOGROUP**

A RADIOGROUP form item can be defined in two different ways:

1. With an item tag and a RADIOGROUP item definition on page 1233 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a RADIOGROUP stack item on page 1211 in a STACK container.

**SCROLLGRID item type**

Defines a scrollable grid view widget.

**Note:** This topic covers the SCROLLGRID item type definition in form files. See also the chapter dedicated to scrollgrid view programming.

**SCROLLGRID item basics**

A SCROLLGRID form item type defines a grid to show a scrolling list of data records in a set of positioned form fields.

The SCROLLGRID basically acts like a TABLE container, in the sense of its function as a record list container.
By default, scrollgrids display a fixed number of rows, and can be configured to be resizable in height.

A SCROLLGRID is controlled by a DISPLAY ARRAY or INPUT ARRAY dialog, see List dialogs on page 1731 for more details about this type of dialogs.

**Defining a SCROLLGRID**

The SCROLLGRID form item defines a formatted list view to show a structured set of data records. It is bound to a screen array grouping form fields which define the list fields of the scrollgrid.

The screen array definition must have exactly the same number of fields as the SCROLLGRID form item. Use PHANTOM fields, if the number of record members in the program array exceeds the number of fields to be displayed in the SCROLLGRID container.

The SCROLLGRID form item declares a formatted text block, defining the dimensions and the position of the logical elements of a screen for a multi-record presentation.

A SCROLLGRID is similar to the GRID, that repeats on several "row-templates", in order to design a view for multiple-records that display with a vertical scrollbar.

Inside a SCROLLGRID, the same layout rules apply as in a GRID container.

Static labels can be used as in a regular GRID container. However, this prevents you from localizing the label text. Consider using LABEL fields with a TEXT attribute, instead of static text labels.

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083 and ScrollGrid style attributes on page 1099.

**Where to use a SCROLLGRID?**

Within a grid-based layout, a SCROLLGRID form item can be defined in two different ways:

1. As a **SCROLLGRID container** in a LAYOUT tree.
2. As a **<SCROLLGRID >** layout tag with a **SCROLLGRID item definition** in the ATTRIBUTES section.

**Defining the scrollgrid size and layout**

The global size of a SCROLLGRID element is defined by its content, and the number of record rows displayed.

**Note:** When using a SCROLLGRID container, you cannot set the GRIDCHILDRENINPARENT attribute. This attribute makes sense only for a scrollgrid defined with a layout tag, within a GRID area.

By default, a scrollgrid is not resizable in height: The number of visible rows is defined by the number of row templates in the form layout. Use the WANTFIXEDPAGESIZE=NO attribute, to allow the scrollgrid to resize.

When using WANTFIXEDPAGESIZE=NO, a resizable scrollgrid is displayed with one single row, if no other element in the form layout makes the scrollgrid stretch implicitly. To force a default number of rows in stretchable scrollgrids, use the INITIALPAGESIZE attribute.

A usual pattern on the web is to render information as a responsive tile list, using tiles displayed in pages. Each tile will flow, depending on the container size.

To render stretchable scrollgrids as a paged responsive tile list, define the **customWidget** presentation style attribute to pagedScrollGrid. With this attribute, each scrollgrid row will be rendered as a tile (the page size of the scrollgrid defines the number of tiles in each page):

```
<Style name="ScrollGrid.paged" >
  <StyleAttribute name= "customWidget" value= "pagedScrollGrid" />
</Style>
```

For more details, see also Controlling scrollgrid rendering on page 1786.

**Related concepts**

TABLE item type on page 1182
Defines a list view widget.

**SLIDER item type**
Defines a slider form item.

**SLIDER item basics**
The SLIDER form item defines a field where the user can set a value in a given range, such as a typical audio volume control widget where you can grab the slider handle to change the value.

Use a SMALLINT or INTEGER variable with a SLIDER form item, larger types like BIGINT or DECIMAL are not supported.

**Defining a SLIDER**
A SLIDER field allows the user to move a handle along a horizontal or vertical groove and translates the handle's position into a value within the legal range.

The VALUEMIN and VALUEMAX attributes define respectively the lower and upper integer limit of the slider information. Any value outside this range will not be displayed. The step between two marks is defined by the STEP attribute. If VALUEMIN and/or VALUEMAX are not specified, they default respectively to 0 (zero) and 5.

The ORIENTATION attribute defines whether the SLIDER is displayed vertically or horizontally.

This item type is not designed for CONSTRUCT, as the user can only select one value.

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083.

**Detecting SLIDER item selection**
To inform the dialog when a value changes, define an ON CHANGE block for the SLIDER field. The program can then react immediately to user changes in the field:

```
-- Form file (grid layout)
SLIDER s1 = options.opts_volume,
   VALUEMIN=0, VALUEMAX=100;

-- Program file:
ON CHANGE opts_volume
   -- A value changed in the slider
```

For more details, see Reacting to field value changes on page 1624.

**Where to use a SLIDER**
A SLIDER form item can be defined in two different ways:

1. With an item tag and a SLIDER item definition on page 1235 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a SLIDER stack item on page 1212 in a STACK container.

**Related concepts**
Binding variables to form fields on page 1620
Some dialogs need program variables to store form field values.

**SPINEDIT item type**
Defines a spin box widget to enter integer values.

**SPINEDIT item basics**
The SPINEDIT form item defines a field dedicated to numeric values. Depending on the front-end platform, the widget may provide buttons to increment/decrement the field value.

Use a SMALLINT or INTEGER variable with a SPINEDIT form item. Larger types like BIGINT or DECIMAL are not supported.

**Defining a SPINEDIT**
The increment between two values is defined by the **STEP** attribute:

```plaintext
SPINEDIT ...
  STEP = 5;
```

The **VALUEMIN** and **VALUEMAX** attributes define respectively the lower and upper integer limit of the spin-edit range. There is no default minimum or maximum value for the SPINEDIT widget.

**Note:** This widget is not designed for CONSTRUCT, as you can only enter an integer value.

Front-ends support different presentation and behavior options, which can be controlled by a **STYLE** attribute. For more details, see Common style attributes on page 1083.

**Detecting SPINEDIT modification**
To inform the dialog when a value changes, define an **ON CHANGE** block for the SPINEDIT field. The program can then react immediately to user changes in the field:

```plaintext
-- Form file (grid layout)
SPINEDIT s1 = options.opts_rate,
  VALUEMIN=0, VALUEMAX=100, STEP=5;

-- Program file:
ON CHANGE opts_rate
  -- The value of the spinedit has changed
```

For more details, see Reacting to field value changes on page 1624.

**Where to use a SPINEDIT**
A SPINEDIT form item can be defined in two different ways:

1. With an item tag and a **SPINEDIT item definition** on page 1235 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a **SPINEDIT stack item** on page 1212 in a STACK container.

**Related concepts**
Binding variables to form fields on page 1620
Some dialogs need program variables to store form field values.

**TABLE item type**
Defines a list view widget.

**Note:** This topic covers the TABLE item type definition in form files. See also the chapter dedicated to table view programming.
TABLE item basics
A TABLE form item type defines a list view to show a scrolling list of data records in a set of columns.

A TABLE is controlled by a DISPLAY ARRAY or INPUT ARRAY dialog, see List dialogs on page 1731 for more details about this type of dialogs.

Defining a TABLE
The TABLE form item defines a list view widget to show a set of data records. It is bound to a screen array grouping form fields which define the columns of the table.

The screen array definition must have exactly the same number of columns as the TABLE form item. Use PHANTOM fields, if the number of record members in the program array exceeds the number of columns to be displayed in the TABLE container.

Column titles can be defined with static labels in the TABLE layout. However, this prevents you from localizing the column text. Consider using the TITLE attribute in the form field definition corresponding to the table columns.

A TABLE container can define AGGREGATE fields to display summary information for columns.

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083 and Table style attributes on page 1101.

Where to use a TABLE
A TABLE form item can be defined in three different ways:

1. As a TABLE container in a LAYOUT tree, within a grid-based layout.
2. As a <TABLE> layout tag with a TABLE item definition in the ATTRIBUTES section, within a grid-based layout.
3. As a TABLE stack item, inside a STACK container, within a stack-based layout.

Defining the TABLE layout and size
The number of field columns composing the TABLE container in the form layout defines the initial width of the table view.

The width of a TABLE container is by default defined by the number of visible columns in its layout, and the initial height is defined by the number of rows. To specify explicitly the width and height of a table, use the WIDTH and HEIGHT attributes.

By default, a table is resizable in width and height. To force a TABLE to keep the height defined in the form file, use the WANTFIXEDPAGESIZE attribute. A table is resizable and scrollable in width, to see all columns.

Table columns can be moved around, their width can be adapted, they can be hidden/shown, and can be selected to sort the record list automatically. To turn off these features, use respectively the UNMOVABLECOLUMNS, UNSIZABLECOLUMNS, UNHIDABLECOLUMNS and UNSORTABLECOLUMNS attributes.

Related concepts
Controlling table rendering on page 1759
Table rendering can be controlled by the use of presentation styles and table attributes.

SCROLLGRID item type on page 1179
Defines a scrollable grid view widget.

ATTRIBUTES section on page 1221
The ATTRIBUTES section describes properties of grid-based layout elements used in the form.

**TEXTEDIT item type**
Defines a multi-line edit field.

**TEXTEDIT item basics**
The TEXTEDIT form item defines a text input field with multiple lines. This type of element is typically used to handle large text values such as comments or addresses that would not fit in a single-line edit field.

Use a VARCHAR(N) or STRING variable to hold the data for a TEXTEDIT form item.

**Defining a TEXTEDIT**
Use the SCROLLBARS attribute to define vertical and/or horizontal scrollbars for the TEXTEDIT form field. By default, this attribute is set to VERTICAL for TEXTEDIT fields.

The STRETCH attribute can be used to force the TEXTEDIT field to stretch when the parent container is re-sized. Values can be NONE, X, Y or BOTH. By default, this attribute is set to NONE for TEXTEDIT fields.

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083 and TextEdit style attributes on page 1109.

**TAB and RETURN**
By default, when the focus is in a TEXTEDIT field, the Tab key moves to the next field, while the Return key adds a newline (ASCII 10) character in the text.

To control the user input when the Tab and Return keys are pressed, specify the WANTTABS and WANTNORETURNS attributes.

With WANTTABS, the Tab key is consumed by the TEXTEDIT field, and a Tab character (ASCII 9) is added to the text. The user can still jump out of the field with the Shift-Tab combination.

With WANTNORETURNS, the Return key is not intercepted or consumed by the TEXTEDIT field, and the action corresponding to the Return key is triggered. The user can still enter a newline character with Shift-Return or Ctrl-Return.

**Where to use a TEXTEDIT**
A TEXTEDIT form item can be defined in two different ways:

1. With an item tag and a TEXTEDIT item definition on page 1237 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a TEXTEDIT stack item on page 1214 in a STACK container.

**Defining the widget size**
In a grid-based layout, the layout behavior of the TEXTEDIT widget can be controlled with the STRETCH and SCROLLBARS attributes.

In a stack-based layout, the TEXTEDIT widget always adapts to the field value to avoid scrollbars. You can control the minimum height of the TEXTEDIT widget by using the HEIGHT attribute. If the field content is null and the HEIGHT attribute is not defined, the minimum size defaults to one line.

**Field input length**
By default, the input length in TEXTEDIT fields is defined by the program variable.

There is no need to define the SCROLL attribute, except you explicitly specify SCROLLBARS=NONE (in a grid-based layout).
Note: When specifying SCROLLBARS=NONE (in a grid-based layout), the TEXTEDIT field will limit the maximum input length to the number of cells defined by the screen item tag.

For more details about the SCROLL attribute, see Input length of form fields on page 1616.

Making the TEXTEDIT read-only

Use the NOTEDITABLE attribute to prevent text modification by the user. This attribute is typically used to display a large piece of text that the user is not required to modify (for example, to show the content of a log file). Yet, the focus can still go to the field, if it is enabled.

Rich Text HTML support

Some front-ends can also support different text formatting based on a style attribute. You can for example display and input HTML content in a TEXTEDIT with the Genero Desktop Client. When this feature is enabled, the TEXTEDIT supports rich text editing. Depending on the front-end, different formatting options are available (bold, font size, and so on) and can be controlled using an integrated toolbox.

Note:
- Each front-end uses its own technology to provide HTML support in TEXTEDIT fields. The HTML representation may vary between front-ends. As a result, the same HTML content may display in a different way on another front-end.
- When using rich text, the FGL_DIALOG_SET_CURSOR() and FGL_DIALOG_SET_SELECTION() functions must be called carefully. Because of the rich text format, having a corresponding cursor position / selection between displayed text and HTML representation may be difficult, especially in the case of hidden parts.

The fglrichtext built-in web component implements an HTML text editor.

TIMEEDIT item type

Defines a line-edit field with a clock widget to pick a time.

TIMEEDIT item basics

The TIMEEDIT form item defines a field that allows the user to edit 24H time values, or time duration (intervals), with a specific clock widget for time input.

To store TIMEEDIT field values, consider using the appropriate DATETIME HOUR TO MINUTE or DATETIME HOUR TO SECOND data type depending on the target front-end.

Important: The display and input precision (with or without seconds) of the TIMEEDIT widget depends on the front-end. On some platforms, native time editors do not handle the seconds. Furthermore, some front-ends (especially on mobile devices) do not allow data types different from DATETIME HOUR TO {MINUTE|SECOND}. If the front-end does not support the data type used for the TIMEEDIT field, the runtime system will raise an error and stop the program. Consider testing your application with all types of front-ends.

On some front-ends, TIMEEDIT fields can also be used to handle INTERVAL values of the class HOUR TO {MINUTE|SECOND}, in order to input a time duration. Note however that in most cases the time interval pickers are limited to 24H hours and allow only positive values. As result, not all values allowed in an INTERVAL HOUR TO MINUTE variable (such as -86 hours 23 minutes) can be displayed by such widgets.

Defining a TIMEEDIT

No specific attribute is needed to define the rendering and behavior of a TIMEEDIT field. Common data validation attributes such NOT NULL, REQUIRED, DEFAULT are allowed.

Note: The time display format is automatically taken from the front-end platform settings. For example, time values can display in the 0-12 hour clock format (with AM/PM indicators), or in the 0-24 hour clock format.
The native widget used for TIMEEDIT fields usually allows only exact time value input, and therefore cannot be used with a CONSTRUCT instruction, where it must be possible to enter search filters like ">=11:00". Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083.

**Detecting TIMEEDIT modification**

To inform the dialog when a date is picked from the clock widget, define an ON CHANGE block for the TIMEEDIT field. The program can then react immediately to user changes in the field:

```plaintext
-- Form file (grid layout)
TIMEEDIT del = order.ord_shiptime,
    NOT NULL;
-- Program file:
ON CHANGE ord_shiptime
    -- A new time value was picked from the clock widget
```

For more details, see Reacting to field value changes on page 1624.

**Where to use a TIMEEDIT**

A TIMEEDIT form item can be defined in two different ways:

1. With an item tag and a TIMEEDIT item definition on page 1237 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a TIMEEDIT stack item on page 1214 in a STACK container.

**Field input length**

The input length in a TIMEEDIT fields is defined by the (DATETIME) program variable. In a grid-based layout, define an item tag wide enough to fit all time value digits (5 positions for HH:MM, 7 positions for HH:MM:SS). For more details, see Input length of form fields on page 1616.

**Related concepts**

- [DATEEDIT item type](#) on page 1168
  - Defines a line-edit with a calendar widget to pick a date.
- [DATETIMEEDIT item type](#) on page 1169
  - Defines a line-edit with a calendar widget to pick a datetime.

**TREE item type**

- Defines a tree view widget.

**Note:** This topic covers the TREE item type definition in form files. See also the chapter dedicated to tree view programming.

**TREE item basics**

- A TREE form item type defines a tree view to show a structured tree of data records with an optional set of columns.
- The TREE basically acts like a TABLE container, in the sense of its function as a record list container. A TREE container renders as a tree view widget, with regular table columns on the right of the tree view.
- A TREE is controlled by a DISPLAY ARRAY dialog, see List dialogs on page 1731 for more details about this type of dialog.

**Defining a TREE**

- The TREE form item defines a tree view widget to show a structured set of data records. It is bound to a screen array grouping form fields which define the columns of the tree view.
The screen array definition must have exactly the same number of columns as the TREE form item. Use PHANTOM fields, if the number of record members in the program array exceeds the number of columns to be displayed in the TREE container.

TREE container definitions are very similar to regular TABLE containers; before reading further about tree views, you may need to familiarize yourself with TABLE containers.

The first column in the TREE must be the field defining the text of the tree view nodes.

Column titles can be defined with static labels in the TREE layout. However, this prevents you from localizing the column text. Consider using the TITLE attribute in the form field definition corresponding to the table columns.

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083 and Tree style attributes on page 1106.

Where to use a TREE

In a grid-based layout, a TREE form item can be defined in two different ways:

1. As a TREE container in a LAYOUT tree.
2. As a <TREE> layout tag with a TREE item definition in the ATTRIBUTES section.

Defining the TREE layout and size

The number of field columns composing the TREE container in the form layout defines the initial width of the tree view.

The width of a TREE container is by default defined by the number of visible columns in its layout, and the initial height is defined by the number of rows. To specify explicitly the width and height of a tree view, use the WIDTH and HEIGHT attributes.

By default, a tree view is resizable in width and height. To force a TREE to keep the height defined in the form file, use the WANTFIXEDPAGESIZE attribute. A tree view is resizable and scrollable in width, to view all columns.

Tree view columns can be moved around, their width can be adapted, they can be hidden/shown, and can be selected to sort the record list automatically. To turn off these features, use respectively the UNMOVABLECOLUMNS, UNSIZABLECOLUMNS, UNHIDABLECOLUMNS and UNSORTABLECOLUMNS attributes.

For more details, see also Controlling table rendering on page 1759.

WEBCOMPONENT item type

Defines a specialized form item that holds an external component.

WEBCOMPONENT item basics

The WEBCOMPONENT form item defines a form field that will hold an external component, implemented with a front-end plug-in mechanism.

This topic describes the WEBCOMPONENT item type in form definition files. For more details see the chapter dedicated to web component programming.

Defining a WEBCOMPONENT

The COMPONENTTYPE attribute identifies gICAPI external objects to be used for the field. The PROPERTIES attribute is typically used to define attributes that are specific to a given gICAPI-based web component. For example, a chart component might have properties to define x-axis and y-axis labels. For more details, see Using a gICAPI web component on page 1835.

If the COMPONENTTYPE attribute is not used, the web component will be a URL-based web component. For more details, see Using a URL-based web component on page 1832.

Front-ends support different presentation and behavior options, which can be controlled by a STYLE attribute. For more details, see Common style attributes on page 1083.
Where to use a WEBCOMPONENT

A WEBCOMPONENT form item can be defined in two different ways:

1. With an item tag and a WEBCOMPONENT item definition on page 1238 in a grid-layout container (GRID, SCROLLGRID and TABLE).
2. As a WEBCOMPONENT stack item on page 1215 in a STACK container.

Built-in Web Components

Genero BDL provides a set of ready-to-use web components, that are deployed by default.

For more details, see Built-in Web Components on page 1875.

Defining the widget size

The size of a WEBCOMPONENT widget can be controlled in grid-based or stack-based layout, based on several attributes such as SIZEPOLICY and STRETCH.

For more details about image sizing, see Controlling the web component layout on page 1827.

Related concepts

SIZEPOLICY attribute on page 1283

The SIZEPOLICY attribute is a sizing directive based on the content of a form item.

Form file structure

A form specification file is defined by a set of sections.

The sections of a form specification file must appear in the following order:

1. SCHEMA section on page 1188
2. ACTION DEFAULTS section on page 1189
3. TOPMENU section on page 1190
4. TOOLBAR section on page 1192
5. TABLES section on page 1219
6. LAYOUT section on page 1194
7. ATTRIBUTES section on page 1221
8. INSTRUCTIONS section on page 1239

Each section must begin with the keyword for which it is named, only the LAYOUT section is mandatory.

Related concepts

Examples on page 1305

Form definition (.per) examples.

SCHEMA section

Defines the database schema file to be used to compile the form.

Each form specification file can begin with a SCHEMA section identifying the database schema (if any) on which the form is based. This can be any database schema that is defined with a database schema file. Form field data types can be automatically extracted from the schema file if you specify the table and column name in the form field definition (see ATTRIBUTES section).

Syntax 1

```
SCHEMA database|@dbserver| string FORMONLY
```

1. `database` is the name of the database schema to be used for the form compilation.
2. `dbserver` identifies the Informix® database server (INFORMIXSERVER).
3. `string` can be a string literal containing the database name.
Syntax 2: (supported for backward compatibility)

```
DATABASE ↓ database[@dbserver] ↓ string ↓ FORMONLY ↓ ↓ WITHOUT NULL INPUT ↓
```

The DATABASE syntax is supported for compatibility with Informix® 4gl; using SCHEMA is recommended.

1. `database` is the name of the database schema to be used for the form compilation.
2. `dbserver` identifies the Informix® database server (INFORMIXSERVER)
3. `string` can be a string literal containing the database name.

Usage
The SCHEMA (or DATABASE) defines the database schema to be used to resolve data types for database column-based fields.

Note: The DATABASE instruction is supported for backward compatibility, we recommend using SCHEMA instead.

The SCHEMA section must appear in the sequence described in form file structure.

The SCHEMA section is optional; if you do not specify it, database schema specification defaults to SCHEMA FORMONLY.

You can create a form that is not related to any database schema by using the FORMONLY keyword after SCHEMA/DATABASE. When using this option, you must omit the TABLES section and define field data types explicitly in the ATTRIBUTES section.

The `database` and `dbserver` specifications are supported (but ignored) for backward compatibility with Informix® form specifications.

When using a specific database schema, the field data types are taken from the schema file during compilation. Make sure that the database schema file of the development database corresponds to the production database; otherwise the form fields defined in the compiled version of your forms will not match the table structures of the production database.

The use of the WITHOUT NULL INPUT option in the DATABASE syntax is supported for backward compatibility, but is ignored.

Example

```
SCHEMA stores
LAYOUT
...
```

Related concepts

Database schema on page 476
Defines database table structures with column type information to be reused in program variable definitions.

TABLES section on page 1219
Defines the list of database tables referenced by form field definitions.

ATTRIBUTES section on page 1221
The ATTRIBUTES section describes properties of grid-based layout elements used in the form.

ACTION DEFAULTS section
The ACTION DEFAULTS section defines local action view default attributes for the form elements.

Syntax

```
ACTION DEFAULTS
    ACTION action-identifier ( action-attribute ↓, ↓, ↓ )
↓↓↓
END
```
1. *action-identifier* defines the name of the action.
2. *action-attribute* defines an attribute for the action.

**Attributes**

*ACCELERATOR, ACCELERATOR2, ACCELERATOR3, ACCELERATOR4, DEFAULTVIEW, COMMENT, CONTEXTMENU, IMAGE, TEXT, VALIDATE.*

**Usage**

The `ACTION DEFAULTS` section centralizes action view attributes (text, comment, image, accelerators) at the form level.

The `ACTION DEFAULTS` section must appear in the sequence described in form file structure.

The `ACTION DEFAULTS` section is optional.

The section holds a list of `ACTION` elements that specify attributes for each action. The action is identified by the name following the `ACTION` keyword, and attributes are specified within a list between parenthesis.

The attributes defined in this section are applied to form action views like buttons, toolbar buttons, or topmenu options, if the individual action views do not explicitly define their own attributes.

Action attributes can be defined at different levels, see action configuration for more details.

**Example**

```
ACTION DEFAULTS
  ACTION accept ( COMMENT="Commit order record changes", CONTEXTMENU=NO )
  ACTION cancel ( TEXT="Stop", IMAGE="stop", ACCELERATOR=SHIFT-F2, VALIDATE=NO )
  ACTION print ( COMMENT="Print order information", ACCELERATOR=CONTROL-P, ACCELERATOR2=F5 )
  ACTION zoom1 ( COMMENT="Open items list", VALIDATE=NO )
  ACTION zoom2 ( COMMENT="Open customers list", VALIDATE=NO )
END
```

**Related concepts**

This topic describes the basics of action views, action events, and action handlers.

ON ACTION block on page 1369

**TOPMENU section**

The `TOPMENU` section defines a pull-down menu with options that are bound to actions.

**Syntax**

```
TOPMENU [menu-identifier] ( menu-attribute [, ...] )
  group
  [ ... ]
END
```

where `group` is:

```
GROUP group-identifier ( group-attribute [, ...] )
  [ command
  [ group
  [ separator
  [ ] ] ] ]
```
where command is:

```
COMMAND command-identifier ( command-attribute [, ...] )
```

and separator is:

```
SEPARATOR [separator-identifier] ( separator-attribute [, ...] )
```

1. menu-identifier defines the name of the top menu (optional).
2. group-identifier defines the name of the group.
3. command-identifier defines the name of the action to bind to.
4. separator-identifier defines the name of the separator (optional).
5. menu-attribute can be: STYLE, TAG.
6. group-attribute is one of: STYLE, TEXT, IMAGE, COMMENT, TAG, HIDDEN.
7. command-attribute is one of: STYLE, TEXT, IMAGE, COMMENT, TAG, HIDDEN, ACCELERATOR.
8. separator-attribute is one of: STYLE, TAG, HIDDEN.

**Attributes**

ACCELERATOR, COMMENT, HIDDEN, IMAGE, STYLE, TEXT, TAG.

**Usage**

The TOPMENU section is used to define a pull-down menu in a form.

The TOPMENU section must appear in the sequence described in form file structure.

The TOPMENU section is optional.

In a TOPMENU section, you build a tree of GROUP elements to design the pull-down menu. A GROUP can contain COMMAND, SEPARATOR or GROUP children. A COMMAND defines a pull-down menu option that triggers an action when it is selected. In the topmenu specification, command-identifier defines which action a menu option is bound to. For example, if you define a topmenu option as "COMMAND zoom", it can be controlled by an "ON ACTION zoom" clause in an interactive instruction.

The topmenu commands are enabled depending on the actions defined by the current interactive instruction. For example, you can define a topmenu option with the action name "cancel" to bind the pull-down item to this predefined dialog action.

An accelerator name can be defined for a topmenu command; this accelerator name will be used for display in the command item. You must define the same accelerator in the action defaults section for the action name of the topmenu command.

TOPMENU elements can get a STYLE attribute in order to use a specific rendering/decoration based on presentation style definitions.

**Example**

```
TOPMENU tm ( STYLE="mystyle" )
  GROUP form ( TEXT="Form" )
    COMMAND help ( TEXT="Help", IMAGE="quest" )
    COMMAND quit ( TEXT="Quit" )
  END
GROUP edit ( TEXT="Edit" )
  COMMAND accept ( TEXT="Validate", IMAGE="ok", TAG="acceptMenu" )
  COMMAND cancel ( TEXT="Cancel", IMAGE="cancel" )
  SEPARATOR
  COMMAND editcut -- Gets its decoration from action defaults
  COMMAND editcopy -- Gets its decoration from action defaults
```
Related concepts

Binding action views to action handlers on page 1664
How are action views of the forms bound to action handlers in the program code?

Topmenus on page 1334
Topmenus define typical pull-down menus that appear at the top of application forms.

ACTION DEFAULTS section on page 1189
The ACTION DEFAULTS section defines local action view default attributes for the form elements.

TOOLBAR section
The TOOLBAR section defines a toolbar with buttons that are bound to actions.

Syntax

```
TOOLBAR [toolbar-identifier] [ ( toolbar-attribute [, ...] ) ] [ 
   ( ITEM item-identifier [ ( item-attribute [, ...] ) ] | 
     SEPARATOR [separator-identifier] [ ( separator-attribute [, ...] ) ] ] ] ... 
END
```

1. `toolbar-identifier` defines the name of the toolbar (optional).
2. `item-identifier` defines the name of the action to bind to.
3. `separator-identifier` defines the name of the separator (optional).
4. `toolbar-attribute` is one of: STYLE, TAG, BUTTONTEXTHIDDEN.
5. `item-attribute` is one of: STYLE, TAG, TEXT, IMAGE, COMMENT, HIDDEN.
6. `separator-attribute` is one of: STYLE, TAG, HIDDEN.

Attributes

BUTTONTEXTHIDDEN, COMMENT, HIDDEN, IMAGE, STYLE, TEXT, TAG.

Usage

The TOOLBAR section defines a toolbar in a form.

The TOOLBAR section must appear in the sequence described in form file structure.

The TOOLBAR section is optional.

A TOOLBAR section defines a set of ITEM elements that can be grouped by using a SEPARATOR element. Each ITEM defines a toolbar button associated with an action by name. The SEPARATOR keyword specifies a vertical line.

The toolbar buttons are enabled depending on the actions defined by the current interactive instruction. For example, you can define a toolbar button with the action name "cancel" to bind the toolbar item to this predefined dialog action.

Toolbar button labels are visible by default. The TOOLBAR supports the BUTTONTEXTHIDDEN attribute to hide the labels of buttons.

TOOLBAR elements can get a STYLE attribute in order to use a specific rendering/decoration following presentation style definitions.
Example

```plaintext
TOOLBAR tb ( STYLE="mystyle" )
  ITEM accept ( TEXT="Ok", IMAGE="ok" )
  ITEM cancel ( TEXT="Cancel", IMAGE="cancel" )
  SEPARATOR
  ITEM editcut -- Gets its decoration from action defaults
  ITEM editycopy -- Gets its decoration from action defaults
  ITEM editpaste -- Gets its decoration from action defaults
  SEPARATOR ( TAG="lastSeparator")
  ITEM append ( TEXT="Append", IMAGE="add" )
  ITEM update ( TEXT="Update", IMAGE="modify" )
  ITEM delete ( TEXT="Delete", IMAGE="del" )
  ITEM search ( TEXT="Search", IMAGE="find" )
END
```

Related concepts

Binding action views to action handlers on page 1664
How are action views of the forms bound to action handlers in the program code?

Toolbars on page 1327
Toolbars define a bar of buttons that appears at the top of application forms.

ACTION DEFAULTS section on page 1189
The ACTION DEFAULTS section defines local action view default attributes for the form elements.

SCREEN section
The SCREEN section defines the form layout for TUI mode forms.

Syntax

```plaintext
SCREEN
  [ SIZE lines [ BY chars ] ]
  [ TITLE "title" ]
  [ TAG "tag-string" ]
  { [ text | item-tag ] [ item-tag ] [ ... ] [ ] }
} [END]
```

1. `lines` is the number of characters the form can display vertically. The default is 24.
2. `chars` is the number of characters the form can display horizontally. The default is the maximum number of characters in any line of the screen definition.
3. `title` is the title for the top window.
4. `tag-string` is a user-defined string.
5. `item-tag` and `text` define form elements in the layout.

Usage

The SCREEN section must be used to design TUI mode screens. For a GUI mode application, use a LAYOUT or STACKED LAYOUT section instead.

The SCREEN section must appear in the sequence described in form file structure.

This section is mandatory, unless you use a LAYOUT section.

The END keyword is optional.

The TAG attribute can be used to specify a string that will help to identify the form at runtime. For more details about this attribute, see TAG.
Inside the SCREEN section, you can define the position of text labels and form fields in the area delimited by the {} curly brackets.

Horizontal lines can be specified with a set of dash characters.

Avoid Tab characters (ASCII 9) inside the curly-brace delimited area. If used, Tab characters will be replaced by 8 blank spaces by fglform.

Example

SCREEN TITLE "Customer info" TAG "regular"
{
  CustId : [f001] Name: [f002]
  Address: [f003]
  [f003]
  ------------------------------------------------
}
END

Related concepts

LAYOUT section on page 1194
The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

Item tags on page 1155
Item tags define the position and size in a grid-based container.

LAYOUT section
The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

Syntax

LAYOUT [ ( layout-attribute [ ,..., ] ) ] root-container
  child-container
  [ ,..., ]
END [END]

1. layout-attribute is an attribute for the whole form.
2. root-container is the first container that holds child-containers.

Attributes

IMAGE, MINHEIGHT, MINWIDTH, SPACING, STYLE, TEXT, TAG, VERSION, WINDOWSTYLE.

Can hold

FORM, VBOX, HBOX, GROUP, FOLDER, GRID, SCROLLGRID, STACK, TABLE, TREE.

Usage

The LAYOUT section is used to define a tree of layout containers, it can mix grid-based layout containers (GRID), with stack-based layout containers (STACK).

The LAYOUT section must appear in the sequence described in form file structure.

This section is mandatory, unless you use a SCREEN section.

Indentation is supported in the LAYOUT section.

The END keyword is optional.
The layout tree of the form is defined by associating layout containers. Different kinds of layout containers are provided, each of them having a specific role. Some containers such as VBOX, HBOX and FOLDER can hold children containers, while others such as GRID and TABLE define a screen area. Containers using a screen area define a formatted region containing static text labels, item tags and layout tags. External form files can be included in the current layout with the FORM clause.

LAYOUT (VERSION="12", STYLE="regular")
  VBOX
    GRID grid1
    grid-area
    END
  GROUP group1
    HBOX
      GRID grid2
      grid-area
      END
    TABLE table1
    table-area
    END
  END
END

The definition would result in a layout tree that looks like this:

```
-- VBOX
  |--- GRID grid1
  |     |--- GROUP group1
  |     |     |--- HBOX
  |     |     |     |--- GRID grid2
  |     |     |--- TABLE table1
```

The layout section can also contain a simple GRID container (equivalent to a V3 SCREEN definition):

```
LAYOUT
  GRID
  grid-area
  END
END
```

**Description of LAYOUT attributes**

The VERSION attribute can be used to specify a version for the form. This allows you to indicate that the form content has changed. Typically used to avoid having the front-end reload the saved window settings.

The MINHEIGHT, MINWIDTH attributes can be used to specify a minimum width and height for the form. You typically use these attributes to force the form to have a bigger size than the default when it is first rendered. If the front-end stores window sizes, these attributes will only be significant the first time the form is opened, or each time the VERSION attribute is changed.

The IMAGE attribute can be used to define the icon of the window that will display the form. This attribute is automatically applied to the parent window node when a form is loaded.

The TEXT attribute can be used to define the title of the window that will display the form. This attribute is automatically applied to the parent window node when a form is loaded.
The `SPACING` attribute can be used to give a hint to the front-end to define the gap between form elements.

The `STYLE` attribute defines the presentation style for form elements, you can for example define a font property for all form elements.

With the `WINDOWSTYLE` attribute, you can define the window type and decoration. This attribute is automatically applied to the parent window when a form is loaded. For backward compatibility, the `STYLE` attribute is used as the default `WINDOWSTYLE` if this attribute is not used.

**Related concepts**

*Stack-based layout* on page 1322
A form file can define a stack-based layout within a tree of stack items.

*SCREEN section* on page 1193
The `SCREEN` section defines the form layout for TUI mode forms.

*ATTRIBUTES section* on page 1221
The `ATTRIBUTES` section describes properties of grid-based layout elements used in the form.

**FORM clause**
Reuse the definition of a form in the current form.

**Syntax**

```
FORM "form-file"
```

1. `form-file` is the form to be included (without `.per` extension).

**Attributes**
None.

**Usage**
The `FORM` clause includes an external form at the current layout position, enforcing form re-usability, or to solve form complexity when using a `DIALOG` instruction; for example to define a common form header for several application forms.

Wherever a layout container can be specified, the layout of an external form can be merged into the layout of the current form, with the `FORM` clause. See *External form inclusion* on page 1161.

The `.per` source of the included form must be readable. If the compiled version (`.42f`) does not exist, or is older than the `.per` source, `fglform` will automatically compile the included form. The included forms can be located in a different directory as the main form.

The form compiler searches for the external form relative to the path of the current compiled form. For example, with `fglform dir1/dir2/main.per`, when the main form includes an external form with `FORM "../otherdir/subform"`, `fglform` will include the form file located in `dir1/otherdir/subform.per`.

The form compiler performs an up-to-date test of the compiled form. Error `-6842` is thrown if the up-to-date test fails.

If the external form contains a `TOOLBAR` or a `TOPMENU` section, error `-6841` is thrown.

The external form must not define a `SCREEN RECORD` or use a `TABLE` already defined in the current form, otherwise error `-2024` is thrown. Consider using the `table alias syntax` to avoid duplicate table names in merged forms.

The external form can define its own `ACTION DEFAULTS` section. The action defaults of the external file will be merged into the action defaults of the current form.

The `TABINDEX` attributes of the elements of the result form will be adjusted. As the result tabbing (`OPTIONS FIELD ORDER FORM` in programs) keeps the visual order of the layout.
Example

```
LAYOUT
  FOLDER
  PAGE page1 (TEXT = "Customer")
    FORM "customer"
  END
  PAGE page2 (TEXT = "Orders")
    FORM "orders"
  END
END
```

Related concepts

- **TOPMENU section** on page 1190
  The TOPMENU section defines a pull-down menu with options that are bound to actions.
- **The SUBDIALOG clause** on page 1496

**HBOX container**

Packs child layout elements horizontally.

**Syntax**

```
HBOX [identifier] [ (attribute [, ...] ) ] [layout-container] [ ... ]
END
```

1. `identifier` defines the name of the element.
2. `attribute` is an attribute for the element.
3. `layout-container` is another child container.

**Attributes**

`COMMENT`, `FONTPITCH`, `HIDDEN`, `STYLE`, `SPLITTER`, `TAG`.

**Can hold**

`VBOX`, `HBOX`, `GROUP`, `FOLDER`, `GRID`, `SCROLLGRID`, `TABLE`, `TREE`.

**Usage**

The **HBOX** container automatically packs the contained elements horizontally from left to right.

Contained elements are packed in the order in which they appear in the LAYOUT section of the form file.

No decoration is added when you use a **HBOX** container.

By combining **VBOX** and **HBOX** containers, you can define any alignment you choose.

**Example**

```
HBOX
  GROUP ( TEXT = "Customer" )
```

VBOX [identifier] { (attribute [, ...] ) } layout-container [...] END
```

1. *identifier* defines the name of the element.
2. *attribute* is an attribute for the element.
3. *layout-container* is another child container.

**Attributes**

```
COMMENT, FONTPITCH, HIDDEN, STYLE, SPLITTER, TAG.
```

**Can hold**

```
VBOX, HBOX, GROUP, FOLDER, GRID, SCROLLGRID, TABLE, TREE.
```

**Usage**

The VBOX container automatically packs the contained elements vertically from top to bottom.

Contained elements are packed in the order in which they appear in the LAYOUT section of the form file.

No decoration is added when you use a VBOX container.

By combining VBOX and HBOX containers, you can define any alignment you choose.
Example

```plaintext
VBOX
    GROUP ( TEXT = "Customer" )
    {
        ...
    }
END
TABLE
    {
        ...
    }
END
END
```

Related concepts

**Grid-based layout** on page 1309
A form file can define a grid-based layout within a tree of layout items.

**LAYOUT section** on page 1194
The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

**Item tags** on page 1155
Item tags define the position and size in a grid-based container.

**Layout tags** on page 1151
Layout tags define layout areas for containers inside the frame of a grid-based container.

**Automatic HBoxes and VBoxes** on page 1312
Horizontal and vertical boxes are added automatically when stretchable elements are used.

**GROUP container**
Defines a layout area to group other layout elements together, in a grid-based layout.

Syntax

```
GROUP [identifier] [ ( attribute [, ...] ) ]
    layout-container
    [ ... ]
END
```

1. `identifier` defines the name of the element.
2. `attribute` is an attribute for the element.
3. `layout-container` is another child container.

Attributes

`COMMENT, FONTPITCH, STYLE, TAG, HIDDEN, TEXT`.

Can hold

`VBOX, HBOX, GROUP, FOLDER, GRID, SCROLLGRID, TABLE, TREE`.

Usage

In a LAYOUT tree definition, use a GROUP container to hold other containers such as a VBOX with children, or a GRID container.

For more details about this item type, see **GROUP item type** on page 1172.
Example

GROUP ( TEXT = "Customer" )
VBOX
  GRID
  { ... }
END
TABLE
  { ... }
END
END
END

Related concepts

Stacked group rendering on page 1324
Groups render in a native way on front-ends supporting the stacked layout.

Layout tags on page 1151
Layout tags define layout areas for containers inside the frame of a grid-based container.

FOLDER container
Defines the parent container for folder pages, in a grid-based layout.

Syntax

FOLDER [identifier] [ ( attribute [, ...] ) ]
  folder-page
[ ... ]
END

1. identifier defines the name of the element.
2. attribute is an attribute for the element.
3. folder-page defines a folder page that contains other form elements.

Attributes

COMMENT, FONTPITCH, STYLE, TAG, HIDDEN.

Can hold

PAGE

Usage

A FOLDER container including PAGE elements defines a folder tab widget.
Define each folder page with a PAGE container inside the FOLDER container.
For more details about this item type, see FOLDER item type on page 1171.

PAGE container
Defines the content of a folder page, in a grid-based layout.

Syntax

PAGE [identifier] [ ( attribute [, ...] ) ]
1. *identifier* defines the name of the element.
2. *attribute* is an attribute for the element.
3. *layout-container* is another child container.

**Attributes**

*ACTION, COMMENT, HIDDEN, IMAGE, STYLE, TAG, TEXT.*

**Can hold**

*VBOX, HBOX, GROUP, FOLDER, GRID, SCROLLGRID, TABLE, TREE.*

**Usage**

In a LAYOUT tree definition, use a PAGE container to define a folder page that holds other containers such as a VBOX with children, or a GRID container.

A PAGE container always belongs to a parent FOLDER container.

For more details about this item type, see PAGE item type on page 1177.

**Example**

```
FOLDER
  PAGE p1 ( TEXT="Global info" )
  GRID
  {
    ...
  }
END
END
PAGE p2 ( IMAGE="list" )
  TABLE
  {
    ...
  }
END
END
```

**GRID container**

Defines a layout area based on a grid of cells.

**Syntax**

```
GRID [identifier] [ ( attribute [, ...] ) ]
{
  text
  item-tag
  hbox-tag
  layout-tag
  horizontal-line
  [ ... ]
}
END
```

1. *text* is literal text that will appear in the form as a static label.
2. *item-tag* defines the position and length of a form item.
3. *hbox-tag* defines the position and length of several form items inside an horizontal box.
4. *layout-tag* defines the position and length of a layout tag.
5. *horizontal-line* is a set of dash characters defining a horizontal line.

**Attributes**

`COMMENT`, `FONTPITCH`, `HIDDEN`, `STYLE`, `TAG`.

**Usage**

The GRID container declares a formatted text block, defining the dimensions and the positions of children form items.

**Note:** Avoid Tab characters (ASCII 9) inside the curly-brace delimited area. If used, Tab characters will be replaced by 8 blanks by *fglform*.

For more details about this item type, see [GRID item type](#) on page 1172.

**Example**

```plaintext
GRID
{
  <GROUP g1
    Id:  [f1] Name:  [f2]
    Addr:  [f3]
  >
}
END
```

**Related concepts**

[Grid-based layout](#) on page 1309
A form file can define a grid-based layout within a tree of layout items.

[Layout tags](#) on page 1151
*Layout tags* define layout areas for containers inside the frame of a grid-based container.

[Item tags](#) on page 1155
*Item tags* define the position and size in a grid-based container.

[Hbox tags](#) on page 1158
*Hbox tags* group several item tags within the same horizontal layout box, in a grid-based container.

[Static items](#) on page 1135
A *static item* defines a simple form item as a final grid element that does not change.

**STACK container**

The STACK container holds stack items defining a logical alignment of form items.

**Important:** This feature is experimental, the syntax/name and semantics/behavior may change in a future version.

**Syntax**

```
STACK
  ↓ scalable-item
  ↓ container-list
↓
END
```

where *container-list* is:

```
grouping-item
```
1. `scalable-item` is a leaf element of the stacked layout, for widgets with a scalable width and height.
2. `grouping-item` is a stacked layout grouping element that holds a list of `leaf-items`.
3. `leaf-item` is a leaf element of the stacked layout, for widgets with a fixed size (non-scalable).

**Can hold**

Scalable stack items: `IMAGE`, `TEXTEDIT`, `WEBCOMPONENT`.

or:

Grouping stack items: `FOLDER`, `GROUP`, `TABLE`.

**Usage**

The `STACK` container is used to define a stack-based layout.

Note: Unlike grid-based containers (`GRID`) where element definition is split in the `LAYOUT` and `ATTRIBUTES` sections, the items in a `STACK` container define both the position and attributes.

The `STACK` container must appear immediately after the `LAYOUT` keyword.

The `STACK` container typically defines a list of elements (such as `GROUP`, `FOLDER`, `TABLE`), grouping leaf stack items (such as form fields) together:

```plaintext
LAYOUT
  STACK
    GROUP custinfo (TEXT="Customer info")
      EDIT customer.cust_num, TITLE="Num:", NOENTRY;
      EDIT customer.cust_name, TITLE="Name:", SCROLL;
      ...
    END
    TABLE cust_orders (STYLE="compact_list", DOUBLECLICK=select)
      LABEL orders.ord_num, TITLE="Num";
      LABEL orders.ord_ship, TITLE="Ship date";
      LABEL orders.ord_value, TITLE="Value";
      ...
    END
  ...
END
```

A stack container can also define a single scalable stack item, such as an `IMAGE`, `TEXTEDIT`, or `WEBCOMPONENT`:

```plaintext
STACK
  IMAGE FORMONLY.picture;
END
```

**Related concepts**

- `GRID container` on page 1201
  Defines a layout area based on a grid of cells.

- `BUTTON stack item`
Defines a push-button that can trigger an action in a stack-based layout.

**Syntax**

\[
\text{BUTTON \ item-name \ , \ attribute-list \ };
\]

1. `item-name` defines the form item name and the action name.
2. `attribute-list` defines the aspect and behavior of the form item.

**Attributes**

`COMMENT, DISCLOSUREINDICATOR, FONTPITCH, HIDDEN, IMAGE, SAMPLE, SIZEPOLICY, STYLE, TABINDEX, TAG, TEXT`.

**Usage**
Define the rendering and behavior of a button stack item, with a `BUTTON` element inside a `STACK` container.

For more details about this item type, see `BUTTON item type` on page 1163.

**Example**

\[
\text{BUTTON print, TEXT="Print Report", IMAGE="printer";}
\]

**BUTTONEDIT stack item**

Defines a line-edit with a push-button that can trigger an action in a stack-based layout.

**Syntax**

\[
\text{BUTTONEDIT \ field-name \ , \ attribute-list \ };
\]

1. `field-name` identifies the name of the screen record field.
2. `attribute-list` defines the aspect and behavior of the form item.

**Attributes**

`ACTION, AUTONEXT, CENTURY, COLOR, COMPLETER, COLOR WHERE, COMMENT, DEFAULT, DISPLAY LIKE, DOWNSHIFT, FONTPITCH, HIDDEN, FORMAT, IMAGE, INCLUDE, INVISIBLE, JUSTIFY, KEY, KEYBOARDHINT, NOT NULL, NOTEDITABLE, NOENTRY, PICTURE, PLACEHOLDER, PROGRAM, REVERSE, SAMPLE, SCROLL, STYLE, REQUIRED, TAG, TITLE, TABINDEX, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, UPSHIFT, VALIDATE LIKE, VERIFY`.

**Usage**
Define the rendering and behavior of a buttonedit stack item, with a `BUTTONEDIT` element inside a `STACK` container.

For more details about this item type, see `BUTTONEDIT item type` on page 1164.

**Example**

\[
\text{BUTTONEDIT customer.state, REQUIRED, IMAGE="smiley", ACTION=zoom;}
\]

**CHECKBOX stack item**
Defines a boolean or three-state checkbox field in a stack-based layout.

**Syntax**

```plaintext
CHECKBOX  field-name [,  attribute-list ];
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

**Attributes**

```plaintext
COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, REQUIRED, SAMPLE, SIZEPOLICY, STYLE, TAG, TABINDEX, TEXT, TITLE, VALIDATE LIKE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALUECHECKED, VALUEUNCHECKED.
```

**Usage**

Define the rendering and behavior of a checkbox stack item, with a `CHECKBOX` element inside a `STACK` container.

For more details about this item type, see **CHECKBOX item type** on page 1165.

**Example**

```plaintext
CHECKBOX customer.active,
        REQUIRED, TEXT="Active",
        VALUECHECKED="Y", VALUEUNCHECKED="N";
```

**COMBOBOX** stack item

Defines a line-edit with a drop-down list of values in a stack-based layout.

**Syntax**

```plaintext
COMBOBOX  field-name [,  attribute-list ];
```

1. *field-name* identifies the name of the screen record field.
2. *attribute-list* defines the aspect and behavior of the form item.

**Attributes**

```plaintext
COLOR, COLOR WHERE, COMMENT, DEFAULT, DOWNSHIFT, FONTPITCH, HIDDEN, KEY, INCLUDE, INITIALIZER, ITEMS, JUSTIFY, NOT NULL, NOENTRY, PLACEHOLDER, QUERYEDITABLE, REQUIRED, SAMPLE, SCROLL, SIZEPOLICY, STYLE, UPSHIFT, TAG, TABINDEX, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, TITLE, VALIDATE LIKE.
```

**Usage**

Define the rendering and behavior of a combobox stack item, with a `COMBOBOX` element inside a `STACK` container.

For more details about this item type, see **COMBOBOX item type** on page 1166.

**Example**

```plaintext
COMBOBOX customer.city,
        ITEMS=((1,"Paris"),
                (2,"Madrid"),
                (3,"London"));
COMBOBOX customer.sector,
        REQUIRED,
        ITEMS=("SA", "SB", "SC");
COMBOBOX customer.state,
DATEEDIT stack item
Defines a line-edit with a calendar widget to pick a date in a stack-based layout.

Syntax

\[
\text{DATEEDIT } \text{field-name} \ [ \text{, attribute-list} ] \ ;
\]

1. field-name identifies the name of the screen record field.
2. attribute-list defines the aspect and behavior of the form item.

Attributes

AUTONEXT, CENTURY, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, FORMAT, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, PLACEHOLDER, REQUIRED, SAMPLE, STYLE, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage
Define the rendering and behavior of a date edit stack item, with a DATEEDIT element inside a STACK container.
For more details about this item type, see DATEEDIT item type on page 1168.

Example

\[
\text{DATEEDIT order.shipdate;}
\]

DATETIMEEDIT stack item
Defines a line-edit with a calendar widget for selecting a datetime in a stack-based layout.

Syntax

\[
\text{DATETIMEEDIT } \text{field-name} \ [ \text{, attribute-list} ] \ ;
\]

1. field-name identifies the name of the screen record field.
2. attribute-list defines the aspect and behavior of the form item.

Attributes

AUTONEXT, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, NOT NULL, NOENTRY, PLACEHOLDER, REQUIRED, SAMPLE, STYLE, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage
Define the rendering and behavior of a date-time edit stack item, with a DATETIMEEDIT element inside a STACK container.
For more details about this item type, see DATETIMEEDIT item type on page 1169.

Example

\[
\text{DATETIMEEDIT package.modts;}
\]
Defines an element to enter a single-line text in a stack-based layout.

**Syntax**

```
EDIT [identifier] , attribute-list ;
```

1. `field-name` identifies the name of the screen record field.
2. `attribute-list` defines the aspect and behavior of the form item.

**Attributes**

`AUTONEXT`, `CENTURY`, `COLOR`, `COLOR WHERE`, `COMMENT`, `COMPLETER`, `DEFAULT`, `DISPLAY LIKE`, `DOWNSHIFT`, `FONTPITCH`, `FORMAT`, `HIDDEN`, `IMAGECOLUMN`, `INCLUDE`, `INVISIBLE`, `JUSTIFY`, `KEY`, `KEYBOARDHINT`, `NOT NULL`, `NOENTRY`, `PICTURE`, `PLACEHOLDER`, `PROGRAM`, `REQUIRED`, `REVERSE`, `SAMPLE`, `STYLE`, `SCROLL`, `TAG`, `TABINDEX`, `TITLE`, `UNSORTABLE`, `UNSIZABLE`, `UNHIDABLE`, `UNMOVABLE`, `UPSHIFT`, `VALIDATE LIKE`, `VERIFY`.

**Usage**

Define the rendering and behavior of an edit stack item, with an `EDIT` element inside a `STACK` container.

For more details about this item type, see `EDIT item type` on page 1170.

**Example**

```
EDIT customer.cust_name, NOT NULL;
```

**FOLDER stack item**

Defines a stack area to hold a set of folder pages, in a stack-based layout.

**Syntax**

```
FOLDER [identifier] [ ( attribute-list ) ] folder-page [ ... ] END
```

1. `identifier` defines the name of the element.
2. `attribute-list` defines the aspect and behavior of the form item.
3. `folder-page` is a page element in the folder definition.

**Attributes**

`COMMENT`, `FONTPITCH`, `STYLE`, `TAG`, `HIDDEN`.

**Can hold**

`PAGE`.

**Usage**

Use a `FOLDER` stack layout element to define a set of folder pages with a folder tab widget.

Define each folder page with a `PAGE` stack item inside the `FOLDER` container.

For more details about this item type, see `FOLDER item type` on page 1171.

For a code example, see `PAGE stack item` on page 1209.

**GROUP stack item**
Defines a stack area to group other layout elements together, in a stack-based layout.

**Syntax**

```
GROUP [identifier] [ ( attribute-list ) ] stack-item [...]
END
```

1. **identifier** defines the name of the element.
2. **attribute-list** defines the aspect and behavior of the form item.
3. **stack-item** is child element in the stack container.

**Attributes**

`COMMENT, FONTPITCH, HIDDEN, STYLE, TAG, TEXT`.

**Can hold**

`BUTTON, BUTTONEDIT, CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, EDIT, IMAGE, LABEL, PROGRESSBAR, PHANTOM, SLIDER, SPINEDIT, TEXTEDIT, TABLE, TIMEEDIT, RADIOGROUP, WEBCOMPONENT`.

**Usage**

Use a GROUP stack layout element to group other stack items together.

For more details about this item type, see **GROUP item type** on page 1172.

**Example**

```
GROUP group1 (TEXT="Customer info")
   EDIT ...
      BUTTONEDIT ...
   ...
END
```

**Related concepts**

- **Stacked group rendering** on page 1324
  Groups render in a native way on front-ends supporting the stacked layout.

- **Layout tags** on page 1151
  `Layout tags` define layout areas for containers inside the frame of a grid-based container.

**IMAGE stack item**

Defines an element to display an image resource in a stack-based layout.

**Syntax 1: Defining a form field image**

```
IMAGE field-name , attribute-list ;
```

**Syntax 2: Defining a static image**

```
IMAGE : item-name , attribute-list ;
```

1. **field-name** identifies the name of the screen record field.
2. **item-name** identifies the form item for a static image.
3. **attribute-list** defines the aspect and behavior of the form item.
Attributes

**ACTION, AUTOSCALE, COMMENT, HEIGHT, HIDDEN, SIZEPOLICY, STYLE, STRETCH, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, WIDTH.**

*Image field only: JUSTIFY, SAMPLE.*

*Static image only: IMAGE.*

Usage

Define the rendering and behavior of an image stack item, with a IMAGE element inside a STACK container.

**Note:** The IMAGE stack item can be used inside a stack container like a group, or as root element of the STACK container: When used directly under the STACK container, the IMAGE stack item must be the only element in the container. It will be rendered a scalable form item that can stretch to fit the front-end screen size.

For more details about this item type, see **IMAGE item type** on page 1174.

**Example**

```plaintext
IMAGE cars.picture, COMMENT="Picture of the car";
```

**LABEL stack item**

Defines a simple text area to display a read-only value in a stack-based layout.

**Syntax 1: Defining a form field label**

```plaintext
LABEL field-name [], attribute-list [];
```

**Syntax 2: Defining a static label**

```plaintext
LABEL : item-name [], attribute-list [];
```

1. **field-name** identifies the name of the screen record field.
2. **item-name** identifies the form element (name attribute in .42f) of a static label.
3. **attribute-list** defines the aspect and behavior of the form item.

Attributes

**COLOR, COLOR WHERE, COMMENT, FONTPITCH, HIDDEN, IMAGECOLUMN, JUSTIFY, REVERSE, SIZEPOLICY, STYLE, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE.**

*Form field label only: FORMAT, SAMPLE.*

*Static label only: TEXT.*

Usage

Define the rendering and behavior of a label stack item, with a LABEL element inside a STACK container.

For more details about this item type, see **LABEL item type** on page 1175.

**Example**

```plaintext
LABEL vehicle.description, STYLE="normal";
```

**PAGE stack item**
Defines the content of a folder page stack item.

Syntax

```plaintext
PAGE [identifier] [(attribute-list)] {
scalable-item
  [grouping-item
    leaf-item
      [...]]
END
[...
END
```

1. `identifier` defines the name of the element.
2. `attribute-list` defines the aspect and behavior of the form item.
3. `scalable-item` is a stacked layout items that can grow and shrink.
4. `grouping-item` is a stacked layout grouping element that holds a list of `stack-items`.
5. `leaf-item` is a leaf element of the stacked layout, for widgets with a fixed size (non-scalable).

Attributes

`ACTION, COMMENT, HIDDEN, IMAGE, STYLE, TAG, TEXT`.

Can hold

`FOLDER, GROUP, TABLE`.

Usage

Use a `PAGE` stack layout element to group other stack items together.

A `PAGE` stack item always belongs to a parent `FOLDER` stack item.

For more details about this item type, see `PAGE item type` on page 1177.

Example

```plaintext
LAYOUT
STACK
  FOLDER folder1 (STYLE="common")
    PAGE page1 (TEXT="Customer info")
      GROUP
      EDIT FORMONLY.cust_num;
      EDIT FORMONLY.cust_name;
    END
    END
  PAGE page2 (TEXT="Picture")
    GROUP
    IMAGE FORMONLY.cust_pic;
    END
    END
  PAGE page3 (TEXT="Comments")
    GROUP
    TEXTEDIT FORMONLY.cust_desc;
    END
    END
  END
END
```
Related concepts
FOLDER stack item on page 1207
Defines a stack area to hold a set of folder pages, in a stack-based layout.

PHANTOM stack item
Defines a form field in a stack-based container, that must not be displayed to the end user.

Syntax

```
PHANTOM [field-name];
```

1. `field-name` identifies the name of the screen record field.

Usage
Define a PHANTOM leaf element in a stack container, to declare a form field to be used by a dialog, without being displayed to the user.

For more details, see Phantom fields on page 1142.

Example

```
PHANTOM customer.cust_name;
```

Related concepts
STACK container on page 1202
The STACK container holds stack items defining a logical alignment of form items.

PHANTOM item definition on page 1223
Defines a form field in a grid-based container, that must not be displayed to the end user.

PROGRESSBAR stack item
Defines a progress indicator field in a stack-based layout.

Syntax

```
PROGRESSBAR field-name, attribute-list;
```

1. `field-name` identifies the name of the screen record field.
2. `attribute-list` defines the aspect and behavior of the form item.

Attributes

```
COLOR, COLOR WHERE, COMMENT, FONTPITCH, HIDDEN, JUSTIFY, VALUEMIN, VALU MAX, SAMPLE, STYLE, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE.
```

Usage
Define the rendering and behavior of a progress bar stack item, with a PROGRESSBAR element inside a STACK container.

For more details about this item type, see PROGRESSBAR item type on page 1177.

Example

```
PROGRESSBAR workstate.position, VALUEMIN=-100, VALUEMAX=+100;
```

RADIOGROUP stack item
Defines a mutual exclusive set of option fields, in a stack-based layout.

**Syntax**

```plaintext
RADIOGROUP field-name [, attribute-list ];
```

1. `field-name` identifies the name of the screen record field.
2. `attribute-list` defines the aspect and behavior of the form item.

**Attributes**

- `COLOR`, `COLOR WHERE`, `COMMENT`, `DEFAULT`, `FONTPITCH`, `HIDDEN`, `INCLUDE`, `ITEMS`, `JUSTIFY`, `KEY`, `NOT NULL`, `NOENTRY`, `ORIENTATION`, `REQUIRED`, `SAMPLE`, `SIZEPOLICY`, `STYLE`, `TAG`, `TABINDEX`, `TITLE`, `UNSORTABLE`, `UNSIZABLE`, `UNHIDABLE`, `UNMOVABLE`, `VALIDATE LIKE`.

**Usage**

Define the rendering and behavior of a radio group stack item, with an EDIT element inside a STACK container.

For more details about this item type, see RADIOGROUP item type on page 1178.

**Example**

```
RADIOGROUP player.level,
   ITEMS=((1,"Beginner"),
           (2,"Normal"),
           (3,"Expert"));
```

**SLIDER stack item**

Defines a slider element in a stack-based layout.

**Syntax**

```plaintext
SLIDER field-name [, attribute-list ];
```

1. `field-name` identifies the name of the screen record field.
2. `attribute-list` defines the aspect and behavior of the form item.

**Attributes**

- `COLOR`, `COLOR WHERE`, `COMMENT`, `DEFAULT`, `FONTPITCH`, `HIDDEN`, `INCLUDE`, `JUSTIFY`, `NOENTRY`, `ORIENTATION`, `SAMPLE`, `STEP`, `STYLE`, `TAG`, `TABINDEX`, `TITLE`, `UNSORTABLE`, `UNSIZABLE`, `UNHIDABLE`, `UNMOVABLE`, `VALIDATE LIKE`, `VALUEMIN`, `VALUEMAX`.

**Usage**

Define the rendering and behavior of a slider stack item, with a SLIDER element inside a STACK container.

For more details about this item type, see SLIDER item type on page 1181.

**Example**

```
SLIDER workstate.duration,
   VALUEMIN=0, VALUEMAX=5,
   STEP=1;
```

**SPINEDIT stack item**
Defines a spin box widget to enter integer values in a stack-based layout.

**Syntax**

```
SPINEDIT  field-name [ , attribute-list ] ;
```

1. `field-name` identifies the name of the screen record field.
2. `attribute-list` defines the aspect and behavior of the form item.

**Attributes**

`AUTONEXT, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, NOT NULL, NOENTRY, PLACEHOLDER, REQUIRED, SAMPLE, STEP, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE, VALUemin, VALUemax`

**Usage**

Define the rendering and behavior of a spin edit stack item, with a `SPINEDIT` element inside a `STACK` container.

For more details about this item type, see `SPINEDIT item type` on page 1182.

**Example**

```
SPINEDIT command.nbitems, STEP=5;
```

---

**TABLE stack item**

Defines a re-sizable table designed to display a list of records in a stack-based layout.

**Syntax**

```
TABLE  identifier [ ( attribute-list ) ]
  stack-item ...
END
```

1. `identifier` defines the name of the element.
2. `attribute-list` defines the aspect and behavior of the form item.
3. `stack-item` is child element in the stack container defining a column in the table.

**Attributes**

`AGGREGATETEXT, COMMENT, DOUBLECLICK, HIDDEN, FONTPITCH, STYLE, TAG, UNHIDABLECOLUMN, UNMOVABLECOLUMN, UNSIZABLECOLUMN, UNSORTABLECOLUMN, WANTFIXEDPAGESIZE, WIDTH, HEIGHT`

**Can hold**

`BUTTONEDIT, CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, EDIT, IMAGE, LABEL, PROGRESSBAR, PHANTOM, SLIDER, SPINEDIT, TIMEEDIT, RADIOGROUP`

**Usage**

The `TABLE` stack layout element defines a list view element in a stack-based layout.

To create a table view in a stacked layout, define the following elements in the form file:

1. The layout of the list, with a `TABLE` stack item.
2. The columns definitions as stack items inside the `TABLE` item.

**Note:** The `TABLE` item must have an identifier, that will be used as screen-array in list dialogs.
For more details about table view programming, see Table views on page 1754

Example

TABLE custlist (STYLE="regular")
EDIT ...  
   BUTTONEDIT ...
   ...
END

TEXTEDIT stack item
Defines a multi-line edit field in a stack-based layout.

Syntax

TEXTEDIT [identifier ] [, attribute-list ] ;

1. field-name identifies the name of the screen record field.
2. attribute-list defines the aspect and behavior of the form item.

Attributes

COLOR,COLOR WHERE, COMMENT, DEFAULT, DOWNSHIFT, FONTPITCH, HIDDEN, INCLUDE, JUSTIFY, KEY,
NOT NULL, NOENTRY, PLACEHOLDER, PROGRAM, REQUIRED, SAMPLE, SCROLL, SCROLLBARS, STYLE,
STRETCH, TAG, TABINDEX, TITLE, UPSHIFT, VALIDATE LIKE, WANTTABS, WANTNORETURNS.

Usage
Define the rendering and behavior of a text edit stack item, with a TEXTEDIT element inside a STACK container.

Note: The TEXTEDIT stack item can be used inside a stack container like a group, or as root element of the STACK container: When used directly under the STACK container, the TEXTEDIT stack item must be the only element in the container. It is rendered as a scalable form item that can stretch to fit the front-end screen size.

For more details about this item type, see TEXTEDIT item type on page 1184.

Example

TEXTEDIT customer.cust_address, HEIGHT=3, REQUIRED;

Related concepts

STACK container on page 1202
The STACK container holds stack items defining a logical alignment of form items.

TEXTEDIT item definition on page 1237
Defines a multi-line edit field, in a grid-based layout.

TIMEEDIT stack item
Defines a line-edit with a clock widget to pick a time, in a stack-based layout.

Syntax

TIMEEDIT field-name [, attribute-list ] ;

1. field-name identifies the name of the screen record field.
2. attribute-list defines the aspect and behavior of the form item.
Attributes

AUTONEXT, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, NOT NULL, NOENTRY, PLACEHOLDER, REQUIRED, SAMPLE, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a time edit stack item, with a TIMEEDIT element inside a STACK container.

For more details about this item type, see TIMEEDIT item type on page 1185.

Example

TIMEEDIT package.arrtime;

WEBCOMPONENT stack item

Defines a generic form field that can receive an external widget, in a stack-based layout.

Syntax

WEBCOMPONENT [identifier] [ , attribute-list ] ;

1. field-name identifies the name of the screen record field.
2. attribute-list defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMPONENTTYPE, COMMENT, DEFAULT, FONTPITCH, HEIGHT, HIDDEN, INCLUDE, JUSTIFY, NOT NULL, NOENTRY, PROPERTIES, REQUIRED, SCROLLBARS, SIZEPOLICY, STYLE, STRETCH, TAG, TABINDEX, TITLE, VALIDATE LIKE, WIDTH.

Usage

Define the rendering and behavior of a web component stack item, with a WEBCOMPONENT element inside a STACK container.

Note: The WEBCOMPONENT stack item can be used inside a stack container like a group, or as root element of the STACK container. When used directly under the STACK container, the WEBCOMPONENT stack item must be the only element in the container. It will be rendered as a scalable form item that can stretch to fit the front-end screen size.

For more details about this item type, see WEBCOMPONENT item type on page 1187.

Example

-- URL-based web component (recommended):
WEBCOMPONENT FORMONLY.mymap;

-- gICAPI web component:
WEBCOMPONENT FORMONLY.mycal,
    COMPONENTTYPE="Calendar", -- lookup "Calendar.html"
    STYLE="regular";

Related concepts

Web component in stack-based layout on page 1828
**SCROLLGRID container**

Defines a scrollable grid view widget, in a grid-based layout.

**Syntax**

```plaintext
SCROLLGRID [identifier] [ ( attribute [, ...] ) ]
{
    row-template
    [{...}]
}
END
```

where `row-template` is a text block containing:

```plaintext
{ text
  ↓ item-tag ↓
  [{...}]
```

1. `text` is literal text that will appear in the form as a static label.
2. `item-tag` defines the position and length of a form item.

**Attributes**

`COMMENT, DOUBLECLICK, FONTPITCH, STYLE, TAG, HIDDEN, WANTFIXEDPAGESIZE`.

**Usage**

The **SCROLLGRID** container declares a formatted text block defining the dimensions and the position of the logical elements of a screen for a multi-record presentation.

**Note:** Avoid Tab characters (ASCII 9) inside the curly-brace delimited area. If used, Tab characters will be replaced by 8 blanks by fglform.

For more details about this item type, see **SCROLLGRID item type** on page 1179.

**Example 1: Resizable scrollgrid (using WANTFIXEDPAGESIZE=NO):**

```plaintext
SCROLLGRID (WANTFIXEDPAGESIZE=NO)
{
    Id: [f001 ]  Name: [f002 ]
    Address: [f003 ]
}
END
```

**Example 2: Scrollgrid with fixed page size, using four rows:**

```plaintext
SCROLLGRID
{
    Id: [f001 ]  Name: [f002 ]
    Address: [f003 ]

    Id: [f001 ]  Name: [f002 ]
    Address: [f003 ]

    Id: [f001 ]  Name: [f002 ]
    Address: [f003 ]

    Id: [f001 ]  Name: [f002 ]
    Address: [f003 ]
}
```
Related concepts

Grid-based layout on page 1309
A form file can define a grid-based layout within a tree of layout items.

Layout tags on page 1151
Layout tags define layout areas for containers inside the frame of a grid-based container.

Item tags on page 1155
Item tags define the position and size in a grid-based container.

Hbox tags on page 1158
Hbox tags group several item tags within the same horizontal layout box, in a grid-based container.

GRID container on page 1201
Defines a layout area based on a grid of cells.

TABLE container
Defines a re-siztable table designed to display a list of records.

Syntax

TABLE [identifier] \ ( attribute [,...] ) \ {
  title [....]
  [col-name |||....]  
  [....]
  [aggr-name |||....]  
}
END

1. identifier defines the name of the element.
2. attribute is an attribute for the element.
3. title is the text to be displayed as column title.
4. col-name is an identifier that references a form field.
5. aggr-name is an identifier that references an aggregate Field.

Attributes

AGGREGATETEXT, COMMENT, DOUBLECLICK, HIDDEN, FONTPITCH, STYLE, TAG, UNHIDABLECOLUMNS, UNMOVABLECOLUMNS, UNSIZABLECOLUMNS, UNSORTABLECOLUMNS, WANTFIXEDPAGESIZE, WIDTH, HEIGHT.

Usage:

The TABLE container defines a list view element in a grid-based layout.

To create a table view in a grid layout, define the following elements in the form file:

1. The layout of the list, with a TABLE container in the LAYOUT section.
2. The column data types and field properties, in the ATTRIBUTES section.
3. The field list definition to group form fields together with a screen array, in the INSTRUCTIONS section.

For more details about this item type, see TABLE item type on page 1182.

Example

SCHEMA videolab
LAYOUT ( TEXT="Customer list" )
TABLE ( TAG="normal" )
Related concepts

Grid-based layout on page 1309
A form file can define a grid-based layout within a tree of layout items.

Layout tags on page 1151
*Layout tags* define layout areas for containers inside the frame of a grid-based container.

Item tags on page 1155
*Item tags* define the position and size in a grid-based container.

TREE container
The *TREE* container defines the presentation of a list of ordered records in a tree-view widget.

Syntax

```
TREE [identifier] [ ( attribute [, ... ] ) ]
{
    [title [, ... ]]
    [name_column | identifier [, ... ]]
    [, ... ]
}
END
```

1. *identifier* defines the name of the element.
2. *attribute* is an attribute for the element.
3. *title* is the text to be displayed as column title.
4. *name_column* is a mandatory column referencing a form item defining the node text.
5. *identifier* references a form item.

Attributes

*COMMENT*, *DOUBLECLICK*, *HIDDEN*, *FONTPITCH*, *STYLE*, *TAG*, *UNHIDABLECOLUMNS*,
*UNMOVABLECOLUMNS*, *UNSIZABLECOLUMNS*, *UNSORTABLECOLUMNS*, *WANTFIXEDPAGESIZE*, *WIDTH*,
*HEIGHT*, *PARENTIDCOLUMN*, *IDCOLUMN*, *EXPANDEDCOLUMN*, *ISNODECOLUMN*, *IMAGEEXPANDED*,
*IMAGECOLLAPSED*, *IMAGELEAF*.

Usage

To create a tree view in a grid-based layout, you must define the following elements in the form file:
1. The layout of the tree-view, with a TREE container in the LAYOUT section.
2. The column data types and field properties, in the ATTRIBUTES section.
3. The field list definition to group form fields together with a screen array, in the INSTRUCTIONS section.

For more details about this item type, see TREE item type on page 1186.

Example

```plaintext
LAYOUT
GRID
{
  <Tree t1>
    Name   Index
    [c1  |c2  ]
    [c1  |c2  ]
    [c1  |c2  ]
    [c1  |c2  ]
  )
END
END

ATTRIBUTES
LABEL c1 = FORMONLY.name;
LABEL c2 = FORMONLY.idx;
PHANTOM FORMONLY.pid;
PHANTOM FORMONLY.id;
TREE t1: tree1
    PARENTIDCOLUMN = pid,
    IDCOLUMN = id;
END

INSTRUCTIONS
SCREEN RECORD sr_tree(name, pid, id, idx);
END
```

Related concepts

Grid-based layout on page 1309
A form file can define a grid-based layout within a tree of layout items.

Layout tags on page 1151
Layout tags define layout areas for containers inside the frame of a grid-based container.

Item tags on page 1155
Item tags define the position and size in a grid-based container.

TABLES section

Defines the list of database tables referenced by form field definitions.

Syntax

```plaintext
TABLES
  [ alias = [database[@dbserver]:][owner.] ] table [ , ... ]
[END]
```

1. `alias` represents an alias name for the given table.
2. `table` is the name of the database table.
3. `database` is the name of the database of the table (see warnings).
4. `@dbserver` identifies the Informix® database server (INFORMIXSERVER)
5. `owner` is the name of the table owner (see warnings).
Usage

The TABLES section lists every database table or view referenced in the form specification file. This section is mandatory when form fields reference database columns defined in the database schema file.

The TABLE section must appear in the sequence described in form file structure.

The END keyword is optional.

The SCHEMA section must also exist to define the database schema.

Field identifiers in programs or in other sections of the form specification file can reference screen fields as column, alias.column, or table.column.

The same alias must also appear in screen interaction statements of programs that reference screen fields linked to the columns of a table that has an alias.

If a table requires the name of an owner or of a database as a qualifier, the TABLES section must also declare an alias for the table. The alias can be the same identifier as table.

For backward compatibility with the Informix® form specification, the comma separator is optional and the database, dbserver and owner specifications are ignored.

Example

```
SCHEMA stores
LAYOUT
GRID
{
    ...
}
END
TABLES
    customer, orders
END
ATTRIBUTES
...
END
```

Related concepts

- Database schema on page 476
  Defines database table structures with column type information to be reused in program variable definitions.

- SCHEMA section on page 1188
  Defines the database schema file to be used to compile the form.

- Hbox tags on page 1158
  Hbox tags group several item tags within the same horizontal layout box, in a grid-based container.

- ui.Form.ensureFieldVisible on page 2359
  Ensure visibility of a form field.

- ui.Form.ensureElementVisible on page 2358
  Ensure the visibility of a form element.

- Form rendering on page 1306
  The section explains the layout rules to render forms on graphical front-ends.

- LAYOUT section on page 1194
The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

**ATTRIBUTES section**
The ATTRIBUTES section describes properties of grid-based layout elements used in the form.

**Syntax**

```
ATTRIBUTES
  [ form-field-definition
  [ phantom-field-definition
  [ form-item-definition ]
  [ ... ]
  [ END ]
```

where `form-field-definition` is:

```
item-type item-tag = field-name , attribute-list ;
```

where `phantom-field-definition` is:

```
PHANTOM field-name ;
```

where `form-item-definition` is:

```
item-type item-tag: item-name , attribute-list ;
```

1. *item-type* defines the type of the Form Item.
2. *item-tag* is the name of the screen element used in the LAYOUT section.
3. *field-name* defines the name of the screen record field.
4. *item-name* identifies the form item that is not a form field containing data.
5. *attribute-list* defines the aspect and behavior of the form item.

where `attribute-list` is:

```
attribute [, ...]
```

1. The attribute list is a comma-separated list of attributes.

where `attribute` is:

```
attribute-name = value | value-list ;
```

1. *attribute* identifies the attribute of the form item.

where `value-list` is:

```
( value | sub-value-list [, ...] )
```

1. *value* is a string, date or numeric literal, or predefined constant like TODAY.
2. *sub-value-list* is a set of values separated by comma, to support subset definitions as in "(1, (21, 22), (31, 32, 33))".

**Usage**

The ATTRIBUTES section is required to define the attributes for the form items used in grid-based containers of the LAYOUT section.

The ATTRIBUTES section must appear in the sequence described in form file structure.
The END keyword is optional.

Every item-tag used in the LAYOUT section must get an item definition in the ATTRIBUTES section.

A form item definition is associated by name to an item tag or layout tag defined in the grid-based container.

In order to define a form field, the form item definition must use the equal sign notation to associate a screen record field with the form item. If the form item is not associated with a screen record field (for example, a push button), you must use the colon notation.

To match the complete structure of a database table record, additional fields can be defined as phantom fields, when no corresponding item tag is used in the layout.

Form item definitions can optionally include an attribute-list to specify the appearance and behavior of the item. For example, you can define acceptable input values, on-screen comments, and default values for fields.

When no screen record is defined in the INSTRUCTION section, a default screen record is built for each set of form items declared with the same table name.

The order in which you list the form items determines the order of fields in the default screen records that the form compiler creates for each table.

To define form items as form fields, you are not required to specify table unless the name column is not unique within the form specification. However, it is recommended that you always specify table.column rather than the unqualified column name. As you can refer to field names collectively through a screen record built upon all the fields linked to the same table, your forms might be easier to work with if you specify table for each field.

When used in a table, some widgets are rendered only when the user enters in the field. For example RadioGroup, CheckBox, ComboBox, ProgressBar.

**Example**

```
SCHEMA game
LAYOUT
GRID
{
  ...
}
END
TABLES
player
END
ATTRIBUTES
  EDIT f001 = player.name, REQUIRED,
           COMMENT="Enter player's name";
  EDIT f002 = player.ident, NOENTRY;
  COMBOBOX f003 = player.level, NOT NULL,
                   ITEMS=((1,"Beginner"), (2,"Normal"),(3,"Expert"));
  CHECKBOX f004 = FORMONLY.winner,
                 VALUECHECKED=1, VALUEUNCHECKED=0,
                 TEXT="Winner";
  BUTTON b1: print, TEXT="Print Report";
  GROUP g1: print, TEXT="Description";
END
```

**Related concepts**

Form items on page 1133
The concept of *form item* includes all elements used in the definition of a form.

**AGGREGATE item definition**
Defines screen-record fields that hold computed values to be displayed as footer cells in a TABLE container.

**Syntax**

\[
\text{AGGREGATE \ item-tag = field-name \[, \ attribute-list \]} \\
\]

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

**Attributes**

AGGREGATETEXT, AGGREGATETYPE.

**Usage**

Aggregate fields must be declared with an AGGREGATE element in the ATTRIBUTES section.

**Important:** This feature is not supported on mobile platforms.

For more details see Aggregate fields on page 1144.

**Example**

\[
\text{AGGREGATE total = FORMONLY.o_total,} \\
\text{AGGREGATETEXT = "Total:",} \\
\text{AGGREGATETYPE = SUM;}
\]

**Related concepts**

- TABLE container on page 1217
  Defines a re-sizable table designed to display a list of records.
- Summary lines in tables on page 1767
  Table views can display a summary line, to show aggregate values for columns.
- Database column fields on page 1139
  Form fields defined with a table and column name get data type from the database schema file.
- Form fields on page 1138
  *Form fields* are form elements designed for data input and/or data display.
- Formonly fields on page 1141
  FORMONLY form fields define their data type explicitly, with or without referencing a database columns.
- Pseudo selectors on page 1068
  Pseudo selectors can be used to apply style only when some conditions are fulfilled.

**Related reference**

Table style attributes on page 1101
Table style presentation attributes apply to a TABLE container.

**PHANTOM item definition**
Defines a form field in a grid-based container, that must not be displayed to the end user.

**Syntax**

\[
\text{PHANTOM \[field-name\]}
\]
User interface

1. *field-name* identifies the name of the screen record field.

**Usage**

Define a phantom form field (that will be used by a dialog, but not displayed in the form layout), with a PHANTOM element in the ATTRIBUTES section.

For more details, see Phantom fields on page 1142.

**Example**

```
PHANTOM customer.cust_name;
```

**Related concepts**

- **Database column fields** on page 1139
  - Form fields defined with a table and column name get data type from the database schema file.

- **Formonly fields** on page 1141
  - FORMONLY form fields define their data type explicitly, with or without referencing a database columns.

- **PHANTOM stack item** on page 1211
  - Defines a form field in a stack-based container, that must not be displayed to the end user.

**BUTTON item definition**

Defines a push-button field that can trigger an action, in a grid-based layout.

**Syntax**

```
BUTTON item-tag: item-name [ , attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *item-name* defines the form item name and the action name.
3. *attribute-list* defines the aspect and behavior of the form item.

**Attributes**

- COMMENT, DISCLOSUREINDICATOR, FONTPITCH, HIDDEN, IMAGE, SAMPLE, SIZEPOLICY, STYLE, TABINDEX, TAG, TEXT.

**Usage**

Defines the rendering and behavior of a button *item tag*, with a BUTTON element in the ATTRIBUTES section.

For more details about this item type, see BUTTON item type on page 1163.

**Example**

```
LAYOUT
GRID
{
[btn1
  ]
  ...
}
END
END

ATTRIBUTES
BUTTON btn1: print, TEXT="Print Report", IMAGE="printer";
  ...
```
**BUTTONEDIT item definition**

Defines a line-edit field with a push-button that can trigger an action, in a grid-based layout.

**Syntax**

```
BUTTONEDIT item-tag = field-name , attribute-list ;
```

1. `item-tag` is an identifier that defines the name of the item tag in the layout section.
2. `field-name` identifies the name of the screen record field.
3. `attribute-list` defines the aspect and behavior of the form item.

**Attributes**

`ACTION`, `AUTONEXT`, `CENTURY`, `COLOR`, `Completer`, `COLOR WHERE`, `COMMENT`, `DEFAULT`, `DISPLAY LIKE`, `DOWNSHIFT`, `FONTPITCH`, `HIDDEN`, `FORMAT`, `IMAGE`, `INCLUDE`, `INVISIBLE`, `JUSTIFY`, `KEY`, `KEYBOARDHINT`, `NOT NULL`, `NOTEDITABLE`, `NOENTRY`, `PICTURE`, `PLACEHOLDER`, `PROGRAM`, `REVERSE`, `SAMPLE`, `SCROLL`, `STYLE`, `REQUIRED`, `TAG`, `TITLE`, `TABINDEX`, `UNSORTABLE`, `UNSIZABLE`, `UNHIDABLE`, `UNMOVALBE`, `UPSHIFT`, `VALIDATE LIKE`, `VERIFY`.

**Usage**

Define the rendering and behavior of a buttonedit item tag, with a BUTTONEDIT element in the ATTRIBUTES section.

For more details about this item type, see **BUTTONEDIT item type** on page 1164.

**Example**

```
LAYOUT
GRID
{
    [f1 ]
    ...
}
END
END

ATTRIBUTES
BUTTONEDIT f1 = customer.state,
    REQUIRED, IMAGE="smiley", ACTION=zoom;
...
```

**CANVAS item definition**

The CANVAS form item defines an area in which you can draw shapes, in a grid-based layout.

**Syntax**

**Important**: This feature is deprecated, and may be removed in a future version.

```
CANVAS item-tag: item-name , attribute-list ;
```

1. `item-tag` is an identifier that defines the name of the item tag in the layout section.
2. `item-name` identifies the form item.
3. `attribute-list` defines the aspect and behavior of the form item.

**Attributes**

`COMMENT`, `HIDDEN`, `TAG`. 
Usage

Define the rendering and behavior of a canvas drawing area item tag, with a CANVAS element in the ATTRIBUTES section.

Note: The CANVAS feature is deprecated, consider using the built-in fglsvgcanvas WEBCOMPONENT.

Example

```
LAYOUT
GRID
{
[cvs1]
[
[
[...
]
]

)
END
END

ATTRIBUTES
CANVAS cvs1: canvas1;
...
```

Related concepts

Canvases on page 1912

Canvases are form drawing areas.

CHECKBOX item definition

Defines a boolean or three-state checkbox field, in a grid-based layout.

Syntax

```
CHECKBOX item-tag = field-name [, attribute-list ] ;
```

1. **item-tag** is an identifier that defines the name of the item tag in the layout section.
2. **field-name** identifies the name of the screen record field.
3. **attribute-list** defines the aspect and behavior of the form item.

Attributes

COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, REQUIRED, SAMPLE, SIZEPOLICY, STYLE, TAG, TABINDEX, TEXT, TITLE, VALIDATE LIKE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALUECHECKED, VALUEUNCHECKED.

Usage

Define the rendering and behavior of a checkbox item tag, with a CHECKBOX element in the ATTRIBUTES section.

For more details about this item type, see CHECKBOX item type on page 1165.

Example

```
LAYOUT
GRID
{
[f1]
[...

}
ATTRIBUTES
CHECKBOX f1 = customer.active,
   REQUIRED, TEXT="Active",
   VALUECHECKED="Y", VALUEUNCHECKED="N";
...

COMBOBOX item definition
Defines a COMBOBOX item in a grid-based layout, in a grid-based layout.

Syntax

```
COMBOBOX item-tag = field-name [, attribute-list ]
```

1. `item-tag` is an identifier that defines the name of the item tag in the layout section.
2. `field-name` identifies the name of the screen record field.
3. `attribute-list` defines the aspect and behavior of the form item.

Attributes

```
COLOR, COLOR WHERE, COMMENT, DEFAULT, DOWNSHIFT, FONTPITCH, HIDDEN, KEY, INCLUDE,
INITIALIZER, ITEMS, JUSTIFY, NOT NULL, NOENTRY, PLACEHOLDER, QUERYEDITABLE, REQUIRED,
SAMPLE, SCROLL, SIZEPOLICY, STYLE, UPSHIFT, TAG, TABINDEX, UNSORTABLE, UNSIZABLE,
UNHIDABLE, UNMOVABLE, TITLE, VALIDATE LIKE.
```

Usage

Define the rendering and behavior of a combobox item tag, with a COMBOBOX element in the ATTRIBUTES section.

For more details about this item type, see COMBOBOX item type on page 1166.

Example

```
LAYOUT
GRID
{
  [f1 ]
  ...

  ]
END
END

ATTRIBUTES
COMBOBOX f1 = customer.city,
   ITEMS=((1,"Paris"),
         (2,"Madrid"),
         (3,"London"));
...
```

Related concepts

Filling a COMBOBOX item list on page 1635
The item list of COMBOBOX fields can be initialized at runtime.

**DATEEDIT item definition**
Defines a line-edit field with a calendar widget to pick a date, in a grid-based layout.

**Syntax**

```
DATEEDIT item-tag = field-name [, attribute-list ];
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

**Attributes**

`AUTONEXT, CENTURY, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, FORMAT, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, PLACEDHOLDER, REQUIRED, SAMPLE, STYLE, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE`.

**Usage**

Define the rendering and behavior of a date edit *item tag*, with a DATEEDIT element in the ATTRIBUTES section.

For more details about this item type, see [DATEEDIT item type](#) on page 1168.

**Example**

```
LAYOUT
GRID
{
  [f1         ]
  ...);
}
END
END

ATTRIBUTES
DATEEDIT f1 = order.shipdate;
...`

**DATETIMEEDIT item definition**
Defines a line-edit field with a calendar widget to pick a datetime, in a grid-based layout.

**Syntax**

```
DATETIMEEDIT item-tag = field-name [, attribute-list ];
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

**Attributes**

`AUTONEXT, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, FORMAT, HIDDEN, IMAGECOLUMN, JUSTIFY, NOT NULL, NOENTRY, PLACEHOLDER, REQUIRED, SAMPLE, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE`.
Usage
Define the rendering and behavior of a date edit item tag, with a DATETIMEEDIT element in the ATTRIBUTES section.

For more details about this item type, see DATETIMEEDIT item type on page 1169.

Example

```
LAYOUT
GRID
{
  [f1       ]
  ...
}
END
END

ATTRIBUTES
DATETIMEEDIT f1 = package.modts;
...
```

EDIT item definition
Defines a simple line-edit field, in a grid-based layout.

Syntax

```
EDIT item-tag = field-name [, attribute-list ] ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

Attributes

AUTONEXT, CENTURY, COLOR, COLOR WHERE, COMMENT, COMPLETER, DEFAULT, DISPLAY LIKE, DOWNSHIFT, FONTPITCH, FORMAT, HIDDEN, IMAGECOLUMN, INCLUDE, INVISIBLE, JUSTIFY, KEY, KEYBOARDHINT, NOT NULL, NOENTRY, PICTURE, PLACEHOLDER, PROGRAM, REQUIRED, REVERSE, SAMPLE, STYLE, SCROLL, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, UPSHIFT, VALIDATE LIKE, VERIFY.

Usage
Define the rendering and behavior of an edit item tag, with an EDIT element in the ATTRIBUTES section.

For more details about this item type, see EDIT item type on page 1170.

Example

```
LAYOUT
GRID
{
  [f1       ]
  ...
}
END
END

ATTRIBUTES
EDIT f1 = customer.cust_state,
```
GROUP item definition
Defines a group-box layout tag, in a grid-based layout.

Syntax

```
GROUP layout-tag: item-name [, attribute-list ] ;
```

1. `layout-tag` is an identifier that defines the name of the layout tag.
2. `item-name` identifies the form item.
3. `attribute-list` defines the aspect and behavior of the form item.

Attributes

`COMMENT, FONTPITCH, GRIDCHILDRENINPARENT, HIDDEN, STYLE, TAG, TEXT`.

Usage

Define the rendering and behavior of a group layout tag, with a `GROUP` element in the `ATTRIBUTES` section. For more details about this item type, see GROUP item type on page 1172.

Example

```
LAYOUT
GRID
{
   <GROUP g1  >
     Num: [f001 ]
     ...  
   }
END
END

ATTRIBUTES
GROUP g1: group1,
   TEXT="Description",
   GRIDCHILDRENINPARENT;
... 
```

Related concepts

GROUP container on page 1199
Defines a layout area to group other layout elements together, in a grid-based layout.

GROUP stack item on page 1207
Defines a stack area to group other layout elements together, in a stack-based layout.

Examples on page 1305
Form definition (.per) examples.

**IMAGE item definition**
Defines an area that can display an image resource, in a grid-based layout.

**Syntax 1: Defining a form field image**

```
IMAGE item-tag = field-name [, attribute-list ];
```

**Syntax 2: Defining a static image**

```
IMAGE item-tag: item-name [, attribute-list ];
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *item-name* identifies the form item for a static image.
4. *attribute-list* defines the aspect and behavior of the form item.

**Attributes**

```
ACTION, AUTOSCALE, COMMENT, HEIGHT, HIDDEN, SIZEPOLICY, STYLE, STRETCH, TAG, TITLE,
UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, WIDTH.
```

*Image field only:* JUSTIFY, SAMPLE.

*Static image only:* IMAGE.

**Usage**

Define the rendering and behavior of an image item tag, with an IMAGE element in the ATTRIBUTES section.

For more details about this item type, see **IMAGE item type** on page 1174.

**Example**

```
LAYOUT
GRID
{
  [ f1  ]
  [ ]
  [ ]
  [ ]
  ...
}
END
END

ATTRIBUTES
IMAGE f1 = cars.picture,
  SIZEPOLICY=FIXED, AUTOSCALE,
  COMMENT="Picture of the car";
...
```
**LABEL item definition**  
Defines a simple text area to display a read-only value, in a grid-based layout.

**Syntax 1: Defining a form field label**

```
LABEL item-tag = field-name [ attribute-list ];
```

**Syntax 2: Defining a static label**

```
LABEL item-tag: item-name [ attribute-list ];
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *item-name* identifies the form element (name attribute in .42f) of a static label.
4. *attribute-list* defines the aspect and behavior of the form item.

**Attributes**

- COLOR, COLOR WHERE, COMMENT, FONTPITCH, HIDDEN, IMAGECOLUMN, JUSTIFY, REVERSE, SIZEPOLICY, STYLE, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE.

**Usage**

Define the rendering and behavior of an label *item tag*, with an LABEL element in the ATTRIBUTES section.

For more details about this item type, see **LABEL item type** on page 1175.

**Example**

```
LAYOUT GRID
{
  [l1 :f1       ]
  ...
}
END
END

ATTRIBUTES
LABEL l1: labell, TEXT="Desc:"; -- This is a static label
LABEL f1 = vehicle.description; -- This is a form field label
...
```

**Related concepts**

- **Hbox tags** on page 1158  
  Hbox tags group several item tags within the same horizontal layout box, in a grid-based container.

**PROGRESSBAR item definition**  
Defines a progress indicator field, in a grid-based layout.

**Syntax**

```
PROGRESSBAR item-tag = field-name [ attribute-list ];
```
1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

**Attributes**

`COLOR, COLOR WHERE, COMMENT, FONTPITCH, HIDDEN, JUSTIFY, VALUemin, VALUemax, SAMPLE, STYLE, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE`

**Usage**

Define the rendering and behavior of a progress bar *item tag*, with a `PROGRESSBAR` element in the `ATTRIBUTES` section.

For more details about this item type, see `PROGRESSBAR item type` on page 1177.

**Example**

```
LAYOUT
GRID
{
[f1         ]
...
}
END
END
ATTRIBUTES
PROGRESSBAR f1 = workstate.position,
   VALUemin=-100, VALUemax=+100;
...
```

**RADIOGROUP item definition**

Defines a mutually-exclusive set of option fields, in a grid-based layout.

**Syntax**

```
RADIOGROUP  item-tag = field-name \ ,  attribute-list \ ;
```

1. *item-tag* is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

**Attributes**

`COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, INCLUDE, ITEMS, JUSTIFY, KEY, NOT NULL, NOENTRY, ORIENTATION, REQUIRED, SAMPLE, SIZEPOLICY, STYLE, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE`

**Usage**

Define the rendering and behavior of a radio group *item tag*, with a `RADIOGROUP` element in the `ATTRIBUTES` section.

For more details about this item type, see `RADIOGROUP item type` on page 1178.

**Example**

```
LAYOUT
```
SCROLLGRID item definition
Defines a scrollgrid layout tag in a grid-based layout.

Syntax

SCROLLGRID layout-tag: item-name [ , attribute-list ] ;

1. layout-tag is an identifier that defines the name of the layout tag.
2. item-name identifies the form item.
3. attribute-list defines the aspect and behavior of the form item.

Attributes

COMMENT, DOUBLECLICK, FONTPITCH, GRIDCHILDRENINPARENT, HIDDEN, INITIALPAGESIZE, STYLE, TAG.

Usage

The SCROLLGRID form item type to specify the attributes of a scrollgrid container defined with a layout tag.

For more details about this item type, see SCROLLGRID item type on page 1179.

Example

LAYOUT
GRID
{  
<SCROLLGRID sg1 >  
[ f001 ]  
...  
}  
END
END

ATTRIBUTES
SCROLLGRID sg1: scrollgrid1,
  GRIDCHILDRENINPARENT;
SLIDER item definition
Defines a slider element, in a grid-based layout.

Syntax

```plaintext
SLIDER item-tag = field-name \, attribute-list \;
```

1. `item-tag` is an identifier that defines the name of the item tag in the layout section.
2. `field-name` identifies the name of the screen record field.
3. `attribute-list` defines the aspect and behavior of the form item.

Attributes

```plaintext
COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, INCLUDE, JUSTIFY, NOENTRY, ORIENTATION, SAMPLE, STEP, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE, VALUemin, VALUemax.
```

Usage

Define the rendering and behavior of a slider item tag, with an SLIDER element in the ATTRIBUTES section.

For more details about this item type, see SLIDER item type on page 1181.

Example

```plaintext
LAYOUT
GRID
{
    [f1         
    ... 
}
END
END
ATTRIBUTES
SLIDER f1 = workstate.duration, 
    VALUemin=0, VALUemax=50, 
    STEP=1;
... 
```

SPINEDIT item definition
Defines a spin box widget to enter integer values, in a grid-based layout.

Syntax

```plaintext
SPINEDIT item-tag = field-name \, attribute-list \;
```

1. `item-tag` is an identifier that defines the name of the item tag in the layout section.
2. `field-name` identifies the name of the screen record field.
3. `attribute-list` defines the aspect and behavior of the form item.

Attributes

```plaintext
AUTONEXT, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, NOT NULL, NOENTRY, PLACEHOLDER, REQUIRED, SAMPLE, STEP, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE, VALUemin, VALUemax.
```
Usage
Define the rendering and behavior of a spin edit item tag, with a SPINEDIT element in the ATTRIBUTES section.
For more details about this item type, see SPINEDIT item type on page 1182.

Example

```
LAYOUT
GRID
{
  [f1         
  ... 
}
END

ATTRIBUTES
SPINEDIT f1 = command.nbitems, STEP=5;
...
```

**TABLE item definition**
Defines attributes for a table layout tag, in a grid-based layout.

Syntax

```
TABLE layout-tag: item-name [, attribute-list ] ;
```

1. `layout-tag` is an identifier that defines the name of the layout tag.
2. `item-name` identifies the form item.
3. `attribute-list` defines the aspect and behavior of the form item.

Attributes

AGGREGATETEXT, COMMENT, DOUBLECLICK, FONTPITCH, HEIGHT, HIDDEN, STYLE, TAG,
UNHIDABLECOLUMNS, UNMOVABLECOLUMNS, UNSIZABLECOLUMNS, UNSORTABLECOLUMNS,
WANTFIXEDPAGESIZE, WIDTH.

Usage
Define a TABLE element in the ATTRIBUTES section, to configure a table layouted with a `<TABLE>` layout tag.
For more details about this item type, see TABLE item type on page 1182.

Example

```
LAYOUT
GRID
{
  <TABLE t1                    >
  [c1  |c2        |c3          ]
  [c1  |c2        |c3          ]
  ... 
}
END

ATTRIBUTES
TABLE t1: table1, UNSORTABLECOLUMNS;
```
TEXTEDIT item definition
Defines a multi-line edit field, in a grid-based layout.

Syntax

```
TEXTEDIT item-tag = field-name \[attribute-list \];
```

1. `item-tag` is an identifier that defines the name of the item tag in the layout section.
2. `field-name` identifies the name of the screen record field.
3. `attribute-list` defines the aspect and behavior of the form item.

Attributes

```
COLOR, COLOR WHERE, COMMENT, DEFAULT, DOWNSHIFT, FONTPITCH, HIDDEN, INCLUDE, JUSTIFY, KEY, NOT NULL, NOENTRY, PLACEHOLDER, PROGRAM, REQUIRED, SAMPLE, SCROLL, SCROLLBARS, STYLE, STRETCH, TAG, TITLE, TABINDEX, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, UPSHIFT, VALIDATE LIKE, WANTTABS, WANTINORETURNS.
```

Usage

Define the rendering and behavior of a text edit item tag, with a TEXTEDIT element in the ATTRIBUTES section.

For more details about this item type, see TEXTEDIT item type on page 1184.

Example

```
LAYOUT
GRID
[
[f1                     ]
[                         ]
[                         ]
[                         ]
...                        
]
END
END

ATTRIBUTES
TEXTEDIT f1 = customer.address,
  WANTTABS, SCROLLBARS=BOTH;
...
```

TIMEEDIT item definition
Defines a line-edit with a clock widget to pick a time, in a grid-based layout.

Syntax

```
TIMEEDIT item-tag = field-name \[attribute-list \];
```

1. `item-tag` is an identifier that defines the name of the item tag in the layout section.
2. `field-name` identifies the name of the screen record field.
3. `attribute-list` defines the aspect and behavior of the form item.
Attributes

AUTONEXT, COLOR, COLOR WHERE, COMMENT, DEFAULT, FONTPITCH, HIDDEN, IMAGECOLUMN, INCLUDE, JUSTIFY, NOT NULL, NOENTRY, PLACEHOLDER, REQUIRED, SAMPLE, STYLE, TABINDEX, TAG, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE LIKE.

Usage

Define the rendering and behavior of a text edit item tag, with an TEXTEXTEDIT element in the ATTRIBUTES section.

For more details about this item type, see TIMEEDIT item type on page 1185.

Example

LAYOUT
GRID
{
[f1 ]
...
}
END
END

ATTRIBUTES
TIMEEDIT f1 = package.arrtime;
...

TREE item definition

Defines attributes for a tree layout tag, in a grid-based layout.

Syntax

TREE layout-tag: item-name [ , attribute-list ] ;

1. layout-tag is an identifier that defines the name of the layout tag.
2. item-name identifies the form item.
3. attribute-list defines the aspect and behavior of the form item.

Attributes

COMMENT, DOUBLECLICK, HIDDEN, FONTPITCH, STYLE, TAG, UNHIDABLECOLUMNS, UNMOVABLECOLUMNS, UNSIZABLECOLUMNS, UNSORTABLECOLUMNS, WANTFIXEDPAGESIZE, WIDTH, HEIGHT, PARENTIDCOLUMN, IDCOLUMN, EXPANDEDCOLUMN, ISNODECOLUMN, IMAGEEXPANDED, IMAGECOLLAPSED, IMAGELEAF.

Usage

The TREE form item type can be used to specify the attributes of a tree container defined with a layout tag.

For more details about this item type, see TREE item type on page 1186.

WEBCOMPONENT item definition

Defines a generic form field that can receive an external widget, in a grid-based layout.

Syntax

WEBCOMPONENT item-tag = field-name [ , attribute-list ] ;

1. item-tag is an identifier that defines the name of the item tag in the layout section.
2. *field-name* identifies the name of the screen record field.
3. *attribute-list* defines the aspect and behavior of the form item.

**Attributes**

COLOR, COLOR WHERE, COMPONENTTYPE, COMMENT, DEFAULT, FONTPITCH, HEIGHT, HIDDEN, INCLUDE,
JUSTIFY, NOT NULL, NOENTRY, PROPERTIES, REQUIRED, SCROLLBARS, SIZEPOLICY, STYLE,
STRETCH, TAG, TABINDEX, TITLE, UNSORTABLE, UNSIZABLE, UNHIDABLE, UNMOVABLE, VALIDATE
LIKE, WIDTH.

**Usage**

Define the rendering and behavior of a web component *item tag*, with an WEBCOMPONENT element in the
ATRIBUTES section.

For more details about this item type, see WEBCOMPONENT item type on page 1187.

**Example**

```
LAYOUT
GRID
{
  [f1             ]
  [               ]
  [               ]
  ... 
  [f2             ]
  [               ]
  [               ]
  ... 
}
END
END

ATTRIBUTES

-- URL-based web component (recommended):
WEBCOMPONENT f1 = FORMONLY.mymap,
  STRETCH=BOTH;

-- gICAPI web component:
WEBCOMPONENT f2 = FORMONLY.mycal,
  COMPONENTTYPE="Calendar", -- lookup "Calendar.html",
  PROPERTIES = (                   
    type = "gregorian",
    week_start = 2,
    days_off = ( 1, 7 )          
  ),
  STRETCH=BOTH, STYLE="regular";
```

**INSTRUCTIONS section**

The INSTRUCTIONS section is used to define screen arrays, non-default screen records, and global form properties.

**Syntax**

```
INSTRUCTIONS
  [ screen-record-definition [;...]]  
  [ DELIMITERS AB [;] ]
  [ DEFAULT SAMPLE = "string" ]
  [END]
```
1. *screen-record-definition* is the definition of a screen record or screen array.

2. A and B define the opening and closing field delimiters for character based terminals.

**Usage**

The `INSTRUCTIONS` section must appear in the sequence described in [form file structure](#).

The `INSTRUCTIONS` section is optional in a form definition.

The `END` keyword is optional.

This section is mainly used to define screen records, to group fields using tables, tree views, scrollgrids, or traditional static field arrays.

**Screen records (or screen arrays)**

A *screen record* is a named group of form fields.

See [Screen records / arrays](#) on page 1147 for more details.

**Field delimiters**

Use the `DELIMITER` keyword to specify the characters to be displayed as field delimiters on the screen.

This option is especially used for TUI mode applications.

**Default sample**

The `DEFAULT SAMPLE` directive defines the default sample text for all fields.

```
DEFAULT SAMPLE = "MMM"
```

See [SAMPLE attribute](#) on page 1281 for more details.

**Example**

```
SCHEMA stores
LAYOUT
GRID
{
     ...
}
END
TABLES
    stock, items
END
ATTRIBUTES
...
END
INSTRUCTIONS
    SCREEN RECORD s_items[10]
        ( stock.*,
            items.quantity,
            FORMONLY.total_price )
    DELIMITERS "[]"
END
```

**Related concepts**

*Binding tables to arrays in dialogs* on page 1758

Program arrays act as data model that are bound to form tables, when implementing list dialogs.

*Stack-based layout* on page 1322
A form file can define a stack-based layout within a tree of stack items.

Grid-based layout on page 1309
A form file can define a grid-based layout within a tree of layout items.

KEYS section
The KEYS section can be used to define default key labels for the current form.

Syntax

```
KEYS
  key-name = [\%1]"label"
  [...]
  [END]
```

1. `key-name` is the name of a key (like F10, Control-z).
2. `label` is the text to be displayed in the button corresponding to the key.

Usage
The KEYS section can be used to define default key labels at the form level.
The KEYS section must appear in the sequence described in form file structure.
The KEYS section is optional in a form definition.
The END keyword is optional.

Note: This feature is supported for backward compatibility. Consider using action attributes to define accelerator keys and decorate actions.

Example

```
KEYS
  F10 = "City list"
  F11 = "State list"
  F15 = "Validate"
END
```

Related concepts
Setting action key labels on page 1676
Labels can be defined to decorate buttons controlled by ON KEY / COMMAND KEY action handlers.

Form item attributes
The form item attributes reference.

• SCROLLBARS attribute on page 1282
The ACCELERATOR is an action attribute defining the primary accelerator key for an action.

**Syntax**

```
ACCELERATOR = key
```

1. `key` defines the accelerator key.

**Usage**

This attribute is an action attribute that can be specified in form `ACTION DEFAULTS`, for more details, see `ACCELERATOR action attribute` on page 1653.

**Related concepts**

- Defining keyboard accelerators for actions on page 1652
ACCELERATOR2 attribute
The ACCELERATOR2 is an action attribute defining the secondary accelerator key for an action.

Syntax

| ACCELERATOR2 = key |

1. key defines the accelerator key.

Usage
This attribute is an action attribute that can be specified in form ACTION DEFAULTS, for more details, see ACCELERATOR2 action attribute on page 1654.

Related concepts
Defining keyboard accelerators for actions on page 1652

ACCELERATOR3 attribute
The ACCELERATOR3 is an action attribute defining the third accelerator key for an action.

Syntax

| ACCELERATOR3 = key |

1. key defines the accelerator key.

Usage
This attribute is an action attribute that can be specified in form ACTION DEFAULTS, for more details, see ACCELERATOR3 action attribute on page 1654.

Related concepts
Defining keyboard accelerators for actions on page 1652

ACCELERATOR4 attribute
The ACCELERATOR4 is an action attribute defining the fourth accelerator key for an action.

Syntax

| ACCELERATOR4 = key |

1. key defines the accelerator key.

Usage
This attribute is an action attribute that can be specified in form ACTION DEFAULTS, for more details, see ACCELERATOR4 action attribute on page 1655.

Related concepts
Defining keyboard accelerators for actions on page 1652

ACTION attribute
The ACTION attribute defines the action associated with the form item.

Syntax

| ACTION = action-name |
1. *action-name* is an identifier that defines the name of the action to be sent.

**Usage**

The *ACTION* attribute defines the name of the action to be sent to the program when the user activates the form item. This attribute can for example be used in a BUTTONEDIT field to identify the corresponding action handle to be executed in the program when the button is pressed.

The action name can be prefixed with a sub-dialog identifier and/or field name, to define a qualified action view (see action handler binding rules for more details).

**Example**

```
BUTTONEDIT f001 = customer.state, ACTION = print;
```

**Related concepts**

- Binding action views to action handlers on page 1664
- How are action views of the forms bound to action handlers in the program code?
- Dialog actions on page 1640
- Describes how to program action handling when the end user triggers an action on the front-end.
- ACTION DEFAULTS section on page 1189
- The ACTION DEFAULTS section defines local action view default attributes for the form elements.
- Configuring actions on page 1646
- Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

**AGGREGATETEXT attribute**

The AGGREGATETEXT attribute defines a label to be displayed for aggregate fields.

**Syntax**

```
AGGREGATETEXT = [%]"string"
```

1. *string* defines the label to be associated with the aggregate cell, with the % prefix it is a localized string.

**Usage**

The AGGREGATETEXT attribute can be specified at the AGGREGATE field level, or globally at the TABLE level, to define a label for the whole summary line. When defining the AGGREGATETEXT attribute at the aggregate field level, the text will be anchored to the value cell. If the AGGREGATETEXT attribute is specified at the TABLE level, the label will appear on the left in the summary line. When an aggregate text is defined at both levels, the global aggregate text of the table will be ignored.

**Example**

```
AGGREGATE tot = FORMONLY.total, AGGREGATETEXT="Total:"
```

**Related concepts**

- Aggregate fields on page 1144
- An AGGREGATE field defines a screen-record field to display summary information for a TABLE column.
- Localized strings on page 430
- *Localized strings* provide a means of writing applications in which the text of strings can be customized on site.
- AGGREGATE item definition on page 1223
- Defines screen-record fields that hold computed values to be displayed as footer cells in a TABLE container.
- TABLE item definition on page 1236
Defines attributes for a table layout tag, in a grid-based layout.

**Summary lines in tables** on page 1767
Table views can display a summary line, to show aggregate values for columns.

**AGGREGATETYPE attribute**
The AGGREGATETYPE attribute defines how the aggregate field value is computed.

**Syntax**

```
AGGREGATETYPE = PROGRAM | SUM | AVG | MIN | MAX | COUNT
```

**Usage**

PROGRAM specifies that the aggregate value will be computed and displayed by the program code.

An aggregate type different from PROGRAM specifies that the aggregate value is computed automatically:

- **SUM** computes the total of all values of the corresponding numeric column.
- **AVG** computes the average of all values of the corresponding numeric column.
- **MIN** displays the minimum value of the corresponding numeric column.
- **MAX** displays the maximum value of the corresponding numeric column.
- **COUNT** computes the number of rows.

The **SUM** and **AVG** aggregate types apply to data types that can be used as operand for an addition, such as INTEGER, DECIMAL, INTERVAL.

The **MIN** and **MAX** aggregate types apply to data types that can be compared, such as INTEGER, DECIMAL, INTERVAL, CHAR, DATETIME.

**Example**

```
AGGREGATE tot = FORMONLY.total, AGGREGATETYPE=PROGRAM;
```

**Related concepts**

**AGGREGATE item definition** on page 1223
Defines screen-record fields that hold computed values to be displayed as footer cells in a TABLE container.

**TABLE item definition** on page 1236
Defines attributes for a table layout tag, in a grid-based layout.

**Summary lines in tables** on page 1767
Table views can display a summary line, to show aggregate values for columns.

**AUTOSCALE attribute**
The AUTOSCALE attribute causes the form element contents to automatically scale to the size given to the item.

**Syntax**

```
AUTOSCALE
```

**Usage**

For images, this attribute forces the image to be stretched to fit in the area reserved for the image.

**Related concepts**

**Controlling the image layout** on page 1047
Explains how image form items can be sized in different front-end layout systems.

**IMAGE item type** on page 1174
Defines an area that can display an image resource.

**AUTONEXT attribute**
The AUTONEXT attribute forces the cursor to automatically leave the current field when full.

**Syntax**

```
AUTONEXT
```

**Usage**

With AUTONEXT, when the user types a character that completely fills the current field, the focus goes automatically to the next field in the input order.

If data values entered in the field do not meet the requirements of other field attributes like INCLUDE or PICTURE, the cursor does not automatically move to the next field. It remains in the current field, and an error message displays.

AUTONEXT is particularly useful with character fields in which the input data is of a standard length, such as numeric postal codes. It is also useful if a character field has a length of 1, as only one keystroke is required to enter data and move to the next field.

**Related concepts**

- EDIT item type on page 1170
  Defines a simple line-edit field.
- BUTTONTEXTHIDDEN attribute
  The BUTTONTEXTHIDDEN attribute indicates that the button labels for an element are not to be displayed.

**Syntax**

```
BUTTONTEXTHIDDEN
```

**Usage**

Use BUTTONTEXTHIDDEN in a TOOLBAR definition to hide the labels of toolbar buttons.

**Related concepts**

- TOOLBAR section on page 1192
  The TOOLBAR section defines a toolbar with buttons that are bound to actions.
- CENTURY attribute
  The CENTURY attribute defines expansion of the year in a DATE or DATETIME field.

**Syntax**

```
CENTURY = ‹R› ‹C› ‹F› ‹P›
```

**Usage**

The CENTURY attribute specifies how to expand abbreviated one- and two-digit year specifications in a DATE and DATETIME field.

Century expansion is based on this attribute and on the current year defined by the system clock.

The CENTURY attribute can specify any of four algorithms to expand abbreviated years into four-digit year values that end with the same digits (or digit) that the user has entered.

CENTURY supports the same settings as the DBCENTURY environment variable, but with a scope that is restricted to a single field.
If the CENTURY and DBCENTURY settings are different, CENTURY takes precedence.

Unlike DBCENTURY, the CENTURY attribute is not case sensitive. However, we recommend that you use uppercase letters in the attribute.

**Related concepts**

DBCENTURY on page 231
Specifies the expansion for the century in DATE and DATETIME values.

**CLASS attribute**
The CLASS attribute defines the behavior of a field defined with the WIDGET attribute.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```
CLASS = "identifier"
```

1. *identifier* is a predefined keyword defining the class of the field.

**Usage**
The CLASS attribute can only be used with the WIDGET attribute. It is ignored if WIDGET is not used.

**Note:** The CLASS attribute is deprecated, use new form item types instead.

**Table 324: Supported field classes**

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEY</td>
<td>Field is used to trigger a keystroke instead of being a normal input field.</td>
</tr>
<tr>
<td></td>
<td>Only supported with WIDGET=&quot;BMP&quot;</td>
</tr>
<tr>
<td>PASSWORD</td>
<td>Field input is masked by replacing normal character echo with stars.</td>
</tr>
</tbody>
</table>

**Related concepts**

WIDGET attribute on page 1299
The WIDGET attribute specifies the type of graphical widget to be used for a field.

**COLOR attribute**
The COLOR attribute defines the foreground color of the text displayed by a form element.

**Syntax**

```
COLOR = color-name
```

1. *color-name* can be: BLACK, BLUE, CYAN, GREEN, MAGENTA, RED, WHITE, and YELLOW.

**Usage**
The COLOR attribute defines the logical color of a value displayed in a field.

For backward compatibility, *color-name* can be combined with an intensity keyword: REVERSE, LEFT, BLINK, and UNDERLINE.
Example

EDIT f001 = customer.name, COLOR = RED;

Related concepts
EDIT item type on page 1170
Defines a simple line-edit field.
COLOR WHERE Attribute on page 1249
The COLOR WHERE attribute defines a condition to set the foreground color dynamically.

COLOR WHERE Attribute
The COLOR WHERE attribute defines a condition to set the foreground color dynamically.

Syntax

COLOR = color-name [... ] WHERE bool-expr

1. color-name can be BLACK, BLUE, CYAN, GREEN, MAGENTA, RED, WHITE, or YELLOW.
2. color-name can also be an intensity keyword: REVERSE, LEFT, BLINK, and UNDERLINE.
3. bool-expr defines a boolean expression with a restricted syntax.

Usage

The attribute COLOR WHERE defines a conditional color. The color will be applied if the condition is true.
The condition in COLOR WHERE can only reference the field for which the attribute is set.

Example

EDIT f001 = item.price, COLOR = RED WHERE f001 < 0;

Note: With form fields such as EDIT, BUTTONEDIT the RED color will be applied when leaving the field. The color will not change while editing the value.

Related concepts
COLOR attribute on page 1248
The COLOR attribute defines the foreground color of the text displayed by a form element.
EDIT item type on page 1170
Defines a simple line-edit field.

Boolean expressions in forms on page 1162
Some form item definitions can include boolean expressions with a form file specific syntax.

CONFIG Attribute
The CONFIG attribute defines the behavior and decoration of a field defined with the WIDGET attribute.

Syntax

Important: This feature is deprecated, and may be removed in a future version.

CONFIG = "parameter [...]"

1. parameter is the value of a configuration parameter.

Usage

The CONFIG attribute can only be used with the WIDGET attribute. It is ignored if WIDGET is not used.
Configuration parameters are separated by blanks.
If a configuration parameter holds blank characters, you must use {} curly brackets to delimit the parameter value.

**Note:** The **CONFIG** attribute is deprecated, use new form item types instead.

**Related concepts**

**WIDGET attribute** on page 1299
The **WIDGET** attribute specifies the type of graphical widget to be used for a field.

**CONTEXTMENU attribute**
The **CONTEXTMENU** attribute defines whether a context menu option must be displayed for an action.

**Syntax**

```
CONTEXTMENU = [AUTO | YES | NO]
```

**Usage**

This attribute is an action attribute that can be specified in form **ACTION DEFAULTS**

**CONTEXTMENU** is an action attribute defining whether the context menu option must be displayed for an action.

**Important:** Actions to be displayed in a context menu must have a **TEXT** attribute. If the **TEXT** attribute is not defined or is empty, the action will not be shown in the context menu.

Possible values for **CONTEXTMENU** are:

1. **NO** indicates that no context menu option must be displayed for this action.
2. **YES** indicates that a context menu option must always be displayed for this action, if the action is visible.
3. **AUTO** means that the context menu option is displayed if no explicit action view is used for that action and the action is visible.

The default is **YES**.

**Note:** With some front-ends, the **CONTEXTMENU=AUTO** attribute will be interpreted as **CONTEXTMENU=YES**. Consider using **CONTEXTMENU=NO** or leave the default (**CONTEXTMENU=YES**).

This attribute applies to the actions defined by the current dialog in the current window. It can be specified as action default attribute in a global .4ad file, in the **ACTION DEFAULTS** section of form files, or as dialog action attribute.

For more details, see **CONTEXTMENU action attribute** on page 1656.

**Related concepts**

**ui.Dialog.setActionHidden** on page 2395
Showing or hiding a default action view.

**Configuring actions** on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with **action attributes**.

**Action display in the context menu** on page 1672
The **CONTEXTMENU** action default attribute allows you to control action visibility in the context menu.

**COMMENT attribute**
The **COMMENT** attribute defines a hint for the user about the form element.

**Syntax**

```
COMMENT = [%l]string%
```

1. **string** is the text to display. With the % prefix, it is a localized string.
Usage

The most common use of the COMMENT attribute is to give information or instructions to the user.

The COMMENT attribute can be used for different types of form elements:

- with form field definitions, to show a message when the field gets the focus.
- with action views, to give a hint to the user about the action.

With form fields, this attribute is particularly appropriate when the field accepts only a limited set of values. The screen location where the message displays depends on external configuration. It can be displayed in the comment line, or in the status bar when using a graphical user interface. If the OPEN WINDOW statement specifies COMMENT LINE OFF, any output to the comment area is hidden even if the window displays a form that includes fields that include the COMMENT attribute.

The COMMENT attribute can, in specific situations, define a value placeholder message when the field is empty. If the COMMENT cannot be rendered in a dedicated area (as is the case with mobile devices), the COMMENT is used as the default PLACEHOLDER.

With actions, this attribute can be defined in the ACTION_DEFAULTS section of a form or directly in an action view (BUTTON). See COMMENT action attribute on page 1655 for more details.

Example

```
-- In a form field definition
EDIT fl = customer.name, COMMENT = "The customer name";

-- As action default
ACTION DEFAULTS
  ACTION print (COMMENT="Print current order information")
END

-- In a form button
BUTTON b1: print, COMMENT = "Print customer details";
```

Related concepts

Localized strings on page 430

Localized strings provide a means of writing applications in which the text of strings can be customized on site.

OPEN WINDOW on page 1034

Creates and displays a new window.

Configuring actions on page 1646

Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

COMPLETER attribute

The COMPLETER attribute enables autocompletion for the edit field.

Syntax

```
COMPLETER
```

Usage:

Form fields with COMPLETER attribute provide suggestions while the end-user types text into the field, it can be used in text edit fields such as EDIT and BUTTONEDIT item types.

Normally, the ON CHANGE trigger is fired for text edit fields when leaving the field and if the content was modified. Form fields defined with the COMPLETER attribute will trigger the ON CHANGE control block when the end user modifies the content of the field.

See Enabling autocompletion on page 1633 for more details.
Example

EDIT f1 = FORMONLY.custname, COMPLETER;

Related concepts
ui.Dialog.setCompleterItems on page 2401
Define autocompletion items for the a field defined with COMPLETER attribute.

EDIT item type on page 1170
Defines a simple line-edit field.

BUTTONEDIT item type on page 1164
Defines a line-edit with a push-button that can trigger an action.

COMPONENTTYPE attribute
The COMPONENTTYPE attribute defines a name identifying the external widget for WEBCOMPONENT fields.

Syntax

COMPONENTTYPE = "name"

1. name defines the HTML file defining the web component.

Usage
The COMPONENTTYPE attribute is used to define the type of a WEBCOMPONENT form item for gICAPI web components.

When this attribute is specified, it defines the name of the HTML file that will be loaded by the front-end. If this attribute is not defined, the web component will be specified by an URL set dynamically by program in the field value. Consider using URL-based web components instead of gICAPI web components.

Example

WEBCOMPONENT f001 = FORMONLY.myca1, COMPONENTTYPE="Calendar";

Related concepts
Web components on page 1825
This section describes how to use web components in your application.

WEBCOMPONENT item type on page 1187
Defines a specialized form item that holds an external component.

DEFAULT attribute
The DEFAULT attribute assigns a default value to a field during data entry.

Syntax

DEFAULT = value

1. value can be any literal expression supported by the form compiler, as long as it matches the form field type.
2. value can be TODAY to specify the current system date as default.
3. value can be CURRENT to specify the current system datetime as default.

Usage
The literal constant specified as default value must match the form field type. For example, when defining a numeric field, use a numeric decimal constant, for character string fields, use a double-quoted character literal.
The effect of the DEFAULT attribute depends on the WITHOUT DEFAULTS configuration option of the dialog using the form.

With the INPUT statement, form default values are ignored when using the WITHOUT DEFAULTS option. With this option, the runtime system displays the values in the program variables to the screen. Otherwise, the form default values will be displayed when the dialog starts.

With the INPUT ARRAY statement, the form default values are always used for new rows inserted by the user. With INPUT ARRAY, the WITHOUT DEFAULTS option indicates if the existing program array elements have to be used. Defaults values can also be specified in the database schema file, for form fields defined with database column reference.

If the field is FORMONLY, you must also specify a data type when you assign the DEFAULT attribute to a field.

If both the DEFAULT attribute and the REQUIRED attribute are assigned to the same field, the REQUIRED attribute is ignored.

If you do not use the WITHOUT NULL INPUT option in the DATABASE section of a form, all fields default to null values unless you have specified a DEFAULT attribute.

Note that DATETIME and INTERVAL literals are not supported in the DEFAULT attribute.

Example

```
EDIT f001 = order.orderdate, DEFAULT = TODAY;
EDIT f012 = FORMONLY.discount TYPE DECIMAL(5,2), DEFAULT=0.10;
```

Related concepts

Record input (INPUT) on page 1373

Editable record list (INPUT ARRAY) on page 1425
The INPUT ARRAY instruction provides always-editable record list handling in an application form.

Database schema on page 476
Defines database table structures with column type information to be reused in program variable definitions.

Form field initialization on page 1622
Form field initialization can be controlled by the WITHOUT DEFAULTS dialog option.

REQUIRED attribute on page 1280
The REQUIRED attribute forces the user to modify the content of a field during an input dialog.

EDIT item type on page 1170
Defines a simple line-edit field.

DEFAULTVIEW attribute
The DEFAULTVIEW attribute defines if a default view (a button) must be displayed for a given action.

Syntax

```
DEFAULTVIEW = [AUTO | YES | NO]
```

Usage

This attribute is an action attribute that can be specified in form ACTION DEFAULTS.

DEFAULTVIEW is an action attribute defining whether the default action view (a button) must be displayed for an action.

Possible values for CONTEXTMENU are:

- NO indicates that no default action view must be displayed for this action.
• YES indicates that a default action view must always be displayed for this action, if the action is visible.
• AUTO means that a default action view is displayed if no explicit action view is used for that action and the action is visible.

The default is AUTO.

For more details, see DEFAULTVIEW action attribute on page 1657.

**Related concepts**

DEFAULT attribute on page 1252
The DEFAULT attribute assigns a default value to a field during data entry.

**DISPLAY LIKE attribute**
The DISPLAY LIKE attribute applies column attributes defined in the database schema files (.att) to a field.

**Syntax**

```
DISPLAY LIKE [table.]column
```

1. `table` is the optional table name to qualify the column.
2. `column` is the name of the column to be used to retrieve display attributes.

**Usage**

Specifying this attribute is equivalent to listing all the attributes that are assigned to `table.column` in the database schema file with the .att extension.

Display attributes are automatically taken from the schema file if the field is linked to `table.column` in the field name specification.

The DISPLAY LIKE attribute is evaluated at compile time, not at runtime. If the database schema file changes, recompile all forms using this attribute. Even if all of the fields in the form are FORMONLY, this attribute requires the form compiler to access the database schema file that contains the description of table.

**Example**

```
EDIT f001 = FORMONLY.fullname, DISPLAY LIKE customer.custname;
```

**Related concepts**

Column Video Attributes File (.att) on page 485
The .att database schema file contains the default video attributes of database table columns.

Formonly fields on page 1141
FORMONLY form fields define their data type explicitly, with or without referencing a database columns.

**DISCLOSUREINDICATOR attribute**
The DISCLOSUREINDICATOR attribute adds a drill-down decoration to the form item.

**Syntax**

```
DISCLOSUREINDICATOR
```

**Usage**

The DISCLOSUREINDICATOR attribute is used on BUTTON form items to add a graphical hint, to indicate that a click on the button will drill down in the application windows, typically to show a detailed view of the information displayed in the current window.

This is a simple decoration attribute, with no other functional purpose.
For example, on iOS devices, the buttons defined with this attribute will show a typical > icon on the right.

**Example**

```plaintext
BUTTON b_details : details,
    TEXT="Show details",
    DISCLOSUREINDICATOR;
```

**Related concepts**

- **Configuring actions** on page 1646
- Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

**DOUBLECLICK attribute**

The **DOUBLECLICK** attribute defines the action for row choice on TABLE/TREE/SCROLLGRID rows.

**Syntax**

```plaintext
DOUBLECLICK = action-name
```

1. *action-name* defines the name of the action to be invoked.

**Usage**

The **DOUBLECLICK** attribute can be used in a TABLE, TREE or SCROLLGRID container, to define the action to be sent when the user chooses a row. By default, on desktop and web front-ends, a row choice (mouse double-click) fires the "accept" action.

- **Important**: The row-choice action can also be defined as DISPLAY ARRAY dialog attribute with the **DOUBLECLICK** option. This dialog attribute has added to be used in conjunction with the **DETAILACTION** and **ACCESSORYTYPE** attributes for mobile apps. When the **DOUBLECLICK** attribute is specified at the dialog level, it takes precedence over the **DOUBLECLICK** attribute defined in the form specification file.

The action defined by **DOUBLECLICK** is by default triggered by a double-click on a front-end using a mouse device, and a finger tap on mobile front-ends. On desktop and web front-ends, the physical event that triggers the row choice action can be controlled by the **rowActionTrigger** style attribute.

- **Note**: List views supporting the **DOUBLECLICK** attribute are TABLE, TREE and SCROLLGRID. The **DOUBLECLICK** attribute does not apply to simple field lists that are defined in the form layout without a parent list container.

For more details about row choice action configuration, see **Defining the action for a row choice** on page 1768.

**Related concepts**

- **TABLE item definition** on page 1236
  - Defines attributes for a table layout tag, in a grid-based layout.
- **TREE item definition** on page 1238
  - Defines attributes for a tree layout tag, in a grid-based layout.
- **SCROLLGRID item definition** on page 1234
  - Defines a scrollgrid layout tag in a grid-based layout.
- **Record list (DISPLAY ARRAY)** on page 1394
The DISPLAY ARRAY instruction provides record list navigation in an application form, with optional record modification actions.

**DOWNSHIFT attribute**  
The DOWNSHIFT attribute forces character input to lowercase letters.

**Syntax**

```
DOWNSHIFT
```

**Usage**

When defining the DOWNSHIFT attribute for a character field, the characters typed by the user are automatically converted to lowercase.

**Note:** In text mode, the results of conversions between uppercase and lowercase letters are based on the locale settings.

Because using uppercase and lowercase letters results in different values in the database, storing character strings in one or the other format can simplify sorting and querying.

**Important:** Values send from the runtime system are displayed as is by the front-ends: No conversion will occur if you display "AbCdE" to a field using UPSHIFT or DOWNSHIFT attributes.

**Example**

```
EDIT f001 = FORMONLY.name, DOWNSHIFT;
```

**Related concepts**

[UPSHIFT attribute](#) on page 1293  
The UPSHIFT attribute forces character input to uppercase letters.

**EXPANDEDCOLUMN attribute**  
The EXPANDEDCOLUMN attribute specifies the form field that indicates whether a tree node is expanded.

**Syntax**

```
EXPANDEDCOLUMN = column-name
```

1. `column-name` is the name of the form field holding the flag indicating whether a tree node is expanded (opened).

**Usage**

This attribute is used in the definition of a TREE container.

You must specify form field column names, not item tag identifiers.

This attribute is optional.

**Related concepts**

[Tree views](#) on page 1789  
Describes how to implement tree views.

[Form fields](#) on page 1138  
*Form fields* are form elements designed for data input and/or data display.

[Item tags](#) on page 1155  
*Item tags* define the position and size in a grid-based container.

[Defining a TREE container](#) on page 1791
Start a tree-view implementation by defining the TREE container in the form definition file.

**FONTPITCH attribute**
The FONTPITCH attribute defines the character font type as fixed or variable when the default font is used.

**Syntax**

```
FONTPITCH = { FIXED | VARIABLE }
```

**Usage**
By default, most front ends use variable width character fonts, but some fields might need to use a fixed font.

**Tip:** Use a STYLE defining a fixed font instead of this attribute.

**Related concepts**
- **STYLE attribute** on page 1287
  The STYLE attribute specifies a presentation style for a form element.
- **Defining a style** on page 1067
  Styles can be defined to be global (for all elements), for an element in general, or for specific types of an element.

**FORMAT attribute**
The FORMAT attribute defines the data formatting for numeric and date time fields, for input and display.

**Syntax**

```
FORMAT = "format"
```

1. *format* is a string of characters that specifies a data format.

**Usage**
The FORMAT attribute can be set to define input and display format for numeric and date fields.
When this attribute is not used, environment variables define the default format:

- For MONEY and numeric fields such as DECIMAL fields, a format can be specified with the DBFORMAT (or DBMONEY) environment variables.
- For DATE fields, the default format is defined by the DBDATE environment variable.

The data format is used when converting the input buffer to the program variable, and when displaying program variable data to form fields. For example, when defining a FORMAT="yyyy-mm-dd" for a form field bound to a program variable defined as a DATE, the user can input a date as 2013-12-24, and the date value will be displayed in the same manner.

Do not confuse the FORMAT and PICTURE attributes: The PICTURE attribute is used to define an input mask for character string fields, such as vehicle registration numbers. Do not mix PICTURE and FORMAT attributes in field definitions.

If the format string is smaller than the field width, you get a compile-time warning, but the form is usable.

The format string can be any valid string expression using formatting characters as described in Formatting numeric values on page 281 and Formatting DATE values on page 284.

**Example**

```
EDIT f001 = order.thedate, FORMAT = "mm/dd/yyyy";
```

**Related concepts**
- **DBDATE** on page 232
Defines the default display and input format for DATE values.

DATE on page 259
The DATE data type stores calendar dates with a Year/Month/Day representation.

DBMONEY on page 236
Defines currency symbol and decimal separator for input and display of numeric values, when DBFORMAT is not defined.

DBFORMAT on page 233
Defines currency symbol, decimal and thousands separator for input and display of numeric values.

DECIMAL(p,s) on page 262
The DECIMAL data type is provided to handle large numeric values with exact decimal storage.

MONEY(p,s) on page 267
The MONEY data type is provided to store currency amounts with exact decimal storage.

GRIDCHILDRENINPARENT attribute
The GRIDCHILDRENINPARENT attribute is used for a container to align its children to the parent container.

Syntax

GRIDCHILDRENINPARENT

Usage
By default, in a grid-based layout, child elements of a container are aligned locally inside the container layout cells.
With the GRIDCHILDRENINPARENT attribute, you can force children to be aligned in a vertical or horizontal direction, based on the layout cells in the parent container of the container to which you assign this attribute.

Important: This feature is not supported on mobile platforms.

Note: The GRIDCHILDRENINPARENT attribute applies only to GROUP and SCROLLGRID containers used inside a parent GRID container.

When the group or scrollgrid containers are placed vertically over each other, the alignment applies on parent grid columns, and when the containers are placed side by side horizontally, the alignment applies on parent grid rows.

Example
With this form definition, the elements in the four group boxes will align vertically and horizontally to the parent grid cells:

```plaintext
LAYOUT
GRID
{
<G ga       ><G gb       >
    Some text
    <a       >b[b     ]
    <<<     >
    <G gc     >><G gd     >
    [c       ] d[d     ]
    <<<     >
}
END
END
ATTRIBUTES
GROUP ga: GRIDCHILDRENINPARENT;
GROUP gb: GRIDCHILDRENINPARENT;
GROUP gc: GRIDCHILDRENINPARENT;
GROUP gd: GRIDCHILDRENINPARENT;
EDIT a = FORMONLY.f_a;
EDIT b = FORMONLY.f_b;
```
**EDIT** c = FORMONLY.f_c;
EDIT d = FORMONLY.f_d;
END

**Related concepts**

*Form rendering* on page 1306
The section explains the layout rules to render forms on graphical front-ends.

*Layout tags* on page 1151
*Layout tags* define layout areas for containers inside the frame of a grid-based container.

**HEIGHT attribute**
The **HEIGHT** attribute forces an explicit height for a form element.

**Syntax**

```
HEIGHT = integer [CHARACTERS|LINES|POINTS|PIXELS]
```

1. `integer` defines the height of the element.

**Usage**

By default, the height of an element is defined by the size of the form item tag in a grid-based layout, or by the type of the form item in a stack-based layout. Use the **HEIGHT** attribute to define a specific height for a form item.

**Note:** As a general rule, consider not specifying a unit, to default to relative characters/lines/columns, instead of specifying exact pixels or points. This is especially important for mobile devices, where the screen resolution can significantly vary depending on the smartphone or tablet model.

In a grid-based layout and stack-based layout, if you don't specify a size unit, it defaults to **CHARACTERS**, which defines a height based on the characters size in the current font.

**Grid-based layout**

For sizable items like **IMAGE**, the default height is defined by the number of lines of the form item tag in the layout, as a vertical character height. Overwrite this default by specifying the **HEIGHT** attribute.

For **TABLE**/**TREE** containers, the default height is defined by the number of lines used in the table layout. Overwrite the default by specifying the **HEIGHT = x LINES** attribute.

```
IMAGE img1: image1, WIDTH = 20, HEIGHT = 12;
```

**Stack-based layout**

For **TABLE** containers, the height of a list is defined by the actual number of rows, this cannot be changed.

For **IMAGE** items, by default the image is rendered full size, which means that the actual size of the image is used. Overwrite the default by specifying the **HEIGHT** attribute:

```
IMAGE image1, HEIGHT = 12, ...;
```

By default, **WEBCOMPONENT** items adapt their size to the content. To force a given size, use the **HEIGHT** attribute:

```
WEBCOMPONENT FORMONLY.chart, HEIGHT = 10, ...;
```

A **TEXTEDIT** item always adapts its size to the text value. By using the **HEIGHT** attribute, you can define a minimum height, when the value of the field is empty:

```
TEXTEDIT FORMONLY.comment, HEIGHT = 5, ...;
```
Related concepts

Explains how image form items can be sized in different front-end layout systems.

Item tags on page 1155
Item tags define the position and size in a grid-based container.

Form rendering basics on page 1307
Get the essentials about form rendering.

WIDTH attribute on page 1302
The WIDTH attribute forces an explicit width of a form element.

HIDDEN attribute
The HIDDEN attribute indicates that the element is not to be displayed.

Syntax

```
HIDDEN \[ USER \]
```

1. HIDDEN sets the underlying item attribute to 1.
2. HIDDEN=USER sets the underlying item attribute to 2.

Usage
By default, all form elements are visible. Specify the HIDDEN attribute to hide a form element, such as a form field or a groupbox.

The runtime system detects hidden form fields: If you write an INPUT statement using a hidden field, the field is ignored (as if it was declared as NOENTRY).

If the HIDDEN keyword is specified alone, the underlying item attribute is set to 1. The value 1 indicates that the element is definitively hidden to the end user, which cannot show the element, for example with the context menu of TABLE headers. In this hidden mode, the UNHIDABLE attribute is ignored by the front end.

With HIDDEN=USER, the underlying item attribute is set to 2. The value 2 indicates that the element is hidden by default, but the end user can show/hide the element as needed. For example, the user can change a hidden column back to visible. Form elements like table columns that are hidden by the user might be automatically re-shown (hidden=0) by the front-end if the program dialog gives the focus to that field for input. In such case the program dialog takes precedence over the hidden attribute.

When you set a hidden attribute for a form field, the model node gets the hidden attribute, not the view node.

Form fields hidden with HIDDEN=USER (value 2) might be shown anyway, if the field is needed by a dialog for input.

Programs may also change the visibility of form elements dynamically with the ui.Form.setElementHidden() or ui.Form.setFieldHidden() methods.

Example

```
EDIT f001 = FORMONLY.field1, HIDDEN;
EDIT col1 = FORMONLY.column1, HIDDEN=USER;
```

Related concepts
Syntax of the INPUT instruction on page 1374
The INPUT statement supports data entry in fields of the current form.

NOENTRY attribute on page 1273
The NOENTRY attribute prevents data entry in the field during an input dialog.

The Form class on page 2353
The `ui.Form` class provides an interface to form objects created by an `OPEN WINDOW WITH FORM` or `DISPLAY FORM` instruction.

**UNHIDABLE attribute** on page 1290
The `UNHIDABLE` attribute indicates that the element cannot be hidden or shown by the user with the context menu.

**UNHIDABLECOLUMNS attribute** on page 1290
The `UNHIDABLECOLUMNS` attribute indicates that the columns of the table cannot be hidden or shown by the user with the context menu.

**IDCOLUMN attribute**
The `IDCOLUMN` attribute specifies the form field that contains the identifier of a tree node.

**Syntax**

```
IDCOLUMN = column-name
```

1. `column-name` is a form field name.

**Usage**

This attribute is used in the definition of a `TREE` container, to define the name of the form field containing the identifier of a node in a tree view.

You must specify form field column names, not item tag identifiers.

This attribute is mandatory.

**Related concepts**
- **Tree views** on page 1789
  Describes how to implement tree views.
- **Form fields** on page 1138
  *Form fields* are form elements designed for data input and/or data display.
- **Item tags** on page 1155
  *Item tags* define the position and size in a grid-based container.
- **PARENTIDCOLUMN attribute** on page 1275
  The `PARENTIDCOLUMN` attribute specifies the form field that contains the identifier of the parent node of a tree node.

**IMAGE attribute**
The `IMAGE` attribute defines the image resource to be displayed for the form item.

**Syntax**

```
IMAGE = "resource"
```

1. `resource` defines the file name, path or URL to the image source.

**Usage:**

The `IMAGE` attribute is used to define the image resource to be displayed for form items such as a `BUTTON`, `BUTTONEDIT`, a `TOOLBAR` button, or a static `IMAGE` item.

For more details about image resource specification, see [Providing the image resource](#) on page 1049.

This attribute is also an action attribute that can be defined in the `ACTION DEFAULTS` section of a form or directly in an action view (`BUTTON`), see [IMAGE action attribute](#) on page 1659 for more details.
Example

-- As action default
ACTION DEFAULTS
  ACTION print (IMAGE="printer")
END

-- In a form buttonedit or button
BUTTONEDIT f001 = FORMONLY.field01, IMAGE = "zoom";
BUTTON b01: open_file, IMAGE = "buttons/fileopen";
BUTTON b02: accept, IMAGE = "http://myserver/images/accept.png";

-- In a static image form item
IMAGE: img1, IMAGE = "mylogo.png"

Related concepts

Describes how to use pictures in the forms of your application.

IMAGE item type on page 1174
Defines an area that can display an image resource.

Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

IMAGECOLUMN attribute
The IMAGECOLUMN attribute defines the form field containing the image for the current field.

Syntax

```
IMAGECOLUMN = column-name
```

1. `column-name` is a form field name.

Usage

The IMAGECOLUMN attribute allows an image to be displayed on the left of the value of the column value. The image can be different for each row.

A typical usage is the TREE container: IMAGECOLUMN will allow a row-specific image to be displayed left of the tree node text. You defined only one image column for a tree node decoration.

When used in the definition of a TABLE column, the image and the column will be displayed in the same table cell. There can be several TABLE columns using an IMAGECOLUMN.

For TREE containers, the images defined by the IMAGESCAPPED, IMAGEEXPANDED and IMAGELEAF attributes take precedence over the images defined by the IMAGECOLUMN cell.

This attribute references form field that contains the name of an image. This form field must be defined as a PHANTOM form field, that will be part of the screen record definition in the INSTRUCTIONS section.

For more details about image resource specification in the PHANTOM column, see Providing the image resource on page 1049.

Example

```
...  
ATTRIBUTES
PHANTOM FORMONLY.icon;
EDIT FORMONLY.file_name, IMAGECOLUMN=icon;
...  
END
INSTRUCTIONS
```
![Screen record sr(FORMONLY.icon, FORMONLY.file_name, ...);
...](image)

**Related concepts**

**Phantom fields** on page 1142
A **phantom** field defines a screen-record field which is not rendered in the layout (it acts as a hidden field).

**Tree views** on page 1789
Describes how to implement tree views.

**IMAGECOLLAPSED attribute** on page 1263
The **IMAGECOLLAPSED** attribute sets the global icon to be used when a tree node is collapsed.

**IMAGEEXPANDED attribute** on page 1263
The **IMAGEEXPANDED** attribute sets the global icon to be used when a tree node is expanded.

**IMAGELEAF attribute** on page 1264
The **IMAGELEAF** attribute defines the global icon for leaf nodes of a **TREE** container.

**IMAGECOLLAPSED attribute**
The **IMAGECOLLAPSED** attribute sets the global icon to be used when a tree node is collapsed.

**Syntax**

```
IMAGECOLLAPSED = "image-name"
```

1. *image-name* is an image resource.

**Usage**
This attribute is used in the definition of a **TREE** container, to define the icon to be used for nodes that are collapsed.
It overwrites the program array image defined by **IMAGECOLUMN**, if both are used.
This attribute is optional.
For more details about image resource specification, see **Providing the image resource** on page 1049.

**Related concepts**

**Using images** on page 1046
Describes how to use pictures in the forms of your application.

**Tree views** on page 1789
Describes how to implement tree views.

**IMAGECOLUMN attribute** on page 1262
The **IMAGECOLUMN** attribute defines the form field containing the image for the current field.

**IMAGEEXPANDED attribute**
The **IMAGEEXPANDED** attribute sets the global icon to be used when a tree node is expanded.

**Syntax**

```
IMAGEEXPANDED = "image-name"
```

1. *image-name* is an image resource.

**Usage**
This attribute is used in the definition of a **TREE** container, to define the icon to be used for nodes that are expanded.
It overwrites the program array image defined by `IMAGECOLUMN`, if both are used.

This attribute is optional.

For more details about image resource specification, see Providing the image resource on page 1049.

**Related concepts**
- Using images on page 1046
- Describes how to use pictures in the forms of your application.
- Tree views on page 1789
- Describes how to implement tree views.

**IMAGECOLLAPSED attribute**
The `IMAGECOLLAPSED` attribute on page 1263
The `IMAGECOLLAPSED` attribute sets the global icon to be used when a tree node is collapsed.

**IMAGELEAF attribute**
The `IMAGELEAF` attribute defines the global icon for leaf nodes of a `TREE` container.

**Syntax**

```
IMAGELEAF = "image-name"
```

1. `image-name` is an image resource.

**Usage**

This attribute is used in the definition of a `TREE` container, to specify the name of the icon that must be used for leaf nodes.

It overwrites the program array image defined by `IMAGECOLUMN`, if both are used.

This attribute is optional.

For more details about image resource specification, see Providing the image resource on page 1049.

**Related concepts**
- Using images on page 1046
- Describes how to use pictures in the forms of your application.
- Tree views on page 1789
- Describes how to implement tree views.

**INCLUDE attribute**
The `INCLUDE` attribute defines a list of possible values for a field.

**Syntax**

```
INCLUDE = ( [ NULL | literal ] [ TO literal ] [ , ... ] )
```

1. `literal` can be any literal expression supported by the form compiler.

**Usage**

The `INCLUDE` attribute specifies acceptable values for a field and causes the runtime system to check the data before accepting an input value.

If the field is FORMONLY, you must also specify a data type when you assign the `INCLUDE` attribute to a field.

Include the `NULL` keyword in the value list to specify that it is acceptable for the user to leave the field without entering any value.
Use the TO keyword to specify an inclusive range of acceptable values. When specifying a range of values, the lower value must appear first. The field value is accepted if it is greater or equal to the first literal, and lower or equal to the second literal.

```
INCLUDE = (1 TO 999)
  is equivalent to:
  ( field_value >= 1 AND field_value <= 999 )
```

Special consideration must be taken for character string fields:

```
INCLUDE = ("AAA" TO "ZZZ")
  is equivalent to:
  ( field_value >= "AAA" AND field_value <= "ZZZ" )
  ABC is accepted
  A!! is not accepted
  Zaa is not accepted
```

When combining several ranges and single values, the value entered by the user is verified for each element of the INCLUDE attribute:

```
INCLUDE = (1 TO 999, -1, NULL)
  is equivalent to:
  ( field_value >= 1 AND field_value <= 999 )
  OR
  ( field_value == -1 )
  OR
  ( field_value IS NULL )
```

Example

```
EDIT f001 = compute.rate, INCLUDE = ( 1 TO 100, 200, NULL);
EDIT f002 = customer.state, INCLUDE = ( "AL" TO "GA", "IA" TO "WY" );
EDIT f003 = FORMONLY.valid TYPE CHAR, INCLUDE = ("Y","N");
```

Related concepts

Form-level validation rules on page 1627
Form-level validation rules can be defined for each field controlled by a dialog.

Formonly fields on page 1141
FORMONLY form fields define their data type explicitly, with or without referencing a database columns.

ITEMS attribute on page 1267
The ITEMS attribute defines a list of possible values that can be used by the form item.

INITIALIZER attribute
The INITIALIZER attribute allows you to specify an initialization function that will be automatically called by the runtime system to set up the form item.

Syntax

```
INITIALIZER = function
```

1. function is an identifier defining the program function to be called.

Usage

The initialization function must exist in the program using the form file and must be defined with a `ui.ComboBox` parameter.

Important:
• The initialization function name is case insensitive.
• The module defining the initialization function must have been loaded when the function is invoked. The error -1338 is raised if the module is not yet loaded, or when the function name mismatches. To make sure that the module is loaded, define other functions in the module, that are invoked with a regular CALL instruction.

Related concepts

The item list of COMBOBOX fields can be initialized at runtime.
ui.ComboBox.setDefaultInitializer on page 2415
Define the default initializer for combobox form items.
fglform on page 1970
The fglform tool compiles form specification files into XML formatted files used by programs.

INITIALPAGESIZE attribute
The INITIALPAGESIZE attribute defines the initial page size of a list element.

Syntax

INITIALPAGESIZE = lines

1. lines is an integer that defines the initial page size for the list element.

Usage
Some list containers such as resizable SCROLLGRID containers display by default a single row, if no other elements in the form layout forces the container size implicitly.

In such case, the INITIALPAGESIZE attribute can be used to specify a default initial number of rows to be displayed.

Related concepts
WANTFIXEDPAGESIZE attribute on page 1298
The WANTFIXEDPAGESIZE attribute controls the vertical resizing of a list element.
SCROLLGRID item type on page 1179
Defines a scrollable grid view widget.

INVISIBLE attribute
The INVISIBLE attribute prevents user-entered data from being echoed on the screen during an interactive statement.

Syntax

INVISIBLE

Usage
The INVISIBLE attribute can be used for EDIT and BUTTONEDIT fields, to hide characters typed by the end user, for example, to enter a password.

Characters that the user enters in a field with the INVISIBLE attribute are not displayed during data entry. Depending on the front end type, the typed characters are converted to blanks, stars, underscores or dots.

The INVISIBLE attribute has no effect when displaying data directly to a field with DISPLAY TO or DISPLAY BY NAME.

Related concepts
Static display (DISPLAY/ERROR/MESSAGE/CLEAR) on page 1343
This section explains the instructions displaying static information to application forms, such as DISPLAY, ERROR, MESSAGE, CLEAR.

**ISNODECOLUMN attribute**
The **ISNODECOLUMN** attribute specifies the form field that indicates whether a tree node has children.

**Syntax**

```
ISNODECOLUMN = column-name
```

1. *column-name* is a form field name.

**Usage**

This attribute is used in the definition of a TREE container, to specify the name of the form field indicating whether a tree node has children.

Even if the program node does not contain child nodes for this tree node, this attribute may be used, to implement dynamic filling of tree views.

You must specify form field column names, not item tag identifiers.

This attribute is optional.

**Related concepts**

- **Tree views** on page 1789
  Describes how to implement tree views.
- **Form fields** on page 1138
  *Form fields* are form elements designed for data input and/or data display.
- **Item tags** on page 1155
  *Item tags* define the position and size in a grid-based container.

**ITEMS attribute**
The **ITEMS** attribute defines a list of possible values that can be used by the form item.

**Syntax**

```
ITEMS = { single-value-list | double-value-list }
```

where *single-value-list* is:

```
( value [, ...] )
```

where *double-value-list* is:

```
( ( value, label-value ) [, ... ] )
```

1. *single-value-list* is a comma-separated list of single values.
2. *double-value-list* is a comma-separated list of (a, b) values pairs within parentheses.
3. *value* is a numeric or string literal, or one of the following keywords: NULL, TRUE, FALSE.
4. *label-value* is a numeric literal, a string literal, or a localized string.

**Usage**

The list must be delimited by parentheses, and each element of the list can be a simple literal value or a pair of literal values delimited by parentheses.
This attribute is not used by the runtime system to validate the field, you must use the INCLUDE attribute to force the possible values.

This example defines a list of simple values:

```plaintext
ITEMS = ("Paris", "London", "New York")
```

This example defines a list of pairs:

```plaintext
```

This attribute can be used, for example, to define the list of a COMBOBOX form item:

```plaintext
COMBOBOX cb01 = FORMONLY.combobox01,
```

In this example, the first value of a pair (1,2,3) defines the data values of the form field and the second value of a pair ("Paris", "London", "New York") defines the value to be displayed in the selection list.

When used in a RADIOGROUP form item, this attribute defines the list of radio buttons:

```plaintext
RADIOGROUP rg01 = FORMONLY.radiogroup01,
```

In this example, the first value of a pair (1,2,3) defines the data values of the form field and the second value of a pair ("Paris", "London", "New York") defines the value to be displayed as the radio button label.

You can specify item labels with localized strings, but this is only possible when you specify a key and a label:

```plaintext
ITEMS  = ((1,%%item1%),(2,%%item2%),(3,%%item3%))
```

It is allowed to define a NULL value for an item (An empty string is equivalent to NULL):

```plaintext
ITEMS  = ((NULL,"Enter bug status"),(1,"Open"),(2,"Resolved"))
```

In this case, the behavior of the field depends on the item type used.

**Related concepts**

- Localized strings on page 430
  
  **Localized strings** provide a means of writing applications in which the text of strings can be customized on site.

- COMBOBOX item type on page 1166
  
  Defines a line-edit with a drop-down list of values.

- RADIOGROUP item type on page 1178
  
  Defines a mutual exclusive set of options field.

**JUSTIFY attribute**

The JUSTIFY attribute defines the alignment of a text field content, and table column headers.

**Syntax**

```plaintext
JUSTIFY = LEFT \ CENTER \ RIGHT
```

**Usage**

With the JUSTIFY attribute, you specify the justification of the content of a text field as LEFT, CENTER or RIGHT when the field is in display state.
**Note:** JUSTIFY has no effect on the content of form item types like IMAGE, CHECKBOX, PROGRESSBAR. It aligns only the content of text fields such as EDIT and BUTTONEDIT.

The JUSTIFY attribute can be used with all form item types. In addition to the text field data alignment, JUSTIFY defines the alignment of table column headers (this means table column header follows the alignment of field data). However, column header alignment in tables may not be enabled by default; check the headerAlignment presentation style attribute for the Table class.

**Important:** Depending on the front-end type, JUSTIFY may not be supported, if the native platform widget does not allow alignment. For example, a DATEEDIT form field may not align the date value. The JUSTIFY attribute is typically used for text data only.

If the field has the focus in a dialog allowing user input, the data alignment rules are front-end specific, and follow either JUSTIFY or the data type of the field variable. When the current dialog is a CONSTRUCT, criteria input is always left-aligned.

With mobile front-ends, tables are rendered as list views with a maximum of two visible columns. By default, the main and the comment columns are displayed vertically in each row (main is above the comment). Use JUSTIFY=RIGHT for the second column, in order to display columns side by side. Note that numeric fields are by default right justified and thus do not need this attribute to be set.

You can also specify the text alignment of static form labels with the JUSTIFY attribute.

**Example**

```plaintext
LABEL t01: TEXT="Hello!", JUSTIFY=RIGHT;
EDIT f01 = order.value, JUSTIFY=CENTER;
```

**Related concepts**

- **FORMAT attribute** on page 1257
  - The FORMAT attribute defines the data formatting for numeric and date time fields, for input and display.

- **Data types** on page 253
  - Selecting the correct data type assists you in the input, storage, and display of your data.

  - Use presentation styles to specify decoration attributes for window and form elements.

**Related reference**

- **Table style attributes** on page 1101
  - Table style presentation attributes apply to a TABLE container.

**KEY attribute**

The KEY attribute is used to define the labels of keys when the field is made current.

**Syntax**

```plaintext
KEY keyname = `<%label%`
```

1. `keyname` is the name of a key (like F10, "Control-z").
2. `label` is the text to be displayed in the button corresponding to the key.

**Usage**

Use the KEY attribute to define a label for the accelerator key corresponding to an action when the focus is in the field.

The `keyname` must be specified in quotes if you want to use Control / Shift / Alt key modifiers.
See the **KEYS** section to define key labels for the whole form.

**Note:** This feature is supported for backward compatibility. Consider using **action attributes** to define accelerator keys and decorate actions.

### Example

```
EDIT f001 = customer.city, KEY F10 = "City list";
EDIT f002 = customer.state, KEY "Control-z" = "Open Zoom";
```

### Related concepts

- **Setting action key labels** on page 1676
- **KEYS section** on page 1241

The **KEYS** section can be used to define default key labels for the current form.

### KEYBOARDHINT attribute

The **KEYBOARDHINT** attribute gives an indication of the kind of data the form field contains, allowing the front-end to adapt the keyboard accordingly.

### Syntax

```
KEYBOARDHINT = { DEFAULT | EMAIL | NUMBER | PHONE }
```

### Usage

The **KEYBOARDHINT** attribute can be used to give a hint to the front-end, regarding the kind of data the form field will contain. Based on this hint, the front-end will open the virtual keyboard adapted to the data type; especially useful when designing application forms for mobile platforms.

Valid values for **KEYBOARDHINT** are:

- **DEFAULT**: No hint, the only hint is the data type of the program variable bound to the form field.
- **EMAIL**: The field is used to enter an email address.
- **NUMBER**: The field is used to enter a numeric value.
- **PHONE**: The field is used to enter a phone number.

For example, when defining a numeric field with the attribute **KEYBOARDHINT=NUMBER**, the iOS device will display a numeric keyboard when entering data into that field.
Figure 47: Mobile application using a numeric keyboard

Example

```
EDIT f23 = customer.cust_phone, KEYBOARDHINT=PHONE;
```

Related concepts

Keyboard type on page 3305
Depending on the data being entered, a mobile device is expected to display the keyboard that is appropriate for the data.

**MINHEIGHT attribute**
The MINHEIGHT attribute defines the minimum height of a form.

**Syntax**

```
MINHEIGHT = integer
```

1. *integer* defines the minimum height of the element, as a number of grid cells.

**Usage**
The MINHEIGHT attribute is used to define a minimum height for the form/window. It must be specified in the attributes of the LAYOUT section.

The unit defaults to a number of grid cells. This is the equivalent of the CHARACTERS in the HEIGHT attribute specification.

**Example**

```
LAYOUT ( MINWIDTH=60, MINHEIGHT=50 )
GRID
...
```

**Related concepts**

- [Widget position and size in grid](#) on page 1313
  - Form items render as widgets in the window, at a given position and with a given size.
- [LAYOUT section](#) on page 1194
  - The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.
- [MINWIDTH attribute](#) on page 1272
  - The MINWIDTH attribute defines the minimum width of a form.

**MINWIDTH attribute**
The MINWIDTH attribute defines the minimum width of a form.

**Syntax**

```
MINWIDTH = integer
```

1. *integer* defines the minimum width of the element, as a number of grid cells.

**Usage**
The MINWIDTH attribute is used to define a minimum width for the form/window. It must be specified in the attributes of the LAYOUT section.

The unit defaults to a number of grid cells. This is the equivalent of the CHARACTERS in the WIDTH attribute specification.

**Example**

```
LAYOUT ( MINWIDTH=60, MINHEIGHT=50 )
GRID
...
```
Related concepts

**Widget position and size in grid** on page 1313
Form items render as widgets in the window, at a given position and with a given size.

**LAYOUT section** on page 1194
The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

**MINHEIGHT attribute** on page 1272
The MINHEIGHT attribute defines the minimum height of a form.

**NOENTRY attribute**
The **NOENTRY** attribute prevents data entry in the field during an input dialog.

Syntax

```
NOENTRY
```

Usage

Use the **NOENTRY** attribute to bypass field input during an **INPUT** or **INPUT ARRAY** statement.

A **NOENTRY** field is like a disabled field, it cannot get the focus.

When compiling a form with a field referencing a SERIAL/BIGSERIAL column in the database schema, the **NOENTRY** attribute is automatically set. However, the attribute will not be set if the field is defined with a **TYPE LIKE** syntax.

When using a **WITHOUT DEFAULTS** dialog option, the content of the corresponding program variable is displayed in the field.

The **NOENTRY** attribute does not prevent data entry into a field during a **CONSTRUCT** statement.

Example

```
EDIT f001 = order.totamount, NOENTRY;
```

Related concepts

**Record input (INPUT)** on page 1373
The **INPUT** instruction provides single record input control in an application form.

**SERIAL data types** on page 788

**Form field initialization** on page 1622
Form field initialization can be controlled by the **WITHOUT DEFAULTS** dialog option.

**Editable record list (INPUT ARRAY)** on page 1425
The **INPUT ARRAY** instruction provides always-editable record list handling in an application form.

**Query by example (CONSTRUCT)** on page 1461
The **CONSTRUCT** instruction implements database query criteria input in an application form.

**NOT NULL attribute**
The **NOT NULL** attribute specifies that the field does not accept **NULL** values.

Syntax

```
NOT NULL
```
**Usage**

The **NOT NULL** attribute requires that the field contains a non-null value. It can be specified explicitly in the form field definition, or in the corresponding column definition in the database schema file. If no column is associated to the field, the **NOT NULL** attribute can also be used in the type definition of **FORMONLY** fields.

The **NOT NULL** attribute is effective only when the field name appears in the list of screen fields of an **INPUT** or **INPUT ARRAY** statement.

If a **DEFAULT** attribute is used for the field and the input dialog does not use the **WITHOUT DEFAULTS** option, the runtime system assumes that the default value satisfies the **NOT NULL** attribute.

Unlike the **REQUIRED** attribute which has no effect when the **INPUT** dialog uses the **WITHOUT DEFAULTS** option, the **NOT NULL** attribute is always checked when validating a dialog.

**Example**

```
EDIT f001 = customer.city, NOT NULL;
```

**Related concepts**

- **Form-level validation rules** on page 1627
  - Form-level validation rules can be defined for each field controlled by a dialog.

- **Form field initialization** on page 1622
  - Form field initialization can be controlled by the **WITHOUT DEFAULTS** dialog option.

- **Database schema** on page 476
  - Defines database table structures with column type information to be reused in program variable definitions.

- **Formonly fields** on page 1141
  - **FORMONLY** form fields define their data type explicitly, with or without referencing a database columns.

- **Editable record list (INPUT ARRAY)** on page 1425
  - The **INPUT ARRAY** instruction provides always-editable record list handling in an application form.

- **DEFAULT attribute** on page 1252
  - The **DEFAULT** attribute assigns a default value to a field during data entry.

- **REQUIRED attribute** on page 1280
  - The **REQUIRED** attribute forces the user to modify the content of a field during an input dialog.

**NOTEDITABLE attribute**

The **NOTEDITABLE** attribute disables the text editor.

**Syntax**

```
NOTEDITABLE
```

**Usage:**

The **NOTEDITABLE** attribute can be used in **BUTTONEDIT** and **TEXTEDIT** fields to disable the text editor.

When the field is enabled/active, it can still get the focus.

When used in a **BUTTONEDIT**, the button of the field remains active, if there is a corresponding active action handler in the current dialog. Use this attribute if you do not want to allow text editing in **BUTTONEDIT** fields, when the value can only be set by an action.

When used in a **TEXTEDIT** field, the **NOTEDITABLE** attribute disallows user input. However, it is still possible to move in the text and select parts to do a copy/paste.

**Related concepts**

- **BUTTONEDIT item type** on page 1164
Defines a line-edit with a push-button that can trigger an action.

**TEXTEDIT item type** on page 1184
Defines a multi-line edit field.

**OPTIONS attribute**
The OPTIONS attribute specifies widget options for the field.

**Syntax**

**Important:** This feature is deprecated, and may be removed in a future version.

```
OPTIONS = "option [...]
```

1. *option* can be `-nolist` (to indicate that the column should appear as an independent field).

**Usage**
The OPTIONS attribute specifies parameters for a form item defined with the WIDGET attribute.

**Note:** The OPTIONS attribute is deprecated, use new form item types instead.

**Related concepts**

**WIDGET attribute** on page 1299
The WIDGET attribute specifies the type of graphical widget to be used for a field.

**ORIENTATION attribute**
The ORIENTATION attribute defines whether an element displays vertically or horizontally.

**Syntax**

```
ORIENTATION = \[ VERTICAL \| HORIZONTAL \]
```

**Usage**
The ORIENTATION attribute is typically used in the definition of a RADIOGROUP form item, to specify how radio items have to be displayed.

**Example**

```
RADIOGROUP f001 = customer.status, ORIENTATION=HORIZONTAL;
```

**Related concepts**

**RADIOGROUP item type** on page 1178
Defines a mutual exclusive set of options field.

**PARENTIDCOLUMN attribute**
The PARENTIDCOLUMN attribute specifies the form field that contains the identifier of the parent node of a tree node.

**Syntax**

```
PARENTIDCOLUMN = column-name
```

1. *column-name* is a form field name.
Usage
This attribute is used in the definition of a TREE container, to define the name of the form field containing the identifier of the tree node that is the parent of the current node in a tree view.

You must specify form field column names, not item tag identifiers.
This attribute is mandatory.

Related concepts
Tree views on page 1789
Describes how to implement tree views.

Form fields on page 1138
Form fields are form elements designed for data input and/or data display.

Item tags on page 1155
Item tags define the position and size in a grid-based container.

IDCOLUMN attribute on page 1261
The IDCOLUMN attribute specifies the form field that contains the identifier of a tree node.

PICTURE attribute
The PICTURE attribute specifies a character pattern for data entry in a text field, and prevents entry of values that conflict with the specified pattern.

Syntax

PICTURE = "format-string"

1. format-string defines the data input pattern of the field.

Usage

format-string can be any combination of characters, where the characters "A", "#" and "X" have a special meaning.

• The character "A" specifies any letter (alpha-numeric) character at a given position.
• The character "#" specifies any digit character at a given position.
• The character "X" specifies any character at a given position.

Any character different from "A", "X" and "#" is treated as a literal. Such characters automatically appear in the field and do not have to be entered by the user.

The PICTURE attribute does not require data entry into the entire field. It only requires that whatever characters are entered conform to format-string.

When PICTURE specifies input formats for DATETIME or INTERVAL fields, the form compiler does not check the syntax of format-string. Any error in format-string such as an incorrect field separator, produces a runtime error.

The typical usage for the PICTURE attribute is for (fixed-length) CHAR fields. It is not recommended to use PICTURE for other data types, especially numeric or date/time fields. The current value of the field must always match the PICTURE attribute.

Understand that the PICTURE attribute defines a mask for data entry. In order to format fields when data is displayed to the field, use the FORMAT attribute instead. FORMAT is typically used for numeric and date fields, while PICTURE is typically used for formatted character string fields requiring input control.

The PICTURE attribute is ignored in CONSTRUCT and DISPLAY/DISPLAY ARRAY instructions. It only effects INPUT and INPUT ARRAY dialogs.

Example

EDIT f001 = carinfo.ident, PICTURE = "AA####-AA(X)";
Related concepts

**DATETIME qual1 TO qual2** on page 260
The DATETIME data type stores date and time data with time units from the year to fractions of a second.

**INTERVAL qual1 TO qual2** on page 265
The INTERVAL data type stores spans of time as Year/Month or Day/Hour/Minute/Second/Fraction units.

**CHAR(size)** on page 257
The CHAR data type is a fixed-length character string data type.

**FORMAT attribute** on page 1257
The FORMAT attribute defines the data formatting for numeric and date time fields, for input and display.

**PLACEHOLDER attribute**
The PLACEHOLDER attribute defines a hint for the user when the field contains no value.

**Syntax**
```
PLACEHOLDER = [%]%"string"
```

1. *string* defines the hint to be displayed when the field is empty, with the % prefix it is a localized string.

**Usage**
The PLACEHOLDER attribute can be used to show hint text in an input field, when a field contains no value.
The placeholder text is displayed when the field value is NULL, during an INPUT, CONSTRUCT or INPUT ARRAY dialog. In the case of INPUT ARRAY, placeholders are only displayed for the current row where the end user enters data.
This attribute is typically used for mobile and web applications, to display grayed text inside empty input fields.

**Note:** The COMMENT attribute can, in specific situations, define a default placeholder message.

**Example**
```
EDIT f001 = customer.cust_name, PLACEHOLDER = "<Enter customer name>";
```

**PROGRAM attribute**
The PROGRAM attribute can specify an external application program to edit TEXT or BYTE fields.

**Syntax**
```
PROGRAM = "editor"
```

1. *editor* is the name of the program that must be used to edit the special field data.

**Usage**
You can assign the PROGRAM attribute to a TEXT or BYTE field to call an external program to work with the BYTE or TEXT values.
This attribute works in TUI mode only.
Users can invoke the external program by pressing the exclamation point ( ! ) key while the screen cursor is in the field.
The external program then takes over control of the screen. When the user exits from the external program, the form is redisplayed with any display attributes besides PROGRAM in effect.
When no PROGRAM attribute is used, the DBEDIT environment variable defines the default editor.
**Related concepts**

**TEXT** on page 271  
The **TEXT** data type stores large text data.

**BYTE** on page 255  
The **BYTE** data type stores any type of binary data, such as images or sounds.

**DBEDIT** on page 233  
Defines the editor program for **TEXT** fields in TUI mode.

**Text mode rendering** on page 1013

**PROPERTIES** attribute

The **PROPERTIES** attribute is used to define a list of widget-specific characteristics.

**Syntax**

\[
\text{PROPERTIES} = ( \downarrow \text{single-property} \downarrow \text{array-property} \downarrow \text{map-property} \downarrow [,\ldots])
\]

where **single-property** is:

\[
\text{identifier} = \text{property-value}
\]

and **array-property** is:

\[
\text{identifier} = ( \text{property-value} [,\ldots])
\]

and **map-property** is:

\[
\text{identifier} = ( \downarrow \text{single-property} \downarrow \text{map-property} \downarrow [,\ldots])
\]

and **property-value** is:

\[
\downarrow \text{boolean-value} \downarrow \text{numeric-value} \downarrow [\%]"\text{string-value}" \downarrow
\]

1. **boolean-value** is true or false.
2. **numeric-value** is an integer or decimal literal.
3. **string-value** is a string literal. % prefix can be used to define a localized string.

**Usage**

The **PROPERTIES** attribute is typically used to define the widget-specific attributes of a **WEBCOMPONENT** form item.

Property names and values are not checked, which allows you to freely set any characteristic of an external widget. You must verify that the front-end side implementation supports the specified properties.

**Example**

\[
\text{WEBCOMPONENT f01 = FORMONLY.myCalendar,}
\text{COMPONENTTYPE = calendar,}
\text{PROPERTIES = (}
\text{type = "gregorian",}
\text{caption = "calendar.caption",}
\text{week_start = 2,}
\text{days_off = ( 1, 7 ),}
\text{dates_off = ( "????-11-25", "????-06-20" ),}
\text{day_titles = ( t1 = "Sunday",}
\text{t2 = "Monday",}
\text{t3 = "Tuesday",}
\text{t4 = "Wednesday",}
\text{)}
\]

t5 = "Thursday",
  t6 = "Friday",
  t7 = "Saturday"
);

**Related concepts**

gICAPI.onProperty() on page 1843
The gICAPI.onProperty() function is executed when web component properties change.

WEBCOMPONENT item type on page 1187
Defines a specialized form item that holds an external component.

**QUERYEDITABLE attribute**
The QUERYEDITABLE attribute makes a COMBOBOX field editable during a CONSTRUCT statement.

**Syntax**

```
QUERYEDITABLE
```

**Usage**
The QUERYEDITABLE attribute is effective only during a CONSTRUCT statement. This attribute is useful when the display values match the real values in the ITEMS attribute, for example when ITEMS=("Paris","London","Madrid").

**Important:** It is not recommended to use the QUERYEDITABLE attribute, when the real field values are mapped to key/label values in the ITEMS attribute. For example with ITEMS=((1,"Paris"),(2,"London"), (3,"Madrid")).

During a CONSTRUCT, a COMBOBOX is not editable by default. The end-user is forced to set one of the values of the list as defined by the ITEMS attribute, or set the 'empty' item.

The QUERYEDITABLE attribute can be used to force the COMBOBOX to be editable during a CONSTRUCT instruction, in order to allow free search criterion input such as "A*".

If QUERYEDITABLE is used and the ITEMS are defined with key/label combinations, the text entered by the user will be automatically searched in the list of items. If a label corresponds, the key will be used in the SQL criterion, otherwise the entered text will be used as is. For example, if the items are defined as ITEMS=((1,"Paris"), (2,"Madrid"),(3,"London")), and the user enters "Paris" in the field, the item (1,"Paris") will match and will produce the SQL condition "colname = 1". If the user enters ">2", the text does not match any item, so it will be used as is and the SQL condition "colname > 2" is produced. Users may enter values like "Par*", but in this case the runtime system will raise an error, because this criterion is not valid for the numeric data type of the field. To avoid end-user confusion, it is not recommended to combine the QUERYEDITABLE attribute with a COMBOBOX defined with key/label combinations.

**Related concepts**

Query by example (CONSTRUCT) on page 1461
The CONSTRUCT instruction implements database query criteria input in an application form.

COMBOBOX item type on page 1166
Defines a line-edit with a drop-down list of values.

ITEMS attribute on page 1267
The **ITEMS attribute** defines a list of possible values that can be used by the form item.

**REQUIRED attribute**
The **REQUIRED** attribute forces the user to modify the content of a field during an input dialog.

**Syntax**

| REQUIRED |

**Usage**
The **REQUIRED** attribute forces the user to modify the content of a field controlled by an input dialog (INPUT or INPUT ARRAY), when the INPUT dialog does not use the **WITHOUT DEFAULTS** option. Within INPUT ARRAY, the **REQUIRED** attribute always applies to newly created rows.

If an INPUT dialog uses the **WITHOUT DEFAULTS** clause, the current value of the variable linked to the **REQUIRED** field is considered as a default value; the runtime system assumes that the field satisfies the **REQUIRED** attribute, even if the variable value is null.

In an INPUT ARRAY dialog, the **REQUIRED** attribute always applies to newly created rows, even if **WITHOUT DEFAULTS** is used. In other words, when creating a new row, INPUT ARRAY behaves like INPUT **without the WITHOUT DEFAULTS** clause.

If **REQUIRED** is effective regarding the **WITHOUT DEFAULTS** conditions, and a **DEFAULT** attribute is used for the field, the runtime system assigns the default value to the field and assumes that the **REQUIRED** attribute is satisfied.

The **REQUIRED** attribute does not prevent fields being null; If the field contains a value, and the user subsequently erases this value during the same input, the runtime system considers the **REQUIRED** attribute satisfied. To insist on a non-null entry, use the **NOT NULL** attribute.

**Example**

```
EDIT f001 = orders.ord_shipcmt, REQUIRED;
```

**Related concepts**

[Form-level validation rules](#) on page 1627
Form-level validation rules can be defined for each field controlled by a dialog.

[DEFAULT attribute](#) on page 1252
The **DEFAULT** attribute assigns a default value to a field during data entry.

[Record input (INPUT)](#) on page 1373
The INPUT instruction provides single record input control in an application form.

[Editable record list (INPUT ARRAY)](#) on page 1425
The INPUT ARRAY instruction provides always-editable record list handling in an application form.

[ITEMS attribute](#) on page 1267
The **ITEMS** attribute defines a list of possible values that can be used by the form item.

[NOT NULL attribute](#) on page 1273
The **NOT NULL** attribute specifies that the field does not accept NULL values.

[Database schema](#) on page 476
Defines database table structures with column type information to be reused in program variable definitions.

**REVERSE attribute**
The REVERSE attribute displays any value in the field in reverse video (dark characters in a bright field).

**Syntax**

```plaintext
REVERSE
```

**Usage**
Use the REVERSE attribute to highlight specific fields in your forms.

On graphical front-ends, the REVERSE attribute is rendered by using the field COLOR attribute as background color. If the COLOR attribute is not defined, the reverse color defaults to gray.

On character based terminals, the REVERSE video escape sequences must be defined in the TERMINFO or TERMCAP databases.

**Example**

```plaintext
EDIT f001 = customer.name, COLOR = BLUE, REVERSE;
```

**Related concepts**
- **COLOR attribute** on page 1248
  The COLOR attribute defines the foreground color of the text displayed by a form element.
- **TERMINFO** on page 230
  Defines the terminfo terminal capabilities database.
- **TERMCAP** on page 229
  Defines the termcap terminal capabilities database on UNIX™ platforms.
- **Text mode rendering** on page 1013

**SAMPLE attribute**
The SAMPLE attribute defines the text to be used to compute the width of a form field.

**Syntax**

```plaintext
SAMPLE = "text"
```

1. `text` is the sample string that will be used to compute the width of the field.

**Usage**
By default, form fields are rendered by the client with a size determined by the current font and the number of characters used in the layout grid. The field width is computed so that the largest value can fit in the widget.

**Important:** This feature is not supported on mobile platforms.

Sometimes the default computed width is too wide for the typical values displayed in the field. For example, numeric fields usually need less space than alphanumerical fields. If the values are always smaller, you can use the SAMPLE attribute to provide a hint for the front end to compute the best width for that form field.

When specifying the SAMPLE attribute, you do not have to fill the sample string up to the width of the corresponding field tag: The front-ends will be able to compute a physical width by applying a ratio to fit the best visual result. For example, for a sample of 'XY' used for a field defined with 10 characters, is equivalent to specifying a sample of 'XYYYYYYYYY'.
If the SAMPLE attribute is not used, the first 6 cells are always computed with the pixel width of the 'M' character in the current font. Next cells are computed with the pixel width of the '0' (zero) character. In other words, the default sample model is "MMMMM000000.....", reduced to the size of the field tag in the layout:

```
-123456789-123456789-  default sample
 [f01 ]                MMMM
 [f02 ]                MMMMMM
 [f03 ]                MMMMMMM0000000000
```

You can define a default sample for all fields used in the form, by specifying a DEFAULT SAMPLE option in the INSTRUCTIONS section.

Example

```
EDIT cid = customer.custid, SAMPLE="0000"
EDIT ccode = customer.ucode, SAMPLE="MMMMMM"
DATEEDIT be01 = customer.created, SAMPLE="00-00-0000"
```

Related concepts

**INSTRUCTIONS section** on page 1239
The INSTRUCTIONS section is used to define screen arrays, non-default screen records, and global form properties.

**Input length of form fields** on page 1616
Field input length defines the amount of characters the user can type in a form field.

**SCROLL attribute**
The SCROLL attribute can be used to enable horizontal scrolling in a character field.

Syntax

```
SCROLL
```

Usage
By default, the maximum data input length is defined by the width of the item-tag of the field. For example, if you define a CHAR field in the form with a length of 3 characters, users can only enter a maximum of 3 characters, even if the program variable used for input is a CHAR(20).

If you want to let the user input more characters than the width of the item-tag of the field, use the SCROLL attribute. The SCROLL attribute applies only to fields with character data input.

Use the SCROLL attribute only when the layout of the form does not allow for defining an item tag that is large enough to hold all possible character string data that fits in the corresponding program variable. Understand that the end user can miss a part of the displayed data when the field is too small. Therefore, times when you would need to use the SCROLL attribute are rare.

Related concepts

**Input length of form fields** on page 1616
Field input length defines the amount of characters the user can type in a form field.

**Item tags** on page 1155
*Item tags* define the position and size in a grid-based container.

**SCROLLBARS attribute**
The SCROLLBARS attribute can be used to specify scrollbars for a form item.

Syntax

```
SCROLLBARS = {NONE | VERTICAL | HORIZONTAL | BOTH }
```
Usage

This attribute defines scrollbars for the form item, such as a TEXTEDIT.

By default, when not specifying the SCROLLBARS attribute, TEXTEDIT fields get a vertical scrollbar.

Example

```
TEXTEDIT f001 = customer.fname, SCROLLBARS=BOTH;
```

Related concepts

**STRETCH attribute** on page 1286

The STRETCH attribute specifies how a widget must resize when the parent container is resized.

**SIZEPOLICY attribute** on page 1283

The SIZEPOLICY attribute is a sizing directive based on the content of a form item.

**TEXTEDIT item type** on page 1184

Defines a multi-line edit field.

**SIZEPOLICY attribute**

The SIZEPOLICY attribute is a sizing directive based on the content of a form item.

Syntax

```
SIZEPOLICY = { INITIAL | FIXED | DYNAMIC }
```

Usage

The SIZEPOLICY attribute defines how front-ends compute the size of some form elements, based on the content of the form field or form item.

The SIZEPOLICY applies only to leaf elements of the layout. It does not apply to containers. It applies to form elements whose content can be resized, typically IMAGE, COMBOBOX, WEBCOMPONENT. Elements allowing user input such as EDIT, or elements where the size does not depend on the value of content such as PROGRESSBAR, SLIDER do not use this attribute.

**Note:** The SIZEPOLICY attribute is ignored for columns used in TABLE or TREE containers. In list views, the size policy is implicitly defined by the cell (this means the size of the column in the form layout). The SIZEPOLICY attribute is also implicitly fixed for fields inside SCROLLGRID and GRID containers that are controlled by a list dialog, such as a DISPLAY ARRAY. With a list dialog, each row can have a different value, which would imply a different widget size for each row; this is not supported.

When the SIZEPOLICY is not specified, the default behavior depends on the type of form item. See Table 325: Behavior of SIZEPOLICY=INITIAL, based on form item type on page 1284.

**SIZEPOLICY = FIXED**

When SIZEPOLICY is FIXED, the form element's size is exactly the size defined in the layout of the form specification file.

The size of the element is computed from the width and height in the form grid and the font used on the front-end side.

The element keeps the size, even if the content is modified. However, if the STRETCH attribute is set to X, Y or BOTH, the form element can still stretch when the parent window size changes.

**Note:** With GMA, when the last element on the right of a grid row is defined with SIZEPOLICY=FIXED and its right hand border does not pass over the screen border, GMA will extend its width to reach the border. The last element with a fixed size policy may only grow. It does not shrink to a smaller width than the width defined in the form.
SIZEPOLICY = DYNAMIC

When SIZEPOLICY is DYNAMIC, the size of the element grows and shrinks depending on the width of the content, during the lifetime of the application.

This can be used for COMBOBOX or RADIOGROUP fields, when the size of the widget must fit exactly to its content, which can vary during the program execution.

**Note:** With SIZEPOLICY=DYNAMIC, some element such as BUTTON, LABEL, IMAGE and RADIOGROUP can shrink and grow all the time, while COMBOBOX elements can only grow.

SIZEPOLICY = INITIAL

When SIZEPOLICY is INITIAL, the size is computed from the initial content, the first time the element appears on the screen. Once the widget displays, its size is frozen. However, if the STRETCH attribute is set to X, Y or BOTH, the form element can still stretch when the parent window size changes.

SIZEPOLICY=INITIAL is typically used when the size of the element must be fixed, but is not known at design time. For example, when populating a COMBOBOX item list from a database table, the size of the COMBOBOX depends on the size of the labels in the drop-down list. This size policy mode is also useful when the text of labels is unknown at design time because of internationalization.

With SIZEPOLICY=INITIAL, the behavior differs depending on the form element type.

**Table 325: Behavior of SIZEPOLICY=INITIAL, based on form item type**

<table>
<thead>
<tr>
<th>Form item</th>
<th>Behavior with SIZEPOLICY=INITIAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUTTON</td>
<td>The size defined in the form is a minimum size. If the initial button text is bigger, the size grows (width and height).</td>
</tr>
<tr>
<td>COMBOBOX</td>
<td>The width defined in the form is a minimum width. If one of the combobox items in the value list is bigger, the size grows in order for the combobox to fully display the largest item. Then the combobox size remains fixed for the life time of the form.</td>
</tr>
<tr>
<td>LABEL, CHECKBOX, RADIOGROUP</td>
<td>These form items adapt to the initial element text(s), then they keep the same size. The size defined in the form is ignored.</td>
</tr>
<tr>
<td>IMAGE</td>
<td>Image form items adapt their size to the initial image displayed and keep that size. If no initial image is displayed (i.e. the image field value is NULL), the form item does not take space in the layout (and also does not adapt the size if an image is displayed later on). Images can use the STRETCH attribute, so that the widget size is dependent on the parent container, overriding the SIZEPOLICY attribute. If the WIDTH and HEIGHT attributes must be used, the SIZEPOLICY attribute must be set to FIXED.</td>
</tr>
<tr>
<td>WEBCOMPONENT</td>
<td>The web component is scaled to the right size, after the first web page is loaded. It stays at that size, except if the STRETCH attribute is used, and the parent container size changes.</td>
</tr>
</tbody>
</table>

**Example**

```plaintext
COMBOBOX f001 = customer.city,
   ITEMS=((1, "Paris"), (2, "Madrid"), (3, "London")),
   SIZEPOLICY=DYNAMIC;

WEBCOMPONENT wc1 = FORMONLY.chart,
   COMPONENTTYPE="chart",
   SIZEPOLICY=FIXED,
   STRETCH=BOTH;
```
**Related concepts**

- **Controlling the image layout** on page 1047
  - Explains how image form items can be sized in different front-end layout systems.

- **Web components** on page 1825
  - This section describes how to use web components in your application.

- **STRETCH attribute** on page 1286
  - The STRETCH attribute specifies how a widget must resize when the parent container is resized.

- **SPACING attribute**
  - The SPACING attribute is a spacing directive to display form elements.

**Syntax**

```
SPACING = \NORMAL \COMPACT
```

**Usage**

This attribute defines the global distance between two neighboring form elements. In \NORMAL mode, the front end displays form elements consistent with the desktop spacing, which is, for example, 6 and 10 pixels on Microsoft® Windows® platforms.

When using the \COMPACT mode, large forms that by default do not fit to the screen can be displayed with less space between elements.

By default, forms are displayed with \COMPACT spacing.

**Example**

```
LAYOUT \{ SPACING=COMPACT \}
```

**Related concepts**

- **LAYOUT section** on page 1194
  - The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

- **SPLITTER attribute**
  - The SPLITTER attribute forces the container to use a splitter widget between each child element.

**Syntax**

```
SPLITTER
```

**Usage**

This attribute indicates that the container (typically, a `VBOX` or `HBOX`) must have a splitter between each child element held by the container. If a container is defined with a splitter and if the children are stretchable (like `TABLE` or `TEXTEDIT`), users can resize the child elements inside the container.

**Example**

```
VBOX \{ SPLITTER \}
```

**Related concepts**

- **VBOX container** on page 1198
  - Packs child layout elements vertically.

- **HBOX container** on page 1197
Packs child layout elements horizontally.

**STEP attribute**
The `STEP` attribute specifies how a value is increased or decreased in one step (by a mouse click or key up/down).

**Syntax**

```
STEP = integer
```

1. `integer` defines a positive integer value to be added (for an increase) or subtracted (for a decrease).

**Usage**

This attribute is typically used with form items allowing the user to change the current integer value by a mouse click like SLIDER, SPINEDIT.

**Example**

```
SLIDER s01 = FORMONLY.slider, STEP=10;
```

**Related concepts**

- SLIDER item type on page 1181
  Defines a slider form item.
- SPINEDIT item type on page 1182
  Defines a spin box widget to enter integer values.

**STRETCH attribute**
The `STRETCH` attribute specifies how a widget must resize when the parent container is resized.

**Syntax**

```
STRETCH = NONE | X | Y | BOTH
```

**Usage**

This attribute is typically used with form items that can be re-sized like IMAGE, TEXTEDIT, or WEBCOMPONENT fields.

By default, such form items have a fixed width and height, but in some cases you may want to force the widget to resize vertically, horizontally, or in both directions.

- To allow the widget to resize vertically only, use `STRETCH=Y`.
- To allow the widget to resize horizontally only, use `STRETCH=X`.
- To allow the widget to resize vertically and horizontally, use `STRETCH=BOTH`.

**Note:** By default, WEBCOMPONENT form items stretch in both directions (`STRETCH=BOTH` is the default).

**Example**

```
IMAGE i01 = FORMONLY.image01, STRETCH=BOTH;
```

**Related concepts**

- Controlling the image layout on page 1047
  Explains how image form items can be sized in different front-end layout systems.
- IMAGE item type on page 1174
  Defines an area that can display an image resource.
- TEXTEDIT item type on page 1184
Defines a multi-line edit field.

**WEBCOMPONENT item type** on page 1187
Defines a specialized form item that holds an external component.

**Packed and unpacked grids** on page 1310
When resizing a window, the content will either grow with the window or be packed in the top left position.

**STYLE attribute**
The `STYLE` attribute specifies a presentation style for a form element.

**Syntax**

```
STYLE = "string"
```

1. `string` is a user-defined style.

**Usage**
This attribute specifies a presentation style to be applied to a form element.

The presentation style can define decoration attributes such as a background color, a font type, and so on.

**Note:** The string used to define this attribute must be a `style-name` only, it must not contain the `element-type` that is typically used to define the style in a .4st file (as `CheckBox.important` for example)

**Example**

```
EDIT c01 = item.comment, STYLE = "important";
```

**Related concepts**

* Using a style on page 1069
  To apply a specific style, set the `style-name` in the `style` attribute of the node representing the graphical element in the abstract user interface tree.

* Presentation styles on page 1065
  Use presentation styles to specify decoration attributes for window and form elements.

**TABINDEX attribute**
The `TABINDEX` attribute defines the tab order for a form item.

**Syntax**

```
TABINDEX = integer
```

1. `integer` defines the order of the item in the tab sequence.

**Usage**
This attribute can be used to define the order in which the form items are selected as the user "tabs" from field to field.

To take `TABINDEX` attributes into account in dialogs, the program must defined the form tabbing order with the `OPTIONS FIELD ORDER FORM` instruction. Alternatively, a dialog can use the `FIELD ORDER FORM` option as well.

**Important:** `TABINDEX` values must be unique in a form.

The `TABINDEX` attribute can also be used to define which field must get the focus when a `FOLDER` page is selected.

By default, form items get a tab index depending on the order in which they appear in the `LAYOUT` section.
**Tip:** TABINDEX can be set to zero in order to exclude the form item from the tabbing list. The item can still get the focus with the mouse.

### Example

```
EDIT f001 = customer.fname, TABINDEX = 1;
EDIT f002 = customer.lname, TABINDEX = 2;
EDIT f003 = customer.comment,
          TABINDEX = 0; -- Excluded from tabbing list
```

### Related concepts

- **Defining field tabbing order method** on page 509
- **LAYOUT section** on page 1194
- **FOLDER container** on page 1200
- **Defining the tabbing order** on page 1630

### TAG attribute

The TAG attribute can be used to identify the form item with a specific string.

#### Syntax

```
TAG = "tag-string"
```

1. *tag-string* is user-defined string.

#### Usage

This attribute is used to identify form items with a specific string. It can be queried in the program to perform specific processing.

You are free to use this attribute as you need. For example, you can define a numeric identifier for each field in the form in order to show context help, or group fields for specific input verification.

If you need to handle multiple data, you can format the text, for example, by using a pipe separator, or even the JSON notation.

#### Example

```
EDIT f001 = customer.fname, TAG = "name";
EDIT f002 = customer.lname, TAG = "name|optional";
```

### Related concepts

- **Form specification files** on page 1132
  Form specification files are the source files defining the layout and content of application forms.

### TEXT attribute

The TEXT attribute defines the label associated with a form item.

#### Syntax

```
TEXT = [%]"string"
```

1. *string* defines the label to be associated with the form item, with the % prefix it is a localized string.
Usage

The TEXT attribute is used to define the label of a form item, for example for a CHECKBOX form field or a BUTTON action view.

Consider using localized strings with the %"string-id" syntax, if you plan to internationalize your application.

This attribute is also an action attribute that can be defined in the ACTION DEFAULTS section of a form or directly in an action view (BUTTON), see TEXT action attribute on page 1660 for more details.

Example

```
-- As form action default
ACTION DEFAULTS
   ACTION print (TEXT="Print")
END

-- As a CHECKBOX label
CHECKBOX cb01 = FORMONLY.checkbox01,
   TEXT="OK" ... ;

-- As a BUTTON label
BUTTON b1: print, TEXT="Print";
```

Related concepts

Localized strings on page 430

Localized strings provide a means of writing applications in which the text of strings can be customized on site.

Configuring actions on page 1646

Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

Form items on page 1133

The concept of form item includes all elements used in the definition of a form.

TITLE attribute

The TITLE attribute defines the title of a form item.

Syntaxis

```
TITLE = [%]"string"
```

1. string defines the title to be associated with the form item, with the % prefix it is a localized string.

Usage

The TITLE attribute is typically used to define the title of a form field that will be defined as a TABLE or TREE column, or form items used in a stacked layout, to define the label associated to the item.

Note: It is recommended to restrict your use of the TITLE attribute to form fields that make up the columns of a table/tree container, or form items used in a stacked layout.

Consider using localized strings with the %"string-id" syntax, if you plan to internationalize your application.

Example

```
EDIT col14 = FORMONLY.ord_shipdate, TITLE="Ship date";
```

Related concepts

Localized strings on page 430

Localized strings provide a means of writing applications in which the text of strings can be customized on site.

TABLE container on page 1217
Defines a re-sizable table designed to display a list of records.

**Form items** on page 1133
The concept of form item includes all elements used in the definition of a form.

**UNHIDABLE attribute**
The UNHIDABLE attribute indicates that the element cannot be hidden or shown by the user with the context menu.

**Syntax**
```
UNHIDABLE
```

**Usage**
By default, a TABLE container allows the user to hide the columns by a right-click on the column header.
Use this attribute to prevent the user from hiding a specific column.
The end user is also not allowed to show columns that are hidden by default with HIDDEN=USER
Makes sense only for a field that is used for the definition of a column in a TABLE container.

**Example**
```
EDIT c01 = item.comment, UNHIDABLE;
```

**Related concepts**
- **TABLE container** on page 1217
  Defines a re-sizable table designed to display a list of records.
- **HIDDEN attribute** on page 1260
  The HIDDEN attribute indicates that the element is not to be displayed.
- **UNHIDABLECOLUMNS attribute** on page 1290
  The UNHIDABLECOLUMNS attribute indicates that the columns of the table cannot be hidden or shown by the user with the context menu.

**UNHIDABLECOLUMNS attribute**
The UNHIDABLECOLUMNS attribute indicates that the columns of the table cannot be hidden or shown by the user with the context menu.

**Syntax**
```
UNHIDABLECOLUMNS
```

**Usage**
When using this attribute in a TABLE definition, the end user will not be allowed to hide columns, or show columns that are hidden by default with HIDDEN=USER.

**Example**
```
TABLE t1 ( UNHIDABLECOLUMNS )
```

**Related concepts**
- **HIDDEN attribute** on page 1260
  The HIDDEN attribute indicates that the element is not to be displayed.
- **TABLE container** on page 1217
Defines a re-sizable table designed to display a list of records.

**UNHIDABLE attribute** on page 1290

The **UNHIDABLE** attribute indicates that the element cannot be hidden or shown by the user with the context menu.

**UNMOVABLE attribute**

The **UNMOVABLE** attribute prevents the user from moving a defined column of a table.

**Syntax**

```
UNMOVABLE
```

**Usage**

By default, a **TABLE** container allows the user to move the columns by dragging and dropping the column header.

Use this attribute to prevent the user from changing the order of a specific column.

Typically, **UNMOVABLE** is used on at least two columns to prevent the user from changing the order of the input on these columns.

**Example**

```
EDIT c01 = item.comment, UNMOVABLE;
```

**Related concepts**

**TABLE container** on page 1217

Defines a re-sizable table designed to display a list of records.

**UNMOVABLECOLUMNS attribute** on page 1291

The **UNMOVABLECOLUMNS** attribute prevents the user from moving columns of a table.

**UNMOVABLECOLUMNS attribute**

The **UNMOVABLECOLUMNS** attribute prevents the user from moving columns of a table.

**Syntax**

```
UNMOVABLECOLUMNS
```

**Usage**

When using this attribute in a **TABLE** definition, the end user will not be allowed to move columns around.

**Example**

```
TABLE t1 ( UNMOVABLECOLUMNS )
```

**Related concepts**

**TABLE container** on page 1217

Defines a re-sizable table designed to display a list of records.
The **UNMOVABLE** attribute prevents the user from moving a defined column of a table.

### UNSIZABLE attribute
The **UNSIZABLE** attribute indicates that the element cannot be resized by the user.

**Syntax**

```plaintext
UNSIZABLE
```

**Usage**

By default, a **TABLE** container allows the user to resize the columns by a drag-click on the column header.

Use this attribute to prevent a resize on a specific column.

Makes sense only for a field that is used for the definition of a column in a **TABLE** container.

**Example**

```plaintext
EDIT c01 = item.comment, UNSIZABLE;
```

**Related concepts**

- **TABLE container** on page 1217
  - Defines a re-sizable table designed to display a list of records.
- **UNSIZABLECOLUMNS attribute** on page 1292
  - The **UNSIZABLECOLUMNS** attribute indicates that the columns of the table cannot be resized by the user.

### UNSIZABLECOLUMNS attribute
The **UNSIZABLECOLUMNS** attribute indicates that the columns of the table cannot be resized by the user.

**Syntax**

```plaintext
UNSIZABLECOLUMNS
```

**Usage**

When using this attribute in a **TABLE** definition, the end user will not be allowed to resize the columns.

**Example**

```plaintext
TABLE t1 ( UNSIZABLECOLUMNS )
```

**Related concepts**

- **TABLE container** on page 1217
  - Defines a re-sizable table designed to display a list of records.
- **UNSIZABLE attribute** on page 1292
  - The **UNSIZABLE** attribute indicates that the element cannot be resized by the user.

### UNSORTABLE attribute
The **UNSORTABLE** attribute indicates that the element cannot be selected by the user for sorting.

**Syntax**

```plaintext
UNSORTABLE
```
Usage
By default, a TABLE container allows the user to sort the columns by a left-click on the column header.
Use the UNSORTABLE attribute to prevent a sort on a specific column.
Makes sense only for a field that is used for the definition of a column in a TABLE container.

Example

| EDIT c01 = item.comment, UNSORTABLE; |

Related concepts

TABLE container on page 1217
Defines a re-sizable table designed to display a list of records.

UNSORTABLECOLUMNS attribute on page 1293
The UNSORTABLECOLUMNS attribute indicates that the columns of the table cannot be selected by the user for sorting.

UNSORTABLECOLUMNS attribute
The UNSORTABLECOLUMNS attribute indicates that the columns of the table cannot be selected by the user for sorting.

Syntax

| UNSORTABLECOLUMNS |

Usage
When using this attribute in a TABLE definition, the end user will not be allowed to sort rows.

Example

| TABLE t1 ( UNSORTABLECOLUMNS ) |

Related concepts

TABLE container on page 1217
Defines a re-sizable table designed to display a list of records.

UNSORTABLE attribute on page 1292
The UNSORTABLE attribute indicates that the element cannot be selected by the user for sorting.

UPSHIFT attribute
The UPSHIFT attribute forces character input to uppercase letters.

Syntax

| UPSHIFT |

Usage
When defining the UPSHIFT attribute for a character field, the characters typed by the user are automatically converted to uppercase.

Note: In text mode, the results of conversions between uppercase and lowercase letters are based on the locale settings.

Because using uppercase and lowercase letters results in different values in the database, storing character strings in one or the other format can simplify sorting and querying.
**Important:** Values send from the runtime system are displayed as is by the front-ends: No conversion will occur if you display "AbCdE" to a field using **UPSHIFT** or **DOWNSHIFT** attributes.

**Example**

```
EDIT f001 = FORMONLY.name, UPSHIFT;
```

**Related concepts**

**DOWNSHIFT** attribute on page 1256  
The **DOWNSHIFT** attribute forces character input to lowercase letters.

**VALIDATE** attribute  
The **VALIDATE** action attribute defines the data validation level for a given action.

**Syntax**

```
VALIDATE = NO
```

**Usage**

This attribute is an action attribute that can be specified in form **ACTION DEFAULTS**.

When the **VALIDATE** action attribute is set to **NO**, it indicates that no data validation must occur for this action. However, current input buffer contains the text modified by the user before triggering the action.

For more details, see **VALIDATE action attribute** on page 1661.

**VALIDATE LIKE** attribute  
The **VALIDATE LIKE** attribute applies column attributes defined in the .val database schema files to a field.

**Syntax**

```
VALIDATE LIKE [table.]column
```

**Note:**

1. **table** is the optional table name to qualify the column.
2. **column** is the name of the column used to search for validation rules.

**Usage**

Specifying the **VALIDATE LIKE** attribute is equivalent to writing in the field definition all the attributes that are assigned to **table.column** in the .val database schema file.

**Note:** The .val attributes are taken automatically from the schema file if the field is linked to **table.column** in the field name specification. The **VALIDATE LIKE** attribute is usually specified for FORMONLY fields.

The **VALIDATE LIKE** attribute is evaluated at compile time, not at runtime. If the database schema file changes, recompile all your forms.

Even if all of the fields in the form are FORMONLY, the **VALIDATE LIKE** attribute requires the form compiler to access the database schema file that contains the description of **table**.

**Example**

```
EDIT f001 = FORMONLY.fullname, VALIDATE LIKE customer.custname;
```

**Related concepts**

**Column Validation File (.val)** on page 482
The .val database schema file holds functional and display attributes of database table columns.

**FORMONLY fields** on page 1141
FORMONLY form fields define their data type explicitly, with or without referencing a database columns.

**VALIDATE** on page 377
The VALIDATE instructions checks a variable value based on database schema validation rules.

**VALUEMIN attribute**
The VALUEMIN attribute defines a lower limit of values displayed in widgets (such as progress bars).

**Syntax**

```
VALUEMIN = integer
```

1. `integer` is an integer literal.

**Usage**
This attribute is typically used to define the lower limit in PROGRESSBAR, SPINEDIT and SLIDER fields.

This attribute is not used by the runtime system to validate the field. You must use the INCLUDE attribute to control value boundaries.

**Example**

```
SLIDER s01 = FORMONLY.slider01,
    VALUEMIN=0,
    VALUEMAX=500;
```

**Related concepts**

**PROGRESSBAR item type** on page 1177
Defines a progress indicator field.

**SPINEDIT item type** on page 1182
Defines a spin box widget to enter integer values.

**SLIDER item type** on page 1181
Defines a slider form item.

**VALUEMAX attribute** on page 1295
The VALUEMAX attribute defines a upper limit of values displayed in widgets (such as progress bars).

**VALUEMAX attribute**
The VALUEMAX attribute defines a upper limit of values displayed in widgets (such as progress bars).

**Syntax**

```
VALUEMAX = integer
```

1. `integer` is an integer literal.

**Usage**
This attribute is typically used to define the upper limit in PROGRESSBAR, SPINEDIT and SLIDER fields.

This attribute is not used by the runtime system to validate the field. You must use the INCLUDE attribute to control value boundaries.

**Example**

```
SLIDER s01 = FORMONLY.slider01,
```
Related concepts

**PROGRESSBAR item type** on page 1177
Defines a progress indicator field.

**SPINEDIT item type** on page 1182
Defines a spin box widget to enter integer values.

**SLIDER item type** on page 1181
Defines a slider form item.

**VALUEMIN attribute** on page 1295
The `VALUEMIN` attribute defines a lower limit of values displayed in widgets (such as progress bars).

**VALUECHECKED attribute**
The `VALUECHECKED` attribute defines the value associated with a checkbox item when it is checked.

**Syntax**

```
VALUECHECKED = value
```

1. `value` is a numeric or string literal, or one of the following keywords: NULL, TRUE, FALSE.

**Usage**

This attribute is used together with the `VALUEUNCHECKED` attribute to define the values corresponding to the states of a **CHECKBOX**.

This attribute is not used by the runtime system to validate the field, you must use the `INCLUDE` attribute to control value boundaries.

**Example**

```
CHECKBOX cb01 = FORMONLY.checkbox01,
    TEXT="OK",
    VALUECHECKED=TRUE,
    VALUEUNCHECKED=FALSE;
```

**Related concepts**

**CHECKBOX item type** on page 1165
Defines a boolean or three-state checkbox field.

**VALUEUNCHECKED attribute** on page 1296
The `VALUEUNCHECKED` attribute defines the value associated with a checkbox item when it is not checked.

**VALUEUNCHECKED attribute**
The `VALUEUNCHECKED` attribute defines the value associated with a checkbox item when it is not checked.

**Syntax**

```
VALUEUNCHECKED = value
```

1. `value` is a numeric or string literal, or one of the following keywords: NULL, TRUE, FALSE.

**Usage**

This attribute is used together with the `VALUECHECKED` attribute to define the values corresponding to the states of a **CHECKBOX**.
This attribute is not used by the runtime system to validate the field, you must use the `INCLUDE` attribute to control value boundaries.

**Example**

```plaintext
CHECKBOX cb01 = FORMONLY.checkbox01,
      TEXT="OK",
      VALUECHECKED="Y",
      VALUEUNCHECKED="N";
```

**Related concepts**

- **CHECKBOX item type** on page 1165
  Defines a boolean or three-state checkbox field.
- **VALUECHECKED attribute** on page 1296
  The `VALUECHECKED` attribute defines the value associated with a checkbox item when it is checked.
- **VERIFY attribute**
  The `VERIFY` attribute requires users to enter data in the field twice to reduce the probability of erroneous data entry.

**Syntax**

```plaintext
VERIFY
```

**Usage**

This attribute supplies an additional step in data entry to ensure the integrity of your data. After the user enters a value into a `VERIFY` field and presses the Return or Tab key, the runtime system erases the field and requests reentry of the value. The user must enter exactly the same data each time, character for character: 15000 is not exactly the same as 15000.00.

The `VERIFY` attribute takes effect in `INPUT` or `INPUT ARRAY` instructions only, it has no effect on `CONSTRUCT` statements.

**Related concepts**

- **REQUIRED attribute** on page 1280
  The `REQUIRED` attribute forces the user to modify the content of a field during an input dialog.
- **NOT NULL attribute** on page 1273
  The `NOT NULL` attribute specifies that the field does not accept NULL values.
- **VERSION attribute**
  The `VERSION` attribute is used to specify a user version string for an element.

**Syntax**

```plaintext
VERSION = { "string" | TIMESTAMP }
```

1. `string` is a user-defined version string.

**Usage**

This attribute specifies a version string to distinguish different versions of a form element. You can specify an explicit version string or use the `TIMESTAMP` keyword to force the form compiler to write a timestamp string into the 42f file.

Typical usage is to specify a version of the form to indicate if the form content has changed. This attribute is used by the front-end to distinguish different form versions and to avoid reloading window/form settings into a new version of a form.
It is recommended that you use the TIMESTAMP only during development.

Example

```plaintext
LAYOUT ( TEXT="Orders", VERSION = "1.23" )
```

Related concepts

**LAYOUT section** on page 1194

The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

**WANTFIXEDPAGESIZE attribute**

The WANTFIXEDPAGESIZE attribute controls the vertical resizing of a list element.

**Syntax**

```plaintext
WANTFIXEDPAGESIZE [ = NO ]
```

**Usage**

The WANTFIXEDPAGESIZE attribute can be used for TABLE, TREE and SCROLLGRID containers to control the vertical resizing of the list element.

By default, a TABLE container is resizable (vertically and horizontally). To freeze the height of the table to the number of lines defined by the form file, use the attribute WANTFIXEDPAGESIZE.

By default, a SCROLLGRID container is not resizable in height. The number of visible scrollgrid rows is defined by the form file. To allow the scrollgrid to stretch vertically, use the attribute WANTFIXEDPAGESIZE=NO.

**Note:** When using a stretchable SCROLLGRID with WANTFIXEDPAGESIZE=NO, one can define the rendering with the customWidget.style attribute.

**Related concepts**

**INITIALPAGESIZE attribute** on page 1266

The INITIALPAGESIZE attribute defines the initial page size of a list element.

**TABLE container** on page 1217

Defines a re-sizeable table designed to display a list of records.

**SCROLLGRID container** on page 1216

Defines a scrollable grid view widget, in a grid-based layout.

**WANTNORETURNS attribute**

The WANTNORETURNS attribute forces a text field to reject newline characters when the user presses the Return key.

**Syntax**

```plaintext
WANTNORETURNS
```

**Usage**

By default, text fields like TEXTEDIT insert a newline (ASCII 10) character in the text when the user presses the Return key. As the Return key is typically used to fire the accept action to validate the dialog, you can force the field to reject Return keys with this attribute.

The user can still enter new line characters with Shift-Return or Ctrl-Return, if these keys are not bound to actions.

**Related concepts**

**TEXTEDIT item type** on page 1184
Defines a multi-line edit field.

**WANTTABS attribute**

The `WANTTABS` attribute forces a text field to insert Tab characters in the text when the user presses the Tab key.

**Syntax**

```
WANTTABS
```

**Usage**

By default, text fields like `TEXTEDIT` do not insert a Tab character in the text when the user presses the Tab key, since the Tab key is used to move to the next field. You can force the field to consume Tab keys with this attribute.

The user can still jump out of the field with Shift-Tab, if this key is not bound to an action.

**Related concepts**

- [TEXTEDIT item type](#) on page 1184
  Defines a multi-line edit field.

**WIDGET attribute**

The `WIDGET` attribute specifies the type of graphical widget to be used for a field.

**Syntax**

```
WIDGET = "identifier"
```

1. `identifier` defines the type of widget, it can be one of the keywords listed in [Table 326: Supported widgets](#) on page 1300.

**Usage**

The `WIDGET` attribute defines the type of widget to be used for a form field.

This attribute is used with `CONFIG`, `CLASS`, and `INCLUDE` attributes, to define parameters for the field widget.

**Note:** The `WIDGET` attribute is deprecated, use new form item types instead.

- Instead of `WIDGET="BMP"`, use a `IMAGE` form item.
- Instead of `WIDGET="CANVAS"`, use a `CANVAS` form item.
- Instead of `WIDGET="CHECK"`, use a `CHECKBOX` form item.
- Instead of `WIDGET="COMBO"`, use a `COMBOBOX` form item.
- Instead of `WIDGET="BUTTON"`, use a `BUTTON` form item.
- Instead of `WIDGET="FIELD_BMP"`, use a `BUTTONEDIT` form item.
- Instead of `WIDGET="RADIO"`, use a `RADIOGROUP` form item.

The `identifier` widget type is case sensitive, only uppercase letters are recognized.

When you use the `WIDGET` attribute, the form cannot be properly displayed on character based terminals, it can only be displayed on graphical front-ends.
### Table 326: Supported widgets

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Effect</th>
<th>Other attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Canvas</td>
<td>The field is used as a drawing area. Field must be declared as FORMONLY field.</td>
<td>None.</td>
</tr>
</tbody>
</table>
| BUTTON  | The field is presented as a button widget with a label.                | CONFIG: The unique parameter defines the key to be sent when the user clicks on the button. Button text is defined in configuration files or from the program with a DISPLAY TO instruction. For example: CONFIG = "Control-z"

| BMP     | The field is presented as a button with an image.                      | CONFIG: First parameter defines the image file to be displayed, second parameter defines the key to be sent when the user clicks on the button. For example: CONFIG = "smiley.bmp F11"

**Important:** Image files are not centralized on the machine where the program is executed; image files must be present on the Workstation. See front-end specific documentation for more details.

| CHECK   | The field is presented as a checkbox widget. It can be used with the CLASS attribute to change the behavior of the widget. | CONFIG: First and second parameters define the values corresponding respectively to the state "Checked" / "Unchecked" of the check box, while the third parameter defines the label of the checkbox. For example: CONFIG = "Y N Confirmation"

If the text part must include spaces, add {} curly brackets around the text:

CONFIG= "Y N {Order validated}"

If the CLASS attribute is used with the "KEY" value, the first and second parameters defines the keys to be sent respectively when the checkbox is "Checked" / "Unchecked", and the third parameter defines the label of the checkbox as with normal checkbox usage.

For example (line breaks added for document readability):

CLASS = "KEY",
CONFIG = "F11 F12 Confirmation"
<table>
<thead>
<tr>
<th>Symbol</th>
<th>Effect</th>
<th>Other attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMBO</td>
<td>The field is presented as a combobox widget. It can be used with the CLASS attribute to change the behavior of the widget.</td>
<td>INCLUDE: This attribute defines the list of acceptable values that will be displayed in the combobox list. For example (line breaks added for document readability): INCLUDE = (&quot;Paris&quot;, &quot;London&quot;, &quot;Madrid&quot;) <strong>Important:</strong> The INCLUDE attribute cannot hold value range definitions, because all items must be explicitly listed to be added to the combobox list. The following example is not supported: INCLUDE = (1 TO 10)</td>
</tr>
<tr>
<td>FIELD_BMP</td>
<td>The field is presented as a normal editbox, plus a button on the right.</td>
<td>CONFIG: The first parameter defines the image file to be displayed in the button; the second parameter defines the key to be sent when the user clicks on the button. For example: CONFIG = &quot;combo.bmp Control-z&quot;</td>
</tr>
<tr>
<td>LABEL</td>
<td>The field is presented as a simple label, a read-only text.</td>
<td>None.</td>
</tr>
<tr>
<td>RADIO</td>
<td>The field is presented as a radiogroup widget.</td>
<td>CONFIG: Parameter pairs define respectively the value and the label corresponding to one radio button. For example (line breaks added for document readability): CONFIG = &quot;AA First BB Second CC Third&quot; If the radio texts must include spaces, add {} curly brackets around the texts (line breaks added for document readability): CONFIG = &quot;AA {First option} BB {Second option} CC {Third option}&quot; If the CLASS attribute is used with the value &quot;KEY&quot;, the first element of each pairs represents the key to be sent when the user selects a radio button. For example (line breaks added for document readability): CLASS = &quot;KEY&quot;, CONFIG = &quot;F11 First F12 Second F13 Third&quot;</td>
</tr>
</tbody>
</table>

**Controlling old style widgets activation**

The following list of widgets can be enabled or disabled from programs with a DISPLAY TO instruction:

- Text buttons (WIDGET="BUTTON")
• Image buttons (WIDGET="BMP")
• Checkboxes of class "KEY" (WIDGET="CHECK", CLASS="KEY")
• Radio buttons of class "KEY" (WIDGET="RADIO", CLASS="KEY")

If you display an exclamation mark in such fields, the button is enabled, but if you display a star (*), it is disabled:

```
DISPLAY "*" TO button1 # disables the button
DISPLAY "!" TO button1 # enables the button
```

### Changing the text of WIDGET="BMP" fields

The text of button fields (WIDGET="BUTTON") can be changed from programs with the DISPLAY TO instruction:

```
DISPLAY "Click me" TO button1
# Sets text and enables the button
```

### Changing the image of WIDGET="BMP" fields:

The image of button fields (WIDGET="BMP") can be changed from programs with the DISPLAY TO instruction:

```
DISPLAY "smiley.bmp" TO button1
# Sets image and enables the button
```

Image files are not centralized on the machine where the program is executed; image files must be present on the Workstation. See front end specific documentation for more details.

### Changing the text of WIDGET="LABEL" fields:

The text of label fields (WIDGET="LABEL") can be changed from programs with the DISPLAY TO instruction:

```
DISPLAY "Firstname" TO l_firstname
# Sets text of the label field
```

### Using WIDGET="Canvas" fields:

The fields declared with the WIDGET="Canvas" attribute can be used by the program as drawing areas. Canvas fields must be defined in the LAYOUT section. A set of drawing functions are provided to fill canvas fields with graphical elements.

**Related concepts**

- **Form items** on page 1133
  The concept of form item includes all elements used in the definition of a form.
- **Migrating form field widgets** on page 210

### WIDTH attribute

The WIDTH attribute forces an explicit width of a form element.

**Syntax**

```
WIDTH = integer [CHARACTERS|COLUMNS|POINTS|PIXELS]
```

1. **integer** defines the width of the element.

**Usage**

By default, the width of an element is defined by the size of the form item tag in a grid-based layout, or by the type of the form item in a stack-based layout. Use the WIDTH attribute to define a specific width for a form item.
**Note:** As a general rule, consider not specifying a unit, to default to relative characters/lines/columns, instead of specifying exact pixels or points. This is especially important for mobile devices, where the screen resolution can significantly vary depending on the smartphone or tablet model.

**Grid-based layout**

For sizable items like `IMAGE`, the default width is defined by the number of horizontal characters used in the form item tag. Overwrite this default by specifying the `WIDTH` attribute.

```plaintext
IMAGE img1: imagel, WIDTH = 20, HEIGHT = 12;
```

For `TABLE/TREE` containers, the default width is defined by the columns used in the table layout. Overwrite the default by specifying the `WIDTH = x COLUMNS` attribute. This will give a small initial width for tables with a large number of columns.

```plaintext
TABLE t1: table1, WIDTH = 5 COLUMNS;
```

In a grid-based layout, if you don't specify a size unit, it defaults to `CHARACTERS`, which defines a width based on the characters size in the current font.

**Stack-based layout**

In a stack-based layout, the `WIDTH` attribute cannot be used. The width of form elements are automatically computed.

**Related concepts**

- **Controlling the image layout** on page 1047
  Explains how image form items can be sized in different front-end layout systems.

- **Item tags** on page 1155
  Item tags define the position and size in a grid-based container.

- **Form rendering basics** on page 1307
  Get the essentials about form rendering.

- **HEIGHT attribute** on page 1259
  The `HEIGHT` attribute forces an explicit height for a form element.

**WINDOWSTYLE attribute**

The `WINDOWSTYLE` attribute defines the style to be used by the parent window of a form.

**Syntax**

```plaintext
WINDOWSTYLE = "string"
```

1. `string` is a user-defined style name.

**Usage**

The `WINDOWSTYLE` attribute can be used to specify the style of the parent window that will hold the form. This attribute is specific to the `LAYOUT` element. Do not confuse this attribute with the `STYLE` attribute, which is used to specify the decoration style of the form elements.

When a form is loaded by the `OPEN WINDOW` or `DISPLAY FORM` instruction, the runtime system automatically assigns the `WINDOWSTYLE` to the `STYLE` attribute of the parent window element.

**Example**

```plaintext
LAYOUT ( STYLE="BigFont", WINDOWSTYLE="dialog" )
```
Related concepts

**STYLE attribute** on page 1287
The **STYLE** attribute specifies a presentation style for a form element.

**OPEN WINDOW** on page 1034
Creates and displays a new window.

**DISPLAY FORM** on page 1044
Displays and associates a form with the current window.

**WORDWRAP Attribute**
The **WORDWRAP** attribute enables a multiple-line editor in TUI mode.

**Syntax**

```plaintext
WORDWRAP [' COMPRESS | NONCOMPRESS ]
```

**Usage**

This attribute is provided for backward compatibility with character-based forms, to support word wrapping in multi-line text input.

In GUI mode, it is recommended that you use a **TEXTEDIT** form item instead. When used, the **WORDWRAP** attribute is ignored, because text input and display is managed by the text editor widget. The text data is not automatically modified by the editor by adding blank spaces to put words on the next line.

In TUI mode, the **WORDWRAP** attribute has following effects:

- During input and display, the runtime system treats all segments that have that field tag as segments of a single field.
- The multi-line editor can *wrap* long character strings to the next line of a multiple-segment field for data entry, data editing, and data display.
- The **COMPRESS** option prevents blanks produced by the editor from being included in the program variable. **COMPRESS** is applied by default and can cause truncation to occur if the sum of intentional characters exceeds the field or column size. Because of editing blanks in the **WORDWRAP** field, the stored value might not correspond exactly to its multiple-line display.
- Specifying **NONCOMPRESS** after the **WORDWRAP** keyword causes any editor blanks to be saved when the string value is saved in a database column, in a variable, or in a file.

Using **WORDWRAP** fields with character-based terminals results in quite different behavior than with graphical front ends. With character-based terminals, the text input and display is modified by the multi-line editor. This editor can automatically modify the text data by adding blank spaces to put words to the next line, in order to make the text fit into the form field. In GUI mode, the text input and display is managed by a multi-line edit control.

The maximum number of bytes a user can enter is the width of the form-field multiplied by the height of the form-field. Blank characters may be intentional blanks or fill blanks. Intentional blanks are initially stored in the target variable where entered by the user. Fill blanks are inserted at the end of a line by the editor when a newline or a word-alignment forces a line-break. It is not possible to set the cursor at a fill blank. Intentional blanks are always displayed (even on the beginning of a line; the word-wrapping method used in reports with **PRINT WORDWRAP** works differently).

When entering characters with Japanese locales, special characters are prohibited from being the first or the last character on a line. If the last character is prohibited from ending a line, this character is wrapped down to the next line. If the first character is prohibited from beginning a line, the preceding character will also wrap down to the next line. This method is called kinsoku. The test for prohibited characters will be done only once for the first and the last character on each line.

Word-wrapping is disabled on the last row of a **WORDWRAP** field. The last word on the last row may be truncated. The **WORDWRAP COMPRESS** attribute instructs the editor to remove fill blanks before assigning the field-buffer to
the target variable. The \texttt{WORDWRAP NONCOMPRESS} attribute instructs the editor to store fill blanks to the target variable. The \texttt{WORDWRAP} and \texttt{WORDWRAP NONCOMPRESS} attributes are equivalent.

The \texttt{WORDWRAP} attribute is not used by the \texttt{CONSTRUCT} instruction.

**Related concepts**

- Query by example (\texttt{CONSTRUCT}) on page 1461
- The \texttt{CONSTRUCT} instruction implements database query criteria input in an application form.

**Text mode rendering** on page 1013

**Examples**

Form definition (.per) examples.

**Example 1: Grid-based layout form**

```plaintext
LAYOUT ( TEXT = "Customer orders" )
  VBOX
    GROUP group1 ( TEXT = "Customer" )
      GRID
        {
          <GROUP Name          >
            [f001]
          <
          <GROUP Identifiers   ><GROUP Contact >
            FCode: [f002]  Phone: [f004]
            LNum: [f003]   EMail: [f005]
          <
          }
        }
    END
  END
  TABLE
    {
      OrdNo  Date       Ship date   Weight
      [c01   |c02       |c03        |c04        ]
      [c01   |c02       |c03        |c04        ]
      [c01   |c02       |c03        |c04        ]
      [c01   |c02       |c03        |c04        ]
    }
  END
FOLDER
  PAGE pg1 ( TEXT = "Address" )
    GRID
      {
        Address: [f011]

Stack-based layout on page 1322
A form file can define a stack-based layout within a tree of stack items.

Example 1: Grid-based layout form on page 1305

Form rendering

The section explains the layout rules to render forms on graphical front-ends.

- Form rendering basics on page 1307
- Grid-based layout on page 1309
- Stack-based layout on page 1322
Form rendering basics
Get the essentials about form rendering.

In the graphical mode (GUI mode), forms are not displayed in a fixed text-mode screen. Application windows can display complex layouts and are resizable by the end user, if the platform allows window resizing (mobile devices versus desktop platforms).

When developing with command line tools, forms are designed with .per form specification files, which are text files. In order to display text-based forms in graphical mode, the text-based form definitions must be converted to graphical forms, which implies specific layout rules. These rules are explained in this section.

We distinguish two type of form rendering techniques:

• Grid-based rendering, based on a grid of cells, to place and size form elements.
• Stack-based rendering, where all form elements are placed over each other vertically.

Related concepts
Form specification files on page 1132
Form specification files are the source files defining the layout and content of application forms.

Character set usage
The character set used to edit and compile .per form specification files is defined by the current locale.

Form elements (typically, labels) can be written with non-ASCII characters of the current codeset.

In a grid-based layout, the form element positions and sizes are determined by counting the width of characters, rather than the number of bytes identifying the characters in the current codeset. This rule can be ignored when using a single-byte character set such as ISO-8859-1 or CP-1252, where each character has width of 1 and codepoint of 1 byte. This rule is important when using a multibyte character set such as BIG5 or UTF-8.

For example, in the UTF-8 multibyte codeset, a Chinese ideogram is encoded with three bytes, while the visual width of the character is twice the size of a Latin character. In the next example, the labels with three Chinese characters have the same width as the labels using six Latin characters. As a result, all the labels will get the same size (6 cells), and all fields will be aligned properly in a proportional font display:

```
LAYOUT
GRID
{
  ### [f001] abcdef [f002]
  abcdef [f003] ### [f004]
}
END
END
```

In a stack-based container, the position of form elements is logical, the current locale does not impact on the form item positions as in a grid-based container:

```
LAYOUT
STACK
GROUP
  EDIT customer.cust_num, TITLE="###";
  EDIT customer.cust_name;
  EDIT customer.cust_address;
END
...
END
```

For maximum portability, it is recommended to write all form specification files in ASCII (7 bit), and use localized strings to internationalize your forms.

The STACK container holds stack items defining a logical alignment of form items.

Adapting to viewport changes

Application forms and functions can be adapted to the front-end viewport size or mobile device orientation.

Detecting viewport size / orientation changes

When the mobile device orientation changes, or when the current window is resized on desktop/web front-ends, the windowresized specific predefined action will be sent, if an ON ACTION handler is defined by the current dialog for this action.

Note: The windowresized action is used only to hide/show items on the current form using the standard user interface API (ui.Form.setElementHidden()) and it is not recommended for reloading forms on the fly.

This predefined action can be used to detect viewport geometry changes and adapt the application form to the new size:

```
ON ACTION windowresized
   -- Code to adapt to the new viewport size
```

Note: In dialogs allowing field input (INPUT / INPUT ARRAY or CONSTRUCT), take care of the current field input: The windowresized action can force the field validation. Therefore, it is not recommended to use this special action in these dialogs. The action can be safely used in DISPLAY ARRAY and MENU dialogs.

To control action view rendering defaults and current field validation behavior when the windowresized action is used, consider setting action default attributes for this action in your .4ad file as follows:

```
<ActionDefaultList>
   ...
   <ActionDefault name="windowresized" validate="no" defaultView="no" contextMenu="no"/>
   ...
</ActionDefaultList>
```

Another option is to define these action defaults attributes in the ON ACTION handler:

```
ON ACTION windowresized (VALIDATE=NO, DEFAULTVIEW=NO)
   ...
```

Querying the geometry of the viewport

Use the feInfo/windowSize front call to query the actual size of the front-end viewport (GDC current window, GBC webview, or mobile screen size):

```
DEFINE size STRING
CALL ui.Interface.frontCall("standard","feInfo","["windowSize"],"size")
IF size == "1200x1824" THEN
   ...
END IF
```
Grid-based layout

A form file can define a grid-based layout within a tree of layout items.

In a .per form specification file, the LAYOUT section defines a tree of layout containers, which hold form items such as labels and form fields.

The GRID container can be used to define a grid of cells that hold form items: in the layout tree, the GRID container acts as a leaf node, which holds the visible widgets (fields, buttons, and so on).

Note: SCROLLGRID and GROUP containers defined by layout tags inside a grid without the GRIDCHILDRENINPARENT attribute, are similar to GRID containers in regards to the layout rules describe in this section.

The .per form specification file defines a form layout based on a character grid, each character defines a cell of the grid:

```
GRID
{
  First Name [fname ]
  Last Name  [lname ]
}
END
```

The .per file layout specification can be shown in a character grid.

```
GRID
{
  0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9
  0 First Name [fname ]
  1 Last Name  [lname ]
}
END
```

Figure 48: Character grid of a form layout

With a fixed-font based front-end (such as a dumb terminal), the forms appear within a screen where each cell is identified by x and y coordinates, as in the SCREEN section of the form specification file. There is no particular layout issue, as all characters can be displayed at the same (relative) position as in the source form file.

With the graphical front-end, text-based forms must be displayed in a graphical window using fonts with a proportional size. In a proportional font, the field label "Key" has a different graphical length than the label "Num", despite having the same number of characters.
In the compiled version of the form specification file, all form items get coordinates in a virtual grid (defined by \texttt{posX} and \texttt{posY} attributes), and the number of cells the item occupies in the grid (in the \texttt{gridWidth} and \texttt{gridHeight} attributes):

![Diagram of grid positioning]

The "First Name" and "Last Name" texts are identified as whole labels, even if the words "First" and "Name" (or "Last" and "Name") are not joined in the form definition, because the form compiler considers a single blank as a word separator within labels.

**Related concepts**

- **GRID container** on page 1201
  - Defines a layout area based on a grid of cells.

- **STACK container** on page 1202
  - The \texttt{STACK} container holds stack items defining a logical alignment of form items.

**Packed and unpacked grids**

When resizing a window, the content will either grow with the window or be packed in the top left position.

If elements in the window can grow, they will follow the window container and resize accordingly. Some elements can grow vertically, some can grow horizontally, and some can grow in both directions. The way resizable form items can grow is controlled by the \texttt{STRETCH} attribute. The window content is packed horizontally, vertically or in both directions, if none of the elements can grow in that direction.

The following form item types can grow horizontally:

- \texttt{TABLE} / \texttt{TREE} items
• IMAGE items (with STRETCH=BOTH or STRETCH=X)
• TEXTEDIT items (with STRETCH=BOTH or STRETCH=X)

The following form item types can grow vertically:

• TABLE / TREE items (without WANTFIXEDPAGESIZE attribute)
• IMAGE items (with STRETCH=BOTH or STRETCH=Y)
• TEXTEDIT items (with STRETCH=BOTH or STRETCH=Y)

In general, a GRID container can grow if any object inside the GRID can grow. There is an exception to this rule. If
there is a single GROUP container (defined without the GRIDCHILDRENINPARENT attribute) inside a GRID and
nothing else, the grid can grow even if the objects inside the grid cannot grow.

This exception allows better rendering of a grouped grid.

Figure 50: Packed grid
Related concepts

GRID container on page 1201
Defines a layout area based on a grid of cells.

GROUP container on page 1199
Defines a layout area to group other layout elements together, in a grid-based layout.

STRETCH attribute on page 1286
The STRETCH attribute specifies how a widget must resize when the parent container is resized.

GRIDCHILDRENINPARENT attribute on page 1258
The GRIDCHILDRENINPARENT attribute is used for a container to align its children to the parent container.

Automatic HBoxes and VBoxes

Horizontal and vertical boxes are added automatically when stretchable elements are used.

When using layout tags in a GRID container, the fglform compiler will automatically add hbox or vbox containers with splitters in the following conditions:

- An hbox is created when two or more stretchable elements are stacked side by side and touch each other (no space between).
- A vbox is created when two or more stretchable elements are stacked vertically and touch each other (no space between).

No hbox or vbox will be created if the elements are in a SCROLLGRID container.

This example defines two tables stacked vertically, generating a vbox with splitter. The ending tags for the tables are omitted.

```xml
<T table1>
  [colA | colB ]
  [colA | colB ]
  [colA | colB ]
  [colA | colB ]
<T table2>
  [colC | colD ]
```
This example defines a layout with two stretchable TEXTEDIT fields placed side by side, which would generate an automatic hbox with splitter. To make both widgets touch, you need to use a pipe delimiter in between the two widgets.

The GRIDCHILDRENINPARENT attribute is used for a container to align its children to the parent container.

Widget position and size in grid
Form items render as widgets in the window, at a given position and with a given size.

To render form items, grid-based rendering follows the layout rules described below:

1. The position of the widgets in the virtual grid is defined by the posX and posY AUI tree attributes.
2. The number of virtual grid cells occupied by a widget is defined by the gridWidth and gridHeight AUI tree attributes.
3. The real size (i.e. pixels) of a widget is defined by the width and height AUI tree attributes.
4. Empty lines and empty columns in the form layout definition take a size of 0 pixels.
5. The size of a cell in the virtual grid depends on the real size of the widgets inside the grid.
6. A widget's minimum size is computed via its real size and the SAMPLE attribute.
7. The preferred size of the widget is computed following the SIZEPOLICY attribute.
8. The final widget size is computed depending on the minimum and preferred size, to fill the cells in the grid.
9. A small spacing is applied in non-empty cells.

The next screenshot shows 2 labels and 2 fields placed in a grid.

Figure 52: Two labels and two fields placed in a grid: Grid view
By default, empty grid rows and empty grid columns get no size when rendered on the front-end. For example, in the above grid sample, the grid columns #10 and #11 are empty.

**Related concepts**

- **SAMPLE attribute** on page 1281
  The SAMPLE attribute defines the text to be used to compute the width of a form field.

- **SIZEPOLICY attribute** on page 1283
  The SIZEPOLICY attribute is a sizing directive based on the content of a form item.

**Form item dependencies in grids**

Form items interact with each other in terms of width, depending on the front-end widget size.

This example illustrates how form items are dependent on each other inside the grid.

```
GRID
{
  [a]
  [b]
}
END
```

This .per implies that form items a and b start at the same position and have the same size, whatever a and b are.

This rule leads to very different results, especially when a large widget is assigned into a small number of cells.

Example:

```
LAYOUT
GRID
{
  [a|b   ][f     ]
  [c|d   ][e     ]
}
END
END

ATTRIBUTES
CHECKBOX a = formonly.a, TEXT="A Checkbox";
EDIT b = formonly.b;
EDIT c = formonly.c;
CHECKBOX d = formonly.d, TEXT="Another Checkbox";
EDIT e = formonly.e;
EDIT f = formonly.f;
END
```

The grid is computed with regard to the character cells in the form definition:
Then the minimum size of each widget and the layout is computed.

Cells (0,1) and (1,3) contain a checkbox; these checkboxes will enlarge columns 1 and 3.

Because the EDIT field "c" is defined to have the same width as checkbox "a", it will be much larger as expected.
To avoid this visual result, you must assign a realistic number of grid cells for each form item.

Even if the grid area is wider in the source form file, the real graphical result will be smaller.

The `SAMPLE` attribute defines the text to be used to compute the width of a form field.

The `SIZEPOLICY` attribute is a sizing directive based on the content of a form item.

These diagrams show the virtual grid of a complex form, with several field item tags.
Figure 59: Grid containing several fields

For each form field, the position and the number of cells is computed by the form compiler.

At runtime, the front-end creates the widgets and sets them on the virtual grid.

Figure 60: Widgets set on grid

Once widgets are on the grid, their minimum size is computed based on widget size, SIZEPOLICY, and SAMPLE attributes.

Then the sizes of the grid cells adapt to the size of the widgets.

Figure 61: Widget size computations
Figure 62: Widgets in rendered form

In this screenshot, the fields \( k \) and \( c \) are much bigger than expected:

- Field \( g \) and \( l \) make columns 33, 34 and 35 bigger than the others,
- Field \( f \) extends columns 25 to 31.
- As field \( c \) has to fill columns 25 to 35, its size grows; the same for field \( k \).

Some fields are proportionally bigger than others because some parameters are variable, while others are fixed.

The width of the widget is the sum of border width, plus the content width (depending on \texttt{SIZEPOLICY} and the \texttt{SAMPLE} attributes).

Since the default \texttt{SAMPLE} is \texttt{MMMMMM000...}, the graphical width of a field is not linearly proportional to the width defined in the form file. For example, a field of 1 will be as wide as 2 borders + 1 'M'. A field of 10 will be as wide as 2 borders + 6 'M' + 4 '0'. This means that a field of 1 is far from being 10 times smaller than a field of 10.

\textbf{Related concepts}

\texttt{SAMPLE} attribute on page 1281
The \texttt{SAMPLE} attribute defines the text to be used to compute the width of a form field.

\texttt{SIZEPOLICY} attribute on page 1283
The \texttt{SIZEPOLICY} attribute is a sizing directive based on the content of a form item.

\textbf{Using hbox tags to align form items}

The hbox tag concept has been introduced to bypass the limitations of the character-based grid in forms.

An hbox tag defines a widget container that arranges child widgets horizontally, like the horizontal box container. All widgets inside this container are no longer dependent on the parent grid.

- \texttt{Defining hbox tags in grids} on page 1318
- \texttt{Spacer items in hbox tags} on page 1320
- \texttt{Widget size within hbox tags} on page 1321

\textit{Defining hbox tags in grids}

An hbox tag is defined by using a : colon in an item tag delimited by square brackets.

This example creates a hbox container containing widgets \( a \), \( b \) and \( c \). These widgets won't be aligned in the grid.

```
GRID
{
[\!a:b:c ]
[\!d|e|f ]
}
END
```
Hbox tags are useful when the form contains large widgets in a small number of cells in one row, and don't want to have dependencies.

We can modify the Form item dependencies in grids example, using hbox tags:
**Figure 66: HBox rendering**

**Related concepts**

Automatic HBoxes and VBoxes on page 1312

Horizontal and vertical boxes are added automatically when stretchable elements are used.

**Spacer items in hbox tags**

HBox tags also introduces the spacer items concept: when a grid hbox is created, the content may be smaller than the container.

```
GRID
{
[a  :b  :c  ]
[d  :e  :f  ]
}
END
```

**Figure 67: Spacer items**

Because of the checkbox, cell 1 is very large, and then the hbox is larger than the three fields. A spacer item object is automatically created by the form compiler; the role of the spacer item is to take all the free space in the container. Then all the widgets are packed to the left side of the hbox.

By default, a spacer item is created at the right of the container, but the spacer can also be defined in another place:

```
GRID
{
[a  :b  :c  ] <- default: spacer on the right
[  :d  :e  :f  ] <- spacer on the left
[g  :   :h    ] <- spacer between g and h
[1: :j: :k  :  :l  ] <- multiple spacers (between i and j, j and k, k and l
}
END
```
Figure 68: Form using spacers

Widget size within hbox tags

By default, the real width of BUTTONEDIT, DATEEDIT, DATETIMEEDIT and COMBOBOX widgets are computed as follows:

```
if item-tag-width > 2
  real-width = item-tag-width - 2
else
  real-width = item-tag-width
```

Where `item-tag-width` represents the number of characters used in the form layout by the item tag, to define the width of the element.

If the default widget size computing does not satisfy the needs, it is possible to specify the exact width of a BUTTONEDIT, DATEEDIT or COMBOBOX with an hbox tag, combined to the `SAMPLE` attribute.

The hbox tag can be used with a `:` (colon) and `–` (dash) marker to define the exact number of characters the field can display, while the `SAMPLE` attribute will define the size.

For example:

```
LAYOUT
GRID
  { ButtonEdit A [ba ]
  ButtonEdit B [bb: ]
  ButtonEdit C [bc : ]
  ButtonEdit D [bd -: ]
  }
END
ATTRIBUTES
BUTTONEDIT ba = FORMONLY.ba, SAMPLE="0", ACTION=zoom1;
BUTTONEDIT bb = FORMONLY.bb, SAMPLE="M", ACTION=zoom2;
BUTTONEDIT bc = FORMONLY.bc, SAMPLE="Pi", ACTION=zoom3;
BUTTONEDIT bd = FORMONLY.bd, SAMPLE="0", ACTION=zoom4;
END
```

Here the `ba` item tag occupies 7 grid columns and gets a real width of 5 (7-2). The `SAMPLE` attribute makes the edit field part as large as 5 characters '0' in the current font, so with this field you can input or display only 5 digits.

The `bb` item tag, which is in an hbox tag that occupies 7 grid columns, gets a width of 2. Since the `SAMPLE` attribute is "M", one can input 2 characters as wide as an "M".

The `bc` item tag, which is in an hbox tag that occupies 7 grid columns, gets a width of 3 (5-2). Since the `SAMPLE` attribute is "Pi", the edit field part will be as large as the word "Pi". (If `SAMPLE` contains more than 1 character it must have the same number of characters as in the field definition).
When using an hbox tag, one can explicitly specify the width of the field with the dash size indicator: The \texttt{bd}, which is in an hbox tag that occupies 7 grid columns, gets a width of 4 (because of the dash size indicator). Since the \texttt{SAMPLE} attribute is "0", the edit field part will be as large as 4 digits.

**Related concepts**

- **Hbox tags** on page 1158
  - \textit{Hbox tags} group several item tags within the same horizontal layout box, in a grid-based container.
- **SAMPLE attribute** on page 1281
  - The \texttt{SAMPLE} attribute defines the text to be used to compute the width of a form field.
- **DATEEDIT item definition** on page 1228
  - Defines a line-edit field with a calendar widget to pick a date, in a grid-based layout.
- **BUTTONEDIT item definition** on page 1225
  - Defines a line-edit field with a push-button that can trigger an action, in a grid-based layout.
- **COMBOBOX item definition** on page 1227
  - Defines a \texttt{COMBOBOX} item in a grid-based layout, in a grid-based layout.
- **Item tags** on page 1155
  - \textit{Item tags} define the position and size in a grid-based container.

**Stack-based layout**

A form file can define a stack-based layout within a tree of stack items.

In a .per form specification file, the \texttt{LAYOUT} section defines a tree of layout containers, which hold layout items such as labels and form fields.

Use the \texttt{STACK} layout container, to define a logical grouping of form elements, to be rendered vertically by the front end.

**Important:** This feature is experimental. The syntax/name and semantics/behavior may change in a future version.

The \texttt{STACK} container must appear immediately after the \texttt{LAYOUT} keyword.

A \texttt{STACK} layout defines a tree of stacked containers, which holds a set of stack items such as form fields. In the sample code, the \texttt{STACK} container holds a \texttt{GROUP} container, which defines some stacked \texttt{EDIT} fields:

```plaintext
LAYOUT
STACK
  GROUP g1(TEXT="Customer info")
  EDIT customer.cust_num, NOENTRY, TITLE="Id:"
  EDIT customer.cust_name, TITLE="Name:"
  EDIT customer.cust_address, TITLE="Address:"
END
END
```

There is no such thing as x,y coordinates in a stack container: The form element position definition is abstract and relative to other elements. Arranging form elements logically allows more flexibility in the final rendering of the form on the front-end.

Stack-based forms are typically used in mobile application design, to get a similar, but adaptable layout rendering on different mobile device brands.

The visual result of the above form definition would look as follows on an iOS mobile device:
**Figure 69: iOS stacked form 2**

**Related concepts**

Grid-based layout on page 1309
A form file can define a grid-based layout within a tree of layout items.

GRID container on page 1201
Defines a layout area based on a grid of cells.

STACK container on page 1202
The STACK container holds stack items defining a logical alignment of form items.

**Label internationalization**

Define form files with stacked containers for different languages.

To internationalize your application, define TITLE attributes using \%"string-id" localized strings, in stack containers and stack item definitions:

```plaintext
-- myform.per
LAYOUT
STACK
  GROUP (TEXT=%"group.custinfo")
    EDIT customer.cust_num, NOENTRY, TITLE=%"cust.label.id";;
    EDIT customer.cust_name, TITLE=%"cust.label.name";
    EDIT customer.cust_address, TITLE=%"cust.label.address";
  END
END
ED

-- myapp.str
"group.custinfo" = "Customer information"
"cust.label.id" = "Id:"
"cust.label.name" = "Name:"
"cust.label.address" = "Address:"
```
If more space is needed for text fields, remove field labels and add a `COMMENT` attribute to show a grayed text inside empty fields:

```
-- myform.per
LAYOUT
STACK
  GROUP {TEXT="%group.custinfo"}
    EDIT customer.cust_num, NOENTRY, TITLE="%cust.label.id";;
    EDIT customer.cust_name, COMMENT=%"cust.comment.name";
    EDIT customer.cust_address, COMMENT=%"cust.comment.address";
  END
END
END
```

```
-- myapp.str
"group.custinfo" = "Customer information"
"cust.label.id" = "Id:"
"cust.comment.name" = "Customer's name"
"cust.comment.address" = "Customer's address"
```

The visual result for the about stack-based form will look like this on an iOS device:

![iOS stacked form 3](image)

**Figure 70: iOS stacked form 3**

**Related concepts**

Localized strings on page 430

Localized strings provide a means of writing applications in which the text of strings can be customized on site.

**Stacked group rendering**

Groups render in a native way on front-ends supporting the stacked layout.

Use `GROUP` containers in your form definition, to control the stacked layout: Fields and other form elements such as buttons can be grouped together by domain.
The header of a group box is defined by the TEXT attribute of the GROUP container.

For example, in a form designed for customer data input, customer identification (number, name) appear in a dedicated group, while address information (street, zip code, state, country fields) may appear under another group:

```plaintext
-- myform.per
LAYOUT
STACK
  GROUP g1 (TEXT=%"cust.group1")
    EDIT FORMONLY.id, TITLE=%"cust.label.id"
    EDIT FORMONLY.name, TITLE=%"cust.label.name"
  END
GROUP g2 (TEXT=%"cust.group2")
  LABEL : l_street, TEXT=%"cust.label.street"
  TEXTEDIT FORMONLY.street, HEIGHT=3;
  EDIT FORMONLY.zipcode, TITLE=%"cust.label.zipcode"
  EDIT FORMONLY.state, TITLE=%"cust.label.state"
  EDIT FORMONLY.country, TITLE=%"cust.label.country"
  END
END
END

-- myapp.str
"cust.group1" = "Customer id"
"cust.label.id" = "Id:"
"cust.label.name" = "Name:"
"cust.group2" = "Address"
"cust.label.street" = "Street:"
"cust.label.zipcode" = "Zip Code:"
"cust.label.state" = "State:"
"cust.label.country" = "Country:"
```

This code example will render as follows on an iOS mobile device:
**User interface**

<table>
<thead>
<tr>
<th>Cancel</th>
<th>Done</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>CUSTOMER ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Id:</td>
</tr>
<tr>
<td>Name:</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ADDRESS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Street:</td>
</tr>
<tr>
<td>45 Curly Bld</td>
</tr>
<tr>
<td>Zip Code:</td>
</tr>
<tr>
<td>State:</td>
</tr>
<tr>
<td>Country:</td>
</tr>
</tbody>
</table>

- Loading a default toolbar from an XML file on page 1330
- Creating the toolbar manually with DOM on page 1330
- Toolbars on mobile devices on page 1331
- Examples on page 1333

Understanding toolbars

This is an introduction to toolbars definition.

A toolbar defines action views presented as a set of buttons that can trigger events in an interactive instruction.

This section describes how to define toolbars with XML in files or in programs as global/default toolbars; it is also possible to define toolbars in forms with the TOOLBAR section, as form-specific toolbars.

Toolbar files can be loaded by a program with the methods `ui.Interface.loadToolBar()` (for default toolbars) or `ui.Form.loadToolBar()` (for form-initializers).

A global toolbar is displayed by default in all windows, or in the global window container when using a window container. The form-specific toolbar is displayed in the form where it is defined. The position and visibility of toolbars can be controlled with a window style attribute. Typical "modal windows" do not display toolbars.

The toolbar items (or buttons) are enabled/disabled based on the ON ACTION handlers defined by the current interactive instruction. A toolbar item is bound to an action handler by name. A click on the toolbar button will execute the user code in the action handler.

Toolbar elements can get a style attribute in order to use a specific rendering/decoration following presentation style definitions.

The DOM tag names are case sensitive; Toolbar is different from ToolBar.

When binding to an action, make sure that you are using the right value in the name attribute. As ON ACTION and COMMAND generate lowercase identifiers, it is recommended to use lowercase names.

It is recommended that you define the decoration of toolbar items for common actions with action defaults.

Related concepts

Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

Presentation styles on page 1065
Use presentation styles to specify decoration attributes for window and form elements.

Binding action views to action handlers on page 1664
How are action views of the forms bound to action handlers in the program code?

Window containers (WCI) on page 1922
WCI containers define window containers to group several programs in a parent multiple document interface presentation.

Defining toolbars in the form file

Toolbars can be defined in the form specification file within the TOOLBAR section.

Form toolbars are only displayed in the window where the form is loaded. Only one toolbar can be defined in a form file. It is recommended that toolbar button attributes that are common to topmenu options are centralized in action defaults.
Example

```xml
TOOLBAR tb
  ITEM accept ( TEXT="Ok", IMAGE="ok" )
  ITEM cancel ( TEXT="Cancel", IMAGE="cancel" )
  SEPARATOR
  ...
END
LAYOUT
GRID
{
  ...
}
```

A .4tb toolbar file is an XML file that holds a tree of elements defining a toolbar structure.

Loading a default toolbar from an XML file
To load a default toolbar from an XML definition file, use the utility method provided by the ui.Interface built-in class.

```
CALL ui.Interface.loadToolbar("standard")
```

The default toolbar will be displayed in all forms.

Related concepts
ui.Interface.loadToolBar on page 2340
Load a default toolbar file.

Syntax of a toolbar file (.4tb) on page 1328
A .4tb toolbar file is an XML file that holds a tree of elements defining a toolbar structure.

Creating the toolbar manually with DOM
Toolbars can be created at runtime by creating the corresponding XML representation in the AUI tree.

This example shows how to create a toolbar in all forms by using the default initialization function and the om.DomNode class:

```
CALL ui.Form.setDefaultInitializer("myinit")
OPEN FORM f1 FROM "form1"
DISPLAY FORM f1
...
FUNCTION myinit(form)
    DEFINE form ui.Form
    DEFINE f om.DomNode
    LET f = form.getNode()
    ...
END FUNCTION
```

After getting the DOM node of the form, create a node with the "ToolBar" tag name:

```
DEFINE tb om.DomNode
LET tb = f.createChild("ToolBar")
```

For each toolbar button, create a sub-node with the "ToolBarItem" tag name and set the attributes to define the button:

```
DEFINE tbi om.DomNode
LET tbi = tb.createChild("ToolBarItem")
CALL tbi.setAttribute("name","update")
CALL tbi.setAttribute("text","Modify")
CALL tbi.setAttribute("comment","Modify the current record")
CALL tbi.setAttribute("image","change")
```

If needed, you can create a "ToolBarSeparator" node to separate toolbar buttons:

```
DEFINE tbs om.DomNode
LET tbs = tb.createChild("ToolBarSeparator")
```

Related concepts
The DomNode class on page 2436
The `on.DomNode` class provides methods to manipulate a DOM node of a data tree.

**Example 2: Toolbar created dynamically** on page 1333

**Toolbars on mobile devices**

Toolbars can be used to control action view rendering on mobile devices.

On mobile devices, actions render usually as default action views, that display implicitly in dedicated panes on the screen. When displaying forms on a mobile front-end, you can use a toolbar to control the rendering of the actions.

**Using toolbars for Android™ devices (GMA)**

On Android devices, a TOOLBAR can be used to define the action views that appear in the [Android action bar](https://developer.android.com/).

![Toolbar example on Android](https://example.com/android_toolbar.png)

Toolbar action views are listed first and ordered as they are defined in the TOOLBAR section, followed by the default action views for remaining actions that are not part of the TOOLBAR definition.

**Using toolbars for iOS devices (GMI)**

On iOS devices, a TOOLBAR renders as the [iOS toolbar panel](https://developer.apple.com/). This toolbar appears at the bottom of the screen, displaying a icon or text for each toolbar item. If there is not enough space to render all toolbar items, a three-dot overflow icon appears on the right, to show up the remaining toolbar items.
The `iosSeparatorStretch` ToolBarSeparator style attribute can be used to stretch the toolbar separators to give more space between action buttons.
The background color for the iOS toolbar must be defined with the `iosToolbarTintColor` style attribute at the Window level.

In order to define the text color for iOS toolbar elements, define the `iosTintColor` style attribute at the Window level. However, other form elements such as Folder, Button, SpinEdit and RadioGroup will be impacted by the attribute defined for Window elements. To overwrite this, define another `iosTintColor` for the Form elements. For more details, see Decorate iOS UI elements on page 3308.

**Related concepts**

- Loading a default topmenu from an XML file on page 1338
- Creating the topmenu dynamically on page 1338
- Topmenus on mobile devices on page 1339
- Examples on page 1341

Understanding topmenus

This is an introduction to topmenu definitions.

A topmenu defines a graphical menu that holds views for actions controlled in programs with ON ACTION handlers. A topmenu renders to the user following the front-end platform standards. On a desktop / web front-end, the topmenu appears as a typical pull-down menu. On mobile devices, a topmenu displays as a flat list of options (Android™), and as a set of option screens the user can drill down (iOS).
This section describes how to define topmenus with XML in files or in programs as global/default topmenus; it is also possible to define topmenus in forms with the TOPMENU section, as form-specific topmenus.

Topmenu files can be loaded by program with the methods `ui.Interface.loadTopMenu()` (for default topmenus) or `ui.Form.loadTopMenu()` (for form-initializers).

In the abstract user interface tree, the TopMenu node must be created under the Form node, and must contain TopMenuGroup nodes. The TopMenuGroup nodes group topmenu commands and other topmenu groups. A TopMenuCommand is a leaf node in the topmenu tree that will trigger an action:

```
TopMenu
   +- TopMenuGroup
      +- TopMenuCommand
      +- TopMenuCommand
      +- TopMenuCommand
   +- TopMenuGroup
      +- TopMenuCommand
      +- TopMenuCommand
     +- TopMenuGroup
      +- TopMenuCommand
      +- TopMenuCommand
      +- TopMenuCommand
END
```

The topmenu options are enabled based on the ON ACTION handlers defined by the current interactive instruction. A topmenu option is bound to an action handler by name. Selecting the topmenu option will execute the user code in the action handler.

Topmenu elements can get a style attribute in order to use a specific rendering/decoration following presentation style definitions.

The DOM tag names are case sensitive; Topmenu is different from TopMenu.

When binding to an action, make sure that you are using the right value in the name attribute. As ON ACTION and COMMAND generate lowercase identifiers, it is recommended to use lowercase names.

It is recommended that you define the decoration of topmenu options for common actions with action defaults.

Images cannot be displayed for the first level of TopMenuGroup elements.

**Related concepts**

- **Configuring actions** on page 1646
  Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

- **Presentation styles** on page 1065
  Use presentation styles to specify decoration attributes for window and form elements.

- **Binding action views to action handlers** on page 1664
  How are action views of the forms bound to action handlers in the program code?

**Defining the topmenu in a form file**

Topmenus can be defined in the form specification file within the TOPMENU section.

Form topmenus will only be displayed in the window where the form is loaded. Only one topmenu can be defined in a form file. It is recommended that topmenu item attributes that are common to toolbar buttons are centralized in action defaults.

**Example**

```
TOPMENU tm
   GROUP form (TEXT="Form")
      COMMAND help (TEXT="Help", IMAGE="quest")
      COMMAND quit (TEXT="Quit")
END
```
Related concepts

**TOPMENU section** on page 1190
The **TOPMENU** section defines a pull-down menu with options that are bound to actions.

**Configuring actions** on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

**Syntax of a topmenu file (.4tm)**
A `.4tm` topmenu file is an XML file that holds a tree of elements defining a topmenu structure.

**Topmenu XML syntax**

```xml
<TopMenu [ topmenu-attribute="value" [....] ]>
  group
  [....]
</TopMenu>
```

where `group` is:

```xml
<TopMenuGroup group-attribute="value" [....]>
  [ <TopMenuSeparator separator-attribute="value" [....] />]
  [ <TopMenuCommand command-attribute="value" [....] />]
  group
  [....]
</TopMenuGroup>
```

1. `topmenu-attribute` defines a property of the TopMenu.
2. `group-attribute` defines a property of a TopMenuGroup.
3. `command-attribute` defines a property of a TopMenuCommand.
4. `separator-attribute` defines a property of a TopMenuSeparator.

### Loading a topmenu from an XML file

Topmenu XML definition files can be loaded at runtime.

To load a `.4tm` topmenu definition file for a form, use the utility method provided by the `ui.Form` built-in class:

```plaintext
CALL myform.loadTopMenu("standard")
```

**Related concepts**

- `ui.Form.loadTopMenu` on page 2362
  Load the form topmenu.

- **Syntax of a topmenu file (.4tm)** on page 1336
  A `.4tm` topmenu file is an XML file that holds a tree of elements defining a topmenu structure.

### Loading a default topmenu from an XML file

To load a default topmenu from an XML definition file, use the utility method provided by the `ui.Interface` built-in class.

```plaintext
CALL ui.Interface.loadTopMenu("standard")
```

The default topmenu will be displayed in all forms.

**Related concepts**

- `ui.Interface.loadTopMenu` on page 2340
  Load a default topmenu file.

- **Syntax of a topmenu file (.4tm)** on page 1336
  A `.4tm` topmenu file is an XML file that holds a tree of elements defining a topmenu structure.

### Creating the topmenu dynamically

Topmenus can be created at runtime by creating the corresponding XML representation in the AUI tree.

This example shows how to create a topmenu in all forms by using the default initialization function and the `om.DomNode` class:

```plaintext
CALL ui.Form.setDefaultInitializer("myinit")
OPEN FORM f1 FROM "form1"
DISPLAY FORM f1
...
FUNCTION myinit(form)
  DEFINE form ui.Form
  DEFINE f om.DomNode
```
LET f = form.getNode()
...
END FUNCTION

After getting the DOM node of the form, create a node with the "TopMenu" tag name:

DEFINE tm om.DomNode
LET tm = f.createChild("TopMenu")

For each Topmenu group, create a subnode with the "TopMenuGroup" tag name and set the attributes to define the group:

DEFINE tmg om.DomNode
LET tmg = tm.createChild("TopMenuGroup")
CALL tmg.setAttribute("text","Reports")

For each Topmenu option, create a sub-node in a group node with the "TopMenuCommand" tag name and set the attributes to define the option:

DEFINE tmi om.DomNode
LET tmi = tmg.createChild("TopMenuCommand")
CALL tmi.setAttribute("name","report")
CALL tmi.setAttribute("text","Order report")
CALL tmi.setAttribute("comment","Orders entered today")
CALL tmi.setAttribute("image","smiley")

If needed, you can create a "TopMenuSeparator" node inside a group, to separate menu options:

DEFINE tms om.DomNode
LET tms = tmg.createChild("TopMenuSeparator")

Related concepts
The DomNode class on page 2436
The om.DomNode class provides methods to manipulate a DOM node of a data tree.

Topmenus on mobile devices
Topmenus can be used to implement a general options menu in mobile apps.

On mobile devices, actions render usually as default action views, that display implicitly in dedicated panes on the screen. When displaying forms on a mobile front-end, you can use a topmenu to get a list of options the end user can choose from.

Using topmenus for Android™ devices (GMA)
On Android devices, a TOPMENU renders as a menu icon on the top left of the screen, in the Android action bar.

When the user taps on this icon, a list with topmenu items shows up. Selecting an option fires the corresponding action handler is fired.

Note: On Android, the topmenu can only display one level of options (no tree of options is possible).
Using topmenus for iOS devices (GMI)

On iOS devices, a TOPMENU renders as a menu icon on the top left corner of the device screen, in the iOS navigation controller.

When the user taps on this icon, a new view appears with the first level of topmenu items. The user can the drill down to a next level, select an option if it's a leaf item, or tap on the back button to move one level up in the topmenu tree. Selecting a leaf item will fire the corresponding action handler and close the menu.
Table 335: TOPMENU rendering with GMI on iOS

Related concepts

Action views are rendered following mobile specific standards.

Examples
Topmenu usage examples.
Example 1: Topmenu in XML format

```xml
<TopMenu>
  <TopMenuGroup text="Form" style="mystyle">
    <TopMenuCommand name="help" text="Help" image="quest"/>
    <TopMenuCommand name="quit" text="Quit" acceleratorName="Alt-F4"/>
  </TopMenuGroup>
  <TopMenuGroup text="Edit">
    <TopMenuCommand name="accept" text="Validate" image="ok"/>
    <TopMenuCommand name="cancel" text="Cancel" image="cancel"/>
  </TopMenuGroup>
</TopMenu>
```
Example 2: Topmenu section in form file

```xml
<TOPMENU
  GROUP form (TEXT="Form", STYLE="mystyle")
    COMMAND help (TEXT="Help", IMAGE="quest")
    COMMAND quit (TEXT="Quit", ACCELERATOR=ALT-F4)
  END

  GROUP edit (TEXT="Edit")
    COMMAND accept (TEXT="Validate", IMAGE="ok")
    COMMAND cancel (TEXT="Cancel", IMAGE="cancel")
    SEPARATOR
    COMMAND editcut -- Gets decoration from action defaults
    COMMAND editcopy -- Gets decoration from action defaults
    COMMAND editpaste -- Gets decoration from action defaults
  END

  GROUP records (TEXT="Records")
    COMMAND append (TEXT="Add", IMAGE="add")
    COMMAND delete (TEXT="Remove", IMAGE="del")
    COMMAND update (TEXT="Modify", IMAGE="change")
    SEPARATOR
    COMMAND search (TEXT="Search", IMAGE="find")
  END

END
```

**Dialog instructions**

This section describes the dialog instructions to control application forms and the concepts related to dialog implementation.

- Static display (DISPLAY/ERROR/MESSAGE/CLEAR) on page 1343
- Prompt for values (PROMPT) on page 1353
- Ring menus (MENU) on page 1358
- Record input (INPUT) on page 1373
- Record list (DISPLAY ARRAY) on page 1394
- Editable record list (INPUT ARRAY) on page 1425
- Query by example (CONSTRUCT) on page 1461
- Multiple dialogs (DIALOG - inside functions) on page 1481
- Declarative dialogs (DIALOG - at module level) on page 1546
- Parallel dialogs (START DIALOG) on page 1600
Static display (DISPLAY/ERROR/MESSAGE/CLEAR)

This section explains the instructions displaying static information to application forms, such as DISPLAY, ERROR, MESSAGE, CLEAR.

- Display of data and messages on page 1343
- DISPLAY (to stdout) on page 1343
- MESSAGE on page 1344
- ERROR on page 1345
- DISPLAY TO on page 1346
- DISPLAY BY NAME on page 1348
- CLEAR FORM on page 1349
- CLEAR SCREEN ARRAY on page 1350
- CLEAR field-list on page 1351
- SCROLL on page 1352

Display of data and messages

The values contained in program variables can be displayed to the current form with the `DISPLAY BY NAME` or `DISPLAY TO` instruction.

Forms can be cleared with the `CLEAR FORM` or `CLEAR field-list` instructions. Complete record lists (in `SCROLLGRID`, `TABLE` or `TREE` containers) can be cleared with the `CLEAR SCREEN ARRAY` instruction.

Application messages and warnings can be displayed to the user with the `MESSAGE` and `ERROR` instructions.

The `DISPLAY BY NAME/TO` instructions are not interactive, and are usually not needed if the program is always in the context of a dialog controlling the form fields. The data of the program variables will be displayed in form fields when the dialog starts, if the `WITHOUT DEFAULTS` option is specified, and during the dialog execution, form fields will be automatically synchronized with the program variables when using the `UNBUFFERED` option.

DISPLAY (to stdout)

The `DISPLAY` instruction displays text in line mode to the standard output channel.

Syntax

```
DISPLAY expression
```

1. `expression` is any expression supported by the language.

Usage

The `DISPLAY` instruction can be used to print information to the standard output channel (stdout) of the terminal the program is attached to.

The `expression` is typically a list of string constants and program variables separated by the comma concatenation operator.

Before displaying to the standard output channel, the expression is converted to a character string. The values contained in variables are formatted depending on the data types and environment settings such as `DBDATE` and `DBMONEY`.
Example

```
MAIN
  DISPLAY "Today's date is: ", TODAY
END MAIN
```

Selecting the correct data type assists you in the input, storage, and display of your data.

MESSAGE

The MESSAGE instruction displays a message to the user.

Syntax

```
MESSAGE expression [, ...]
  [ ATTRIBUTES ( display-attribute [, ...] ) ]
```

where display-attribute is:

```
  BLACK | BLUE | CYAN | GREEN
  MAGENTA | RED | WHITE | YELLOW
  BOLD | DIM | INVISIBLE | NORMAL
  REVERSE | BLINK | UNDERLINE
  STYLE = "style-name"
```

1. expression is any expression supported by the language.
2. style-name is a presentation style name.

Usage

The MESSAGE instruction displays a message to the user in an interactive program.

In TUI mode, the text is displayed in the message line of the current window. The message line can be defined by the OPTIONS MESSAGE LINE instruction. Note that the default message line position is the same as the MENU option comment line.

In GUI mode, the text is displayed in a specific area, depending on the STYLE attribute. When you specify the STYLE attribute, you can reference a style defined in the presentation styles file. This allows you to display errors or messages in GUI mode with more sophisticated visual effects than the regular TTY attributes. Advanced automatic rendering can be obtained with message specific style attributes. If you want to apply a style automatically to all program messages displayed with the MESSAGE instruction, you can use the :message pseudo selector in the style definition.

Example

```
INPUT BY NAME custrec.* ...
  BEFORE INPUT
    MESSAGE "Enter customer data."
  ...
```
ERROR
The ERROR instruction displays an error message to the user.

Syntax

```
ERROR expression
   \ ATTRIBUTES ( display-attribute [, ...] ) \n```

where `display-attribute` is:

```
<table>
<thead>
<tr>
<th>BLACK</th>
<th>BLUE</th>
<th>CYAN</th>
<th>GREEN</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAGENTA</td>
<td>RED</td>
<td>WHITE</td>
<td>YELLOW</td>
</tr>
<tr>
<td>BOLD</td>
<td>DIM</td>
<td>INVISIBLE</td>
<td>NORMAL</td>
</tr>
<tr>
<td>REVERSE</td>
<td>BLINK</td>
<td>UNDERLINE</td>
<td></td>
</tr>
<tr>
<td>STYLE = &quot;style-name&quot;</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

1. `expression` is any expression supported by the language.
2. `style-name` is a presentation style name.

Usage
The ERROR instruction displays an error message to the user in an interactive program.

In TUI mode, the error text is displayed in the error line of the screen. The text of the ERROR statement is always displayed independently to the current window. The error line can be defined by the OPTIONS ERROR LINE instruction.

In GUI mode, the text is displayed in a specific area, depending on the `STYLE` attribute. When you specify the `STYLE` attribute, you can reference a style defined in the presentation styles file. This allows you to display errors or messages in GUI mode with more sophisticated visual effects as the regular TTY attributes. Advanced automatic rendering can be obtained with message specific style attributes. If you want to apply a style automatically to all program warnings displayed with the ERROR instruction, you can use the `:error` pseudo selector in the style definition.

Example

```
...  
UPDATE tab1 SET col1 = ...  
IF sqlca.sqlcode < 0 THEN  
   ERROR SFMT("Row update failed (err=%1)", sqlca.sqlcode)  
   ATTRIBUTES(STYLE="important")  
   ...  
END IF  
...  
```

Related concepts
Windows and forms on page 1032

Defining the position of reserved lines on page 506  
The OPTIONS element LINE defines position of dedicated screen lines.
The **OPTIONS** element **LINE** defines position of dedicated screen lines.

**Text mode rendering** on page 1013

**DISPLAY TO**

The **DISPLAY TO** instruction displays data to form fields explicitly.

**Syntax**

```
DISPLAY expression [,...] TO field-spec [,...]
\downarrow ATTRIBUTES ( display-attribute [,...] ) \downarrow
```

where **field-spec** is:

```
| field-name  
| table-name.* 
| table-name.field-name 
| screen-array[line].* 
| screen-array[line].field-name 
| screen-record.* 
| screen-record.field-name 
\downarrow [,...]
```

where **display-attribute** is:

```
| BLACK \uparrow BLUE \uparrow CYAN \uparrow GREEN 
| MAGENTA \uparrow RED \uparrow WHITE \uparrow YELLOW 
| BOLD \uparrow DIM \uparrow NORMAL 
| REVERSE \uparrow BLINK \uparrow UNDERLINE 
\downarrow
```

1. **expression** is any expression supported by the language.
2. **field-name** is the identifier of a field of the current form.
3. **table-name** is the identifier of a database table of the current form.
4. **screen-record** is the identifier of a screen record of the current form.
5. **screen-array** is the screen array that will be used in the form.

**Usage**

A **DISPLAY TO** statement copies the data from program variables to the form fields specified after the **TO** keyword.

When the program variables do not have the same names as the form fields, you must use the **TO** clause to explicitly map the variables to form fields using a **screen record** or **screen array**. You can list the fields individually, or you can use the **screen-record.*** or **screen-record[n].** notation, where **screen-record[n].** specifies all the fields in line **n** of a screen array.

In this example, the values in the **p_items** program record are displayed in the first row of the **s_items** screen array:

```
DISPLAY p_items.* TO s_items[1].*
```

The expanded list of screen fields must correspond in order and in number to the expanded list of identifiers after the **DISPLAY** keyword. Identifiers and their corresponding fields must have the same or compatible data types. For example, the next **DISPLAY** statement displays the values in the **p_customer** program record in fields of the **s_customer** screen record:

```
DISPLAY p_customer.* TO s_customer.*
```
For this example, the `p_customer` program record and the `s_customer` screen record require compatible declarations. The following `DEFINE` statement declares the `p_customer` program record:

```
DEFINE p_customer RECORD
    customer_num LIKE customer.customer_num,
    fname LIKE customer.fname,
    lname LIKE customer.lname,
    phone LIKE customer.phone
END RECORD
```

This fragment of a form specification declares the `s_customer` screen record:

```
ATTRIBUTES
    f000 = customer.customer_num;
    f001 = customer.fname;
    f002 = customer.lname;
    f003 = customer.phone;
END
```

The `DISPLAY TO` instruction is usually not needed if the program is always in the context of a dialog controlling the form fields.

**DISPLAY TO changes the touched flag**

The `DISPLAY TO` statement changes the 'touched' status of the target fields. When you modify a field value with this instruction, the `FIELD_TOUCHED()` operator returns true and the `ON CHANGE` and `ON ROW CHANGE` triggers may be invoked if the current field value was changed with a `DISPLAY TO`.

In dialogs controlling field input such as `INPUT` or `INPUT ARRAY`, use the `UNBUFFERED` attribute to display data to fields automatically without changing the 'touched' status of fields. The `UNBUFFERED` clause will perform automatic form field and program variable synchronization. When using the `UNBUFFERED` mode, the touched flag can be set with `DIALOG.setFieldTouched()` if you want to get the same effect as a `DISPLAY TO`.

**Specifying TTY attributes in the DISPLAY TO statement**

The `ATTRIBUTES` clause temporarily overrides any default display attributes or any attributes specified in the `OPTIONS` or `OPEN WINDOW` statements for the fields. When the `DISPLAY TO` statement completes execution, the default display attributes are restored. In a `DISPLAY TO` statement, any screen attributes specified in the `ATTRIBUTES` clause apply to all the fields that you specify after the `TO` keyword.

The `REVERSE`, `BLINK`, `INVISIBLE`, and `UNDERLINE` attributes are not sensitive to the color or monochrome status of the terminal, if the terminal is capable of displaying these intensity modes. The `ATTRIBUTES` clause can include zero or more of the `BLINK`, `REVERSE`, and `UNDERLINE` attributes, and zero or one of the other attributes. That is, all of the attributes except `BLINK`, `REVERSE`, and `UNDERLINE` are mutually exclusive.

The `DISPLAY TO` statement ignores the `INVISIBLE` attribute, regardless of whether you specify it in the `ATTRIBUTES` clause.

**Related concepts**

- `DISPLAY BY NAME` on page 1348
- The `DISPLAY BY NAME` instruction displays data to form fields explicitly by name.
- `Variables` on page 366
Explains how to define program variables.

**DISPLAY BY NAME**

The `DISPLAY BY NAME` instruction displays data to form fields explicitly *by name*.

**Syntax**

```
DISPLAY BY NAME { variable | record.* | ..., }
[ ATTIBUTES ( display-attribute [, ...] ) ]
```

where `display-attribute` is:

- BLACK
- BLUE
- CYAN
- GREEN
- MAGENTA
- RED
- WHITE
- YELLOW
- BOLD
- DIM
- NORMAL
- REVERSE
- BLINK
- UNDERLINE

1. `variable` is a program variable that has the same name as a form field.
2. `record.*` is a record variable that has members with the same names as form fields.

**Usage**

A `DISPLAY BY NAME` statement copies the data from program variables to the form fields associated to the variables by name. The program variables used in `DISPLAY BY NAME` must have the same name as the form fields where they have to be displayed. The language ignores any record structure name prefix when matching the names. The names must be unique and unambiguous; if not, the instruction raises an error.

For example, the following statement displays the values for the specified variables in the form fields with corresponding names (company and address1):

```
DISPLAY BY NAME p_customer.cust_company,
     p_customer.cust_address1
```

The `DISPLAY BY NAME` instruction is usually not needed if the program is always in the context of a dialog controlling the form fields.

**DISPLAY BY NAME uses the default screen record**

Unlike the `DISPLAY TO` instruction where you can explicitly specify a screen record or screen array, `DISPLAY BY NAME` displays data to the screen fields of the default screen records. The default screen records are those having the names of the tables defined in the `TABLES` section of the form specification file. When the form fields define a record list in the layout, only the first row can be referenced with the default screen record. In the next example, the form contains a static record list definition in the layout.

```
SCHEMA mystock
SCREEN
{ [f01 | f02 | f03 ]
  [f01 | f02 | f03 ]
  [f01 | f02 | f03 ]
  [f01 | f02 | f03 ]
}
END
TABLES
customer
END
ATTRIBUTES
f01 = customer.cust_key;
f02 = customer.cust_name;
```
f03 = customer.cust_address;
END

In the program, a DISPLAY BY NAME statement will display the data in the first line of the record list in the form:

```
DISPLAY BY NAME record_cust.*
```

**DISPLAY BY NAME changes the touched flag**

The DISPLAY BY NAME statement changes the 'touched' status of the target fields. When you modify a field value with this instruction, the FIELD_TOUCHED() operator returns true and the ON CHANGE and ON ROW CHANGE triggers may be invoked if the current field value was changed with a DISPLAY BY NAME.

In dialogs controlling field input such as INPUT or INPUT ARRAY, use the UNBUFFERED attribute to display data to fields automatically without changing the 'touched' status of fields. The UNBUFFERED clause will perform automatic form field and program variable synchronization. When using the UNBUFFERED mode, the touched flag can be set with DIALOG.setFieldTouched() if you want to get the same effect as a DISPLAY BY NAME statement.

**Specifying TTY attributes in the DISPLAY BY NAME statement**

The ATTRIBUTES clause temporarily overrides any default display attributes or any attributes specified in the OPTIONS or OPEN WINDOW statements for the fields. When the DISPLAY BY NAME statement completes execution, the default display attributes are restored.

The REVERSE, BLINK, INVISIBLE, and UNDERLINE attributes are not sensitive to the color or monochrome status of the terminal, if the terminal is capable of displaying these intensity modes. The ATTRIBUTES clause can include zero or more of the BLINK, REVERSE, and UNDERLINE attributes, and zero or one of the other attributes. That is, all of the attributes except BLINK, REVERSE, and UNDERLINE are mutually exclusive.

The DISPLAY BY NAME statement ignores the INVISIBLE attribute, regardless of whether you specify it in the ATTRIBUTES clause.

**Related concepts**

- DISPLAY TO on page 1346
  The DISPLAY TO instruction displays data to form fields explicitly.
- Variables on page 366
  Explains how to define program variables.

**CLEAR FORM**

The CLEAR FORM instruction clears all fields in the current form.

**Syntax**

```
CLEAR FORM
```

**Usage**

The CLEAR FORM instruction clears all form fields of the current form. It has no effect on any part of the screen display except the form fields.

Similar to CLEAR field-list, the CLEAR FORM instruction is typically used when the program is not inside a dialog block execution controlling the form fields. For example, after a database query with a CONSTRUCT instruction, you might want to clear all search criteria entered by the user with this instruction, to cleanup the form.

**Note:** CLEAR FORM clears the field values and resets the TTY attributes to NORMAL.

The CLEAR FORM instruction is usually not needed if the program is always in the context of a dialog controlling the form fields.
Example

CONSTRUCT BY NAME sql
  ON cust_name, cust_address, ...
  ...
END CONSTRUCT
CLEAR FORM
  ...

Related concepts

The dynamic user interface architecture is based on the Model-View-Controller (MVC) paradigm.

Screen records / arrays on page 1147
Form fields can be grouped in a screen record or screen array definition.

CLEAR field-list on page 1351
The CLEAR field-list instruction clears specific fields in the current form.

CLEAR WINDOW on page 1042
Clears the contents of a window.

CLEAR SCREEN on page 1045
Clears the complete application screen.

CLEAR SCREEN ARRAY
The CLEAR SCREEN ARRAY instruction clears the values of all rows of the form list identified by the specified screen array.

Syntax

CLEAR SCREEN ARRAY screen-array.*

1. screen-array is a screen array specified in the form.

Usage

After executing a DISPLAY ARRAY or INPUT ARRAY instruction, values remain in the form list identified by the screen array.

The CLEAR SCREEN ARRAY instruction automatically clears all rows of the list, regardless of the view: a TABLE, TREE, SCROLLGRID, or in a matrix of fields (an old-style/text-mode static screen array).

The CLEAR SCREEN ARRAY instruction replaces code which clears each individual row through the use of a loop:

```
-- Clearing each row individually
FOR i=1 TO <screen-array-length>
  CLEAR screen-array[i].*
END FOR
-- Unique instruction to clear a list
CLEAR SCREEN ARRAY screen-array.*
```

Using the CLEAR SCREEN ARRAY instruction eliminates the need for calculating the screen array length, a value which can change when using a TABLE container, that can be resized.

Note: CLEAR SCREEN ARRAY clears the field values and resets the TTY attributes to NORMAL.

The CLEAR SCREEN ARRAY instruction is usually not needed if the program is always in the context of a dialog controlling the form fields.

Example

...
DISPLAY ARRAY cust_arr TO sa.*
...
CLEAR SCREEN ARRAY sa.*
...

**Related concepts**

The model-view-controller paradigm on page 1608
The dynamic user interface architecture is based on the Model-View-Controller (MVC) paradigm.

CLEAR FORM on page 1349
The CLEAR FORM instruction clears all fields in the current form.

CLEAR field-list on page 1351
The CLEAR field-list instruction clears specific fields in the current form.

**CLEAR field-list**
The CLEAR field-list instruction clears specific fields in the current form.

**Syntax**

```
CLEAR field-list
```

where field-list is:

```
<table>
<thead>
<tr>
<th>field-name</th>
</tr>
</thead>
<tbody>
<tr>
<td>table-name.*</td>
</tr>
<tr>
<td>table-name.field-name</td>
</tr>
<tr>
<td>screen-array[line].*</td>
</tr>
<tr>
<td>screen-array[line].field-name</td>
</tr>
<tr>
<td>screen-record.*</td>
</tr>
<tr>
<td>screen-record.field-name</td>
</tr>
</tbody>
</table>
```

1. *field-name* is the identifier of a field of the current form.
2. *table-name* is the identifier of a database table of the current form.
3. *screen-record* is the identifier of a screen record of the current form.
4. *screen-array* is the screen array that will be used in the form.

**Usage**

The CLEAR field-list instruction can be used to clear the content of the specified form fields.

The fields to be cleared can be specified individually or by referencing a screen record or screen array, eventually with the .* notation to specify all fields.

Similar to CLEAR FORM, the CLEAR field-list is typically used when the program is not inside a dialog block execution controlling the form fields. For example, after a database query with a CONSTRUCT instruction, you might want to clear all search criteria entered by the user with this instruction, to cleanup the form.

**Note:** CLEAR field-list clears the field values and resets the TTY attributes to NORMAL.

The CLEAR field-list instruction is usually not needed if the program is always in the context of a dialog controlling the form fields.

**Example**

```
CONSTRUCT BY NAME sql
  ON s_customer.*
  ...
END CONSTRUCT
CLEAR s_customer.*
```
The dynamic user interface architecture is based on the Model-View-Controller (MVC) paradigm.

The CLEAR SCREEN ARRAY instruction clears the values of all rows of the form list identified by the specified screen array.

The CLEAR FORM instruction clears all fields in the current form.

The SCROLL instruction moves data rows up or down in a screen array.

**Syntax**

``` SCROLL field-list { UP | DOWN } [ BY lines ]
```

where `field-list` is:

```  | field-name  
  | table-name.*  
  | table-name.field-name  
  | screen-array[line].*  
  | screen-array[line].field-name  
  | screen-record.*  
  | screen-record.field-name  
  | [, ...]
```

1. `field-name` is the identifier of a field of the current form.
2. `table-name` is the identifier of a database table of the current form.
3. `screen-record` is the identifier of a screen record of the current form.
4. `screen-array` is the name of the screen array used of the current form.
5. `lines` is an integer expression that specifies how far (in lines) to scroll the display.

**Usage**

The SCROLL instruction specifies vertical movements of displayed values in all or some of the fields of a screen array within the current form.

The fields to be scrolled can be specified individually or by referencing a screen record or screen array, eventually with the .* notation to specify all fields.

The SCROLL instruction is supported for applications running in TUI mode, to scroll screen array rows when no interactive instruction is executing. In a GUI application, use a TABLE container with a DISPLAY ARRAY instruction.

**Related concepts**

*Form fields* are form elements designed for data input and/or data display.

**Windows and forms** on page 1032
The section describes the concept of windows and forms in the language.

**Prompt for values (PROMPT)**

The PROMPT instruction provides unique field input in an automatic pop-up window.

- Understanding the PROMPT instruction on page 1353
- Syntax of PROMPT instruction on page 1354
- Using simple prompt inputs on page 1355
  - PROMPT programming steps on page 1355
  - PROMPT instruction configuration on page 1355
  - Default actions in PROMPT on page 1355
  - Interaction blocks on page 1356
- Examples on page 1358
  - Example 1: Simple PROMPT statements on page 1358
  - Example 2: Simple PROMPT with Interrupt Checking on page 1358
  - Example 3: PROMPT with ATTRIBUTES and ON ACTION handlers on page 1358

**Understanding the PROMPT instruction**

The PROMPT instruction is used to query for a single value from the user.

PROMPT requires the text of the question to be displayed to the user and the variable that receives the value entered by the user. The variable can be of any simple data type except `TEXT` and `BYTE`.

The runtime system displays the question in the prompt area, waits for the user to enter a value, reads whatever value was entered until the user validates (for example with the Enter key), and stores this value in a response variable. The prompt dialog remains visible until the user enters a response.

The prompt finishes after `ON IDLE`, `ON ACTION`, or `ON KEY` block execution (to ensure backwards compatibility).

**Prompt display in TUI mode**

In TUI mode, the PROMPT question and input field is displayed in the prompt line of the current window, which is defined by the `OPTIONS PROMPT LINE` instruction or with the `ATTRIBUTES` clause of `OPEN WINDOW`. If the prompt line is not as wide as the prompt string, runtime error -1146 occurs.

**Prompt display in GUI mode**

In GUI mode, the PROMPT instruction opens a modal window with an OK and a Cancel button, and waits for input from the user.

**Figure 72: PROMPT window**

![Prompt window](image)

**Related concepts**

- Defining the position of reserved lines on page 506
- The `OPTIONS element LINE` defines position of dedicated screen lines.
- Dialog programming basics on page 1608
This section describes basic dialog programming concepts.

**Syntax of PROMPT instruction**
The PROMPT statement assigns a user-supplied value to a variable.

**Syntax**

```
PROMPT question
   [ ATTRIBUTES ( display-attribute [, ...] ) ]
   FOR [CHARACTER] variable
   [ HELP number ]
   [ ATTRIBUTES ( control-attribute [, ...] ) ]
   [ dialog-control-block
      [ ... ]
   ]
END PROMPT
```

where `dialog-control-block` is one of:

```
| ON IDLE seconds |
| ON TIMER seconds |
| ON ACTION action-name |
| ON KEY ( key-name [, ...] ) |
```

where `statement` is:

```
statement
   [ ... ]
```

where `display-attribute` is:

```
| BLACK | BLUE | CYAN | GREEN |
| MAGENTA | RED | WHITE | YELLOW |
| BOLD | DIM | INVISIBLE | NORMAL |
| REVERSE | BLINK | UNDERLINE |
```

where `control-attribute` is:

```
| ACCEPT [ = boolean ] |
| CANCEL [ = boolean ] |
| CENTURY = "century-spec" |
| FORMAT = "format-spec" |
| PICTURE = "picture-spec" |
| SHIFT = [ "up" | "down" ] |
| HELP = help-number |
| UNBUFFERED [ = boolean ] |
| WITHOUT DEFAULTS [ = boolean ] |
```

1. `question` is a string expression displayed as a message for the input of the value.
2. `variable` is the name of the variable that receives the data typed by the user.
3. The `FOR` clause exits the prompt statement when the first character has been typed.
4. `number` is the help message number to be displayed when the user presses the help key.
5. `key-name` is an hot-key identifier (such as F11 or Control-z).
6. `action-name` identifies an action that can be executed by the user.
7. `seconds` is an integer literal or variable that defines a number of seconds.
8. `statement` is an instruction that is executed when the user presses the key defined by `key-name`.
9. `century-spec` is a string specifying the century input rule, like the `CENTURY` attribute.
10. `format-spec` is a string defining the display format for the prompt field, like the `FORMAT` attribute.
11. `picture-spec` is a string defining the input format for the prompt field, like the `PICTURE` attribute.

Variables on page 366
Explains how to define program variables.
Message files on page 1059
Message files centralize strings and larger texts identified by a number, that can be used in programs.

Using simple prompt inputs
Dialog coding concepts, configuration and code structure.
PROMPT programming steps
To use the PROMPT statement, you must:
1. Declare a program variable with the DEFINE statement.
2. Set the INT_FLAG variable to FALSE.
3. Define the PROMPT statement, with dialog control blocks to control the instruction. Use the FOR CHAR clause if a single character is to be entered.
4. After executing the PROMPT, check the INT_FLAG variable to determine whether the input was validated or canceled by the user.

Related concepts
Example 2: Simple PROMPT with Interrupt Checking on page 1358

PROMPT instruction configuration

HELP option
The HELP clause specifies the number of a help message to display if the user invokes the help while executing the instruction. The predefined help action is automatically created by the runtime system. You can bind action views to the help action.
The HELP clause overrides the HELP attribute.

ACCEPT option
The ACCEPT attribute can be set to FALSE to avoid the automatic creation of the accept default action.

CANCEL option
The CANCEL attribute can be set to FALSE to avoid the automatic creation of the cancel default action. This is useful for example when you only need a validation action (accept), or when you want to write a specific cancellation procedure, by using EXIT INPUT.
If the CANCEL=FALSE option is set, no close action will be created, and you must write an ON ACTION close control block to create an explicit action.

Related concepts
Syntax of PROMPT instruction on page 1354
The PROMPT statement assigns a user-supplied value to a variable.

Default actions in PROMPT
When a PROMPT instruction executes, the runtime system creates a set of default actions.
Depending on the invoked default action, field validation occurs and different PROMPT control blocks are executed.
This table lists the default actions created for this dialog:
Table 336: Default actions created for the PROMPT dialog

<table>
<thead>
<tr>
<th>Default action</th>
<th>Description</th>
</tr>
</thead>
</table>
| accept         | Validates the PROMPT dialog (validates field criteria)  
                 *Creation can be avoided with the ACCEPT attribute.* |
| cancel         | Cancels the PROMPT dialog (no validation, INT_FLAG is set)  
                 *Creation can be avoided with the CANCEL attribute.* |
| close          | By default, cancels the PROMPT dialog (no validation, INT_FLAG is set)  
                 Default action view is hidden. See Implementing the close action on page 1672. |
| help           | Shows the help topic defined by the HELP clause.  
                 *Only created when a HELP clause is defined.* |

Related concepts

**INPUT ARRAY control blocks execution order** on page 1434

**Dialog programming basics** on page 1608

This section describes basic dialog programming concepts.

**Interaction blocks**

**ON ACTION block**

You can use **ON ACTION** blocks to execute a sequence of instructions when the user raises a specific action. This is the preferred solution compared to **ON KEY** blocks, because **ON ACTION** blocks use abstract names to control user interaction.

**Important:** The PROMPT instruction is automatically finished after **ON IDLE, ON ACTION, or ON KEY** block execution.

**Related concepts**

**Dialog actions** on page 1640

Describes how to program action handling when the end user triggers an action on the front-end.

**ON IDLE block**

The **ON IDLE seconds** clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

As **ON IDLE** can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of **ON IDLE** must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the **ON IDLE** trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or gets a phone call. The program can then execute some code before the user gets the control back.

```plaintext
ON IDLE 30
IF ask_question("Do you want to reload information from the database?") THEN
-- Fetch data back from the db server
```
Important: The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

Related concepts
Get program control if user inactive on page 1613
Execute some code after a given number of seconds, when the user does not interact with the program.

ON TIMER block on page 1357

ON KEY block
An ON KEY (key-name) block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The ON KEY block is supported for backward compatibility with TUI mode applications.

An ON KEY block can specify up to four different keys. Each key creates a specific action object that will be identified by the key name in lowercase. For example, ON KEY (F5, F6) creates two actions with the names f5 and f6. Each action object will get an acceleratorName attribute assigned, with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for ON KEY actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully ON KEY CONTROL-? statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, ON KEY statements used with ESC, TAB, UP, DOWN, LEFT, RIGHT, HELP, NEXT, PREVIOUS, INSERT, CONTROL-M, CONTROL-X, CONTROL-V, CONTROL-C and CONTROL-A should be avoided for use in GUI programs, because it’s very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, ON KEY actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a text attribute with the action defaults.

```
ON KEY (CONTROL-Z)
    CALL open_zoom()
```

Related concepts
Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

Default action views on page 1645
A default action view is created to render an action handler when no explicit action view exists for it.

ON TIMER block
The ON TIMER seconds clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

As ON TIMER can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of ON TIMER must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON TIMER trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
    CALL check_for_messages()
```
Important: The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

Examples
PROMPT dialog examples.

Example 1: Simple PROMPT statements

```plaintext
MAIN
    DEFINE birth DATE
    DEFINE chkey CHAR(1)
    PROMPT "Please enter your birthday: " FOR birth
    DISPLAY "Your birthday is: " || birth
    PROMPT "Now press a key... " FOR CHAR chkey
    DISPLAY "You pressed: " || chkey
END MAIN
```

Example 2: Simple PROMPT with Interrupt Checking

```plaintext
MAIN
    DEFINE birth DATE
    LET INT_FLAG = FALSE
    PROMPT "Please enter your birthday: " FOR birth
    IF INT_FLAG THEN
        DISPLAY "Interrupt received."
    ELSE
        DISPLAY "Your birthday is: " || birth
    END IF
END MAIN
```

Example 3: PROMPT with ATTRIBUTES and ON ACTION handlers

```plaintext
MAIN
    DEFINE birth DATE
    LET birth = TODAY
    PROMPT "Please enter your birthday: " FOR birth
        ATTRIBUTES(WITHOUT DEFAULTS)
        ON ACTION action1
            DISPLAY "Action 1"
    END PROMPT
    DISPLAY "Your birthday is " || birth
END MAIN
```

Ring menus (MENU)

The MENU instruction implements a list of options the end user can choose from.

- Understanding ring menus on page 1359
- Syntax of the MENU instruction on page 1359
- MENU programming steps on page 1361
- Using ring menus on page 1361
  - Rendering modes of a menu on page 1361
  - Binding action views to menu options on page 1365
Understanding ring menus

The **MENU** instruction implements a set of choices, also known as action handlers.

A **MENU** dialog defines a list of options that can trigger actions to execute associated program code. Ring menus are implemented with the **MENU** interactive instruction. A **MENU** block lists the possible actions that can be triggered in a given place in the program, with the associated program code to be executed.

```plaintext
MENU "Sample"
  COMMAND "Say hello"
    DISPLAY "Hello, world!"
  COMMAND "Exit"
  EXIT MENU
END MENU
```

A ring menu can only define a set of options for a given level of the program. You cannot define all menu options of your program in a single **MENU** instruction; you must implement nested menus.

The **MENU** instruction is mainly designed for text mode applications, displaying ring menus at the top of the screen. A typical TUI mode application starts with a global menu, defining general options to access subroutines, which in turn implement specific menus with database record handling options such as 'Append', 'Delete', 'Modify', and 'Search'.

Ring menus can also be used in a GUI application. However, as this instruction does not handle form fields, other parts of the form are disabled during the menu dialog execution. In GUI applications, ring menus are typically used to open a modal window with Yes / No / Cancel options.

  The dynamic user interface architecture is based on the Model-View-Controller (MVC) paradigm.

Syntax of the **MENU** instruction

The **MENU** instruction defines a set of options the end user can select to trigger actions in a program.

```plaintext
MENU [title]
  [ATTRIBUTES ( menu-attribute [, ] )]
  [BEFORE MENU menu-statement]
  [menu-option [, ]]
END MENU
```
where *menu-option* is one of:

\[
\text{\textbf{COMMAND} option-name} \[ \text{option-comment} \] \[ \text{HELP} \ help-number \] \text{menu-statement} \\
\text{\textbf{COMMAND KEY} ( key-name ) option-name} \[ \text{option-comment} \] \[ \text{HELP} \ help-number \] \text{menu-statement} \\
\text{\textbf{COMMAND KEY} ( key-name ) \text{menu-statement}} \\
\text{\textbf{ON ACTION} action-name} \[ \text{ATTRIBUTES} \ ( \text{action-attributes-menu} ) \] \text{menu-statement} \\
\text{\textbf{ON IDLE} seconds} \text{menu-statement} \\
\text{\textbf{ON TIMER} seconds} \text{menu-statement}
\]

where *action-attributes-menu* is:

\[
\text{\textbf{TEXT} = string} \\
\text{\textbf{COMMENT} = string} \\
\text{\textbf{IMAGE} = string} \\
\text{\textbf{ACCELERATOR} = string} \\
\text{\textbf{DEFAULTVIEW} = \{ \text{YES} \mid \text{NO} \mid \text{AUTO} \}} \\
\text{\textbf{CONTEXTMENU} = \{ \text{YES} \mid \text{NO} \mid \text{AUTO} \}} \\
\text{\textbf{DISCLOSUREINDICATOR}} \\
\]

where *menu-statement* is:

\[
\text{statement} \\
\text{CONTINUE MENU} \\
\text{EXIT MENU} \\
\text{NEXT OPTION} \text{ option} \\
\text{SHOW OPTION} \downarrow \text{ ALL} \downarrow \text{ option} \downarrow \text{, , , \ldots} \\
\text{HIDE OPTION} \downarrow \text{ ALL} \downarrow \text{ option} \downarrow \text{, , , \ldots}
\]

where *menu-attribute* is:

\[
\text{STYLE} = \{ \text{"default" \mid "popup" \mid "dialog"} \} \\
\text{COMMENT} = \text{"string"} \\
\text{IMAGE} = \text{"string"}
\]

1. *title* is a string expression defining the title of the menu.
2. *menu-attribute* is an attribute that defines the behavior and presentation of the menu.
3. *key-name* is an hot-key identifier (like F11 or Control-z).
4. *option-name* is a string expression defining the label of the menu option and identifying the action that can be executed by the user.
5. *option-comment* is a string expression containing a description for the menu option, displayed when *option-name* is the current.
6. *help-number* is an integer that allows you to associate a help message number with the menu option.
7. *action-name* identifies an action that can be executed by the user.
8. *seconds* is an integer literal or variable that defines a number of seconds.
9. *action-name* identifies an action that can be executed by the user.
10. *action-attributes* are dialog-specific action attributes.

**Related concepts**

The dynamic user interface architecture is based on the Model-View-Controller (MVC) paradigm.

**Configuring actions** on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

**Message files** on page 1059
Message files centralize strings and larger texts identified by a number, that can be used in programs.

**MENU programming steps**

Follow this procedure to use the MENU dialog instruction.

To implement a MENU statement:

1. Create a MENU block with a title and write the end of the menu block with the END MENU keywords.
2. Depending on the type of menu rendering you need, add an ATTRIBUTES clause with the required STYLE attribute.
3. List all the options that you want to offer to the end user when the menu executes. Typical CRUD programs will implement "Append", "Modify", "Delete" operations for a given database application entity (customers, orders, items tables). Typical dialog box menus have "Yes" / "No" / "Cancel" options.
4. According to TUI or GUI mode, define action views (topmenu, toolbar or form buttons) for each menu action, and use either COMMAND [KEY] or ON ACTION clauses to define the menu options.
5. When the menu is not a pop-up or dialog menu, do not forget to implement an option to leave the menu with the EXIT MENU control instruction.
6. Implement the code to be executed in every option.

**Using ring menus**

Dialog coding concepts, configuration and code structure.

**Rendering modes of a menu**

**Purpose of MENU styles**

When you add a style to a MENU's attributes list, you define the look-and-feel of that menu and how that menu acts.

**MENU rendering specification**

The rendering mode of a MENU instruction can be controlled with the STYLE dialog attribute:

```
MENU "Test" ATTRIBUTES ( STYLE = "mode" )
  ...
END MENU
```

**Note:** MENU ... ATTRIBUTES(STYLE="mode") is not a presentation style defined in a 4st file: It defines a display mode, a rendering hint for front-ends.

The decoration of the different rendering modes of a MENU depends on the front-end type and the platform used. Consider testing the menu instruction with all front-ends that you intend to support for end users.
**Default MENU rendering**

By default, if no **STYLE** attribute is used in the **MENU** instruction, each menu option will be displayed as a push button in a dedicated area of the current window, depending on the front end. This dedicated area is called the action frame.

Note that when an explicit action view (for example, a **BUTTON** in form layout) is associated with a menu option, the default button will not appear in the action frame area.

The default rendering of a **MENU**, including the position of the action frame in the window, can be controlled with **window presentation style** attributes.

```
MAIN
  MENU "File"
    COMMAND "New"
      DISPLAY "New"
    COMMAND "Open"
      DISPLAY "Open"
    COMMAND "Save"
      DISPLAY "Save"
    COMMAND "Import"
      DISPLAY "Import"
    COMMAND "Quit"
      EXIT MENU
  END MENU
END MAIN
```

**Figure 73: Default rendering of MENU with the Genero Desktop Client**

**Modal dialog MENU rendering**

Menus can be rendered in a modal dialog window by specifying the **STYLE="dialog"** attribute in the **MENU** instruction.

```
MAIN
  MENU "Example of dialog menu"
    ATTRIBUTES ( STYLE="dialog", COMMENT="Delete the file?" )
    COMMAND "Yes"
      DISPLAY "Yes"
    COMMAND "No"
      DISPLAY "No"
    COMMAND "Cancel"
      DISPLAY "Cancel"
  END MENU
END MAIN
```
When the user clicks on an option, the `MENU` instruction automatically exits and the modal dialog window closes. There is no need for an `EXIT MENU` command.

With `STYLE="dialog"`, when the user clicks on an option, the `MENU` instruction automatically exits and the pop-up menu closes. There is no need for an `EXIT MENU` command.

**Figure 74: MENU displayed as a modal dialog with the Genero Desktop Client**

![Example of dialog menu](image)

**Pop-up MENU rendering**

Menus can also be displayed as pop-up choice lists, when the `STYLE="popup"` attribute is used in the `MENU` instruction.

```plaintext
MAIN
  DEFINE r INTEGER
  MENU "test"
    COMMAND "popup"
    DISPLAY popup()
    COMMAND "quit"
    EXIT MENU
  END MENU
END MAIN

FUNCTION popup()
  DEFINE r INTEGER
  LET r = -1
  MENU "unused" ATTRIBUTES ( STYLE="popup" )
    COMMAND "Copy all"
    LET r = 1
    COMMAND "Copy current"
    LET r = 2
    COMMAND "Paste all"
    LET r = 3
    COMMAND "Paste current"
    LET r = 4
  END MENU
  RETURN r
END FUNCTION
```

With `STYLE="popup"`, when the user clicks on an option, the `MENU` instruction automatically exits and the pop-up menu closes. There is no need for an `EXIT MENU` command.
**Figure 75: MENU displayed as pop-up list with the Genero Desktop Client**

**MENU rendering on mobile platforms**

On mobile devices, the rendering of the MENU dialog depends on whether or not the current window has a form.

If a MENU is active and the current Window has no form, then the MENU is shown as a list of actions.

If a MENU is active and has a FORM, then the menu actions are rendered like all other dialog actions (see Mobile programming chapter for more details).

For example, when executing the following code with and without a form as program argument:

```plaintext
MAIN
    IF num_args()==1 THEN
        OPEN FORM f1 FROM arg_val(1)
        DISPLAY FORM f1
    END IF
    MENU "Farbee logistics"
    COMMAND "Orders" "Enter orders"
    COMMAND "Customers" "Manage customer information"
    COMMAND "Stock" "Check stock status"
    COMMAND "Setting" "Change app settings"
    COMMAND "Quit"
    EXIT MENU
END MENU
END MAIN
```

You get the following rendering in Genero Mobile for Android. On the left side (without form), the MENU shows up as a list of options that can be selected. On the right (with form), the MENU options render as default action views in the Android™ action bar.
Binding action views to menu options

A MENU statement is a controller for user actions, defining action handlers triggered by action views. Actions views in the form file (i.e. toolbar buttons, topmenu items or push buttons) are bound to menu options by name. For example, if a MENU instruction defines ON ACTION sendmail, a form BUTTON with the name "sendmail" will be attached to that action handler.

When binding action views to menu option clauses, the action name is case sensitive. The compiler converts COMMAND labels and ON ACTION identifiers to lowercase to create the action name. It is recommended that you use all lowercase letters when defining the action name for action views and menu options.

Menu options can also be defined with the COMMAND clause. Unlike ON ACTION, the COMMAND clause takes a string literal as argument, that defines both the action name and the default text to be displayed in the default action view. For example, COMMAND "Help" will define the action name help and the default button text "Help". Action views must be bound with the action name in lower case (help).

When the menu is rendered as a pop-up of dialog box, no explicit action views need to be defined, default action views will be created and will get the decoration specified in action defaults.

Defines a push-button that can trigger an action.

Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

MENU instruction configuration

The rendering and behavior of a MENU instruction can be configured with the ATTRIBUTES clause:

```
MENU "Question"
  ATTRIBUTES {
    STYLE="dialog",
    COMMENT="Do you want to commit your changes?"
  }
```

When the STYLE dialog attribute is set to 'default' or when you do not specify the menu type, the runtime system generates a default decoration as a set of buttons in a specific area of the current window.

When the STYLE attribute is set to 'dialog', the menu options appear as buttons at the bottom in a temporary modal window, in which you can define the message and the icon with the COMMENT and IMAGE attributes.

When the STYLE is set to 'popup', the menu appears as a pop-up menu (a context menu).

If the menu is a "dialog" or "popup", the dialog is automatically exited after any action clause such as ON ACTION, COMMAND or ON IDLE.

Related concepts

Rendering modes of a menu on page 1361
Syntax of the MENU instruction on page 1359
The MENU instruction defines a set of options the end user can select to trigger actions in a program.

Default actions in MENU

When an MENU instruction executes, the runtime system creates a set of default actions.

Table 338: Default actions created for the MENU instruction

<table>
<thead>
<tr>
<th>Default action</th>
<th>Control Block execution order</th>
</tr>
</thead>
<tbody>
<tr>
<td>close</td>
<td>Created to execute COMMAND KEY (INTERRUPT) if used (can be overwritten with ON ACTION close)</td>
</tr>
<tr>
<td></td>
<td>Default action view is hidden. See Implementing the close action on page 1672.</td>
</tr>
<tr>
<td>help</td>
<td>Shows the help topic defined by the HELP clause.</td>
</tr>
<tr>
<td></td>
<td>Default action view is hidden.</td>
</tr>
</tbody>
</table>

Window close events can be trapped with COMMAND KEY (INTERRUPT) clause.

Related concepts

The model-view-controller paradigm on page 1608
The dynamic user interface architecture is based on the Model-View-Controller (MVC) paradigm.

**MENU control blocks**

**BEFORE MENU block**

If the MENU block contains a BEFORE MENU clause, statements within this clause are executed before the menu dialog starts.

This block is typically used to hide or disable some menu options depending on the current context of the program. For example, when the current user is not allowed to create new records, the menu options can be disabled as follows:

```
MENU "Orders"
BEFORE MENU
    CALL DIALOG.setActionActive("append", can_user_append() )
    ... 
    COMMAND "Append" -- creates "append" action (lowercase)
    ...
    ...
END MENU
```

In TUI mode, the menu options can also be disabled, but they will still be displayed on the screen. The end user will see the option, but cannot select it. In this case it's more convenient to hide the option from the end user with the DIALOG.setActionHidden() method, instead of disabling the action.

**Related concepts**

- The ui.Dialog class provides a set of methods to configure, query and control the current interactive instruction.

**MENU interaction blocks**

**COMMAND [KEY()] "option" block**

The COMMAND [KEY(key-name)] "option-name" clause defines a menu action handler with a set of instructions to be executed when an action is invoked. The option text (option-name), converted to lowercase letters, defines the name of the action.

For example, when defining:

```
COMMAND "Hello"
```

The name of the action will be "hello" (not "Hello" with a capital H).

When used with the KEY() clause, the command specifies both accelerator keys and an option text. For backward compatibility, a comma-separated key list is supported in the KEY() specification. Consider using a single key for new developments, or prefer accelerator definition with action defaults.

Action defaults will be applied by using the action name defined by the option text (converted to lower case).

Explicit action views defined in the form (BUTTON in layout, TOPMENU or TOOLBAR items) will get all action defaults associated to the menu command, while default action views (i.e. buttons in the action frame) will be decorated with the menu option text and comment specified in the program (i.e. the TEXT and COMMENT attributes of the corresponding action defaults entry are not used for the default action views). However, other attributes such as the IMAGE will also be applied to default action views.

For example, when defining:

```
COMMAND "Hello" "This is the Hello option"
```

The name of the action will become "hello", the default action view button text will be "Hello", and the button hint will be "This is the Hello option", even if an action default defines a different text or comment for
the "hello" action. If the corresponding action default defines a IMAGE icon, it will display in the default action view button.

The KEY() clause can specify up to four accelerator attributes for the action. The keys defined in the program will take precedence over accelerators defined with action defaults.

The first letter of the display text of a COMMAND menu clause can be used as default accelerator. When this first letter is not used by other menu option labels, pressing the key corresponding to that letter will execute that action. When the first letter is also used in other menu options, pressing the key will toggle the focus between all default action views that share the same letter. For example:

```
MENU
  COMMAND "Start"
  DISPLAY "Start"
  COMMAND "Stop"
  DISPLAY "Stop"
  COMMAND "Quit"
  EXIT MENU
END MENU
```

In this example, when pressing S on the keyboard, the focus will toggle between "Start" and "Stop" buttons, and the current option can be selected with the Return or Space key. When pressing Q, the "Quit" action will be fired.

To write abstract code without decoration in your programs, use the ON ACTION clause instead of COMMAND [KEY], except if the action view must get the focus.

Note that if you use an ampersand (&) in the command name, some front-ends consider the letter following & as an Alt-key accelerator, and the letter will be underscored. However the ampersand forms part of the action name. For example, COMMAND "&Save" will create an action with the name "\&save".

In TUI mode, actions created with COMMAND [KEY] do not get accelerators from action defaults; Only actions defined with ON ACTION will get accelerators of action defaults.

Action handling basics on page 1640
This topic describes the basics of action views, action events, and action handlers.

COMMAND KEY() block

The COMMAND KEY(key-name) block (without an option text) defines a menu action handler with a set of instructions to be executed when an action is invoked. The KEY() clause defines one or several accelerator keys separated by a comma. The specified key name must be one of the virtual keys.

For backward compatibility, a comma-separated key list is supported in the KEY() specification. Consider using a single key for new developments, or prefer accelerator definition with action defaults.

While a COMMAND KEY(key-name) "option-name" (with option text) defines the name of the action with the option text (converted to lowercase), a COMMAND KEY(key-name) (without option text), defines the action name from the last key in the KEY() list, converted to lowercase letters. For example, with COMMAND KEY(F10, F12, Control-Z), the name of the action will be "control-z".

Action defaults will be applied by using the key name of the KEY() clause. With a list of keys, the last key name will be used to apply action defaults, because it defines the action name.
The `KEY()` clause can specify up to four accelerator attributes for the action. The keys defined in the program will take precedence over accelerators defined with action defaults.

By default, `COMMAND KEY(key-name)` actions are not decorated with a default action (i.e. a button in the action frame will not appear for these actions). However, by defining the `text` attribute within action defaults, the default action view button will be visible. This allows you to decorate existing `COMMAND KEY(key-name)` clauses with graphical buttons without changing the program code.

To write abstract code without decoration in your programs, use the `ON ACTION` clause instead of `COMMAND [KEY]`, except if the action view must get the focus.

In TUI mode, actions created with `COMMAND [KEY]` do not get accelerators from action defaults; Only actions defined with `ON ACTION` will get accelerators of action defaults.

**Related concepts**

- The model-view-controller paradigm on page 1608
- The dynamic user interface architecture is based on the Model-View-Controller (MVC) paradigm.
- Configuring actions on page 1646
- Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.
- ON ACTION block on page 1369
- Syntax of the `MENU` instruction on page 1359
- The `MENU` instruction defines a set of options the end user can select to trigger actions in a program.

**ON ACTION block**

The `ON ACTION action-name` blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
ON ACTION action-name
    instruction
    ...
```

Action blocks are bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

This example defines an action block to open a typical zoom window and let the user select a customer record:

```
ON ACTION zoom
    CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as `INPUT`, `INPUT ARRAY` and `CONSTRUCT`, if an action is specific to a field, add the `INFIELD` clause to have the action automatically enabled when the corresponding field gets the focus:

```
ON ACTION zoom INFIELD cust_city
    CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the `ON ACTION` handler needs to define its own attributes at the program level. This can be done by adding the `ATTRIBUTES()` clause of `ON ACTION`:

```
ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
    CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1640.
**ON IDLE block**

The ON IDLE seconds clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

As ON IDLE can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of ON IDLE must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON IDLE trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or gets a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
  IF ask_question("Do you want to reload information from the database?") THEN
    -- Fetch data back from the db server
  END IF
```

**Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

**Related concepts**

- [Get program control if user inactive](#)
- [Execute some code after a given number of seconds, when the user does not interact with the program](#)

**ON TIMER block**

The ON TIMER seconds clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

As ON TIMER can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of ON TIMER must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON TIMER trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
  CALL check_for_messages()
```

**Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

- [Execute some code after a given number of seconds, with or without user interaction with the program](#)
MENU control instructions

SHOW/HIDE OPTION instruction

Syntax:

```
{ HIDE | SHOW } OPTION
  { ALL
    option-name [ , ... ]
  }
```

Usage

The SHOW OPTION instruction will show/enable action views corresponding the listed menu options. The default action views (buttons in action frame) are made visible and the explicit action views (buttons in form) are enabled. The HIDE OPTION instruction will hide default action views and disable explicit action views.

Use the ALL keyword reference all menu options. In a menu that contains many options, you typically do a HIDE OPTIONS ALL followed by HIDE OPTION to show a subset of the menu options.

The SHOW OPTION and HIDE OPTION instructions are provided for backward compatibility. To hide and show default action views, use the DIALOG.setActionHidden() method instead. In GUI applications, it is recommended that you rather disable actions, instead of hiding them to the end user.

Example

```
MENU "Customers"
  BEFORE MENU
    HIDE OPTION ALL
    SHOW OPTION "Add", "Exit"
  ...
```

Related concepts

ui.Dialog.setActionHidden on page 2395
Showing or hiding a default action view.

EXIT MENU instruction

Syntax

```
EXIT MENU
```

Usage

EXIT MENU statement terminates the MENU block and continues the program flow with the statement after the menu block.

Example

```
MENU "Stock"
  ...
  COMMAND "Exit"
  EXIT MENU
END MENU
```

Related concepts

EXIT block-name on page 347
The EXIT block instruction transfers control out of the current program block.

**CONTINUE MENU instruction**

**Syntax**

```
CONTINUE MENU
```

**Usage**

The CONTINUE MENU instruction resumes the execution of a MENU block.

CONTINUE MENU ignores the remaining instructions in the current program section of a MENU block, re-displays the menu options and gives the control back to the user to select a new menu option.

The statements following the CONTINUE MENU instruction are skipped.

**Example**

```
MENU "Stock"
...
COMMAND "Exit"
   IF question("Exit the program?")==FALSE THEN
       CONTINUE MENU
   END IF
   CALL commit_changes()
   EXIT MENU
END MENU
```

**Related concepts**

CONTINUE block-name on page 346

The CONTINUE block-name instruction resumes execution of a loop or dialog statement.

**Examples**

MENU dialog examples.

**Example 1: MENU with abstract action options**

```
MAIN
MENU
   ON ACTION new
       CALL newFile()
   ON ACTION open
       CALL openFile()
   ON ACTION save
       CALL saveFile()
   ON ACTION import
       LOAD FROM "infile.dat" INSERT INTO table
   ON ACTION quit
       EXIT PROGRAM
END MENU
END MAIN
```

**Example 2: MENU with text-mode options**

```
MAIN
MENU "File"
   COMMAND KEY ( CONTROL-N ) "New" "Creates New File" HELP 101
       CALL newFile()
   COMMAND KEY ( CONTROL-O ) "Open" "Open existing File" HELP 102
       CALL openFile()
   COMMAND KEY ( CONTROL-S ) "Save" "Save Current File" HELP 103
```
Example 3: MENU with STYLE="dialog"

The next code example implements typical message box utility functions implemented with MENU dialogs:

```plaintext
FUNCTION mbox_ync(title,msg)
    DEFINE title, msg STRING
    DEFINE res SMALLINT
    MENU title ATTRIBUTES(STYLE="dialog",COMMENT=msg)
        ON ACTION yes LET res = 1
        ON ACTION no LET res = 0
        ON ACTION cancel LET res = -1
    END MENU
    RETURN res
END FUNCTION

FUNCTION mbox_yn(title,msg)
    DEFINE title, msg STRING
    DEFINE res BOOLEAN
    MENU title ATTRIBUTES(STYLE="dialog",COMMENT=msg)
        ON ACTION yes LET res = TRUE
        ON ACTION no LET res = FALSE
    END MENU
    RETURN res
END FUNCTION

FUNCTION mbox_ok(title,msg)
    DEFINE title, msg STRING
    MENU title ATTRIBUTES(STYLE="dialog",COMMENT=msg)
        ON ACTION accept
    END MENU
END FUNCTION
```

Record input (INPUT)

The INPUT instruction provides single record input control in an application form.

  - Default actions in INPUT on page 1380
  - INPUT control blocks on page 1381
  - INPUT interaction blocks on page 1386
  - INPUT control instructions on page 1388
- Examples on page 1392
  - Example 1: INPUT with binding by field position on page 1392
  - Example 2: INPUT with binding by field name on page 1392
Understanding the INPUT instruction

The INPUT instruction controls a single record input from form fields.

The INPUT statement binds program variables to screen-records for data entry in form fields. The INPUT statement uses the current form in the current window. Before executing the INPUT statement, record data must be fetched from the database table into the program variables using the input statement.

During the INPUT statement execution, the user can edit the record fields, while the program controls the behavior of the instruction with control blocks.

To terminate the INPUT execution, the user can validate (or cancel) the dialog to commit (or invalidate) the modifications made in the record.

When the statement completes execution, the form is deactivated. After the user terminates the input (for example, with the "accept" key), the program must test the INT_FLAG variable to check if the dialog was validated (or canceled), and then can use the INSERT or UPDATE SQL statements to modify the appropriate database tables.

Related concepts

Dialog programming basics on page 1608

This section describes basic dialog programming concepts.

Syntax of the INPUT instruction

The INPUT statement supports data entry in fields of the current form.

Syntax

```
INPUT [ BY NAME { variable | record.* } [, ...] ] [ WITHOUT DEFAULTS ]
[ variable | record.* ] [, ...]
[ WITHOUT DEFAULTS ]
FROM field-list

[ ATTRIBUTES ( { display-attribute | control-attribute } [, ...] ) ]
[ HELP help-number ]
[ dialog-control-block ]
END INPUT
```

where dialog-control-block is one of:

```
| BEFORE INPUT  |
| AFTER INPUT   |
| BEFORE FIELD   |
| AFTER FIELD    |
| ON CHANGE      |
| ON IDLE        |
| ON TIMER       |
| ON ACTION      |
| ON KEY         |
```

where action-attributes-input is:

```
| TEXT = string |
| COMMENT = string |
```
1. `variable` is a program variable that will be filled by the `INPUT` statement.
2. `record.*` is a record variable that will be filled by the `INPUT` statement.
3. *help-number* is an integer that allows you to associate a help message number with the instruction.
4. *field-name* is the identifier of a field of the current form.
5. *table-name* is the identifier of a database table of the current form.
6. *screen-record* is the identifier of a screen record of the current form.
7. *screen-array* is the screen array that will be used in the form.
8. *line* is a screen array line in the form.
9. *key-name* is a hot-key identifier (like F11 or Control-z).
10. *dialog-name* is the identifier of the dialog.
11. *seconds* is an integer literal or variable that defines a number of seconds.
12. *action-name* identifies an action that can be executed by the user.
13. *statement* is any instruction supported by the language.
14. *boolean* is a boolean expression evaluated when the dialog starts.
15. *action-attributes* are dialog-specific action attributes.

**Related concepts**

  Form fields can be grouped in a screen record or screen array definition.
- **Configuring actions** on page 1646
  Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.
- **Message files** on page 1059
  Message files centralize strings and larger texts identified by a number, that can be used in programs.

**INPUT programming steps**

Follow this procedure to use the INPUT dialog instruction.

To implement the INPUT statement:

1. Create a form specification file, with an optional screen record.
   The screen record identifies the presentation elements to be used by the runtime system to display the records. If you omit the declaration of the screen record in the form file, the runtime system will use the default screen records created by the form compiler for each table listed in the TABLES section and for the FORMONLY pseudo-table.
2. Make sure that the program controls interruption handling with DEFER INTERRUPT, to manage the validation/cancellation of the interactive dialog.
3. Define a program record with the DEFINE instruction.
   The members of the program record must correspond to the elements of the screen record, by number and data types.
4. Open and display the form, using an OPEN WINDOW with the WITH FORM clause or the OPEN FORM/DISPLAY FORM instructions.
5. If needed, fill the program record with data, for example with a result set cursor.
6. Set the INT_FLAG variable to FALSE.
7. Write the INPUT statement to handle data input.
8. Inside the INPUT statement, control the behavior of the instruction with BEFORE INPUT, BEFORE FIELD, AFTER FIELD, AFTER INPUT, and ON ACTION blocks.
9. After the interaction statement block, test the INT_FLAG predefined variable to check if the dialog was canceled (INT_FLAG=TRUE) or validated (INT_FLAG=FALSE).
   If the INT_FLAG variable is TRUE, you should reset it to FALSE so as not to disturb code that relies on this variable to detect interruption events from the GUI front-end or TUI console.

Using simple record inputs
Dialog coding concepts, configuration and code structure.

Variable binding in INPUT
The INPUT instruction binds program variables (typically, members of a RECORD) to the fields of a screen record of the current form, and synchronizes the data between field input buffers and program variables.

Binding variables and fields by name
The INPUT BY NAME variable-list instruction implicitly binds the fields to the program variables that have the same identifiers as the form field names. The program variables are typically defined within a record declared with a LIKE table.* based a database schema, to get the same names as the form fields defined with database column references. The runtime system ignores any record name prefix when making the match, only record member names matter. The unqualified names of the variables and of the fields must be unique and unambiguous within their respective domains. If they are not, the runtime system generates an exception.

```
SCHEMA stock
DEFINE custrec RECORD LIKE customer.*
...
INPUT BY NAME custrec.*
...
END INPUT
```

Binding variables and fields by position
The INPUT variable-list FROM field-list clause explicitly binds the variables to form fields by position. The form can include other fields that are not part of the specified variable list, but the number of variables or record members must equal the number of form fields listed in the FROM clause. Each variable must be of the same (or a compatible) data type as the corresponding form field. When the user enters data, the runtime system checks the entered value against the data type of the variable, not the data type of the form field.

```
SCHEMA stock
DEFINE custrec RECORD LIKE customer.*,
        comment VARCHAR(100)
...
INPUT custrec.*, comment FROM sr_cust.*, cmt
...
END INPUT
```
When using the `FROM` clause with a screen record followed by a `.,*` (dot star), keep in mind that program variables are bound to screen record fields by position, so you must make sure that the program variables are defined (or listed) in the same order as the screen array fields.

**Serial column support**

The program variables can be of any data type: The runtime system will adapt input and display rules to the variable type. If a variable is declared with the `LIKE` clause and uses a column defined as `SERIAL / SERIAL8 / BIGSERIAL`, the runtime system will treat the field as if it was defined with the `NOENTRY` attribute in the form file: Since values of serial columns are automatically generated by the database server, no user input is required for such fields.

**The UNBUFFERED mode**

The variables act as data model to display data or to get user input through the `INPUT` instruction. Always use the variables if you want to change some field values by program. When using the `UNBUFFERED` attribute, the instruction is sensitive to program variable changes. If you need to display new data during the `INPUT` execution, just assign the values to the program variables; the runtime system will automatically display the values to the screen:

```plaintext
INPUT p_items.* FROM s_items.* ATTRIBUTES (UNBUFFERED)
ON CHANGE code
   IF p_items.code = "A34" THEN
      LET p_items.desc = "Item A34"
   END IF
END INPUT
```

**Handling default field values**

When the `INPUT` instruction executes, any column default values are displayed in the screen fields, unless you specify the `WITHOUT DEFAULTS` keywords. The column default values are specified in the form specification file with the `DEFAULT` attribute, or in the database schema files.

If you specify the `WITHOUT DEFAULTS` option. However, the form fields display the current values of the variables when the `INPUT` statement begins. This option is available with both the `BY NAME` and the `FROM` binding clauses.

```plaintext
LET p_items.code = "A34"
INPUT p_items.* FROM s_items.* WITHOUT DEFAULTS
BEFORE INPUT
   MESSAGE "it is recommended that you see A34 in field 'code'..."
END INPUT
```

**Using PHANTOM fields**

If the program record has the same structure as a database table (this is the case when the record is defined with a `LIKE` clause), you may not want to display/use some of the columns. You can achieve this by used PHANTOM fields in the screen record definition. Phantom fields will only be used to bind program variables, and will not be transmitted to the front-end for display.

Defines database table structures with column type information to be reused in program variable definitions.

**Phantom fields** on page 1142
A **PHANTOM** field defines a screen-record field which is not rendered in the layout (it acts as a hidden field).

**INPUT instruction configuration**

This section describes the options that can be specified in the **ATTRIBUTES** clause of the **INPUT** instruction. The options of the **ATTRIBUTES** clause override all default attributes and temporarily override any display attributes that the **OPTIONS** or the **OPEN WINDOW** statement specified for these fields. With the **INPUT** statement, the **INVISIBLE** attribute is ignored.

**NAME option**
The **NAME** attribute can be used to name the **INPUT** dialog. This is especially used to identify actions of the dialog.

**HELP option**
The **HELP** clause specifies the number of a help message to display if the user invokes the help while the focus is in any field used by the instruction. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The **HELP** clause overrides the **HELP** attribute.

**WITHOUT DEFAULTS option**
Indicates if the fields controlled by **INPUT** must be filled (**FALSE**) or not (**TRUE**) with the column default values defined in the form specification file or the database schema files. The runtime system assumes that the field satisfies the **REQUIRED** attribute when **WITHOUT DEFAULTS** is used. If the **WITHOUT DEFAULT** option is not used, all fields defined with the **REQUIRED** attribute must be visited and modified. Fields not defined as **NOT NULL** can be left empty.

**FIELD ORDER FORM option**
By default, the tabbing order is defined by the variable binding list in the instruction description. You can control the tabbing order by using the **FIELD ORDER FORM** attribute: When this attribute is used, the tabbing order is defined by the **TABINDEX** attribute of the form fields. If this attribute is used, the **Dialog.fieldOrder** FGLPROFILE entry is ignored.

The **OPTIONS** instruction can also change the behavior of the **INPUT** instruction, with the **INPUT WRAP** or **FIELD ORDER FORM options**.

**UNBUFFERED option**
Indicates that the dialog must be sensitive to program variable changes. When using this option, you bypass the traditional "buffered" mode.

When using the traditional "buffered" mode, program variable changes are not automatically displayed to form fields; You need to execute a **DISPLAY TO** or **DISPLAY BY NAME**. Additionally, if an action is triggered, the value of the current field is not validated and is not copied into the corresponding program variable. The only way to get the text of the current field is to use **GET_FLDBUF()**.

If the "unbuffered" mode is used, program variables and form fields are automatically synchronized. You don't need to display explicitly values with a **DISPLAY TO** or **DISPLAY BY NAME**. When an action is triggered, the value of the current field is validated and is copied into the corresponding program variable.
**ACCEPT option**

The `ACCEPT` attribute can be set to `FALSE` to avoid the automatic creation of the accept default action. This option can be used for example when you want to write a specific validation procedure, by using `ACCEPT INPUT`.

**CANCEL option**

The `CANCEL` attribute can be set to `FALSE` to avoid the automatic creation of the cancel default action. This is useful for example when you only need a validation action (accept), or when you want to write a specific cancellation procedure, by using `EXIT INPUT`.

If the `CANCEL=FALSE` option is set, no `close` action will be created, and you must write an `ON ACTION close` control block to create an explicit action.

**Related concepts**

- *Syntax of the INPUT instruction* on page 1374
- The `INPUT` statement supports data entry in fields of the current form.
- *Database schema* on page 476
  Defines database table structures with column type information to be reused in program variable definitions.

**Default actions in INPUT**

When an `INPUT` instruction executes, the runtime system creates a set of default actions.

Depending on the invoked default action, field validation occurs and different `INPUT` control blocks are executed.

This table lists the default actions created for this dialog:

**Table 339: Default actions created for the INPUT dialog**

<table>
<thead>
<tr>
<th>Default action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>accept</td>
<td>Validates the <code>INPUT</code> dialog (validates fields and leaves the dialog)</td>
</tr>
<tr>
<td></td>
<td><em>Creation can be avoided with <code>ACCEPT</code> attribute.</em></td>
</tr>
<tr>
<td>cancel</td>
<td>Cancels the <code>INPUT</code> dialog (no validation, <code>INT_FLAG</code> is set to <code>TRUE</code>)</td>
</tr>
<tr>
<td></td>
<td><em>Creation can be avoided with <code>CANCEL</code> attribute.</em></td>
</tr>
<tr>
<td>close</td>
<td>By default, cancels the <code>INPUT</code> dialog (no validation, <code>INT_FLAG</code> is set to <code>TRUE</code>)</td>
</tr>
<tr>
<td></td>
<td>Default action view is hidden. See <em>Implementing the close action</em> on page 1672.</td>
</tr>
<tr>
<td>help</td>
<td>Shows the help topic defined by the <code>HELP</code> clause.</td>
</tr>
<tr>
<td></td>
<td><em>Only created when a <code>HELP</code> clause is defined.</em></td>
</tr>
</tbody>
</table>

The accept and cancel default actions can be avoided with the `ACCEPT` and `CANCEL` dialog control attributes:

```
INPUT BY NAME field1 ATTRIBUTES ( CANCEL=FALSE )
...```

BEFORE INPUT block on page 1381

AFTER INPUT block on page 1382

BEFORE FIELD block on page 1383

ON CHANGE block on page 1384

AFTER FIELD block on page 1385

**BEFORE INPUT block**

**BEFORE INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs**

In a singular INPUT, INPUT ARRAY instruction, or when used as parallel dialog, the BEFORE INPUT is only executed once when the dialog is started.

The BEFORE INPUT block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```plaintext
INPUT BY NAME cust_rec.* ...
BEFORE INPUT
MESSAGE "Input customer information"
CALL DIALOG.setActionActive("check_info", is_super_user() )
CALL DIALOG.setFieldActive("cust_comment", is_super_user() )
...
```
The fields are initialized with the defaults values before the **BEFORE INPUT** block is executed. When the **INPUT** instruction uses the **WITHOUT DEFAULTS** option, the default values are taken from the program variables bound to the fields, otherwise (with defaults), the **DEFAULT** attributes of the form fields are used.

Use the **NEXT FIELD** control instruction in the **BEFORE INPUT** block, to jump to a specific field when the dialog starts.

### **BEFORE INPUT** block in **INPUT** and **INPUT ARRAY** of procedural **DIALOG**

In an **INPUT** or **INPUT ARRAY** sub-dialog of a procedural **DIALOG** instruction, the **BEFORE INPUT** block is executed when the focus goes to a group of fields driven by the sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

When the focus is in a list driven by an **INPUT ARRAY** sub-dialog, moving to a different row will not invoke the **BEFORE INPUT** block.

**BEFORE INPUT** is executed after the **BEFORE DIALOG** block and before the **BEFORE ROW**, **BEFORE FIELD** blocks.

In this example, the **BEFORE INPUT** block is used to set up a specific action and display a message:

```
INPUT BY NAME p_order.*
BEFORE INPUT
    CALL DIALOG.setActionActive("validate_order", TRUE)
```

### Related concepts

- **BEFORE CONSTRUCT** block on page 1469
- **BEFORE DISPLAY** block on page 1402
- **AFTER INPUT** block on page 1382

### **AFTER INPUT** block

#### **AFTER INPUT** block in singular and parallel **INPUT**, **INPUT ARRAY** dialogs

In a singular **INPUT**, **INPUT ARRAY** instruction, or when used as parallel dialog, the **AFTER INPUT** is only executed once when dialog ends.

The **AFTER INPUT** block is executed after the user has validated or canceled the **INPUT** or **INPUT ARRAY** dialog with the accept or cancel default actions, or when the **ACCEPT INPUT** instruction is executed.

The **AFTER INPUT** block is not executed when the **EXIT INPUT** instruction is performed.

In singular and parallel dialogs, this block is typically used to implement global dialog validation rules depending from several fields. If the values entered by the user do not satisfy the constraints, use the **NEXT FIELD** instruction to force the dialog to continue. The **CONTINUE INPUT** instruction can be used instead of **NEXT FIELD**, when no particular field has to be select.

Before checking the validation rules, make sure that the **INT_FLAG** variable is **FALSE**: in case if the user cancels the dialog, the validation rules must be skipped.

```
INPUT BY NAME cust_rec.*
    WITHOUT DEFAULTS ATTRIBUTES ( UNBUFFERED )
...

AFTER INPUT
    IF NOT INT_FLAG THEN
        IF cust_rec.cust_address IS NOT NULL
            AND cust_rec.cust_zipcode IS NULL THEN
                ERROR "Address is incomplete, enter a zipcode."
                NEXT FIELD zipcode
        END IF
    END IF
END IF
```
To limit the validation to fields that have been modified by the end user, you can call the `FIELD_TOUCHED()` function or the `DIALOG.getFieldTouched()` method to check if a field has changed during the dialog execution. This will make your validation code faster if the user has only modified a couple of fields in a large form.

**AFTER INPUT block in INPUT and INPUT ARRAY of procedural DIALOG**

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `AFTER INPUT` block is executed when the focus is lost by a group of fields driven by an `INPUT` or `INPUT ARRAY` sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus. When the focus is in a list driven by an `INPUT ARRAY` sub-dialog, moving to a different row will not invoke the `AFTER INPUT` block.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

`AFTER INPUT` is executed after the `AFTER FIELD`, `AFTER ROW` blocks and before the `AFTER DIALOG` block.

Executing a `NEXT FIELD` in the `AFTER INPUT` control block will keep the focus in the group of fields. Within an `INPUT ARRAY` sub-dialog, `NEXT FIELD` will keep the focus in the list and stay in the current row. You typically use this behavior to control user input.

In this example, the `AFTER INPUT` block is used to validate data and disable an action that can only be used in the current group:

```plaintext
INPUT BY NAME p_order.*
AFTER INPUT
  IF NOT check_order_data(DIALOG) THEN
    NEXT FIELD CURRENT
  END IF
  CALL DIALOG.setFieldActive("validate_order", FALSE)
END INPUT
```

**Related concepts**

- [AFTER DISPLAY block](#) on page 1403
- [AFTER CONSTRUCT block](#) on page 1470
- [BEFORE INPUT block](#) on page 1381

**BEFORE FIELD block**

In dialog instructions `INPUT`, `INPUT ARRAY`, `CONSTRUCT` or in a `DISPLAY ARRAY` using the `FOCUSONFIELD` attribute, the `BEFORE FIELD` block is executed every time the specified field gets the focus.

For single record inputs driven by `INPUT` or query by example (QBEs) driven by `CONSTRUCT`, the `BEFORE FIELD` block is executed when moving the focus from field to field.

For editable lists driven by `INPUT ARRAY`, the `BEFORE FIELD` block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by `DISPLAY ARRAY` using the `FOCUSONFIELD` attribute, the `BEFORE FIELD` block is executed when moving the focus from field to field. However, the fields will not be editable as in an `INPUT ARRAY`.

**Important:** The `BEFORE FIELD` block is also executed when performing a `NEXT FIELD` instruction.

The `BEFORE FIELD` keywords must be followed by a list of form field specification. The screen-record name can be omitted.

`BEFORE FIELD` is executed after `BEFORE INPUT`, `BEFORE CONSTRUCT`, `BEFORE ROW` and `BEFORE INSERT`.

Use this block to do some field value initialization, or to display a message to the user:

```plaintext
INPUT BY NAME p_cust.* ...
```
BEFORE FIELD cust_status
    LET p_cust.cust_comment = NULL
    MESSAGE "Enter customer status"

When using the default FIELD ORDER CONSTRAINT mode, the dialog executes the BEFORE FIELD block of the field corresponding to the first variable of an INPUT or INPUT ARRAY, even if that field is not editable (NOENTRY, hidden or disabled). The block is executed when you enter the dialog and every time you create a new row in the case of INPUT ARRAY. This behavior is supported for backward compatibility. The block is not executed when using the FIELD ORDER FORM, the mode recommended for DIALOG instructions.

With the FIELD ORDER FORM mode, for each dialog executing the first time with a specific form, the BEFORE FIELD block will be invoked for the first field of the initial tabbing list defined by the form, even if that field was hidden or moved around in a table. The dialog then behaves as if a NEXT FIELD first-visible-column would have been done in the BEFORE FIELD of that field.

When form-level validation occurs and a field contains an invalid value, the dialog gives the focus to the field, but no BEFORE FIELD trigger will be executed.

Related concepts
NEXT FIELD instruction on page 1389
Form-level validation rules on page 1627
Form-level validation rules can be defined for each field controlled by a dialog.
AFTER FIELD block on page 1385

ON CHANGE block

The ON CHANGE block can be used to detect that a field changed by user input. The ON CHANGE block is executed if the value has changed since the field got the focus and if the modification flag is set.

The ON CHANGE block can be used in INPUT, INPUT ARRAY and CONSTRUCT dialogs.

For editable fields defined as EDIT, TEXTEDIT or BUTTONEDIT, the ON CHANGE block is executed when leaving a field, if the value of the specified field has changed since the field got the focus and if the modification flag is set for the field. You leave the field when you validate the dialog, when you move to another field, or when you move to another row in an INPUT ARRAY. However, if the text edit field is defined with the COMPLETER attribute to enable autocompletion, the ON CHANGE trigger will be fired after a short period of time, when the user has typed characters in.

For editable fields defined as CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, TIMEEDIT, RADIOGROUP, SPINEDIT, SLIDER or URL-based WEBCOMPONENT (when the COMPONENTTYPE attribute is not used), the ON CHANGE block is invoked immediately when the user changes the value with the widget edition feature. For example, when toggling the state of a CHECKBOX, when selecting an item in a COMBOBOX list, or when choosing a date in the calendar of a DATEEDIT. Note that for such item types, when ON CHANGE is fired, the modification flag is always set.

ON CHANGE order_checked -- Defined as CHECKBOX
    CALL setup_dialog(DIALOG)

Note: If both an ON CHANGE block and AFTER FIELD block are defined for a field, the ON CHANGE block is executed before the AFTER FIELD block.

When changing the value of the current field by program in an ON ACTION block, the ON CHANGE block will be executed when leaving the field if the value is different from the reference value and if the modification flag is set (after previous user input or when the touched flag has been changed by program).

In an INPUT or INPUT ARRAY, the field value change is related to value of the variable bound to the field. In a CONSTRUCT dialog, the field value change is related to the input buffer / displayed value.

Note: When using the NEXT FIELD instruction, the comparison value is reassigned as if the user had left and reentered the field. Therefore, when using NEXT FIELD in ON CHANGE block or in an ON ACTION block, the
ON CHANGE block will only be invoked again if the value is different from the reference value. This prevents field validation in ON CHANGE blocks; you must do validations in AFTER FIELD blocks and/or AFTER INPUT blocks.

**Related concepts**

Input field modification flag on page 1623
Each input field controlled by a dialog instruction has a modification flag.

Enabling autocompletion on page 1633
Autocompletion allows a list of completion proposals to be displayed while the user is typing text into a field.

AFTER FIELD block on page 1385
COMPLETER attribute on page 1251
The COMPLETER attribute enables autocompletion for the edit field.

**AFTER FIELD block**

In dialog instructions INPUT, INPUT ARRAY, CONSTRUCT or in a DISPLAY ARRAY using the FOCUSONFIELD attribute, the AFTER FIELD block is executed every time the focus leaves the specified field.

For single record inputs driven by INPUT or query by example (QBEs) driven by CONSTRUCT, the AFTER FIELD block is executed when moving the focus from field to field.

For editable lists driven by INPUT ARRAY, the AFTER FIELD block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by DISPLAY ARRAY using the FOCUSONFIELD attribute, the AFTER FIELD block is executed when moving the focus from field to field. However, the fields will not be editable as in an INPUT ARRAY.

The AFTER FIELD keywords must be followed by a list of form field specifications. The screen-record name can be omitted.

AFTER FIELD is executed before AFTER INSERT, ON ROW CHANGE, AFTER ROW, AFTER INPUT or AFTER CONSTRUCT.

When a NEXT FIELD instruction is executed in an AFTER FIELD block, the cursor moves to the specified field, which can be the current field. This can be used to prevent the user from moving to another field/row during data input. Note that the BEFORE FIELD block is also executed when NEXT FIELD is invoked.

The AFTER FIELD block of the current field is not executed when performing a NEXT FIELD; only BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW, and BEFORE FIELD of the target item might be executed, based on the sub-dialog type.

When ACCEPT DIALOG, ACCEPT INPUT, or ACCEPT CONTRACT is performed, the AFTER FIELD trigger of the current field is executed.

Use the AFTER FIELD block to implement field validation rules:

```
INPUT BY NAME p_item.* ...
AFTER FIELD item_quantity
  IF p_item.item_quantity <= 0 THEN
    ERROR "Item quantity cannot be negative or zero"
    LET p_item.item_quantity = 0
    NEXT FIELD item_quantity
  END IF
```

**Related concepts**

NEXT FIELD instruction on page 1389
ACCEPT DIALOG instruction on page 1538
BEFORE FIELD block on page 1383
ON CHANGE block on page 1384
**INPUT interaction blocks**

**ON ACTION block**

The ON ACTION *action-name* blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
ON ACTION action-name
    instruction
    ...
```

Action blocks are bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

This example defines an action block to open a typical zoom window and let the user select a customer record:

```
ON ACTION zoom
    CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as INPUT, INPUT ARRAY and CONSTRUCT, if an action is specific to a field, add the INFIELD clause to have the action automatically enabled when the corresponding field gets the focus:

```
ON ACTION zoom INFIELD cust_city
    CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the ON ACTION handler needs to define its own attributes at the program level. This can be done by adding the ATTRIBUTES() clause of ON ACTION:

```
ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
    CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1640.

**ON IDLE block**

The ON IDLE *seconds* clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

As ON IDLE can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of ON IDLE must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON IDLE trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or gets a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
    IF ask_question("Do you want to reload information from the database?") THEN
        -- Fetch data back from the db server
    END IF
```

**Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.
**Related concepts**

*Get program control if user inactive* on page 1613

Execute some code after a given number of seconds, when the user does not interact with the program.

**ON TIMER block** on page 1357

**ON KEY block**

An **ON KEY** *(key-name)* block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The **ON KEY** block is supported for backward compatibility with TUI mode applications.

An **ON KEY** block can specify up to four different keys. Each key creates a specific action object that will be identified by the key name in lowercase. For example, **ON KEY** *(F5,F6)* creates two actions with the names *f5* and *f6*. Each action object will get an *acceleratorName* attribute assigned, with the corresponding accelerator name. The specified keys must be one of the *virtual keys*.

In GUI mode, action defaults are applied for **ON KEY** actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully **ON KEY** CONTROL-? statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, **ON KEY** statements used with ESC, TAB, UP, DOWN, LEFT, RIGHT, HELP, NEXT, PREVIOUS, INSERT, CONTROL-M, CONTROL-X, CONTROL-V, CONTROL-C and CONTROL-A should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, **ON KEY** actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a *text* attribute with the action defaults.

```
ON KEY (CONTROL-Z)
   CALL open_zoom()
```

**Related concepts**

*Configuring actions* on page 1646

Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

**Default action views** on page 1645

A default action view is created to render an action handler when no explicit action view exists for it.

**ON TIMER block**

The **ON TIMER** *seconds* clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

As **ON TIMER** can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of **ON TIMER** must be an integer literal or variable. If the value is zero, the dialog timeout is disabled. It is not recommended to use the **ON TIMER** trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
   CALL check_for_messages()
```

**Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.
**Related concepts**

Get program control on a regular (timed) basis on page 1614

Execute some code after a given number of seconds, with or without user interaction with the program.

**ON IDLE block** on page 1356

**INPUT control instructions**

**ACCEPT INPUT instruction**

The ACCEPT INPUT instruction validates the INPUT instruction and exits the dialog block if no error is raised.

The AFTER FIELD, ON CHANGE, etc. control blocks will be executed.

The statements after the ACCEPT INPUT instruction will not be executed.

```plaintext
INPUT BY NAME cust_rec.*
...
ON ACTION process_order
   CALL set_missing_defaults()
   ACCEPT INPUT
...
END INPUT
```

The INPUT instruction creates the default accept action to let the user validate the dialog. Use of the ACCEPT INPUT instruction is recommended only in specific cases when the default accept action is not appropriated.

**Related concepts**

NEXT FIELD instruction on page 1389

EXIT INPUT instruction on page 1388

CONTINUE INPUT instruction on page 1388

**Related reference**

INPUT control blocks execution order on page 1381

**CONTINUE INPUT instruction**

CONTINUE INPUT skips all subsequent statements in the current control block and gives the control back to the dialog. This instruction is useful when program control is nested within multiple conditional statements, and you want to return the control to the dialog.

If this instruction is called in a control block that is not AFTER INPUT, further control blocks might be executed according to the context. CONTINUE INPUT instructs the dialog to continue as if the code in the control block was terminated (i.e. it's a kind of GOTO end_of_control_block). However, when executed in AFTER INPUT, the focus returns to the most recently occupied field in the current form, giving the user another chance to enter data in that field. In this case the BEFORE FIELD of the current field will be invoked.

As alternative, use the NEXT FIELD control instruction to give the focus to a specific field and force the dialog to continue. However, unlike CONTINUE INPUT, the NEXT FIELD instruction will skip the further control blocks that are normally executed.

**Related concepts**

NEXT FIELD instruction on page 1389

EXIT INPUT instruction on page 1388

ACCEPT INPUT instruction on page 1388

**Related reference**

INPUT control blocks execution order on page 1381

**EXIT INPUT instruction**

The EXIT INPUT instruction terminates the INPUT instruction and resumes the program execution at the instruction following the INPUT block.
Performing an EXIT INPUT instruction during a dialog is equivalent to cancel the dialog: No field validation will occur, and the AFTER FIELD or AFTER INPUT blocks will not be executed. The dialog is exited immediately. However, INT_FLAG will not be set to TRUE as when the cancel action is fired.

**Related concepts**
- NEXT FIELD instruction on page 1389
- ACCEPT INPUT instruction on page 1388
- CONTINUE INPUT instruction on page 1388

**Related reference**
- INPUT control blocks execution order on page 1381

### CLEAR instruction in dialogs

The CLEAR field-list and CLEAR SCREEN ARRAY screen-array.* instructions clear the value buffer of specified form fields. The buffers are directly changed in the current form, and the program variables bound to the dialog are left unchanged. CLEAR can be used outside any dialog instruction, such as the DISPLAY BY NAME / TO instructions.

When a dialog is configured with the UNBUFFERED mode, there is no reason to clear field buffers since any variable assignment will synchronize field buffers. Actually, changing the field buffers with DISPLAY or CLEAR instruction in an UNBUFFERED dialog will have no visual effect, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. To clear fields of an UNBUFFERED dialog, just set to NULL the variables bound to the dialog. However, when using a CONSTRUCT, no program variables are associated with the dialog and no UNBUFFERED concept exits, and the CLEAR or DISPLAY TO / BY NAME instructions are the only way to modify the CONSTRUCT fields.

A screen array with a screen-line specification doesn't make much sense in a GUI application using TABLE containers, you can therefore use the CLEAR SCREEN ARRAY instruction to clear all rows of a list.

**Related concepts**
- CLEAR field-list on page 1351
- CLEAR SCREEN ARRAY on page 1350
- TABLE container on page 1217

The buffered and unbuffered modes on page 1618

The buffered and unbuffered mode control the synchronization of program variables and form fields.

### NEXT FIELD instruction

**Understanding the NEXT FIELD instruction**

The NEXT FIELD field-name instruction gives the focus to the specified field and forces the dialog to stay in that field.

This instruction can be used to control field input, in BEFORE FIELD, ON CHANGE or AFTER FIELD blocks, it can also force a DISPLAY ARRAY or INPUT ARRAY to stay in the current row when NEXT FIELD is used in the AFTER ROW block.

If it exists, the BEFORE FIELD block of the corresponding field is executed.

In editable dialogs, the purpose of the NEXT FIELD instruction is to give the focus to an editable field. Make sure that the field specified in NEXT FIELD is active, or use NEXT FIELD CURRENT. Non-editable fields are fields defined with the NOENTRY attribute, fields disabled at runtime with DIALOG.setFieldActive(), or fields using a widget that does not allow input, such as a LABEL.
In a DISPLAY ARRAY using the FOCUSONFIELD attribute, NEXT FIELD can be used in conjunction with DIALOG.setCurrentRow(), to set the focus to a specific cell in the list.

Instead of the NEXT FIELD instruction, you can use the DIALOG.nextField("field-name") method to register a field, for example when the name is not known at compile time. However, this method only registers the field. It does not stop code execution, like the NEXT FIELD instruction does. You must execute a CONTINUE DIALOG to get the same behavior as NEXT FIELD.

Form field identification with NEXT FIELD

With the NEXT FIELD instruction, fields are identified by the form field name specification, not the program variable name used by the dialog. Form fields are bound to program variables with the binding clause of the dialog instruction (INPUT variable-list FROM field-list, INPUT BY NAME variable-list, CONSTRUCT BY NAME sql ON column-list, CONSTRUCT sql ON column-list FROM field-list, INPUT ARRAY array-name FROM screen-array.*).

The field name specification can be any of the following:

- field-name
- table-name.field-name
- screen-record-name.field-name
- FORMONLY.field-name

Here are some examples:

- "cust_name"
- "customer.cust_name"
- "cust_screen_record.cust_name"
- "item_screen_array.item_label"
- "formonly.total"

When no field name prefix is used, the first form field matching that simple field name is used.

When using a prefix in the field name specification, it must match the field prefix assigned by the dialog field binding method used at the beginning of the interactive statement: When no screen-record has been explicitly specified in the field binding clause (for example, when using INPUT BY NAME variable-list), the field prefix must be the database table name (or FORMONLY) used in the form file, or any valid screen-record using that field. When the FROM clause of the dialog specifies an explicit sub-record (for example, in INPUT variable-list FROM screen-record.* / field-list-with-screen-record-prefix or INPUT ARRAY array-name FROM screen-array.*), the field prefix must be the screen-record name used in the FROM clause.

Abstract field identification is supported with the CURRENT, NEXT and PREVIOUS keywords. These keywords represent the current, next and previous fields respectively. When using FIELD ORDER FORM, the NEXT and PREVIOUS options follow the tabbing order defined by the form. Otherwise, they follow the order defined by the input binding list (with the FROM or BY NAME clause).

In a procedural dialog, if the focus is in the first field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD PREVIOUS will jump out of the current sub-dialog and set the focus to the previous sub-dialog. If the focus is in the last field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD NEXT will jump out of the current sub-dialog and set the focus to the next sub-dialog. NEXT FIELD NEXT or NEXT FIELD PREVIOUS also jumps to another sub-dialog when the focus is in a DISPLAY ARRAY sub-dialog. However, when using an INPUT ARRAY sub-dialog, NEXT FIELD NEXT from within the last column will loop to the first column of the current row, and NEXT FIELD PREVIOUS from within the first column will jump to the last column of the current row - the focus stays in the current INPUT ARRAY sub-dialog. When another sub-dialog gets the focus because of a NEXT FIELD NEXT/PREVIOUS, the newly-selected field depends on the sub-dialog type, following the tabbing order as if the end-user had pressed the tab or Shift-Tab key combination.
**NEXT FIELD to a non-editable INPUT / INPUT ARRAY / CONSTRUCT field**

Non-editable fields are fields defined with the NOENTRY attribute, fields disabled with `ui.Dialog.setFieldActive("field-name", FALSE)`, or fields using a widget that does not allow input, such as a LABEL.

If a NEXT FIELD instruction specifies a non-editable field, the BEFORE FIELD block of that field is executed. Then the dialog tries to give the focus to that field. Since the field cannot get the focus, the dialog will perform the last pressed navigation key (Tab, Shift-Tab, Left, Right, Up, Down, Accept) and execute the related control blocks, including the AFTER FIELD block of the non-editable field. If no last key is identified, the dialog considers Tab as fallback and moves to the next editable field as defined by the FIELD ORDER mode used by the dialog. Doing a NEXT FIELD to a non-editable field can lead to infinite loops in the dialog; Use NEXT FIELD CURRENT instead.

When selecting a non-editable field with NEXT FIELD NEXT, the runtime system will re-select the current field since it is the next editable field in the dialog. As a result the end user sees no change.

**NEXT FIELD in procedural DIALOG blocks**

In a procedural dialog block, the NEXT FIELD field-name instruction gives the focus to the specified field controlled by INPUT, INPUT ARRAY or CONSTRUCT, or to a read-only list when using DISPLAY ARRAY.

When using a DISPLAY ARRAY sub-dialog, it is possible to give the focus to the list, by specifying the name of the first column as argument for NEXT FIELD.

If the target field specified in the NEXT FIELD instruction is inside the current sub-dialog, neither AFTER FIELD nor AFTER ROW will be invoked for the field or list you are leaving. However, the BEFORE FIELD control blocks of the destination field (or the BEFORE ROW in case of read-only list) will be executed.

If the target field specified in the NEXT FIELD instruction is outside the current sub-dialog, the AFTER FIELD, AFTER INSERT, AFTER ROW, and AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be invoked for the field or list you are leaving. Form-level validation rules will also be checked, as if the user had selected the new sub-dialog himself. This guarantees the current sub-dialog is left in a consistent state. The BEFORE INPUT/DISPLAY/CONSTRUCT, BEFORE ROW and the BEFORE FIELD control blocks of the destination field / list will then be executed.

**NEXT FIELD in record list control blocks**

When using NEXT FIELD in AFTER ROW or in ON ROW CHANGE of a DISPLAY ARRAY or INPUT ARRAY, the dialog will stay in the current row and give control back to the user. This behavior allows you to implement data input rules:

```
AFTER ROW
  IF NOT int_flag AND arr_count()<=arr_curr() THEN
    IF arr[arr_curr()].it_count * arr[arr_curr()].it_value > maxval THEN
      ERROR "Amount of line exceeds max value."
    NEXT FIELD item_count
  END IF
END IF
```

Examples
INPUT dialog examples.

Example 1: INPUT with binding by field position

Form definition file "form1.per":

```
SCHEMA office

LAYOUT
GRID
{
  Customer id: [f001 ]
  First Name : [f002 ]
  Last Name  : [f003 ]
}
END
END

TABLES
customer
END

ATTRIBUTES
  f001 = customer.id;
  f002 = customer.fname;
  f003 = customer.lname, UPSHIFT;
END

INSTRUCTIONS
  SCREEN RECORD sr_cust(customer.*);
END
```

Program source code:

```
SCHEMA office

MAIN

  DEFINE custrec RECORD LIKE customer.*

  OPTIONS INPUT WRAP

  OPEN FORM f FROM "form1"
  DISPLAY FORM f

  LET INT_FLAG = FALSE
  INPUT custrec.* FROM sr_cust.*

  IF INT_FLAG = FALSE THEN
    DISPLAY custrec.*
    LET INT_FLAG = FALSE
  END IF

END MAIN
```

Example 2: INPUT with binding by field name

Form definition file "form1.per":

```
SCHEMA office
```
LAYOUT
GRID
{
  Customer id: [f001 ]
  First Name : [f002 ]
  Last Name  : [f003 ]
}
END
END

TABLES
  customer
END

ATTRIBUTES
  f001 = customer.id;
  f002 = customer.fname;
  f003 = customer.lname, UPSHIFT;
END

INSTRUCTIONS
  SCREEN RECORD sr_cust(customer.*);
END

Program source code:

SCHEMA shop

MAIN

  DEFINE custrec RECORD LIKE customer.*
  DEFINE upd INTEGER

  DATABASE shop
  OPTIONS INPUT WRAP
  OPEN FORM f FROM "form1"
  DISPLAY FORM f

  LET custrec.id = arg_val(1)
  LET upd = (custrec.id < 0)

  LET INT_FLAG = FALSE
  INPUT BY NAME custrec.* ATTRIBUTES(UNBUFFERED, WITHOUT DEFAULTS=upd)
  BEFORE INPUT
    MESSAGE "Enter customer information..."
    IF upd THEN
      SELECT fname, lname INTO custrec.fname, customer.lname
        FROM customer WHERE customer.id = custrec.id
    END IF
  AFTER FIELD fname
    IF FIELD_TOUCHED(custrec.fname) AND custrec.fname IS NULL THEN
      LET custrec.lname = NULL
    END IF
  AFTER INPUT
    MESSAGE "Input terminated..."
  END INPUT

  IF INT_FLAG = FALSE THEN
    DISPLAY custrec.*
    LET INT_FLAG = FALSE
  END IF

END MAIN
Record list (DISPLAY ARRAY)

The DISPLAY ARRAY instruction provides record list navigation in an application form, with optional record modification actions.

  - Example 2: DISPLAY ARRAY using paged mode on page 1421
  - Example 3: DISPLAY ARRAY using modification triggers on page 1422
  - Example 4: DISPLAY ARRAY with structured array on page 1423

Understanding the DISPLAY ARRAY instruction

The DISPLAY ARRAY dialog controls a list of records. DISPLAY ARRAY is designed to browse a list of records, binding a static or dynamic array model to a screen array of the current displayed form.

A DISPLAY ARRAY instruction supports additional features such as drag & drop, tree-view management, built-in sort and search, multi-row selection and list modification triggers. For a detailed description of these features, see Table views on page 1754.

Use the DISPLAY ARRAY instruction to let the end user browse in a list of rows, after fetching a result set from the database. The result set is produced with a database cursor executing a SELECT statement. The SELECT SQL statement is usually completed at runtime with a WHERE clause produced from a CONSTRUCT dialog. When the DISPLAY ARRAY statement completes execution, the program must test the INT_FLAG variable to check if the dialog was validated (or canceled) to take into account (or ignore) the row that was chosen by the user.

Syntax of DISPLAY ARRAY instruction

The DISPLAY ARRAY instruction controls the display of a program array on the screen.

Syntax

```sql
DISPLAY ARRAY array TO screen-array.*
  [HELP help-number]
  [ATTRIBUTES ( [display-attribute]
                   [control-attribute] )...]
  [dialog-control-block...]
END DISPLAY
```
where `dialog-control-block` is one of:

```plaintext
   BEFORE DISPLAY  
   AFTER DISPLAY   
   BEFORE ROW     
   AFTER ROW      
   ON IDLE seconds
   ON TIMER seconds
   ON ACTION action-name
      [ ATTRIBUTES ( action-attributes-display-array ) ]
   ON FILL BUFFER
   ON SELECTION CHANGE
   ON SORT
   ON APPEND [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
   ON INSERT [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
   ON UPDATE [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
   ON DELETE [ ATTRIBUTES ( action-attributes-listmod-triggers ) ]
   ON EXPAND ( row-index )
   ON COLLAPSE ( row-index )
   ON DRAG_START ( dnd-object )
   ON DRAG_FINISH ( dnd-object )
   ON DRAG_ENTER ( dnd-object )
   ON DRAG_OVER ( dnd-object )
   ON DROP ( dnd-object )
   ON KEY ( key-name [, ...] )
```

```plaintext
dialog-statement
    [...]
```

where `action-attributes-display-array` is:

```plaintext
   TEXT = string
   COMMENT = string
   IMAGE = string
   ACCELERATOR = string
   DEFAULTVIEW = [ YES | NO | AUTO ]
   CONTEXTMENU = [ YES | NO | AUTO ]
   ROWBOUND
      [, ...] 
```

where `action-attributes-listmod-triggers` is:

```plaintext
   TEXT = string
   COMMENT = string
   IMAGE = string
   ACCELERATOR = string
   DEFAULTVIEW = [ YES | NO | AUTO ]
   CONTEXTMENU = [ YES | NO | AUTO ]
```

where `dialog-statement` is one of:

```plaintext
   statement
   EXIT DISPLAY
   CONTINUE DISPLAY
   ACCEPT DISPLAY
```

where `display-attribute` is:

```plaintext
   BLACK | BLUE | CYAN | GREEN
   MAGENTA | RED | WHITE | YELLOW
```
where control-attribute is:

```plaintext
ACCEPT [ = boolean ]
CANCEL [ = boolean ]
KEEP CURRENT ROW [ = boolean ]
HELP = help-number
COUNT = row-count
UNBUFFERED [ = boolean ]
DETAILACTION = action-name
DOUBLECLICK = action-name
ACCESSORYTYPE = { DETAILBUTTON | DISCLOSUREINDICATOR | CHECKMARK }
FOCUSONFIELD
```

1. **array** is a static or dynamic array containing the records you want to display.
2. **screen-array** is the name of the screen array used to display data.
3. **help-number** is an integer that associates a help message number with the instruction.
4. **action-name** identifies an action that can be executed by the user.
5. **seconds** is an integer literal or variable that defines a number of seconds.
6. **row-index** identifies the program variable which holds the row index corresponding to the tree view node that has been expanded or collapsed.
7. **dnd-object** references a `ui.DragDrop` variable defined in the scope of the dialog.
8. **key-name** is an hot-key identifier (such as `F11` or `Control-z`).
9. **statement** is any instruction supported by the language.
10. **row-count** defines the total number of rows for a static array.
11. **boolean** is a boolean expression that evaluates to TRUE or FALSE.
12. **action-attributes** are dialog-specific action attributes.

**Related concepts**

- **Arrays** on page 386
  Arrays (static or dynamic) allow to handle an ordered collection of elements.

- **Configuring actions** on page 1646
  Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

- **Screen records / arrays** on page 1147
  Form fields can be grouped in a screen record or screen array definition.

- **Message files** on page 1059
  Message files centralize strings and larger texts identified by a number, that can be used in programs.

**DISPLAY ARRAY programming steps**

Follow this procedure to use the DISPLAY ARRAY dialog instruction.

To implement a DISPLAY ARRAY statement:

1. Create a form specification file containing a screen array. The screen array identifies the presentation elements to be used by the runtime system to display the rows.
2. Make sure that the program controls interruption handling with DEFER INTERRUPT, to manage the validation/cancellation of the interactive dialog.
3. Define an array of records with the DEFINE instruction. The members of the program array must correspond to the elements of the screen array, by number and data types. Static or a dynamic arrays can be used for the full list mode, but the paged mode requires a dynamic array. For new developments, use dynamic arrays in both cases.
4. Open and display the form, using OPEN WINDOW WITH FORM or the OPEN FORM/DISPLAY FORM instructions.
5. If you want to use the full list mode, fill the program array with data, typically with a result set cursor, counting the number of program records being filled with retrieved data.

6. Set the INT_FLAG on page 518 variable to FALSE.

7. Write the DISPLAY ARRAY statement block. When using a static array, specify the number of rows with the COUNT attribute in the ATTRIBUTES clause, or call the SET_COUNT() function before the dialog block. With dynamic arrays, the number of rows is automatically known by the dialog. Consider using the UNBUFFERED mode in new developments.

8. If you want to use the paged mode, define the total number of rows with the COUNT attribute (can be -1 for infinite number of rows), and add the ON FILL BUFFER clause that will contain the code to fill the dynamic array with the expected rows from fgl_dialog_getBufferStart() to fgl_dialog_getBufferLength().

9. If multi-row selection is needed, call the ui.Dialog.setSelectionMode() method in BEFORE DISPLAY to enable this mode.

10. Inside the DISPLAY ARRAY block, control the behavior of the instruction with BEFORE ROW, AFTER ROW and ON ACTION blocks.

11. After the interaction statement block, test the INT_FLAG predefined variable to check if the dialog was canceled (INT_FLAG=TRUE) or validated (INT_FLAG=FALSE). If the INT_FLAG variable is TRUE, reset it to FALSE to not disturb code that relies on this variable to detect interruption events from the GUI front-end or TUI console.

12. If needed, get the current row with the ARR_CURR() built-in function after dialog execution. During dialog execution, you can also use DIALOG.getCurrentRow().

  A built-in function is a predefined function that is part of the runtime system, or provided as a library function automatically loaded when a program starts. The built-in functions are part of the language.

Using record lists

Dialog coding concepts, configuration and code structure.

**Variable binding in DISPLAY ARRAY**

The DISPLAY ARRAY statement binds the members of the array of record to the screen array fields specified with the TO keyword. Array members and screen array fields are bound by position (not by name). The number of members in the program array must match the number of fields in the screen record (that is, in a single row of the screen array).

```
SCHEMA stock
DEFINE cust_arr DYNAMIC ARRAY OF customer.*
...
DISPLAY ARRAY cust_arr TO sr.*
    ATTRIBUTES(UNBUFFERED)
    ...
END DISPLAY
```
Keep in mind that array members are bound to screen array fields by position, so you must make sure that the members of the array are defined in the same order as the screen array fields.

Note that the array is usually defined with a flat list of members with ARRAY OF RECORD / END RECORD. However, the array can be structured with sub-records and still be used with a DISPLAY ARRAY dialog. This is especially useful when you need to define arrays from database tables, and additional information needs to be managed at runtime (for example to hold image resource for each row, to be displayed with the IMAGECOLUMN attribute):

```plaintext
SCHEMA shop
DEFINE a_items DYNAMIC ARRAY OF RECORD
    item_data RECORD LIKE items.*,
    it_image STRING,
    it_count INTEGER
END RECORD
...
DISPLAY ARRAY a_items TO sr.*
...
```

When using the UNBUFFERED attribute, the instruction is sensitive to program variable changes. This means that you do not have to DISPLAY the values; setting the program variable used by the dialog automatically displays the data in the corresponding form field.

```plaintext
ON ACTION change
    LET arr[arr_curr()].field1 = newValue()
```

If the program array has the same structure as a database table (this is the case when the array is defined with a DEFINE LIKE clause), you may not want to display/use some of the columns. You can achieve this by using PHANTOM fields in the screen array definition. Phantom fields will only be used to bind program variables, and will not be transmitted to the front-end for display.

**Related concepts**

- Arrays on page 386
  Arrays (static or dynamic) allow to handle an ordered collection of elements.

- DEFINE on page 367
  A variable contains volatile information of a specific data type.

- Screen records / arrays on page 1147
  Form fields can be grouped in a screen record or screen array definition.

- Phantom fields on page 1142
  A PHANTOM field defines a screen-record field which is not rendered in the layout (it acts as a hidden field).

**DISPLAY ARRAY instruction configuration**

This section describes the options that can be specified in the ATTRIBUTES clause of the DISPLAY ARRAY instruction. The options of the ATTRIBUTES clause override all default attributes and temporarily overrides any display attributes that the OPTIONS or the OPEN WINDOW statement specified for these fields. With the DISPLAY ARRAY statement, the INVISIBLE attribute is ignored.

**HELP option**

The HELP clause specifies the number of a help message to display if the user invokes the help in the DISPLAY ARRAY dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The HELP clause overrides the HELP attribute.
COUNT option

When using a dynamic array, the number of rows to be displayed is defined by the number of elements in the dynamic array; the COUNT attribute is ignored.

When using a static array or the paged mode, the number of rows to be displayed is defined by the COUNT attribute. You can also use the SET_COUNT() built-in function, but it is supported for backward compatibility only. If you don't know the total number of rows for the paged mode, you can specify -1 for the COUNT attribute (or in the SET_COUNT() call before the dialog block). With COUNT=-1, the dialog will ask for rows by executing ON FILL BUFFER until less rows are provided than are required, or if you reset the number of rows to a value higher than -1 with ui.Dialog.setArrayLength().

KEEP CURRENT ROW option

Depending on the list container used in the form, the current row may be highlighted during the execution of the dialog, and cleared when the instruction ends. You can change this default behavior by using the KEEP CURRENT ROW attribute, to force the runtime system to keep the current row highlighted.

ACCEPT option

The ACCEPT attribute can be set to FALSE to avoid the automatic creation of the default accept action. Use this attribute when you want to avoid dialog validation, or if you need to write a specific validation procedure using ACCEPT DISPLAY.

CANCEL option

The CANCEL attribute can be set to FALSE to avoid the automatic creation of the cancel default action. Use this attribute when you only need a validation action (accept), or when you want to write a specific cancellation procedure using EXIT DISPLAY.

If the CANCEL=FALSE option is set, no close action will be created, and you must write an ON ACTION close control block to create an explicit action.

DOUBLECLICK option

The DOUBLECLICK option can be used to define the action that will be fired when the user chooses a row from the list. Different configuration options are available to control the row selection action of desktop and mobile devices. For more details, see Defining the action for a row choice on page 1768.

DETAILACTION option

Important: This feature is only for mobile platforms.

The DETAILACTION attribute can be used to define the action that will be fired when the user selects the detail button of a row. The detail button is typically shown with a (i) icon on iOS devices. Note that the DOUBLECLICK attribute can be used to distinguish the action when the user selects the row instead of the detail button in the row. For more details, see Row configuration on iOS devices on page 1777.

FOCUSONFIELD option

Important: This feature is not supported on mobile platforms.

When the FOCUSONFIELD option is used, the DISPLAY ARRAY allows focus at the field (or cell) level. It is then possible to implement BEFORE FIELD and AFTER FIELD blocks, as well as using NEXT FIELD instructions. However, the dialog still manages a read-only list. For more details, see Field-level focus in DISPLAY ARRAY on page 1740.

ACCESSORYTYPE option

Important: This feature is only for mobile platforms.
The ACCESSORYTYPE attribute can be used to define the decoration of rows, typically used on an iOS device. Values can be DETAILBUTTON, DISCLOSUREINDICATOR, CHECKMARK to respectively get a (i), > or check mark icon. For more details, see Row configuration on iOS devices on page 1777.

Related concepts
Syntax of DISPLAY ARRAY instruction on page 1394
The DISPLAY ARRAY instruction controls the display of a program array on the screen.

Default actions in DISPLAY ARRAY
When an DISPLAY ARRAY instruction executes, the runtime system creates a set of default actions.
Field validation occurs and different DISPLAY ARRAY control blocks are executed, based on the invoked default action.
This table lists the default actions created for this dialog:

Table 341: Default actions created for the DISPLAY ARRAY dialog

<table>
<thead>
<tr>
<th>Default action</th>
<th>Description</th>
</tr>
</thead>
</table>
| accept         | Validates the DISPLAY ARRAY dialog (validates current row selection) 
Creation can be avoided with ACCEPT attribute. |
| cancel         | Cancels the DISPLAY ARRAY dialog (no validation, INT_FLAG is set to TRUE) 
Creation can be avoided with CANCEL attribute. |
| close          | By default, cancels the DISPLAY ARRAY dialog (no validation, INT_FLAG is set to TRUE) 
Default action view is hidden. See Implementing the close action on page 1672. |
| help           | Shows the help topic defined by the HELP clause. 
Only created when a HELP clause is defined. |
| nextrow        | Moves to the next row in a list displayed in one row of fields. 
Only created if DISPLAY ARRAY used with a screen record having only one row. |
| prevrow        | Moves to the previous row in a list displayed in one row of fields. 
Only created if DISPLAY ARRAY used with a screen record having only one row. |
| firstrow       | Moves to the first row in a list displayed in one row of fields. 
Only created if DISPLAY ARRAY used with a screen record having only one row. |
| lastrow        | Moves to the last row in a list displayed in one row of fields. 
Only created if DISPLAY ARRAY used with a screen record having only one row. |
| find           | Opens the fglfind dialog window to let the user enter a search value, and seeks to the row matching the value. 
Only created if the context allows built-in find. |
| findnext       | Seeks to the next row matching the value entered during the fglfind dialog. 
Only created if the context allows built-in find. |
The accept and cancel default actions can be avoided with the ACCEPT and CANCEL dialog control attributes:

```
DISPLAY ARRAY arr TO sr.* ATTRIBUTES( CANCEL=FALSE, ... )
```

**Related concepts**

This section describes basic dialog programming concepts.

**DISPLAY ARRAY data blocks**

Data blocks are dialog triggers that are invoked when the dialog controller needs data to feed the view with values. Such blocks are typically used when record list data is provided dynamically, with the display array paged mode of when implementing dynamic tree-views.

**ON FILL BUFFER block**

The `ON FILL BUFFER` block is used to fill a page of rows into the dynamic array, based on an offset and a number of rows.

This data block is only used in `DISPLAY ARRAY` data blocks.

The offset can be retrieved with the `FGL_DIALOG_GETBUFFERSTART()` built-in function and the number of rows to provide is defined by the `FGL_DIALOG_GETBUFFERLENGTH()` built-in function.

**Related concepts**
- Populating a DISPLAY ARRAY on page 1742

The program array must be filled with rows to populate the `DISPLAY ARRAY` dialog.

**ON EXPAND block**

The `ON EXPAND` block is executed when a tree view node is expanded (i.e. opened).

This data block is used to implement dynamic trees in a `DISPLAY ARRAY`, where nodes are added, depending on the nodes opened by the end user.

**Related concepts**
- Dynamic filling of very large trees on page 1797

How to optimize the implementation of large tree-views?

**ON COLLAPSE block**

The `ON COLLAPSE` block is executed when a tree view node is collapsed (i.e. closed).

This data block is used to implement dynamic trees in a `DISPLAY ARRAY`, where nodes are removed from view by the user closing or collapsing them.

**Related concepts**

BEFORE DISPLAY block

BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a singular DISPLAY ARRAY instruction, or when used as parallel dialog, the BEFORE DISPLAY is only executed once when the dialog is started.

The BEFORE DISPLAY block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating actions the user is not allowed to execute.

```dialog
DISPLAY ARRAY p_items TO s_items.*
BEFORE DISPLAY
   CALL DIALOG.setActionActive("clear_item_list", is_super_user())
```

BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a DISPLAY ARRAY sub-dialog of a procedural DIALOG instruction, the BEFORE DISPLAY block is executed when a DISPLAY ARRAY list gets the focus.

BEFORE DISPLAY is executed before the BEFORE ROW block.
In this example the **BEFORE DISPLAY** block enables an action and displays a message:

```plaintext
DISPLAY ARRAY p_items TO s_items.*
BEFORE DISPLAY
CALL DIALOG.setActionActive("print_list", TRUE)
MESSAGE "You are now in the list of items"
```

**Related concepts**

- **BEFORE INPUT block** on page 1381
- **BEFORE CONSTRUCT block** on page 1469
- **AFTER DISPLAY block** on page 1403

**AFTER DISPLAY block**

**AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs**

In a singular `DISPLAY ARRAY` instruction, or when used as parallel dialog, the **AFTER DISPLAY** is only executed once when dialog is ended.

You typically implement dialog finalization in this block.

```plaintext
DISPLAY ARRAY p_items TO s_items.*
AFTER DISPLAY
DISPLAY "Current row is: ", arr_curr()
```

**AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs**

In a `DISPLAY ARRAY` sub-dialog of a procedural `DIALOG` instruction, the **AFTER DISPLAY** block is executed when a `DISPLAY ARRAY` list loses the focus and goes to another sub-dialog.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

**AFTER DISPLAY** is executed after the **AFTER ROW** block.

In this example, the **AFTER DISPLAY** block disables an action that is specific to the current list:

```plaintext
DISPLAY ARRAY p_items TO s_items.*
AFTER DISPLAY
CALL DIALOG.setActionActive("clear_item_list", FALSE)
```

**Related concepts**

- **AFTER INPUT block** on page 1382
- **AFTER CONSTRUCT block** on page 1470
- **BEFORE DISPLAY block** on page 1402

**BEFORE ROW block**

**BEFORE ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs**

In a singular `DISPLAY ARRAY, INPUT ARRAY` instruction, or when used as parallel dialog, the **BEFORE ROW** block is executed each time the user moves to another row. This trigger can also be executed in other situations, such as when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the **BEFORE ROW** block, because it indicates that the user selected a new row or entered in the list.

When the dialog starts, **BEFORE ROW** will be executed for the current row, but only if there are data rows in the array.
When called in this block, `DIALOG.getCurrentRow() / arr_curr()` return the index of the current row.

In this example, the `BEFORE ROW` block gets the new row number and displays it in a message:

```
DISPLAY ARRAY ...
...
BEFORE ROW
  MESSAGE "We are on row # ", arr_curr()
...
```

**BEFORE ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG**

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `BEFORE ROW` block is executed when a `DISPLAY ARRAY` or `INPUT ARRAY` list gets the focus, or when the user moves to another row inside a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the `BEFORE ROW` block, because it indicates that the user selected a new row. Do not use this trigger to detect focus changes; Use the `BEFORE DISPLAY` or `BEFORE INPUT` blocks instead.

In `DISPLAY ARRAY`, `BEFORE ROW` is executed after the `BEFORE DISPLAY` block. In `INPUT ARRAY`, `BEFORE ROW` is executed before the `BEFORE INSERT` and `BEFORE FIELD` blocks and after the `BEFORE INPUT` blocks.

When the procedural dialog starts, `BEFORE ROW` will only be executed if the list has received the focus and there is a current row (the array is not empty). If you have other elements in the form which can get the focus before the list, `BEFORE ROW` will not be triggered when the dialog starts. You must pay attention to this, because this behavior is different to the behavior of singular `DISPLAY ARRAY` or `INPUT ARRAY`. In singular dialogs, the `BEFORE ROW` block is always executed when the dialog starts (and there are rows in the array).

When called in this block, `DIALOG.getCurrentRow() / arr_curr()` return the index of the current row.

In this example the `BEFORE ROW` block displays a message with the current row number:

```
DISPLAY ARRAY p_items TO s_items.*
BEFORE ROW
  MESSAGE "We are in items, on row ", DIALOG.getCurrentRow("s_items")
```

**Related concepts**

- `BEFORE INPUT block` on page 1381
- `BEFORE DISPLAY block` on page 1402

**AFTER ROW block**

**AFTER ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs**

In a singular `DISPLAY ARRAY`, `INPUT ARRAY` instruction, or when used as parallel dialog, the `AFTER ROW` block is executed each time the user moves to another row, before the current row is left. This trigger can also be executed in other situations, such as when you delete a row, or when the user inserts a new row.

A `NEXT FIELD` instruction executed in the `AFTER ROW` control block will keep the user entry in the current row. Use this behavior to implement row validation and prevent the user from leaving the list or moving to another row.

When called in this block, `DIALOG.getCurrentRow() / arr_curr()` return the index of the row that you are leaving.

**AFTER ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG**

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `AFTER ROW` block is executed when a `DISPLAY ARRAY` or `INPUT ARRAY` list loses the focus, or when the user moves to another row in a list.
This trigger can also be executed in other situations, for example when you delete a row, or when the user inserts a new row.

**AFTER ROW** is executed after the **AFTER FIELD**, **AFTER INSERT** and before **AFTER DISPLAY** or **AFTER INPUT** blocks.

When called in this block, `DIALOG.getCurrentRow() / arr_curr()` return the index of the of the row that you are leaving.

For both **INPUT ARRAY** and **DISPLAY ARRAY** sub-dialogs, a **NEXT FIELD** executed in the **AFTER ROW** control block will keep the focus in the list and stay in the current row. Use this feature to implement row validation and prevent the user from leaving the list or moving to another row.

**AFTER ROW and temporary rows in INPUT ARRAY**

**Important:** After creating a temporary row at the end of a list driven by **INPUT ARRAY**, if you leave that row to a previous row without data input (setting the touched flag), or when the cancel action is invoked, the temporary row will be automatically removed. The **AFTER ROW** block will be executed for the temporary row, but `DIALOG.getCurrentRow() / arr_curr()` will be one row greater than `DIALOG.getArrayLength() / ARR_COUNT()`. In this case, it is recommended that you ignore the **AFTER ROW** event. For example, it is recommended that you avoid executing a **NEXT FIELD** or **CONTINUE INPUT** instruction, and trying to access the dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array.

In this example, the **AFTER ROW** block checks the current row index and verifies a variable value to forces the focus to stay in the current row if the value is wrong:

```plaintext
INPUT ARRAY p_items FROM s_items.*

...  
AFTER ROW
    LET r = DIALOG.getCurrentRow("s_items")
    IF r <= DIALOG.getArrayLength("s_items") THEN
        IF NOT item_is_valid_quantity(p_item[r].item_quantity) THEN
            ERROR "Item quantity is not valid"
            NEXT FIELD item_quantity'
        END IF
    END IF
END IF
```

Another way to handle the case of temporary rows in **AFTER ROW** is to use a flag to know if the **AFTER INSERT** block was executed: The **AFTER INSERT** block is not executed if the temporary row is automatically removed. By setting a first value in **BEFORE INSERT** and changing the flag in **AFTER INSERT**, you can detect if the row was permanently added to the list:

```plaintext
INPUT ARRAY p_items FROM s_items.*

...  
BEFORE INSERT
    LET op = "I"
...  
AFTER INSERT
    LET op = "I"
...  
AFTER ROW
    IF op == "I" THEN
        IF NOT item_is_valid_quantity(p_item[arr_curr()].item_quantity) THEN
            ERROR "Item quantity is not valid"
            NEXT FIELD item_quantity
        END IF
    WHENEVER ERROR CONTINUE
    INSERT INTO items (item_num, item_name, item_quantity)
       VALUES ( p_item[arr_curr()].* )
    WHENEVER ERROR STOP
```
IF SQLCA.SQLCODE<0 THEN
  ERROR "Could not insert the record into database!"
  NEXT FIELD CURRENT
ELSE
  MESSAGE "Record has been inserted successfully"
END IF
END IF

Related concepts
NEXT FIELD instruction on page 1389
BEFORE ROW block on page 1403
ON ROW CHANGE block on page 1439

BEFORE FIELD block
In dialog instructions INPUT, INPUT ARRAY, CONSTRUCT or in a DISPLAY ARRAY using the FOCUSONFIELD attribute, the BEFORE FIELD block is executed every time the specified field gets the focus.

For single record inputs driven by INPUT or query by example (QBEs) driven by CONSTRUCT, the BEFORE FIELD block is executed when moving the focus from field to field.

For editable lists driven by INPUT ARRAY, the BEFORE FIELD block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by DISPLAY ARRAY using the FOCUSONFIELD attribute, the BEFORE FIELD block is executed when moving the focus from field to field. However, the fields will not be editable as in an INPUT ARRAY.

Important: The BEFORE FIELD block is also executed when performing a NEXT FIELD instruction.

The BEFORE FIELD keywords must be followed by a list of form field specification. The screen-record name can be omitted.

BEFORE FIELD is executed after BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW and BEFORE INSERT.

Use this block to do some field value initialization, or to display a message to the user:

```
INPUT BY NAME p_cust.* ...
BEFORE FIELD cust_status
  LET p_cust.cust_comment = NULL
  MESSAGE "Enter customer status"
```

When using the default FIELD ORDER CONSTRAINT mode, the dialog executes the BEFORE FIELD block of the field corresponding to the first variable of an INPUT or INPUT ARRAY, even if that field is not editable (NOENTRY, hidden or disabled). The block is executed when you enter the dialog and every time you create a new row in the case of INPUT ARRAY. This behavior is supported for backward compatibility. The block is not executed when using the FIELD ORDER FORM, the mode recommended for DIALOG instructions.

With the FIELD ORDER FORM mode, for each dialog executing the first time with a specific form, the BEFORE FIELD block will be invoked for the first field of the initial tabbing list defined by the form, even if that field was hidden or moved around in a table. The dialog then behaves as if a NEXT FIELD first-visible-column would have been done in the BEFORE FIELD of that field.

When form-level validation occurs and a field contains an invalid value, the dialog gives the focus to the field, but no BEFORE FIELD trigger will be executed.

Related concepts
NEXT FIELD instruction on page 1389
Form-level validation rules on page 1627
Form-level validation rules can be defined for each field controlled by a dialog.

AFTER FIELD block on page 1385
**AFTER FIELD block**

In dialog instructions `INPUT, INPUT ARRAY, CONSTRUCT` or in a `DISPLAY ARRAY` using the `FOCUSONFIELD` attribute, the `AFTER FIELD` block is executed every time the focus leaves the specified field.

For single record inputs driven by `INPUT` or query by example (QBEs) driven by `CONSTRUCT`, the `AFTER FIELD` block is executed when moving the focus from field to field.

For editable lists driven by `INPUT ARRAY`, the `AFTER FIELD` block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by `DISPLAY ARRAY` using the `FOCUSONFIELD` attribute, the `AFTER FIELD` block is executed when moving the focus from field to field. However, the fields will not be editable as in an `INPUT ARRAY`.

The `AFTER FIELD` keywords must be followed by a list of form field specifications. The screen-record name can be omitted.

`AFTER FIELD` is executed before `AFTER INSERT`, `ON ROW CHANGE`, `AFTER ROW`, `AFTER INPUT` or `AFTER CONSTRUCT`.

When a `NEXT FIELD` instruction is executed in an `AFTER FIELD` block, the cursor moves to the specified field, which can be the current field. This can be used to prevent the user from moving to another field / row during data input. Note that the `BEFORE FIELD` block is also executed when `NEXT FIELD` is invoked.

The `AFTER FIELD` block of the current field is not executed when performing a `NEXT FIELD`; only `BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW, and BEFORE FIELD` of the target item might be executed, based on the sub-dialog type.

When `ACCEPT DIALOG, ACCEPT INPUT, or ACCEPT CONTRUCT` is performed, the `AFTER FIELD` trigger of the current field is executed.

Use the `AFTER FIELD` block to implement field validation rules:

```plaintext
INPUT BY NAME p_item.* ...
AFTER FIELD item_quantity
  IF p_item.item_quantity <= 0 THEN
    ERROR "Item quantity cannot be negative or zero"
    LET p_item.item_quantity = 0
    NEXT FIELD item_quantity
  END IF
```

**Related concepts**

- [ON CHANGE block](#) on page 1384

**DISPLAY ARRAY interaction blocks**

**ON ACTION block**

The `ON ACTION action-name` blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```plaintext
ON ACTION action-name
  instruction
  ...
```

Action blocks are bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.
This example defines an action block to open a typical zoom window and let the user select a customer record:

```
ON ACTION zoom
    CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as `INPUT`, `INPUT ARRAY` and `CONSTRUCT`, if an action is specific to a field, add the `INFIELD` clause to have the action automatically enabled when the corresponding field gets the focus:

```
ON ACTION zoom INFIELD cust_city
    CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the `ON ACTION` handler needs to define its own attributes at the program level. This can be done by adding the `ATTRIBUTES()` clause of `ON ACTION`:

```
ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
    CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1640.

**ON IDLE block**

The `ON IDLE seconds` clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

As `ON IDLE` can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of `ON IDLE` must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON IDLE` trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or gets a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
    IF ask_question("Do you want to reload information from the database?") THEN
        -- Fetch data back from the db server
    END IF
```

**Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

**Related concepts**

Get program control if user inactive on page 1613
Execute some code after a given number of seconds, when the user does not interact with the program.

**ON TIMER block** on page 1357

**ON KEY block**

An `ON KEY (key-name)` block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The `ON KEY` block is supported for backward compatibility with TUI mode applications.

An `ON KEY` block can specify up to four different keys. Each key creates a specific action object that will be identified by the key name in lowercase. For example, `ON KEY (F5, F6)` creates two actions with the names F5 and
f6. Each action object will get an acceleratorName attribute assigned, with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for ON KEY actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully ON KEY CONTROL-? statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, ON KEY statements used with ESC, TAB, UP, DOWN, LEFT, RIGHT, HELP, NEXT, PREVIOUS, INSERT, CONTROL-M, CONTROL-X, CONTROL-V, CONTROL-C and CONTROL-A should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, ON KEY actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a text attribute with the action defaults.

```plaintext
ON KEY (CONTROL-Z)
    CALL open_zoom()
```

**Related concepts**

- **Configuring actions** on page 1646
  Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

- **Default action views** on page 1645
  A default action view is created to render an action handler when no explicit action view exists for it.

**ON TIMER block**

The ON TIMER seconds clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

As ON TIMER can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of ON TIMER must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON TIMER trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```plaintext
ON TIMER 30
    CALL check_for_messages()
```

**Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

**Related concepts**

- **Get program control on a regular (timed) basis** on page 1614
  Execute some code after a given number of seconds, with or without user interaction with the program.

- **ON IDLE block** on page 1356

**ON APPEND block**

Similarly to the ON INSERT control block, the ON APPEND trigger can be used to enable row creation during a DISPLAY ARRAY dialog. If this block is defined, the dialog will automatically create the append action. This action can be decorated, enabled and disabled as a regular action.

If the dialog defines an ON ACTION append interaction block and the ON APPEND block is used, the compiler will stop with error -8408.
When the user fires the append action, the dialog first executes the user code of the \texttt{AFTER \ ROW} block if defined. Then the dialog moves to the end of the list, and creates a new row after the last existing row. After creating the row, the dialog executes the user code of the \texttt{ON \ APPEND} block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular \texttt{INPUT} statement, to let the end user enter data for the new created row. This is typically done with an \texttt{INPUT} binding explicitly array fields to the screen record fields. The new current row in the program array is identified with \texttt{arr\_curr()}, and the current screen line in the form is defined by \texttt{SCR\_LINE()}:

```plaintext
DISPLAY ARRAY arr TO sr.*
...  
ON APPEND
    INPUT arr[arr\_curr()].* FROM sr[scr\_line()].* ;
...  
```

Pay attention to the semicolon ending the \texttt{INPUT} instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the \texttt{INT\_FLAG} global variable is \texttt{FALSE} and \texttt{STATUS} is zero, the new row is kept in the program array, and the \texttt{BEFORE \ ROW} block is executed for the new created row.
- If the \texttt{INT\_FLAG} global variable is \texttt{TRUE} or \texttt{STATUS} is different from zero, the new row is removed from the program array, and the \texttt{BEFORE \ ROW} block is executed for the row that was existing at the current position, before the new row was created.

The \texttt{DISPLAY \ ARRAY} dialog always resets \texttt{INT\_FLAG} to \texttt{FALSE} and \texttt{STATUS} to zero before executing the user code of the \texttt{ON \ APPEND} block.

The append action is disabled if the maximum number of rows is reached.

If needed, the \texttt{ON \ APPEND} handler can be configured with action attributes by added an \texttt{ATTRIBUTES()} clause, as with user-defined action handlers:

```plaintext
ON APPEND ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

\textbf{Related concepts}

- \texttt{STATUS} on page 517
  \texttt{STATUS} is a predefined variable that contains the execution status of the last instruction.

  \texttt{INT\_FLAG} is a predefined variable set to \texttt{TRUE} when an interruption event is detected.
- \texttt{BEFORE \ ROW} block on page 1403
- \texttt{arr\_curr()} on page 2153
  Returns the current row in a \texttt{DISPLAY \ ARRAY} or \texttt{INPUT \ ARRAY}.
- \texttt{scr\_line()} on page 2154
  Returns the index of the current row in the screen array.
- \texttt{Record input (INPUT)} on page 1373
  The \texttt{INPUT} instruction provides single record input control in an application form.
- \texttt{ON \ INSERT} block on page 1410
- \texttt{ON \ UPDATE} block on page 1412
- \texttt{ON \ DELETE} block on page 1413

\texttt{ON \ INSERT} block

Similarly to the \texttt{ON \ APPEND} control block, the \texttt{ON \ INSERT} trigger can be used to enable row creation during a \texttt{DISPLAY \ ARRAY} dialog. If this block is defined, the dialog will automatically create the insert action. This action can be decorated, enabled and disabled as a regular action.
If the dialog defines an `ON_ACTION insert` interaction block and the `ON_INSERT` block is used, the compiler will stop with error -8408.

When the user fires the insert action, the dialog first execute the user code of the `AFTER_ROW` block if defined. Then the new row is created: The insert action creates a new row before current row in the list. After creating the row, the dialog executes the user code of the `ON_INSERT` block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular `INPUT` statement, to let the end user enter data for the new created row. This is typically done with an `INPUT` binding explicitly array fields to the screen record fields. The new current row in the program array is identified with `arrCurr()`, and the current screen line in the form is defined by `scr_line()`:

```plaintext
DISPLAY ARRAY arr TO sr.*
  ...
  ON_INSERT
    INPUT arr[arrCurr()].* FROM sr[scr_line()].* ;
  ...
```

Pay attention to the semicolon ending the `INPUT` instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the `INT_FLAG` global variable is `FALSE` and `STATUS` is zero, the new row is kept in the program array, and the `BEFORE_ROW` block is executed for the new created row.
- If the `INT_FLAG` global variable is `TRUE` or `STATUS` is different from zero, the new row is removed from the program array, and the `BEFORE_ROW` block is executed for the row that was existing at the current position, before the new row was created.

The `DISPLAY ARRAY` dialog always resets `INT_FLAG` to `FALSE` and `STATUS` to zero before executing the user code of the `ON_INSERT` block.

The insert action is disabled if the maximum number of rows is reached.

If needed, the `ON_INSERT` handler can be configured with action attributes by added an `ATTRIBUTES()` clause, as with user-defined action handlers:

```plaintext
ON_INSERT ATTRIBUTES(TEXT="%custlist.delete", IMAGE="listdel")
```

**Related concepts**

- **STATUS** on page 517
  STATUS is a predefined variable that contains the execution status of the last instruction.
- **INT_FLAG** on page 518
  INT_FLAG is a predefined variable set to `TRUE` when an interruption event is detected.
- **BEFORE ROW block** on page 1403
  Returns the current row in a `DISPLAY ARRAY` or `INPUT ARRAY`.
- **arrCurr()** on page 2153
  Returns the index of the current row in the screen array.

- **Record input (INPUT)** on page 1373
  The `INPUT` instruction provides single record input control in an application form.
- **ON APPEND block** on page 1409
- **ON UPDATE block** on page 1412
- **ON DELETE block** on page 1413
**ON UPDATE block**

The **ON UPDATE** trigger can be used to enable row modification during a **DISPLAY ARRAY** dialog. If this block is defined, the dialog will automatically create the update action. This action can be decorated, enabled and disabled as regular actions.

You typically configure the **TABLE** container in the form by defining the **DOUBLECLICK** attribute to "update", in order to trigger the update action when the user double-clicks on a row.

If the dialog defines an **ON ACTION update** interaction block and the **ON UPDATE** block is used, the compiler will stop with error -8408.

When the user fires the **update** action, the dialog executes the user code of the **ON UPDATE** block.

The dialog handles only the row modification action and navigation, you must program the record input with a regular **INPUT** statement, to let the end user modify the data of the current row. This is typically done with an **INPUT** binding explicitly array fields to the screen record fields, with the **WITHOUT DEFAULTS** clause. The current row in the program array is identified with **arr_curr()**, and the current screen line in the form is defined by **scr_line()**:

```sql
DISPLAY ARRAY arr TO sr.*

... 
ON UPDATE
  INPUT arr[arr_curr()].* WITHOUT DEFAULTS FROM sr[scr_line()].* ;

... 
```

Pay attention to the semicolon ending the **INPUT** instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the **INT_FLAG** global variable is **FALSE** and **STATUS** is zero, the modified values of the current row are kept in the program array.
- If the **INT_FLAG** global variable is **TRUE** or **STATUS** is different from zero, the old values of the current row are restored in the program array.

The **DISPLAY ARRAY** dialog always resets **INT_FLAG** to **FALSE** and **STATUS** to zero before executing the user code of the **ON UPDATE** block.

If needed, the **ON UPDATE** handler can be configured with action attributes by added an **ATTRIBUTES()** clause, as with user-defined action handlers:

```sql
ON UPDATE ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

**Related concepts**

- **TABLE container** on page 1217
  Defines a re-sizable table designed to display a list of records.

- **DOUBLECLICK attribute** on page 1255
  The **DOUBLECLICK** attribute defines the action for row choice on **TABLE/TREE/SCROLLGRID** rows.

The **INPUT** instruction provides single record input control in an application form.

**ON INSERT block** on page 1410  
**ON APPEND block** on page 1409  
**ON DELETE block** on page 1413

**ON DELETE block**
The **ON DELETE** trigger can be used to enable row deletion during a **DISPLAY ARRAY** dialog. If this block is defined, the dialog will automatically create the delete action. This action can be decorated, enabled and disabled as regular actions.

If the dialog defines an **ON ACTION delete** interaction block and the **ON DELETE** block is used, the compiler will stop with error **-8408**.

When the user fires the delete action, the dialog executes the user code of the **ON DELETE** block.

The dialog handles only the row deletion action and navigation, you can typically program a validation dialog box to let the user confirm the deletion. The current row in the program array is identified with **arr_curr()**:  

```
DISPLAY ARRAY arr TO sr.*  
...  
ON DELETE  
  IF fgl_winQuestion("Delete",  
    "Do you want to delete this record?",  
    "yes", "no|yes", "help", 0) == "no"  
  THEN  
    LET int_flag = TRUE  
  END IF  
...  
```

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the **INT_FLAG** global variable is **FALSE** and **STATUS** is zero, the current row is deleted from the program array, and the **BEFORE ROW** block is executed for the next row in the list.
- If the **INT_FLAG** global variable is **TRUE** or **STATUS** is different from zero, the current row is kept in the program array, and the **BEFORE ROW** block is executed again for the current row.

The **DISPLAY ARRAY** dialog always resets **INT_FLAG** to **FALSE** and **STATUS** to zero before executing the user code of the **ON DELETE** block.

If needed, the **ON DELETE** handler can be configured with action attributes by added an **ATTRIBUTES()** clause, as with user-defined action handlers:

```
ON DELETE ATTRIBUTES(TEXT="%custlist.delete", IMAGE="listdel")
```

ON SELECTION CHANGE block

The **ON SELECTION CHANGE** trigger can be used to enable multi-row selection and detect when rows are selected or de-selected by the end user during a **DISPLAY ARRAY** dialog. If this block is defined, multi-row selection is automatically enabled. However, the feature can be enabled/disabled with the `setSelectionMode()` dialog method.

**Related concepts**

- **Multiple row selection** on page 1752
  Multiple row selection allows the end user to select several rows within a list of records.

ON SORT block

**Basics**

The **ON SORT** interaction block can be used to detect when rows have to be sorted in a **DISPLAY ARRAY** or **INPUT ARRAY** dialog.

**ON SORT** is used in two different contexts:

1. In a regular (full-list) **DISPLAY ARRAY** / **INPUT ARRAY** dialog, the **ON SORT** trigger can be used to detect that a list sort was performed.

2. In a **DISPLAY ARRAY** using paged mode (**ON FILL BUFFER**), use **ON SORT** to detect a sort request from the user and re-fetch the rows from the database in the required order.

**ON SORT in regular full-list DISPLAY ARRAY or INPUT ARRAY**

In a regular **DISPLAY ARRAY** / **INPUT ARRAY** dialog not using paged mode, the **ON SORT** trigger can be used to detect that a list sort was performed.

When the **ON SORT** block executes in this context, the (visual) sort is already done by the runtime system and the **ON SORT** block is only used to execute post-sort tasks, such as displaying current row information.

To display the row position information, use the `arrayToVisualIndex()` dialog method to convert the current program row number to the visual row number:

```
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON SORT
    MESSAGE SFMT( "Row: %1/%2",
                   DIALOG.arrayToVisualIndex( "sr", DIALOG.getCurrentRow("sr") ),
                   DIALOG.getArrayLength( "sr" )
    )
  ...
```

If needed, you can get the sort column and sort order with the `getSortKey()` and `isSortReverse()` dialog methods:

```
DISPLAY ARRAY arr TO sr.* ...
  ...
  ON SORT
    MESSAGE SFMT( "Sort on %1, %2 order",
                   DIALOG.getSortKey("sr"),
                   IIF( DIALOG.isSortReverse("sr"), "descending", "ascending" )
    )
  ...
```

**ON SORT in DISPLAY ARRAY using the paged mode**

In a **DISPLAY ARRAY** implementing paged mode with **ON FILL BUFFER** trigger, built-in row sorting is not available because data is provided by pages.
Use the **ON SORT** trigger, to detect a sort request and perform a new SQL query to re-order the rows. In this context, the sort column and sort order are available with the **getSortKey()** and **isSortReverse()** dialog methods:

```plaintext
DEFINE key STRING, rev BOOLEAN

DISPLAY ARRAY arr TO sr.* ...
... 
ON SORT
   -- Re-execute the SQL statement to fill the page of rows in ON FILL BUFFER
   -- Assuming that form field names match table column names
   LET key = DIALOG.getSortKey("sa")
   LET rev = DIALOG.isSortReverse("sa")
   IF key IS NULL THEN
      CALL execute_sql( NULL )
   ELSE
      CALL execute_sql( "ORDER BY " || key || IIF(rev," DESC"," ") )
   END IF

See Paged mode of DISPLAY ARRAY on page 1743 for more details about the paged mode in DISPLAY ARRAY and how to implement sort in this type of record list dialog.

**Related concepts**

**List ordering** on page 1764
List controllers implement a built-in sort. This feature can be disabled if not required.

**ON DRAG_START block**

The **ON DRAG_START** block is executed when the end user has begun the drag operation. If this dialog trigger has not been defined, default dragging is enabled for this dialog.

In the **ON DRAG_START** block, the program typically specifies the type of drag & drop operation by calling **ui.DragDrop.setOperation()** with "move" or "copy". This call will define the default and unique drag operation. If needed, the program can allow another type of drag operation with **ui.DragDrop.addPossibleOperation()**. The end user can then choose to move or copy the dragged object, if the drag & drop target allows it.

If the dragged object can be dropped outside the program, must define the MIME type and drag/drop data with **ui.DragDrop.setMimeType()** and **ui.DragDrop.setBuffer()** methods.

Example:

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
... 
ON DRAG_START (dnd)
   CALL dnd.setOperation("move")  -- Move is the default operation
   CALL dnd.addPossibleOperation("copy")  -- User can toggle to copy if needed
   CALL dnd.setMimeType("text/plain")
   CALL dnd.setBuffer(arr[arr_curr()].cust_name)
...
END DISPLAY
```

**Related concepts**

**Handle drag & drop data with MIME types** on page 1821
How to handle MIME types with drag & drop?

**The DragDrop class** on page 2422
The `ui.DragDrop` class is used to control the events related to drag & drop events.

**ON DRAG_FINISHED block**

Execution of the ON DRAG_FINISHED block notifies the dialog where the drag started and that the drop operation has been completed or terminated.

Call `ui.DragDrop.getOperation()` to get the final type of operation of the drop. On successful completion, the method returns "move" or "copy"; otherwise the function returns NULL. If NULL is returned, the ON DRAG_FINISHED trigger can be ignored.

In cases of successful moves to a target out of the current DISPLAY ARRAY, the application must remove the transferred data from the source model. For example, if a row was moved from dialog A to B, dialog A will get an ON DRAG_FINISHED execution after the row was dropped into B, which removes the row from the list A.

The ON DRAG_FINISHED interaction block is optional.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_START (dnd)
  LET last_dragged_row = arr_curr()
...
ON DRAG_FINISHED (dnd)
  IF dnd.getOperation() == "move" THEN
    CALL DIALOG.deleteRow(last_dragged_row)
  END IF
...
END DISPLAY
```

**Related concepts**

The `DragDrop` class on page 2422

The `ui.DragDrop` class is used to control the events related to drag & drop events.

**ON DRAG_ENTER block**

When the ON DROP control block is defined, the ON DRAG_ENTER block will be executed when the mouse cursor enters the visual boundaries of the drop target dialog. Entering the target dialog is accepted by default if no ON DRAG_ENTER block is defined. However, when ON DROP is defined, it is recommended that you also define ON DRAG_ENTER to deny the drop of objects with an unsupported MIME type that come from other applications.

The program can decide to deny or allow a specific drop operation with a call to `ui.DragDrop.setOperation()`; passing a NULL to the method will deny drop.

To check what MIME type is available in the drag & drop buffer, the program uses the `ui.DragDrop.selectMimeType()` method. This method takes the MIME type as a parameter and returns TRUE if the passed MIME type is used. You can call this method several times to check the availability of different MIME types.

You may also define the visual effect when hovering over the target list with `ui.DragDrop.setFeedback()`.

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER (dnd)
  IF dnd.selectMimeType("text/plain") THEN
    CALL dnd.setOperation("copy")
    CALL dnd.setFeedback("all")
  ELSE
    CALL dnd.setOperation(NULL)
  END IF
```
ON DROP (dnd)

END DISPLAY

Once the mouse has entered the target area, subsequent mouse cursor moves can be detected with the `ON DRAG_OVER` trigger.

When using a table or tree-view as drop target, you can control the visual effect when the mouse moves over the rows, depending on the type of drag & drop you want to achieve.

Basically, a dragged object can be:

1. Inserted in between two rows (visual effect must show where the object will be inserted)
2. Copied/merged to the current row (visual effect must show the row under the mouse)
3. Dropped somewhere on the target widget (the exact location inside the widget does not matter)

The visual effect can be defined with the `ui.DragDrop.setFeedback()` method, typically called in the `ON DRAG_ENTER` block.

The values to pass to the `setFeedback()` method to get the desired visual effects described are respectively:

1. `insert` (default)
2. `select`
3. `all`

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER (dnd)
  IF canDrop() THEN
    CALL dnd.setOperation(NULL)
  ELSE
    CALL dnd.setFeedback("select")
  END IF
...
END DISPLAY
```

**Related concepts**

The DragDrop class [on page 2422](#)

The `ui.DragDrop` class is used to control the events related to drag & drop events.

**ON DRAG_OVER block**

When the `ON DROP` control block is defined, the `ON DRAG_OVER` block will be executed after `ON DRAG_ENTER`, when the mouse cursor is moving over the drop target, or when the drag & drop operation has changed (toggling copy/move).

`ON DRAG_OVER` will be called only once per row, even if the mouse cursor moves over the row.

In the `ON DRAG_OVER` block, the method `ui.DragDrop.getLocationRow()` returns the index of the row in the target array, and can be used to allow or deny the drop. When using a tree-view, you must also check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and allow/deny the drop operation accordingly.

The program can change the drop operation at any execution of the `ON DRAG_OVER` block. You can deny or allow a specific drop operation with a call to `ui.DragDrop.setOperation()`; passing a `NULL` to the method will deny the drop.

The current operation (returned by `ui.DragDrop.getOperation()`) is the value set in previous `ON DRAG_ENTER` or `ON DRAG_OVER` events, or the operation selected by the end user, if it can toggle between copy and move. Thus, `ON DRAG_OVER` can occur even if the mouse position has not changed.
If dropping has been denied with `ui.DragDrop.setOperation(NULL)` in the previous `ON DRAG_OVER` event, the program can reset the operation to allow a drop with a call to `ui.DragDrop.setOperation()` with the operation parameter "move" or "copy".

`ON DRAG_OVER` will not be called if drop has been disabled in `ON DRAG_ENTER` with `ui.DragDrop.setOperation(NULL)`

`ON DRAG_OVER` is optional, and must only be defined if the operation or the acceptance of the drag object depends on the target row of the drop target.

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER (dnd)
...
ON DRAG_OVER (dnd)
  IF arr[dnd.getLocationRow()].acceptsCopy THEN
    CALL dnd.setOperation("copy")
  ELSE
    CALL dnd.setOperation(NULL)
  END IF
ON DROP (dnd)
...
END DISPLAY
```

During a drag & drop process, the end user (or the target application) can decide to modify the type of the operation, to indicate whether the dragged object has to be copied or moved from the source to the target. For example, in a typical file explorer, by default files are moved when doing a drag & drop on the same disk. To make a copy of a file, you must press the Ctrl key while doing the drag & drop with the mouse.

In the drop target dialog, you can detect such operation changes in the `ON DRAG_OVER` trigger and query the `ui.DragDrop` object for the current operation with `ui.DragDrop.getOperation()`. In the drag source dialog, you typically check `ui.DragDrop.getOperation()` in the `ON DRAG_FINISHED` trigger to know what sort of operation occurred, to keep ("copy" operation) or delete ("move" operation) the original dragged object.

This example tests the current operation in the drop target list and displays a message accordingly:

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER (dnd)
...
ON DRAG_OVER (dnd)
  CASE dnd.getOperation()
    WHEN "move"
      MESSAGE "The object will be moved to row ", dnd.getLocationRow()
    WHEN "copy"
      MESSAGE "The object will be copied to row ", dnd.getLocationRow()
  END CASE
...
ON DROP (dnd)
...
END DISPLAY
```

The `ui.DragDrop` class is used to control the events related to drag & drop events.

Tree views on page 1789
Describes how to implement tree views.

**ON DROP block**

To enable drop actions on a list, you must define the **ON DROP** block; otherwise the list will not accept drop actions. The **ON DROP** block is executed after the end user has released the mouse button to drop the dragged object. **ON DROP** will not occur if drop has been denied in the previous **ON DRAG_OVER** event or in **ON DRAG_ENTER** with a call to `ui.DragDrop.setOperation(NULL)`.

When **ON DROP** executes, the MIME type of the dragged object can be checked with `ui.DragDrop.getSelectedMimeType()`. Then call the `ui.DragDrop.getBuffer()` method to retrieve drag & drop data from external applications.

Ideally, the drop operation is accepted (there is no need for additional calls to `ui.DragDrop.setOperation()`).

In this block, the `ui.DragDrop.getLocationRow()` method returns the index of the row in the target array, and can be used to execute the code to get the drop data / object into the row that has been chosen by the user.

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ... 
...
  ON DROP (dnd)
    LET arr[dnd.getLocationRow()].capacity == dnd.getBuffer()
...
END DISPLAY
```

If the drag & drop operations are local to the same list or tree-view controller, you can use the `ui.DragDrop.dropInternal()` method to simplify the code. This method implements the typical move of the dragged rows or tree-view node. This is especially useful in case of a tree-view, but is also the preferred way to move rows around in simple tables.

This **ON DROP** code example uses the `dropInternal()` method:

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr_tree TO sr_tree.* ... 
...
  ON DROP (dnd)
    CALL dnd.dropInternal()
...
END DISPLAY
```

If you want to implement by hand the code to drop a node in a tree-view, you must check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and execute the code corresponding to the drop operation: If the drop target row index returned by `getLocationRow()` is a child of the parent row index returned by `getLocationParent()`, the new row must be inserted before `getLocationRow()`, otherwise the new row must be added as a child of the parent node identified by `getLocationParent()`.

**Related concepts**

- [The DragDrop class](#) on page 2422
- The `ui.DragDrop` class is used to control the events related to drag & drop events.

**DISPLAY ARRAY control instructions**

- [CONTINUE DISPLAY instruction](#)

  `CONTINUE DISPLAY` skips all subsequent statements in the current control block and gives the control back to the dialog.
The CONTINUE DISPLAY instruction is useful when program control is nested within multiple conditional statements, and you want to return the control to the dialog. If this instruction is called in a control block that is not AFTER DISPLAY, further control blocks might be executed depending on the context.

Actually, CONTINUE DISPLAY just instructs the dialog to continue as if the code in the control block was terminated (i.e. it's a kind of GOTO end_of_control_block). However, when executed in AFTER DISPLAY, the focus returns to the current row in the list, giving the user another chance to browse and select a row. In this case the BEFORE ROW of the current row will be invoked.

**Related concepts**
- ACCEPT DISPLAY instruction on page 1420
- EXIT DISPLAY instruction on page 1420

**EXIT DISPLAY instruction**

Use the EXIT DISPLAY to terminate the DISPLAY ARRAY instruction and resume the program execution at the instruction immediately following the DISPLAY ARRAY block.

**Related concepts**
- ACCEPT DISPLAY instruction on page 1420
- CONTINUE DISPLAY instruction on page 1419

**ACCEPT DISPLAY instruction**

The ACCEPT DISPLAY instruction validates the DISPLAY ARRAY instruction and exits the dialog block.

The AFTER DISPLAY control block will be executed. Statements after ACCEPT DISPLAY will not be executed.

**Related concepts**
- EXIT DISPLAY instruction on page 1420
- CONTINUE DISPLAY instruction on page 1419

Understanding the INPUT ARRAY instruction

The INPUT ARRAY dialog controls a list of records than can by directly edited.

INPUT ARRAY is designed to browse and modify a list of record, binding a static or dynamic array model to a screen array of the current displayed form.

**Important:** This feature is not supported on mobile platforms.

An INPUT ARRAY instruction supports additional features, built-in sort and search, multi-row selection and list modification triggers. For a detailed description of these features, see Table views on page 1754.
Use the INPUT ARRAY instruction to let the end user update, delete and create new records in a list, after fetching a result set from the database. The result set is produced with a database cursor executing a SELECT statement. The SELECT SQL statement is usually completed at runtime with a WHERE clause produced from a CONSTRUCT dialog.

The INPUT ARRAY instruction associates a program array of records with a screen-array defined in a form so that the user can update the list of records. The INPUT ARRAY statement activates the current form (the form that was most recently displayed or the form in the current window).

During the INPUT ARRAY execution, the user can edit or delete existing rows, insert new rows, and move inside the list of records. The program controls the behavior of the instruction with control blocks such as BEFORE DELETE, BEFORE INSERT, etc.

To terminate the INPUT ARRAY execution, the user can validate (or cancel) the dialog to commit (or invalidate) the modifications made in the list of records.

When the statement completes execution, the program must test the INT_FLAG variable to check if the dialog was validated (or canceled) and then use INSERT, DELETE, or UPDATE SQL statements to modify the appropriate database tables. The database can also be updated during the execution of the INPUT ARRAY statement.

**Syntax of INPUT ARRAY instruction**

The INPUT ARRAY supports data entry by users into a screen array and stores the entered data in an array of records.

**Syntax**

```
INPUT ARRAY array
   \ WITHOUT DEFAULTS \n   FROM screen-array.*
   \ ATTRIBUTES ( \ display-attribute
   \ control-attribute
   \ [, ...] ) \n   \ HELP help-number \n   \ dialog-control-block
   \ [, ...] \nEND INPUT \n```

where **dialog-control-block** is one of:

```
\ BEFORE INPUT
\ AFTER INPUT
\ AFTER DELETE
\ BEFORE ROW
\ AFTER ROW
\ BEFORE FIELD field-spec [, ...]
\ AFTER FIELD field-spec [, ...]
\ ON ROW CHANGE
\ ON CHANGE field-spec [, ...]
\ ON IDLE seconds
\ ON TIMER seconds
\ ON ACTION action-name
   \ INFIELD field-spec \n   \ ATTRIBUTES ( action-attributes-input-array ) \n\ ON KEY ( key-name [, ...] )
\ BEFORE INSERT
\ AFTER INSERT
```
```plaintext
| BEFORE DELETE |
| dialog-statement |

where action-attributes-input-array is:

| TEXT = string |
| COMMENT = string |
| IMAGE = string |
| ACCELERATOR = string |
| DEFAULTVIEW = YES | NO | AUTO |
| VALIDATE = NO |
| CONTEXTMENU = YES | NO | AUTO |
| ROWBOUND |

where dialog-statement is one of:

| statement |
| ACCEPT INPUT |
| CONTINUE INPUT |
| EXIT INPUT |
| NEXT FIELD CURRENT | NEXT | PREVIOUS field-spec |
| CANCEL DELETE |
| CANCEL INSERT |

where field-spec identifies a unique field with one of:

| field-name |
| table-name.field-name |
| screen-array.field-name |
| screen-record.field-name |

where display-attribute is:

| BLACK | BLUE | CYAN | GREEN |
| MAGENTA | RED | WHITE | YELLOW |
| BOLD | DIM | INVISIBLE | NORMAL |
| REVERSE | BLINK | UNDERLINE |

where control-attribute is:

| ACCEPT = boolean |
| APPEND ROW = boolean |
| AUTO APPEND = boolean |
| CANCEL = boolean |
| COUNT = row-count |
| DELETE ROW = boolean |
| FIELD ORDER FORM |
| HELP = help-number |
| INSERT ROW = boolean |
| KEEP CURRENT ROW = boolean |
| MAXCOUNT = max-row-count |
| UNBUFFERED = boolean |
| WITHOUT DEFAULTS = boolean |
```
1. array is the array of records that will be filled by the INPUT ARRAY statement.
2. help-number is an integer that allows you to associate a help message number with the instruction.
3. field-name is the identifier of a field of the current form.
4. table-name is the identifier of a database table of the current form.
5. screen-record is the identifier of a screen record of the current form.
6. screen-array is the screen array that will be used in the form.
7. action-name identifies an action that can be executed by the user.
8. seconds is an integer literal or variable that defines a number of seconds.
9. key-name is a hot-key identifier (like F11 or Control-z).
10. statement is any instruction supported by the language.
11. row-count defines the initial number of rows for a static array.
12. max-row-count is the maximum number of rows that can be created.
13. boolean is a boolean expression that evaluates to TRUE or FALSE.
14. action-attributes are dialog-specific action attributes.

Message files centralize strings and larger texts identified by a number, that can be used in programs.

INPUT ARRAY programming steps
Follow this procedure to use the INPUT ARRAY dialog instruction.

To implement an INPUT ARRAY statement:

1. Create a form specification file containing a screen array. The screen array identifies the presentation elements to be used by the runtime system to display the rows.
2. Make sure that the program controls interruption handling with DEFER INTERRUPT, to manage the validation/cancellation of the interactive dialog.
3. Define an array of records with the DEFINE instruction. The members of the program array must correspond to the elements of the screen array, by number and data types. If you want to input data from a reduced set of columns, you must define a second screen array, containing the limited list of form fields, in the form file. You can then use the second screen array in an INPUT ARRAY a FROM sa.* instruction.
4. Open and display the form, using a OPEN WINDOW WITH FORM or the OPEN FORM/DISPLAY FORM instructions.
5. If needed, fill the program array with data, for example with a result set cursor, counting the number of program records being filled with retrieved data.
6. Set the INT_FLAG variable to FALSE.
7. Write the INPUT ARRAY statement to handle data input.
8. Inside the INPUT ARRAY statement, control the behavior of the instruction with control blocks such as BEFORE INSERT, BEFORE DELETE, BEFORE ROW, BEFORE FIELD, AFTER INSERT, AFTER DELETE, AFTER FIELD, AFTER ROW, AFTER INPUT and ON ACTION blocks.
9. Get the new number of rows with the ARR_COUNT() built-in function or with DIALOG.getArrayLength().
10. After the interaction statement block, test the INT_FLAG predefined variable to check if the dialog was canceled (INT_FLAG=TRUE) or validated (INT_FLAG=FALSE). If the INT_FLAG variable is TRUE, it is recommended that you reset it to FALSE to not disturb code that relies on this variable to detect interruption events from the GUI front-end or TUI console.

**Related concepts**

  Arrays (static or dynamic) allow to handle an ordered collection of elements.
- The Dialog class on page 2367
  The ui.Dialog class provides a set of methods to configure, query and control the current interactive instruction.
- INPUT ARRAY control blocks on page 1434
- Built-in functions on page 2149
  A built-in function is a predefined function that is part of the runtime system, or provided as a library function automatically loaded when a program starts. The built-in functions are part of the language.

**Using editable record lists**
Dialog coding concepts, configuration and code structure.

**Variable binding in INPUT ARRAY**
The INPUT ARRAY statement binds the members of the array of record to the screen array fields specified with the FROM keyword. Array members and screen array fields are bound by position (not by name). The number of members in the program array must match the number of fields in the screen record (that is, in a single row of the screen array).

```plaintext
SCHEMA stock
DEFINE cust_arr DYNAMIC ARRAY OF customer.*
...
INPUT ARRAY cust_arr FROM sr.*
   ATTRIBUTES(UNBUFFERED)
   ...
END INPUT
```

Keep in mind that array members are bound to screen array fields by position, so you must make sure that the members of the array are defined in the same order as the screen array fields.

Note that the array is usually defined with a flat list of members with ARRAY OF RECORD / END RECORD. However, the array can be structured with sub-records and still be used with an INPUT ARRAY dialog. This is especially useful when you need to define arrays from database tables, and additional information needs to be managed at runtime (for example to hold image resource for each row, to be displayed with the IMAGECOLUMN attribute):

```plaintext
SCHEMA shop
DEFINE a_items DYNAMIC ARRAY OF RECORD
   item_data RECORD LIKE items.*,
   it_image STRING,
   it_count INTEGER
   END RECORD
...
INPUT ARRAY a_items FROM sr.*
```
When using a static array, the initial number of rows is defined by the COUNT attribute and the size of the array determines how many rows can be inserted. When using a dynamic array, the initial number of rows is defined by the number of elements in the dynamic array (the COUNT attribute is ignored), and the maximum rows is unlimited. For both static and dynamic arrays, the maximum number of rows the user can enter can be defined with the MAXCOUNT attribute.

The FROM clause binds the screen records in the screen array to the program records of the program array. The form can include other fields that are not part of the specified screen array, but the number of member variables in each record of the program array must equal the number of fields in each row of the screen array. When the user enters data, the runtime system checks the entered value against the data type of the variable, not the data type of the screen field.

The variables of the record array are the interface to display data or to get the user input through the INPUT ARRAY instruction. Always use the variables if you want to change some field values by program. When using the UNBUFFERED attribute, the instruction is sensitive to program variable changes. If you need to display new data during the INPUT ARRAY execution, use the UNBUFFERED attribute and assign the values to the program array row; the runtime system will automatically display the values to the screen:

```
INPUT ARRAY p_items FROM s_items.*
ATTRIBUTES(UNBUFFERED)
ON CHANGE code
  IF p_items[arr_curr()].code = "A34" THEN
    LET p_items[arr_curr()].desc = "Item A34"
  END IF
END_INPUT
```

The runtime system adapts input and display rules to the data type of the array record members. If a member is declared with the DEFINE LIKE instruction and uses a column defined as SERIAL / SERIAL8 / BIGSERIAL, the runtime system will treat the field as if it was defined with the NOENTRY attribute in the form file. Since values of serial columns are automatically generated by the database server, no user input is required for such fields.

The default order in which the focus moves from field to field in the screen array is determined by the declared order of the corresponding member variables, in the array of the record definition. The program OPTIONS instruction can also change the behavior of the INPUT ARRAY instruction, with the INPUT WRAP or FIELD ORDER FORM options.

By default the INPUT ARRAY instruction clears the program array when starting, unless you specify the WITHOUT DEFAULTS keywords or option. With this option, the dialog displays the program array rows in the screen fields. Unlike the INPUT dialog, the column default values defined in the form specification file with the DEFAULT attribute or in the database schema files are always used when a new row is inserted in the list.

If the program array has the same structure as a database table (this is the case when the array is defined with a DEFINE LIKE clause), you may not want to display/use some of the columns. You can achieve this by using PHANTOM fields in the screen array definition. Phantom fields will only be used to bind program variables, and will not be transmitted to the front-end for display.

**Related concepts**
- Editable record list (INPUT ARRAY) on page 1425
- The INPUT ARRAY instruction provides always-editable record list handling in an application form.
- DEFINE on page 367
- A variable contains volatile information of a specific data type.
- Screen records / arrays on page 1147

Database schema on page 476
Defines database table structures with column type information to be reused in program variable definitions.

Phantom fields on page 1142
A PHANTOM field defines a screen-record field which is not rendered in the layout (it acts as a hidden field).

The buffered and unbuffered modes on page 1618
The buffered and unbuffered mode control the synchronization of program variables and form fields.

INPUT ARRAY instruction configuration

This section describes the options that can be specified in the ATTRIBUTES clause of the INPUT ARRAY instruction. The options of the ATTRIBUTES clause override all default attributes and temporarily override any display attributes that the OPTIONS or the OPEN WINDOW statement specified for these fields. With the INPUT ARRAY statement, the INVISIBLE attribute is ignored.

HELP option

The HELP clause specifies the number of a help message to display if the user invokes the help the INPUT ARRAY dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The HELP clause overrides the HELP attribute.

WITHOUT DEFAULTS option

The WITHOUT DEFAULT clause defines whether the program array elements are populated (and to be displayed) when the dialog begins. Once the dialog is started, existing rows are always handled as records to be updated in the database (i.e. WITHOUT DEFAULTS=TRUE), while newly-created rows are handled as records to be inserted in the database (i.e. WITHOUT DEFAULTS=FALSE). In other words, the REQUIRED and DEFAULT attributes defined in the form are only used for newly-created rows.

It is unusual to implement an INPUT ARRAY with no WITHOUT DEFAULTS option, because the data of the program variables would be cleared and the list empty. So, you typically use the WITHOUT DEFAULTS clause in INPUT ARRAY. In a singular INPUT ARRAY, the default is WITHOUT DEFAULTS=FALSE.

FIELD ORDER FORM option

By default, the form tabbing order is defined by the variable list in the binding specification. You can control the tabbing order by using the FIELD ORDER FORM attribute. When this attribute is used, the tabbing order is defined by the TABINDEX attribute of the form items. With FIELD ORDER FORM, if you jump from one field to another with the mouse, the BEFORE FIELD/AFTER FIELD triggers of intermediate fields are not executed (actually, the Dialog.fieldOrder FGLPROFILE entry is ignored.)

If the form uses a TABLE container, the front-end resets the tab indexes when the user moves columns around. This way, the visual column order always corresponds to the input tabbing order. The order of the columns in an editable list can be important; you may want to freeze the table columns with the UNMOVABLECOLUMNS attribute.

UNBUFFERED option

The UNBUFFERED attribute indicates that the dialog must be sensitive to program variable changes. When using this option, you bypass the traditional "buffered" mode.

When using the traditional "buffered" mode, program variable changes are not automatically displayed to form fields; you need to execute a DISPLAY TO or DISPLAY BY NAME. Additionally, if an action is triggered, the value of the current field is not validated and is not copied into the corresponding program variable. The only way to get the text of the current field is to use GET_FLDBUF().
If the "unbuffered" mode is used, program variables and form fields are automatically synchronized. You don't need to display explicitly values with a DISPLAY TO or DISPLAY BY NAME. When an action is triggered, the value of the current field is validated and is copied into the corresponding program variable.

**COUNT option**

The COUNT attribute defines the number of valid rows in the static array to be displayed as default rows. If you do not use the COUNT attribute, the runtime system cannot determine how much data to display, so the screen array remains empty. You can also use the SET_COUNT() built-in function, but it is supported for backward compatibility only. The COUNT option is ignored when using a dynamic array. If you specify the COUNT attribute, the WITHOUT DEFAULTS option is not required because it is implicit. If the COUNT attribute is greater than MAXCOUNT, the runtime system will take MAXCOUNT as the actual number of rows. If the value of COUNT is negative or zero, it defines an empty list.

**MAXCOUNT option**

The MAXCOUNT attribute defines the maximum number of rows that can be inserted in the program array. This attribute allows you to give an upper limit of the total number of rows the user can enter, when using both static or dynamic arrays.

When binding a static array, MAXCOUNT is used as upper limit if it is lower or equal to the actual declared static array size. If MAXCOUNT is greater than the array size, the size of the static array is used as the upper limit. If MAXCOUNT is lower than the COUNT attribute (or to the SET_COUNT() parameter), the actual number of rows in the array will be reduced to MAXCOUNT.

When binding a dynamic array, the user can enter an infinite number of rows unless the MAXCOUNT attribute is used. If MAXCOUNT is lower than the actual size of the dynamic array, the number of rows in the array will be reduced to MAXCOUNT.

If MAXCOUNT is negative or equal to zero, the user cannot insert rows.

**ACCEPT option**

The ACCEPT attribute can be set to FALSE to avoid the automatic creation of the accept default action. This option can be used for example when you want to write a specific validation procedure, by using ACCEPT INPUT.

**CANCEL option**

The CANCEL attribute can be set to FALSE to avoid the automatic creation of the cancel default action. This is useful for example when you only need a validation action (accept), or when you want to write a specific cancellation procedure, by using EXIT INPUT.

If the CANCEL=FALSE option is set, no close action will be created, and you must write an ON ACTION close control block to create an explicit action.

**APPEND ROW option**

The APPEND ROW attribute can be set to FALSE to avoid the append default action, and prevent the user adding rows at the end of the list. If APPEND ROW=FALSE, it is still possible to insert rows in the middle of the list. Use the INSERT ROW attribute to disallow the user from inserting rows. To deny automatic temporary row creation if only APPEND ROW=FALSE is used, set AUTO APPEND is not set to FALSE.

**INSERT ROW option**

The INSERT ROW attribute can be set to FALSE to avoid the insert default action, and prevent the user inserting new rows in the middle of the list. However, even if INSERT ROW is FALSE, it is still possible to append rows at the end of the list. Use the APPEND ROW attribute to disallow the user from appending rows. To deny automatic temporary row creation if only INSERT ROW=FALSE is used, set AUTO APPEND is not set to FALSE.
DELETE ROW option

The DELETE ROW attribute can be set to FALSE to avoid the delete default action, and prevent the user removing rows from the list.

AUTO APPEND option

By default, an INPUT ARRAY controller creates a temporary row when needed (for example, when the user deletes the last row of the list, a new row will be automatically created). You can prevent this default behavior by setting the AUTO APPEND attribute to FALSE. When this attribute is set to FALSE, the only way to create a new temporary row is to execute the append action.

If both the APPEND ROW and INSERT ROW attributes are set to FALSE, the dialog automatically behaves as if AUTO APPEND equals FALSE.

KEEP CURRENT ROW option

Depending on the list container used in the form, the current row may be highlighted during the execution of the dialog, and cleared when the instruction ends. You can change this default behavior by using the KEEP CURRENT ROW attribute, to force the runtime system to keep the current row highlighted.

Related concepts

Syntax of INPUT ARRAY instruction on page 1426

The INPUT ARRAY supports data entry by users into a screen array and stores the entered data in an array of records.

Default actions in INPUT ARRAY

When an INPUT ARRAY instruction executes, the runtime system creates a set of default actions. Field validation occurs and different INPUT ARRAY control blocks are executed based on the invoked default action.

This table lists the default actions created for this dialog:

Table 343: Default actions for INPUT ARRAY

<table>
<thead>
<tr>
<th>Default action</th>
<th>Description</th>
</tr>
</thead>
</table>
| accept         | Validates the INPUT ARRAY dialog (validates fields and leaves the dialog)  
                  *Creation can be avoided with ACCEPT attribute.*  
| cancel         | Cancels the INPUT ARRAY dialog (no validation, INT_FLAG is set to TRUE)  
                  *Creation can be avoided with CANCEL attribute.*  
| close          | By default, cancels the INPUT ARRAY dialog (no validation, INT_FLAG is set to TRUE)  
                  Default action view is hidden. See Implementing the close action on page 1672.  
| insert         | Inserts a new row before current row.  
                  *Creation can be avoided with INSERT ROW = FALSE attribute.*  
| append         | Appends a new row at the end of the list.  
                  *Creation can be avoided with APPEND ROW = FALSE attribute.* |
<table>
<thead>
<tr>
<th>Default action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>delete</td>
<td>Deletes the current row. <em>Creation can be avoided with DELETE ROW = FALSE attribute.</em></td>
</tr>
<tr>
<td>help</td>
<td>Shows the help topic defined by the HELP clause. <em>Only created when a HELP clause is defined.</em></td>
</tr>
<tr>
<td>nextrow</td>
<td>Moves to the next row in a list displayed in one row of fields. <em>Only created if DISPLAY ARRAY used with a screen record having only one row.</em></td>
</tr>
<tr>

**BEFORE INPUT block**

**BEFORE INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs**

In a singular INPUT, INPUT ARRAY instruction, or when used as parallel dialog, the **BEFORE INPUT** is only executed once when the dialog is started.
The BEFORE_INPUT block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```
INPUT BY NAME cust_rec.* ... 
BEFORE_INPUT
  MESSAGE "Input customer information"
  CALL DIALOG.setActionActive("check_info", is_super_user() )
  CALL DIALOG.setFieldActive("cust_comment", is_super_user() )
...
```

The fields are initialized with the defaults values before the BEFORE_INPUT block is executed. When the INPUT instruction uses the WITHOUT_DEFAULTS option, the default values are taken from the program variables bound to the fields, otherwise (with defaults), the DEFAULT attributes of the form fields are used.

Use the NEXT_FIELD control instruction in the BEFORE_INPUT block, to jump to a specific field when the dialog starts.

**BEFORE_INPUT block in INPUT and INPUT ARRAY of procedural DIALOG**

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the BEFORE_INPUT block is executed when the focus goes to a group of fields driven by the sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

When the focus is in a list driven by an INPUT ARRAY sub-dialog, moving to a different row will not invoke the BEFORE_INPUT block.

BEFORE_INPUT is executed after the BEFORE_DIALOG block and before the BEFORE_ROW, BEFORE_FIELD blocks.

In this example, the BEFORE_INPUT block is used to set up a specific action and display a message:

```
INPUT BY NAME p_order.*
BEFORE_INPUT
  CALL DIALOG.setActionActive("validate_order", TRUE)
```

**Related concepts**

- BEFORE_CONSTRUCT block on page 1469
- BEFORE_DISPLAY block on page 1402
- AFTER_INPUT block on page 1382

**AFTER_INPUT block**

**AFTER_INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs**

In a singular INPUT, INPUT ARRAY instruction, or when used as parallel dialog, the AFTER_INPUT is only executed once when dialog ends.

The AFTER_INPUT block is executed after the user has validated or canceled the INPUT or INPUT ARRAY dialog with the accept or cancel default actions, or when the ACCEPT_INPUT instruction is executed.

The AFTER_INPUT block is not executed when the EXIT_INPUT instruction is performed.

In singular and parallel dialogs, this block is typically used to implement global dialog validation rules depending from several fields. If the values entered by the user do not satisfy the constraints, use the NEXT_FIELD instruction to force the dialog to continue. The CONTINUE_INPUT instruction can be used instead of NEXT_FIELD, when no particular field has to be select.
Before checking the validation rules, make sure that the INT_FLAG variable is FALSE: in case if the user cancels the dialog, the validation rules must be skipped.

```
INPUT BY NAME cust_rec.*
   WITHOUT DEFAULTS ATTRIBUTES ( UNBUFFERED )
   ...
   AFTER INPUT
      IF NOT INT_FLAG THEN
         IF cust_rec.cust_address IS NOT NULL
            AND cust_rec.cust_zipcode IS NULL THEN
               ERROR "Address is incomplete, enter a zipcode."
               NEXT FIELD zipcode
            END IF
      END IF
   END IF
END INPUT
```

To limit the validation to fields that have been modified by the end user, you can call the FIELD_TOUCHED() function or the DIALOG.getFieldTouched() method to check if a field has changed during the dialog execution. This will make your validation code faster if the user has only modified a couple of fields in a large form.

**AFTER INPUT block in INPUT and INPUT ARRAY of procedural DIALOG**

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the AFTER INPUT block is executed when the focus is lost by a group of fields driven by an INPUT or INPUT ARRAY sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus. When the focus is in a list driven by an INPUT ARRAY sub-dialog, moving to a different row will not invoke the AFTER INPUT block.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

**AFTER INPUT** is executed after the AFTER FIELD, AFTER ROW blocks and before the AFTER DIALOG block.

Executing a NEXT FIELD in the AFTER INPUT control block will keep the focus in the group of fields. Within an INPUT ARRAY sub-dialog, NEXT FIELD will keep the focus in the list and stay in the current row. You typically use this behavior to control user input.

In this example, the AFTER INPUT block is used to validate data and disable an action that can only be used in the current group:

```
INPUT BY NAME p_order.*
   AFTER INPUT
      IF NOT check_order_data(DIALOG) THEN
         NEXT FIELD CURRENT
      END IF
      CALL DIALOG.setFieldActive("validate_order", FALSE)
   END IF
```

**Related concepts**

- AFTER DISPLAY block on page 1403
- AFTER CONSTRUCT block on page 1470
- BEFORE INPUT block on page 1381

**BEFORE ROW block**

**BEFORE ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs**

In a singular DISPLAY ARRAY, INPUT ARRAY instruction, or when used as parallel dialog, the BEFORE ROW block is executed each time the user moves to another row. This trigger can also be executed in other situations,
such as when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the BEFORE ROW block, because it indicates that the user selected a new row or entered in the list.

When the dialog starts, BEFORE ROW will be executed for the current row, but only if there are data rows in the array.

When called in this block, `DIALOG.getCurrentRow()` / `arr_curr()` return the index of the current row.

In this example, the BEFORE ROW block gets the new row number and displays it in a message:

```plaintext
DISPLAY ARRAY ...
... 
BEFORE ROW 
  MESSAGE "We are on row # ", arr_curr() 
... 
```

**BEFORE ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG**

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the BEFORE ROW block is executed when a DISPLAY ARRAY or INPUT ARRAY list gets the focus, or when the user moves to another row inside a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the BEFORE ROW block, because it indicates that the user selected a new row. Do not use this trigger to detect focus changes; Use the BEFORE DISPLAY or BEFORE INPUT blocks instead.

In DISPLAY ARRAY, BEFORE ROW is executed after the BEFORE DISPLAY block. In INPUT ARRAY, BEFORE ROW is executed before the BEFORE INSERT and BEFORE FIELD blocks and after the BEFORE INPUT blocks.

When the procedural dialog starts, BEFORE ROW will only be executed if the list has received the focus and there is a current row (the array is not empty). If you have other elements in the form which can get the focus before the list, BEFORE ROW will not be triggered when the dialog starts. You must pay attention to this, because this behavior is different to the behavior of singular DISPLAY ARRAY or INPUT ARRAY. In singular dialogs, the BEFORE ROW block is always executed when the dialog starts (and there are rows in the array).

When called in this block, `DIALOG.getCurrentRow()` / `arr_curr()` return the index of the current row.

In this example the BEFORE ROW block displays a message with the current row number:

```plaintext
DISPLAY ARRAY p_items TO s_items.*
BEFORE ROW
  MESSAGE "We are in items, on row ", DIALOG.getCurrentRow("s_items")
```

**Related concepts**

BEFORE INPUT block on page 1381

BEFORE DISPLAY block on page 1402

**ON ROW CHANGE block**

The ON ROW CHANGE block is executed in a list controlled by an INPUT ARRAY, when leaving the current row and when the row has been modified since it got the focus. This is typically used to detect row modification.

The code in ON ROW CHANGE will not be executed when leaving new rows created by the user with the default append or insert action. To detect row creation, you must use the BEFORE INSERT or AFTER INSERT control blocks.

The ON ROW CHANGE block is only executed if at least one field value in the current row has changed since the row was entered, and the modification flag of the field is set. The modified field(s) may not be the current field, and several field values can be changed. Values may have been changed by the user or by the program. The modification
flag is reset for all fields when entering another row, when going to another sub-dialog, or when leaving the dialog instruction.

ON ROW CHANGE is executed after the AFTER FIELD block and before the AFTER ROW block.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the current row that has been changed.

You can, for example, code database modifications (UPDATE) in the ON ROW CHANGE block:

```
INPUT ARRAY p_items FROM s_items.*
...
ON ROW CHANGE
  LET r = DIALOG.getCurrentRow("s_items")
  UPDATE items SET
  items.item_code        = p_items[r].item_code,
  items.item_description = p_items[r].item_description,
  items.item_price       = p_items[r].item_price,
  items.item_updatedate  = TODAY
WHERE items.item_num = p_items[r].item_num
```

Related concepts
Input field modification flag on page 1623
Each input field controlled by a dialog instruction has a modification flag.

AFTER ROW block on page 1404

AFTER ROW block

AFTER ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs

In a singular DISPLAY ARRAY, INPUT ARRAY instruction, or when used as parallel dialog, the AFTER ROW block is executed each time the user moves to another row, before the current row is left. This trigger can also be executed in other situations, such as when you delete a row, or when the user inserts a new row.

A NEXT FIELD instruction executed in the AFTER ROW control block will keep the user entry in the current row. Use this behavior to implement row validation and prevent the user from leaving the list or moving to another row.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the row that you are leaving.

AFTER ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the AFTER ROW block is executed when a DISPLAY ARRAY or INPUT ARRAY list loses the focus, or when the user moves to another row in a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user inserts a new row.

AFTER ROW is executed after the AFTER FIELD, AFTER INSERT and before AFTER DISPLAY or AFTER INPUT blocks.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the of the row that you are leaving.

For both INPUT ARRAY and DISPLAY ARRAY sub-dialogs, a NEXT FIELD executed in the AFTER ROW control block will keep the focus in the list and stay in the current row. Use this feature to implement row validation and prevent the user from leaving the list or moving to another row.

AFTER ROW and temporary rows in INPUT ARRAY

Important: After creating a temporary row at the end of a list driven by INPUT ARRAY, if you leave that row to a previous row without data input (setting the touched flag), or when the cancel action is invoked, the temporary row will be automatically removed. The AFTER ROW block will be executed for
the temporary row, but `ui.Dialog.getCurrentRow(arr_curr)` will be one row greater than `ui.Dialog.getArrayLength(ARR_COUNT)`. In this case, it is recommended that you ignore the AFTER ROW event. For example, it is recommended that you avoid executing a NEXT FIELD or CONTINUE INPUT instruction, and trying to access the dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array.

In this example, the AFTER ROW block checks the current row index and verifies a variable value to forces the focus to stay in the current row if the value is wrong:

```
INPUT ARRAY p_items FROM s_items.*
...
AFTER ROW
   LET r = DIALOG.getCurrentRow("s_items")
   IF r <= DIALOG.getArrayLength("s_items") THEN
      IF NOT item_is_valid_quantity(p_item[r].item_quantity) THEN
         ERROR "Item quantity is not valid"
         NEXT FIELD item_quantity'
      END IF
   END IF
END IF
```

Another way to handle the case of temporary rows in AFTER ROW is to use a flag to know if the AFTER INSERT block was executed: The AFTER INSERT block is not executed if the temporary row is automatically removed. By setting a first value in BEFORE INSERT and changing the flag in AFTER INSERT, you can detect if the row was permanently added to the list:

```
INPUT ARRAY p_items FROM s_items.*
...
BEFORE INSERT
   LET op = "T"
...
AFTER INSERT
   LET op = "I"
...
AFTER ROW
   IF op == "I" THEN
      IF NOT item_is_valid_quantity(p_item[arr_curr()].item_quantity) THEN
         ERROR "Item quantity is not valid"
         NEXT FIELD item_quantity
      END IF
      WHENEVER ERROR CONTINUE
      INSERT INTO items (item_num, item_name, item_quantity)
      VALUES ( p_item[arr_curr()].* )
      WHENEVER ERROR STOP
      IF SQLCA.SQLCODE<0 THEN
         ERROR "Could not insert the record into database!"
         NEXT FIELD CURRENT
      ELSE
         MESSAGE "Record has been inserted successfully"
      END IF
   END IF
END IF
...
**BEFORE INSERT block**

The **BEFORE INSERT** block is executed when a new row is created in an **INPUT ARRAY**. You typically use this trigger to set some default values in the new created row. A new row can be created by moving down after the last row, by executing an insert action, or by executing an append action.

The **BEFORE INSERT** block is executed after the **BEFORE ROW** block and before the **BEFORE FIELD** block.

When called in this block, `DIALOG.getCurrentRow()` / `arr_curr()` return the index of the new created row.

To distinguish row insertion from an appended row, compare the current row (`DIALOG.getCurrentRow("screen-array")`) with the total number of rows (`DIALOG.getArrayLength("screen-array")`). If the current row index and the total number of rows correspond, the **BEFORE INSERT** concerns a temporary row, otherwise it concerns an inserted row.

Row creation can be stopped by using the **CANCEL INSERT** instruction inside **BEFORE INSERT**. If possible, it is however better to disable the insert and append actions to prevent the user to execute the actions with `DIALOG.setActionActive()`.

In this example, the **BEFORE INSERT** block checks if the user can create rows and denies new row creation if needed; otherwise, it sets some default values:

```plaintext
INPUT ARRAY p_items FROM s_items.*
...
BEFORE INSERT
    IF NOT user_can_append THEN
        ERROR "You are not allowed to append rows"
        CANCEL INSERT
    END IF
LET r = DIALOG.getCurrentRow("s_items")
LET p_items[r].item_num = get_new_serial("items")
LET p_items[r].item_name = "undefined"
```

**Related concepts**

**Appending rows in INPUT ARRAY** on page 1749
Rows appended at the end of an editable list are temporary until they are edited.

**BEFORE ROW block** on page 1403

**AFTER INSERT block**

The **AFTER INSERT** block of **INPUT ARRAY** is executed when the creation of a new row is validated. In this block, you can for example implement SQL to insert a new row in the database table.

When called in this block, `DIALOG.getCurrentRow()` / `arr_curr()` return the index of the new created row.

When the user appends a new row at the end of the list, then moves UP to another row or validates the dialog, the **AFTER INSERT** block is only executed if at least one field was edited. If no data entry is detected, the dialog automatically removes the new appended row and thus does not trigger the **AFTER INSERT** block.

When executing a **NEXT FIELD** in the **AFTER INSERT** block, the dialog will keep the focus in the list and stay in the current row. Use this behavior to implement row input validation and prevent the user from leaving the list or moving to another row. However, this will not cancel the row insertion and will not invoke the **BEFORE INSERT / AFTER INSERT** triggers again. The only way to keep the focus in the current row after the row was inserted is to execute a **NEXT FIELD** in the **AFTER ROW** block.

In this example, the **AFTER INSERT** block inserts a new row in the database and cancels the operation if the SQL command fails:

```plaintext
INPUT ARRAY p_items FROM s_items.*
...
AFTER INSERT
```
WHENEVER ERROR CONTINUE
   INSERT INTO items VALUES
   ( p_items[DIALOG.getCurrentRow("s_items").* ]
WHENEVER ERROR STOP
   IF SQLCA.SQLCODE<>0 THEN
      ERROR SQLERRMESSAGE
      CANCEL INSERT
   END IF

Related concepts
NEXT FIELD instruction on page 1389
AFTER ROW block on page 1404

BEFORE DELETE block

The BEFORE DELETE block is executed each time the user deletes a row of an INPUT ARRAY list, before the row is removed from the list.

You typically code the database table synchronization in the BEFORE DELETE block, by executing a DELETE SQL statement using the primary key of the current row. In the BEFORE DELETE block, the row to be deleted still exists in the program array, so you can access its data to identify what record needs to be removed.

The BEFORE DELETE block is executed before the AFTER DELETE block.

If needed, the deletion can be canceled with the CANCEL DELETE instruction.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the row that will be deleted.

The next example uses the BEFORE DELETE block to remove the row from the database table and cancels the deletion operation if an SQL error occurs:

```
INPUT ARRAY p_items FROM s_items.*
BEFORE DELETE
   LET r = DIALOG.getCurrentRow("s_items")
   WHENEVER ERROR CONTINUE
   DELETE FROM items
      WHERE item_num = p_items[r].item_num
   WHENEVER ERROR STOP
   IF SQLCA.SQLCODE<>0 VALUES
      ERROR SQLERRMESSAGE
      CANCEL DELETE
   END IF
...```

Related concepts
AFTER DELETE block on page 1443

AFTER DELETE block

The AFTER DELETE block is executed each time the user deletes a row of an INPUT ARRAY list, after the row has been deleted from the list.

The AFTER DELETE block is executed after the BEFORE DELETE block and before the AFTER ROW block for the deleted row and the BEFORE ROW block of the new current row.

When an AFTER DELETE block executes, the program array has already been modified; the deleted row no longer exists in the array (except in the special case when deleting the last row). The arr_curr() function or the ui.Dialog.getCurrentRow() method returns the same index as in BEFORE ROW, but it is the index of the new current row. The AFTER ROW block is also executed just after the AFTER DELETE block.

Important: When deleting the last row of the list, AFTER DELETE is executed for the delete row, and DIALOG.getCurrentRow() / arr_curr() will be one greater than DIALOG[arrayLength] /
**ARR_COUNT()**. Ensure you avoid accessing a dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array. When using a static array, you must ignore the values in the rows after **ARR_COUNT()**.

Here the **AFTER DELETE** block is used to re-number the rows with a new item line number (note that **DIALOG.getArrayLength() / ARR_COUNT()** may return zero):

```plaintext
INPUT ARRAY p_items FROM s_items.*
AFTER DELETE
    LET r = DIALOG.getCurrentRow("s_items")
    FOR i=r TO DIALOG.getArrayLength("s_items")
        LET p_items[i].item_lineno = i
    END FOR
...```

It is not possible to use the **CANCEL DELETE** instruction in an **AFTER DELETE** block. At this time it is too late to cancel row deletion, as the data row no longer exists in the program array.

**Related concepts**
- **BEFORE INSERT block** on page 1442
- **AFTER ROW block** on page 1404
- **BEFORE FIELD block**

In dialog instructions **INPUT**, **INPUT ARRAY**, **CONSTRUCT** or in a **DISPLAY ARRAY** using the **FOCUSONFIELD** attribute, the **BEFORE FIELD** block is executed every time the specified field gets the focus.

For single record inputs driven by **INPUT** or query by example (QBEs) driven by **CONSTRUCT**, the **BEFORE FIELD** block is executed when moving the focus from field to field.

For editable lists driven by **INPUT ARRAY**, the **BEFORE FIELD** block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by **DISPLAY ARRAY** using the **FOCUSONFIELD** attribute, the **BEFORE FIELD** block is executed when moving the focus from field to field. However, the fields will not be editable as in an **INPUT ARRAY**.

**Important:** The **BEFORE FIELD** block is also executed when performing a **NEXT FIELD** instruction.

The **BEFORE FIELD** keywords must be followed by a list of form field specification. The screen-record name can be omitted.

**BEFORE FIELD** is executed after **BEFORE INPUT**, **BEFORE CONSTRUCT**, **BEFORE ROW** and **BEFORE INSERT**.

Use this block to do some field value initialization, or to display a message to the user:

```plaintext
INPUT BY NAME p_cust.* ...
BEFORE FIELD cust_status
    LET p_cust.cust_comment = NULL
    MESSAGE "Enter customer status"
```

When using the default **FIELD ORDER CONSTRAINT** mode, the dialog executes the **BEFORE FIELD** block of the field corresponding to the first variable of an **INPUT** or **INPUT ARRAY**, even if that field is not editable (**NOENTRY**, hidden or disabled). The block is executed when you enter the dialog and every time you create a new row in the case of **INPUT ARRAY**. This behavior is supported for backward compatibility. The block is **not** executed when using the **FIELD ORDER FORM** mode, the mode recommended for **DIALOG** instructions.

With the **FIELD ORDER FORM** mode, for each dialog executing the first time with a specific form, the **BEFORE FIELD** block will be invoked for the first field of the initial tabbing list defined by the form, even if that field was hidden or moved around in a table. The dialog then behaves as if a **NEXT FIELD** first-visible-column would have been done in the **BEFORE FIELD** of that field.
When form-level validation occurs and a field contains an invalid value, the dialog gives the focus to the field, but no BEFORE FIELD trigger will be executed.

**Related concepts**

- NEXT FIELD instruction on page 1389
- Form-level validation rules on page 1627
- Form-level validation rules can be defined for each field controlled by a dialog.
- AFTER FIELD block on page 1385

**ON CHANGE block**

The **ON CHANGE** block can be used to detect that a field changed by user input. The **ON CHANGE** block is executed if the value has changed since the field got the focus and if the modification flag is set.

The **ON CHANGE** block can be used in **INPUT**, **INPUT ARRAY** and **CONSTRUCT** dialogs.

For editable fields defined as **EDIT**, **TEXTEDIT** or **BUTTONEDIT**, the **ON CHANGE** block is executed when leaving a field, if the value of the specified field has changed since the field got the focus and if the modification flag is set for the field. You leave the field when you validate the dialog, when you move to another field, or when you move to another row in an **INPUT ARRAY**. However, if the text edit field is defined with the **COMPLETER** attribute to enable autocompletion, the **ON CHANGE** trigger will be fired after a short period of time, when the user has typed characters in.

For editable fields defined as **CHECKBOX**, **COMBOBOX**, **DATEEDIT**, **DATETIMEEDIT**, **TIMEEDIT**, **RADIOGROUP**, **SPINEDIT**, **SLIDER** or **URL-based WEBCOMPONENT** (when the **COMPONENTTYPE** attribute is not used), the **ON CHANGE** block is invoked immediately when the user changes the value with the widget edition feature. For example, when toggling the state of a **CHECKBOX**, when selecting an item in a **COMBOBOX** list, or when choosing a date in the calendar of a **DATEEDIT**. Note that for such item types, when **ON CHANGE** is fired, the modification flag is always set.

```
ON CHANGE order_checked -- Defined as CHECKBOX
CALL setup_dialog(DIALOG)
```

**Note:** If both an **ON CHANGE** block and an **AFTER FIELD** block are defined for a field, the **ON CHANGE** block is executed before the **AFTER FIELD** block.

When changing the value of the current field by program in an **ON ACTION** block, the **ON CHANGE** block will be executed when leaving the field if the value is different from the reference value and if the modification flag is set (after previous user input or when the touched flag has been changed by program).

In an **INPUT** or **INPUT ARRAY**, the field value change is related to value of the variable bound to the field. In a **CONSTRUCT** dialog, the field value change is related to the input buffer / displayed value.

**Note:** When using the **NEXT FIELD** instruction, the comparison value is reassigned as if the user had left and reentered the field. Therefore, when using **NEXT FIELD** in an **ON CHANGE** block or in an **ON ACTION** block, the **ON CHANGE** block will only be invoked again if the value is different from the reference value. This prevents field validation in **ON CHANGE** blocks; you must do validations in **AFTER FIELD** blocks and/or **AFTER INPUT** blocks.

**Related concepts**

- Input field modification flag on page 1623
- Each input field controlled by a dialog instruction has a modification flag.
- Enabling autocompletion on page 1633
- Autocompletion allows a list of completion proposals to be displayed while the user is typing text into a field.
- **AFTER FIELD block** on page 1385
- **COMPLETEER attribute** on page 1251
The COMPLETER attribute enables autocompletion for the edit field.

**AFTER FIELD block**

In dialog instructions INPUT, INPUT ARRAY, CONSTRUCT or in a DISPLAY ARRAY using the FOCUSONFIELD attribute, the AFTER FIELD block is executed every time the focus leaves the specified field.

For single record inputs driven by INPUT or query by example (QBEs) driven by CONSTRUCT, the AFTER FIELD block is executed when moving the focus from field to field.

For editable lists driven by INPUT ARRAY, the AFTER FIELD block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by DISPLAY ARRAY using the FOCUSONFIELD attribute, the AFTER FIELD block is executed when moving the focus from field to field. However, the fields will not be editable as in an INPUT ARRAY.

The AFTER FIELD keywords must be followed by a list of form field specifications. The screen-record name can be omitted.

AFTER FIELD is executed before AFTER INSERT, ON ROW CHANGE, AFTER ROW, AFTER INPUT or AFTER CONSTRUCT.

When a NEXT FIELD instruction is executed in an AFTER FIELD block, the cursor moves to the specified field, which can be the current field. This can be used to prevent the user from moving to another field / row during data input. Note that the BEFORE FIELD block is also executed when NEXT FIELD is invoked.

The AFTER FIELD block of the current field is not executed when performing a NEXT FIELD; only BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW, and BEFORE FIELD of the target item might be executed, based on the sub-dialog type.

When ACCEPT DIALOG, ACCEPT INPUT, or ACCEPT CONTRACT is performed, the AFTER FIELD trigger of the current field is executed.

Use the AFTER FIELD block to implement field validation rules:

```
INPUT BY NAME p_item.* ...
  AFTER FIELD item_quantity
    IF p_item.item_quantity <= 0 THEN
      ERROR "Item quantity cannot be negative or zero"
      LET p_item.item_quantity = 0
    NEXT FIELD item_quantity
END IF
```

**Related concepts**

NEXT FIELD instruction on page 1389
ACCEPT DIALOG instruction on page 1538
BEFORE FIELD block on page 1383
ON CHANGE block on page 1384

**INPUT ARRAY interaction blocks**

**ON ACTION block**

The ON ACTION action-name blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
ON ACTION action-name
  instruction
  ...
```

Action blocks are bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.
This example defines an action block to open a typical zoom window and let the user select a customer record:

```
ON ACTION zoom
    CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as `INPUT`, `INPUT ARRAY` and `CONSTRUCT`, if an action is specific to a field, add the `INFIELD` clause to have the action automatically enabled when the corresponding field gets the focus:

```
ON ACTION zoom INFIELD cust_city
    CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the `ON ACTION` handler needs to define its own attributes at the program level. This can be done by adding the `ATTRIBUTES()` clause of `ON ACTION`:

```
ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
    CALL show_customer_info()
```

For more details about action handlers, and action configuration, see `Dialog actions` on page 1640.

**ON IDLE block**

The `ON IDLE seconds` clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

As `ON IDLE` can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of `ON IDLE` must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON IDLE` trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or gets a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
    IF ask_question("Do you want to reload information from the database?") THEN
        -- Fetch data back from the db server
    END IF
```

**Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

**Related concepts**

- `Get program control if user inactive` on page 1613
- Execute some code after a given number of seconds, when the user does not interact with the program.

**ON TIMER block** on page 1357

**ON KEY block**

An `ON KEY (key-name)` block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The `ON KEY` block is supported for backward compatibility with TUI mode applications.

An `ON KEY` block can specify up to four different keys. Each key creates a specific action object that will be identified by the key name in lowercase. For example, `ON KEY (F5, F6)` creates two actions with the names `F5` and
Each action object will get an `acceleratorName` attribute assigned, with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for `ON KEY` actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully `ON KEY` statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, `ON KEY` statements used with ESC, TAB, UP, DOWN, LEFT, RIGHT, HELP, NEXT, PREVIOUS, INSERT, CONTROL-M, CONTROL-X, CONTROL-V, CONTROL-C, and CONTROL-A should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, `ON KEY` actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a `text` attribute with the action defaults.

```
ON KEY (CONTROL-Z)
    CALL open_zoom()
```

**Related concepts**

- **Configuring actions** on page 1646
  Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

- **Default action views** on page 1645
  A default action view is created to render an action handler when no explicit action view exists for it.

**ON SORT block**

**Basics**

The `ON SORT` interaction block can be used to detect when rows have to be sorted in a `DISPLAY ARRAY` or `INPUT ARRAY` dialog.

`ON SORT` is used in two different contexts:

1. In a regular (full-list) `DISPLAY ARRAY`/`INPUT ARRAY` dialog, the `ON SORT` trigger can be used to detect that a list sort was performed.
2. In a `DISPLAY ARRAY` using paged mode (`ON FILL BUFFER`), use `ON SORT` to detect a sort request from the user and re-fetch the rows from the database in the required order.

**ON SORT in regular full-list DISPLAY ARRAY or INPUT ARRAY**

In a regular `DISPLAY ARRAY`/`INPUT ARRAY` dialog not using paged mode, the `ON SORT` trigger can be used to detect that a list sort was performed.

When the `ON SORT` block executes in this context, the (visual) sort is already done by the runtime system and the `ON SORT` block is only used to execute post-sort tasks, such as displaying current row information.

To display the row position information, use the `arrayToVisualIndex()` dialog method to convert the current program row number to the visual row number:

```
DISPLAY ARRAY arr TO sr.* ...

... 
ON SORT
    MESSAGE SFMT( "Row: %1/%2",
        DIALOG.arrayToVisualIndex( "sr", DIALOG.getCurrentRow("sr") ),
        DIALOG.getArrayLength( "sr" )
    )
... 
```
If needed, you can get the sort column and sort order with the `getSortKey()` and `isSortReverse()` dialog methods:

```sql
DISPLAY ARRAY arr TO sr.* ...
...
ON SORT
  MESSAGE SFMT( "Sort on %1, %2 order",
      DIALOG.getSortKey("sr"),
      IIF( DIALOG.isSortReverse("sr"), "descending", "ascending" )
  )
...
```

**ON SORT in DISPLAY ARRAY using the paged mode**

In a `DISPLAY ARRAY` implementing paged mode with `ON FILL BUFFER` trigger, built-in row sorting is not available because data is provided by pages.

Use the `ON SORT` trigger, to detect a sort request and perform a new SQL query to re-order the rows. In this context, the sort column and sort order are available with the `getSortKey()` and `isSortReverse()` dialog methods:

```sql
DEFINE key STRING, rev BOOLEAN
DISPLAY ARRAY arr TO sr.* ...
...
ON SORT
  -- Re-execute the SQL statement to fill the page of rows in ON FILL BUFFER
  -- Assuming that form field names match table column names
  LET key = DIALOG.getSortKey("sa")
  LET rev = DIALOG.isSortReverse("sa")
  IF key IS NULL THEN
    CALL execute_sql( NULL )
  ELSE
    CALL execute_sql( "ORDER BY " || key || IIF(rev," DESC"," " ) )
  END IF
...
```

See **Paged mode of DISPLAY ARRAY** on page 1743 for more details about the paged mode in `DISPLAY ARRAY` and how to implement sort in this type of record list dialog.

**Related concepts**

**List ordering** on page 1764
List controllers implement a built-in sort. This feature can be disabled if not required.

**ON TIMER block**

The `ON TIMER seconds` clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

As `ON TIMER` can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of `ON TIMER` must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the `ON TIMER` trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```sql
ON TIMER 30
  CALL check_for_messages()
```

**Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after
the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

**Related concepts**

Get program control on a regular (timed) basis on page 1614
Execute some code after a given number of seconds, with or without user interaction with the program.

**ON IDLE block** on page 1356

**INPUT ARRAY control instructions**

**ACCEPT INPUT instruction**

The ACCEPT INPUT instruction validates the INPUT instruction and exits the INPUT ARRAY instruction if no error is raised. The AFTER FIELD, ON CHANGE, etc. control blocks will be executed. Statements after the ACCEPT INPUT will not be executed.

Input field validation is a process that does several successive validation tasks, as listed here:

1. The current field value is checked, the check is based on the program variable data type (for example, the user must input a valid date in a DATE field).
2. NOT NULL field attributes are checked for all input fields. This attribute forces the field to have a value set by program or entered by the user. If the field contains no value, the constraint is not satisfied. Input values are right-trimmed, so if the user inputs only spaces, this corresponds to a NULL value which does not fulfill the NOT NULL constraint.
3. INCLUDE field attributes are checked for all input fields. This attribute forces the field to contain a value that is listed in the include list. If the field contains a value that is not in the list, the constraint is not satisfied.
4. REQUIRED field attributes are checked for all input fields. This attribute forces the field to have a default value, or to be "touched" by the user or by program. If the field was not edited during the dialog, the constraint is not satisfied.

If a field does not satisfy one of these constraints, dialog termination is canceled, an error message is displayed, and the focus goes to the first field causing a problem.

**Related concepts**

NOT NULL attribute on page 1273
The NOT NULL attribute specifies that the field does not accept NULL values.

INCLUDE attribute on page 1264
The INCLUDE attribute defines a list of possible values for a field.

REQUIRED attribute on page 1280
The REQUIRED attribute forces the user to modify the content of a field during an input dialog.

**EXIT INPUT instruction**

Use the EXIT INPUT to terminate the INPUT ARRAY instruction and resume the program execution at the instruction following the INPUT ARRAY block.

```
ON ACTION leave_now
  EXIT INPUT
```

When leaving the INPUT ARRAY instruction, all form items used by the dialog will be disabled until another interactive statement takes control.

**Related concepts**

ACCEPT INPUT instruction on page 1450

**CANCEL DELETE instruction**

In a list controlled by an INPUT ARRAY, row deletion can be canceled by using the CANCEL DELETE instruction in the BEFORE DELETE block. Using this instruction in a different place will generate a compilation error.
When the CANCEL DELETE instruction is executed, the current BEFORE DELETE block is terminated without any other trigger execution (no BEFORE ROW or BEFORE FIELD is executed), and the program execution continues in the user event loop.

You can, for example, prevent row deletion based on some condition:

```plaintext
BEFORE DELETE
   IF user_can_delete() == FALSE THEN
      ERROR "You are not allowed to delete rows"
      CANCEL DELETE
   END IF
```

The instructions that appear after CANCEL DELETE will be skipped.

If the row deletion condition is known before the delete action occurs, disable the delete action to prevent the user from performing a delete row action with the `DIALOG.setActionActive()` method:

```plaintext
CALL DIALOG.setActionActive("delete", FALSE)
```

It is also possible to prevent the user from deleting rows with the `DELETE ROW = FALSE` option in the ATTRIBUTE clause.

**Related concepts**

BEFORE DELETE block on page 1443

CANCEL INSERT instruction

In a list controlled by an INPUT ARRAY, row creation can be canceled by the program with the CANCEL INSERT instruction. This instruction can only be used in the BEFORE INSERT and AFTER INSERT control blocks. If it appears at a different place, the compiler will generate an error.

The instructions that appear after CANCEL INSERT will be skipped.

If the row creation condition is known before the insert/append action occurs, disable the insert and/or append actions to prevent the user from creating new rows, with `DIALOG.setActionActive()`:

```plaintext
CALL DIALOG.setActionActive("insert", FALSE)
CALL DIALOG.setActionActive("append", FALSE)
```

However, this will not prevent the user from appending a new temporary row at the end of the list, when moving down after the last row. To prevent row creation completely, use the `INSERT ROW = FALSE` and `APPEND ROW = FALSE` options in the ATTRIBUTE clause of INPUT ARRAY, or combine with the `AUTO APPEND = FALSE` attribute.

**CANCEL INSERT in BEFORE INSERT**

A CANCEL INSERT executed inside a BEFORE INSERT block prevents the new row creation. The following tasks are performed:

1. No new row will be created (the new row is not yet shown to the user).
2. The BEFORE INSERT block is terminated (further instructions are skipped).
3. The BEFORE ROW and BEFORE FIELD triggers are executed.
4. Control goes back to the user.

You can, for example, cancel a row creation if the user is not allowed to create rows:

```plaintext
BEFORE INSERT
   IF NOT user_can_insert THEN
      ERROR "You are not allowed to insert rows"
      CANCEL INSERT
   END IF
```
Executing \texttt{CANCEL INSERT} in \texttt{BEFORE INSERT} will also cancel a temporary row creation, except when there are no more rows in the list. In this case, \texttt{CANCEL INSERT} will just be ignored and leave the new row as is (otherwise, the instruction would loop without end). You can prevent automatic temporary row creation with the \texttt{AUTO APPEND=FALSE} attribute. If \texttt{AUTO APPEND=FALSE} and a \texttt{CANCEL INSERT} is executed in \texttt{BEFORE INSERT} (user has invoked an append action), the temporary row will be deleted and list will remain empty if it was the last row.

\textbf{CANCEL INSERT in AFTER INSERT}

A \texttt{CANCEL INSERT} executed inside an \texttt{AFTER INSERT} block removes the newly created row. The following tasks are performed:

1. The newly created row is removed from the list (the row exists now and user has entered data).
2. The \texttt{AFTER INSERT} block is terminated (further instructions are skipped).
3. The \texttt{BEFORE ROW} and \texttt{BEFORE FIELD} triggers are executed.
4. The control goes back to the user.

You can, for example, cancel a row insertion if a database error occurs when you try to insert the row into a database table:

\begin{verbatim}
AFTER INSERT
  WHENEVER ERROR CONTINUE
  LET r = DIALOG.getCurrentRow("s_items")
  INSERT INTO items VALUES ( p_items[r].* )
  WHENEVER ERROR STOP
  IF SQLCA.SQLCODE>0 THEN
    ERROR SQLERRMESSAGE
    CANCEL INSERT
  END IF
\end{verbatim}

\textbf{Related concepts}

- \texttt{BEFORE DELETE block} on page 1443
- \texttt{Appending rows in INPUT ARRAY} on page 1749

Rows appended at the end of an editable list are temporary until they are edited.

\textbf{CONTINUE INPUT instruction}

\texttt{CONTINUE INPUT} skips all subsequent statements in the current control block and gives the control back to the dialog. This instruction is useful when program control is nested within multiple conditional statements, and you want to return the control to the dialog. If this instruction is called in a control block that is not \texttt{AFTER INPUT}, further control blocks might be executed depending on the context. Actually, \texttt{CONTINUEINPUT} just instructs the dialog to continue as if the code in the control block was terminated (i.e. it's a kind of \texttt{GOTO end_of_control_block}). However, when executed in \texttt{AFTER INPUT}, the focus returns to the current row and current field in the list, giving the user another chance to enter data in that field. In this case the \texttt{BEFORE ROW} and \texttt{BEFORE FIELD} triggers will be invoked.

In this example, an \texttt{ON ACTION} block gives control back to the dialog, skipping all instructions after line 04:

\begin{verbatim}
ON ACTION zoom
  IF p_cust.cust_id IS NULL OR p_cust.cust_name IS NULL THEN
    ERROR "Zoom window cannot be opened."
    CONTINUE INPUT
  END IF
  IF p_cust.cust_address IS NULL THEN
    ...
\end{verbatim}

You can also use the \texttt{NEXT FIELD} control instruction to give the focus to a specific field and force the dialog to continue. However, unlike \texttt{CONTINUE INPUT}, the \texttt{NEXT FIELD} instruction will also skip the further control blocks that are normally executed.
The Dialog class on page 2367
The `ui.Dialog` class provides a set of methods to configure, query and control the current interactive instruction.

**NEXT FIELD instruction**

**Understanding the NEXT FIELD instruction**

The NEXT FIELD `field-name` instruction gives the focus to the specified field and forces the dialog to stay in that field.

This instruction can be used to control field input, in BEFORE FIELD, ON CHANGE or AFTER FIELD blocks, it can also force a DISPLAY ARRAY or INPUT ARRAY to stay in the current row when NEXT FIELD is used in the AFTER ROW block.

If it exists, the BEFORE FIELD block of the corresponding field is executed.

In editable dialogs, the purpose of the NEXT FIELD instruction is to give the focus to an editable field. Make sure that the field specified in NEXT FIELD is active, or use NEXT FIELD CURRENT. Non-editable fields are fields defined with the NOENTRY attribute, fields disabled at runtime with `DIALOG.setFieldActive()`, or fields using a widget that does not allow input, such as a LABEL.

In a DISPLAY ARRAY using the FOCUSONFIELD attribute, NEXT FIELD can be used in conjunction with `DIALOG.setCurrentRow()`, to set the focus to a specific cell in the list.

Instead of the NEXT FIELD instruction, you can use the `DIALOG.nextField("field-name")` method to register a field, for example when the name is not known at compile time. However, this method only registers the field. It does not stop code execution, like the NEXT FIELD instruction does. You must execute a CONTINUE DIALOG to get the same behavior as NEXT FIELD.

**Form field identification with NEXT FIELD**

With the NEXT FIELD instruction, fields are identified by the form field name specification, not the program variable name used by the dialog. Form fields are bound to program variables with the binding clause of the dialog instruction (INPUT `variable-list` FROM `field-list`, INPUT BY NAME `variable-list`, CONSTRUCT BY NAME `sql` ON `column-list`, CONSTRUCT `sql` ON `column-list` FROM `field-list`, INPUT ARRAY `array-name` FROM `screen-array.*`).

The field name specification can be any of the following:

- `field-name`
- `table-name.field-name`
- `screen-record-name.field-name`
- `FORMONLY.field-name`

Here are some examples:

- "cust_name"
- "customer.cust_name"
- "cust_screen_record.cust_name"
- "item_screen_array.item_label"
- "formonly.total"

When no field name prefix is used, the first form field matching that simple field name is used.

When using a prefix in the field name specification, it must match the field prefix assigned by the dialog field binding method used at the beginning of the interactive statement: When no screen-record has been explicitly specified in the field binding clause (for example, when using INPUT BY NAME `variable-list`), the field prefix must be
the database table name (or FORMONLY) used in the form file, or any valid screen-record using that field. When the FROM clause of the dialog specifies an explicit screen-record (for example, in INPUT variable-list FROM screen-record.* / field-list-with-screen-record-prefix or INPUT ARRAY array-name FROM screen-array.*), the field prefix must be the screen-record name used in the FROM clause.

Abstract field identification is supported with the CURRENT, NEXT and PREVIOUS keywords. These keywords represent the current, next and previous fields respectively. When using FIELD ORDER FORM, the NEXT and PREVIOUS options follow the tabbing order defined by the form. Otherwise, they follow the order defined by the input binding list (with the FROM or BY NAME clause).

In a procedural dialog, if the focus is in the first field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD PREVIOUS will jump out of the current sub-dialog and set the focus to the previous sub-dialog. If the focus is in the last field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD NEXT will jump out of the current sub-dialog and set the focus to the next sub-dialog. NEXT FIELD NEXT or NEXT FIELD PREVIOUS also jumps to another sub-dialog when the focus is in a DISPLAY ARRAY sub-dialog. However, when using an INPUT ARRAY sub-dialog, NEXT FIELD NEXT from within the last column will loop to the first column of the current row, and NEXT FIELD PREVIOUS from within the first column will jump to the last column of the current row - the focus stays in the current INPUT ARRAY sub-dialog. When another sub-dialog gets the focus because of a NEXT FIELD NEXT/ PREVIOUS, the newly-selected field depends on the sub-dialog type, following the tabbing order as if the end-user had pressed the tab or Shift-Tab key combination.

**NEXT FIELD to a non-editable INPUT / INPUT ARRAY / CONSTRUCT field**

Non-editable fields are fields defined with the NOENTRY attribute, fields disabled with ui.Dialog.setFieldActive("field-name", FALSE), or fields using a widget that does not allow input, such as a LABEL.

If a NEXT FIELD instruction specifies a non-editable field, the BEFORE FIELD block of that field is executed. Then the dialog tries to give the focus to that field. Since the field cannot get the focus, the dialog will perform the last pressed navigation key (Tab, Shift-Tab, Left, Right, Up, Down, Accept) and execute the related control blocks, including the AFTER FIELD block of the non-editable field. If no last key is identified, the dialog considers Tab as fallback and moves to the next editable field as defined by the FIELD ORDER mode used by the dialog. Doing a NEXT FIELD to a non-editable field can lead to infinite loops in the dialog; Use NEXT FIELD CURRENT instead.

When selecting a non-editable field with NEXT FIELD NEXT, the runtime system will re-select the current field since it is the next editable field in the dialog. As a result the end user sees no change.

**NEXT FIELD in procedural DIALOG blocks**

In a procedural dialog block, the NEXT FIELD field-name instruction gives the focus to the specified field controlled by INPUT, INPUT ARRAY or CONSTRUCT, or to a read-only list when using DISPLAY ARRAY.

When using a DISPLAY ARRAY sub-dialog, it is possible to give the focus to the list, by specifying the name of the first column as argument for NEXT FIELD.

If the target field specified in the NEXT FIELD instruction is inside the current sub-dialog, neither AFTER FIELD nor AFTER ROW will be invoked for the field or list you are leaving. However, the BEFORE FIELD control blocks of the destination field (or the BEFORE ROW in case of read-only list) will be executed.

If the target field specified in the NEXT FIELD instruction is outside the current sub-dialog, the AFTER FIELD, AFTER INSERT, AFTER ROW, and AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be invoked for the field or list you are leaving. Form-level validation rules will also be checked, as if the user had selected the new sub-dialog himself. This guarantees the current sub-dialog is left in a consistent state. The BEFORE INPUT/ DISPLAY/CONSTRUCT, BEFORE ROW and the BEFORE FIELD control blocks of the destination field / list will then be executed.
**NEXT FIELD in record list control blocks**

When using `NEXT FIELD` in `AFTER ROW` or in `ON ROW CHANGE` of a `DISPLAY ARRAY` or `INPUT ARRAY`, the dialog will stay in the current row and give control back to the user. This behavior allows you to implement data input rules:

```
AFTER ROW
  IF NOT int_flag AND arr_count()<=arr_curr() THEN
    IF arr[arr_curr()].it_count * arr[arr_curr()].it_value > maxval THEN
      ERROR "Amount of line exceeds max value."
    NEXT FIELD item_count
  END IF
END IF
```

**Related concepts**

  How to force the focus to move or stay in a specific form element using program code.

- **The Dialog class** on page 2367
  The `ui.Dialog` class provides a set of methods to configure, query and control the current interactive instruction.

- **NOENTRY attribute** on page 1273
  The `NOENTRY` attribute prevents data entry in the field during an input dialog.

- **Form-level validation rules** on page 1627
  Form-level validation rules can be defined for each field controlled by a dialog.

- **Understanding multiple dialogs** on page 1481
  *Multiple dialogs* are defined with `DIALOG` blocks inside a `FUNCTION`.

- **CLEAR instruction in dialogs**
  The `CLEAR field-list` and `CLEAR SCREEN ARRAY screen-array.*` instructions clear the value buffer of specified form fields. The buffers are directly changed in the current form, and the program variables bound to the dialog are left unchanged. `CLEAR` can be used outside any dialog instruction, such as the `DISPLAY BY NAME / TO` instructions.

  When a dialog is configured with the `UNBUFFERED` mode, there is no reason to clear field buffers since any variable assignment will synchronize field buffers. Actually, changing the field buffers with `DISPLAY` or `CLEAR` instruction in an `UNBUFFERED` dialog will have no visual effect, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. To clear fields of an `UNBUFFERED` dialog, just set to `NULL` the variables bound to the dialog. However, when using a `CONSTRUCT`, no program variables are associated with the dialog and no `UNBUFFERED` concept exits, and the `CLEAR` or `DISPLAY TO / BY NAME` instructions are the only way to modify the `CONSTRUCT` fields.

  A screen array with a screen-line specification doesn't make much sense in a GUI application using `TABLE` containers, you can therefore use the `CLEAR SCREEN ARRAY` instruction to clear all rows of a list.

**Related concepts**

- **CLEAR field-list** on page 1351
  The `CLEAR field-list` instruction clears specific fields in the current form.

- **CLEAR SCREEN ARRAY** on page 1350
  The `CLEAR SCREEN ARRAY` instruction clears the values of all rows of the form list identified by the specified screen array.

- **TABLE container** on page 1217
  Defines a re-sizable table designed to display a list of records.

- **The buffered and unbuffered modes** on page 1618
The buffered and unbuffered mode control the synchronization of program variables and form fields.

**Examples**

**INPUT ARRAY dialog examples.**

**Example 1: INPUT ARRAY with empty record list**

Form definition file "custlist.per":

```plaintext
SCHEMA shop
LAYOUT
TABLE
{
    Id       First name   Last name
    [f001    |f002        |f003        ]
    [f001    |f002        |f003        ]
    [f001    |f002        |f003        ]
    [f001    |f002        |f003        ]

Query by example (CONSTRUCT)

The CONSTRUCT instruction implements database query criteria input in an application form.

  - Example 2: CONSTRUCT with binding by field name on page 1480

Understanding the CONSTRUCT instruction

The CONSTRUCT instruction provides database query, by entering search filters directly in form fields.

Query by example enables a user to query a database by specifying values (or ranges of values) for screen fields that correspond to the database columns. The runtime system converts the query values entered by the user into a boolean SQL condition that can be used in the WHERE clause of a prepared SELECT statement.

The CONSTRUCT statement produces an SQL condition corresponding to all search criteria that a user specifies in the fields. The instruction fills a character variable with that SQL condition, and you can use the content of this variable to create the WHERE clause of a SELECT statement. The SELECT statement must be executed with the dynamic SQL management instructions PREPARE or DECLARE ident CURSOR FROM sqltext:

The CONSTRUCT instruction uses the data types of the form field to verify user input and to produce the SQL condition.

Important: The SQL condition is generated based on the current database session, which defines the type of database server. Therefore, the program must be connected to a database server before entering the CONSTRUCT block. The generated SQL condition is specific to the database server and may not be used with other types of database servers.

If no criteria were entered, the string '1=1' is assigned to the string variable. This is a boolean SQL expression that always evaluates to true so that all rows are returned.
The CONSTRUCT dialog activates the current form. This is the form most recently displayed or, if you are using more than one window, the form currently displayed in the current window. When the CONSTRUCT statement completes execution, the form is cleared and deactivated.

During a CONSTRUCT instruction, edit field input is left-aligned, independently to the form field data type: During an INPUT, numeric fields are right-aligned, during a CONSTRUCT, they are left-aligned.

By default the screen field tabbing order is defined by the order of the field names in the FROM clause; by default this is the list of column names in the ON clause when no FROM clause is specified. If needed, change the field tabbing order with the FIELD ORDER FORM option and TABINDEX field attributes.

This section describes basic dialog programming concepts.

Syntax of CONSTRUCT instruction
The CONSTRUCT instruction provides database query by example, producing a WHERE condition for SELECT.

Syntax

```
CONSTRUCT {  
  BY NAME variable ON column-list  
  | variable ON column-list FROM field-list  
  | ATTRIBUTES ( | display-attribute  
  | control-attribute |  
  |, ... | ) |  
  | HELP help-number |  
  | dialog-control-block  
  | [...]  
END CONSTRUCT |
```

where `column-list` defines a list of database columns as:

```
| column-name  
| table-name.*  
| table-name. column-name  
| [...]  
```

where `field-list` defines a list of fields with one or more of:

```
| field-name  
| table-name.*  
| table-name.field-name  
| screen-array[line].*  
| screen-array[line].field-name  
| screen-record.*  
| screen-record.field-name  
| [...]  
```

where `dialog-control-block` is one of:

```
| BEFORE CONSTRUCT  
| AFTER CONSTRUCT  
| BEFORE FIELD field-spec [,... |  
| ON CHANGE field-spec [,... |  
| AFTER FIELD field-spec [,... |  
| ON IDLE seconds  
| ON TIMER seconds  
| ON ACTION action-name  
  | [ INFIELD field-spec ]  
  | [ ATTRIBUTES ( action-attributes-construct ) ]  
```
ON KEY ( key-name [, ...] )

dialog-statement
[ , ... ]

where action-attributes-construct is:

TEXT = string
COMMENT = string
IMAGE = string
ACCELERATOR = string
DEFAULTVIEW = [ YES | NO | AUTO ]
CONTEXTMENU = [ YES | NO | AUTO ]

where dialog-statement is one of:

statement
NEXT FIELD [ NEXT ] PREVIOUS [ field-spec ]
CONTINUE CONSTRUCT
EXIT CONSTRUCT

where field-spec identifies a unique field with one of:

field-name
table-name.field-name
screen-array.field-name
screen-record.field-name

where display-attribute is:

BLACK | BLUE | CYAN | GREEN
MAGENTA | RED | WHITE | YELLOW
BOLD | DIM | INVISIBLE | NORMAL
REVERSE | BLINK | UNDERLINE

where control-attribute is:

ACCEPT [ = boolean ]
CANCEL [ = boolean ]
FIELD ORDER FORM
HELP = help-number
NAME = "dialog-name"

1. variable is the variable that will contain the SQL condition built by the CONSTRUCT instruction.
2. column-name is the identifier of a database column of the current form.
3. table-name is the identifier of a database table of the current form.
4. field-name is the identifier of a field of the current form.
5. screen-array is the screen array that will be used in the current form.
6. line is a screen array line in the form.
7. screen-record is the identifier of a screen record of the current form.
8. help-number is an integer that allows you to associate a help message number with the instruction.
9. key-name is a hot-key identifier (like F11 or Control-z).
10. dialog-name is the identifier of the dialog.
11. action-name identifies an action that can be executed by the user.
12. *seconds* is an integer literal or variable that defines a number of seconds.
13. *statement* is any instruction supported by the language.
14. *action-attributes* are dialog-specific action attributes.

**Related concepts**
- **Records** on page 382
Records allow structured program variables definitions.
- **Configuring actions** on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.
- **Screen records / arrays** on page 1147
Form fields can be grouped in a *screen record* or *screen array* definition.
- **Message files** on page 1059
Message files centralize strings and larger texts identified by a number, that can be used in programs.

**CONSTRUCT programming steps**
Follow this procedure to use the *CONSTRUCT* dialog instruction.

To implement a *CONSTRUCT* statement:

1. Declare a variable with the *DEFINE* statement, it can be *CHAR*, *VARCHAR* or **STRING** on page 269. *STRING* is preferred in order to avoid any size limitation.
2. Open and display the form, using an *OPEN WINDOW WITH FORM* or an *OPEN FORM/DISPLAY FORM* instruction.
3. Set the *INT_FLAG* on page 518 variable to *FALSE*.
4. Define the *CONSTRUCT* block with the list of form fields to be used for the query by example. If needed, define dialog control blocks to implement rules for the query by example.
5. Inside the *CONSTRUCT* statement, control the behavior of the instruction with *BEFORE CONSTRUCT*, *BEFORE FIELD*, *AFTER FIELD*, *AFTER CONSTRUCT* and *ON ACTION* blocks.
6. After the interaction statement block, test the *INT_FLAG* predefined variable to check if the dialog was canceled (*INT_FLAG*=TRUE) or validated (*INT_FLAG*=FALSE).
   - If the *INT_FLAG* variable is TRUE, you should reset it to FALSE to not disturb code that relies on this variable to detect interruption events from the GUI front-end or TUI console.
7. To build the complete SQL statement, concatenate "SELECT ... WHERE" to the string variable that contains the boolean SQL expression produced by *CONSTRUCT*.
8. Define a database cursor with the *DECLARE FROM* instruction, by using the *SELECT* statement.
9. Execute the cursor and fetch the rows found by the database server. You can for example implement a FOREACH loop to fill a program array, to be shown by a *DISPLAY ARRAY* statement.

**Related concepts**
- **DEFER INTERRUPT / QUIT** on page 516
The *DEFER* instruction defines the program behavior when *interruption* or *quit* signals are received.
- **Form specification files** on page 1132
Form specification files are the source files defining the layout and content of application forms.
- **DISPLAY FORM** on page 1044
Displays and associates a form with the current window.
- **Result set processing** on page 661
Shows how to fetch rows from a database query.

**Using query by example**
Dialog coding concepts, configuration, and code structure.

**Form field specification in CONSTRUCT**
In order to produce an SQL condition, the *CONSTRUCT* instruction uses a list of database columns that must match form fields for user input. Unlike *INPUT, DISPLAY ARRAY* and *INPUT ARRAY*, the *CONSTRUCT* dialog does not
use a program variable for each form field. Only one string variable is required, to hold the SQL condition. Individual field criteria is available in the input buffers (GET_FLDBUF()).

The list of database columns specified in the `CONSTRUCT` statement will appear in the SQL condition produced.

**Binding columns and fields by name**

The `CONSTRUCT BY NAME` variable `ON` `column-list` syntax maps the field names to database column names by name. Form fields are typically defined in the form by following a database schema, specifying the column name and data type.

```plaintext
SCHEMA stock
DEFINE where_part STRING
...
CONSTRUCT BY NAME where_part ON cust_name, cust_address
...
END CONSTRUCT
```

**Binding columns and fields by position**

The `CONSTRUCT` variable `ON` `column-list` `FROM` `field-list` clause explicitly maps database columns to form fields by position. The form can include other fields that are not part of the specified column list, but the number of variables or record members must equal the number of form fields listed in the `FROM` clause. Each database column must be of the same (or a compatible) data type as the corresponding form field. When the user enters data, the runtime system checks the entered value against the data type of the form field.

```plaintext
DEFINE where_part STRING
...
CONSTRUCT where_part ON cust_name, cust_address
    FROM field_02, field_04
...
END CONSTRUCT
```

**Related concepts**

- **Variables** on page 366
  Explains how to define program variables.
- **Screen records / arrays** on page 1147
  Form fields can be grouped in a *screen record* or *screen array* definition.
- **Database schema** on page 476
  Defines database table structures with column type information to be reused in program variable definitions.
- **Database column fields** on page 1139
  Form fields defined with a table and column name get data type from the database schema file.

**Query operators in CONSTRUCT**

The `CONSTRUCT` instruction supports a specific query syntax, using wildcard characters and comparison operators.

**Table 345: CONSTRUCT query operators**

<td>A character in the specified set, at this position</td>
</tr>
<tr>
<td>[^c1c2 [...]]</td>
<td>A character NOT in the specified set, at this position</td>
</tr>
</tbody>
</table>

Queries based on character types are case sensitive, because SQL is case sensitive, except if the database server is configured to be case-insensitive.

The * (star) and ? (question mark) wildcards are specific to character string type queries, and will generate a MATCHES expression or a LIKE expression, depending on the type of database used. When entering a * or ?, the pattern can also contain a character range specification with the square brackets notation [a–z] or [xyz]. A caret (^) as the first character within the square brackets specifies the logical complement of the set, and matches any character that is not listed. For example, the search value [^AB]* specifies all strings beginning with characters other than A or B.

Some syntaxes can produce an "Error in field" dialog error if the feature is supported by the pattern matching operator of the database server. For example, not all db servers support the [a–z] character range specification in the LIKE pattern.

If you want to search for rows with values containing a * star, a ? question mark or a \ backslash, you must escape the wildcard character with a backslash. Specifying a backslash before another character will have no effect.

### CONSTRUCT instruction configuration

This section describes the options that can be specified in the `ATTRIBUTES` clause of the `CONSTRUCT` instruction. The options of the `ATTRIBUTES` clause override all default attributes and temporarily override any display attributes that the `OPTIONS` or the `OPEN WINDOW` statement specified for these fields. With the `CONSTRUCT` statement, the `INVISIBLE` attribute is ignored.

#### NAME option

The `NAME` attribute can be used to name the `CONSTRUCT` dialog. This is especially used to identify actions of the dialog.

The clause specifies the number of a message to display if the user invokes the help dialog. The predefined 'help' action is automatically created by the runtime system. You can bind to the 'help' action.

#### HELP option

**HELP help message**

The `HELP` clause overrides the `HELP` attribute.

#### FIELD ORDER FORM option

By default, the tabbing order is defined by the variable binding list in the instruction description. You can control the tabbing order by using the `FIELD ORDER FORM` attribute. When this attribute is used, the tabbing order is defined by the `TABINDEX` attribute of the form fields. If this attribute is used, the `Dialog.fieldOrder` FGLPROFILE entry is ignored.

The `OPTIONS` instruction can also change the behavior of the `INPUT` instruction, with the `INPUT WRAP` or `FIELD ORDER FORM` options.

#### ACCEPT option

The `ACCEPT` attribute can be set to `FALSE` to avoid the automatic creation of the accept default action. This option can be used for example when you want to write a specific validation procedure, by using `ACCEPT INPUT`.
**CANCEL option**

The `CANCEL` attribute can be set to `FALSE` to avoid the automatic creation of the cancel default action. This is useful for example when you only need a validation action (accept), or when you want to write a specific cancellation procedure, by using `EXIT INPUT`.

If the `CANCEL=FALSE` option is set, no close action will be created, and you must write an ON ACTION close control block to create an explicit action.

**Related concepts**

Syntax of CONSTRUCT instruction on page 1462

The CONSTRUCT instruction provides database query by example, producing a `WHERE` condition for `SELECT`.

**Default actions IN CONSTRUCT**

When an `CONSTRUCT` instruction executes, the runtime system creates a set of default actions.

Depending on the invoked default action, field validation occurs and different `CONSTRUCT` control blocks are executed.

This table lists the default actions created for this dialog:

**Table 348: Default actions created for the CONSTRUCT dialog**

<table>
<thead>
<tr>
<th>Default action</th>
<th>Description</th>
</tr>
</thead>
</table>
| accept         | Validates the CONSTRUCT dialog (validates field criteria)  
                 *Creation can be avoided with ACCEPT attribute.*  
| cancel         | Cancels the CONSTRUCT dialog (no validation, INT_FLAG is set)  
                 *Creation can be avoided with CANCEL attribute.*  
| close          | By default, cancels the CONSTRUCT dialog (no validation, INT_FLAG is set)  
                 Default action view is hidden. See Implementing the close action on page 1672.  
| help           | Shows the help topic defined by the HELP clause.  
                 *Only created when a HELP clause is defined.* |

The accept and cancel default actions can be avoided with the ACCEPT and CANCEL dialog control attributes:

```sql
CONSTRUCT BY NAME cond ON field1 ATTRIBUTES (CANCEL=FALSE)...
```

**Related concepts**

BEFORE CONSTRUCT block on page 1469
AFTER CONSTRUCT block on page 1470
BEFORE FIELD block on page 1383
AFTER FIELD block on page 1385

**BEFORE CONSTRUCT block**

**BEFORE CONSTRUCT block in singular and parallel CONSTRUCT dialogs**

In a singular CONSTRUCT instruction, or when used as parallel dialog, the BEFORE CONSTRUCT is only executed once when dialog is started.

The BEFORE CONSTRUCT block is executed once at dialog start-up, before the runtime system gives control to the user for criteria input. This block can be used to display messages to the user, initialize form fields with default search criteria values, and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```plaintext
CONSTRUCT BY NAME where_part ON ...
    BEFORE CONSTRUCT
    MESSAGE "Enter customer search filter"
    CALL DIALOG.setActionActive("clean", FALSE )
    ...
```

The fields are cleared before the BEFORE CONSTRUCT block is executed.

You can use the NEXT FIELD control instruction in the BEFORE CONSTRUCT block, to jump to a specific field when the dialog starts.

**BEFORE CONSTRUCT block in CONSTRUCT of procedural DIALOG**

In a CONSTRUCT sub-dialog of a procedural DIALOG instruction, the BEFORE CONSTRUCT block is executed when the focus goes to a group of fields driven by a CONSTRUCT sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

BEFORE CONSTRUCT is executed after the BEFORE DIALOG block and before the BEFORE FIELD blocks.

In this example, the BEFORE CONSTRUCT block is used to display a message:

```plaintext
CONSTRUCT BY NAME sql ON customer.*
    BEFORE CONSTRUCT
    MESSAGE "Enter customer search filter"
```
Related concepts
BEFORE INPUT block on page 1381
BEFORE DISPLAY block on page 1402
AFTER CONSTRUCT block on page 1470

AFTER CONSTRUCT block

AFTER CONSTRUCT block in singular and parallel CONSTRUCT dialogs
In a singular CONSTRUCT instruction, or when used as parallel dialog, the AFTER CONSTRUCT is only executed once when dialog is ended.

Use an AFTER CONSTRUCT block to execute instructions after the user has finished search criteria input.

AFTER CONSTRUCT is not executed if an EXIT CONSTRUCT is performed.

The code in AFTER CONSTRUCT can for example check if a criteria combination of different fields is required or denied, and force the end use to enter all

Before checking the content of the fields used in the CONSTRUCT, make sure that the INT_FLAG variable is FALSE.

In the case that the user cancels the dialog, the validation rules must be skipped.

Since no program variables are associated with the form fields, you must query the input buffers of the fields to get the values entered by the user.

```
CONSTRUCT BY NAME where_part ON ...
...
  AFTER CONSTRUCT
    IF NOT INT_FLAG THEN
      IF length(DIALOG.getFieldBuffer(cust_name))==0
        OR length(DIALOG.getFieldBuffer(cust_addr))==0 THEN
        ERROR "Enter a search criteria for customer name and address fields."
      NEXT FIELD CURRENT
    END IF
  END IF
END CONSTRUCT
```

To limit the validation to fields that have been modified by the end user, you can call the FIELD_TOUCHED() function or the DIALOG.getFieldTouched() method to check if a field has changed during the dialog execution. This makes your validation code execute faster if the user has only modified a couple of fields in a large form.

AFTER CONSTRUCT block in CONSTRUCT of procedural DIALOG

In a CONSTRUCT sub-dialog of a procedural DIALOG instruction, the AFTER CONSTRUCT block is executed when the focus is lost by a group of fields driven by a CONSTRUCT sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

AFTER CONSTRUCT is executed after the AFTER FIELD and before the AFTER DIALOG block.

Executing a NEXT FIELD in the AFTER CONSTRUCT control block will keep the focus in the group of fields.

In this example, the AFTER CONSTRUCT block is used to build the SELECT statement:

```
CONSTRUCT BY NAME sql ON customer.*
  AFTER CONSTRUCT
    LET sql = "SELECT * FROM customers WHERE " || sql
```

...
**BEFORE FIELD block**

In dialog instructions `INPUT`, `INPUT ARRAY`, `CONSTRUCT` or in a `DISPLAY ARRAY` using the `FOCUSONFIELD` attribute, the **BEFORE FIELD** block is executed every time the specified field gets the focus.

For single record inputs driven by `INPUT` or query by example (QBEs) driven by `CONSTRUCT`, the **BEFORE FIELD** block is executed when moving the focus from field to field.

For editable lists driven by `INPUT ARRAY`, the **BEFORE FIELD** block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by `DISPLAY ARRAY` using the `FOCUSONFIELD` attribute, the **BEFORE FIELD** block is executed when moving the focus from field to field. However, the fields will not be editable as in an `INPUT ARRAY`.

**Important:** The **BEFORE FIELD** block is also executed when performing a NEXT FIELD instruction.

The **BEFORE FIELD** keywords must be followed by a list of form field specification. The screen-record name can be omitted.

**BEFORE FIELD** is executed after **BEFORE INPUT**, **BEFORE CONSTRUCT**, **BEFORE ROW** and **BEFORE INSERT**.

Use this block to do some field value initialization, or to display a message to the user:

```plaintext
INPUT BY NAME p_cust.* ...
BEFORE FIELD cust_status
  LET p_cust.cust_comment = NULL
  MESSAGE "Enter customer status"
```

When using the default `FIELD ORDER CONSTRAINT` mode, the dialog executes the **BEFORE FIELD** block of the field corresponding to the first variable of an `INPUT` or `INPUT ARRAY`, even if that field is not editable (`NOENTRY`, hidden or disabled). The block is executed when you enter the dialog and every time you create a new row in the case of `INPUT ARRAY`. This behavior is supported for backward compatibility. The block is not executed when using the `FIELD ORDER FORM` mode, the mode recommended for `DIALOG` instructions.

With the `FIELD ORDER FORM` mode, for each dialog executing the first time with a specific form, the **BEFORE FIELD** block will be invoked for the first field of the initial tabbing list defined by the form, even if that field was hidden or moved around in a table. The dialog then behaves as if a NEXT FIELD first-visible-column would have been done in the **BEFORE FIELD** of that field.

When form-level validation occurs and a field contains an invalid value, the dialog gives the focus to the field, but no **BEFORE FIELD** trigger will be executed.

**Related concepts**

- **AFTER DISPLAY block** on page 1403
- **AFTER INPUT block** on page 1382
- **BEFORE CONSTRUCT block** on page 1469

**ON CHANGE block**

The **ON CHANGE** block can be used to detect that a field changed by user input. The **ON CHANGE** block is executed if the value has changed since the field got the focus and if the modification flag is set.

The **ON CHANGE** block can be used in `INPUT`, `INPUT ARRAY` and `CONSTRUCT` dialogs.

For editable fields defined as `EDIT`, `TEXTEDIT` or `BUTTONEDIT`, the **ON CHANGE** block is executed when leaving a field, if the value of the specified field has changed since the field got the focus and if the modification flag is set.
for the field. You leave the field when you validate the dialog, when you move to another field, or when you move to another row in an INPUT ARRAY. However, if the text edit field is defined with the COMPLETER attribute to enable autocompletion, the ON CHANGE trigger will be fired after a short period of time, when the user has typed characters in.

For editable fields defined as CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, TIMEEDIT, RADIOGROUP, SPINEDIT, SLIDER or URL-based WEBCOMPONENT (when the COMPONENTTYPE attribute is not used), the ON CHANGE block is invoked immediately when the user changes the value with the widget edition feature. For example, when toggling the state of a CHECKBOX, when selecting an item in a COMBOBOX list, or when choosing a date in the calendar of a DATEEDIT. Note that for such item types, when ON CHANGE is fired, the modification flag is always set.

```
ON CHANGE order_checked -- Defined as CHECKBOX
CALL setup_dialog(DIALOG)
```

**Note:** If both an ON CHANGE block and AFTER FIELD block are defined for a field, the ON CHANGE block is executed before the AFTER FIELD block.

When changing the value of the current field by program in an ON ACTION block, the ON CHANGE block will be executed when leaving the field if the value is different from the reference value and if the modification flag is set (after previous user input or when the touched flag has been changed by program).

In an INPUT or INPUT ARRAY, the field value change is related to value of the variable bound to the field. In a CONSTRUCT dialog, the field value change is related to the input buffer / displayed value.

**Note:** When using the NEXT FIELD instruction, the comparison value is reassigned as if the user had left and reentered the field. Therefore, when using NEXT FIELD in ON CHANGE block or in an ON ACTION block, the ON CHANGE block will only be invoked again if the value is different from the reference value. This prevents field validation in ON CHANGE blocks; you must do validations in AFTER FIELD blocks and/or AFTER INPUT blocks.

**Related concepts**

- **Input field modification flag** on page 1623
- Each input field controlled by a dialog instruction has a modification flag.

- **Enabling autocompletion** on page 1633
  Autocompletion allows a list of completion proposals to be displayed while the user is typing text into a field.

- **AFTER FIELD block** on page 1385
- **COMPLETER attribute** on page 1251
  The COMPLETER attribute enables autocompletion for the edit field.

**AFTER FIELD block**

In dialog instructions INPUT, INPUT ARRAY, CONSTRUCT or in a DISPLAY ARRAY using the FOCUSONFIELD attribute, the AFTER FIELD block is executed every time the focus leaves the specified field.

For single record inputs driven by INPUT or query by example (QBEs) driven by CONSTRUCT, the AFTER FIELD block is executed when moving the focus from field to field.

For editable lists driven by INPUT ARRAY, the AFTER FIELD block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by DISPLAY ARRAY using the FOCUSONFIELD attribute, the AFTER FIELD block is executed when moving the focus from field to field. However, the fields will not be editable as in an INPUT ARRAY.

The AFTER FIELD keywords must be followed by a list of form field specifications. The screen-record name can be omitted.

AFTER FIELD is executed before AFTER INSERT, ON ROW CHANGE, AFTER ROW, AFTER INPUT or AFTER CONSTRUCT.
When a NEXT FIELD instruction is executed in an AFTER FIELD block, the cursor moves to the specified field, which can be the current field. This can be used to prevent the user from moving to another field / row during data input. Note that the BEFORE FIELD block is also executed when NEXT FIELD is invoked.

The AFTER FIELD block of the current field is not executed when performing a NEXT FIELD: only BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW, and BEFORE FIELD of the target item might be executed, based on the sub-dialog type.

When ACCEPT DIALOG, ACCEPT INPUT, or ACCEPT CONSTRUCT is performed, the AFTER FIELD trigger of the current field is executed.

Use the AFTER FIELD block to implement field validation rules:

```
INPUT BY NAME p_item.* ...
AFTER FIELD item_quantity
  IF p_item.item_quantity <= 0 THEN
    ERROR "Item quantity cannot be negative or zero"
    LET p_item.item_quantity = 0
  NEXT FIELD item_quantity
END IF
```

CONSTRUCT interaction blocks

ON ACTION block

The ON ACTION action-name blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
ON ACTION action-name
  instruction
  ...
```

Action blocks are bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

This example defines an action block to open a typical zoom window and let the user select a customer record:

```
ON ACTION zoom
  CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as INPUT, INPUT ARRAY and CONSTRUCT, if an action is specific to a field, add the INFIELD clause to have the action automatically enabled when the corresponding field gets the focus:

```
ON ACTION zoom INFIELD cust_city
  CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the ON ACTION handler needs to define its own attributes at the program level. This can be done by adding the ATTRIBUTES() clause of ON ACTION:

```
ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
  CALL show_customer_info()
```
For more details about action handlers, and action configuration, see Dialog actions on page 1640.

**ON IDLE block**

The ON IDLE seconds clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

As ON IDLE can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of ON IDLE must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON IDLE trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or gets a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
  IF ask_question("Do you want to reload information from the database?") THEN
    -- Fetch data back from the db server
  END IF
```

**Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

**Related concepts**

- Get program control if user inactive on page 1613
- Execute some code after a given number of seconds, when the user does not interact with the program.

**ON TIMER block** on page 1357

**ON KEY block**

An ON KEY (key-name) block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The ON KEY block is supported for backward compatibility with TUI mode applications.

An ON KEY block can specify up to four different keys. Each key creates a specific action object that will be identified by the key name in lowercase. For example, ON KEY (F5, F6) creates two actions with the names f5 and f6. Each action object will get an acceleratorName attribute assigned, with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for ON KEY actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully ON KEY CONTROL-? statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, ON KEY statements used with ESC, TAB, UP, DOWN, LEFT, RIGHT, HELP, NEXT, PREVIOUS, INSERT, CONTROL-M, CONTROL-X, CONTROL-V, CONTROL-C and CONTROL-A should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, ON KEY actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a text attribute with the action defaults.

```
ON KEY (CONTROL-Z)
  CALL open_zoom()
```
Related concepts

Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

Default action views on page 1645
A default action view is created to render an action handler when no explicit action view exists for it.

ON TIMER block

The ON TIMER seconds clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

As ON TIMER can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of ON TIMER must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON TIMER trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```plaintext
ON TIMER 30
  CALL check_for_messages()
```

Important: The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

Related concepts

Get program control on a regular (timed) basis on page 1614
Execute some code after a given number of seconds, with or without user interaction with the program.

ON IDLE block on page 1356

CONSTRUCT control instructions

ACCEPT CONSTRUCT instruction

The ACCEPT CONSTRUCT instruction validates the CONSTRUCT instruction and exits the dialog block if no error is raised.

The AFTER FIELD and AFTER CONSTRUCT control blocks will be executed.

The statements after the ACCEPT CONSTRUCT will not be executed.

```plaintext
CONSTRUCT BY NAME where_part ON ...
  ...
  ON ACTION default_query
    CALL set_default_filter()
    ACCEPT CONSTRUCT
  ...
END CONSTRUCT
```

The CONSTRUCT instruction creates the default accept action to let the user validate the dialog. Use the ACCEPT CONSTRUCT instruction only in specific cases when the default accept action is not appropriate.

Related concepts

CONSTRUCT control blocks execution order on page 1468
NEXT FIELD instruction on page 1389
EXIT CONSTRUCT instruction on page 1476
CONTINUE CONSTRUCT instruction on page 1476
CONTINUE CONSTRUCT instruction

CONTINUE CONSTRUCT skips all subsequent statements in the current control block and gives the control back to the dialog. This instruction is useful when program control is nested within multiple conditional statements, and you want to return the control to the dialog. If this instruction is called in a control block that is not AFTER CONSTRUCT, further control blocks might be executed depending on the context. Actually, CONTINUE CONSTRUCT just instructs the dialog to continue as if the code in the control block was terminated (therefore it acts as a kind of GOTO end_of_control_block). However, when executed in AFTER CONSTRUCT, the focus returns to the most recently occupied field in the current form, giving the user another chance to enter data in that field. In this case the BEFORE FIELD of the current field will be invoked.

As alternative, use the NEXT FIELD control instruction to give the focus to a specific field and force the dialog to continue. However, unlike CONTINUE CONSTRUCT, the NEXT FIELD instruction will skip the next control blocks that are normally executed.

Related concepts
CONSTRUCT control blocks execution order on page 1468
NEXT FIELD instruction on page 1389
ACCEPT CONSTRUCT instruction on page 1475
EXIT CONSTRUCT instruction on page 1476

EXIT CONSTRUCT instruction

The EXIT CONSTRUCT instruction terminates the CONSTRUCT instruction and resumes the program execution at the instruction following the INPUT block.

Performing an EXIT CONSTRUCT instruction during a dialog is equivalent to canceling the dialog: No field validation will occur, and the AFTER FIELD or AFTER CONSTRUCT blocks will not be executed. The dialog is exited immediately. However, INT_FLAG will not be set to TRUE as when the cancel action is fired.

Related concepts
CONSTRUCT control blocks execution order on page 1468
NEXT FIELD instruction on page 1389
ACCEPT CONSTRUCT instruction on page 1475
CONTINUE CONSTRUCT instruction on page 1476

NEXT FIELD instruction

Understanding the NEXT FIELD instruction

The NEXT FIELD field-name instruction gives the focus to the specified field and forces the dialog to stay in that field.

This instruction can be used to control field input, in BEFORE FIELD, ON CHANGE or AFTER FIELD blocks, it can also force a DISPLAY ARRAY or INPUT ARRAY to stay in the current row when NEXT FIELD is used in the AFTER ROW block.

If it exists, the BEFORE FIELD block of the corresponding field is executed.

In editable dialogs, the purpose of the NEXT FIELD instruction is to give the focus to an editable field. Make sure that the field specified in NEXT FIELD is active, or use NEXT FIELD CURRENT. Non-editable fields are fields defined with the NOENTRY attribute, fields disabled at runtime with DIALOG.setFieldActive(), or fields using a widget that does not allow input, such as a LABEL.

In a DISPLAY ARRAY using the FOCUSONFIELD attribute, NEXT FIELD can be used in conjunction with DIALOG.setCurrentRow(), to set the focus to a specific cell in the list.

Instead of the NEXT FIELD instruction, you can use the DIALOG.nextField("field-name") method to register a field, for example when the name is not known at compile time. However, this method only registers the field. It does not stop code execution, like the NEXT FIELD instruction does. You must execute a CONTINUE DIALOG to get the same behavior as NEXT FIELD.
Form field identification with NEXT FIELD

With the NEXT FIELD instruction, fields are identified by the form field name specification, not the program variable name used by the dialog. Form fields are bound to program variables with the binding clause of the dialog instruction (INPUT variable-list FROM field-list, INPUT BY NAME variable-list, CONSTRUCT BY NAME sql ON column-list, CONSTRUCT sql ON column-list FROM field-list, INPUT ARRAY array-name FROM screen-array.*).

The field name specification can be any of the following:

- field-name
- table-name.field-name
- screen-record-name.field-name
- FORMONLY.field-name

Here are some examples:

- "cust_name"
- "customer.cust_name"
- "cust_screen_record.cust_name"
- "item_screen_array.item_label"
- "formonly.total"

When no field name prefix is used, the first form field matching that simple field name is used.

When using a prefix in the field name specification, it must match the field prefix assigned by the dialog field binding method used at the beginning of the interactive statement: When no screen-record has been explicitly specified in the field binding clause (for example, when using INPUT BY NAME variable-list), the field prefix must be the database table name (or FORMONLY) used in the form file, or any valid screen-record using that field. When the FROM clause of the dialog specifies an explicit screen-record (for example, in INPUT variable-list FROM screen-record.* / field-list-with-screen-record-prefix or INPUT ARRAY array-name FROM screen-array.*), the field prefix must be the screen-record name used in the FROM clause.

Abstract field identification is supported with the CURRENT, NEXT and PREVIOUS keywords. These keywords represent the current, next and previous fields respectively. When using FIELD ORDER FORM, the NEXT and PREVIOUS options follow the tabbing order defined by the form. Otherwise, they follow the order defined by the input binding list (with the FROM or BY NAME clause).

In a procedural dialog, if the focus is in the first field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD PREVIOUS will jump out of the current sub-dialog and set the focus to the previous sub-dialog. If the focus is in the last field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD NEXT will jump out of the current sub-dialog and set the focus to the next sub-dialog. NEXT FIELD NEXT or NEXT FIELD PREVIOUS also jumps to another sub-dialog when the focus is in a DISPLAY ARRAY sub-dialog. However, when using an INPUT ARRAY sub-dialog, NEXT FIELD NEXT from within the last column will loop to the first column of the current row, and NEXT FIELD PREVIOUS from within the first column will jump to the last column of the current row - the focus stays in the current INPUT ARRAY sub-dialog. When another sub-dialog gets the focus because of a NEXT FIELD NEXT/PREVIOUS, the newly-selected field depends on the sub-dialog type, following the tabbing order as if the end-user had pressed the tab or Shift-Tab key combination.

NEXT FIELD to a non-editable INPUT / INPUT ARRAY / CONSTRUCT field

Non-editable fields are fields defined with the NOENTRY attribute, fields disabled with ui.Dialog.setFieldActive("field-name", FALSE), or fields using a widget that does not allow input, such as a LABEL.

If a NEXT FIELD instruction specifies a non-editable field, the BEFORE FIELD block of that field is executed. Then the dialog tries to give the focus to that field. Since the field cannot get the focus, the dialog will perform the last pressed navigation key (Tab, Shift-Tab, Left, Right, Up, Down, Accept) and execute the related control blocks, including the AFTER FIELD block of the non-editable field. If no last key is identified, the dialog considers Tab
as fallback and moves to the next editable field as defined by the FIELD ORDER mode used by the dialog. Doing a NEXT FIELD to a non-editable field can lead to infinite loops in the dialog; Use NEXT FIELD CURRENT instead.

When selecting a non-editable field with NEXT FIELD NEXT, the runtime system will re-select the current field since it is the next editable field in the dialog. As a result the end user sees no change.

**NEXT FIELD in procedural DIALOG blocks**

In a procedural dialog block, the NEXT FIELD field-name instruction gives the focus to the specified field controlled by INPUT, INPUT ARRAY or CONSTRUCT, or to a read-only list when using DISPLAY ARRAY.

When using a DISPLAY ARRAY sub-dialog, it is possible to give the focus to the list, by specifying the name of the first column as argument for NEXT FIELD.

If the target field specified in the NEXT FIELD instruction is inside the current sub-dialog, neither AFTER FIELD nor AFTER ROW will be invoked for the field or list you are leaving. However, the BEFORE FIELD control blocks of the destination field (or the BEFORE ROW in case of read-only list) will be executed.

If the target field specified in the NEXT FIELD instruction is outside the current sub-dialog, the AFTER FIELD, AFTER INSERT, AFTER ROW, and AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be invoked for the field or list you are leaving. Form-level validation rules will also be checked, as if the user had selected the new sub-dialog himself. This guarantees the current sub-dialog is left in a consistent state. The BEFORE INPUT/DISPLAY/CONSTRUCT, BEFORE ROW and the BEFORE FIELD control blocks of the destination field / list will then be executed.

**NEXT FIELD in record list control blocks**

When using NEXT FIELD in AFTER ROW or in ON ROW CHANGE of a DISPLAY ARRAY or INPUT ARRAY, the dialog will stay in the current row and give control back to the user. This behavior allows you to implement data input rules:

```plaintext
AFTER ROW
    IF NOT int_flag AND arr_count()<=arr_curr() THEN
        IF arr[arr_curr()].it_count * arr[arr_curr()].it_value > maxval THEN
            ERROR "Amount of line exceeds max value."
            NEXT FIELD item_count
        END IF
    END IF
```

Form-level validation rules can be defined for each field controlled by a dialog.

**Understanding multiple dialogs** on page 1481  
*Multiple dialogs* are defined with DIALOG blocks inside a FUNCTION.

**CLEAR instruction in dialogs**

The CLEAR field-list and CLEAR SCREEN ARRAY screen-array.* instructions clear the value buffer of specified form fields. The buffers are directly changed in the current form, and the program variables bound to the dialog are left unchanged. CLEAR can be used outside any dialog instruction, such as the DISPLAY BY NAME / TO instructions.
When a dialog is configured with the **UNBUFFERED** mode, there is no reason to clear field buffers since any variable assignment will synchronize field buffers. Actually, changing the field buffers with **DISPLAY** or **CLEAR** instruction in an **UNBUFFERED** dialog will have no visual effect, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. To clear fields of an **UNBUFFERED** dialog, just set to **NULL** the variables bound to the dialog. However, when using a **CONSTRUCT**, no program variables are associated with the dialog and no **UNBUFFERED** concept exits, and the **CLEAR** or **DISPLAY TO / BY NAME** instructions are the only way to modify the **CONSTRUCT** fields.

A screen array with a screen-line specification doesn’t make much sense in a GUI application using **TABLE** containers, you can therefore use the **CLEAR SCREEN ARRAY** instruction to clear all rows of a list.

**Example 1: CONSTRUCT with binding by field position**

Form definition file "form1.per":

```plaintext
SCHEMA office

LAYOUT
GRID
{
  Customer id: [f001 ]
  First Name : [f002 ]
  Last Name  : [f003 ]
}
END

TABLES
customer
END

ATTRIBUTES
  f001 = customer.id;
  f002 = customer.fname;
  f003 = customer.lname, UPSHIFT;
END

INSTRUCTIONS
  SCREEN RECORD sr_cust(customer.*);
END
```

Program source code:

```plaintext
MAIN
  DEFINE condition STRING
  DATABASE office
  OPEN FORM f1 FROM "form1"
```
Example 2: CONSTRUCT with binding by field name

Form definition file "form1.per":

```
SCHEMA office
LAYOUT
GRID
{
  Customer id: [f001 ]
  First Name : [f002 ]
  Last Name  : [f003 ]
}
END
END

TABLES
  customer
END

ATTRIBUTES
  f001 = customer.id;
  f002 = customer.fname;
  f003 = customer.lname, UPSHIFT;
END

INSTRUCTIONS
  SCREEN RECORD sr_cust(customer.*);
END
```

Program source code:

```
SCHEMA office
MAIN
  DEFINE condition STRING
  DEFINE statement STRING
  DEFINE cust RECORD LIKE customer.*

  DATABASE office

  OPEN FORM f1 FROM "form1"
  DISPLAY FORM f1

  CONSTRUCT BY NAME condition ON customer.*
    BEFORE CONSTRUCT
      DISPLAY "A*" TO fname
      DISPLAY "B*" TO lname
    END CONSTRUCT

  LET statement =
    "SELECT fname, lname FROM customer WHERE " || condition
  DISPLAY "SQL: " || statement

  DECLARE c1 CURSOR FROM statement
  FOREACH c1 INTO cust.*
    DISPLAY cust.*
```
Multiple dialogs (DIALOG - inside functions)

The procedural DIALOG instruction allows for the combination of record list, record input, and query criteria input in the same application form.

Understanding multiple dialogs

Multiple dialogs are defined with DIALOG blocks inside a FUNCTION.

The concept of multiple dialogs refers to the usage of a procedural DIALOG block, to control several elements of a form. During the execution of a procedural dialog, no other window/form can be accessed: multiple dialogs are in the category of modal dialogs.

The DIALOG procedural instruction handles different parts of a form simultaneously, including simple display fields, simple input fields, read-only list of records, editable list of records, query by example fields, and action views. The DIALOG instruction acts as a collection of singular dialogs working in parallel.
"Singular interactive instructions" refer to `INPUT`, `CONSTRUCT`, `DISPLAY ARRAY` and `INPUT ARRAY` independent blocks not surrounded by the `DIALOG / END DIALOG` keywords. While the `DIALOG` instruction reuses some of the semantics and behaviors of singular interactive instructions, there are some differences.

Like the singular interactive instructions, `DIALOG` is an interactive instruction. You can execute a `DIALOG` instruction from one of the singular dialogs, or execute a singular dialog from a `DIALOG` block. The parent dialog will be disabled until the child dialog returns.

A `DIALOG` procedural instruction consist of several sub-dialog blocks declared inside the `DIALOG` instruction, or external dialog blocks declared in scope outside of the current function. The external dialogs are attached to the current dialog with the `SUBDIALOG` clause.

The `DIALOG` instruction binds program variables (such as simple records or arrays of records) with a screen-record or screen-array defined in a form, allowing the user to view and update application data.

When a `DIALOG` block executes, it activates the current form (the form most recently displayed or the form in the current window). When the statement completes execution, the form is deactivated.
The screenshot is from a demo program called "Query customers" that you can find in FGLDIR/demo/MultipleDialogs. This demo involves a DIALOG block that contains a simple INPUT block, a CONSTRUCT block, and a DISPLAY ARRAY block:

The syntax of the DIALOG instruction is very close to singular dialogs, using common triggers such as BEFORE FIELD, ON ACTION, and so on. Despite the similarities, the behavior and semantics of DIALOG are a bit different from singular dialogs.

Understand that the DIALOG instruction is not provided to replace singular dialogs. Singular dialogs are still supported. It is recommended that you use singular dialogs if no multiple dialog is required.

Unlike singular dialogs, the DIALOG instruction does not use the INT_FLAG variable. You must implement ON ACTION accept or ON ACTION cancel to handle dialog validation or cancellation. These actions do not exist by default in DIALOG.

Unlike singular dialogs creating implicit accept and cancel actions, by default there is no way to quit the DIALOG instruction. You must implement your own action handler and execute EXIT DIALOG or ACCEPT DIALOG.

A good practice is to write a setup dialog function to centralize all field and action activations for a specific context. Call that setup function at any place in the DIALOG code where the field and action activation rules may change.

While static arrays are supported by the DIALOG instruction, it is strongly recommended that you use dynamic arrays instead. With a dynamic array, the actual number of rows is automatically defined by the array variable, while static arrays need an additional step to define the total number of rows.

When needed, use the UNBUFFERED mode with multiple dialogs to force model/view synchronization, and use the FIELD ORDER FORM option to follow the TABINDEX definitions in the form file.

This example is of a DIALOG procedural instruction that includes both an INPUT and a DISPLAY ARRAY sub-dialog, plus a sub-dialog defined externally and included with the SUBDIALOG keyword:

```plaintext
SCHEMA stores
DEFINE p_customer RECORD LIKE customer.*
DEFINE p_orders DYNAMIC ARRAY OF RECORD LIKE order.*
FUNCTION customer_dialog()
  DIALOG ATTRIBUTES(UNBUFFERED, FIELD ORDER FORM)
    INPUT BY NAME p_customer.*
    AFTER FIELD cust_name
      CALL setup_dialog(DIALOG)
    END INPUT
    DISPLAY ARRAY p_orders TO s_orders.*
    BEFORE ROW
      CALL setup_dialog(DIALOG)
    END DISPLAY
    SUBDIALOG common_footer
    ON ACTION close
      EXIT DIALOG
    END DIALOG
  END DIALOG
END FUNCTION
```

All elements of the dialog are active at the same time, so you must handle tabbing order properly. By default - as in singular dialogs - the tabbing order is driven by the binding list (order of program variables). It is strongly recommended that you use the FIELD ORDER FORM option and the TABINDEX field attributes instead.

Like the singular INPUT ARRAY instruction, DIALOG creates implicit insert, append, and delete actions. These actions are only active when the focus is in the list.

<tbody>
<tr>
<td>table-name.*</td>
</tr>
<tr>
<td>table-name.column-name</td>
</tr>
<tr>
<td>, ....</td>
</tr>
</tbody>
</table>
```

1. variable-definition is a variable declaration with data type as in a regular DEFINE statement.
2. array is the array of records used by the DIALOG statement.
3. help-number is an integer that allows you to associate a help message number with the command.
4. field-name is the identifier of a field of the current form.
5. option-name is a string expression defining the label of the action and identifying the action that can be executed by the user.
6. option-comment is a string expression containing a description for the menu option, displayed when option-name is the current.
7. column-name is the identifier of a database column of the current form.
8. table-name is the identifier of a database table of the current form.
9. variable is a simple program variable (not a record).
10. record is a program record (structured variable).
11. screen-array is the screen array that will be used in the current form.
12. line is a screen array line in the form.
13. screen-record is the identifier of a screen record of the current form.
14. action-name identifies an action that can be executed by the user.
15. seconds is an integer literal or variable that defines a number of seconds.
16. key-name is a hot-key identifier (like F11 or Control-z).
17. row-index identifies the program variable which holds the row index corresponding to the tree node that has been expanded or collapsed.
18. dnd-object references a ui.DragDrop variable defined in the scope of the dialog.
19. statement is any instruction supported by the language.
20. action-attributes are dialog-specific action attributes for the action.

**Procedural dialog programming steps**

Follow this procedure to use the DIAOG instruction.

To implement a procedural DIALOG block:
1. Create a form specification file containing screen record(s) and/or screen array(s). The screen records and screen arrays identify the presentation elements to be used by the runtime system to display the data models (the content of program variables bound to the DIALOG blocks).

2. With the DEFINE instruction, declare program variables (records and arrays) that will be used as data models. For record lists (DISPLAY ARRAY or INPUT ARRAY), the members of the program array must correspond to the elements of the screen array, by number and data types. To handle record lists, use dynamic arrays instead of static arrays.

3. Open and display the form, using the OPEN WINDOW WITH FORM clause or the OPEN FORM/DISPLAY FORM instructions.

4. Fill the program variables (the model) with data. For lists, you typically use a result set cursor.

5. Implement the DIALOG instruction block to handle interaction. Define each sub-dialog with program variables to be used as data models. The sub-dialogs will define how variables will be used (display or input).
   a) Inside each sub-dialog instruction, define the behavior with control blocks such as BEFORE DIALOG, AFTER ROW, BEFORE FIELD, and interaction blocks such as ON ACTION.
   b) To end the DIALOG instruction, implement an ON ACTION close or ON ACTION accept/ON ACTION cancel to handle dialog validation and cancellation, with the ACCEPT DIALOG and EXIT DIALOG control instructions. The INT_FLAG variable will not be set as in singular dialogs.

Using multiple dialogs
Dialog coding concepts, configuration and code structure.

Identifying sub-dialogs in procedural DIALOG
Sub-dialogs need to be identified by a name to distinguish the different contexts.

A procedural DIALOG block is a collection of sub-dialogs that act as controllers for different parts of a form. In order to program a procedural DIALOG block, there must be a unique identifier for each sub-dialog.

For example, to set the current row of a screen array with the DIALOG.setCurrentRow() method, you pass the name of the screen array to specify the sub-dialog to be affected. Sub-dialog identifiers are also used as a prefix to specify actions for the sub-dialog.

The following topics describe how to specify the names of the different types of DIALOG sub-dialogs:

- Identifying an INPUT sub-dialog on page 1492
- Identifying a DISPLAY ARRAY sub-dialog on page 1494
- Identifying an INPUT ARRAY sub-dialog on page 1496
- Identifying a CONSTRUCT sub-dialog on page 1493
- The SUBDIALOG clause on page 1496.

Related concepts

The ui.Dialog class provides a set of methods to configure, query and control the current interactive instruction.

Binding action views to action handlers on page 1664
How are action views of the forms bound to action handlers in the program code?

Structure of a procedural DIALOG block

A procedural DIALOG instruction is made up of several sub-dialogs, plus global control blocks such as BEFORE DIALOG and action handlers such as ON ACTION or COMMAND.

Sub-dialogs can be defined inside the DIALOG instruction, or can be declared externally in another module and attached to the current DIALOG block with the SUBDIALOG clause. A dialog defined in the scope of a function is know as a procedural dialog block, while a dialog declared in the scope of a module is named a declarative dialog block.
The sub-dialogs bind program variables to form fields and define the type of interaction that will take place for the data model (simple input, list input or query). The sub-dialogs implement individual control blocks which let you control the behavior of the interactive instruction. Sub-dialogs can also hold action handlers, which will define local sub-dialog actions.

The DIALOG procedural instruction can hold the following type of sub-dialogs:

1. Simple record input with the INPUT sub-dialog block.
2. Query by example input with the CONSTRUCT sub-dialog block.
3. Read-only record list navigation with the DISPLAY ARRAY sub-dialog block.
4. Editable record list handling with the INPUT ARRAY sub-dialog block.
5. A SUBDIALOG clause referencing a declarative sub-dialog by name.

Related concepts
Declarative dialogs (DIALOG - at module level) on page 1546
DIALOG/END DIALOG defined at module level implement declarative dialogs that can be used in procedural dialogs or in parallel dialogs.

The INPUT sub-dialog
The INPUT sub-dialog implements single record input in fields of the current form.

Program variable to form field binding
Each record member variable is bound to the corresponding field of a screen record, in order to manipulate the values that the user enters in the form fields.

The INPUT clause can be used in two forms:

1. INPUT BY NAME variable-list
2. INPUT variable-list FROM field-list

The BY NAME clause implicitly binds the fields to the variables that have the same identifiers as the field names. The variables must be declared with the same names as the fields from which they accept input. The runtime system ignores any record name prefix when making the match. The unqualified names of the variables and of the fields must be unique and unambiguous within their respective domains. If they are not, the runtime system generates an exceptions, and sets the STATUS variable to a negative value.

```
DEFINE p_cust RECORD
  cust_num INTEGER,
  cust_name VARCHAR(50),
  cust_address VARCHAR(100)
END RECORD
...
DIALOG
  INPUT BY NAME p_cust.*
    BEFORE FIELD cust_name
  ...
END INPUT
...
END DIALOG
```

The FROM clause explicitly binds the fields in the screen record to a list of program variables by position. The number of variables or record members must equal the number of fields listed in the FROM clause. Each variable must be of the same (or a compatible) data type as the corresponding screen field. When the user enters data, the runtime system checks the entered value against the data type of the variable, not the data type of the screen field.

```
DEFINE c_name VARCHAR(50)
  c_addr VARCHAR(100)
...
DIALOG
  INPUT c_name,
```
Identifying an INPUT sub-dialog

The name of an INPUT sub-dialog can be used to qualify sub-dialog actions with a prefix.

In order to identify the INPUT sub-dialog with a specific name, you can use the ATTRIBUTES clause to set the NAME attribute:

```plaintext
INPUT BY NAME p_cust.*
ATTRIBUTES (NAME = "cust")
...```

Control blocks in INPUT

Simple record input declared with the INPUT sub-dialog can raise the following triggers:

- **BEFORE INPUT**
- **BEFORE FIELD**
- **ON CHANGE**
- **AFTER FIELD**
- **AFTER INPUT**

In the singular INPUT instruction, BEFORE INPUT and AFTER INPUT blocks are typically used as initialization and finalization blocks. In an INPUT sub-dialog of a DIALOG block, BEFORE INPUT and AFTER INPUT blocks will be executed each time the focus goes to (BEFORE) or leaves (AFTER) the group of fields defined by this sub-dialog.

Related concepts

- **Records** on page 382
  Records allow structured program variables definitions.
- **Screen records / arrays** on page 1147
  Form fields can be grouped in a screen record or screen array definition.
- **INPUT ATTRIBUTES clause** on page 1499
  Attributes of the INPUT clause of a DIALOG block.

**The CONSTRUCT sub-dialog**

The CONSTRUCT sub-dialog provides database query by example feature, converting search criteria entered by the user into an SQL WHERE condition that can be used to execute a SELECT statement.

Defining query by example fields

The CONSTRUCT sub-dialog requires a character string variable to hold the WHERE clause, and a list of screen fields where the user can enter search criteria.

```plaintext
DEFINE sql_condition STRING
...
DIALOG
  CONSTRUCT BY NAME sql_condition
      ON customer.cust_name, customer.cust_address
  BEFORE FIELD cust_name
...```
Make sure the character string variable is large enough to store all possible SQL conditions. It is better to use a `STRING` data type to avoid any size problems.

`CONSTRUCT` uses the field data types defined in the current form file to produce the SQL conditions. This is different from other interactive instructions, where the data types of the program variables define the way to handle input/display. It is strongly recommended (but not mandatory) that the form field data types correspond to the data types of the program variables used for input. This is implicit if both form fields and program variables are based on the database schema file.

The `CONSTRUCT` clause can be used in two forms:

1. `CONSTRUCT BY NAME string-variable ON column-list`
2. `CONSTRUCT string-variable ON column-list FROM field-list`

The `BY NAME` clause implicitly binds the form fields to the columns, where the form field identifiers match the column names specified in the column-list after the `ON` keyword. You can specify the individual column names (separated by commas) or use the `tablename.*` shortcut to include all columns defined for a table in the database schema file.

The `FROM` clause explicitly binds the form fields listed after the `FROM` keyword with the column definitions listed after the `ON` keyword.

In both cases, the name of the columns in `column-list` will be used to produce the SQL condition in `string-variable`.

### Identifying a `CONSTRUCT` sub-dialog

The name of a `CONSTRUCT` sub-dialog can be used to qualify sub-dialog actions with a prefix. In order to identify the `CONSTRUCT` sub-dialog with a specific name, use the `ATTRIBUTES` clause to set the `NAME` attribute:

```
CONSTRUCT BY NAME sql_condition ON customer.*
  ATTRIBUTES (NAME = "q_cust")

...```

### Control blocks in `CONSTRUCT`

A Query By Example declared with the `CONSTRUCT` clause can raise the following triggers:

- `BEFORE CONSTRUCT`
- `BEFORE FIELD`
- `AFTER FIELD`
- `AFTER CONSTRUCT`

In the singular `CONSTRUCT` instruction, `BEFORE CONSTRUCT` and `AFTER CONSTRUCT` blocks are typically used as initialization and finalization blocks. In `DIALOG` block, `BEFORE CONSTRUCT` and `AFTER CONSTRUCT` blocks will be executed each time the focus goes to (`BEFORE`) or leaves (`AFTER`) the group of fields defined by this sub-dialog.

The **DISPLAY ARRAY** sub-dialog
The DISPLAY ARRAY sub-dialog is the controller to implement the navigation in a list of records, with option data modification actions.

**Program array to screen array binding**
The DISPLAY ARRAY sub-dialog binds the members of the flat record (or the primitive member) of an array to the screen-array or screen-record fields specified with the TO keyword. The number of variables in each record of the program array must be the same as the number of fields in each screen record (that is, in a single row of the screen array).

You typically bind a program array to a screen-array in order to display a page of records. However, the DIALOG instruction can also bind the program array to a simple flat screen-record. In this case, only one record will be visible at a time.

The next code example defines an array with a flat record and binds it to a screen array:

```plaintext
DEFINE p_items DYNAMIC ARRAY OF RECORD
    item_num INTEGER,
    item_name VARCHAR(50),
    item_price DECIMAL(6,2)
END RECORD
...
DIALOG
    DISPLAY ARRAY p_items TO sa.*
    BEFORE ROW
...
END DISPLAY
...
END DIALOG
```

If the screen array is defined with one field only, you can bind an array defined with a primitive type:

```plaintext
DEFINE p_names DYNAMIC ARRAY OF VARCHAR(50)
...
DIALOG
    DISPLAY ARRAY p_names TO sa.*
    BEFORE DELETE
...
END DISPLAY
...
END DIALOG
```

**Identifying a DISPLAY ARRAY sub-dialog**
The name of the screen array specified with the TO clause identifies the list. The dialog class method takes the name of the screen array as the parameter, identifying the list. For example, you would use DIALOG.getCurrentRow("screen-array") to query for the current row in the list identified by 'screen-array'. The name of the screen-array is also used to qualify sub-dialog actions with a prefix.

**Control blocks in DISPLAY ARRAY**
Read-only record lists declared with the DISPLAY ARRAY sub-dialog can raise the following triggers:

- **BEFORE DISPLAY**
- **BEFORE ROW**
- **AFTER ROW**
- **AFTER DISPLAY**
In the singular DISPLAY ARRAY instruction, BEFORE DISPLAY and AFTER DISPLAY blocks are typically used as initialization and finalization blocks. In a DISPLAY ARRAY sub-dialog of a DIALOG block, BEFORE DISPLAY and AFTER DISPLAY blocks will be executed each time the focus goes to (BEFORE) or leaves (AFTER) the group of fields defined by this sub-dialog.

**Related concepts**
- **Records** on page 382
  Records allow structured program variables definitions.
- **Screen records / arrays** on page 1147
  Form fields can be grouped in a *screen record or screen array* definition.
- **DISPLAY ARRAY ATTRIBUTES clause** on page 1499
  Attributes of the DISPLAY ARRAY clause of a DIALOG block.

**The INPUT ARRAY sub-dialog**
The INPUT ARRAY sub-dialog is the controller to implement the navigation and edition in a list of records.

**Important**: This feature is not supported on mobile platforms.

**Program array to screen array binding**
The INPUT ARRAY sub-dialog binds the members of the flat record (or the primitive member) of an array to the screen-array or screen-record fields specified with the FROM keyword. The number of variables in each record of the program array must be the same as the number of fields in each screen record (that is, in a single row of the screen array).

You typically bind a program array to a screen-array in order to display a page of records. However, the DIALOG instruction can also bind the program array to a simple flat screen-record. In this case, only one record will be visible at a time.

The next code example defines an array with a flat record and binds it to a screen array:

```plaintext
DEFINE p_items DYNAMIC ARRAY OF RECORD  
  item_num INTEGER,  
  item_name VARCHAR(50),  
  item_price DECIMAL(6,2)  
END RECORD  
...  
DIALOG  
  INPUT ARRAY p_items FROM sa.*  
  BEFORE INSERT  
  ...  
  END INPUT  
  ...  
END DIALOG
```

If the screen array is defined with one field only, you can bind an array defined with a primitive type:

```plaintext
DEFINE p_names DYNAMIC ARRAY OF VARCHAR(50)  
...  
DIALOG  
  INPUT ARRAY p_names FROM sa.*  
  BEFORE DELETE  
  ...  
  END INPUT  
  ...  
END DIALOG
```
Identifying an INPUT ARRAY sub-dialog

The name of the screen array specified with the FROM clause will be used to identify the list. For example, the dialog class method such as `DIALOG.getCurrentRow("screen-array")` takes the name of the screen array as the parameter, to identify the list you want to query for the current row. The name of the screen-array is also used to qualify sub-dialog actions with a prefix.

Control blocks in INPUT ARRAY

Editable record lists declared with the INPUT ARRAY sub-dialog can raise the following triggers:

- BEFORE INPUT
- BEFORE ROW
- BEFORE FIELD
- ON CHANGE
- AFTER FIELD
- ON ROW CHANGE
- AFTER ROW
- BEFORE DELETE
- AFTER DELETE
- BEFORE INSERT
- AFTER INSERT
- AFTER INPUT

In the singular INPUT ARRAY instruction, BEFORE INPUT and AFTER INPUT blocks are typically used as initialization and finalization blocks. In the INPUT ARRAY sub-dialog of a DIALOG block, BEFORE INPUT and AFTER INPUT blocks are executed each time the focus goes to (BEFORE) or leaves (AFTER) the group of fields defined by this sub-dialog.

The SUBDIALOG clause

Purpose of SUBDIALOG

The SUBDIALOG clause defines a declarative dialog to be attached to the current procedural DIALOG block.

By using form inclusion (with the FORM clause in LAYOUT sections) and declarative dialogs + SUBDIALOG, you enforce code reusability in your application sources.

Note: Declarative dialog blocks can also be used to implement parallel dialogs.

Defining the declarative dialog

The declarative dialog is implemented outside the scope of the using DIALOG block, at the same level as a function.

The declarative dialog can be defined in a different module, to be reused in other DIALOG instructions. The sub-dialog module must be imported with the IMPORT FGL instruction.

Like other module elements such as functions and reports, the name specification is mandatory when defining a declarative dialog. The name of the declarative dialog will be referenced in a SUBDIALOG clause of a procedural dialog instruction.
In the "comment.4gl" module:

```
DIALOG comment_input()
...
END DIALOG
```

In the using module (note that we use the module prefix here):

```
IMPORT FGL comment
...
FUNCTION mydialog()
  DIALOG ...
    ...
    SUBDIALOG comment.comment_input
    ...
  END DIALOG
END FUNCTION
```

See also Identifying sub-dialogs in procedural DIALOG on page 1490.

**Sub-dialogs in form definitions**

Implementing a sub-dialog as a declarative dialog in a separate module is typically used in conjunction with the FORM clause, in the LAYOUT section of form specification files:

```
LAYOUT
...
FORM "comment"
...
END
```

**Semantics with SUBDIALOG**

In terms of semantics, behavior and control block execution, a declarative dialog attached to a procedural dialog with SUBDIALOG, behaves like a sub-dialog that is defined inside the procedural DIALOG block.

For example, BEFORE_INPUT inside an INPUT block of a declarative dialog will be executed when the focus goes to one of the fields of that sub-dialog.

**Scope of dialog instructions**

Other sub-dialogs can reference the attached declarative dialog in the current scope.

For example, to execute a NEXT FIELD instruction referencing a field in another sub-dialog:

```
DIALOG ...
  NEXT FIELD the_comment  -- Field of the declarative dialog.
  ...
END DIALOG
```

**Scope of DIALOG keyword**

When using the DIALOG keyword inside a declarative dialog block to use ui.Dialog class methods, it references the current procedural dialog object:

```
DIALOG comment_input()
  ...
  CALL DIALOG.setFieldActive("the_comment",TRUE)
  ...
```
Writing generic code

To be reused by different procedural DIALOG instructions, the code of sub-dialog modules must be generic. However, if the sub-dialog code needs to interact with the parent DIALOG, it must be possible to call a function from the parent DIALOG.

You achieve this by using function references. Parent modules can then configure the sub-dialog module at runtime, with callback functions:

1. Create a user-defined TYPE with the FUNCTION type matching the callback function of the using module.
2. Define a module variable, with the declared function type. If you want to keep it private to the module, define a setter function to assign the variable with the callback function reference.
3. When the parent DIALOG needs to be notified by some change in the sub-dialog, check that the callback variable is not NULL, and call the function with appropriate values.

Tip: You do not have to implement a lot of complex callback functions. The main purpose is to indicate to the parent DIALOG, that something happened in the sub-dialog. The parent DIALOG can then query the sub-dialog module for more information, as long as the sub-dialog module provides functions to query its status.

```plaintext
PUBLIC TYPE cb_comment_event FUNCTION (event STRING)
PRIVATE DEFINE cb_ce cb_comment_event
...
PUBLIC FUNCTION set_event_callback(f cb_comment_event)
   LET cb_ce = f
END FUNCTION

DIALOG comment_input()
...
   IF cb_ce IS NOT NULL THEN
      CALL cb_ce("comment_changed")
   END IF
...
END DIALOG
```

For a complete example, see Example 3: DIALOG with SUBDIALOG on page 1544.

Procedural DIALOG block configuration

This section describes the ATTRIBUTES clause attributes that can be used to configure a procedural DIALOG instruction and its sub-dialogs.

The ATTRIBUTES clause of dialogs overrides all default attributes and temporarily overrides any display attributes that the OPTIONS or the OPEN Window statement specified for these fields.

**DIALOG ATTRIBUTES clause**

**FIELD ORDER FORM option**

By default, the form tabbing order is defined by the variable list in the binding specification. You can control the tabbing order by using the FIELD ORDER FORM attribute; when this attribute is used, the tabbing order is defined by the TABINDEX attribute of the form items.

The field order mode can also be specified globally with the OPTIONS FIELD ORDER instruction.

With FIELD ORDER FORM, if the user changes the focus from field A to a distant field B with the mouse, the dialog does not execute the BEFORE FIELD/AFTER FIELD triggers of intermediate fields which appear in the binding specification between field A and field B. Unlike singular dialogs, if the default FIELD ORDER CONSTRAINT mode is used in a multiple dialog instruction, intermediate triggers are never executed (i.e. the Dialog.fieldOrder FGLPROFILE entry is ignored by DIALOG.)

See also Defining the tabbing order on page 1630.
UNBUFFERED option

The UNBUFFERED attribute indicates that the dialog is sensitive to program variable changes. When using this option, you bypass the compatible "buffered" mode.

The unbuffered mode can be set globally for all DIALOG instructions with the `ui.Dialog.setDefaultUnbuffered()` class method:

```java
CALL ui.Dialog.setDefaultUnbuffered(TRUE)
DIALOG -- Will work in UNBUFFERED mode ...
END DIALOG
```

INPUT ATTRIBUTES clause

Attributes of the INPUT clause of a DIALOG block.

HELP option

The HELP attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the INPUT sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action. The HELP clause overrides the HELP attribute.

NAME option

The NAME attribute can be used to identify the INPUT sub-dialog, especially useful to qualify sub-dialog actions.

WITHOUT DEFAULTS option

By default, sub-dialogs use the default values defined in the form files. If you want to use the values stored in the program variables bound to the dialog, you must use the WITHOUT DEFAULTS attribute. For more details see WITHOUT DEFAULTS option.

DISPLAY ARRAY ATTRIBUTES clause

Attributes of the DISPLAY ARRAY clause of a DIALOG block.

HELP option

The HELP attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the DISPLAY ARRAY sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action. The HELP clause overrides the HELP attribute.

COUNT option

The COUNT attribute defines the number of valid rows in the static array to be displayed as default rows. If you do not use the COUNT attribute, the runtime system cannot determine how much data to display, so the screen array remains empty. The COUNT option is ignored when using a dynamic array, unless page mode is used. In this case, the COUNT attribute must be used to define the total number of rows, because the dynamic array will only hold a page of the entire row set. If the value of COUNT is negative or zero, it defines an empty list.

See also Controlling the number of rows on page 1734.

DOUBLECLICK option

The DOUBLECLICK option can be used to define the action that will be fired when the user chooses a row from the list. Different configuration options are available to control the row selection action of desktop and mobile devices. For more details, see Defining the action for a row choice on page 1768.

ACCESSORYTYPE option

Important: This feature is only for mobile platforms.
The ACCESSORYTYPE attribute can be used to define the decoration of rows, typically used on an iOS device. Values can be DETAILBUTTON, DISCLOSUREINDICATOR, CHECKMARK to respectively get a (i), > or check mark icon. For more details, see Row configuration on iOS devices on page 1777.

**DETAILACTION option**

**Important:** This feature is only for mobile platforms.

The DETAILACTION attribute can be used to define the action that will be fired when the user selects the detail button of a row. The detail button is typically shown with a (i) icon on iOS devices. Note that the DOUBLECLICK attribute can be used to distinguish the action when the user selects the row instead of the detail button in the row. For more details, see Row configuration on iOS devices on page 1777.

**FOCUSONFIELD option**

**Important:** This feature is not supported on mobile platforms.

When the FOCUSONFIELD option is used, the DISPLAY ARRAY allows focus at the field (or cell) level. It it then possible to implement BEFORE FIELD and AFTER FIELD blocks, as well as using NEXT FIELD instructions. However, the dialog still manages a read-only list. For more details, see Field-level focus in DISPLAY ARRAY on page 1740.

**INPUT ARRAY ATTRIBUTES clause**

Attributes of the INPUT ARRAY clause of a DIALOG block.

INPUT ARRAY specific attributes can be defined in the ATTRIBUTE clause of the sub-dialog header:

**HELP option**

The HELP clause specifies the number of a help message to display if the user invokes the help the INPUT ARRAY dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action. The HELP clause overrides the HELP attribute.

**COUNT option**

The COUNT attribute defines the number of valid rows in the static array to be displayed as default rows. If you do not use the COUNT attribute, the runtime system cannot determine how much data to display, so the screen array remains empty. The COUNT option is ignored when using a dynamic array. If you specify the COUNT attribute, the WITHOUT DEFAULTS option is not required because it is implicit. If the COUNT attribute is greater than MAXCOUNT, the runtime system will take MAXCOUNT as the actual number of rows. If the value of COUNT is negative or zero, it defines an empty list.

**MAXCOUNT option**

The MAXCOUNT attribute defines the maximum number of rows that can be inserted in the program array. This attribute allows you to give an upper limit of the total number of rows the user can enter. It can be used with static or dynamic arrays.

When binding a static array, MAXCOUNT is used as upper limit if it is lower or equal to the actual declared static array size. If MAXCOUNT is greater than the array size, the size of the static array is used as the upper limit. If MAXCOUNT is lower than the COUNT attribute (or to the SET_COUNT() parameter when using a singular INPUT ARRAY), the actual number of rows in the array will be reduced to MAXCOUNT.

When binding a dynamic array, the user can enter an infinite number of rows unless the MAXCOUNT attribute is used. If MAXCOUNT is lower than the actual size of the dynamic array, the number of rows in the array will be reduced to MAXCOUNT.

If MAXCOUNT is negative or equal to zero, the user cannot insert rows.
APPEND ROW option

The APPEND ROW attribute can be set to false to avoid the append default action, and deny the user to add rows at the end of the list. If APPEND ROW = FALSE, it is still possible to insert rows in the middle of the list. Use the INSERT ROW attribute to disallow the user from inserting rows. Additionally, even with APPEND ROW = FALSE and INSERT ROW = FALSE, you can still get automatic temporary row creation if AUTO APPEND is not set to FALSE.

INSERT ROW option

The INSERT ROW attribute can be set to FALSE to avoid the insert default action, and deny the user to insert new rows in the middle of the list. However, even if INSERT ROW is FALSE, it is still possible to append rows at the end of the list. Use the APPEND ROW attribute to disallow the user from appending rows. Additionally, even with APPEND ROW = FALSE and INSERT ROW = FALSE, you can still get automatic temporary row creation if AUTO APPEND is not set to FALSE.

DELETE ROW option

The DELETE ROW attribute can be set to FALSE to avoid the delete default action, and deny the user to remove rows from the list.

AUTO APPEND option

By default, an INPUT ARRAY controller creates a temporary row when needed (for example, when the user deletes the last row of the list, a new row will be automatically created). You can prevent this default behavior by setting the AUTO APPEND attribute to FALSE. When this attribute is set to FALSE, the only way to create a new temporary row is to execute the append action.

If both the APPEND ROW and INSERT ROW attributes are set to FALSE, the dialog automatically behaves as if AUTO APPEND equals FALSE.

KEEP CURRENT ROW option

Depending on the list container used in the form, the current row may be highlighted during the execution of the dialog, and cleared when the instruction ends. You can change this default behavior by using the KEEP CURRENT ROW attribute, to force the runtime system to keep the current row highlighted.

WITHOUT DEFAULTS option

You typically use the INPUT ARRAY sub-dialog with the WITHOUT DEFAULTS attribute. If this attribute is not set when using an INPUT ARRAY sub-dialog, the list is empty even if the array holds data. For more details see WITHOUT DEFAULTS option.

CONSTRUCT ATTRIBUTES clause

Attributes of the CONSTRUCT clause of a DIALOG block.

HELP option

The HELP attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the CONSTRUCT sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The HELP clause overrides the HELP attribute.

NAME option

The NAME attribute can be used to identify the CONSTRUCT sub-dialog; this is especially useful to qualify sub-dialog actions.
**Default actions created by a DIALOG block**

Default actions ease the implementation of the controller by providing expected actions.

The runtime system creates a set of **default actions** based on the sub-dialogs defined in a (declarative or procedural) **DIALOG** block. These actions are provided to ease the implementation of the controller. For example, when using an **INPUT ARRAY** sub-dialog, the dialog instruction will automatically create the insert, append and delete default actions.

**Table 350: Default actions created for the DIALOG block** on page 1502 lists the default actions created for the **DIALOG** interactive instruction, for each type of sub-dialogs:

<table>
<thead>
<tr>
<th>Default action</th>
<th>Control Block execution order</th>
</tr>
</thead>
<tbody>
<tr>
<td>help</td>
<td>Shows the help topic defined by the <code>HELP</code> clause. Only created when a <code>HELP</code> clause or option is defined for the sub-dialog.</td>
</tr>
<tr>
<td>insert</td>
<td>Inserts a new row before current row. Only for <strong>INPUT ARRAY</strong> dialogs. Action creation can be avoided with <code>INSERT ROW = FALSE</code> attribute.</td>
</tr>
<tr>
<td>append</td>
<td>Appends a new row at the end of the list. Only for <strong>INPUT ARRAY</strong> dialogs. Action creation can be avoided with <code>APPEND ROW = FALSE</code> attribute.</td>
</tr>
<tr>
<td>delete</td>
<td>Deletes the current row. Only for <strong>INPUT ARRAY</strong> dialogs. Action creation can be avoided with <code>DELETE ROW = FALSE</code> attribute.</td>
</tr>
<tr>
<td>nextrow</td>
<td>Moves to the next row in a list displayed in one row of fields. See note (1).</td>
</tr>
<tr>
<td>prevrow</td>
<td>Moves to the previous row in a list displayed in one row of fields. See note (1).</td>
</tr>
<tr>
<td>firstrow</td>
<td>Moves to the first row in a list displayed in one row of fields. See note (1).</td>
</tr>
<tr>
<td>lastrow</td>
<td>Moves to the last row in a list displayed in one row of fields. See note (1).</td>
</tr>
<tr>
<td>find</td>
<td>Opens the fglfind dialog window to let the user enter a search value, and seeks to the row matching the value. See note (2).</td>
</tr>
</tbody>
</table>
Default action | Control Block execution order
--- | ---
findnext | Seeks to the next row matching the value entered during the fglfind dialog.

See note (2).

**Notes:**

1. The action is only created with a DISPLAY ARRAY or INPUT ARRAY using a screen record bound to a set of form fields in a GRID container. The action is not created when using a screen array bound to a list container such as TABLE, TREE and SCROLLGRID.

2. The action is only created if the context allows built-in find.

The insert, append and delete default actions can be avoided with dialog control attributes:

```plaintext
INPUT ARRAY arr TO sr.* ATTRIBUTES( INSERT ROW=FALSE, APPEND ROW=FALSE, ... )
...```

**Related concepts**

**DIALOG data blocks**

*Dialog data blocks* are dialog triggers invoked when the dialog controller needs data to feed the view with values.

Such blocks are typically used when record list data is provided dynamically, with the paged mode or when implementing dynamic tree-views.

- **ON FILL BUFFER block** on page 1401
- **ON EXPAND block** on page 1401
- **ON COLLAPSE block** on page 1401

**ON FILL BUFFER block**

The **ON FILL BUFFER** block is used to fill a page of rows into the dynamic array, based on an offset and a number of rows.

This data block is only used in **DISPLAY ARRAY** data blocks.

The offset can be retrieved with the `FGL_DIALOG_GETBUFFERSTART()` built-in function and the number of rows to provide is defined by the `FGL_DIALOG_GETBUFFERLENGTH()` built-in function.

**Related concepts**

Populating a **DISPLAY ARRAY** on page 1742
The program array must be filled with rows to populate the **DISPLAY ARRAY** dialog.

**ON EXPAND block**

The **ON EXPAND** block is executed when a tree view node is expanded (i.e. opened).

This data block is used to implement dynamic trees in a **DISPLAY ARRAY**, where nodes are added, depending on the nodes opened by the end user.

**Related concepts**

Dynamic filling of very large trees on page 1797
How to optimize the implementation of large tree-views?

**ON COLLAPSE block**

The **ON COLLAPSE** block is executed when a tree view node is collapsed (i.e. closed).

This data block is used to implement dynamic trees in a **DISPLAY ARRAY**, where nodes are removed from view by the user closing or collapsing them.

**Related concepts**

- Dynamic filling of very large trees on page 1797
- How to optimize the implementation of large tree-views?

**DIALOG control blocks**

*Dialog control blocks* are predefined dialog triggers where you can implement specific code to control the interactive instruction.

The code may involve using `ui.Dialog` class methods or dialog specific instructions such as `NEXT FIELD` or `CONTINUE DIALOG`.

- **BEFORE FIELD** block on page 1383
- **AFTER FIELD** block on page 1385
- **ON CHANGE** block on page 1384
- **BEFORE INPUT** block on page 1381
- **AFTER INPUT** block on page 1382
- **BEFORE CONSTRUCT** block on page 1469
- **AFTER CONSTRUCT** block on page 1470
- **BEFORE DISPLAY** block on page 1402
- **AFTER DISPLAY** block on page 1403
- **BEFORE ROW** block on page 1403
- **ON ROW CHANGE** block on page 1439
- **AFTER ROW** block on page 1404
- **BEFORE INSERT** block on page 1442
- **AFTER INSERT** block on page 1442
- **BEFORE DELETE** block on page 1443
- **AFTER DELETE** block on page 1443
- **BEFORE MENU** block on page 1367

**Control block execution order in multiple dialogs**

This table shows the order in which control blocks are executed in a procedural **DIALOG** instruction, depending on the context and user action:

**Table 351: Control block execution order for a procedural dialog**

<table>

6. **BEFORE FIELD** (field in the new current row) |
| Moving to a different row in an INPUT ARRAY list when current row was modified | 1. **ON CHANGE** (if value of current field has changed)  
2. **AFTER FIELD** (for field A in the row you leave)  
3. **ON ROW CHANGE** (the values in current row have changed)  
4. **AFTER ROW** (for the row that was modified)  
5. **BEFORE ROW** (the new current row)  
6. **BEFORE FIELD** (field in the new current row) |
| Inserting or appending a new row in an INPUT ARRAY list                | 1. *Triggers raised by the context of the sub-dialog you leave*  
2. **BEFORE INSERT** (for the new current row)  
3. **BEFORE ROW** (the new current row)  
4. **BEFORE FIELD** (field in the new current row) |
| Deleting a row in an INPUT ARRAY list                                  | 1. **BEFORE DELETE** (for the current row to be deleted)  
2. **AFTER DELETE** (now the deleted row is removed)  
3. **AFTER ROW** (for the deleted row)  
4. **BEFORE ROW** (the new current row) |
| Firing the *insert or append* action for the ON INSERT block in a DISPLAY ARRAY list | 1. **AFTER ROW**  
2. **ON INSERT**  
3. **BEFORE ROW** |
| Firing the *delete* action for the ON DELETE block in a DISPLAY ARRAY list | 1. **AFTER ROW**  
2. **ON DELETE**  
3. **BEFORE ROW** |
| Validating the dialog with ACCEPT DIALOG                                | 1. **ON CHANGE** (if focus is in input field and value has changed)  
2. **AFTER FIELD** (if focus is in input field)  
3. **AFTER INSERT** (if INPUT ARRAY and current row was just created)  
or  
**ON ROW CHANGE** (if INPUT ARRAY and a value in the row has changed)  
4. **AFTER ROW** (if focus is in a list)  
5. **AFTER INPUT, AFTER CONSTRUCT** or **AFTER CONSTRUCT** (current sub-dialog)  
6. **AFTER DIALOG** |
| Canceling the dialog with EXIT DIALOG                                   | None of the control blocks will be executed; we just leave the dialog instruction. |
**BEFORE DIALOG block**

The **BEFORE DIALOG** block is executed one time as the first trigger when the **DIALOG** instruction starts, before the runtime system gives control to the user. You can implement variable initialization and dialog configuration in this block.

**Note:** Like all control blocks of the procedural **DIALOG** / **END DIALOG** instruction, the **BEFORE DIALOG** block must appear after the sub-dialog definitions. For a detailed description, see the procedural **DIALOG** instruction syntax.

In the next code example, the **BEFORE DIALOG** block performs some dialog setup and gives the focus to a specific field:

```plaintext
DIALOG
  DISPLAY ARRAY ...
  ...
  END DISPLAY
  INPUT BY NAME ...
  ...
  END INPUT
  ...
  BEFORE DIALOG
    CALL DIALOG.setActionActive("save",FALSE)
    CALL DIALOG.setFieldActive("cust_status", is_admin())
    IF cust_is_new() THEN
      NEXT FIELD cust_name
    END IF
  ...
END DIALOG
```

A **DIALOG** instruction can include no more than one **BEFORE DIALOG** control block.

**Related concepts**

The Dialog class on page 2367
The **ui.Dialog** class provides a set of methods to configure, query and control the current interactive instruction.

Control block execution order in multiple dialogs on page 1504

**AFTER DIALOG block**

The **AFTER DIALOG** block is executed one time as the last trigger when the **DIALOG** instruction terminates, when performing an **ACCEPT DIALOG** instruction. Dialog finalization code can be implemented in this block.

The dialog terminates when an **ACCEPT DIALOG** or **EXIT DIALOG** control instruction is executed. However, the **AFTER DIALOG** block is **not** executed if an **EXIT DIALOG** is performed.

If you execute one of the following control instructions in an **AFTER DIALOG** block, the dialog will not terminate and it will give control back to the user:

1. **NEXT FIELD**
2. **NEXT OPTION**
3. **CONTINUE DIALOG**

In the next example, the **AFTER DIALOG** block checks whether a field value is correct and gives control back to the dialog if the value is wrong:

```plaintext
ON ACTION accept
  ACCEPT DIALOG
  ...
AFTER DIALOG
  IF NOT cust_is_valid_status(p_cust.cust_status) THEN
    ERROR "Customer state is not valid"
```
**BEFORE FIELD block**

In dialog instructions INPUT, INPUT ARRAY, CONSTRUCT or in a DISPLAY ARRAY using the FOCUSONFIELD attribute, the BEFORE FIELD block is executed every time the specified field gets the focus.

For single record inputs driven by INPUT or query by example (QBEs) driven by CONSTRUCT, the BEFORE FIELD block is executed when moving the focus from field to field.

For editable lists driven by INPUT ARRAY, the BEFORE FIELD block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by DISPLAY ARRAY using the FOCUSONFIELD attribute, the BEFORE FIELD block is executed when moving the focus from field to field. However, the fields will not be editable as in an INPUT ARRAY.

**Important:** The BEFORE FIELD block is also executed when performing a NEXT FIELD instruction.

The BEFORE FIELD keywords must be followed by a list of form field specification. The screen-record name can be omitted.

BEFORE FIELD is executed after BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW and BEFORE INSERT.

Use this block to do some field value initialization, or to display a message to the user:

```plaintext
INPUT BY NAME p_cust.* ...
BEFORE FIELD cust_status
  LET p_cust.cust_comment = NULL
  MESSAGE "Enter customer status"
```

When using the default FIELD ORDER CONSTRAINT mode, the dialog executes the BEFORE FIELD block of the field corresponding to the first variable of an INPUT or INPUT ARRAY, even if that field is not editable (NOENTRY, hidden or disabled). The block is executed when you enter the dialog and every time you create a new row in the case of INPUT ARRAY. This behavior is supported for backward compatibility. The block is not executed when using the FIELD ORDER FORM, the mode recommended for DIALOG instructions.

With the FIELD ORDER FORM mode, for each dialog executing the first time with a specific form, the BEFORE FIELD block will be invoked for the first field of the initial tabbing list defined by the form, even if that field was hidden or moved around in a table. The dialog then behaves as if a NEXT FIELD first-visible-column would have been done in the BEFORE FIELD of that field.

When form-level validation occurs and a field contains an invalid value, the dialog gives the focus to the field, but no BEFORE FIELD trigger will be executed.

**Related concepts**

NEXT FIELD instruction on page 1389
Form-level validation rules on page 1627
Form-level validation rules can be defined for each field controlled by a dialog.

AFTER FIELD block on page 1385

AFTER FIELD block

In dialog instructions INPUT, INPUT ARRAY, CONSTRUCT or in a DISPLAY ARRAY using the FOCUSONFIELD attribute, the AFTER FIELD block is executed every time the focus leaves the specified field.
For single record inputs driven by INPUT or query by example (QBEs) driven by CONSTRUCT, the AFTER FIELD block is executed when moving the focus from field to field.

For editable lists driven by INPUT ARRAY, the AFTER FIELD block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by DISPLAY ARRAY using the FOCUSONFIELD attribute, the AFTER FIELD block is executed when moving the focus from field to field. However, the fields will not be editable as in an INPUT ARRAY.

The AFTER FIELD keywords must be followed by a list of form field specifications. The screen-record name can be omitted.

AFTER FIELD is executed before AFTER INSERT, ON ROW CHANGE, AFTER ROW, AFTER INPUT or AFTER CONSTRUCT.

When a NEXT FIELD instruction is executed in an AFTER FIELD block, the cursor moves to the specified field, which can be the current field. This can be used to prevent the user from moving to another field / row during data input. Note that the BEFORE FIELD block is also executed when NEXT FIELD is invoked.

The AFTER FIELD block of the current field is not executed when performing a NEXT FIELD; only BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW, and BEFORE FIELD of the target item might be executed, based on the sub-dialog type.

When ACCEPT DIALOG, ACCEPT INPUT, or ACCEPT CONSTRUCT is performed, the AFTER FIELD trigger of the current field is executed.

Use the AFTER FIELD block to implement field validation rules:

```
INPUT BY NAME p_item.* ...
AFTER FIELD item.*
  IF p_item.item_quantity <= 0 THEN
    ERROR "Item quantity cannot be negative or zero"
    LET p_item.item_quantity = 0
  NEXT FIELD item_quantity
END IF
```

**Related concepts**

NEXT FIELD instruction on page 1389

ACCEPT DIALOG instruction on page 1538

BEFORE FIELD block on page 1383

ON CHANGE block on page 1384

**ON CHANGE block**

The ON CHANGE block can be used to detect that a field changed by user input. The ON CHANGE block is executed if the value has changed since the field got the focus and if the modification flag is set.

The ON CHANGE block can be used in INPUT, INPUT ARRAY and CONSTRUCT dialogs.

For editable fields defined as EDIT, TEXTEDIT or BUTTONEDIT, the ON CHANGE block is executed when leaving a field, if the value of the specified field has changed since the field got the focus and if the modification flag is set for the field. You leave the field when you validate the dialog, when you move to another field, or when you move to another row in an INPUT ARRAY. However, if the text edit field is defined with the COMPLETER attribute to enable autocompletion, the ON CHANGE trigger will be fired after a short period of time, when the user has typed characters in.

For editable fields defined as CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, TIMEEDIT, RADIOGROUP, SPINEDIT, SLIDER or URL-based WEBCOMPONENT (when the COMPONENTTYPE attribute is not used), the ON CHANGE block is invoked immediately when the user changes the value with the widget edition feature. For example, when toggling the state of a CHECKBOX, when selecting an item in a COMBOBOX list, or when choosing a date in the
calendar of a DATEEDIT. Note that for such item types, when ON CHANGE is fired, the modification flag is always set.

```plaintext
ON CHANGE order_checked -- Defined as CHECKBOX
CALL setup_dialog(DIALOG)
```

**Note:** If both an ON CHANGE block and AFTER FIELD block are defined for a field, the ON CHANGE block is executed before the AFTER FIELD block.

When changing the value of the current field by program in an ON ACTION block, the ON CHANGE block will be executed when leaving the field if the value is different from the reference value and if the modification flag is set (after previous user input or when the touched flag has been changed by program).

In an INPUT or INPUT ARRAY, the field value change is related to value of the variable bound to the field. In a CONSTRUCT dialog, the field value change is related to the input buffer / displayed value.

**Note:** When using the NEXT FIELD instruction, the comparison value is reassigned as if the user had left and reentered the field. Therefore, when using NEXT FIELD in ON CHANGE block or in an ON ACTION block, the ON CHANGE block will only be invoked again if the value is different from the reference value. This prevents field validation in ON CHANGE blocks; you must do validations in AFTER FIELD blocks and/or AFTER INPUT blocks.

**Related concepts**

- Input field modification flag [on page 1623](#)
- Each input field controlled by a dialog instruction has a modification flag.
- Enabling autocompletion [on page 1633](#)
- Autocompletion allows a list of completion proposals to be displayed while the user is typing text into a field.
- **AFTER FIELD block** [on page 1385](#)
- **COMPLETER attribute** [on page 1251](#)
- The COMPLETER attribute enables autocompletion for the edit field.

**BEFORE INPUT block**

**BEFORE INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs**

In a singular INPUT, INPUT ARRAY instruction, or when used as parallel dialog, the **BEFORE INPUT** is only executed once when the dialog is started.

The **BEFORE INPUT** block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```plaintext
INPUT BY NAME cust_rec.* ...
BEFORE INPUT
    MESSAGE "Input customer information"
    CALL DIALOG.setActionActive("check_info", is_super_user() )
    CALL DIALOG.setFieldActive("cust_comment", is_super_user() )
...
```

The fields are initialized with the defaults values before the **BEFORE INPUT** block is executed. When the INPUT instruction uses the **WITHOUT DEFAULTS** option, the default values are taken from the program variables bound to the fields, otherwise (with defaults), the DEFAULT attributes of the form fields are used.

Use the **NEXT FIELD** control instruction in the **BEFORE INPUT** block, to jump to a specific field when the dialog starts.
BEFORE INPUT block in INPUT and INPUT ARRAY of procedural DIALOG

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the BEFORE INPUT block is executed when the focus goes to a group of fields driven by the sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

When the focus is in a list driven by an INPUT ARRAY sub-dialog, moving to a different row will not invoke the BEFORE INPUT block.

BEFORE INPUT is executed after the BEFORE DIALOG block and before the BEFORE ROW, BEFORE FIELD blocks.

In this example, the BEFORE INPUT block is used to set up a specific action and display a message:

```
INPUT BY NAME p_order.*
BEFORE INPUT
   CALL DIALOG.setActionActive("validate_order", TRUE)
```

Related concepts
BEFORE CONSTRUCT block on page 1469
BEFORE DISPLAY block on page 1402
AFTER INPUT block on page 1382

AFTER INPUT block

AFTER INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs

In a singular INPUT, INPUT ARRAY instruction, or when used as parallel dialog, the AFTER INPUT is only executed once when dialog ends.

The AFTER INPUT block is executed after the user has validated or canceled the INPUT or INPUT ARRAY dialog with the accept or cancel default actions, or when the ACCEPT INPUT instruction is executed.

The AFTER INPUT block is not executed when the EXIT INPUT instruction is performed.

In singular and parallel dialogs, this block is typically used to implement global dialog validation rules depending from several fields. If the values entered by the user do not satisfy the constraints, use the NEXT FIELD instruction to force the dialog to continue. The CONTINUE INPUT instruction can be used instead of NEXT FIELD, when no particular field has to be select.

Before checking the validation rules, make sure that the INT_FLAG variable is FALSE: in case if the user cancels the dialog, the validation rules must be skipped.

```
INPUT BY NAME cust_rec.*
   WITHOUT DEFAULTS ATTRIBUTES ( UNBUFFERED )
   ...
AFTER INPUT
   IF NOT INT_FLAG THEN
      IF cust_rec.cust_address IS NOT NULL
         AND cust_rec.cust_zipcode IS NULL THEN
            ERROR "Address is incomplete, enter a zipcode."
         NEXT FIELD zipcode
      END IF
   END IF
END INPUT
```

To limit the validation to fields that have been modified by the end user, you can call the FIELD_TOUCHED() function or the DIALOG.getFieldTouched() method to check if a field has changed during the dialog execution. This will make your validation code faster if the user has only modified a couple of fields in a large form.
AFTER INPUT block in INPUT and INPUT ARRAY of procedural DIALOG

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the AFTER INPUT block is executed when the focus is lost by a group of fields driven by an INPUT or INPUT ARRAY sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus. When the focus is in a list driven by an INPUT ARRAY sub-dialog, moving to a different row will not invoke the AFTER INPUT block.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

AFTER INPUT is executed after the AFTER FIELD, AFTER ROW blocks and before the AFTER DIALOG block.

Executing a NEXT FIELD in the AFTER INPUT control block will keep the focus in the group of fields. Within an INPUT ARRAY sub-dialog, NEXT FIELD will keep the focus in the list and stay in the current row. You typically use this behavior to control user input.

In this example, the AFTER INPUT block is used to validate data and disable an action that can only be used in the current group:

```plaintext
INPUT BY NAME p_order.*
AFTER INPUT
  IF NOT check_order_data(DIALOG) THEN
    NEXT FIELD CURRENT
  END IF
CALL DIALOG.setFieldActive("validate_order", FALSE)
```

Related concepts

AFTER DISPLAY block on page 1403
AFTER CONSTRUCT block on page 1470
BEFORE INPUT block on page 1381

BEFORE CONSTRUCT block

BEFORE CONSTRUCT block in singular and parallel CONSTRUCT dialogs

In a singular CONSTRUCT instruction, or when used as parallel dialog, the BEFORE CONSTRUCT is only executed once when dialog is started.

The BEFORE CONSTRUCT block is executed once at dialog start-up, before the runtime system gives control to the user for criteria input. This block can be used to display messages to the user, initialize form fields with default search criteria values, and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```plaintext
CONSTRUCT BY NAME where_part ON ...
  BEFORE CONSTRUCT
    MESSAGE "Enter customer search filter"
    CALL DIALOG.setActionActive("clean", FALSE)
  ...
```

The fields are cleared before the BEFORE CONSTRUCT block is executed.

You can use the NEXT FIELD control instruction in the BEFORE CONSTRUCT block, to jump to a specific field when the dialog starts.

BEFORE CONSTRUCT block in CONSTRUCT of procedural DIALOG

In a CONSTRUCT sub-dialog of a procedural DIALOG instruction, the BEFORE CONSTRUCT block is executed when the focus goes to a group of fields driven by a CONSTRUCT sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

BEFORE CONSTRUCT is executed after the BEFORE DIALOG block and before the BEFORE FIELD blocks.
In this example, the BEFORE CONSTRUCT block is used to display a message:

```
CONSTRUCT BY NAME sql ON customer.*
    BEFORE CONSTRUCT
        MESSAGE "Enter customer search filter"
```

Related concepts
BEFORE INPUT block on page 1381  
BEFORE DISPLAY block on page 1402  
AFTER CONSTRUCT block on page 1470

**AFTER CONSTRUCT block**

**AFTER CONSTRUCT block in singular and parallel CONSTRUCT dialogs**

In a singular CONSTRUCT instruction, or when used as parallel dialog, the AFTER CONSTRUCT is only executed once when dialog is ended.

Use an AFTER CONSTRUCT block to execute instructions after the user has finished search criteria input.

AFTER CONSTRUCT is not executed if an EXIT CONSTRUCT is performed.

The code in AFTER CONSTRUCT can for example check if a criteria combination of different fields is required or denied, and force the end user to enter all

Before checking the content of the fields used in the CONSTRUCT, make sure that the INT_FLAG variable is FALSE.

In the case that the user cancels the dialog, the validation rules must be skipped.

Since no program variables are associated with the form fields, you must query the input buffers of the fields to get the values entered by the user.

```
CONSTRUCT BY NAME where_part ON ...
    ...
    AFTER CONSTRUCT
        IF NOT INT_FLAG THEN
            IF length(DIALOG.getFieldBuffer(cust_name))==0
                OR length(DIALOG.getFieldBuffer(cust_addr))==0 THEN
                ERROR "Enter a search criteria for customer name and address fields."
            NEXT FIELD CURRENT
        END IF
    END IF
END CONSTRUCT
```

To limit the validation to fields that have been modified by the end user, you can call the FIELD_TOUCHED() function or the DIALOG.getFieldTouched() method to check if a field has changed during the dialog execution. This makes your validation code execute faster if the user has only modified a couple of fields in a large form.

**AFTER CONSTRUCT block in CONSTRUCT of procedural DIALOG**

In a CONSTRUCT sub-dialog of a procedural DIALOG instruction, the AFTER CONSTRUCT block is executed when the focus is lost by a group of fields driven by a CONSTRUCT sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

AFTER CONSTRUCT is executed after the AFTER FIELD and before the AFTER DIALOG block.

Executing a NEXT FIELD in the AFTER CONSTRUCT control block will keep the focus in the group of fields.
In this example, the **AFTER CONSTRUCT** block is used to build the SELECT statement:

```plaintext
CONSTRUCT BY NAME sql ON customer.*
  AFTER CONSTRUCT
    LET sql = "SELECT * FROM customers WHERE " || sql
```

**Related concepts**

- **AFTER DISPLAY block** on page 1403
- **AFTER INPUT block** on page 1382
- **BEFORE CONSTRUCT block** on page 1469

**BEFORE DISPLAY block**

**BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs**

In a singular `DISPLAY ARRAY` instruction, or when used as parallel dialog, the **BEFORE DISPLAY** is only executed once when the dialog is started.

The **BEFORE DISPLAY** block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating actions the user is not allowed to execute.

```plaintext
DISPLAY ARRAY p_items TO s_items.*
BEFORE DISPLAY
  CALL DIALOG.setActionActive("clear_item_list", is_super_user())
```

**BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs**

In a `DISPLAY ARRAY` sub-dialog of a procedural `DIALOG` instruction, the **BEFORE DISPLAY** block is executed when a `DISPLAY ARRAY` list gets the focus.

**BEFORE DISPLAY** is executed **before** the **BEFORE ROW** block.

In this example the **BEFORE DISPLAY** block enables an action and displays a message:

```plaintext
DISPLAY ARRAY p_items TO s_items.*
BEFORE DISPLAY
  CALL DIALOG.setActionActive("print_list", TRUE)
  MESSAGE "You are now in the list of items"
```

**Related concepts**

- **BEFORE INPUT block** on page 1381
- **BEFORE CONSTRUCT block** on page 1469
- **AFTER DISPLAY block** on page 1403

**AFTER DISPLAY block**

**AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs**

In a singular `DISPLAY ARRAY` instruction, or when used as parallel dialog, the **AFTER DISPLAY** is only executed once when dialog is ended.

You typically implement dialog finalization in this block.

```plaintext
DISPLAY ARRAY p_items TO s_items.*
  AFTER DISPLAY
    DISPLAY "Current row is: ", arr_curr()
```
AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs

In a DISPLAY ARRAY sub-dialog of a procedural DIALOG instruction, the AFTER DISPLAY block is executed when a DISPLAY ARRAY list loses the focus and goes to another sub-dialog.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

AFTER DISPLAY is executed after the AFTER ROW block.

In this example, the AFTER DISPLAY block disables an action that is specific to the current list:

```
DISPLAY ARRAY p_items TO s_items.*
    AFTER DISPLAY
        CALL DIALOG.setActionActive("clear_item_list", FALSE)
```

Related concepts

AFTER INPUT block on page 1382
AFTER CONSTRUCT block on page 1470
BEFORE DISPLAY block on page 1402

BEFORE ROW block

BEFORE ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs

In a singular DISPLAY ARRAY, INPUT ARRAY instruction, or when used as parallel dialog, the BEFORE ROW block is executed each time the user moves to another row. This trigger can also be executed in other situations, such as when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the BEFORE ROW block, because it indicates that the user selected a new row or entered in the list.

When the dialog starts, BEFORE ROW will be executed for the current row, but only if there are data rows in the array.

When called in this block, `DIALOG.getCurrentRow() / arr_curr()` return the index of the current row.

In this example, the BEFORE ROW block gets the new row number and displays it in a message:

```
DISPLAY ARRAY ...
    ...
    BEFORE ROW
        MESSAGE "We are on row # ", arr_curr()
    ...
```

BEFORE ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the BEFORE ROW block is executed when a DISPLAY ARRAY or INPUT ARRAY list gets the focus, or when the user moves to another row inside a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the BEFORE ROW block, because it indicates that the user selected a new row. Do not use this trigger to detect focus changes; Use the BEFORE DISPLAY or BEFORE INPUT blocks instead.

In `DISPLAY ARRAY, BEFORE ROW` is executed after the BEFORE DISPLAY block. In `INPUT ARRAY, BEFORE ROW` is executed before the BEFORE INSERT and BEFORE FIELD blocks and after the BEFORE INPUT blocks.

When the procedural dialog starts, BEFORE ROW will only be executed if the list has received the focus and there is a current row (the array is not empty). If you have other elements in the form which can get the focus before the list,
BEFORE ROW will not be triggered when the dialog starts. You must pay attention to this, because this behavior is different to the behavior of singular DISPLAY ARRAY or INPUT ARRAY. In singular dialogs, the BEFORE ROW block is always executed when the dialog starts (and there are rows in the array).

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the current row.

In this example the BEFORE ROW block displays a message with the current row number:

```plaintext
DISPLAY ARRAY p_items TO s_items.*
BEFORE ROW
  MESSAGE "We are in items, on row ", DIALOG.getCurrentRow("s_items")
```

**Related concepts**

BEFORE INPUT block on page 1381

BEFORE DISPLAY block on page 1402

**ON ROW CHANGE block**

The ON ROW CHANGE block is executed in a list controlled by an INPUT ARRAY, when leaving the current row and when the row has been modified since it got the focus. This is typically used to detect row modification.

The code in ON ROW CHANGE will not be executed when leaving new rows created by the user with the default append or insert action. To detect row creation, you must use the BEFORE INSERT or AFTER INSERT control blocks.

The ON ROW CHANGE block is only executed if at least one field value in the current row has changed since the row was entered, and the modification flag of the field is set. The modified field(s) may not be the current field, and several field values can be changed. Values may have been changed by the user or by the program. The modification flag is reset for all fields when entering another row, when going to another sub-dialog, or when leaving the dialog instruction.

ON ROW CHANGE is executed after the AFTER FIELD block and before the AFTER ROW block.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the current row that has been changed.

You can, for example, code database modifications (UPDATE) in the ON ROW CHANGE block:

```plaintext
INPUT ARRAY p_items FROM s_items.*
...
ON ROW CHANGE
  LET r = DIALOG.getCurrentRow("s_items")
  UPDATE items SET
    items.item_code        = p_items[r].item_code,
    items.item_description = p_items[r].item_description,
    items.item_price       = p_items[r].item_price,
    items.item_updatedate  = TODAY
  WHERE items.item_num = p_items[r].item_num
```

**Related concepts**

Input field modification flag on page 1623

Each input field controlled by a dialog instruction has a modification flag.

AFTER ROW block on page 1404

**AFTER ROW block**

**AFTER ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs**

In a singular DISPLAY ARRAY, INPUT ARRAY instruction, or when used as parallel dialog, the AFTER ROW block is executed each time the user moves to another row, before the current row is left. This trigger can also be executed in other situations, such as when you delete a row, or when the user inserts a new row.
A NEXT FIELD instruction executed in the AFTER ROW control block will keep the user entry in the current row. Use this behavior to implement row validation and prevent the user from leaving the list or moving to another row.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the row that you are leaving.

**AFTER ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG**

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the AFTER ROW block is executed when a DISPLAY ARRAY or INPUT ARRAY list loses the focus, or when the user moves to another row in a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user inserts a new row.

AFTER ROW is executed after the AFTER FIELD, AFTER INSERT and before AFTER DISPLAY or AFTER INPUT blocks.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the row that you are leaving.

For both INPUT ARRAY and DISPLAY ARRAY sub-dialogs, a NEXT FIELD executed in the AFTER ROW control block will keep the focus in the list and stay in the current row. Use this feature to implement row validation and prevent the user from leaving the list or moving to another row.

**AFTER ROW and temporary rows in INPUT ARRAY**

Important: After creating a temporary row at the end of a list driven by INPUT ARRAY, if you leave that row to a previous row without data input (setting the touched flag), or when the cancel action is invoked, the temporary row will be automatically removed. The AFTER ROW block will be executed for the temporary row, but ui.Dialog.getCurrentRow() / arr_curr() will be one row greater than ui.Dialog.getArrayLength() / ARR_COUNT(). In this case, it is recommended that you ignore the AFTER ROW event. For example, it is recommended that you avoid executing a NEXT FIELD or CONTINUE INPUT instruction, and trying to access the dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array.

In this example, the AFTER ROW block checks the current row index and verifies a variable value to forces the focus to stay in the current row if the value is wrong:

```plaintext
INPUT ARRAY p_items FROM s_items.*
...
AFTER ROW
  LET r = DIALOG.getCurrentRow("s_items")
  IF r <= DIALOG.getArrayLength("s_items") THEN
    IF NOT item_is_valid_quantity(p_item[r].item_quantity) THEN
      ERROR "Item quantity is not valid"
      NEXT FIELD item_quantity'
    END IF
  END IF
END IF
```

Another way to handle the case of temporary rows in AFTER ROW is to use a flag to know if the AFTER INSERT block was executed: The AFTER INSERT block is not executed if the temporary row is automatically removed. By setting a first value in BEFORE INSERT and changing the flag in AFTER INSERT, you can detect if the row was permanently added to the list:

```plaintext
INPUT ARRAY p_items FROM s_items.*
...
BEFORE INSERT
  LET op = "T"
...
AFTER INSERT
  LET op = "I"
```
AFTER ROW
   IF op == "I" THEN
      IF NOT item_is_valid_quantity(p_item[arr_curr()].item_quantity) THEN
         ERROR "Item quantity is not valid"
         NEXT FIELD item_quantity
      END IF
      WHENEVER ERROR CONTINUE
      INSERT INTO items (item_num, item_name, item_quantity)
         VALUES ( p_item[arr_curr()].* )
      WHENEVER ERROR STOP
      IF SQLCA.SQLCODE<0 THEN
         ERROR "Could not insert the record into database!"
         NEXT FIELD CURRENT
      ELSE
         MESSAGE "Record has been inserted successfully"
      END IF
   END IF
END IF

BEFORE ROW block on page 1403
ON ROW CHANGE block on page 1439

BEFORE INSERT block
The BEFORE INSERT block is executed when a new row is created in an INPUT ARRAY. You typically use this trigger to set some default values in the new created row. A new row can be created by moving down after the last row, by executing a insert action, or by executing an append action.

The BEFORE INSERT block is executed after the BEFORE ROW block and before the BEFORE FIELD block.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the new created row.

To distinguish row insertion from an appended row, compare the current row (DIALOG.getCurrentRow("screen-array")) with the total number of rows (DIALOG.getArrayLength("screen-array")). If the current row index and the total number of rows correspond, the BEFORE INSERT concerns a temporary row, otherwise it concerns an inserted row.

Row creation can be stopped by using the CANCEL INSERT instruction inside BEFORE INSERT. If possible, it is however better to disable the insert and append actions to prevent the user to execute the actions with DIALOG.setActionActive().

In this example, the BEFORE INSERT block checks if the user can create rows and denies new row creation if needed; otherwise, it sets some default values:

```
INPUT ARRAY p_items FROM s_items.*
   ...
   BEFORE INSERT
      IF NOT user_can_append THEN
         ERROR "You are not allowed to append rows"
         CANCEL INSERT
      END IF
      LET r = DIALOG.getCurrentRow("s_items")
      LET p_items[r].item_num = get_new_serial("items")
      LET p_items[r].item_name = "undefined"
```

Related concepts
Appending rows in INPUT ARRAY on page 1749
Rows appended at the end of an editable list are temporary until they are edited.
BEFORE ROW block on page 1403
**AFTER INSERT block**

The AFTER INSERT block of INPUT ARRAY is executed when the creation of a new row is validated. In this block, you can for example implement SQL to insert a new row in the database table.

The AFTER INSERT block is executed after the AFTER FIELD block and before the AFTER ROW block.

When called in this block, `DIALOG.getCurrentRow() / arr_curr()` return the index of the new created row.

When the user appends a new row at the end of the list, then moves UP to another row or validates the dialog, the AFTER INSERT block is only executed if at least one field was edited. If no data entry is detected, the dialog automatically removes the new appended row and thus does not trigger the AFTER INSERT block.

When executing a NEXT FIELD in the AFTER INSERT block, the dialog will keep the focus in the list and stay in the current row. Use this behavior to implement row input validation and prevent the user from leaving the list or moving to another row. However, this will not cancel the row insertion and will not invoke the BEFORE INSERT / AFTER INSERT triggers again. The only way to keep the focus in the current row after the row was inserted is to execute a NEXT FIELD in the AFTER ROW block.

In this example, the AFTER INSERT block inserts a new row in the database and cancels the operation if the SQL command fails:

```sql
INPUT ARRAY p_items FROM s_items.*
...
AFTER INSERT
    WHENEVER ERROR CONTINUE
    INSERT INTO items VALUES
    ( p_items[DIALOG.getCurrentRow("s_items")].* )
    WHENEVER ERROR STOP
    IF SQLCA.SQLCODE<>0 THEN
    ERROR SQLERRMESSAGE
    CANCEL INSERT
    END IF
```

**Related concepts**

NEXT FIELD instruction on page 1389

AFTER ROW block on page 1404

**BEFORE DELETE block**

The BEFORE DELETE block is executed each time the user deletes a row of an INPUT ARRAY list, before the row is removed from the list.

You typically code the database table synchronization in the BEFORE DELETE block, by executing a DELETE SQL statement using the primary key of the current row. In the BEFORE DELETE block, the row to be deleted still exists in the program array, so you can access its data to identify what record needs to be removed.

The BEFORE DELETE block is executed before the AFTER DELETE block.

If needed, the deletion can be canceled with the CANCEL DELETE instruction.

When called in this block, `DIALOG.getCurrentRow() / arr_curr()` return the index of the row that will be deleted.

The next example uses the BEFORE DELETE block to remove the row from the database table and cancels the deletion operation if an SQL error occurs:

```sql
INPUT ARRAY p_items FROM s_items.*
BEFORE DELETE
    LET r = DIALOG.getCurrentRow("s_items")
    WHENEVER ERROR CONTINUE
    DELETE FROM items
        WHERE item_num = p_items[r].item_num
    WHENEVER ERROR STOP
```
Related concepts
AFTER DELETE block on page 1443

AFTER DELETE block

The AFTER DELETE block is executed each time the user deletes a row of an INPUT ARRAY list, after the row has been deleted from the list.

The AFTER DELETE block is executed after the BEFORE DELETE block and before the AFTER ROW block for the deleted row and the BEFORE ROW block of the new current row.

When an AFTER DELETE block executes, the program array has already been modified; the deleted row no longer exists in the array (except in the special case when deleting the last row). The arr_curr() function or the ui.Dialog.getCurrentRow() method returns the same index as in BEFORE ROW, but it is the index of the new current row. The AFTER ROW block is also executed just after the AFTER DELETE block.

Important: When deleting the last row of the list, AFTER DELETE is executed for the delete row, and DIALOG.getCurrentRow() / arr_curr() will be one greater than DIALOG.getArrayLength() / ARR_COUNT(). Ensure you avoid accessing a dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array. When using a static array, you must ignore the values in the rows after ARR_COUNT().

Here the AFTER DELETE block is used to re-number the rows with a new item line number (note that DIALOG.getArrayLength() / ARR_COUNT() may return zero):

```plaintext
INPUT ARRAY p_items FROM s_items.*
AFTER DELETE
    LET r = DIALOG.getCurrentRow("s_items")
    FOR i=r TO DIALOG.getArrayLength("s_items")
    LET p_items[i].item_lineno = i
    END FOR
  ...```

It is not possible to use the CANCEL DELETE instruction in an AFTER DELETE block. At this time it is too late to cancel row deletion, as the data row no longer exists in the program array.

DIALOG interaction blocks

Dialog interaction blocks are dialog triggers that can be used to execute specific code when the user executes an action in the dialog. For example, when pressing a button in the form, the corresponding ON ACTION interaction block will be executed.

Interaction blocks also include special handlers such as timeout event handler, drag & drop handlers, and modification triggers for DISPLAY ARRAY sub-dialogs.

- ON ACTION block on page 1369
- ON IDLE block on page 1356
- ON KEY block on page 1357
- ON APPEND block on page 1409
- ON INSERT block on page 1410
- ON UPDATE block on page 1412
ON ACTION block

The ON ACTION action-name blocks execute a sequence of instructions when the user triggers a specific action. A typical action handler block looks like this:

```plaintext
ON ACTION action-name
    instruction
...
```

Action blocks are bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

This example defines an action block to open a typical zoom window and let the user select a customer record:

```plaintext
ON ACTION zoom
    CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as INPUT, INPUT ARRAY and CONSTRUCT, if an action is specific to a field, add the INFIELD clause to have the action automatically enabled when the corresponding field gets the focus:

```plaintext
ON ACTION zoom INFIELD cust_city
    CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the ON ACTION handler needs to define its own attributes at the program level. This can be done by adding the ATTRIBUTES() clause of ON ACTION:

```plaintext
ON ACTION custinfo ATTRIBUTES(_DISCLOSUREINDICATOR, IMAGE="info")
    CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1640.

ON IDLE block

The ON IDLE seconds clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

As ON IDLE can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of ON IDLE must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON IDLE trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or gets a phone call. The program can then execute some code before the user gets the control back.

```plaintext
ON IDLE 30
    IF ask_question("Do you want to reload information from the database?") THEN
        -- Fetch data back from the db server
```
Important: The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

Related concepts

ON TIMER block on page 1357

ON KEY block
An ON KEY (key-name) block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The ON KEY block is supported for backward compatibility with TUI mode applications.

An ON KEY block can specify up to four different keys. Each key creates a specific action object that will be identified by the key name in lowercase. For example, ON KEY (F5, F6) creates two actions with the names f5 and f6. Each action object will get an acceleratorName attribute assigned, with the corresponding accelerator name. The specified keys must be one of the virtual keys.

In GUI mode, action defaults are applied for ON KEY actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully ON KEY CONTROL-? statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, ON KEY statements used with ESC, TAB, UP, DOWN, LEFT, RIGHT, HELP, NEXT, PREVIOUS, INSERT, CONTROL-M, CONTROL-X, CONTROL-V, CONTROL-C and CONTROL-A should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, ON KEY actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a text attribute with the action defaults.

```
ON KEY (CONTROL-Z)
    CALL open_zoom()
```

Related concepts

Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

Default action views on page 1645
A default action view is created to render an action handler when no explicit action view exists for it.

ON TIMER block
The ON TIMER seconds clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

As ON TIMER can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of ON TIMER must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON TIMER trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```
ON TIMER 30
    CALL check_for_messages()
```
Important: The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

ON IDLE block on page 1356

COMMAND [KEY] block
Use COMMAND [KEY] blocks as global procedural DIALOG action handler to execute a sequence of instructions when the user clicks on a button or presses a specific key. COMMAND defines the text and comment decoration attributes as well as accelerator keys for a specific action. COMMAND is especially useful when writing TUI programs. However, it's legal to use such handler when programming new GUI dialogs, especially when the action view (BUTTON in form) must take the focus.

Declaring a COMMAND block in DIALOG is similar to an ON ACTION block, except that COMMAND defines an implicit text and comment decoration attribute. The name of the action will be the command text converted to lowercase letters. For example, with the following code:

```plaintext
COMMAND "Open" "Opens a new file"
```

The name of the action will be "open", and the default decoration text will be "Open" with a capital letter.

Note that if you use an ampersand (&) in the command name, some front-ends consider the letter following & as an Alt-key accelerator, and the letter will be underscored. However the ampersand forms part of the action name. For example, COMMAND "&Save" will create an action with the name "&save". It is not recommended to use & ampersand characters in action names.

Unlike ON KEY actions, if no explicit action view is defined in the form, the default action view will be visible for a COMMAND handler (i.e. the automatic button will appear for this action on the front-end).

action defaults will be applied by using the action name. For explicit action views such as a BUTTON in the form layout, the text/comment defined in the corresponding action default entry will overwrite the values used in the COMMAND handler. When no explicit action view is defined in the form, the text/comment defined in the program COMMAND clause take precedence over action defaults, to display the default action view (button on action frame).

Inside DIALOG instruction, COMMAND blocks can only be defined as global dialog actions; Sub-dialog specific COMMAND handlers cannot be defined. When binding a form BUTTON to a COMMAND handler, the button can get the focus and will be managed in the tabbing list, using preferably the FIELD ORDER FORM option.

When using the optional KEY clause, COMMAND defines also an implicit accelerator key. The key name must be specified between parentheses with COMMAND KEY:

```plaintext
COMMAND KEY (F5) "Open" "Opens a new file"
```

The COMMAND KEY syntax allows multiple key names in the syntax. When using multiple keys in an COMMAND KEY clause, the DIALOG instruction will assign the specified keys as accelerators:

```plaintext
COMMAND KEY (F5, CONTROL-P, CONTROL-Z) "Open" "Opens a new file"
```

With the above code example, the action name will be "open" and accelerators will be F5, CONTROL-P and CONTROL-Z.

The keys defined by program will take precedence over the accelerators defined in the action default entry corresponding to the action.
The **COMMAND** [KEY] block specification can also define a help number with the **HELP** clause, to display the corresponding text of the current help file.

```
COMMAND "Open" "Opens a new file" HELP 34
```

**Related concepts**
- **Binding action views to action handlers** on page 1664
- **Configuring actions** on page 1646

Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with **action attributes**.

**BUTTON item type** on page 1163

Defines a push-button that can trigger an action.

**ON APPEND block**

Similarly to the **ON INSERT** control block, the **ON APPEND** trigger can be used to enable row creation during a **DISPLAY ARRAY** dialog. If this block is defined, the dialog will automatically create the append action. This action can be decorated, enabled and disabled as a regular action.

If the dialog defines an **ON ACTION append** interaction block and the **ON APPEND** block is used, the compiler will stop with error -8408.

When the user fires the append action, the dialog first execute the user code of the **AFTER ROW** block if defined. Then the dialog moves to the end of the list, and creates a new row after the last existing row. After creating the row, the dialog executes the user code of the **ON APPEND** block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular **INPUT** statement, to let the end user enter data for the new created row. This is typically done with an **INPUT** binding explicitly array fields to the screen record fields. The new current row in the program array is identified with `arr_curr()`, and the current screen line in the form is defined by `SCR_LINE()`:

```
DISPLAY ARRAY arr TO sr.*

... ON APPEND
   INPUT arr[arr_curr()].* FROM sr[scr_line()].* ;
...
```

Pay attention to the semicolon ending the **INPUT** instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the **INT_FLAG** global variable is **FALSE** and **STATUS** is zero, the new row is kept in the program array, and the **BEFORE ROW** block is executed for the new created row.
- If the **INT_FLAG** global variable is **TRUE** or **STATUS** is different from zero, the new row is removed from the program array, and the **BEFORE ROW** block is executed for the row that was existing at the current position, before the new row was created.

The **DISPLAY ARRAY** dialog always resets **INT_FLAG** to **FALSE** and **STATUS** to zero before executing the user code of the **ON APPEND** block.

The append action is disabled if the maximum number of rows is reached.

If needed, the **ON APPEND** handler can be configured with action attributes by added an **ATTRIBUTES()** clause, as with user-defined action handlers:

```
ON APPEND ATTRIBUTES(TEXT="%custlist.delete", IMAGE="listdel")
```

**Related concepts**
- **STATUS** on page 517
STATUS is a predefined variable that contains the execution status of the last instruction.

INT_FLAG is a predefined variable set to TRUE when an interruption event is detected.

BEFORE ROW block

arr_curr() Returns the current row in a DISPLAY ARRAY or INPUT ARRAY.

scr_line() Returns the index of the current row in the screen array.

Record input (INPUT)
The INPUT instruction provides single record input control in an application form.

ON INSERT block

Similarly to the ON APPEND control block, the ON INSERT trigger can be used to enable row creation during a DISPLAY ARRAY dialog. If this block is defined, the dialog will automatically create the insert action. This action can be decorated, enabled and disabled as a regular action.

If the dialog defines an ON ACTION insert interaction block and the ON INSERT block is used, the compiler will stop with error -8408.

When the user fires the insert action, the dialog first execute the user code of the AFTER ROW block if defined. Then the new row is created: The insert action creates a new row before current row in the list. After creating the row, the dialog executes the user code of the ON INSERT block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular INPUT statement, to let the end user enter data for the new created row. This is typically done with an INPUT binding explicitly array fields to the screen record fields. The new current row in the program array is identified with arr_curr(), and the current screen line in the form is defined by scr_line():

```
DISPLAY ARRAY arr TO sr.*
  ...
  ON INSERT
    INPUT arr[arr_curr()].* FROM sr[scr_line()].* ;
  ...
```

Pay attention to the semicolon ending the INPUT instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the INT_FLAG global variable is FALSE and STATUS is zero, the new row is kept in the program array, and the BEFORE ROW block is executed for the new created row.
- If the INT_FLAG global variable is TRUE or STATUS is different from zero, the new row is removed from the program array, and the BEFORE ROW block is executed for the row that was existing at the current position, before the new row was created.

The DISPLAY ARRAY dialog always resets INT_FLAG to FALSE and STATUS to zero before executing the user code of the ON INSERT block.

The insert action is disabled if the maximum number of rows is reached.

If needed, the ON INSERT handler can be configured with action attributes by added an ATTRIBUTES() clause, as with user-defined action handlers:

```
ON INSERT ATTRIBUTES(TEXT="%custlist.delete", IMAGE="listdel")
```

**ON APPEND block** on page 1409  
**ON UPDATE block** on page 1412  
**ON DELETE block** on page 1413

### ON UPDATE block

The **ON UPDATE** trigger can be used to enable row modification during a DISPLAY ARRAY dialog. If this block is defined, the dialog will automatically create the update action. This action can be decorated, enabled and disabled as regular actions.

You typically configure the **TABLE** container in the form by defining the **DOUBLECLICK** attribute to "update", in order to trigger the update action when the user double-clicks on a row.

If the dialog defines an **ON ACTION update** interaction block and the **ON UPDATE** block is used, the compiler will stop with error -8408.

When the user fires the **update** action, the dialog executes the user code of the **ON UPDATE** block.

The dialog handles only the row modification action and navigation, you must program the record input with a regular **INPUT** statement, to let the end user modify the data of the current row. This is typically done with an **INPUT** binding explicitly array fields to the screen record fields, with the **WITHOUT DEFAULTS** clause. The current row in the program array is identified with **arr_curr()**, and the current screen line in the form is defined by **scr_line()**:

```plaintext
DISPLAY ARRAY arr TO sr.*
...
ON UPDATE
  INPUT arr[arr_curr()].* WITHOUT DEFAULTS FROM sr[scr_line()].*;
...
```

Pay attention to the semicolon ending the **INPUT** instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the **INT_FLAG** global variable is **FALSE** and **STATUS** is zero, the modified values of the current row are kept in the program array.
- If the **INT_FLAG** global variable is **TRUE** or **STATUS** is different from zero, the old values of the current row are restored in the program array.

The **DISPLAY ARRAY** dialog always resets **INT_FLAG** to **FALSE** and **STATUS** to zero before executing the user code of the **ON UPDATE** block.
If needed, the ON UPDATE handler can be configured with action attributes by added an ATTRIBUTES() clause, as with user-defined action handlers:

```
ON UPDATE ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

- **ON INSERT block** on page 1410
- **ON APPEND block** on page 1409
- **ON DELETE block** on page 1413

**ON DELETE block**

The ON DELETE trigger can be used to enable row deletion during a DISPLAY ARRAY dialog. If this block is defined, the dialog will automatically create the delete action. This action can be decorated, enabled and disabled as regular actions.

If the dialog defines an ON ACTION delete interaction block and the ON DELETE block is used, the compiler will stop with error -8408.

When the user fires the delete action, the dialog executes the user code of the ON DELETE block.

The dialog handles only the row deletion action and navigation, you can typically program a validation dialog box to let the user confirm the deletion. The current row in the program array is identified with arr_curr():

```
DISPLAY ARRAY arr TO sr.*
...
ON DELETE
   IF fgl_winQuestion("Delete",
      "Do you want to delete this record?",
      "yes", "no|yes", "help", 0) == "no"
   THEN
      LET int_flag = TRUE
   END IF
...
```

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the INT_FLAG global variable is FALSE and STATUS is zero, the current row is deleted from the program array, and the BEFORE ROW block is executed for the next row in the list.
- If the INT_FLAG global variable is TRUE or STATUS is different from zero, the current row is kept in the program array, and the BEFORE ROW block is executed again for the current row.
The DISPLAY ARRAY dialog always resets INT_FLAG to FALSE and STATUS to zero before executing the user code of the ON DELETE block.

If needed, the ON DELETE handler can be configured with action attributes by added an ATTRIBUTES() clause, as with user-defined action handlers:

```
ON DELETE ATTRIBUTES(TEXT="%custlist.delete", IMAGE="listdel")
```

**ON SELECTION CHANGE block**

The ON SELECTION CHANGE trigger can be used to enable multi-row selection and detect when rows are selected or de-selected by the end user during a DISPLAY ARRAY dialog. If this block is defined, multi-row selection is automatically enabled. However, the feature can be enabled/disabled with the setSelectionMode() dialog method.

**Related concepts**

- Multiple row selection on page 1752
- Multiple row selection allows the end user to select several rows within a list of records.

**ON SORT block**

**Basics**

The ON SORT interaction block can be used to detect when rows have to be sorted in a DISPLAY ARRAY or INPUT ARRAY dialog.

ON SORT is used in two different contexts:

1. In a regular (full-list) DISPLAY ARRAY / INPUT ARRAY dialog, the ON SORT trigger can be used to detect that a list sort was performed.
2. In a DISPLAY ARRAY using paged mode (ON FILL BUFFER), use ON SORT to detect a sort request from the user and re-fetch the rows from the database in the required order.

**ON SORT in regular full-list DISPLAY ARRAY or INPUT ARRAY**

In a regular DISPLAY ARRAY / INPUT ARRAY dialog not using paged mode, the ON SORT trigger can be used to detect that a list sort was performed.

When the ON SORT block executes in this context, the (visual) sort is already done by the runtime system and the ON SORT block is only used to execute post-sort tasks, such as displaying current row information.

To display the row position information, use the arrayToVisualIndex() dialog method to convert the current program row number to the visual row number:

```
DISPLAY ARRAY arr TO sr.* ...
... 
  ON SORT 
  MESSAGE SFMT( "Row: %1/%2", 
```
DIALOG.arrayToVisualIndex( "sr", DIALOG.getCurrentRow("sr"), DIALOG.getArrayLength( "sr" )
)

If needed, you can get the sort column and sort order with the `getSortKey()` and `isSortReverse()` dialog methods:

```plaintext
DISPLAY ARRAY arr TO sr.* ...

... ON SORT
    MESSAGE SFMT( "Sort on %1, %2 order",";
        DIALOG.getSortKey("sr"),
        IIF( DIALOG.isSortReverse("sr"), "descending", "ascending" )
    )

..."
```

**ON SORT in DISPLAY ARRAY using the paged mode**

In a `DISPLAY ARRAY` implementing paged mode with `ON FILL BUFFER` trigger, built-in row sorting is not available because data is provided by pages. Use the `ON SORT` trigger, to detect a sort request and perform a new SQL query to re-order the rows. In this context, the sort column and sort order are available with the `getSortKey()` and `isSortReverse()` dialog methods:

```plaintext
DEFINE key STRING, rev BOOLEAN
DISPLAY ARRAY arr TO sr.* ...

... ON SORT
    -- Re-execute the SQL statement to fill the page of rows in ON FILL BUFFER
    -- Assuming that form field names match table column names
    LET key = DIALOG.getSortKey("sa")
    LET rev = DIALOG.isSortReverse("sa")
    IF key IS NULL THEN
        CALL execute_sql( NULL )
    ELSE
        CALL execute_sql( "ORDER BY " || key || IIF(rev," DESC"," " ) )
    END IF
```

See [Paged mode of DISPLAY ARRAY](#) on page 1743 for more details about the paged mode in `DISPLAY ARRAY` and how to implement sort in this type of record list dialog.

**Related concepts**

[List ordering](#) on page 1764
List controllers implement a built-in sort. This feature can be disabled if not required.

**ON DRAG_START block**

The `ON DRAG_START` block is executed when the end user has begun the drag operation. If this dialog trigger has not been defined, default dragging is enabled for this dialog.

In the `ON DRAG_START` block, the program typically specifies the type of drag & drop operation by calling `ui.DragDrop.setOperation()` with "move" or "copy". This call will define the default and unique drag operation. If needed, the program can allow another type of drag operation with `ui.DragDrop.addPossibleOperation()`. The end user can then choose to move or copy the dragged object, if the drag & drop target allows it.

If the dragged object can be dropped outside the program, must define the MIME type and drag/drop data with `ui.DragDrop.setMimeType()` and `ui.DragDrop.setBuffer()` methods.
Example:

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_START (dnd)
    CALL dnd.setOperation("move") -- Move is the default operation
    CALL dnd.addPossibleOperation("copy") -- User can toggle to copy if needed
    CALL dnd.setMimeType("text/plain")
    CALL dnd.setBuffer(arr[arr_curr()].cust_name)
...
END DISPLAY
```

Related concepts

- How to handle MIME types with drag & drop?
- The **DragDrop class** on page 2422
  The `ui.DragDrop` class is used to control the events related to drag & drop events.

**ON DRAG_FINISHED block**

Execution of the `ON DRAG_FINISHED` block notifies the dialog where the drag started and that the drop operation has been completed or terminated.

Call `ui.DragDrop.getOperation()` to get the final type of operation of the drop. On successful completion, the method returns "move" or "copy"; otherwise the function returns `NULL`. If `NULL` is returned, the `ON DRAG_FINISHED` trigger can be ignored.

In cases of successful moves to a target out of the current `DISPLAY ARRAY`, the application must remove the transferred data from the source model. For example, if a row was moved from dialog A to B, dialog A will get an `ON DRAG_FINISHED` execution after the row was dropped into B, which removes the row from the list A.

The `ON DRAG_FINISHED` interaction block is optional.

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_START (dnd)
    LET last_dragged_row = arr_curr()
...
ON DRAG_FINISHED (dnd)
    IF dnd.getOperation() == "move" THEN
        CALL DIALOG.deleteRow(last_dragged_row)
    END IF
...
END DISPLAY
```

Related concepts

- The **DragDrop class** on page 2422
  The `ui.DragDrop` class is used to control the events related to drag & drop events.

**ON DRAG_ENTER block**

When the `ON DROP` control block is defined, the `ON DRAG_ENTER` block will be executed when the mouse cursor enters the visual boundaries of the drop target dialog. Entering the target dialog is accepted by default if no `ON DRAG_ENTER` block is defined. However, when `ON DROP` is defined, it is recommended that you also define `ON DRAG_ENTER` to deny the drop of objects with an unsupported MIME type that come from other applications.
The program can decide to deny or allow a specific drop operation with a call to
\texttt{ui.DragDrop.setOperation}(): passing a NULL to the method will deny drop.

To check what MIME type is available in the drag & drop buffer, the program uses the
\texttt{ui.DragDrop.selectMimeType}() method. This method takes the MIME type as a parameter and returns
\texttt{TRUE} if the passed MIME type is used. You can call this method several times to check the availability of different
MIME types.

You may also define the visual effect when hovering over the target list with \texttt{ui.DragDrop.setFeedback}().

\begin{verbatim}
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER (dnd)
  IF dnd.selectMimeType("text/plain") THEN
    CALL dnd.setOperation("copy")
    CALL dnd.setFeedback("all")
  ELSE
    CALL dnd.setOperation(NULL)
    END IF
ON DROP (dnd)
...
END DISPLAY
\end{verbatim}

Once the mouse has entered the target area, subsequent mouse cursor moves can be detected with the \texttt{ON DRAG_OVER} trigger.

When using a table or tree-view as drop target, you can control the visual effect when the mouse moves over the
rows, depending on the type of drag & drop you want to achieve.

Basically, a dragged object can be:

1. Inserted in between two rows (visual effect must show where the object will be inserted)
2. Copied/merged to the current row (visual effect must show the row under the mouse)
3. Dropped somewhere on the target widget (the exact location inside the widget does not matter)

The visual effect can be defined with the \texttt{ui.DragDrop.setFeedback}() method, typically called in the \texttt{ON DRAG_ENTER} block.

The values to pass to the \texttt{setFeedback}() method to get the desired visual effects described are respectively:

1. insert (default)
2. select
3. all

\begin{verbatim}
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER (dnd)
  IF canDrop() THEN
    CALL dnd.setOperation(NULL)
  ELSE
    CALL dnd.setFeedback("select")
  END IF
ON DROP (dnd)
...
END DISPLAY
\end{verbatim}

Related concepts
The DragDrop class on page 2422
The ui.DragDrop class is used to control the events related to drag & drop events.

**ON DRAG_OVER block**

When the ON DROP control block is defined, the ON DRAG_OVER block will be executed after ON DRAG_ENTER, when the mouse cursor is moving over the drop target, or when the drag & drop operation has changed (toggling copy/move).

ON DRAG_OVER will be called only once per row, even if the mouse cursor moves over the row.

In the ON DRAG_OVER block, the method `ui.DragDrop.getLocationRow()` returns the index of the row in the target array, and can be used to allow or deny the drop. When using a tree-view, you must also check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and allow/deny the drop operation accordingly.

The program can change the drop operation at any execution of the ON DRAG_OVER block. You can deny or allow a specific drop operation with a call to `ui.DragDrop.setOperation()`. Passing a NULL to the method will deny the drop.

The current operation (returned by `ui.DragDrop.getOperation()`) is the value set in previous ON DRAG_ENTER or ON DRAG_OVER events, or the operation selected by the end user, if it can toggle between copy and move. Thus, ON DRAG_OVER can occur even if the mouse position has not changed.

If dropping has been denied with `ui.DragDrop.setOperation(NULL)` in the previous ON DRAG_OVER event, the program can reset the operation to allow a drop with a call to `ui.DragDrop.setOperation()` with the operation parameter "move" or "copy".

ON DRAG_OVER will not be called if drop has been disabled in ON DRAG_ENTER with `ui.DragDrop.setOperation(NULL)`.

ON DRAG_OVER is optional, and must only be defined if the operation or the acceptance of the drag object depends on the target row of the drop target.

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER (dnd)
...
ON DRAG_OVER (dnd)
  IF arr[dnd.getLocationRow()].acceptsCopy THEN
    CALL dnd.setOperation("copy")
  ELSE
    CALL dnd.setOperation(NULL)
  END IF
ON DROP (dnd)
...
END DISPLAY
```

During a drag & drop process, the end user (or the target application) can decide to modify the type of the operation, to indicate whether the dragged object has to be copied or moved from the source to the target. For example, in a typical file explorer, by default files are moved when doing a drag & drop on the same disk. To make a copy of a file, you must press the Ctrl key while doing the drag & drop with the mouse.

In the drop target dialog, you can detect such operation changes in the ON DRAG_OVER trigger and query the ui.DragDrop object for the current operation with `ui.DragDrop.getOperation()`. In the drag source dialog, you typically check `ui.DragDrop.getOperation()` in the ON DRAG_FINISHED trigger to know what sort of operation occurred, to keep ("copy" operation) or delete ("move" operation) the original dragged object.

This example tests the current operation in the drop target list and displays a message accordingly:

```plaintext
DEFINE dnd ui.DragDrop
...
```
DISPLAY ARRAY arr TO sr.* ...

... ON DRAG_ENTER (dnd) ...

... ON DRAG_OVER (dnd)
  CASE dnd.getOperation()
    WHEN "move"
      MESSAGE "The object will be moved to row ", dnd.getLocationRow()
    WHEN "copy"
      MESSAGE "The object will be copied to row ", dnd.getLocationRow()
  END CASE

... ON DROP (dnd)
...
END DISPLAY

Tree views on page 1789
Describes how to implement tree views.

ON DROP block
To enable drop actions on a list, you must define the ON DROP block; otherwise the list will not accept drop actions.

The ON DROP block is executed after the end user has released the mouse button to drop the dragged object. ON DROP will not occur if drop has been denied in the previous ON DRAG_OVER event or in ON DRAG_ENTER with a call to ui.DragDrop.setOperation(NULL).

When ON DROP executes, the MIME type of the dragged object can be checked with ui.DragDrop.getSelectedMimeType(). Then call the ui.DragDrop.getBuffer() method to retrieve drag & drop data from external applications.

Ideally, the drop operation is accepted (there is no need for additional calls to ui.DragDrop.setOperation()).

In this block, the ui.DragDrop.getLocationRow() method returns the index of the row in the target array, and can be used to execute the code to get the drop data / object into the row that has been chosen by the user.

DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
  ON DROP (dnd)
    LET arr[dnd.getLocationRow()].capacity == dnd.getBuffer()
  ...
END DISPLAY

If the drag & drop operations are local to the same list or tree-view controller, you can use the ui.DragDrop.dropInternal() method to simplify the code. This method implements the typical move of the dragged rows or tree-view node. This is especially useful in case of a tree-view, but is also the preferred way to move rows around in simple tables.

This ON DROP code example uses the dropInternal() method:

DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr_tree TO sr_tree.* ...
...
  ON DROP (dnd)
    CALL dnd.dropInternal()
If you want to implement by hand the code to drop a node in a tree-view, you must check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and execute the code corresponding to the drop operation: If the drop target row index returned by `getLocationRow()` is a child of the parent row index returned by `getLocationParent()`, the new row must be inserted before `getLocationRow()`; otherwise the new row must be added as a child of the parent node identified by `getLocationParent()`.

**Related concepts**

The `ui.DragDrop` class is used to control the events related to drag & drop events.

**DIALOG control instructions**

*Dialog control instructions* are language instructions dedicated to dialog control, to programmatically force the dialog to behave in a given way.

For example the `NEXT FIELD` instruction forces the focus to a specific form field.

- `NEXT FIELD` instruction on page 1389
- `CLEAR instruction in dialogs` on page 1389
- `DISPLAY TO / BY NAME instruction` on page 1537
- `CONTINUE DIALOG instruction` on page 1537
- `EXIT DIALOG instruction` on page 1538
- `ACCEPT DIALOG instruction` on page 1538
- `CANCEL DIALOG instruction` on page 1539
- `CANCEL DELETE instruction` on page 1450
- `CANCEL INSERT instruction` on page 1451

**Understanding the NEXT FIELD instruction**

The `NEXT FIELD field-name` instruction gives the focus to the specified field and forces the dialog to stay in that field.

This instruction can be used to control field input, in `BEFORE FIELD`, `ON CHANGE` or `AFTER FIELD` blocks, it can also force a `DISPLAY ARRAY` or `INPUT ARRAY` to stay in the current row when `NEXT FIELD` is used in the `AFTER ROW` block.

If it exists, the `BEFORE FIELD` block of the corresponding field is executed.

In editable dialogs, the purpose of the `NEXT FIELD` instruction is to give the focus to an editable field. Make sure that the field specified in `NEXT FIELD` is active, or use `NEXT FIELD CURRENT`. Non-editable fields are fields defined with the `NOENTRY` attribute, fields disabled at runtime with `DIALOG.setFieldActive()`, or fields using a widget that does not allow input, such as a `LABEL`.

In a `DISPLAY ARRAY` using the `FOCUSONFIELD` attribute, `NEXT FIELD` can be used in conjunction with `DIALOG.setCurrentRow()`, to set the focus to a specific cell in the list.

Instead of the `NEXT FIELD` instruction, you can use the `DIALOG.nextField("field-name")` method to register a field, for example when the name is not known at compile time. However, this method only registers the field. It does not stop code execution, like the `NEXT FIELD` instruction does. You must execute a `CONTINUE DIALOG` to get the same behavior as `NEXT FIELD`.

**Form field identification with NEXT FIELD**

With the `NEXT FIELD` instruction, fields are identified by the form field name specification, not the program variable name used by the dialog. Form fields are bound to program variables with the binding clause of the
dialog instruction (INPUT variable-list FROM field-list, INPUT BY NAME variable-list,
CONSTRUCT BY NAME sql ON column-list, CONSTRUCT sql ON column-list FROM field-
list, INPUT ARRAY array-name FROM screen-array.*).

The field name specification can be any of the following:

- field-name
- table-name.field-name
- screen-record-name.field-name
- FORMONLY.field-name

Here are some examples:

- "cust_name"
- "customer.cust_name"
- "cust_screen_record.cust_name"
- "item_screen_array.item_label"
- "formonly.total"

When no field name prefix is used, the first form field matching that simple field name is used.

When using a prefix in the field name specification, it must match the field prefix assigned by the dialog field binding method used at the beginning of the interactive statement: When no screen-record has been explicitly specified in the field binding clause (for example, when using INPUT BY NAME variable-list), the field prefix must be the database table name (or FORMONLY) used in the form file, or any valid screen-record using that field. When the FROM clause of the dialog specifies an explicit screen-record (for example, in INPUT variable-list FROM screen-record.* / field-list-with-screen-record-prefix or INPUT ARRAY array-name FROM screen-array.*), the field prefix must be the screen-record name used in the FROM clause.

Abstract field identification is supported with the CURRENT, NEXT and PREVIOUS keywords. These keywords represent the current, next and previous fields respectively. When using FIELD ORDER FORM, the NEXT and PREVIOUS options follow the tabbing order defined by the form. Otherwise, they follow the order defined by the input binding list (with the FROM or BY NAME clause).

In a procedural dialog, if the focus is in the first field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD PREVIOUS will jump out of the current sub-dialog and set the focus to the previous sub-dialog. If the focus is in the last field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD NEXT will jump out of the current sub-dialog and set the focus to the next sub-dialog. NEXT FIELD NEXT or NEXT FIELD PREVIOUS also jumps to another sub-dialog when the focus is in a DISPLAY ARRAY sub-dialog. However, when using an INPUT ARRAY sub-dialog, NEXT FIELD NEXT from within the last column will loop to the first column of the current row, and NEXT FIELD PREVIOUS from within the first column will jump to the last column of the current row - the focus stays in the current INPUT ARRAY sub-dialog. When another sub-dialog gets the focus because of a NEXT FIELD NEXT/ PREVIOUS, the newly-selected field depends on the sub-dialog type, following the tabbing order as if the end-user had pressed the tab or Shift-Tab key combination.

**NEXT FIELD to a non-editable INPUT / INPUT ARRAY / CONSTRUCT field**

Non-editable fields are fields defined with the NOENTRY attribute, fields disabled with 
ui.Dialog.setFieldActive("field-name", FALSE), or fields using a widget that does not allow input, such as a LABEL.

If a NEXT FIELD instruction specifies a non-editable field, the BEFORE FIELD block of that field is executed. Then the dialog tries to give the focus to that field. Since the field cannot get the focus, the dialog will perform the last pressed navigation key (Tab, Shift-Tab, Left, Right, Up, Down, Accept) and execute the related control blocks, including the AFTER FIELD block of the non-editable field. If no last key is identified, the dialog considers Tab as fallback and moves to the next editable field as defined by the FIELD ORDER mode used by the dialog. Doing a NEXT FIELD to a non-editable field can lead to infinite loops in the dialog; Use NEXT FIELD CURRENT instead.

When selecting a non-editable field with NEXT FIELD NEXT, the runtime system will re-select the current field since it is the next editable field in the dialog. As a result the end user sees no change.
NEXT FIELD in procedural DIALOG blocks

In a procedural dialog block, the NEXT FIELD field-name instruction gives the focus to the specified field controlled by INPUT, INPUT ARRAY or CONSTRUCT, or to a read-only list when using DISPLAY ARRAY.

When using a DISPLAY ARRAY sub-dialog, it is possible to give the focus to the list, by specifying the name of the first column as argument for NEXT FIELD.

If the target field specified in the NEXT FIELD instruction is inside the current sub-dialog, neither AFTER FIELD nor AFTER ROW will be invoked for the field or list you are leaving. However, the BEFORE FIELD control blocks of the destination field (or the BEFORE ROW in case of read-only list) will be executed.

If the target field specified in the NEXT FIELD instruction is outside the current sub-dialog, the AFTER FIELD, AFTER INSERT, AFTER ROW, and AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be invoked for the field or list you are leaving. Form-level validation rules will also be checked, as if the user had selected the new sub-dialog himself. This guarantees the current sub-dialog is left in a consistent state. The BEFORE INPUT/DISPLAY/CONSTRUCT, BEFORE ROW and the BEFORE FIELD control blocks of the destination field / list will then be executed.

NEXT FIELD in record list control blocks

When using NEXT FIELD in AFTER ROW or in ON ROW CHANGE of a DISPLAY ARRAY or INPUT ARRAY, the dialog will stay in the current row and give control back to the user. This behavior allows you to implement data input rules:

```plaintext
AFTER ROW
  IF NOT int_flag AND arr_count()<=arr_curr() THEN
    IF arr[arr_curr()].it_count * arr[arr_curr()].it_value > maxval THEN
      ERROR "Amount of line exceeds max value."
      NEXT FIELD item_count
    END IF
  END IF
END IF
```

The NOENTRY attribute prevents data entry in the field during an input dialog.

Form-level validation rules on page 1627
Form-level validation rules can be defined for each field controlled by a dialog.

Understanding multiple dialogs on page 1481
Multiple dialogs are defined with DIALOG blocks inside a FUNCTION.

CLEAR instruction in dialogs

The CLEAR field-list and CLEAR SCREEN ARRAY screen-array.* instructions clear the value buffer of specified form fields. The buffers are directly changed in the current form, and the program variables bound to the dialog are left unchanged. CLEAR can be used outside any dialog instruction, such as the DISPLAY BY NAME / TO instructions.

When a dialog is configured with the UNBUFFERED mode, there is no reason to clear field buffers since any variable assignment will synchronize field buffers. Actually, changing the field buffers with DISPLAY or CLEAR instruction in an UNBUFFERED dialog will have no visual effect, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. To clear fields of an UNBUFFERED dialog, just set to NULL the variables bound to the dialog. However, when using a CONSTRUCT, no program variables are associated
with the dialog and no UNBUFFERED concept exits, and the CLEAR or DISPLAY TO / BY NAME instructions are the only way to modify the CONSTRUCT fields.

A screen array with a screen-line specification doesn't make much sense in a GUI application using TABLE containers, you can therefore use the CLEAR SCREEN ARRAY instruction to clear all rows of a list.

**Related concepts**

The CLEAR field-list instruction clears specific fields in the current form.

CLEAR SCREEN ARRAY on page 1350
The CLEAR SCREEN ARRAY instruction clears the values of all rows of the form list identified by the specified screen array.

TABLE container on page 1217
Defines a re-sizable table designed to display a list of records.

The buffered and unbuffered modes on page 1618
The buffered and unbuffered mode control the synchronization of program variables and form fields.

**DISPLAY TO / BY NAME instruction**

The DISPLAY variable-list TO field-list or DISPLAY BY NAME variable-list instruction fills the value buffers of specified form fields with the values contained in the specified program variables. The DISPLAY instruction changes the buffers directly in the current form, not the program variables bound to the dialog. DISPLAY can be used outside any dialog instruction, in the same way as the CLEAR instruction. DISPLAY also sets the modification flag of fields.

As DIALOG is typically used with the UNBUFFERED mode, there is no reason to set field buffers in a DIALOG block since any variable assignment will synchronize field buffers. Actually, changing the field buffers with the DISPLAY or CLEAR instruction will have no visual effect if the fields are used by a dialog working in UNBUFFERED mode, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. So if you want to set field values, just assign the variables and the fields will be synchronized. However, when using a CONSTRUCT binding, you may want to set field buffers with this DISPLAY instruction, as there are no program variables bound to fields (with CONSTRUCT, only one string variable is bound to hold the SQL condition).

Instead of using a DISPLAY instruction to set the modification flag of fields to simulate user input, use the DIALOG.setFieldTouched() method instead.

**Related concepts**

The buffered and unbuffered mode control the synchronization of program variables and form fields.

The CONSTRUCT sub-dialog on page 1492
The CONSTRUCT sub-dialog provides database query by example feature, converting search criteria entered by the user into an SQL WHERE condition that can be used to execute a SELECT statement.

**CONTINUE DIALOG instruction**

The CONTINUE DIALOG statement continues the execution of a DIALOG instruction, skipping all statements appearing after this instruction.
Control returns to the dialog instruction, which executes remaining control blocks as if the program reached the end of the current control block. Then the control goes back to the user and the dialog waits for a new event.

The CONTINUE DIALOG statement is useful when program control is nested within multiple conditional statements, and you want to return control to the user by skipping the rest of the statements.

In the following code example, an ON ACTION block gives control back to the dialog, skipping all instructions below line 04:

```plaintext
ON ACTION zoom
  IF p_cust.cust_id IS NULL OR p_cust.cust_name IS NULL THEN
    ERROR "Zoom window cannot be opened if no info to identify customer"
    CONTINUE DIALOG
  END IF
  IF p_cust.cust_address IS NULL THEN
    ...
```

If CONTINUE DIALOG is called in a control block that is not AFTER DIALOG, further control blocks might be executed depending on the context. Actually, CONTINUE DIALOG just instructs the dialog to continue as if the code in the control block was terminated (it is a kind of GOTO end_of_control_block). However, when executed in AFTER DIALOG, the focus returns to the current field or read-only list. In this case the BEFORE ROW and BEFORE FIELD triggers will be invoked.

A CONTINUE DIALOG in AFTER FIELD, AFTER INPUT, AFTER DISPLAY or AFTER CONSTRUCT will only stop the program flow of the current block of statements; instructions after CONTINUE DIALOG will not be executed. If the user has selected a field in a different sub-dialog, this new field will get the focus and all necessary AFTER / BEFORE control blocks will be executed.

In case of input error in a field, the best practice is to use a NEXT FIELD instruction to stay in the dialog and set the focus to the field that the user has to correct.

**Related concepts**

NEXT FIELD instruction on page 1389

**EXIT DIALOG instruction**

The EXIT DIALOG statement terminates a procedural DIALOG block without any further control block execution.

**Note:** When used in a declarative DIALOG block, the EXIT DIALOG instruction does only make sense when the declarative dialog block is included in a procedural dialog block with the SUBDIALOG clause.

Program flow resumes at the Instruction following the END DIALOG keywords. Blocks such as AFTER DIALOG will not be executed.

```
ON ACTION quit
  EXIT DIALOG
```

When leaving the DIALOG instruction, all form items used by the dialog will be disabled until another interactive statement takes control.

The EXIT DIALOG instruction leaves the DIALOG block immediately, while CANCEL DIALOG makes some additional tasks.

**Related concepts**

CANCEL DIALOG instruction on page 1539

ACCEPT DIALOG instruction on page 1538

**ACCEPT DIALOG instruction**

The ACCEPT DIALOG statement validates all input fields bound to the DIALOG instruction and leaves the block if no error is raised.
Note: When used in a declarative DIALOG block, the ACCEPT DIALOG instruction does only make sense when the declarative dialog block is included in a procedural dialog block with the SUBDIALOG clause.

When defined in the dialog block, ON CHANGE, AFTER FIELD, AFTER ROW, AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be executed when ACCEPT DIALOG is performed.

The statements appearing after the ACCEPT DIALOG instruction will be skipped.

You typically code an ACCEPT DIALOG in an ON ACTION accept block:

```
ON ACTION accept ACCEPT DIALOG
```

Important: Any usage of ACCEPT DIALOG outside an ON ACTION accept block is not intended and its behavior is undefined.

Input field validation is a process that does several successive validation tasks:

1. The current field value is checked, depending on the variable data type (for example, the user must input a valid date in a DATE field).
2. NOT NULL field attributes are checked for all input fields. This attribute forces the field to have a value set by program or entered by the user. If the field contains no value, the constraint is not satisfied. Input values are right-trimmed, so if the user inputs only spaces, this corresponds to a NULL value which does not fulfill the NOT NULL constraint.
3. REQUIRED field attributes are checked for all input fields. This attribute forces the field to have a default value, or to be modified by the user or by program with a DISPLAY TO / BY NAME or DIALOG.setFieldTouched() call. If the field was not modified during the dialog, the REQUIRED constraint is not satisfied.
4. INCLUDE field attributes are checked for all input fields. This attribute forces the field to contain a value that is listed in the include list. If the field contains a value that is not in the list, the constraint is not satisfied.

If a field does not satisfy one of these constraints, dialog termination is canceled, an error message is displayed, and the focus goes to the first field causing a problem.

After input field validation has succeeded, different types of control blocks will be executed, such as AFTER FIELD, AFTER ROW, AFTER INPUT and AFTER DIALOG.

In order to validate some parts of the dialog without leaving the block, use the DIALOG.validate() method.

Related concepts

Input field modification flag on page 1623
Each input field controlled by a dialog instruction has a modification flag.

CANCEL DIALOG instruction on page 1539
EXIT DIALOG instruction on page 1538

CANCEL DIALOG instruction

The CANCEL DIALOG statement terminates a procedural DIALOG block, after executing the AFTER INPUT/DISPLAY/CONSTRUCT control block of the current sub-dialog, and the AFTER DIALOG control block.

Note: When used in a declarative DIALOG block, the CANCEL DIALOG instruction does only make sense when the declarative dialog block is included in a procedural dialog block with the SUBDIALOG clause.

The CANCEL DIALOG instruction can be used from multiple dialogs to mimic the cancel default action of single dialogs.

The CANCEL DIALOG instruction makes the following:

1. Set the INT_FLAG register to TRUE.
2. If defined, execute the code in the AFTER INPUT, AFTER DISPLAY or AFTER CONSTRUCT block of the current sub-dialog.
3. If defined, execute the code in the AFTER DIALOG block.
The statements appearing after the CANCEL DIALOG instruction will be skipped.

You typically code an CANCEL DIALOG in an ON ACTION cancel block:

```
ON ACTION cancel CANCEL DIALOG
```

**Note:** The default settings regarding action attributes for the cancel action define the validate attribute to "no", in order to avoid current field validation for this action. This is important when using the UNBUFFERED mode. For more details, see Actions configuration for field validation on page 1620.

**Related concepts**

EXIT DIALOG instruction on page 1538  
ACCEPT DIALOG instruction on page 1538

**CANCEL DELETE instruction**

In a list controlled by an INPUT ARRAY, row deletion can be canceled by using the CANCEL DELETE instruction in the BEFORE DELETE block. Using this instruction in a different place will generate a compilation error.

When the CANCEL DELETE instruction is executed, the current BEFORE DELETE block is terminated without any other trigger execution (no BEFORE ROW or BEFORE FIELD is executed), and the program execution continues in the user event loop.

You can, for example, prevent row deletion based on some condition:

```
BEFORE DELETE
  IF user_can_delete() == FALSE THEN
    ERROR "You are not allowed to delete rows"
    CANCEL DELETE
  END IF
```

The instructions that appear after CANCEL DELETE will be skipped.

If the row deletion condition is known before the delete action occurs, disable the delete action to prevent the user from performing a delete row action with the DIALOG.setActionActive() method:

```
CALL DIALOG.setActionActive("delete", FALSE)
```

It is also possible to prevent the user from deleting rows with the DELETE ROW = FALSE option in the ATTRIBUTE clause.

**Related concepts**

BEFORE DELETE block on page 1443

**CANCEL INSERT instruction**

In a list controlled by an INPUT ARRAY, row creation can be canceled by the program with the CANCEL INSERT instruction. This instruction can only be used in the BEFORE INSERT and AFTER INSERT control blocks. If it appears at a different place, the compiler will generate an error.

The instructions that appear after CANCEL INSERT will be skipped.

If the row creation condition is known before the insert/append action occurs, disable the insert and/or append actions to prevent the user from creating new rows, with DIALOG.setActionActive():

```
CALL DIALOG.setActionActive("insert", FALSE)
CALL DIALOG.setActionActive("append", FALSE)
```

However, this will not prevent the user from appending a new temporary row at the end of the list, when moving down after the last row. To prevent row creation completely, use the INSERT ROW = FALSE and APPEND ROW = FALSE options in the ATTRIBUTE clause of INPUT ARRAY, or combine with the AUTO APPEND = FALSE attribute.
CANCEL INSERT in BEFORE INSERT

A CANCEL INSERT executed inside a BEFORE INSERT block prevents the new row creation. The following tasks are performed:

1. No new row will be created (the new row is not yet shown to the user).
2. The BEFORE INSERT block is terminated (further instructions are skipped).
3. The BEFORE ROW and BEFORE FIELD triggers are executed.
4. Control goes back to the user.

You can, for example, cancel a row creation if the user is not allowed to create rows:

```plaintext
BEFORE INSERT
  IF NOT user_can_insert THEN
    ERROR "You are not allowed to insert rows"
    CANCEL INSERT
  END IF
```

Executing CANCEL INSERT in BEFORE INSERT will also cancel a temporary row creation, except when there are no more rows in the list. In this case, CANCEL INSERT will just be ignored and leave the new row as is (otherwise, the instruction would loop without end). You can prevent automatic temporary row creation with the AUTO APPEND=FALSE attribute. If AUTO APPEND=FALSE and a CANCEL INSERT is executed in BEFORE INSERT (user has invoked an append action), the temporary row will be deleted and list will remain empty if it was the last row.

CANCEL INSERT in AFTER INSERT

A CANCEL INSERT executed inside an AFTER INSERT block removes the newly created row. The following tasks are performed:

1. The newly created row is removed from the list (the row exists now and user has entered data).
2. The AFTER INSERT block is terminated (further instructions are skipped).
3. The BEFORE ROW and BEFORE FIELD triggers are executed.
4. The control goes back to the user.

You can, for example, cancel a row insertion if a database error occurs when you try to insert the row into a database table:

```plaintext
AFTER INSERT
  WHENEVER ERROR CONTINUE
  LET r = DIALOG.getCurrentRow("s_items")
  INSERT INTO items VALUES ( p_items[r].* )
  WHENEVER ERROR STOP
  IF SQLCA.SQLCODE<>0 THEN
    ERROR SQLERRMESSAGE
    CANCEL INSERT
  END IF
```

Understanding declarative dialogs

Declarative dialogs are defined with DIALOG blocks at the module level.

A declarative dialog block is a module element defined at the same level as a FUNCTION or REPORT routine:

```gml
-- Module orders.4gl
SCHEMA stock
DEFINE arr DYNAMIC ARRAY OF RECORD LIKE orders.*
DIALOG orders_dlg()
  DEFINE x INT
  DISPLAY ARRAY arr TO sr_orders.*
  ...
END DISPLAY
END DIALOG
```

The name of a declarative dialog is mandatory. It can be referenced by a SUBDIALOG clause, by a START DIALOG and TERMINATE DIALOG instruction, and can identify sub-dialog actions with a prefix. Specifically, the name of the declarative dialog will be referenced in a START DIALOG and TERMINATE DIALOG instruction to implement parallel dialogs.

When using the DIALOG keyword inside a declarative dialog block to use ui.Dialog class methods, it references the current instance of the dialog object.

**Syntax of the declarative DIALOG block**
The declarative DIALOG block defines an interactive instruction that can be used by a parent DIALOG, or as parallel dialog.

**Syntax**

```
| PRIVATE | PUBLIC | DIALOG dialog-name ()
| define-block |
| menu-block |
| record-input-block |
| construct-block |
| display-array-block |
| input-array-block |
| END DIALOG |
```

1. `dialog-name` defines the identifier for the declarative DIALOG block.

where `define-block` is a **local variable declaration block**.

where `menu-block` is:

```
MENU
  | BEFORE MENU
  | menu-statement
  | [...]
  | menu-option
  | [...]
END MENU
```

where `menu-option` is:

```
COMMAND option-name |
  [option-comment] [ HELP help-number ]
  menu-statement
  [...]
COMMAND KEY ( key-name ) option-name |
  [option-comment] [ HELP help-number ]
  menu-statement
  [...]
COMMAND KEY ( key-name )
  menu-statement
  [...]
ON ACTION action-name |
  [ ATTRIBUTES ( action-attributes-menu ) ]
  menu-statement
  [...]
```

where `action-attributes-menu` is:

```
| TEXT = string |
| COMMENT = string |
| IMAGE = string |
| ACCELERATOR = string |
| DEFAULTVIEW = YES | NO | AUTO |
| CONTEXTMENU = YES | NO | AUTO |
| DISCLOSUREINDICATOR |
```
where menu-statement is:

```plaintext
statement
  NEXT OPTION option
  SHOW OPTION [ ALL ] option [, ... , ]
  HIDE OPTION [ ALL ] option [, ... , ]
```

1. `key-name` is a hot-key identifier (like F11 or Control-z).
2. `option-name` is a string expression defining the label of the menu option and identifying the action that can be executed by the user.
3. `option-comment` is a string expression containing a description for the menu option, displayed when `option-name` is the current.
4. `help-number` is an integer that allows you to associate a help message number with the menu option.
5. `action-name` identifies an action that can be executed by the user.
6. `idle-seconds` is an integer literal or variable that defines a number of seconds.
7. `action-name` identifies an action that can be executed by the user.
8. `action-attributes` are dialog-specific action attributes.

where record-input-block is:

```plaintext
INPUT { BY NAME { variable | record.* } [, ... , ]
  variable | record.* } [, ... , ] FROM field-list
  ATTRIBUTES ( input-control-attribute [, ... , ] )
  input-control-block
  ...
END INPUT
```

where input-control-attribute is:

```plaintext
HELP = help-number
NAME = "sub-dialog-name"

  | table-name.*
  | table-name.column-name
  | [, ...]
```

1. **variable-definition** is a variable declaration with data type as in a regular **DEFINE** statement.
2. **array** is the array of records used by the **DIALOG** statement.
3. **help-number** is an integer that allows you to associate a help message number with the command.
4. **field-name** is the identifier of a field of the current form.
5. **option-name** is a string expression defining the label of the action and identifying the action that can be executed by the user.
6. **option-comment** is a string expression containing a description for the menu option, displayed when **option-name** is the current.
7. **column-name** is the identifier of a database column of the current form.
8. **table-name** is the identifier of a database table of the current form.
9. **variable** is a simple program variable (not a record).
10. **record** is a program record (structured variable).
11. **screen-array** is the screen array that will be used in the current form.
12. **line** is a screen array line in the form.
13. **screen-record** is the identifier of a screen record of the current form.
14. **action-name** identifies an action that can be executed by the user.
15. **seconds** is an integer literal or variable that defines a number of seconds.
16. **key-name** is a hot-key identifier (like F11 or Control-z).
17. **row-index** identifies the program variable which holds the row index corresponding to the tree node that has been expanded or collapsed.
18. **dnd-object** references a **ui.DragDrop** variable defined in the scope of the dialog.
19. **statement** is any instruction supported by the language.
20. **action-attributes** are dialog-specific action attributes for the action.

**Related concepts**

- Starts the instance of a declarative dialog.
- Syntax of the **TERMINATE DIALOG instruction** on page 1604
Terminates the instance of a declarative dialog.

**Declarative dialog programming steps**

This procedure describes how to implement a declarative DIALOG block.

To implement a declarative DIALOG block:

1. Create a form specification file containing screen record(s) and/or screen array(s). The screen records and screen arrays identify the presentation elements to be used by the runtime system to display the data models (the content of program variables bound to the DIALOG blocks).

2. Create a dedicated .4gl module to implement the declarative DIALOG block.

3. With the DEFINE instruction, declare program variables (records and arrays) that will be used as data models. These will typically be defined as PRIVATE module variables. For record lists (DISPLAY ARRAY or INPUT ARRAY), the members of the program array must correspond to the elements of the screen array, by number and data types. To handle record lists, use dynamic arrays instead of static arrays.

4. Define the declarative DIALOG block in the module, to handle interaction. Define a sub-dialog with program variables to be used as data models. The sub-dialog will define how variables will be used (display or input).
   a) Inside the sub-dialog instruction, define the behavior with control blocks such as BEFORE ROW, AFTER ROW, BEFORE FIELD, and interaction blocks such as ON ACTION.

5. A declarative dialog can be used as SUBDIALOG in a procedural DIALOG block, or as parallel dialog with the START DIALOG/TERMINATE DIALOG instructions.

**Related concepts**

- Using declarative dialogs on page 1553
- Dialog coding concepts, configuration and code structure.

**Using declarative dialogs**

Dialog coding concepts, configuration and code structure.

**Structure of a declarative DIALOG block**

A declarative DIALOG instruction is made of a single sub-dialog block, with an optional DEFINE clause to declare local variables.

**Important:** Unlike procedural DIALOG blocks, declarative DIALOG blocks can only define one sub-dialog block.

The dialog instruction in the declarative DIALOG block binds program variables to form fields and defines the type of interaction that will take place for the data model (simple input, list input or query). The dialog implements individual control blocks that allows you to control the behavior of the interactive instruction. The dialog can also hold action handlers.

The declarative DIALOG block can define the following dialog types:

- A list of choices controlled by a MENU sub-dialog block.
- Simple record input with the INPUT sub-dialog block.
- Query by example input with the CONSTRUCT sub-dialog block.
- Read-only record list navigation with the DISPLAY ARRAY sub-dialog block.
- Editable record list handling with the INPUT ARRAY sub-dialog block.

**Related concepts**

- Structure of a procedural DIALOG block on page 1490

**The DEFINE clause**

The DEFINE clause can be used to define program variables with a scope that is local to the declarative dialog block.

This clause must be placed before any other sub-dialog block:

```plaintext
DIALOG ()
    DEFINE checked BOOLEAN,
    tmp STRING

    INPUT BY NAME ... 
```
The DEFINE clause is only allowed in declarative dialog blocks. Variables used locally in a procedural dialog block must be defined in the scope of the function containing the procedural dialog block.

**Related concepts**

- **Variables** on page 366
  Explains how to define program variables.

**The MENU sub-dialog**

The MENU sub-dialog implements a list of choices for the user by using action handlers.

**MENU implements a list of action handlers**

The following code example shows a MENU sub-dialog implementing a couple of action handlers with an ON ACTION clause or with a COMMAND clause (action views of COMMAND can get the focus):

```
DIALOG ()
    MENU
        ON ACTION customer_view
            ...
        ON ACTION order_view
            ...
    END MENU
END DIALOG
```

**Control blocks in MENU**

Simple record input declared with the INPUT sub-dialog can raise the following triggers:

- **BEFORE MENU**

  In the singular MENU instruction, BEFORE MENU and AFTER MENU blocks are typically used as initialization and finalization blocks. In an MENU sub-dialog of a DIALOG block, BEFORE MENU and AFTER MENU blocks will be executed each time the focus goes to (BEFORE) or leaves (AFTER) the action views (buttons) controlled by this sub-dialog.

**Related concepts**

- **Dialog actions** on page 1640
  Describes how to program action handling when the end user triggers an action on the front-end.

- **DIALOG control blocks** on page 1504
  *Dialog control blocks* are predefined dialog triggers where you can implement specific code to control the interactive instruction.

- **Ring menus (MENU)** on page 1358
  The MENU instruction implements a list of options the end user can choose from.

**The INPUT sub-dialog**

The INPUT sub-dialog implements single record input in fields of the current form.

**Program variable to form field binding**

Each record member variable is bound to the corresponding field of a screen record, in order to manipulate the values that the user enters in the form fields.

The INPUT clause can be used in two forms:

1. **INPUT BY NAME variable-list**
2. INPUT variable-list FROM field-list

The BY NAME clause implicitly binds the fields to the variables that have the same identifiers as the field names. The variables must be declared with the same names as the fields from which they accept input. The runtime system ignores any record name prefix when making the match. The unqualified names of the variables and of the fields must be unique and unambiguous within their respective domains. If they are not, the runtime system generates an exceptions, and sets the STATUS variable to a negative value.

```
DEFINE p_cust RECORD
  cust_num INTEGER,
  cust_name VARCHAR(50),
  cust_address VARCHAR(100)
END RECORD
...
DIALOG
  INPUT BY NAME p_cust.*
    BEFORE FIELD cust_name
  ...
END INPUT
...}
END DIALOG
```

The FROM clause explicitly binds the fields in the screen record to a list of program variables by position. The number of variables or record members must equal the number of fields listed in the FROM clause. Each variable must be of the same (or a compatible) data type as the corresponding screen field. When the user enters data, the runtime system checks the entered value against the data type of the variable, not the data type of the screen field.

```
DEFINE c_name VARCHAR(50)
  c_addr VARCHAR(100)
...
DIALOG
  INPUT c_name,
  c_addr
    FROM FORMONLY.field01,
    FORMONLY.field02
    BEFORE FIELD cust_name
  ...
END INPUT
...}
END DIALOG
```

### Identifying an INPUT sub-dialog

The name of an INPUT sub-dialog can be used to qualify sub-dialog actions with a prefix.

In order to identify the INPUT sub-dialog with a specific name, you can use the ATTRIBUTES clause to set the NAME attribute:

```
INPUT BY NAME p_cust.*
    ATTRIBUTES (NAME = "cust")
  ...
```

### Control blocks in INPUT

Simple record input declared with the INPUT sub-dialog can raise the following triggers:

- BEFORE INPUT
- BEFORE FIELD
- ON CHANGE
- AFTER FIELD
• **AFTER INPUT**

In the singular INPUT instruction, **BEFORE** INPUT and **AFTER** INPUT blocks are typically used as initialization and finalization blocks. In an INPUT sub-dialog of a DIALOG block, **BEFORE** INPUT and **AFTER** INPUT blocks will be executed each time the focus goes to (**BEFORE**) or leaves (**AFTER**) the group of fields defined by this sub-dialog.

**Related concepts**

- **Records** on page 382
  Records allow structured program variables definitions.
- **Screen records / arrays** on page 1147
  Form fields can be grouped in a *screen record* or *screen array* definition.
- **INPUT ATTRIBUTES clause** on page 1499
  Attributes of the INPUT clause of a DIALOG block.

**The CONSTRUCT sub-dialog**

The CONSTRUCT sub-dialog provides database query by example feature, converting search criteria entered by the user into an SQL WHERE condition that can be used to execute a SELECT statement.

**Defining query by example fields**

The CONSTRUCT sub-dialog requires a character string variable to hold the WHERE clause, and a list of screen fields where the user can enter search criteria.

```
DEFINE sql_condition STRING
    ...
DIALOG
    CONSTRUCT BY NAME sql_condition
        ON customer.cust_name, customer.cust_address
        BEFORE FIELD cust_name
        ...
    END CONSTRUCT
    ...
END DIALOG
```

Make sure the character string variable is large enough to store all possible SQL conditions. It is better to use a STRING data type to avoid any size problems.

CONSTRUCT uses the field data types defined in the current form file to produce the SQL conditions. This is different from other interactive instructions, where the data types of the program variables define the way to handle input/display. It is strongly recommended (but not mandatory) that the form field data types correspond to the data types of the program variables used for input. This is implicit if both form fields and program variables are based on the database schema file.

The CONSTRUCT clause can be used in two forms:

1. **CONSTRUCT BY NAME** string-variable **ON** column-list
2. **CONSTRUCT** string-variable **ON** column-list **FROM** field-list

The **BY NAME** clause implicitly binds the form fields to the columns, where the form field identifiers match the column names specified in the column-list after the **ON** keyword. You can specify the individual column names (separated by commas) or use the `tablename.*` shortcut to include all columns defined for a table in the database schema file.

The **FROM** clause explicitly binds the form fields listed after the **FROM** keyword with the column definitions listed after the **ON** keyword.

In both cases, the name of the columns in `column-list` will be used to produce the SQL condition in `string-variable`. 
Identifying a CONSTRUCT sub-dialog

The name of a CONSTRUCT sub-dialog can be used to qualify sub-dialog actions with a prefix. In order to identify the CONSTRUCT sub-dialog with a specific name, use the ATTRIBUTES clause to set the NAME attribute:

```
CONSTRUCT BY NAME sql_condition ON customer.*
  ATTRIBUTES (NAME = "q_cust")
...```

Control blocks in CONSTRUCT

A Query By Example declared with the CONSTRUCT clause can raise the following triggers:

- BEFORE CONSTRUCT
- BEFORE FIELD
- AFTER FIELD
- AFTER CONSTRUCT

In the singular CONSTRUCT instruction, BEFORE CONSTRUCT and AFTER CONSTRUCT blocks are typically used as initialization and finalization blocks. In DIALOG block, BEFORE CONSTRUCT and AFTER CONSTRUCT blocks will be executed each time the focus goes to (BEFORE) or leaves (AFTER) the group of fields defined by this sub-dialog.

Related concepts

- Query operators in CONSTRUCT on page 1465
- Screen records / arrays on page 1147
- Database schema on page 476
- CONSTRUCT ATTRIBUTES clause on page 1501

The DISPLAY ARRAY sub-dialog

The DISPLAY ARRAY sub-dialog is the controller to implement the navigation in a list of records, with option data modification actions.

Program array to screen array binding

The DISPLAY ARRAY sub-dialog binds the members of the flat record (or the primitive member) of an array to the screen-array or screen-record fields specified with the TO keyword. The number of variables in each record of the program array must be the same as the number of fields in each screen record (that is, in a single row of the screen array).

You typically bind a program array to a screen-array in order to display a page of records. However, the DIALOG instruction can also bind the program array to a simple flat screen-record. In this case, only one record will be visible at a time.

The next code example defines an array with a flat record and binds it to a screen array:

```
DEFINE p_items DYNAMIC ARRAY OF RECORD
  item_num INTEGER,
  item_name VARCHAR(50),
  item_price DECIMAL(6,2)
END RECORD
...
DIALOG
  DISPLAY ARRAY p_items TO sa.*
  BEFORE ROW
  ...
```
If the screen array is defined with one field only, you can bind an array defined with a primitive type:

```plsql
DEFINE p_names DYNAMIC ARRAY OF VARCHAR(50)
...
DIALOG
   DISPLAY ARRAY p_names TO sa.*
   BEFORE DELETE
   ...
   END DISPLAY
   ...
END DIALOG
```

**Identifying a DISPLAY ARRAY sub-dialog**

The name of the screen array specified with the TO clause identifies the list. The dialog class method takes the name of the screen array as the parameter, identifying the list. For example, you would use `DIALOG.getCurrentRow("screen-array")` to query for the current row in the list identified by 'screen-array'. The name of the screen-array is also used to qualify sub-dialog actions with a prefix.

**Control blocks in DISPLAY ARRAY**

Read-only record lists declared with the DISPLAY ARRAY sub-dialog can raise the following triggers:

- **BEFORE DISPLAY**
- **BEFORE ROW**
- **AFTER ROW**
- **AFTER DISPLAY**

In the singular DISPLAY ARRAY instruction, BEFORE DISPLAY and AFTER DISPLAY blocks are typically used as initialization and finalization blocks. In a DISPLAY ARRAY sub-dialog of a DIALOG block, BEFORE DISPLAY and AFTER DISPLAY blocks will be executed each time the focus goes to (BEFORE) or leaves (AFTER) the group of fields defined by this sub-dialog.

**Related concepts**

- **Records** on page 382
  Records allow structured program variables definitions.
- **Screen records / arrays** on page 1147
  Form fields can be grouped in a screen record or screen array definition.
- **DISPLAY ARRAY ATTRIBUTES clause** on page 1499
  Attributes of the DISPLAY ARRAY clause of a DIALOG block.

**The INPUT ARRAY sub-dialog**

The INPUT ARRAY sub-dialog is the controller to implement the navigation and edition in a list of records.

**Important:** This feature is not supported on mobile platforms.

**Program array to screen array binding**

The INPUT ARRAY sub-dialog binds the members of the flat record (or the primitive member) of an array to the screen-array or screen-record fields specified with the FROM keyword. The number of variables in each record of the program array must be the same as the number of fields in each screen record (that is, in a single row of the screen array).
You typically bind a program array to a screen-array in order to display a page of records. However, the DIALOG instruction can also bind the program array to a simple flat screen-record. In this case, only one record will be visible at a time.

The next code example defines an array with a flat record and binds it to a screen array:

```
DEFINE p_items DYNAMIC ARRAY OF RECORD
    item_num INTEGER,
    item_name VARCHAR(50),
    item_price DECIMAL(6,2)
END RECORD
...
DIALOG
    INPUT ARRAY p_items FROM sa.*
    BEFORE INSERT
    ...
    END INPUT
    ...
END DIALOG
```

If the screen array is defined with one field only, you can bind an array defined with a primitive type:

```
DEFINE p_names DYNAMIC ARRAY OF VARCHAR(50)
...
DIALOG
    INPUT ARRAY p_names FROM sa.*
    BEFORE DELETE
    ...
    END INPUT
    ...
END DIALOG
```

**Identifying an INPUT ARRAY sub-dialog**

The name of the screen array specified with the FROM clause will be used to identify the list. For example, the dialog class method such as DIALOG.getCurrentRow("screen-array") takes the name of the screen array as the parameter, to identify the list you want to query for the current row. The name of the screen-array is also used to qualify sub-dialog actions with a prefix.

**Control blocks in INPUT ARRAY**

Editable record lists declared with the INPUT ARRAY sub-dialog can raise the following triggers:

- BEFORE INPUT
- BEFORE ROW
- BEFORE FIELD
- ON CHANGE
- AFTER FIELD
- ON ROW CHANGE
- AFTER ROW
- BEFORE DELETE
- AFTER DELETE
- BEFORE INSERT
- AFTER INSERT
- AFTER INPUT

In the singular INPUT ARRAY instruction, BEFORE INPUT and AFTER INPUT blocks are typically used as initialization and finalization blocks. In the INPUT ARRAY sub-dialog of a DIALOG block, BEFORE INPUT and
AFTER INPUT blocks are executed each time the focus goes to (BEFORE) or leaves (AFTER) the group of fields defined by this sub-dialog.

**Related concepts**
- **Records** on page 382
  Records allow structured program variables definitions.
- **Screen records / arrays** on page 1147
  Form fields can be grouped in a *screen record* or *screen array* definition.

**INPUT ARRAY ATTRIBUTES clause** on page 1500
Attributes of the INPUT ARRAY clause of a DIALOG block.

**Declarative DIALOG block configuration**
Attributes defined in the ATTRIBUTES clause of dialogs can be used to configure a declarative DIALOG block and its subdialogs.

The ATTRIBUTES clause of dialogs overrides all default attributes and temporarily override any display attributes that the OPTIONS or the OPEN WINDOW statement specified for these fields.

- **INPUT ATTRIBUTES clause** on page 1499
- **DISPLAY ARRAY ATTRIBUTES clause** on page 1499
- **INPUT ARRAY ATTRIBUTES clause** on page 1500
- **CONSTRUCT ATTRIBUTES clause** on page 1501

**INPUT ATTRIBUTES clause**
Attributes of the INPUT clause of a DIALOG block.

**HELP option**
The HELP attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the INPUT sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action. The HELP clause overrides the HELP attribute.

**NAME option**
The NAME attribute can be used to identify the INPUT sub-dialog, especially useful to qualify sub-dialog actions.

**WITHOUT DEFAULTS option**
By default, sub-dialogs use the default values defined in the form files. If you want to use the values stored in the program variables bound to the dialog, you must use the WITHOUT DEFAULTS attribute. For more details see **WITHOUT DEFAULTS option**.

**DISPLAY ARRAY ATTRIBUTES clause**
Attributes of the DISPLAY ARRAY clause of a DIALOG block.

**HELP option**
The HELP attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the DISPLAY ARRAY sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The HELP clause overrides the HELP attribute.

**COUNT option**
The COUNT attribute defines the number of valid rows in the static array to be displayed as default rows. If you do not use the COUNT attribute, the runtime system cannot determine how much data to display, so the screen array remains empty. The COUNT option is ignored when using a dynamic array, unless page mode is used. In this case, the COUNT...
attribute must be used to define the total number of rows, because the dynamic array will only hold a page of the entire row set. If the value of COUNT is negative or zero, it defines an empty list.

See also Controlling the number of rows on page 1734.

**DOUBLECLICK option**

The DOUBLECLICK option can be used to define the action that will be fired when the user chooses a row from the list. Different configuration options are available to control the row selection action of desktop and mobile devices. For more details, see Defining the action for a row choice on page 1768.

**ACCESSORYTYPE option**

*Important:* This feature is only for mobile platforms.

The ACCESSORYTYPE attribute can be used to define the decoration of rows, typically used on an iOS device. Values can be DETAILBUTTON, DISCLOSUREINDICATOR, CHECKMARK to respectively get a (i), > or check mark icon. For more details, see Row configuration on iOS devices on page 1777.

**DETAILACTION option**

*Important:* This feature is only for mobile platforms.

The DETAILACTION attribute can be used to define the action that will be fired when the user selects the detail button of a row. The detail button is typically shown with a (i) icon on iOS devices. Note that the DOUBLECLICK attribute can be used to distinguish the action when the user selects the row instead of the detail button in the row. For more details, see Row configuration on iOS devices on page 1777.

**FOCUSONFIELD option**

*Important:* This feature is not supported on mobile platforms.

When the FOCUSONFIELD option is used, the DISPLAY ARRAY allows focus at the field (or cell) level. It then possible to implement BEFORE FIELD and AFTER FIELD blocks, as well as using NEXT FIELD instructions. However, the dialog still manages a read-only list. For more details, see Field-level focus in DISPLAY ARRAY on page 1740.

**INPUT ARRAY ATTRIBUTES clause**

Attributes of the INPUT ARRAY clause of a DIALOG block.

INPUT ARRAY specific attributes can be defined in the ATTRIBUTE clause of the sub-dialog header:

**HELP option**

The HELP clause specifies the number of a help message to display if the user invokes the help the INPUT ARRAY dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action. The HELP clause overrides the HELP attribute.

**COUNT option**

The COUNT attribute defines the number of valid rows in the static array to be displayed as default rows. If you do not use the COUNT attribute, the runtime system cannot determine how much data to display, so the screen array remains empty. The COUNT option is ignored when using a dynamic array. If you specify the COUNT attribute, the WITHOUT DEFAULTS option is not required because it is implicit. If the COUNT attribute is greater than MAXCOUNT, the runtime system will take MAXCOUNT as the actual number of rows. If the value of COUNT is negative or zero, it defines an empty list.
MAXCOUNT option

The MAXCOUNT attribute defines the maximum number of rows that can be inserted in the program array. This attribute allows you to give an upper limit of the total number of rows the user can enter. It can be used with static or dynamic arrays.

When binding a static array, MAXCOUNT is used as upper limit if it is lower or equal to the actual declared static array size. If MAXCOUNT is greater than the array size, the size of the static array is used as the upper limit. If MAXCOUNT is lower than the COUNT attribute (or to the SET_COUNT() parameter when using a singular INPUT ARRAY), the actual number of rows in the array will be reduced to MAXCOUNT.

When binding a dynamic array, the user can enter an infinite number of rows unless the MAXCOUNT attribute is used. If MAXCOUNT is lower than the actual size of the dynamic array, the number of rows in the array will be reduced to MAXCOUNT.

If MAXCOUNT is negative or equal to zero, the user cannot insert rows.

APPEND ROW option

The APPEND ROW attribute can be set to FALSE to avoid the append default action, and deny the user to add rows at the end of the list. If APPEND ROW =FALSE, it is still possible to insert rows in the middle of the list. Use the INSERT ROW attribute to disallow the user from inserting rows. Additionally, even with APPEND ROW=FALSE and INSERT ROW=FALSE, you can still get automatic temporary row creation if AUTO APPEND is not set to FALSE.

INSERT ROW option

The INSERT ROW attribute can be set to FALSE to avoid the insert default action, and deny the user to insert new rows in the middle of the list. However, even if INSERT ROW is FALSE, it is still possible to append rows at the end of the list. Use the APPEND ROW attribute to disallow the user from appending rows. Additionally, even with APPEND ROW=FALSE and INSERT ROW=FALSE, you can still get automatic temporary row creation if AUTO APPEND is not set to FALSE.

DELETE ROW option

The DELETE ROW attribute can be set to FALSE to avoid the delete default action, and deny the user to remove rows from the list.

AUTO APPEND option

By default, an INPUT ARRAY controller creates a temporary row when needed (for example, when the user deletes the last row of the list, an new row will be automatically created). You can prevent this default behavior by setting the AUTO APPEND attribute to FALSE. When this attribute is set to FALSE, the only way to create a new temporary row is to execute the append action.

If both the APPEND ROW and INSERT ROW attributes are set to FALSE, the dialog automatically behaves as if AUTO APPEND equals FALSE.

KEEP CURRENT ROW option

Depending on the list container used in the form, the current row may be highlighted during the execution of the dialog, and cleared when the instruction ends. You can change this default behavior by using the KEEP CURRENT ROW attribute, to force the runtime system to keep the current row highlighted.

WITHOUT DEFAULTS option

You typically use the INPUT ARRAY sub-dialog with the WITHOUT DEFAULTS attribute. If this attribute is not set when using an INPUT ARRAY sub-dialog, the list is empty even if the array holds data. For more details see WITHOUT DEFAULTS option.
**CONSTRUCT ATTRIBUTES clause**
Attributes of the CONSTRUCT clause of a DIALOG block.

**HELP option**
The HELP attribute defines the number of the help message to be displayed when invoked and focus is in the list controlled by the CONSTRUCT sub-dialog. The predefined 'help' action is automatically created by the runtime system. You can bind action views to the 'help' action.

The HELP clause overrides the HELP attribute.

**NAME option**
The NAME attribute can be used to identify the CONSTRUCT sub-dialog; this is especially useful to qualify sub-dialog actions.

**Default actions created by a DIALOG block**
Default actions ease the implementation of the controller by providing expected actions.

The runtime system creates a set of default actions based on the sub-dialogs defined in a (declarative or procedural) DIALOG block. These actions are provided to ease the implementation of the controller. For example, when using an INPUT ARRAY sub-dialog, the dialog instruction will automatically create the insert, append and delete default actions.

**Table 352: Default actions created for the DIALOG block** on page 1563 lists the default actions created for the DIALOG interactive instruction, for each type of sub-dialogs:

<table>
<thead>
<tr>
<th>Default action</th>
<th>Control Block execution order</th>
</tr>
</thead>
<tbody>
<tr>
<td>help</td>
<td>Shows the help topic defined by the HELP clause. Only created when a HELP clause or option is defined for the sub-dialog.</td>
</tr>
<tr>
<td>insert</td>
<td>Inserts a new row before current row. Only for INPUT ARRAY dialogs. Action creation can be avoided with INSERT ROW = FALSE attribute.</td>
</tr>
<tr>
<td>append</td>
<td>Appends a new row at the end of the list. Only for INPUT ARRAY dialogs. Action creation can be avoided with APPEND ROW = FALSE attribute.</td>
</tr>
<tr>
<td>delete</td>
<td>Deletes the current row. Only for INPUT ARRAY dialogs. Action creation can be avoided with DELETE ROW = FALSE attribute.</td>
</tr>
<tr>
<td>nextrow</td>
<td>Moves to the next row in a list displayed in one row of fields. See note (1).</td>
</tr>
<tr>
<td>prevrow</td>
<td>Moves to the previous row in a list displayed in one row of fields. See note (1).</td>
</tr>
</tbody>
</table>
### Default action

<table>
<thead>
<tr>
<th>Default action</th>
<th>Control Block execution order</th>
</tr>
</thead>
<tbody>
<tr>
<td>firstrow</td>
<td>Moves to the first row in a list displayed in one row of fields.</td>
</tr>
<tr>
<td></td>
<td>See note (1).</td>
</tr>
<tr>
<td>lastrow</td>
<td>Moves to the last row in a list displayed in one row of fields.</td>
</tr>
<tr>
<td></td>
<td>See note (1).</td>
</tr>
<tr>
<td>find</td>
<td>Opens the fglfind dialog window to let the user enter a search value, and seeks to the row matching the value.</td>
</tr>
<tr>
<td></td>
<td>See note (2).</td>
</tr>
<tr>
<td>findnext</td>
<td>Seeks to the next row matching the value entered during the fglfind dialog.</td>
</tr>
<tr>
<td></td>
<td>See note (2).</td>
</tr>
</tbody>
</table>

#### Notes:

1. The action is only created with a DISPLAY ARRAY or INPUT ARRAY using a screen record bound to a set of form fields in a GRID container. The action is not created when using a screen array bound to a list container such as TABLE, TREE and SCROLLGRID.

2. The action is only created if the context allows built-in find.

The insert, append and delete default actions can be avoided with dialog control attributes:

```plaintext
INPUT ARRAY arr TO sr.* ATTRIBUTES( INSERT ROW=FALSE, APPEND ROW=FALSE, ... )
```

---

### Related concepts

  Attributes of the DISPLAY ARRAY clause of a DIALOG block.

- **INPUT ARRAY ATTRIBUTES clause** on page 1500
  Attributes of the INPUT ARRAY clause of a DIALOG block.

### DIALOG data blocks

*Dialog data blocks* are dialog triggers invoked when the dialog controller needs data to feed the view with values.

Such blocks are typically used when record list data is provided dynamically, with the paged mode or when implementing dynamic tree-views.

- **ON FILL BUFFER block** on page 1401
- **ON EXPAND block** on page 1401
- **ON COLLAPSE block** on page 1401

#### ON FILL BUFFER block

The **ON FILL BUFFER** block is used to fill a page of rows into the dynamic array, based on an offset and a number of rows.

This data block is only used in **DISPLAY ARRAY** data blocks.

The offset can be retrieved with the `FGL_DIALOG_GETBUFFERSTART()` built-in function and the number of rows to provide is defined by the `FGL_DIALOG_GETBUFFERLENGTH()` built-in function.
**Related concepts**

*Populating a DISPLAY ARRAY* on page 1742  
The program array must be filled with rows to populate the DISPLAY ARRAY dialog.

**ON EXPAND block**

The **ON EXPAND** block is executed when a tree view node is expanded (i.e. opened).

This data block is used to implement dynamic trees in a DISPLAY ARRAY, where nodes are added, depending on the nodes opened by the end user.

**Related concepts**

*Dynamic filling of very large trees* on page 1797  
How to optimize the implementation of large tree-views?

**ON COLLAPSE block**

The **ON COLLAPSE** block is executed when a tree view node is collapsed (i.e. closed).

This data block is used to implement dynamic trees in a DISPLAY ARRAY, where nodes are removed from view by the user closing or collapsing them.

**Related concepts**

*Dynamic filling of very large trees* on page 1797  
How to optimize the implementation of large tree-views?

**DIALOG control blocks**

*Dialog control blocks* are predefined dialog triggers where you can implement specific code to control the interactive instruction.

The code may involve using `ui.Dialog` class methods or dialog specific instructions such as `NEXT FIELD` or `CONTINUE DIALOG`.

- **BEFORE FIELD block** on page 1383  
- **AFTER FIELD block** on page 1385  
- **ON CHANGE block** on page 1384  
- **BEFORE INPUT block** on page 1381  
- **AFTER INPUT block** on page 1382  
- **BEFORE CONSTRUCT block** on page 1469  
- **AFTER CONSTRUCT block** on page 1470  
- **BEFORE DISPLAY block** on page 1402  
- **AFTER DISPLAY block** on page 1403  
- **BEFORE ROW block** on page 1403  
- **ON ROW CHANGE block** on page 1439  
- **AFTER ROW block** on page 1404  
- **BEFORE INSERT block** on page 1442  
- **AFTER INSERT block** on page 1442  
- **BEFORE DELETE block** on page 1443  
- **AFTER DELETE block** on page 1443  
- **BEFORE MENU block** on page 1367  

**Control block execution order with declarative dialogs**

**Note:** Depending on the usage context, dialog-starting and ending control blocks such as **BEFORE INPUT / AFTER INPUT** are executed each time the focus goes to an element controlled by the dialog, or only once, when the dialog is started/ended. See control block specific topics for more details.
Control block execution order when in multiple dialogs

When the declarative dialog is used with a SUBDIALOG keyword in the context of a procedural DIALOG block, the control blocks are executed in the same order as if the declarative dialog was included in the procedural DIALOG block.

For more details, see Control block execution order in multiple dialogs on page 1504.

Control block execution order in parallel dialogs

The order in which control blocks are executed in a declarative DIALOG used as parallel dialog is the same as when executing a singular dialog.

According to the type of dialog defined in the declarative DIALOG, see:

- INPUT control blocks execution order on page 1381
- DISPLAY ARRAY control blocks execution order on page 1401
- CONSTRUCT control blocks execution order on page 1468
- INPUT ARRAY control blocks execution order on page 1434

BEFORE FIELD block

In dialog instructions INPUT, INPUT ARRAY, CONSTRUCT or in a DISPLAY ARRAY using the FOCUSONFIELD attribute, the BEFORE FIELD block is executed every time the specified field gets the focus.

For single record inputs driven by INPUT or query by example (QBEs) driven by CONSTRUCT, the BEFORE FIELD block is executed when moving the focus from field to field.

For editable lists driven by INPUT ARRAY, the BEFORE FIELD block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by DISPLAY ARRAY using the FOCUSONFIELD attribute, the BEFORE FIELD block is executed when moving the focus from field to field. However, the fields will not be editable as in an INPUT ARRAY.

Important: The BEFORE FIELD block is also executed when performing a NEXT FIELD instruction.

The BEFORE FIELD keywords must be followed by a list of form field specification. The screen-record name can be omitted.

BEFORE FIELD is executed after BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW and BEFORE INSERT.

Use this block to do some field value initialization, or to display a message to the user:

```
INPUT BY NAME p_cust.* ...
BEFORE FIELD cust_status
  LET p_cust.cust_comment = NULL
  MESSAGE "Enter customer status"
```

When using the default FIELD ORDER CONSTRAINT mode, the dialog executes the BEFORE FIELD block of the field corresponding to the first variable of an INPUT or INPUT ARRAY, even if that field is not editable (NOENTRY, hidden or disabled). The block is executed when you enter the dialog and every time you create a new row in the case of INPUT ARRAY. This behavior is supported for backward compatibility. The block is not executed when using the FIELD ORDER FORM, the mode recommended for DIALOG instructions.

With the FIELD ORDER FORM mode, for each dialog executing the first time with a specific form, the BEFORE FIELD block will be invoked for the first field of the initial tabbing list defined by the form, even if that field was hidden or moved around in a table. The dialog then behaves as if a NEXT FIELD first-visible-column would have been done in the BEFORE FIELD of that field.

When form-level validation occurs and a field contains an invalid value, the dialog gives the focus to the field, but no BEFORE FIELD trigger will be executed.
**Related concepts**

NEXT FIELD instruction on page 1389  
Form-level validation rules on page 1627  
Form-level validation rules can be defined for each field controlled by a dialog.  
AFTER FIELD block on page 1385

**AFTER FIELD block**

In dialog instructions INPUT, INPUT ARRAY, CONSTRUCT or in a DISPLAY ARRAY using the FOCUSONFIELD attribute, the AFTER FIELD block is executed every time the focus leaves the specified field.

For single record inputs driven by INPUT or query by example (QBEs) driven by CONSTRUCT, the AFTER FIELD block is executed when moving the focus from field to field.

For editable lists driven by INPUT ARRAY, the AFTER FIELD block is executed when moving the focus from field to field in the same row, or when moving to another row in the same column.

For record lists driven by DISPLAY ARRAY using the FOCUSONFIELD attribute, the AFTER FIELD block is executed when moving the focus from field to field. However, the fields will not be editable as in an INPUT ARRAY.

The AFTER FIELD keywords must be followed by a list of form field specifications. The screen-record name can be omitted.

AFTER FIELD is executed before AFTER INSERT, ON ROW CHANGE, AFTER ROW, AFTER INPUT or AFTER CONSTRUCT.

When a NEXT FIELD instruction is executed in an AFTER FIELD block, the cursor moves to the specified field, which can be the current field. This can be used to prevent the user from moving to another field / row during data input. Note that the BEFORE FIELD block is also executed when NEXT FIELD is invoked.

The AFTER FIELD block of the current field is not executed when performing a NEXT FIELD; only BEFORE INPUT, BEFORE CONSTRUCT, BEFORE ROW, and BEFORE FIELD of the target item might be executed, based on the sub-dialog type.

When ACCEPT DIALOG, ACCEPT INPUT, or ACCEPT CONTRUCT is performed, the AFTER FIELD trigger of the current field is executed.

Use the AFTER FIELD block to implement field validation rules:

```
INPUT BY NAME p_item.* ...  
AFTER FIELD item_quantity  
  IF p_item.item_quantity <= 0 THEN  
    ERROR "Item quantity cannot be negative or zero"  
    LET p_item.item_quantity = 0  
    NEXT FIELD item_quantity  
  END IF
```

**Related concepts**

NEXT FIELD instruction on page 1389  
ACCEPT DIALOG instruction on page 1538  
BEFORE FIELD block on page 1383  
ON CHANGE block on page 1384

**ON CHANGE block**

The ON CHANGE block can be used to detect that a field changed by user input. The ON CHANGE block is executed if the value has changed since the field got the focus and if the modification flag is set.

The ON CHANGE block can be used in INPUT, INPUT ARRAY and CONSTRUCT dialogs.

For editable fields defined as EDIT, TEXTEDIT or BUTTONEDIT, the ON CHANGE block is executed when leaving a field, if the value of the specified field has changed since the field got the focus and if the modification flag is set.
for the field. You leave the field when you validate the dialog, when you move to another field, or when you move to another row in an INPUT ARRAY. However, if the text edit field is defined with the COMPLETER attribute to enable autocompletion, the ON CHANGE trigger will be fired after a short period of time, when the user has typed characters in.

For editable fields defined as CHECKBOX, COMBOBOX, DATEEDIT, DATETIMEEDIT, TIMEEDIT, RADIOGROUP, SPINEDIT, SLIDER or URL-based WEBCOMPONENT (when the COMPONENTTYPE attribute is not used), the ON CHANGE block is invoked immediately when the user changes the value with the widget edition feature. For example, when toggling the state of a CHECKBOX, when selecting an item in a COMBOBOX list, or when choosing a date in the calendar of a DATEEDIT. Note that for such item types, when ON CHANGE is fired, the modification flag is always set.

```
ON CHANGE order_checked -- Defined as CHECKBOX
   CALL setup_dialog(DIALOG)
```

**Note:** If both an ON CHANGE block and AFTER FIELD block are defined for a field, the ON CHANGE block is executed before the AFTER FIELD block.

When changing the value of the current field by program in an ON ACTION block, the ON CHANGE block will be executed when leaving the field if the value is different from the reference value and if the modification flag is set (after previous user input or when the touched flag has been changed by program).

In an INPUT or INPUT ARRAY, the field value change is related to value of the variable bound to the field. In a CONSTRUCT dialog, the field value change is related to the input buffer / displayed value.

**Note:** When using the NEXT FIELD instruction, the comparison value is reassigned as if the user had left and reentered the field. Therefore, when using NEXT FIELD in ON CHANGE block or in an ON ACTION block, the ON CHANGE block will only be invoked again if the value is different from the reference value. This prevents field validation in ON CHANGE blocks; you must do validations in AFTER FIELD blocks and/or AFTER INPUT blocks.

**Related concepts**

- **Input field modification flag** on page 1623
  Each input field controlled by a dialog instruction has a modification flag.

- **Enabling autocompletion** on page 1633
  Autocompletion allows a list of completion proposals to be displayed while the user is typing text into a field.

- **AFTER FIELD block** on page 1385
  The COMPLETER attribute on page 1251
  The COMPLETER attribute enables autocompletion for the edit field.

**BEFORE INPUT block**

**BEFORE INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs**

In a singular INPUT, INPUT ARRAY instruction, or when used as parallel dialog, the BEFORE INPUT is only executed once when the dialog is started.

The BEFORE INPUT block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```
INPUT BY NAME cust_rec.* ...
BEFORE INPUT
   MESSAGE "Input customer information"
   CALL DIALOG.setActionActive("check_info", is_super_user() )
   CALL DIALOG.setFieldActive("cust_comment", is_super_user() )
...
```
The fields are initialized with the defaults values before the BEFORE INPUT block is executed. When the INPUT instruction uses the WITHOUT DEFAULTS option, the default values are taken from the program variables bound to the fields, otherwise (with defaults), the DEFAULT attributes of the form fields are used.

Use the NEXT FIELD control instruction in the BEFORE INPUT block, to jump to a specific field when the dialog starts.

**BEFORE INPUT block in INPUT and INPUT ARRAY of procedural DIALOG**

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the BEFORE INPUT block is executed when the focus goes to a group of fields driven by the sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

When the focus is in a list driven by an INPUT ARRAY sub-dialog, moving to a different row will not invoke the BEFORE INPUT block.

BEFORE INPUT is executed after the BEFORE DIALOG block and before the BEFORE ROW, BEFORE FIELD blocks.

In this example, the BEFORE INPUT block is used to set up a specific action and display a message:

```
INPUT BY NAME p_order.*
BEFORE INPUT
    CALL DIALOG.setActionActive("validate_order", TRUE)
```

**Related concepts**

- BEFORE CONSTRUCT block on page 1469
- BEFORE DISPLAY block on page 1402
- AFTER INPUT block on page 1382

**AFTER INPUT block**

**AFTER INPUT block in singular and parallel INPUT, INPUT ARRAY dialogs**

In a singular INPUT, INPUT ARRAY instruction, or when used as parallel dialog, the AFTER INPUT is only executed once when dialog ends.

The AFTER INPUT block is executed after the user has validated or canceled the INPUT or INPUT ARRAY dialog with the accept or cancel default actions, or when the ACCEPT INPUT instruction is executed.

The AFTER INPUT block is not executed when the EXIT INPUT instruction is performed.

In singular and parallel dialogs, this block is typically used to implement global dialog validation rules depending from several fields. If the values entered by the user do not satisfy the constraints, use the NEXT FIELD instruction to force the dialog to continue. The CONTINUE INPUT instruction can be used instead of NEXT FIELD, when no particular field has to be select.

Before checking the validation rules, make sure that the INT_FLAG variable is FALSE: in case if the user cancels the dialog, the validation rules must be skipped.

```
INPUT BY NAME cust_rec.*
    WITHOUT DEFAULTS ATTRIBUTES ( UNBUFFERED )
...

AFTER INPUT
    IF NOT INT_FLAG THEN
        IF cust_rec.cust_address IS NOT NULL
            AND cust_rec.cust_zipcode IS NULL THEN
                ERROR "Address is incomplete, enter a zipcode."
            NEXT FIELD zipcode
        END IF
    END IF
```
To limit the validation to fields that have been modified by the end user, you can call the `FIELD_TOUCHED()` function or the `DIALOG.getFieldTouched()` method to check if a field has changed during the dialog execution. This will make your validation code faster if the user has only modified a couple of fields in a large form.

**AFTER INPUT block in INPUT and INPUT ARRAY of procedural DIALOG**

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `AFTER INPUT` block is executed when the focus is lost by a group of fields driven by an `INPUT` or `INPUT ARRAY` sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus. When the focus is in a list driven by an `INPUT ARRAY` sub-dialog, moving to a different row will not invoke the `AFTER INPUT` block.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

`AFTER INPUT` is executed after the `AFTER FIELD`, `AFTER ROW` blocks and before the `AFTER DIALOG` block. Executing a `NEXT FIELD` in the `AFTER INPUT` control block will keep the focus in the group of fields. Within an `INPUT ARRAY` sub-dialog, `NEXT FIELD` will keep the focus in the list and stay in the current row. You typically use this behavior to control user input.

In this example, the `AFTER INPUT` block is used to validate data and disable an action that can only be used in the current group:

```
INPUT BY NAME p_order.*
  AFTER INPUT
    IF NOT check_order_data(DIALOG) THEN
      NEXT FIELD CURRENT
    END IF
  CALL DIALOG.setFieldActive("validate_order", FALSE)
```

**Related concepts**

- **AFTER DISPLAY block** on page 1403
- **AFTER CONSTRUCT block** on page 1470
- **BEFORE INPUT block** on page 1381

**BEFORE CONSTRUCT block**

**BEFORE CONSTRUCT block in singular and parallel CONSTRUCT dialogs**

In a singular `CONSTRUCT` instruction, or when used as parallel dialog, the `BEFORE CONSTRUCT` is only executed once when dialog is started.

The `BEFORE CONSTRUCT` block is executed once at dialog start-up, before the runtime system gives control to the user for criteria input. This block can be used to display messages to the user, initialize form fields with default search criteria values, and setup the dialog instance by deactivating unused fields or actions the user is not allowed to execute.

```
CONSTRUCT BY NAME where_part ON ...
  BEFORE CONSTRUCT
    MESSAGE "Enter customer search filter"
    CALL DIALOG.setActionActive("clean", FALSE)
  ...
```

The fields are cleared before the `BEFORE CONSTRUCT` block is executed.

You can use the `NEXT FIELD` control instruction in the `BEFORE CONSTRUCT` block, to jump to a specific field when the dialog starts.
**BEFORE CONSTRUCT block in CONSTRUCT of procedural DIALOG**

In a CONSTRUCT sub-dialog of a procedural DIALOG instruction, the BEFORE CONSTRUCT block is executed when the focus goes to a group of fields driven by a CONSTRUCT sub-dialog. This trigger is only invoked if a field of the sub-dialog gets the focus, and none of the other fields had the focus.

BEFORE CONSTRUCT is executed after the BEFORE DIALOG block and before the BEFORE FIELD blocks.

In this example, the BEFORE CONSTRUCT block is used to display a message:

```sql
CONSTRUCT BY NAME sql ON customer.*
BEFORE CONSTRUCT
  MESSAGE "Enter customer search filter"
```

**Related concepts**

BEFORE INPUT block on page 1381
BEFORE DISPLAY block on page 1402
AFTER CONSTRUCT block on page 1470

**AFTER CONSTRUCT block**

**AFTER CONSTRUCT block in singular and parallel CONSTRUCT dialogs**

In a singular CONSTRUCT instruction, or when used as parallel dialog, the AFTER CONSTRUCT is only executed once when dialog is ended.

Use an AFTER CONSTRUCT block to execute instructions after the user has finished search criteria input.

AFTER CONSTRUCT is not executed if an EXIT CONSTRUCT is performed.

The code in AFTER CONSTRUCT can for example check if a criteria combination of different fields is required or denied, and force the end use to enter all

Before checking the content of the fields used in the CONSTRUCT, make sure that the INT_FLAG variable is FALSE.

In the case that the user cancels the dialog, the validation rules must be skipped.

Since no program variables are associated with the form fields, you must query the input buffers of the fields to get the values entered by the user.

```sql
CONSTRUCT BY NAME where_part ON ...
  ...
  AFTER CONSTRUCT
    IF NOT INT_FLAG THEN
      IF length(DIALOG.getFieldBuffer(cust_name))==0
        OR length(DIALOG.getFieldBuffer(cust_addr))==0 THEN
        ERROR "Enter a search criteria for customer name and address fields."
      NEXT FIELD CURRENT
    END IF
  END IF
END CONSTRUCT
```

To limit the validation to fields that have been modified by the end user, you can call the FIELD_TOUCHED() function or the DIALOG.getFieldTouched() method to check if a field has changed during the dialog execution. This makes your validation code execute faster if the user has only modified a couple of fields in a large form.

**AFTER CONSTRUCT block in CONSTRUCT of procedural DIALOG**

In a CONSTRUCT sub-dialog of a procedural DIALOG instruction, the AFTER CONSTRUCT block is executed when the focus is lost by a group of fields driven by a CONSTRUCT sub-dialog. This trigger is invoked if a field of the sub-dialog loses the focus, and a field of a different sub-dialog gets the focus.
If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

**AFTER CONSTRUCT** is executed after the **AFTER FIELD** and before the **AFTER DIALOG** block.

Executing a **NEXT FIELD** in the **AFTER CONSTRUCT** control block will keep the focus in the group of fields.

In this example, the **AFTER CONSTRUCT** block is used to build the **SELECT** statement:

```
CONSTRUCT BY NAME sql ON customer.*
  AFTER CONSTRUCT
    LET sql = "SELECT * FROM customers WHERE " || sql
```

**Related concepts**
- **AFTER DISPLAY block** on page 1403
- **AFTER INPUT block** on page 1382
- **BEFORE CONSTRUCT block** on page 1469

**BEFORE DISPLAY block**

**BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs**

In a singular **DISPLAY ARRAY** instruction, or when used as parallel dialog, the **BEFORE DISPLAY** is only executed once when the dialog is started.

The **BEFORE DISPLAY** block is executed once at dialog startup, before the runtime system gives control to the user. This block can be used to display messages to the user, initialize program variables and setup the dialog instance by deactivating actions the user is not allowed to execute.

```
DISPLAY ARRAY p_items TO s_items.*
BEFORE DISPLAY
  CALL DIALOG.setActionActive("clear_item_list", is_super_user())
```

**BEFORE DISPLAY block in singular and parallel DISPLAY ARRAY dialogs**

In a **DISPLAY ARRAY** sub-dialog of a procedural **DIALOG** instruction, the **BEFORE DISPLAY** block is executed when a **DISPLAY ARRAY** list gets the focus.

**BEFORE DISPLAY** is executed before the **BEFORE ROW** block.

In this example the **BEFORE DISPLAY** block enables an action and displays a message:

```
DISPLAY ARRAY p_items TO s_items.*
BEFORE DISPLAY
  CALL DIALOG.setActionActive("print_list", TRUE)
  MESSAGE "You are now in the list of items"
```

**Related concepts**
- **BEFORE INPUT block** on page 1381
- **BEFORE CONSTRUCT block** on page 1469
- **AFTER DISPLAY block** on page 1403

**AFTER DISPLAY block**

**AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs**

In a singular **DISPLAY ARRAY** instruction, or when used as parallel dialog, the **AFTER DISPLAY** is only executed once when dialog is ended.
You typically implement dialog finalization in this block.

```plaintext
DISPLAY ARRAY p_items TO s_items.*
AFTER DISPLAY
  DISPLAY "Current row is: ", arr_curr()
```

**AFTER DISPLAY block in singular and parallel DISPLAY ARRAY dialogs**

In a `DISPLAY ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `AFTER DISPLAY` block is executed when a `DISPLAY ARRAY` list loses the focus and goes to another sub-dialog.

If the focus leaves the current group and goes to an action view, this trigger is not executed, because the focus did not go to another sub-dialog yet.

`AFTER DISPLAY` is executed after the `AFTER ROW` block.

In this example, the `AFTER DISPLAY` block disables an action that is specific to the current list:

```plaintext
DISPLAY ARRAY p_items TO s_items.*
AFTER DISPLAY
  CALL DIALOG.setActionActive("clear_item_list", FALSE)
```

**Related concepts**

- **AFTER INPUT block** on page 1382
- **AFTER CONSTRUCT block** on page 1470
- **BEFORE DISPLAY block** on page 1402

**BEFORE ROW block**

**BEFORE ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs**

In a singular `DISPLAY ARRAY`, `INPUT ARRAY` instruction, or when used as parallel dialog, the `BEFORE ROW` block is executed each time the user moves to another row. This trigger can also be executed in other situations, such as when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.

You typically do some dialog setup / message display in the `BEFORE ROW` block, because it indicates that the user selected a new row or entered in the list.

When the dialog starts, `BEFORE ROW` will be executed for the current row, but only if there are data rows in the array.

When called in this block, `DIALOG.getCurrentRow() / arr_curr()` return the index of the current row.

In this example, the `BEFORE ROW` block gets the new row number and displays it in a message:

```plaintext
DISPLAY ARRAY ...
  ...
  BEFORE ROW
    MESSAGE "We are on row # ", arr_curr()
  ...
```

**BEFORE ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG**

In an `INPUT` or `INPUT ARRAY` sub-dialog of a procedural `DIALOG` instruction, the `BEFORE ROW` block is executed when a `DISPLAY ARRAY` or `INPUT ARRAY` list gets the focus, or when the user moves to another row inside a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user tries to insert a row but the maximum number of rows in the list is reached.
| User interface | 1574

You typically do some dialog setup / message display in the BEFORE ROW block, because it indicates that the
user selected a new row. Do not use this trigger to detect focus changes; Use the BEFORE DISPLAY or BEFORE
INPUT blocks instead.
In DISPLAY ARRAY, BEFORE ROW is executed after the BEFORE DISPLAY block. In INPUT ARRAY, BEFORE
ROW is executed before the BEFORE INSERT and BEFORE FIELD blocks and after the BEFORE INPUT blocks.
When the procedural dialog starts, BEFORE ROW will only be executed if the list has received the focus and there is
a current row (the array is not empty). If you have other elements in the form which can get the focus before the list,
BEFORE ROW will not be triggered when the dialog starts. You must pay attention to this, because this behavior is
different to the behavior of singular DISPLAY ARRAY or INPUT ARRAY. In singular dialogs, the BEFORE ROW
block is always executed when the dialog starts (and there are rows in the array).
When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the current row.
In this example the BEFORE ROW block displays a message with the current row number:
DISPLAY ARRAY p_items TO s_items.*
BEFORE ROW
MESSAGE "We are in items, on row #", DIALOG.getCurrentRow("s_items")
Related concepts
BEFORE INPUT block on page 1381
BEFORE DISPLAY block on page 1402
ON ROW CHANGE block
The ON ROW CHANGE block is executed in a list controlled by an INPUT ARRAY, when leaving the current row
and when the row has been modified since it got the focus. This is typically used to detect row modification.
The code in ON ROW CHANGE will not be executed when leaving new rows created by the user with the default
append or insert action. To detect row creation, you must use the BEFORE INSERT or AFTER INSERT control
blocks.
The ON ROW CHANGE block is only executed if at least one field value in the current row has changed since the
row was entered, and the modification flag of the field is set. The modified field(s) may not be the current field, and
several field values can be changed. Values may have been changed by the user or by the program. The modification
flag is reset for all fields when entering another row, when going to another sub-dialog, or when leaving the dialog
instruction.
ON ROW CHANGE is executed after the AFTER FIELD block and before the AFTER ROW block.
When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the current row that has
been changed.
You can, for example, code database modifications (UPDATE) in the ON ROW CHANGE block:
INPUT ARRAY p_items FROM s_items.*
...
ON ROW CHANGE
LET r = DIALOG.getCurrentRow("s_items")
UPDATE items SET
items.item_code
= p_items[r].item_code,
items.item_description = p_items[r].item_description,
items.item_price
= p_items[r].item_price,
items.item_updatedate = TODAY
WHERE items.item_num = p_items[r].item_num
Related concepts
Input field modification flag on page 1623
Each input field controlled by a dialog instruction has a modification flag.
AFTER ROW block on page 1404


**AFTER ROW block**

**AFTER ROW block in singular and parallel DISPLAY ARRAY, INPUT ARRAY dialogs**

In a singular DISPLAY ARRAY, INPUT ARRAY instruction, or when used as parallel dialog, the AFTER ROW block is executed each time the user moves to another row, before the current row is left. This trigger can also be executed in other situations, such as when you delete a row, or when the user inserts a new row.

A NEXT FIELD instruction executed in the AFTER ROW control block will keep the user entry in the current row. Use this behavior to implement row validation and prevent the user from leaving the list or moving to another row.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the row that you are leaving.

**AFTER ROW block in DISPLAY ARRAY and INPUT ARRAY of procedural DIALOG**

In an INPUT or INPUT ARRAY sub-dialog of a procedural DIALOG instruction, the AFTER ROW block is executed when a DISPLAY ARRAY or INPUT ARRAY list loses the focus, or when the user moves to another row in a list. This trigger can also be executed in other situations, for example when you delete a row, or when the user inserts a new row.

AFTER ROW is executed after the AFTER FIELD, AFTER INSERT and before AFTER DISPLAY or AFTER INPUT blocks.

When called in this block, DIALOG.getCurrentRow() / arr_curr() return the index of the of the row that you are leaving.

For both INPUT ARRAY and DISPLAY ARRAY sub-dialogs, a NEXT FIELD executed in the AFTER ROW control block will keep the focus in the list and stay in the current row. Use this feature to implement row validation and prevent the user from leaving the list or moving to another row.

**AFTER ROW and temporary rows in INPUT ARRAY**

Important: After creating a temporary row at the end of a list driven by INPUT ARRAY, if you leave that row to a previous row without data input (setting the touched flag), or when the cancel action is invoked, the temporary row will be automatically removed. The AFTER ROW block will be executed for the temporary row, but ui.Dialog.getCurrentRow() / arr_curr() will be one row greater than ui.Dialog.getArrayLength() / ARR_COUNT(). In this case, it is recommended that you ignore the AFTER ROW event. For example, it is recommended that you avoid executing a NEXT FIELD or CONTINUE INPUT instruction, and trying to access the dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array.

In this example, the AFTER ROW block checks the current row index and verifies a variable value to forces the focus to stay in the current row if the value is wrong:

```
INPUT ARRAY p_items FROM s_items.*
...
AFTER ROW
  LET r = DIALOG.getCurrentRow("s_items")
  IF r <= DIALOG.getArrayLength("s_items") THEN
    IF NOT item_is_valid_quantity(p_item[r].item_quantity) THEN
      ERROR "Item quantity is not valid"
      NEXT FIELD item_quantity'
    END IF
  END IF
END IF
```

Another way to handle the case of temporary rows in AFTER ROW is to use a flag to know if the AFTER INSERT block was executed: The AFTER INSERT block is not executed if the temporary row is automatically removed. By
setting a first value in BEFORE INSERT and changing the flag in AFTER INSERT, you can detect if the row was permanently added to the list:

```plaintext
INPUT ARRAY p_items FROM s_items.*
...
BEFORE INSERT
  LET op = "I"
...
AFTER INSERT
  LET op = "I"
...
AFTER ROW
  IF op == "I" THEN
    IF NOT item_is_valid_quantity(p_item[arr_curr()].item_quantity) THEN
      ERROR "Item quantity is not valid"
      NEXT FIELD item_quantity
    END IF
    WHENEVER ERROR CONTINUE
    INSERT INTO items (item_num, item_name, item_quantity) VALUES ( p_item[arr_curr()].* )
    WHENEVER ERROR STOP
  IF SQLCA.SQLCODE<0 THEN
    ERROR "Could not insert the record into database!"
    NEXT FIELD CURRENT
  ELSE
    MESSAGE "Record has been inserted successfully"
  END IF
  END IF
...
```

Related concepts

NEXT FIELD instruction on page 1389
BEFORE ROW block on page 1403
ON ROW CHANGE block on page 1439

**BEFORE INSERT block**

The BEFORE INSERT block is executed when a new row is created in an INPUT ARRAY. You typically use this trigger to set some default values in the new created row. A new row can be created by moving down after the last row, by executing a insert action, or by executing an append action.

The BEFORE INSERT block is executed after the BEFORE ROW block and before the BEFORE FIELD block.

When called in this block, `DIALOG.getCurrentRow() / arr_curr()` return the index of the new created row.

To distinguish row insertion from an appended row, compare the current row (`DIALOG.getCurrentRow()") with the total number of rows (`DIALOG.getArrayLength("screen-array")`). If the current row index and the total number of rows correspond, the BEFORE INSERT concerns a temporary row, otherwise it concerns an inserted row.

Row creation can be stopped by using the CANCEL INSERT instruction inside BEFORE INSERT. If possible, it is however better to disable the insert and append actions to prevent the user to execute the actions with `DIALOG.setActionActive()`.

In this example, the BEFORE INSERT block checks if the user can create rows and denies new row creation if needed; otherwise, it sets some default values:

```plaintext
INPUT ARRAY p_items FROM s_items.*
...
BEFORE INSERT
  IF NOT user_can_append THEN
    ERROR "You are not allowed to append rows"
  END IF
```
Related concepts

**Appending rows in INPUT ARRAY** on page 1749
Rows appended at the end of an editable list are temporary until they are edited.

**BEFORE ROW block** on page 1403

**AFTER INSERT block**

The **AFTER INSERT** block of **INPUT ARRAY** is executed when the creation of a new row is validated. In this block, you can for example implement SQL to insert a new row in the database table.

The **AFTER INSERT** block is executed **after** the **AFTER FIELD** block and **before** the **AFTER ROW** block.

When called in this block, `DIALOG.getCurrentRow() / arr_curr()` return the index of the new created row.

When the user appends a new row at the end of the list, then moves UP to another row or validates the dialog, the **AFTER INSERT** block is only executed if at least one field was edited. If no data entry is detected, the dialog automatically removes the new appended row and thus does not trigger the **AFTER INSERT** block.

When executing a **NEXT FIELD** in the **AFTER INSERT** block, the dialog will keep the focus in the list and stay in the current row. Use this behavior to implement row validation and prevent the user from leaving the list or moving to another row. However, this will not cancel the row insertion and will not invoke the **BEFORE INSERT/AFTER INSERT** triggers again. The only way to keep the focus in the current row after the row was inserted is to execute a **NEXT FIELD** in the **AFTER ROW** block.

In this example, the **AFTER INSERT** block inserts a new row in the database and cancels the operation if the SQL command fails:

```java
INPUT ARRAY p_items FROM s_items.*
...
AFTER INSERT
    WHENEVER ERROR CONTINUE
    INSERT INTO items VALUES
    ( p_items[DIALOG.getCurrentRow("s_items")].* )
    WHENEVER ERROR STOP
    IF SQLCA.SQLCODE<>0 THEN
        ERROR SQLERRMESSAGE
        CANCEL INSERT
    END IF
```

Related concepts

**NEXT FIELD instruction** on page 1389

**AFTER ROW block** on page 1404

**BEFORE DELETE block**

The **BEFORE DELETE** block is executed each time the user deletes a row of an **INPUT ARRAY** list, **before** the row is removed from the list.

You typically code the database table synchronization in the **BEFORE DELETE** block, by executing a DELETE SQL statement using the primary key of the current row. In the **BEFORE DELETE** block, the row to be deleted still exists in the program array, so you can access its data to identify what record needs to be removed.

The **BEFORE DELETE** block is executed **before** the **AFTER DELETE** block.

If needed, the deletion can be canceled with the **CANCEL DELETE** instruction.
When called in this block, `DIALOG.getCurrentRow() / arr_curr()` return the index of the row that will be deleted.

The next example uses the `BEFORE DELETE` block to remove the row from the database table and cancels the deletion operation if an SQL error occurs:

```sql
INPUT ARRAY p_items FROM s_items.*
BEFORE DELETE
   LET r = DIALOG.getCurrentRow("s_items")
   WHENEVER ERROR CONTINUE
   DELETE FROM items
      WHERE item_num = p_items[r].item_num
   WHENEVER ERROR STOP
   IF SQLCA.SQLCODE<>0 VALUES
      ERROR SQLERRMESSAGE
      CANCEL DELETE
END IF
```

**Related concepts**

AFTER DELETE block on page 1443

**AFTER DELETE block**

The `AFTER DELETE` block is executed each time the user deletes a row of an `INPUT ARRAY` list, after the row has been deleted from the list.

The `AFTER DELETE` block is executed after the `BEFORE DELETE` block and before the `AFTER ROW` block for the deleted row and the `BEFORE ROW` block of the new current row.

When an `AFTER DELETE` block executes, the program array has already been modified; the deleted row no longer exists in the array (except in the special case when deleting the last row). The `arr_curr()` function or the `ui.Dialog.getCurrentRow()` method returns the same index as in `BEFORE ROW`, but it is the index of the new current row. The `AFTER ROW` block is also executed just after the `AFTER DELETE` block.

**Important:** When deleting the last row of the list, `AFTER DELETE` is executed for the delete row, and `DIALOG.getCurrentRow() / arr_curr()` will be one greater than `DIALOG.getArrayLength() / ARR_COUNT()`. Ensure you avoid accessing a dynamic array with a row index that is greater than the total number of rows, otherwise the runtime system will adapt the total number of rows to the actual number of rows in the program array. When using a static array, you must ignore the values in the rows after `ARR_COUNT()`.

Here the `AFTER DELETE` block is used to re-number the rows with a new item line number (note that `DIALOG.getArrayLength() / ARR_COUNT()` may return zero):

```sql
INPUT ARRAY p_items FROM s_items.*
AFTER DELETE
   LET r = DIALOG.getCurrentRow("s_items")
   FOR i=r TO DIALOG.getArrayLength("s_items")
      LET p_items[i].item_lineno = i
   END FOR
```

It is not possible to use the `CANCEL DELETE` instruction in an `AFTER DELETE` block. At this time it is too late to cancel row deletion, as the data row no longer exists in the program array.

**Related concepts**

BEFORE INSERT block on page 1442

AFTER ROW block on page 1404
**BEFORE MENU block**

If the MENU block contains a BEFORE MENU clause, statements within this clause are executed before the menu dialog starts.

This block is typically used to hide or disable some menu options depending on the current context of the program. For example, when the current user is not allowed to create new records, the menu options can be disabled as follows:

```
MENU "Orders"
BEFORE MENU
    CALL DIALOG.setActionActive("append", can_user_append() )
    COMMAND "Append" -- creates "append" action (lowercase)
END MENU
```

In TUI mode, the menu options can also be disabled, but they will still be displayed on the screen. The end user will see the option, but cannot select it. In this case it's more convenient to hide the option from the end user with the DIALOG.setActionHidden() method, instead of disabling the action.

**Related concepts**

The model-view-controller paradigm on page 1608
The dynamic user interface architecture is based on the Model-View-Controller (MVC) paradigm.

The Dialog class on page 2367
The `ui.Dialog` class provides a set of methods to configure, query and control the current interactive instruction.

**DIALOG interaction blocks**

Dialog interaction blocks are dialog triggers that can be used to execute specific code when the user executes an action in the dialog. For example, when pressing a button in the form, the corresponding **ON ACTION** interaction block will be executed.

Interaction blocks also include special handlers such as timeout event handler, drag & drop handlers, and modification triggers for DISPLAY ARRAY sub-dialogs.

- **ON ACTION block** on page 1369
- **ON IDLE block** on page 1356
- **ON KEY block** on page 1357
- **ON APPEND block** on page 1409
- **ON INSERT block** on page 1410
- **ON UPDATE block** on page 1412
- **ON DELETE block** on page 1413
- **ON SELECTION CHANGE block** on page 1414
- **ON DRAG_START block** on page 1415
- **ON DRAG_FINISHED block** on page 1416
- **ON DRAG_ENTER block** on page 1416
- **ON DRAG_OVER block** on page 1417
- **ON DROP block** on page 1419

**ON ACTION block**

The **ON ACTION action-name** blocks execute a sequence of instructions when the user triggers a specific action.

A typical action handler block looks like this:

```
ON ACTION action-name
    instruction
    ...
```
Action blocks are bound by name to action views (like buttons) in the current form. Action views can be buttons in forms, toolbar buttons, topmenu options, and if no explicit action view is defined, actions are rendered with a default action view, depending on the type of front-end.

This example defines an action block to open a typical zoom window and let the user select a customer record:

```
ON ACTION zoom
  CALL zoom_customers() RETURNING st, rec.cust_id, rec.cust_name
```

In a dialog handling user input such as INPUT, INPUT ARRAY and CONSTRUCT, if an action is specific to a field, add the INFIELD clause to have the action automatically enabled when the corresponding field gets the focus:

```
ON ACTION zoom INFIELD cust_city
  CALL zoom_cities() RETURN st, rec.cust_city
```

In most cases actions are decoration with action defaults in form files, but there can be cases where the ON ACTION handler needs to define its own attributes at the program level. This can be done by adding the ATTRIBUTES() clause of ON ACTION:

```
ON ACTION custinfo ATTRIBUTES(DISCLOSUREINDICATOR, IMAGE="info")
  CALL show_customer_info()
```

For more details about action handlers, and action configuration, see Dialog actions on page 1640.

**ON IDLE block**

The ON IDLE seconds clause defines a set of instructions that must be executed after a given period of user inactivity. This interaction block can be used, for example, to quit the dialog after the user has not interacted with the program for a specified period of time.

As ON IDLE can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of ON IDLE must be an integer literal or variable. If it the value is zero, the dialog timeout is disabled.

It is not recommended to use the ON IDLE trigger with a short timeout period such as 1 or 2 seconds; The purpose of this trigger is to give the control back to the program after a relatively long period of inactivity (10, 30 or 60 seconds). This is typically the case when the end user leaves the workstation, or gets a phone call. The program can then execute some code before the user gets the control back.

```
ON IDLE 30
  IF ask_question("Do you want to reload information from the database?") THEN
    -- Fetch data back from the db server
  END IF
```

**Important:** The timeout value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, any change of the variable will have no effect if the variable is changed after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

**Related concepts**

Execute some code after a given number of seconds, when the user does not interact with the program.

**ON TIMER block** on page 1357

**ON KEY block**

An ON KEY (key-name) block defines an action with a hidden action view (no default button is visible), that executes a sequence of instructions when the user presses the specified key.

The ON KEY block is supported for backward compatibility with TUI mode applications.
An **ON KEY** block can specify up to four different keys. Each key creates a specific action object that will be identified by the key name in lowercase. For example, **ON KEY (F5, F6)** creates two actions with the names *f5* and *f6*. Each action object will get an `acceleratorName` attribute assigned, with the corresponding accelerator name. The specified keys must be one of the **virtual keys**.

In GUI mode, action defaults are applied for **ON KEY** actions by using the name of the action (the key name). You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully **ON KEY CONTROL-?** statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, **ON KEY** statements used with ESC, TAB, UP, DOWN, LEFT, RIGHT, HELP, NEXT, PREVIOUS, INSERT, CONTROL-M, CONTROL-X, CONTROL-V, CONTROL-C and CONTROL-A should be avoided for use in GUI programs, because it's very likely to clash with default accelerators defined in the factory action defaults file provided by default.

By default, **ON KEY** actions are not decorated with a default button in the action frame (the default action view). You can show the default button by configuring a `text` attribute with the action defaults.

```plaintext
ON KEY (CONTROL-Z)
    CALL open_zoom()
```

### Related concepts

Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

**Default action views** on page 1645  
A default action view is created to render an action handler when no explicit action view exists for it.

### ON TIMER block

The **ON TIMER seconds** clause defines a set of instructions that must be executed at regular intervals. This interaction block can be used, for example, to check if a message has arrived in a queue, and needs to be processed.

As **ON TIMER** can fire field input validation, it is therefore not recommended in dialogs allowing input.

The parameter of **ON TIMER** must be an integer literal or variable. If the value is zero, the dialog timeout is disabled.

It is not recommended to use the **ON TIMER** trigger with a short timeout period, such as 1 or 2 seconds. The purpose of this trigger is to give the control back to the program after a reasonable period of time, such as 10, 20 or 60 seconds.

```plaintext
ON TIMER 30
    CALL check_for_messages()
```

**Important:** The timer value is taken into account when the dialog initializes its internal data structures. If you use a program variable instead of an integer constant, a change of the variable has no effect if the change takes place after the dialog has initialized. If you want to change the value of the timeout variable, it must be done before the dialog block.

### Related concepts

**Get program control on a regular (timed) basis** on page 1614  
Execute some code after a given number of seconds, with or without user interaction with the program.

**ON IDLE block** on page 1356

**ON APPEND block**

Similarly to the **ON INSERT** control block, the **ON APPEND** trigger can be used to enable row creation during a **DISPLAY ARRAY** dialog. If this block is defined, the dialog will automatically create the append action. This action can be decorated, enabled and disabled as a regular action.

If the dialog defines an **ON ACTION append** interaction block and the **ON APPEND** block is used, the compiler will stop with error -8408.
When the user fires the append action, the dialog first execute the user code of the \texttt{AFTER ROW} block if defined. Then the dialog moves to the end of the list, and creates a new row after the last existing row. After creating the row, the dialog executes the user code of the \texttt{ON APPEND} block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular \texttt{INPUT} statement, to let the end user enter data for the new created row. This is typically done with an \texttt{INPUT} binding explicitly array fields to the screen record fields. The new current row in the program array is identified with \texttt{arr\_curr()}, and the current screen line in the form is defined by \texttt{scr\_line()}:

\begin{verbatim}
DISPLAY ARRAY arr TO sr.*
...
ON APPEND
  INPUT arr[arr\_curr()].* FROM sr[scr\_line()].* ;
...
\end{verbatim}

Pay attention to the semicolon ending the \texttt{INPUT} instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the \texttt{INT\_FLAG} global variable is \texttt{FALSE} and \texttt{STATUS} is zero, the new row is kept in the program array, and the \texttt{BEFORE ROW} block is executed for the new created row.
- If the \texttt{INT\_FLAG} global variable is \texttt{TRUE} or \texttt{STATUS} is different from zero, the new row is removed from the program array, and the \texttt{BEFORE ROW} block is executed for the row that was existing at the current position, before the new row was created.

The \texttt{DISPLAY ARRAY} dialog always resets \texttt{INT\_FLAG} to \texttt{FALSE} and \texttt{STATUS} to zero before executing the user code of the \texttt{ON APPEND} block.

The append action is disabled if the maximum number of rows is reached.

If needed, the \texttt{ON APPEND} handler can be configured with action attributes by added an \texttt{ATTRIBUTES()} clause, as with user-defined action handlers:

\begin{verbatim}
ON APPEND ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
\end{verbatim}

**Related concepts**

- \texttt{ON INSERT block} on page 1410

- \texttt{ON UPDATE block} on page 1412

- \texttt{ON DELETE block} on page 1413

**ON INSERT block**

Similarly to the \texttt{ON APPEND} control block, the \texttt{ON INSERT} trigger can be used to enable row creation during a \texttt{DISPLAY ARRAY} dialog. If this block is defined, the dialog will automatically create the insert action. This action can be decorated, enabled and disabled as a regular action.
If the dialog defines an ON ACTION insert interaction block and the ON INSERT block is used, the compiler will stop with error -8408.

When the user fires the insert action, the dialog first execute the user code of the AFTER ROW block if defined. Then the new row is created: The insert action creates a new row before current row in the list. After creating the row, the dialog executes the user code of the ON INSERT block.

The dialog handles only row creation actions and navigation, you must program the record input with a regular INPUT statement, to let the end user enter data for the new created row. This is typically done with an INPUT binding explicitly array fields to the screen record fields. The new current row in the program array is identified with arr_curr(), and the current screen line in the form is defined by scr_line():

```
DISPLAY ARRAY arr TO sr.*
... ON INSERT
  INPUT arr[arr_curr()].* FROM sr[scr_line()].* ;
...```

Pay attention to the semicolon ending the INPUT instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the new row as follows:

- If the INT_FLAG global variable is FALSE and STATUS is zero, the new row is kept in the program array, and the BEFORE ROW block is executed for the new created row.
- If the INT_FLAG global variable is TRUE or STATUS is different from zero, the new row is removed from the program array, and the BEFORE ROW block is executed for the row that was existing at the current position, before the new row was created.

The DISPLAY ARRAY dialog always resets INT_FLAG to FALSE and STATUS to zero before executing the user code of the ON INSERT block.

The insert action is disabled if the maximum number of rows is reached.

If needed, the ON INSERT handler can be configured with action attributes by added an ATTRIBUTES() clause, as with user-defined action handlers:

```
ON INSERT ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

**Related concepts**

- **STATUS** on page 517
  STATUS is a predefined variable that contains the execution status of the last instruction.

- **ON APPEND block** on page 1409
  **ON UPDATE block** on page 1412
  **ON DELETE block** on page 1413
**ON UPDATE block**

The **ON UPDATE** trigger can be used to enable row modification during a **DISPLAY ARRAY** dialog. If this block is defined, the dialog will automatically create the update action. This action can be decorated, enabled and disabled as regular actions.

You typically configure the **TABLE** container in the form by defining the **DOUBLECLICK** attribute to "update", in order to trigger the update action when the user double-clicks on a row.

If the dialog defines an **ON ACTION update** interaction block and the **ON UPDATE** block is used, the compiler will stop with error -8408.

When the user fires the **update** action, the dialog executes the user code of the **ON UPDATE** block.

The dialog handles only the row modification action and navigation, you must program the record input with a regular **INPUT** statement, to let the end user modify the data of the current row. This is typically done with an **INPUT** binding explicitly array fields to the screen record fields, with the **WITHOUT DEFAULTS** clause. The current row in the program array is identified with **arr_curr()**, and the current screen line in the form is defined by **scr_line()**:

```plaintext
DISPLAY ARRAY arr TO sr.*
...
ON UPDATE
  INPUT arr[arr_curr()].* WITHOUT DEFAULTS FROM sr[scr_line()].* ;
...
```

Pay attention to the semicolon ending the **INPUT** instruction, which is usually needed here to solve a language grammar conflict when nested dialog instructions are implemented.

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the **INT_FLAG** global variable is **FALSE** and **STATUS** is zero, the modified values of the current row are kept in the program array.
- If the **INT_FLAG** global variable is **TRUE** or **STATUS** is different from zero, the old values of the current row are restored in the program array.

The **DISPLAY ARRAY** dialog always resets **INT_FLAG** to **FALSE** and **STATUS** to zero before executing the user code of the **ON UPDATE** block.

If needed, the **ON UPDATE** handler can be configured with action attributes by added an **ATTRIBUTES()** clause, as with user-defined action handlers:

```plaintext
ON UPDATE ATTRIBUTES(TEXT="%"custlist.delete", IMAGE="listdel")
```

**Related concepts**

**ON INSERT block** on page 1410  
**ON APPEND block** on page 1409  
**ON DELETE block** on page 1413

**ON DELETE block**

The **ON DELETE** trigger can be used to enable row deletion during a **DISPLAY ARRAY** dialog. If this block is defined, the dialog will automatically create the delete action. This action can be decorated, enabled and disabled as regular actions.

If the dialog defines an **ON ACTION delete** interaction block and the **ON DELETE** block is used, the compiler will stop with error `-8408`.

When the user fires the delete action, the dialog executes the user code of the **ON DELETE** block.

The dialog handles only the row deletion action and navigation, you can typically program a validation dialog box to let the user confirm the deletion. The current row in the program array is identified with `arr_curr()`:

```
DISPLAY ARRAY arr TO sr.*
...
ON DELETE
  IF fgl_winQuestion("Delete",
    "Do you want to delete this record?",
    "yes", "no|yes", "help", 0) == "no"
  THEN
    LET int_flag = TRUE
  END IF
END IF
...
```

After the user code is executed, the dialog gets the control back and processes the current row as follows:

- If the `INT_FLAG` global variable is **FALSE** and `STATUS` is zero, the current row is deleted from the program array, and the **BEFORE ROW** block is executed for the next row in the list.
- If the `INT_FLAG` global variable is **TRUE** or `STATUS` is different from zero, the current row is kept in the program array, and the **BEFORE ROW** block is executed again for the current row.

The **DISPLAY ARRAY** dialog always resets `INT_FLAG` to **FALSE** and `STATUS` to zero before executing the user code of the **ON DELETE** block.

If needed, the **ON DELETE** handler can be configured with action attributes by added an **ATTRIBUTES()** clause, as with user-defined action handlers:

```
ON DELETE ATTRIBUTES(TEXT=%"custlist.delete", IMAGE="listdel")
```

**Related concepts**

**ON UPDATE block** on page 1412
**ON SELECTION CHANGE block**

The **ON SELECTION CHANGE** trigger can be used to enable multi-row selection and detect when rows are selected or de-selected by the end user during a **DISPLAY ARRAY** dialog. If this block is defined, multi-row selection is automatically enabled. However, the feature can be enabled/disabled with the `setSelectionMode()` dialog method.

**Related concepts**

- **Multiple row selection** on page 1752
  Multiple row selection allows the end user to select several rows within a list of records.

**ON SORT block**

**Basics**

The **ON SORT** interaction block can be used to detect when rows have to be sorted in a **DISPLAY ARRAY** or **INPUT ARRAY** dialog.

**ON SORT** is used in two different contexts:

1. In a regular (full-list) **DISPLAY ARRAY** / **INPUT ARRAY** dialog, the **ON SORT** trigger can be used to detect that a list sort was performed.
2. In a **DISPLAY ARRAY** using paged mode (**ON FILL BUFFER**), use **ON SORT** to detect a sort request from the user and re-fetch the rows from the database in the required order.

**ON SORT in regular full-list DISPLAY ARRAY or INPUT ARRAY**

In a regular **DISPLAY ARRAY** / **INPUT ARRAY** dialog not using paged mode, the **ON SORT** trigger can be used to detect that a list sort was performed.

When the **ON SORT** block executes in this context, the (visual) sort is already done by the runtime system and the **ON SORT** block is only used to execute post-sort tasks, such as displaying current row information.

To display the row position information, use the `arrayToVisualIndex()` dialog method to convert the current program row number to the visual row number:

```plaintext
DISPLAY ARRAY arr TO sr.* ...

... 
ON SORT 
  MESSAGE SFMT( "Row: %1/%2", 
    DIALOG.arrayToVisualIndex( "sr", DIALOG.getCurrentRow("sr") ), 
    DIALOG.getArrayLength( "sr" ) 
  )
... 
```

If needed, you can get the sort column and sort order with the `getSortKey()` and `isSortReverse()` dialog methods:

```plaintext
DISPLAY ARRAY arr TO sr.* ...

... 
ON SORT 
  MESSAGE SFMT( "Sort on %1, %2 order", 
    DIALOG.getSortKey("sr"), 
    IIF( DIALOG.isSortReverse("sr"), "descending", "ascending" ) 
  )
... 
```

**ON SORT in DISPLAY ARRAY using the paged mode**

In a **DISPLAY ARRAY** implementing paged mode with **ON FILL BUFFER** trigger, built-in row sorting is not available because data is provided by pages.
Use the ON SORT trigger, to detect a sort request and perform a new SQL query to re-order the rows. In this context, the sort column and sort order are available with the getSortKey() and isSortReverse() dialog methods:

```plaintext
DEFINE key STRING, rev BOOLEAN
DISPLAY ARRAY arr TO sr.* ... 
... 
ON SORT  
  -- Re-execute the SQL statement to fill the page of rows in ON FILL BUFFER  
  -- Assuming that form field names match table column names  
  LET key = DIALOG.getSortKey( "sa" )  
  LET rev = DIALOG.isSortReverse( "sa" )  
  IF key IS NULL THEN  
    CALL execute_sql( NULL )  
  ELSE  
    CALL execute_sql( "ORDER BY " || key || IIF( rev, " DESC", "" ) )  
  END IF
```

See Paged mode of DISPLAY ARRAY on page 1743 for more details about the paged mode in DISPLAY ARRAY and how to implement sort in this type of record list dialog.

**Related concepts**

- List ordering on page 1764
- List controllers implement a built-in sort. This feature can be disabled if not required.

**ON DRAG_START block**

The ON DRAG_START block is executed when the end user has begun the drag operation. If this dialog trigger has not been defined, default dragging is enabled for this dialog.

In the ON DRAG_START block, the program typically specifies the type of drag & drop operation by calling `ui.DragDrop.setOperation()` with "move" or "copy". This call will define the default and unique drag operation. If needed, the program can allow another type of drag operation with `ui.DragDrop.addPossibleOperation()`. The end user can then choose to move or copy the dragged object, if the drag & drop target allows it.

If the dragged object can be dropped outside the program, must define the MIME type and drag/drop data with `ui.DragDrop.setMimeType()` and `ui.DragDrop.setBuffer()` methods.

Example:

```plaintext
DEFINE dnd ui.DragDrop
... 
DISPLAY ARRAY arr TO sr.* ... 
... 
ON DRAG_START (dnd)
  CALL dnd.setOperation("move") -- Move is the default operation
  CALL dnd.addPossibleOperation("copy") -- User can toggle to copy if needed
  CALL dnd.setMimeType( "text/plain" )
  CALL dnd.setBuffer( arr[arr_curr()].cust_name )
... 
END DISPLAY
```

**Related concepts**

- Handle drag & drop data with MIME types on page 1821
- How to handle MIME types with drag & drop?
- The DragDrop class on page 2422
The `ui.DragDrop` class is used to control the events related to drag & drop events.

**ON DRAG_FINISHED block**

Execution of the `ON DRAG_FINISHED` block notifies the dialog where the drag started and that the drop operation has been completed or terminated.

Call `ui.DragDrop.getOperation()` to get the final type of operation of the drop. On successful completion, the method returns "move" or "copy"; otherwise the function returns NULL. If NULL is returned, the `ON DRAG_FINISHED` trigger can be ignored.

In cases of successful moves to a target out of the current `DISPLAY ARRAY`, the application must remove the transferred data from the source model. For example, if a row was moved from dialog A to B, dialog A will get an `ON DRAG_FINISHED` execution after the row was dropped into B, which removes the row from the list A.

The `ON DRAG_FINISHED` interaction block is optional.

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_START (dnd)
  LET last_dragged_row = arr_curr()
...
ON DRAG_FINISHED (dnd)
  IF dnd.getOperation() == "move" THEN
    CALL DIALOG.deleteRow(last_dragged_row)
  END IF
...
END DISPLAY
```

**Related concepts**

The `DragDrop class` on page 2422

The `ui.DragDrop` class is used to control the events related to drag & drop events.

**ON DRAG_ENTER block**

When the `ON DROP` control block is defined, the `ON DRAG_ENTER` block will be executed when the mouse cursor enters the visual boundaries of the drop target dialog. Entering the target dialog is accepted by default if no `ON DRAG_ENTER` block is defined. However, when `ON DROP` is defined, it is recommended that you also define `ON DRAG_ENTER` to deny the drop of objects with an unsupported MIME type that come from other applications.

The program can decide to deny or allow a specific drop operation with a call to `ui.DragDrop.setOperation()`, passing a NULL to the method will deny drop.

To check what MIME type is available in the drag & drop buffer, the program uses the `ui.DragDrop.selectMimeType()` method. This method takes the MIME type as a parameter and returns TRUE if the passed MIME type is used. You can call this method several times to check the availability of different MIME types.

You may also define the visual effect when hovering over the target list with `ui.DragDrop.setFeedback()`.

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER (dnd)
  IF dnd.selectMimeType("text/plain") THEN
    CALL dnd.setOperation("copy")
    CALL dnd.setFeedback("all")
  ELSE
    CALL dnd.setOperation(NULL)
  END IF
```
Once the mouse has entered the target area, subsequent mouse cursor moves can be detected with the **ON DROP** trigger.

When using a table or tree-view as drop target, you can control the visual effect when the mouse moves over the rows, depending on the type of drag & drop you want to achieve.

Basically, a dragged object can be:

1. Inserted in between two rows (visual effect must show where the object will be inserted)
2. Copied/merged to the current row (visual effect must show the row under the mouse)
3. Dropped somewhere on the target widget (the exact location inside the widget does not matter)

The visual effect can be defined with the `ui.DragDrop.setFeedback()` method, typically called in the **ON DRAG_ENTER** block.

The values to pass to the `setFeedback()` method to get the desired visual effects described are respectively:

1. `insert` (default)
2. `select`
3. `all`

```
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER (dnd)
  IF canDrop() THEN
    CALL dnd.setOperation(NULL)
  ELSE
    CALL dnd.setFeedback("select")
  END IF
...
END DISPLAY
```

**Related concepts**

The [DragDrop class](#) on page 2422

The `ui.DragDrop` class is used to control the events related to drag & drop events.

**ON DRAG_OVER block**

When the `ON DROP` control block is defined, the `ON DRAG_OVER` block will be executed after `ON DRAG_ENTER`, when the mouse cursor is moving over the drop target, or when the drag & drop operation has changed (toggling copy/move).

`ON DRAG_OVER` will be called only once per row, even if the mouse cursor moves over the row.

In the `ON DRAG_OVER` block, the method `ui.DragDrop.getLocationRow()` returns the index of the row in the target array, and can be used to allow or deny the drop. When using a tree-view, you must also check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and allow/deny the drop operation accordingly.

The program can change the drop operation at any execution of the `ON DRAG_OVER` block. You can deny or allow a specific drop operation with a call to `ui.DragDrop.setOperation()`; passing a `NULL` to the method will deny the drop.

The current operation (returned by `ui.DragDrop.getOperation()`) is the value set in previous `ON DRAG_ENTER` or `ON DRAG_OVER` events, or the operation selected by the end user, if it can toggle between copy and move. Thus, `ON DRAG_OVER` can occur even if the mouse position has not changed.
If dropping has been denied with `ui.DragDrop.setOperation(NULL)` in the previous `ON DRAG_OVER` event, the program can reset the operation to allow a drop with a call to `ui.DragDrop.setOperation()` with the operation parameter "move" or "copy".

`ON DRAG_OVER` will not be called if drop has been disabled in `ON DRAG_ENTER` with `ui.DragDrop.setOperation(NULL)`

`ON DRAG_OVER` is optional, and must only be defined if the operation or the acceptance of the drag object depends on the target row of the drop target.

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER (dnd)
...
ON DRAG_OVER (dnd)
  IF arr[dnd.getLocationRow()].acceptsCopy THEN
    CALL dnd.setOperation("copy")
  ELSE
    CALL dnd.setOperation(NULL)
  END IF
ON DROP (dnd)
...
END DISPLAY
```

During a drag & drop process, the end user (or the target application) can decide to modify the type of the operation, to indicate whether the dragged object has to be copied or moved from the source to the target. For example, in a typical file explorer, by default files are moved when doing a drag & drop on the same disk. To make a copy of a file, you must press the Ctrl key while doing the drag & drop with the mouse.

In the drop target dialog, you can detect such operation changes in the `ON DRAG_OVER` trigger and query the `ui.DragDrop` object for the current operation with `ui.DragDrop.getOperation()`. In the drag source dialog, you typically check `ui.DragDrop.getOperation()` in the `ON DRAG_FINISHED` trigger to know what sort of operation occurred, to keep ("copy" operation) or delete ("move" operation) the original dragged object.

This example tests the current operation in the drop target list and displays a message accordingly:

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
ON DRAG_ENTER (dnd)
...
ON DRAG_OVER (dnd)
  CASE dnd.getOperation()
    WHEN "move"
      MESSAGE "The object will be moved to row ", dnd.getLocationRow()
    WHEN "copy"
      MESSAGE "The object will be copied to row ", dnd.getLocationRow()
  END CASE
...
ON DROP (dnd)
...
END DISPLAY
```

Describes how to implement tree views.

**ON DROP block**

To enable drop actions on a list, you must define the **ON DROP** block; otherwise the list will not accept drop actions. The **ON DROP** block is executed after the end user has released the mouse button to drop the dragged object. **ON DROP** will not occur if drop has been denied in the previous **ON DRAG_OVER** event or in **ON DRAG_ENTER** with a call to `ui.DragDrop.setOperation(NULL)`.

When **ON DROP** executes, the MIME type of the dragged object can be checked with `ui.DragDrop.getSelectedMimeType()`. Then call the `ui.DragDrop.getBuffer()` method to retrieve drag & drop data from external applications.

Ideally, the drop operation is accepted (there is no need for additional calls to `ui.DragDrop.setOperation()`).

In this block, the `ui.DragDrop.getLocationRow()` method returns the index of the row in the target array, and can be used to execute the code to get the drop data / object into the row that has been chosen by the user.

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr TO sr.* ...
...
  ON DROP (dnd)
    LET arr[dnd.getLocationRow()].capacity == dnd.getBuffer()
...
END DISPLAY
```

If the drag & drop operations are local to the same list or tree-view controller, you can use the `ui.DragDrop.dropInternal()` method to simplify the code. This method implements the typical move of the dragged rows or tree-view node. This is especially useful in case of a tree-view, but is also the preferred way to move rows around in simple tables.

This **ON DROP** code example uses the `dropInternal()` method:

```plaintext
DEFINE dnd ui.DragDrop
...
DISPLAY ARRAY arr_tree TO sr_tree.* ...
...
  ON DROP (dnd)
    CALL dnd.dropInternal()
...
END DISPLAY
```

If you want to implement by hand the code to drop a node in a tree-view, you must check the index returned by the `ui.DragDrop.getLocationParent()` method to detect if the object was dropped as a sibling or as a child node, and execute the code corresponding to the drop operation: If the drop target row index returned by `getLocationRow()` is a child of the parent row index returned by `getLocationParent()`, the new row must be inserted before `getLocationRow()`: otherwise the new row must be added as a child of the parent node identified by `getLocationParent()`.

**Related concepts**

- The `ui.DragDrop` class is used to control the events related to drag & drop events.

**DIALOG control instructions**

_Dialog control instructions_ are language instructions dedicated to dialog control, to programmatically force the dialog to behave in a given way.

For example the **NEXT FIELD** instruction forces the focus to a specific form field.

- **NEXT FIELD instruction** on page 1389
• CLEAR instruction in dialogs on page 1389
• DISPLAY TO / BY NAME instruction on page 1537
• CONTINUE DIALOG instruction on page 1537
• EXIT DIALOG instruction on page 1538
• ACCEPT DIALOG instruction on page 1538
• CANCEL DIALOG instruction on page 1539
• CANCEL DELETE instruction on page 1450
• CANCEL INSERT instruction on page 1451

NEXT FIELD instruction

Understanding the NEXT FIELD instruction

The NEXT FIELD field-name instruction gives the focus to the specified field and forces the dialog to stay in that field.

This instruction can be used to control field input, in BEFORE FIELD, ON CHANGE or AFTER FIELD blocks, it can also force a DISPLAY ARRAY or INPUT ARRAY to stay in the current row when NEXT FIELD is used in the AFTER ROW block.

If it exists, the BEFORE FIELD block of the corresponding field is executed.

In editable dialogs, the purpose of the NEXT FIELD instruction is to give the focus to an editable field. Make sure that the field specified in NEXT FIELD is active, or use NEXT FIELD CURRENT. Non-editable fields are fields defined with the NOENTRY attribute, fields disabled at runtime with DIALOG.setFieldActive(), or fields using a widget that does not allow input, such as a LABEL.

In a DISPLAY ARRAY using the FOCUSONFIELD attribute, NEXT FIELD can be used in conjunction with DIALOG.setCurrentRow(), to set the focus to a specific cell in the list.

Instead of the NEXT FIELD instruction, you can use the DIALOG.nextField("field-name") method to register a field, for example when the name is not known at compile time. However, this method only registers the field. It does not stop code execution, like the NEXT FIELD instruction does. You must execute a CONTINUE DIALOG to get the same behavior as NEXT FIELD.

Form field identification with NEXT FIELD

With the NEXT FIELD instruction, fields are identified by the form field name specification, not the program variable name used by the dialog. Form fields are bound to program variables with the binding clause of the dialog instruction (INPUT variable-list FROM field-list, INPUT BY NAME variable-list, CONSTRUCT BY NAME sql ON column-list, CONSTRUCT sql ON column-list FROM field-list, INPUT ARRAY array-name FROM screen-array.*).

The field name specification can be any of the following:

• field-name
• table-name.field-name
• screen-record-name.field-name
• FORMONLY.field-name

Here are some examples:

• "cust_name"
• "customer.cust_name"
• "cust_screen_record.cust_name"
• "item_screen_array.item_label"
• "formonly.total"

When no field name prefix is used, the first form field matching that simple field name is used.
When using a prefix in the field name specification, it must match the field prefix assigned by the dialog field binding method used at the beginning of the interactive statement: When no screen-record has been explicitly specified in the field binding clause (for example, when using INPUT BY NAME variable-list), the field prefix must be the database table name (or FORMONLY) used in the form file, or any valid screen-record using that field. When the FROM clause of the dialog specifies an explicit screen-record (for example, in INPUT variable-list FROM screen-record.* / field-list-with-screen-record-prefix or INPUT ARRAY array-name FROM screen-array.*), the field prefix must be the screen-record name used in the FROM clause.

Abstract field identification is supported with the CURRENT, NEXT and PREVIOUS keywords. These keywords represent the current, next and previous fields respectively. When using FIELD ORDER FORM, the NEXT and PREVIOUS options follow the tabbing order defined by the form. Otherwise, they follow the order defined by the input binding list (with the FROM or BY NAME clause).

In a procedural dialog, if the focus is in the first field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD PREVIOUS will jump out of the current sub-dialog and set the focus to the previous sub-dialog. If the focus is in the last field of an INPUT or CONSTRUCT sub-dialog, NEXT FIELD NEXT will jump out of the current sub-dialog and set the focus to the next sub-dialog. NEXT FIELD NEXT or NEXT FIELD PREVIOUS also jumps to another sub-dialog when the focus is in a DISPLAY ARRAY sub-dialog. However, when using an INPUT ARRAY sub-dialog, NEXT FIELD NEXT from within the last column will loop to the first column of the current row, and NEXT FIELD PREVIOUS from within the first column will jump to the last column of the current row - the focus stays in the current INPUT ARRAY sub-dialog. When another sub-dialog gets the focus because of a NEXT FIELD NEXT/ PREVIOUS, the newly-selected field depends on the sub-dialog type, following the tabbing order as if the end-user had pressed the tab or Shift-Tab key combination.

**NEXT FIELD to a non-editable INPUT / INPUT ARRAY / CONSTRUCT field**

Non-editable fields are fields defined with the NOENTRY attribute, fields disabled with ui.Dialog.setFieldActive("field-name", FALSE), or fields using a widget that does not allow input, such as a LABEL.

If a NEXT FIELD instruction specifies a non-editable field, the BEFORE FIELD block of that field is executed. Then the dialog tries to give the focus to that field. Since the field cannot get the focus, the dialog will perform the last pressed navigation key (Tab, Shift-Tab, Left, Right, Up, Down, Accept) and execute the related control blocks, including the AFTER FIELD block of the non-editable field. If no last key is identified, the dialog considers Tab as fallback and moves to the next editable field as defined by the FIELD ORDER mode used by the dialog. Doing a NEXT FIELD to a non-editable field can lead to infinite loops in the dialog; Use NEXT FIELD CURRENT instead.

When selecting a non-editable field with NEXT FIELD NEXT, the runtime system will re-select the current field since it is the next editable field in the dialog. As a result the end user sees no change.

**NEXT FIELD in procedural DIALOG blocks**

In a procedural dialog block, the NEXT FIELD field-name instruction gives the focus to the specified field controlled by INPUT, INPUT ARRAY or CONSTRUCT, or to a read-only list when using DISPLAY ARRAY.

When using a DISPLAY ARRAY sub-dialog, it is possible to give the focus to the list, by specifying the name of the first column as argument for NEXT FIELD.

If the target field specified in the NEXT FIELD instruction is inside the current sub-dialog, neither AFTER FIELD nor AFTER ROW will be invoked for the field or list you are leaving. However, the BEFORE FIELD control blocks of the destination field (or the BEFORE ROW in case of read-only list) will be executed.

If the target field specified in the NEXT FIELD instruction is outside the current sub-dialog, the AFTER FIELD, AFTER INSERT, AFTER ROW, and AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be invoked for the field or list you are leaving. Form-level validation rules will also be checked, as if the user had selected the new sub-dialog himself. This guarantees the current sub-dialog is left in a consistent state. The BEFORE INPUT/DISPLAY/CONSTRUCT, BEFORE ROW and the BEFORE FIELD control blocks of the destination field / list will then be executed.
NEXT FIELD in record list control blocks

When using NEXT FIELD in AFTER ROW or in ON ROW CHANGE of a DISPLAY ARRAY or INPUT ARRAY, the dialog will stay in the current row and give control back to the user. This behavior allows you to implement data input rules:

```plaintext
AFTER ROW  
  IF NOT int_flag AND arr_count() <= arr_curr() THEN  
    IF arr[arr_curr()].it_count * arr[arr_curr()].it_value > maxval THEN  
      ERROR "Amount of line exceeds max value."  
      NEXT FIELD item_count  
    END IF  
  END IF
```

  - Form-level validation rules can be defined for each field controlled by a dialog.

- **Understanding multiple dialogs** on page 1481
  - Multiple dialogs are defined with DIALOG blocks inside a FUNCTION.

- **CLEAR instruction in dialogs**

  The CLEAR field-list and CLEAR SCREEN ARRAY screen-array.* instructions clear the value buffer of specified form fields. The buffers are directly changed in the current form, and the program variables bound to the dialog are left unchanged. CLEAR can be used outside any dialog instruction, such as the DISPLAY BY NAME / TO instructions.

  When a dialog is configured with the UNBUFFERED mode, there is no reason to clear field buffers since any variable assignment will synchronize field buffers. Actually, changing the field buffers with DISPLAY or CLEAR instruction in an UNBUFFERED dialog will have no visual effect, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. To clear fields of an UNBUFFERED dialog, just set to NULL the variables bound to the dialog. However, when using a CONSTRUCT, no program variables are associated with the dialog and no UNBUFFERED concept exits, and the CLEAR or DISPLAY TO / BY NAME instructions are the only way to modify the CONSTRUCT fields.

  A screen array with a screen-line specification doesn't make much sense in a GUI application using TABLE containers, you can therefore use the CLEAR SCREEN ARRAY instruction to clear all rows of a list.

- **Related concepts**

  - **CLEAR field-list** on page 1351
    - The CLEAR field-list instruction clears specific fields in the current form.

  - **CLEAR SCREEN ARRAY** on page 1350
    - The CLEAR SCREEN ARRAY instruction clears the values of all rows of the form list identified by the specified screen array.

  - **TABLE container** on page 1217
    - Defines a re-sizable table designed to display a list of records.

  - **The buffered and unbuffered modes** on page 1618
The buffered and unbuffered mode control the synchronization of program variables and form fields.

**DISPLAY TO / BY NAME instruction**

The `DISPLAY variable-list TO field-list` or `DISPLAY BY NAME variable-list` instruction fills the value buffers of specified form fields with the values contained in the specified program variables. The `DISPLAY` instruction changes the buffers directly in the current form, not the program variables bound to the dialog. `DISPLAY` can be used outside any dialog instruction, in the same way as the `CLEAR` instruction. `DISPLAY` also sets the modification flag of fields.

As `DIALOG` is typically used with the `UNBUFFERED` mode, there is no reason to set field buffers in a `DIALOG` block since any variable assignment will synchronize field buffers. Actually, changing the field buffers with the `DISPLAY` or `CLEAR` instruction will have no visual effect if the fields are used by a dialog working in `UNBUFFERED` mode, because the variables bound to the dialog will be used to reset the field buffer just before giving control back to the user. So if you want to set field values, just assign the variables and the fields will be synchronized. However, when using a `CONSTRUCT` binding, you may want to set field buffers with this `DISPLAY` instruction, as there are no program variables bound to fields (with `CONSTRUCT`, only one string variable is bound to hold the SQL condition).

Instead of using a `DISPLAY` instruction to set the modification flag of fields to simulate user input, use the `DIALOG.setFieldTouched()` method instead.

**Related concepts**

- `ui.Dialog.setFieldTouched` on page 2403
  Sets the modification flag of the specified field.
- `DISPLAY BY NAME` on page 1348
  The `DISPLAY BY NAME` instruction displays data to form fields explicitly *by name*.
- `DISPLAY TO` on page 1346
  The `DISPLAY TO` instruction displays data to form fields explicitly.
- `Input field modification flag` on page 1623
  Each input field controlled by a dialog instruction has a modification flag.
- `The buffered and unbuffered modes` on page 1618
  The buffered and unbuffered mode control the synchronization of program variables and form fields.
- `The CONSTRUCT sub-dialog` on page 1492
  The `CONSTRUCT` sub-dialog provides database query by example feature, converting search criteria entered by the user into an SQL *WHERE* condition that can be used to execute a `SELECT` statement.

**CONTINUE DIALOG instruction**

The `CONTINUE DIALOG` statement continues the execution of a `DIALOG` instruction, skipping all statements appearing after this instruction.

Control returns to the dialog instruction, which executes remaining control blocks as if the program reached the end of the current control block. Then the control goes back to the user and the dialog waits for a new event.

The `CONTINUE DIALOG` statement is useful when program control is nested within multiple conditional statements, and you want to return control to the user by skipping the rest of the statements.

In the following code example, an `ON ACTION` block gives control back to the dialog, skipping all instructions below line 04:

```plaintext
ON ACTION zoom
  IF p_cust.cust_id IS NULL OR p_cust.cust_name IS NULL THEN
    ERROR "Zoom window cannot be opened if no info to identify customer"
    CONTINUE DIALOG
  END IF
  IF p_cust.cust_address IS NULL THEN
    ...
```
If CONTINUE DIALOG is called in a control block that is not AFTER DIALOG, further control blocks might be executed depending on the context. Actually, CONTINUE DIALOG just instructs the dialog to continue as if the code in the control block was terminated (it is a kind of GOTO end_of_control_block). However, when executed in AFTER DIALOG, the focus returns to the current field or read-only list. In this case the BEFORE ROW and BEFORE FIELD triggers will be invoked.

A CONTINUE DIALOG in AFTER FIELD, AFTER INPUT, AFTER DISPLAY or AFTER CONSTRUCT will only stop the program flow of the current block of statements; instructions after CONTINUE DIALOG will not be executed. If the user has selected a field in a different sub-dialog, this new field will get the focus and all necessary AFTER / BEFORE control blocks will be executed.

In case of input error in a field, the best practice is to use a NEXT FIELD instruction to stay in the dialog and set the focus to the field that the user has to correct.

**Related concepts**

NEXT FIELD instruction on page 1389

**EXIT DIALOG instruction**

The EXIT DIALOG statement terminates a procedural DIALOG block without any further control block execution.

**Note:** When used in a declarative DIALOG block, the EXIT DIALOG instruction does only make sense when the declarative dialog block is included in a procedural dialog block with the SUBDIALOG clause.

Program flow resumes at the Instruction following the END DIALOG keywords. Blocks such as AFTER DIALOG will not be executed.

```
ON ACTION quit
   EXIT DIALOG
```

When leaving the DIALOG instruction, all form items used by the dialog will be disabled until another interactive statement takes control.

The EXIT DIALOG instruction leaves the DIALOG block immediately, while CANCEL DIALOG makes some additional tasks.

**Related concepts**

CANCEL DIALOG instruction on page 1539
ACCEPT DIALOG instruction on page 1538

**ACCEPT DIALOG instruction**

The ACCEPT DIALOG statement validates all input fields bound to the DIALOG instruction and leaves the block if no error is raised.

**Note:** When used in a declarative DIALOG block, the ACCEPT DIALOG instruction does only make sense when the declarative dialog block is included in a procedural dialog block with the SUBDIALOG clause.

When defined in the dialog block, ON CHANGE, AFTER FIELD, AFTER ROW, AFTER INPUT/DISPLAY/CONSTRUCT control blocks will be executed when ACCEPT DIALOG is performed.

The statements appearing after the ACCEPT DIALOG instruction will be skipped.

You typically code an ACCEPT DIALOG in an ON ACTION accept block:

```
ON ACTION accept ACCEPT DIALOG
```

**Important:** Any usage of ACCEPT DIALOG outside an ON ACTION accept block is not intended and its behavior is undefined.

Input field validation is a process that does several successive validation tasks:

1. The current field value is checked, depending on the variable data type (for example, the user must input a valid date in a DATE field).
2. **NOT NULL** field attributes are checked for all input fields. This attribute forces the field to have a value set by program or entered by the user. If the field contains no value, the constraint is not satisfied. Input values are right-trimmed, so if the user inputs only spaces, this corresponds to a NULL value which does not fulfill the **NOT NULL** constraint.

3. **REQUIRED** field attributes are checked for all input fields. This attribute forces the field to have a default value, or to be modified by the user or by program with a **DISPLAY TO / BY NAME** or **DIALOG.setFieldTouched()** call. If the field was not modified during the dialog, the **REQUIRED** constraint is not satisfied.

4. **INCLUDE** field attributes are checked for all input fields. This attribute forces the field to contain a value that is listed in the include list. If the field contains a value that is not in the list, the constraint is not satisfied.

If a field does not satisfy one of these constraints, dialog termination is canceled, an error message is displayed, and the focus goes to the first field causing a problem.

After input field validation has succeeded, different types of control blocks will be executed, such as **AFTER FIELD**, **AFTER ROW**, **AFTER INPUT** and **AFTER DIALOG**.

In order to validate some parts of the dialog without leaving the block, use the **DIALOG.validate()** method.

**Related concepts**

- **Input field modification flag** on page 1623
- Each input field controlled by a dialog instruction has a modification flag.
- **CANCEL DIALOG instruction** on page 1539
- **EXIT DIALOG instruction** on page 1538

**CANCEL DIALOG instruction**

The **CANCEL DIALOG** statement terminates a procedural **DIALOG** block, after executing the **AFTER INPUT/DISPLAY/CONSTRUCT** control block of the current sub-dialog, and the **AFTER DIALOG** control block.

**Note:** When used in a declarative **DIALOG** block, the **CANCEL DIALOG** instruction does only make sense when the declarative dialog block is included in a procedural dialog block with the **SUBDIALOG** clause.

The **CANCEL DIALOG** instruction can be used from multiple dialogs to mimic the cancel default action of single dialogs.

The **CANCEL DIALOG** instruction makes the following:

1. Set the **INT_FLAG** register to **TRUE**.
2. If defined, execute the code in the **AFTER INPUT, AFTER DISPLAY** or **AFTER CONSTRUCT** block of the current sub-dialog.
3. If defined, execute the code in the **AFTER DIALOG** block.

The statements appearing after the **CANCEL DIALOG** instruction will be skipped.

You typically code an **CANCEL DIALOG** in an **ON ACTION cancel** block:

```
ON ACTION cancel CANCEL DIALOG
```

**Note:** The default settings regarding action attributes for the cancel action define the **validate** attribute to "no", in order to avoid current field validation for this action. This is important when using the **UNBUFFERED** mode. For more details, see **Actions configuration for field validation** on page 1620.

**Related concepts**

- **EXIT DIALOG instruction** on page 1538
- **ACCEPT DIALOG instruction** on page 1538

**CANCEL DELETE instruction**

In a list controlled by an **INPUT ARRAY**, row deletion can be canceled by using the **CANCEL DELETE** instruction in the **BEFORE DELETE** block. Using this instruction in a different place will generate a compilation error.
When the CANCEL DELETE instruction is executed, the current BEFORE DELETE block is terminated without any other trigger execution (no BEFORE ROW or BEFORE FIELD is executed), and the program execution continues in the user event loop.

You can, for example, prevent row deletion based on some condition:

```plaintext
BEFORE DELETE
  IF user_can_delete() == FALSE THEN
    ERROR "You are not allowed to delete rows"
    CANCEL DELETE
  END IF
```

The instructions that appear after CANCEL DELETE will be skipped.

If the row deletion condition is known before the delete action occurs, disable the delete action to prevent the user from performing a delete row action with the DIALOG.setActionActive() method:

```plaintext
CALL DIALOG.setActionActive("delete", FALSE)
```

It is also possible to prevent the user from deleting rows with the DELETE ROW = FALSE option in the ATTRIBUTE clause.

**Related concepts**

CANCEL INSERT instruction

In a list controlled by an INPUT ARRAY, row creation can be canceled by the program with the CANCEL INSERT instruction. This instruction can only be used in the BEFORE INSERT and AFTER INSERT control blocks. If it appears at a different place, the compiler will generate an error.

The instructions that appear after CANCEL INSERT will be skipped.

If the row creation condition is known before the insert/append action occurs, disable the insert and/or append actions to prevent the user from creating new rows, with DIALOG.setActionActive():

```plaintext
CALL DIALOG.setActionActive("insert", FALSE)
CALL DIALOG.setActionActive("append", FALSE)
```

However, this will not prevent the user from appending a new temporary row at the end of the list, when moving down after the last row. To prevent row creation completely, use the INSERT ROW = FALSE and APPEND ROW = FALSE options in the ATTRIBUTE clause of INPUT ARRAY, or combine with the AUTO APPEND = FALSE attribute.

**CANCEL INSERT in BEFORE INSERT**

A CANCEL INSERT executed inside a BEFORE INSERT block prevents the new row creation. The following tasks are performed:

1. No new row will be created (the new row is not yet shown to the user).
2. The BEFORE INSERT block is terminated (further instructions are skipped).
3. The BEFORE ROW and BEFORE FIELD triggers are executed.
4. Control goes back to the user.

You can, for example, cancel a row creation if the user is not allowed to create rows:

```plaintext
BEFORE INSERT
  IF NOT user_can_insert THEN
    ERROR "You are not allowed to insert rows"
    CANCEL INSERT
  END IF
```
Executing CANCEL INSERT in BEFORE INSERT will also cancel a temporary row creation, except when there are no more rows in the list. In this case, CANCEL INSERT will just be ignored and leave the new row as is (otherwise, the instruction would loop without end). You can prevent automatic temporary row creation with the AUTO APPEND=FALSE attribute. If AUTO APPEND=FALSE and a CANCEL INSERT is executed in BEFORE INSERT (user has invoked an append action), the temporary row will be deleted and list will remain empty if it was the last row.

CANCEL INSERT in AFTER INSERT

A CANCEL INSERT executed inside an AFTER INSERT block removes the newly created row. The following tasks are performed:

1. The newly created row is removed from the list (the row exists now and user has entered data).
2. The AFTER INSERT block is terminated (further instructions are skipped).
3. The BEFORE ROW and BEFORE FIELD triggers are executed.
4. The control goes back to the user.

You can, for example, cancel a row insertion if a database error occurs when you try to insert the row into a database table:

```plaintext
AFTER INSERT
  WHENEVER ERROR CONTINUE
  LET r = DIALOG.getCurrentRow("s_items")
  INSERT INTO items VALUES ( p_items[r].* )
  WHENEVER ERROR STOP
  IF SQLCA.SQLCODE<>0 THEN
    ERROR SQLERRMESSAGE
    CANCEL INSERT
  END IF
```

Related concepts

BEFORE DELETE block on page 1443
Appending rows in INPUT ARRAY on page 1749

Rows appended at the end of an editable list are temporary until they are edited.

Examples

Declarative dialogs usage examples.

Example 1: Simple input

The module "comment.4gl":

```plaintext
PUBLIC TYPE cb_comment_event FUNCTION (event STRING)
PRIVATE DEFINE cb_ce cb_comment_event

PRIVATE DEFINE the_comment VARCHAR(200)

PUBLIC FUNCTION set_event_callback(f cb_comment_event)
  LET cb_ce = f
END FUNCTION

PUBLIC FUNCTION get_comment()
  RETURN the_comment
END FUNCTION

DIALOG comment_input()
  INPUT BY NAME the_comment
  ON ACTION add_sep ATTRIBUTES(TEXT="Add sep")
    LET the_comment = the_comment || "\n---"
  IF cb_ce IS NOT NULL THEN
    CALL cb_ce("comment_changed")
  END IF
```
ON ACTION clr_cmt ATTRIBUTES(TEXT="Clear")
    LET the_comment = NULL
    IF cb_ce IS NOT NULL THEN
        CALL cb_ce("comment_changed")
    END IF
END INPUT
END DIALOG

For the complete example, see Example 3: DIALOG with SUBDIALOG on page 1544.

**Example 2: Simple list**

The module "list1.4gl":

```plaintext
DEFINE arr DYNAMIC ARRAY OF RECORD
    id INTEGER,
    name VARCHAR(50)
END RECORD

FUNCTION start_list1()
    DEFINE i INTEGER
    IF ui.Window.forName("w_list1") IS NULL THEN
        FOR i=1 TO 10
            LET arr[i].id = i
            LET arr[i].name = "Record "||i
        END FOR
        OPEN WINDOW w_list1 WITH FORM "simple_list"
        START DIALOG control_list1
    ELSE
        CURRENT WINDOW IS w_list1
    END IF
END FUNCTION

FUNCTION terminate_list1()
    TERMINATE DIALOG control_list1
    CLOSE WINDOW w_list1
END FUNCTION

DIALOG control_list1()
    DISPLAY ARRAY arr TO sr.*
    ON ACTION add_row
        CALL DIALOG.appendRow("sr")
        LET arr[arr.getLength()].id = arr.getLength()
        LET arr[arr.getLength()].name = "[new record]"
    ON ACTION close
        CALL terminate_list1()
    END DISPLAY
END DIALOG
```

For the complete example, see Example 1: Two independent record lists on page 1606.

**Parallel dialogs (START DIALOG)**

The **START DIALOG** and **TERMINATE DIALOG** instructions provide dialogs functionality executing concurrently in different application forms.

- Understanding parallel dialogs on page 1601
- Syntax of the **START DIALOG** instruction on page 1603
- Syntax of the **TERMINATE DIALOG** instruction on page 1604
- Parallel dialog programming steps on page 1604
- Using parallel dialogs on page 1605
- Examples on page 1606
• Example 1: Two independent record lists on page 1606

Understanding parallel dialogs

Parallel dialogs allow to control several forms simultaneously.

Parallel dialogs use different declarative DIALOG blocks, in conjunction with the START DIALOG and TERMINATE DIALOG instructions, and an event loop using the fgl_eventLoop() built-in function, in order to control several forms simultaneously.

Important: This feature is only for mobile platforms.

Each dialog acts independently to control several elements of a window/form. During the execution of parallel dialogs, the user can switch to a window/form that is controlled by another running declarative DIALOG block. For more details about categories of dialogs, see What are dialog controllers? on page 1608.

Important: On mobile devices, parallel dialogs do not support INPUT ARRAY declarative dialogs.

The START DIALOG and TERMINATE DIALOG instructions use declarative dialogs, described in detail in the Declarative dialogs (DIALOG - at module level) on page 1546 chapter.

The parallel dialog feature was introduced to implement mobile applications, where several forms can be accessed simultaneously, for example to get "split views" on mobile devices:
In terms of semantics, behavior and control block execution, a declarative dialog started with a START DIALOG instruction behaves like a procedural DIALOG block.

**Important**: Parallel dialogs implicitly use the UNBUFFERED mode. It is not possible to change this mode when using parallel dialogs.

In order to execute parallel dialogs, you must implement a main interaction event loop, by using the fgl_eventLoop() built-in function. The minimal event loop code to implement is:

```c
WHILE fgl_eventLoop()
END WHILE
```

Once the declarative dialogs and the interaction event loop are defined, it is possible to create the windows with OPEN WINDOW, and initiate the dialogs with the START DIALOG instruction.

If needed, show a given dialog window with the CURRENT WINDOW instruction. Additionally, (especially when implementing split views), you may want to “restart” a detail dialog, for example when selecting a new row in the main record list. To restart the detail dialog, execute TERMINATE DIALOG, followed by START DIALOG for the detail dialog. See split view programming for more details.
To finish a given dialog, execute the TERMINATE DIALOG instruction and close the dedicated window with CLOSE WINDOW window-name.

From a set of running parallel dialogs, it is possible to switch to a modal dialog by creating a dedicated window, and executing a procedural dialog instruction. When the procedural dialog is terminated, close the dedicated window, and the control will go back to the parallel dialog set.

**Related concepts**

*Windows and forms* on page 1032
The section describes the concept of windows and forms in the language.

*fgl_eventloop()* on page 2165
Waits for a user interaction event.

**Syntax of the START DIALOG instruction**

Starts the instance of a declarative dialog.

**Syntax**

```
START DIALOG dialog-name
```

1. *dialog-name* is the identifier of a declarative DIALOG block.

**Usage**

The START DIALOG instruction starts the declarative dialog block identified by the name passed.

The current window/form will be used to attach form fields and action views to the variables and action handlers implemented in the referenced declarative dialog.

The START DIALOG does in fact register the specified dialog to be activated when the parallel dialog event loop executes.

The started dialog can be terminated with TERMINATE DIALOG.

**Example**

This example shows a START DIALOG instruction in a function that initializes a parallel dialog in a split view context:

```
FUNCTION params()
  IF ui.Window.forName("w_params") IS NULL THEN
    OPEN WINDOW w_params WITH FORM "parameters" ATTRIBUTES(TYPE=LEFT)
    LET params.user_name="Tom"
    LET params.auto_sync="Y"
    DISPLAY BY NAME params.*
    START DIALOG d_params_menu
  END IF
  CURRENT WINDOW IS w_params
END FUNCTION
```

**Related concepts**

*Syntax of the TERMINATE DIALOG instruction* on page 1604
Terminates the instance of a declarative dialog.

*Syntax of the declarative DIALOG block* on page 1547
The declarative DIALOG block defines an interactive instruction that can be used by a parent DIALOG, or as parallel dialog.

*fgl_eventloop()* on page 2165
Waits for a user interaction event.

Syntax of the TERMINATE DIALOG instruction
Terminates the instance of a declarative dialog.

Syntax

```
TERMINATE DIALOG dialog-name
```

1. *dialog-name* is the identifier of a declarative DIALOG block.

Usage

The TERMINATE DIALOG instruction stops a declarative dialog identified by the name passed.

If the intent is to finish the parallel dialog, the corresponding window/form bound to the dialog should be closed after TERMINATE DIALOG.

However, TERMINATE DIALOG can also be used in conjunction with START DIALOG, to achieve a "restart" of the parallel dialog.

**Note:** TERMINATE DIALOG will not raise an error, if the dialog was not yet started with START DIALOG. This is required to implement the "restart" pattern.

The next code example shows a typical restart pattern on a detail parallel dialog, when a new row is selected in the master list:

```
DIALOG d_list_view()
  DISPLAY ARRAY arr TO sr.*
    ATTRIBUTES(ACCESSORYTYPE=DISCLOSUREINDICATOR)
    BEFORE ROW -- in BEFORE ROW, we restart the details view
      CURRENT WINDOW IS w_right
      TERMINATE DIALOG d_detail_view
      LET curr_pa = arr_curr()
      DISPLAY BY NAME arr[curr_pa],*
      DISPLAY SFMT("tapped row %1",arr_curr()) TO info
      START DIALOG d_detail_view
      CURRENT WINDOW IS w_left
  ...
```

Parallel dialog programming steps

This procedure describes how to implement parallel dialogs with a declarative DIALOG block.

1. Create the forms and declarative dialog modules as described in Declarative dialog programming steps on page 1553.

2. Define a FUNCTION to create the dialog instance.

   a) Add a test to check if the window and form combination dedicated to the dialog is already created, using `ui.Window.forName()`. If the window does not yet exist, create it by using the OPEN WINDOW *window-name* WITH FORM instruction. If the window exists, make it current with the CURRENT WINDOW IS *window-name* instruction.
b) Fill the module variables (the data model) with data. For lists, you typically use a result set cursor.
c) Start the dialog with the `START DIALOG dialog-name` instruction.

3. Define a `FUNCTION` to terminate the dialog instance.
   a) In the function, finish the dialog with `TERMINATE DIALOG dialog-name`.
   b) Close the window dedicated to the dialog with `CLOSE WINDOW window-name`.
   c) If needed, free the data model (clear large program arrays) and database cursors, to save memory.

4. If needed, add an `ON ACTION close` action handler to the declarative dialog, that calls the terminate function. This allows the end user to close the front-end window and stop the dialog.

5. In another module, implement the `WHILE` loop using the `fgl_eventLoop()` built-in function to handle interaction events for parallel dialogs. This module uses the start and terminate functions to control the individual dialog modules.

   The simplest form of the user interaction event loop is:

   ```
   WHILE fgl_eventLoop()
   END WHILE
   ```

**Related concepts**

*Using parallel dialogs* on page 1605
Dialog coding concepts, configuration and code structure.

**Using parallel dialogs**
Dialog coding concepts, configuration and code structure.

Parallel dialogs are implemented with declarative `DIALOG` blocks:

```
DIALOG control_list1()
   DISPLAY ARRAY arr TO sr.*
   ...
END DISPLAY
END DIALOG
```

Instances of declarative dialogs are started with the `START DIALOG` instruction (typically preceded by an `OPEN WINDOW` instruction that creates the corresponding window+form):

```
OPEN WINDOW w_list1 WITH FORM "simple_list"
START DIALOG control_list1
```

Instances of declarative dialogs are stopped with the `TERMINATE DIALOG` instruction:

```
TERMINATE DIALOG control_list1
```

In order to initiate parallel dialogs, the program must run the user interface event loop by calling the `fgl_eventloop()` on page 2165 built-in function in a `WHILE` loop.

The simplest form of the user interaction event loop is:

```
WHILE fgl_eventLoop()
END WHILE
```

Before or during the user interface event loop, modal dialogs can be executed without conflicts. For more details about parallel dialogs versus modal dialogs, see *What are dialog controllers?* on page 1608.
Examples
Parallel dialogs usage examples.
Example 1: Two independent record lists

Form file "simple_list.per":

```
LAYOUT
GRID
{
  <T t1                             >
  [c1  |c2                          ]
  [c1  |c2                          ]
  [c1  |c2                          ]
}
END
END
ATTRIBUTES
  c1 = FORMONLY.col1;
  c2 = FORMONLY.col2;
END
INSTRUCTIONS
  SCREEN RECORD sr(FORMONLY.*);
END
```

The module "list1.4gl":

```
DEFINE arr DYNAMIC ARRAY OF RECORD
  id INTEGER,
  name VARCHAR(50)
END RECORD

FUNCTION start_list1()
  DEFINE i INTEGER
  IF ui.Window.forName("w_list1") IS NULL THEN
    FOR i=1 TO 10
      LET arr[i].id = i
      LET arr[i].name = "Record "||i
    END FOR
    OPEN WINDOW w_list1 WITH FORM "simple_list"
    START DIALOG control_list1
  ELSE
    CURRENT WINDOW IS w_list1
  END IF
END FUNCTION

FUNCTION terminate_list1()
  TERMINATE DIALOG control_list1
  CLOSE WINDOW w_list1
END FUNCTION

DIALOG control_list1()
  DISPLAY ARRAY arr TO sr.*
  ON ACTION add_row
    CALL DIALOG.appendRow("sr")
    LET arr[arr.getLength()].id = arr.getLength()
    LET arr[arr.getLength()].name = "[new record]"
  END ACTION
  ON ACTION close
    CALL terminate_list1()
  END ACTION
END DISPLAY
END DIALOG
```
The module "list2.4gl" (quite the same code as list1.4gl):

```plaintext
DEFINE arr DYNAMIC ARRAY OF RECORD
    id INTEGER,
    name VARCHAR(50)
END RECORD

FUNCTION start_list2()
    DEFINE i INTEGER
    IF ui.Window.forName("w_list2") IS NULL THEN
        FOR i=1 TO 10
            LET arr[i].id = i
            LET arr[i].name = "Record "||i
        END FOR
        OPEN WINDOW w_list2 WITH FORM "simple_list"
        START DIALOG control_list2
    ELSE
        CURRENT WINDOW IS w_list2
    END IF
END FUNCTION

FUNCTION terminate_list2()
    TERMINATE DIALOG control_list2
    CLOSE WINDOW w_list2
END FUNCTION

DIALOG control_list2()
    DISPLAY ARRAY arr TO sr.*
    ON ACTION clear_row
        INITIALIZE arr[arr_curr()].* TO NULL
    ON ACTION close
        CALL terminate_list2()
END DISPLAY
END DIALOG
```

Program source code:

```plaintext
IMPORT FGL list1
IMPORT FGL list2
MAIN
    OPTIONS INPUT WRAP
    CALL start_list1()
    CALL start_list2()
    WHILE fgl_eventloop()
        END WHILE
END MAIN
```

- Front-End function calls on page 1615

The model-view-controller paradigm

The dynamic user interface architecture is based on the Model-View-Controller (MVC) paradigm. The model defines the object to be displayed (typically the application data that is stored in program variables). The view defines the decoration of the model (how the model must be displayed to the screen, this is typically the form). The controller is the interactive instruction that implements the program code to handle the model.

Views are defined in the abstract user interface tree from compiled .42f forms loaded by programs. The program variables act as models, and you implement the controllers with interactive instructions, such as DIALOG or INPUT. Controllers also define action handlers that contain the program code to be executed when an action view is triggered.

Normally the controllers are not intended to provide any decoration information, as that is the purpose of views. Over the course of the history of the language, however, some interactive instructions such as MENU define both the controller and some presentation information such as menu title, command labels, and comments. In this case, the runtime system automatically creates the view with that information; you can still associate other views to the same controller.

- Variables on page 366

What are dialog controllers?

Application forms are controlled by interactive instruction blocks called dialogs. These blocks perform the common tasks associated with the form, such as field input and action handling.

The interactive instructions allow the program to respond to user actions and data input.
Simple display (non-interactive)

The DISPLAY BY NAME / TO instruction allows you to display program variable data in the fields of a form and continue the program flow without giving control to the end user. This is in fact not an interactive instruction, as it just displays data to the current form, and returns immediately. However, it may be used in interactive instructions to display information to the end user.

**Note:** When using the UNBUFFERED mode of a dialog, you do not need to use the DISPLAY BY NAME / TO instruction to synchronize program variables and form fields.

The MESSAGE and ERROR instructions are also simple display instructions without user interaction. These instructions are typically used to display a warning message to the end user.

Modal dialogs and parallel dialogs

Interactive instructions can be implemented as modal or parallel dialogs. *Modal dialogs* control a given window, and that window closes when the dialog is accepted or canceled. The window displays on top of any existing windows which are not accessible while the modal dialog executes. *Parallel dialogs* allow access to several windows simultaneously; the user can switch from one window to the other. Parallel dialogs are mainly used to implement split views on mobile platforms.

The interactive dialog blocks

The singular MENU instruction handles a list of choices to activate a specific function of the program. No field input is possible with this instruction. The user can only select an action from the list.

The singular INPUT instruction is designed for simple record input. It enables the fields in a form for input, waits while the user types data into the fields, and proceeds after the user accepts or cancels the dialog.

The singular DISPLAY ARRAY instruction is used to browse a list of records. It allows the user to view the contents of a program array of records, scrolling the record list on the screen and choosing a specific record. DISPLAY ARRAY implements by default a read-only list of records, but can be extended to become a modifiable list with list modification triggers such as ON INSERT.

The singular INPUT ARRAY instruction supports record list input. It allows the user to alter the contents of records of a program array, and to insert and delete records.

The singular CONSTRUCT instruction is designed to let the user enter search criteria for a database query. The user can enter a value or a range of values for one or several form fields, and your program looks up the database rows that satisfy the requirements.

The procedural DIALOG instruction (placed in the program flow) allows you to combine several INPUT, DISPLAY ARRAY, INPUT ARRAY and CONSTRUCT functionality within the same form.

The declarative DIALOG block (defined in a module at the same level as a function) allows you to implement individual MENU, INPUT, DISPLAY ARRAY, INPUT ARRAY and CONSTRUCT functionality, that will perform in parallel on several forms, when used with the START DIALOG and TERMINATE DIALOG instructions. Declarative DIALOG blocks can also be associated with a procedural DIALOG instruction through the SUBDIALOG clause, it will then act as a procedural DIALOG sub-dialog. See Using declarative dialogs on page 1553.

Dynamic dialogs

When the form structure and field definitions can only be determined at runtime, it is possible to implement Dynamic Dialogs on page 1903, using generic code that will control a form generated on the fly.

Dynamic dialogs can implement all types of dialogs like static dialogs do. However, this feature should only be used in specific cases where regular static dialog instructions cannot be used. Static dialog code is more readable than generic code implementing dynamic dialogs. A generic record selection from a list (zoom) is the perfect candidate for a dynamic dialog.

The START DIALOG and TERMINATE DIALOG instructions provide dialogs functionality executing concurrently in different application forms.

### Dialog configuration with FGLPROFILE
FGLPROFILE parameters can be used to configure dialog behavior.

By setting global parameters in FGLPROFILE, you can control the behavior of all dialogs of the program. These options are provided as global parameters to define a common pattern for all dialogs of your application. A complete description is available in the runtime configuration section.

List of FGLPROFILE entries affecting the behavior of dialogs:

1. Dialog.fieldOrder (only used by singular dialogs like INPUT)
2. Dialog.currentRowVisibleAfterSort

#### The Dialog.fieldOrder entry

```plaintext
Dialog.fieldOrder = [true|false]
```

The Dialog.fieldOrder FGLPROFILE entry defines the execution of BEFORE FIELD and AFTER FIELD triggers of intermediate fields.

When this parameter is set to `true`, as the end user moves to a new field with a mouse click, the runtime system executes the BEFORE FIELD and AFTER FIELD dialog control blocks of the input fields between the source field and the destination field. When the parameter is set to `false`, intermediate field triggers are not executed.

The Dialog.fieldOrder configuration parameter is ignored by the DIALOG multiple-dialog instruction or when using the FIELD ORDER FORM option in singular dialogs such as INPUT.

Do not use this feature for new developments: GUI applications allow users to jump from one field to any other field of the form by using the mouse. Therefore, it makes no sense to execute the BEFORE FIELD and AFTER FIELD triggers of intermediate fields in a graphical application.

**Important:** The default setting for the runtime system is `false`; while the default setting in FGLPROFILE for Dialog.fieldOrder is `true`. As a result, the overall setting after installation is `true`. To modify the behavior of intermediate field trigger execution, change the setting of Dialog.fieldOrder in FGLPROFILE to `false`, or use the FIELD ORDER FORM program option.

#### The Dialog.currentRowVisibleAfterSort entry

```plaintext
Dialog.currentRowVisibleAfterSort = [true|false]
```
The Dialog.currentRowVisibleAfterSort FGLPROFILE entry controls the visibility of the current row after a sort in tables.

When this parameter is set to true, the offset of table page is automatically adapted to show the current row after a sort. By default, the offset is not changed and current row may not be visible after sorting rows of a table. Changing this parameter has no impact on existing code, it is just an indicator to force the dialog to shift to the page of rows having the current row, as if the end-user had scrollbar. You can use this parameter to get the same behavior as well known e-mail readers.

**Related concepts**
The FGLPROFILE file(s) on page 220
FGLPROFILE environment variable defines Genero BDL configuration files

**The DIALOG control class**

This topic explains the purpose of the ui.DIALOG class.

Inside a dialog instruction, the DIALOG predefined keyword represents the current dialog object. This dialog object can be used to execute methods provided by the ui.Dialog built-in class.

For example, you can enable or disable an action with the setActionActive() dialog method, or you can hide or show the default action view with the setActionHidden() method:

```
BEFORE INPUT
   CALL DIALOG.setActionActive("zoom",FALSE)
AFTER FIELD field1
   CALL DIALOG.setActionHidden("zoom",TRUE)
```

The setFieldActive() method can be used to enable or disable a field during the dialog:

```
ON CHANGE custname
   CALL DIALOG.setFieldActive( "custaddr",
                             (rec.custname IS NOT NULL) )
```

The ui.Dialog class provides also methods to configure the dialog, for example to enable multiple row selection:

```
BEFORE DIALOG
   CALL DIALOG.setSelectionMode( "sr1", 1 )
```

**Related concepts**
The Dialog class on page 2367
The ui.Dialog class provides a set of methods to configure, query and control the current interactive instruction.

Dynamic Dialogs on page 1903
Dialogs can be created at runtime with the ui.Dialog class.

**Dialog control functions**
The language provides several built-in functions and operators to be used in a dialog instruction.

Use the dialog functions and operators to keep track of the relative states of the current row, the program array, and the screen array, or to access the field buffers and keystroke buffers.

Typical control functions used in dialogs are: arr_curr(), arr_count(), fgl_set_arr_curr(), set_count(), field_touched(), GET_FLDBUF(), INFIELD(), fgl_dialog_getfieldname(), fgl_dialog_getbuffer().

As an alternative to functions and operators (especially for those taking hard-coded parameters such as INFIELD()), use the methods provided in the ui.Dialog class.
User interruption handling
Allow the end user to cancel the execution of a procedure in the program.

When do we need interruption handling?
If the program executes an interactive instruction, the GUI front end can send action events based on user actions. When the program performs a long process like a loop, a report, or a database query, the front end has no control. You might want to permit the user to stop a long-running process in the such case.

Detecting user interruptions in programs
To detect user interruptions coming from a GUI front-end, you define an action view with the name 'interrupt':

```plaintext
BUTTON sb: interrupt, TEXT="Stop";
```

When the runtime system takes control to process program code or execute a long running SQL query, the front end automatically enables the local 'interrupt' action to let the user send an asynchronous interruption request to the program.

A program (i.e. the runtime system) can also receive a SIGINT interruption signal from the operating system. The interruption request that comes from the front-end is a different source. However, the runtime system handles both type of interruption events the same way.

When receiving an interrupt event from the front-end with an 'interrupt' special action, or from the system (SIGINT) the runtime system sets the INT_FLAG register to `TRUE`.

Consider using `DEFER INTERRUPT` and test the INT_FLAG register to properly handle user interruptions, and avoid immediate program termination: If the `DEFER INTERRUPT` instruction is not used, the program will stop immediately when an interruption event is caught. With `DEFER INTERRUPT`, the program continues, and can test INT_FLAG to check if an interruption event occurred. It is good practice to reset INT_FLAG to `FALSE` after detecting interruption:

```plaintext
WHILE ...
  IF INT_FLAG THEN
    LET INT_FLAG=FALSE
    ERROR "Procedure was interrupted by the user"
    EXIT WHILE
  END IF
  ...
END WHILE
```

SQL queries can be interrupted too, if the target database supports this feature. However, since the control is on the database server side while the SQL statement is running, it is not possible to execute program code to check INT_FLAG. In order to detect an SQL interruption, check the SQLCA.SQLCODE register after the query for SQL error -213, indicating that the last SQL statement was interrupted.

```plaintext
WHENEVER ERROR CONTINUE
  -- Long running SQL statement
WHENEVER ERROR STOP
  IF SQLCA.SQLCODE == -213 THEN
    ERROR "Database query interrupted by user"
    ...
  END IF
```

When not using `DEFER INTERRUPT`, if the program enters in a long running procedure, a button with the action name 'interrupt' will become active. The user can then press that button, and the runtime system will stop the program, since `DEFER INTERRUPT` is not used. However, this will not happen when a dialog is active, because the 'interrupt' button will be automatically disabled in that context. Such situation can confuse the end user, expecting that the 'interrupt' button can stop the program in any context.
Note that the front end can not handle interruption requests properly if the display generates a lot of network traffic. In this case, the front end has to process a lot of user interface modifications and has no time to detect a mouse click on the 'interrupt' action view. A typical example is a program doing a loop from 1 to 10000, just displaying the value of the counter to a field and doing a refresh. This would generate hundreds of AUI tree modifications in a short period of time. In such a case, we recommended that you calculate a modulo and display steps 10 by 10 or 100 by 100.

### Implementing interruption of a long running SQL query

```plaintext
-- db_busy.per
LAYOUT
GRID
  {  Database query in progress...
     [sb         ]
  }  END
END
ATTRIBUTES
  BUTTON sb: interrupt, TEXT="Stop";
END

MAIN
  DEFINE oc INT
  DEFER INTERRUPT
  OPTIONS SQL INTERRUPT ON
  DATABASE stores
  OPEN FORM f FROM "db_busy"
  DISPLAY FORM f
  CALL ui.Interface.refresh()
  WHENEVER ERROR CONTINUE
  SELECT COUNT(*) INTO oc FROM orders
  WHENEVER ERROR STOP
  IF SQLCA.SQLCODE == -213 THEN
    ERROR "Database query has been interrupted..."
  END IF
END MAIN
```

**Related concepts**

- **DEFER INTERRUPT / QUIT** on page 516
  The DEFER instruction defines the program behavior when interruption or quit signals are received.

- **Using SQL interruption** on page 539
  Interrupt long running SQL queries, or interrupt queries waiting for locked data.

- **Configuring actions** on page 1646
  Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

**Get program control if user inactive**

Execute some code after a given number of seconds, when the user does not interact with the program.

**When to use the ON IDLE trigger?**

If an interactive instruction has the control, the program waits for a user interaction like an action or field input. If the end user leaves the workstation, or switches to another application, the program cannot get the control and is frozen until the user comes back. You might want to execute some code, after a period of inactivity, for example to refresh the displayed data by doing a new database query, or even after a long period, to terminate the program automatically.

**Implementing the ON IDLE trigger**

To detect user inactivity during a dialog, define an **ON IDLE** trigger in the dialog. This trigger is dialog specific, it is typically defined in the main dialog of the program, but it can also be defined in every dialog.
Important:

- Consider using the **ON IDLE** only in dialogs that do not handle field input, such as **DISPLAY ARRAY** and **MENU**. If used in input dialogs, this trigger may execute while the current field contains an incomplete value. The trigger will produce field value validation and raise an input error. However, **ON IDLE** can be used in input dialogs where the user cannot enter invalid values (for example when using **CHECKBOX**, **RADIOGROUP**, **COMBOBOX**, and character-type fields like **TEXTEDIT**).

- When implementing multiple or parallel dialogs with **DIALOG** block, do not mix several **ON IDLE** clauses in different sub-dialog blocks: specify a unique **ON IDLE** clause at the **DIALOG** block level. Obviously, it does not make much sense to mix **ON TIMER** and **ON IDLE** clauses.

For example:

```plaintext
DEFINE seconds SMALLINT
LET seconds = 120
DISPLAY ARRAY ...
  ...
  ON IDLE seconds
    MESSAGE "Automatic data refresh..."
    -- Reload the array with a new database result set
  ...
```

Note that the parameter of the **ON IDLE** trigger can be an integer variable, but it will only be read when the dialog is started. Changing the variable during dialog execution will have no effect.

A value of zero or less than zero disables the timeout trigger.

**Related concepts**

Get program control on a regular (timed) basis on page 1614

Execute some code after a given number of seconds, with or without user interaction with the program.

Get program control on a regular (timed) basis

Execute some code after a given number of seconds, with or without user interaction with the program.

**When to use the **ON TIMER** trigger?**

In some cases, an application needs to execute code at a regular interval, for example to process a message arrived in a queue, refresh data on a dashboard, or display resources in time-based graphs.

**Important:** Unlike the **ON IDLE** trigger which executes when there is no user activity, the **ON TIMER** trigger executes even when the user interacts with the application. Therefore, the code executed in an **ON TIMER** trigger must perform quickly, otherwise the end user will experience poor performance. As a general rule, make sure the time spent in the **ON TIMER** code is less than the timer interval. For example, if the processing time takes about 2 seconds, it doesn’t make sense to have an **ON TIMER** that triggers every second.

**Implementing the **ON TIMER** trigger**

To return control to the program on regular intervals, use the **ON TIMER seconds** trigger in dialogs. This trigger is dialog specific. It is typically defined in the main dialog of the program, but it can be defined in every dialog.

**Important:**

- Consider using the **ON TIMER** only in dialogs that do not handle field input, such as **DISPLAY ARRAY** and **MENU**. If used in input dialogs, this trigger may execute in the middle of a field input, which can produce field value validation and raise an input error. However, **ON TIMER** can be used in input dialogs where the user cannot enter invalid values (for example when using **CHECKBOX**, **RADIOGROUP**, **COMBOBOX**, and character-type fields like **TEXTEDIT**)

- When implementing multiple or parallel dialogs with **DIALOG** block, do not mix several **ON TIMER** clauses in different sub-dialog blocks: Specify a unique **ON TIMER** clause at the **DIALOG** block level. Obviously, it does not make much sense to mix **ON TIMER** and **ON IDLE** clauses.
For example:

```
DEFINE seconds SMALLINT
LET seconds = 120
DISPLAY ARRAY ... 
  ... 
  ON TIMER seconds
    MESSAGE "Check for messages in queue..."
    -- Query the message server for new messages.
  ...
```

Note that the parameter of the `ON TIMER` trigger can be an integer variable, but it will only be read when the dialog is started. Changing the variable during dialog execution will have no effect.

A value of zero or less than zero disables the timeout trigger.

**Related concepts**

- **ON TIMER block** on page 1357
- **Get program control if user inactive** on page 1613

Execute some code after a given number of seconds, when the user does not interact with the program.

**Front-End function calls**

The language allows to execute specific functions on the front-end platform.

A set of built-in front calls is available in Genero front-ends, to execute a specific task on the platform where the front-end executes.

In order to perform a front call, use the `ui.Interface.frontCall()` method. For example, when using a mobile front-end, you can instruct the mobile device to take a picture and return the identifier of the asset containing the image:

```
DEFINE path STRING
CALL ui.Interface.frontCall( "mobile", "takePhoto", [], [path] )
```

For a complete list of available front calls, see **Built-in front calls** on page 2485.

**Input fields**

Describes various concepts related to form field management in dialogs

- **Immediate detection of user changes** on page 1625
- **Form-level validation rules** on page 1627
- **Form field deactivation** on page 1628
- **Identifying sub-dialogs in procedural DIALOG** on page 1490
- **Defining the tabbing order** on page 1630
- **Which form item has the focus?** on page 1630
- **Giving the focus to a form element** on page 1631
- **Detection of focus changes** on page 1632
- **Enabling autocompletion** on page 1633
- **Filling a COMBOBOX item list** on page 1635
- **Field-anchored windows** on page 1637
**Input length of form fields**
Field input length defines the amount of characters the user can type in a form field.

**Input length basics**
The *field input length* is used by interactive instructions to limit the size of the data that can be entered by the user.

The field input length also matters when displaying a program variable to a form field with the `DISPLAY TO` or `DISPLAY BY NAME` instruction, that may truncate the text resulting from the data conversion.

**Note:** For non-character values, if the resulting text does not fit into the input length, the field will show * stars to indicate an overflow.

**Input length definition**
The field input length is defined from:

1. The type of layout (grid-based or stack-based layout)
2. The data type of the program variable bound to the field by the interactive instruction.
3. In grid-based layout:
   - The size (number of cells) of the form item tag.
   - The usage of the *SCROLL* attribute for *CHAR/VARCHAR/STRING* types.

**Trailing blanks in input fields**
When the user enters data in a form field, the runtime system automatically truncates the trailing blanks.

The resulting value in the corresponding program variable or in the field input buffer (`DIALOG.getFieldBuffer()`) is right-trimmed.

**Character length semantics and input length**
Character string input limit depends also from the *Byte Length Semantics (BLS)* or *Char Length Semantics (CLS)* usage.

**Note:** In this section, the term "character width" relates to the horizontal sizes of characters, especially in a fixed font size. Typically, the width of an Chinese character is 2, while characters of occidental languages usually have a width of 1. For more details, see *Character size unit and length semantics* on page 411.

When using BLS (the default), the input length represents the maximum number of bytes that the field can hold, in the current character set of the runtime system.

For example:

- When using a Single Byte Character Set (SBCS) like ISO-8859-15 (and BLS): Each characters of this codeset uses one byte (and has a width of 1). A field with an input length of 5 cells can hold 5 characters of this codeset.
- When using a Chinese BIG5 encoding (and BLS): Latin characters (a,b,c) use one byte each, while Chinese characters use 2 bytes. A field with an input length of 5 cells can hold:
  - 5 Latin characters (5x1B=5B),
  - 3 Latin characters and 1 Chinese character (3x1B+1x2B=5B),
  - 1 Latin character and 2 Chinese characters (1x1B+2x2B=5B),
  - it cannot hold 3 Chinese characters (3x2B=6B > 5B).
- When using UTF-8 and BLS (not recommended, use CLS with UTF-8): ASCII characters (like "e") use one byte, Latin acute characters (like "é") use 2 bytes and Chinese characters use 3 bytes. A field with an input length of 5 cells can hold:
  - 5 ASCII characters (5x1B=5B),
  - 1 ASCII character and 2 Latin acute characters (1x1B+2x2B=5B),
  - 2 ASCII characters and 1 Chinese character (2x1B+1x3B=5B),
• it cannot hold 3 Chinese characters (3x3B=9B > 5B).

When using character length semantics (FGL_LENGTH_SEMANTICS=CHAR), the input length is expressed in character width. The runtime system will truncate the entered text by computing the total width of the string. Trailing characters that do not fit into the field input length (interpreted as a maximum width) will be truncated when moving to another field or when validating the dialog instruction.

For example:
• When using UTF-8 and CLS: ASCII characters (like "e") use one byte, Latin acute characters (like "é") use 2 bytes and Chinese characters use 3 bytes. A field with an input length of 5 cells can hold:
  • 5 Latin characters (5x1W=5W),
  • 3 Latin characters and one Chinese character (3x1W+1x2W=5W),
  • 2 Chinese characters (2x2W=4W < 5),
  • it cannot hold 3 Chinese characters (3x2W=6W > 5).

Field width definition in grid-based containers

In a grid-based container, by default the input length is defined by the width of the field item tag in the LAYOUT section. The width of a field item tag is defined by the number of cell positions used between the square brackets:

```
LAYOUT
GRID
{
  [f1 ]  -- width = 3 cells
  [f2    ] -- width = 6 cells
  ...
}
```

As a general rule, forms must define fields that can hold all possible values that the corresponding program variable can contain. For example, a DATE field must be defined with 10 cells, to hold date values in the format DD/MM/YYYY.

If the program variable is defined with a numeric data type like INTEGER or DECIMAL, the input length is defined by the form field width. For example, if the form item tag defines a width of 5 cells and is bound to an INTEGER variable by the input dialog, even if the integer variable can hold larger values, the user can only enter 5 digits or the negative sign and 4 digits. As result, the value range will be -9999 to 99999.

If the program variable is defined with a DATE, DATETIME or INTERVAL data type, the input length is defined by the form field width. The user can potentially enter any kind of characters. However, when the date/time field is checked by the dialog instruction, it must represent a valid date/time value.

If the program variable is defined with character data type such as CHAR, VARCHAR or STRING, by default, the input length is defined by the form field width. The SCROLL attribute can be used to bypass this limit and force the input length to be as large as the program variable. For example, when using a CHAR(20) variable with a form field defined with width of 6, the maximum input length will be a width of 20 instead of 6.

Note: Using the SCROLL attribute must be an exception: it is recommended to allow a size for form fields to hold all possible characters that fit in the corresponding program variable. Note also that for specific item types like TEXTEDIT, the SCROLL attribute behavior is implicit when the element is stretchable or allows scrollbars.

Field width definition in stack-based containers

In a stack-based layout, the input length is defined by the data type of the program variable.

In this example, the cust_id field will allow numeric input length in the range of the INTEGER data type, and the cust_name field will allow up to 50 characters:

```
-- Form file
LAYOUT
STACK
  EDIT customer.cust_id;
```
EDIT customer.cust_name;
...

-- Program
MAIN
DEFcust_rec RECORD
  cust_id INTEGER,  
  cust_name VARCHAR(50)
END RECORD
...
INPUT BY NAME cust_rec.*
...

If the program variable is defined with a numeric data type like INTEGER or DECIMAL or a character data type such as CHAR, VARCHAR or STRING, the input length is defined by the value range of the program variable. For numeric values, you can use the INCLUDE attribute to define the range of possible values.

If the program variable is defined with a DATE, DATETIME or INTERVAL data type, the input length is defined by the data type. For example a DATE field allows 10 characters.

The SAMPLE attribute defines the text to be used to compute the width of a form field.

The buffered and unbuffered modes
The buffered and unbuffered mode control the synchronization of program variables and form fields.

Data model / view / controller paradigm
When bound to an interactive instruction (such as dialog), program variables act as a data model to display data or to get user input. To change the values of form fields by program code, the corresponding variables must be set and displayed.

Synchronization of program variables with the form fields depends on the buffer mode used by the dialog. Use the unbuffered mode to get automatic data model / form field synchronization.

Configuring the buffer mode
By default, singular dialogs (INPUT, DISPLAY ARRAY) and procedural DIALOG blocks use the buffered mode, while parallel dialogs use the unbuffered mode by default.

The unbuffered mode can be set per (modal) dialog instruction, with the UNBUFFERED dialog attribute:

```plaintext
INPUT BY NAME p_site.* ATTRIBUTES(UNBUFFERED)
...
END INPUT
```

When using a procedural DIALOG block, all sub dialogs defined locally or included with the SUBDIALOG clause inherit the buffer mode of the parent procedural dialog block:

```plaintext
DIALOG ATTRIBUTES(UNBUFFERED)
  INPUT BY NAME p_site.* -- unbuffered
  ...
END INPUT
DISPLAY ARRAY a_events TO sr_events.* -- unbuffered
  ...
END DISPLAY
SUBDIALOG d_comments -- unbuffered
```
The unbuffered mode can also be set globally with the `ui.Dialog.setDefaultUnbuffered()` method, for singular and procedural dialogs:

```plaintext
CALL ui.Dialog.setDefaultUnbuffered(TRUE)
... INPUT BY NAME rec_cust.* WITHOUT DEFAULTS -- uses unbuffered mode
END INPUT
```

In contrast with modal dialogs described above, when implementing parallel dialogs, all started dialogs implicitly use the unbuffered mode, and it is not possible to use the buffered mode:

```plaintext
DIALOG d_customers()
   INPUT BY NAME r_cust.*
   ... END INPUT
END DIALOG
... START DIALOG d_customers -- will be unbuffered by default
... END DIALOG
```

### The buffered mode

When you use the default "buffered" mode, program variable changes are not automatically displayed to form fields; you need to execute `DISPLAY TO` or `DISPLAY BY NAME`. Additionally, if an action is triggered, the value of the current field is not validated and is not copied into the corresponding program variable. The only way to get the text of a field is to use `GET_FLDBUF()` or `DIALOG.getFieldBuffer()`. These functions return the current text, which might not be a valid representation of a value of the field data type:

```plaintext
INPUT BY NAME p_item.*
   ON ACTION zoom
      CALL select_item()
      RETURNING p_item.code, p_item.desc
      DISPLAY BY NAME p_item.code, p_item.desc
      END IF
   ... END INPUT
```

### The unbuffered mode

With the unbuffered mode, program variables and form fields are automatically synchronized, and the dialog instruction is sensitive to program variable changes: You don't need to display values explicitly with `DISPLAY TO` or `DISPLAY BY NAME`. When an action is triggered, the value of the current field is validated and is copied into the corresponding program variable. If you need to display new data during the dialog execution, just assign the values to the program variables; the runtime system will automatically display the values to the screen after user code of the current control or interaction block has been executed:

```plaintext
INPUT BY NAME p_site.* ATTRIBUTES(UNBUFFERED)
   ON ACTION zoom
      CALL select_item()
      RETURNING p_item.code, p_item.desc
      -- no need to display desc.
      END IF
   ... END INPUT
```
**Actions configuration for field validation**

During data input, values entered by the user in form fields are automatically validated and copied into the program variables. Actually the value entered in form fields is first available in the form field buffer. This buffer can be queried with built-in functions or dialog class methods. With the unbuffered mode, the field buffer is used to synchronize program variables each time control returns to the runtime system - for example, when the user clicks on a button to execute an action.

With the unbuffered mode, data validation must be prevented for some actions such as cancel or close. To avoid field validation for a given action, set the `validate` action default attribute to "no", in the .4ad file or in the ACTION DEFAULTS section of the form file:

```
ACTION DEFAULTS
  ACTION undo (TEXT = "Undo", VALIDATE = NO)
...
END
```

**Note:** Actions such as `dialogtouched`, `cancel`, `delete`, `close`, `help` are by default defined with the `validate=no` attribute in the $FGLDIR/lib/default.4ad file.

If field validation is disabled for an action, the code executed in the ON ACTION block acts as if the dialog was in buffered mode. The program variable is not set. However, the input buffer of the current field is updated. When returning from the user code, the dialog will not synchronize the form fields with program variables, and the current field will display the input buffer content. Therefore, if you change the value of the program variable during an ON ACTION block where validation is disabled, you must explicitly display the values to the fields with DISPLAY TO / BY NAME.

To illustrate this case, imagine that you want to implement an undo action to allow the modifications done by the user to be reverted (before these have been saved to the database of course). You typically copy the current record into a clone variable when the dialog starts, and copy these old values back to the input record when the undo action is invoked. An undo action is a good candidate to avoid field validation, since you want to ignore current values. If you don't re-display the values, the input buffer of the current field will remain when returning from the ON ACTION block:

```
DIALOG ATTRIBUTES(UNBUFFERED)
INPUT BY NAME p_cust.*
  BEFORE INPUT
    LET p_cust_copy.* = p_cust.*
  ON ACTION undo -- Defined with VALIDATE=NO
    LET p_cust.* = p_cust_copy.*
    DISPLAY BY NAME p_cust.*
END INPUT
END DIALOG
```

For more details, see Data validation at action invocation on page 1665.

**Related concepts**

**Binding variables to form fields** on page 1620

Some dialogs need program variables to store form field values.

**Binding variables to form fields**

Some dialogs need program variables to store form field values.

**Program variables are the data model for dialog instructions**

Dialogs handling data fields input or display (INPUT, INPUT ARRAY, DISPLAY ARRAY) need program variables to store the information displayed in form fields during the dialog execution. The exception is `CONSTRUCT`, which needs only one string variable that holds the SQL condition produced.
When implementing a dialog controlling form fields, you specify what program variables must be bound to the form fields of the current displayed form:

```
INPUT BY NAME custrec.* ...
... END INPUT
```

Program variables (simple records and arrays) used in dialogs can have a flat definition, or structured definition with sub-records.

**Dialog variables binding methods**

There are different ways to bind program variables to screen record fields.

Program variables can be bound to form fields by name or by position, depending on the binding clause used in the dialog definition.

**Note:** When binding program variables with a screen record followed by a . * (dot star), program variables are bound to screen record fields by position. Make sure that the program variables are defined (or listed) in the same order as the screen array fields. This is true for INPUT, DISPLAY ARRAY and INPUT ARRAY.

For more details about binding methods, see dialog-specific syntax reference topics in Dialog instructions on page 1342.

**Variables and form fields data types**

The program variables can be of any simple data type supported by the dialogs; the runtime system will adapt input and display rules to the variable type. When the user enters data for an INPUT or INPUT ARRAY instruction, the runtime system checks the entered value against the data type of the variable, not the data type of the form field. For example, if you want to use a DATE variable, the dialog will check for a valid date value when the user enters a value in the corresponding form field.

With CONSTRUCT, no program variable is used for fields: Only one string variable is required, to hold the generated SQL condition.

**Note:** The CONSTRUCT dialog uses the field data types defined in the form file.

Program variables are typically declared with a DEFINE LIKE clause to get the data type of a column as defined in the database schema file. When the form fields are also defined like a column of the database schema, this ensures that the program variable and form field data type matches the underlying database column type. If a variable is declared LIKE a SERIAL / SERIAL8 / BIGSERIAL column, the runtime system will treat the field as if it was defined as NOENTRY in the form file. Since values of serial columns are automatically generated by the database server, no user input is required for such fields.

**Note:** If the program variable has the same structure as a database table (this is the case when the variable is defined with a DEFINE LIKE clause), you may want to use only some of the fields in your form layout. You can achieve this by using PHANTOM fields in the screen array definition of the form. Phantom fields are only used to bind program variables, and are not transmitted to the front-end for display.

**Data formatting**

Data format for input and display of numeric (DECIMAL, INTEGER) and DATE fields can be defined with the FORMAT attribute.

A default data format can be defined with environment variables (DBDATE, DBFORMAT, etc)

**Data validation rules**

Data validation rules can be defined at the form level, such as NOT NULL, REQUIRED and INCLUDE attributes.

Data validation constraints are checked when leaving a field, or when the dialog is validated (for example, with the ACCEPT DIALOG instruction inside a DIALOG multiple dialog block).
Note: Trailing blanks entered by the user will be removed when leaving the input field.

Phantom fields on page 1142
A PHANTOM field defines a screen-record field which is not rendered in the layout (it acts as a hidden field).

Form field initialization

Form field initialization can be controlled by the WITHOUT DEFAULTS dialog option.

The INPUT and INPUT ARRAY dialogs provide the WITHOUT DEFAULTS option to use program variable values when the dialog starts, or to apply the DEFAULT attribute defined in forms. The semantics of this option is slightly different in INPUT and INPUT ARRAY dialogs. Use of the WITHOUT DEFAULTS clause is always recommended in INPUT ARRAY.

The WITHOUT DEFAULTS option can be used in the binding clause or as an ATTRIBUTES option. When used in the binding clause, the option is defined statically at compile time as TRUE. When used as an ATTRIBUTES option, it can be specified with an integer expression that is evaluated when the DIALOG interactive instruction starts:

```
INPUT BY NAME p_cust.* ATTRIBUTES (WITHOUT DEFAULTS = NOT new)
... END INPUT
```

The WITHOUT DEFAULTS clause in INPUT

In the default mode, an INPUT clears the program variables and assigns the values defined by the DEFAULT attribute in the form file (or indirectly, the default value defined in the database schema files). This mode is typically used to input and INSERT a new record in the database. The REQUIRED field attributes are checked to make sure that the user has entered all data that is mandatory. Note that REQUIRED only forces the user to enter the field, and can leave the value NULL unless the NOT NULL attribute is used. Therefore, if you have an AFTER FIELD or ON CHANGE control block with validation rules, you can use the REQUIRED attribute to force the user to enter the field and trigger that block.

In contrast, the WITHOUT DEFAULTS option starts the INPUT dialog with the existing values of program variables. This mode is typically used in order to UPDATE an existing database row. Existing values are considered valid, thus the REQUIRED attributes are ignored when this option is used.

The NOT NULL field attribute is always checked at dialog validation, even if the WITHOUT DEFAULTS option is set.

The WITHOUT DEFAULTS clause in INPUT ARRAY

With an INPUT ARRAY, the WITHOUT DEFAULT option defines whether the program array is populated when the dialog begins. Once the dialog is started, existing rows are always handled as records to be updated in the database (WITHOUT DEFAULTS=TRUE), while newly created rows are handled as records to be inserted in the database (WITHOUT DEFAULTS=FALSE). In other words, column default values defined in the form specification file or the database schema files are only used for new created rows.
It is unusual to implement an INPUT ARRAY with no WITHOUT DEFAULTS option, because the program array would be cleared and the list would appear empty.

Important: The default in INPUT ARRAY used inside DIALOG is WITHOUT DEFAULTS=TRUE, but in a singular INPUT ARRAY dialog, the default is WITHOUT DEFAULTS=FALSE.

Form specification files are the source files defining the layout and content of application forms.

Input field modification flag
Each input field controlled by a dialog instruction has a modification flag.

The modification flag is used to execute form-level validation rules and trigger ON CHANGE blocks. The flag can also be queried to detect if a field was touched/changed during the DIALOG instruction, for example with the FIELD_TOUCHED() operator or with ui.Dialog.getFieldTouched().

Both FIELD_TOUCHED() and ui.Dialog.getFieldTouched() accept a list of fields and/or the screen-record.* notation in order to check the modification flag of multiple fields in a unique function call. You can also pass a simple * star as parameter, to reference all fields used by the dialog.

The modification flag is set to TRUE when the user enters data in a field, or when the program executes a DISPLAY TO/DISPLAY BY NAME instruction. The flag can also be set by program to TRUE or reset to FALSE with the ui.Dialog.setFieldTouched() method, to emulate user input by program or to reset the modification flags after data were saved in the database.

The modification flags of all fields are automatically reset to FALSE by the interactive instruction in the following cases:

- When the dialog instruction starts.
- In a DIALOG block, when entering a group of fields controlled by an INPUT or a CONSTRUCT sub-dialog.
- When moving to (or creating) a new row in an INPUT ARRAY.
- Within a DISPLAY ARRAY, the modification flags are always TRUE for all fields.

When using a DISPLAY ARRAY, the modification flags are set to TRUE for all fields. This behavior exists because of backward compatibility. Since values cannot be modified by the user, the modification flags are not relevant in this dialog. However, you must pay attention when implementing nested dialogs, because DISPLAY ARRAY will set the modification flags of the fields driven by the parent dialog, for example when executing a DISPLAY ARRAY from an INPUT ARRAY.

Query the modification flags with the ui.Dialog.getFieldTouched() method, typically in the context of AFTER INPUT, AFTER CONSTRUCT, AFTER INSERT or AFTER ROW control blocks.

When using a list driven by an INPUT ARRAY binding, a temporary row added at the end of the list will be automatically removed if all fields have the modification flag is set to FALSE.

For typical EDIT fields, the modification flag is set when leaving the field. If you want to detect data modification earlier, it is recommended that you use the dialogtouched predefined action. However, this event is only an indicator that the user started to modify a field, the value will not be available in the program variables.

Reacting to field value changes
This section describes the purpose of the ON CHANGE interaction block.

The ON CHANGE interaction block can be used in different ways:

- With form fields allowing only entire value input such as CHECKBOX, or using an additional widget such as a calendar in a DATEEDIT: ON CHANGE can be used to detect an immediate value change, or the selection of a value in the additional widget, without leaving the field.
- With text fields like EDIT (allowing incomplete values), defined with the COMPLETER attribute to implement autocompletion: In this case the ON CHANGE trigger is fired without leaving the field, when the user types characters in (after a short delay).
- With text fields like EDIT (allowing incomplete values): ON CHANGE can be used to detect a value change, when the field is left.

A typical usage of ON CHANGE is for example with a CHECKBOX, to enable/disable other form elements depending on the value of the checkbox field:

```
INPUT BY NAME rec.* ...
  ...
  ON CHANGE input_details -- can be TRUE or FALSE
    CALL DIALOG.setFieldActive("address1", rec.input_details)
    CALL DIALOG.setFieldActive("address2", rec.input_details)
  ...
END INPUT
```

Important: The dialogtouched predefined action can also be used to detect field changes immediately, but with this action you cannot get the data in the target variables. Use of this special action is only recommended to detect if the user has started to modify data in the current dialog.

Related concepts

Immediate detection of user changes on page 1625
This section describes the dialogtouched predefined action.

Enabling autocompletion on page 1633
Autocompletion allows a list of completion proposals to be displayed while the user is typing text into a field.

**Immediate detection of user changes**
This section describes the *dialogtouched* predefined action.

**Purpose of the *dialogtouched* action**
The *dialogtouched* predefined action is a special action that can be used to detect user changes immediately without leaving the current field.

The event is trapped with an **ON ACTION** *dialogtouched* block, to execute code in your program.

**Important:** The *dialogtouched* action must be enabled/disabled in accordance with the needs of the dialog:
When this action is enabled, the **ON ACTION** *dialogtouched* block will be invoked each time the user modifies the value with copy/paste actions, or uses the widget input helper (like the calendar of a DATEEDIT). In client/server mode, this can generate more network traffic as needed. As soon as the *dialogtouched* action is fired, it should be disabled to avoid unnecessary network round-trips, and it should only be re-enabled when needed.

When the form item type allows value changes to be detected immediately, for example with COMBOBOX, CHECKBOX or DATEEDIT fields, the alternative to *dialogtouched* to detect field input changes is to use the **ON CHANGE** trigger.

**Typical usage of *dialogtouched* action**
Singular interactive instructions are typically ended with an accept or cancel action. For example, a singular INPUT statement allows the end user to enter a database record, and validate or cancel the changes. The INPUT statement is then re-executed, to enter or modify another record.

Unlike singular dialogs, the DIALOG instruction can be used continuously for several data operations, such as navigation, creation, or modification. Typically, the default is the navigation mode, and as soon as the user starts to modify a field, it switches to edit mode, to modify a record, or create a new record. Only a user-defined close or exit action will terminate a DIALOG block. In such case, the dialog must be notified when the user starts to modify the current record. This can be achieved with the *dialogtouched* predefined action.

**What user events fire a *dialogtouched* action?**
The *dialogtouched* action works for any field controlled by the current interactive instruction, and with any type of form field.

Every time the user modifies the value of a field (without leaving the field), the **ON ACTION** *dialogtouched* block will be executed, if it is enabled.

The *dialogtouched* action can be triggered by typing characters in a text editor field, using copy/paste, clicking on a CHECKBOX/RADIOGROUP, moving the cursor of a SLIDER or changing a date with the calendar of a DATEEDIT.

**Field value validation when *dialogtouched* occurs**
When a *dialogtouched* action occurs, the current field may contain some text that does not represent a correct value corresponding to the field data type. For example, a form field bound to a DATE variable may contain only a part of a valid date string, such as “12/24/”. For this reason, the target variable bound to the field cannot hold the current text displayed on the screen when the **ON ACTION** *dialogtouched* code is executed, even when using the UNBUFFERED mode.

To avoid data validation on action code execution, the *dialogtouched* action is defined with `validate="no"` attribute in the FGLDIR/lib/default.4ad action defaults file. This is mandatory when using the UNBUFFERED mode; otherwise the runtime would try to copy the input buffer into the program variable when a *dialogtouched* action is invoked.
Note: Do not define validate="yes" for the dialogtouched action, otherwise non-string data fields will in most cases produce a conversion error, when the user enters data.

**Programming steps to handle a "save" button**

By default, the dialogtouched action and navigation actions are enabled.

In the ON ACTION dialogtouched block, detect the beginning of a record modification in a DIALOG block.

To prevent further dialogtouched action events, disable the action with a DIALOG.setActionActive() method, disable also navigation actions, and enable the save action.

Set a flag/status variable to track that the dialog is in edit mode.

When user input is validated and committed in the database, the dialogtouched and navigation actions can be enabled again, and the save action can be disabled.

Set a flag/status variable to indicate that the dialog is back to navigation mode.

In the action handler for the close or exit action, which can be used to close the form, check the status flag to know if the user has started to edit the fields, and show a warning box before leaving the dialog with EXIT DIALOG.

Code example:

```plaintext
DEFINE editing BOOLEAN

DIALOG
  ...
  ON ACTION dialogtouched
    CALL setup_dialog(DIALOG,TRUE)
  ...
  ON ACTION save
    CALL save_record()
    CALL setup_dialog(DIALOG,FALSE)
  ...
  ON ACTION close
    IF NOT check_close(DIALOG) THEN
      CONTINUE DIALOG
    END IF
    EXIT DIALOG
  ...
END DIALOG

FUNCTION setup_dialog(d,e)
  DEFINE d ui.Dialog, e BOOLEAN
  LET editing = e
  CALL DIALOG.setActionActive("dialogtouched", NOT editing)
  CALL DIALOG.setActionActive("save", editing)
  CALL DIALOG.setActionActive("query", NOT editing)
END FUNCTION

FUNCTION check_close(d)
  DEFINE d ui.Dialog
  IF editing THEN
    CALL setup_dialog(d,editing)
    RETURN mbox_yn("Do you want to close the form without saving changes?")
  END IF
  RETURN TRUE
END FUNCTION
```

Reacting to field value changes on page 1624
This section describes the purpose of the ON CHANGE interaction block.

Form-level validation rules
Form-level validation rules can be defined for each field controlled by a dialog.

Form-level validation can be specified at the form field level with attributes such as NOT NULL, REQUIRED and INCLUDE. These attributes are part of the business rules of the application and must be checked before saving data into the database.

Implicit validation rule checking
An INPUT or INPUT ARRAY block automatically executes form-level validation rules in the following cases:

• The NOT NULL attribute is satisfied if a value is in the field. NOT NULL is checked:
  • when the user moves to a different row in a list controlled by an INPUT ARRAY. However, if the row is temporary and none of the fields is touched, the attribute is ignored.
  • in a DIALOG block, when focus leaves the sub-dialog controlling the field.
  • in a DIALOG block, when NEXT FIELD gives the focus to a field in a different sub-dialog than the current sub-dialog.
  • when the dialog instruction is ended, for example when a procedural DIALOG is ended with ACCEPT DIALOG, or when an singular INPUT is ended with ACCEPT INPUT or with the implicit accept action.

• The REQUIRED attribute is satisfied if the field modification flag is true, if a DEFAULT value is defined, or if the WITHOUT DEFAULTS option is used. REQUIRED is checked:
  • when the user moves to a different row in a list controlled by an INPUT ARRAY. However, if the row is temporary and none of the fields is touched, the attribute is ignored.
  • in a DIALOG block, when focus leaves the sub-dialog controlling the field.
  • in a DIALOG block, when NEXT FIELD gives the focus to a field in a different sub-dialog than the current sub-dialog.
  • when the dialog instruction is ended, for example when a procedural DIALOG is ended with ACCEPT DIALOG, or when an singular INPUT is ended with ACCEPT INPUT or with the implicit accept action.

• The INCLUDE attribute is satisfied if the value is in the list defined by the attribute. INCLUDE is checked when the target program variable must be assigned. This happens:
  • when UNBUFFERED mode is used, focus is in the field, and an action is invoked;
  • when the focus leaves the field.
  • when the user moves to a different row in a list controlled by an INPUT ARRAY. However, if the row is temporary and none of the fields is touched, the attribute is ignored.
  • in a DIALOG block, when focus leaves the sub-dialog controlling the field.
  • in a DIALOG block, when NEXT FIELD gives the focus to a field in a different sub-dialog than the current sub-dialog.
  • when the dialog instruction is ended, for example when a procedural DIALOG is ended with ACCEPT DIALOG, or when an singular INPUT is ended with ACCEPT INPUT or with the implicit accept action.

Performing validation rules explicitly
Singular input dialogs (INPUT / INPUT ARRAY) create default accept / cancel actions. The form-level validation rules are typically performed when the implicit accept action is triggered.

The DIALOG procedural instruction can be used as in singular interactive instructions, with the typical OK / Cancel buttons (accept / cancel actions) to finish the instruction. The accept/cancel action handlers would respectively execute the ACCEPT DIALOG and EXIT DIALOG instructions. This solution allows the user to input or modify one record at a time, and the program flow must reenter the DIALOG instruction to edit or create another record. Alternatively, the DIALOG instruction can let the user input / modify multiple records without leaving the dialog. In
this case, you need a way to execute the form-level validation rules defined for each field, before saving the data to
the database.

To validate a subset of fields controlled by the DIALOG instruction, use the ui.Dialog.validate("field-
list") method, as shown in this example:

```plaintext
ON ACTION save
    IF DIALOG.validate("cust.*") < 0 THEN
        CONTINUE DIALOG
    END IF
    CALL customer_save()
```

This method automatically displays an error message and registers the next field in case of error. It is mandatory to
execute a CONTINUE DIALOG instruction if the function returns an error.

Within singular input dialogs, form-level validation rules can also be explicitly performed with the ACCEPT INPUT
instruction, or with the DIALOG.validate("**") API call, followed by a CONTINUE INPUT in case of error.

REQUIRED attribute on page 1280
The REQUIRED attribute forces the user to modify the content of a field during an input dialog.

NOT NULL attribute on page 1273
The NOT NULL attribute specifies that the field does not accept NULL values.

Form field deactivation
The form fields bound to a dialog are by default active (i.e. they can get the focus). When needed, disable the fields
that do not require user input, and reactivate them later during the dialog execution. For example, imagine a form
containing an "Industry" COMBOBOX field, with the options Healthcare, Education, Government, Manufacturing,
and Other. If the user selects "Other", a secondary EDIT field is expected to be activated automatically, to let the
user input the specific description of the industry. But if one of the predefined values is selected, there is no need for
the additional field, so the secondary field can be left disabled.

This can be achieved by enabling/disabling fields with the ui.Dialog.setFieldActive() method depending
on the context. The "Industry" field case described can be implemented as follows:

```plaintext
DIALOG ATTRIBUTES(UNBUFFERED)
    INPUT BY NAME rec.*
    ON CHANGE industry
        -- A value of 99 corresponds to the "Other" item
        CALL DIALOG.setFieldActive( "cust.industry", (rec.industry!=99) )
    ...
END INPUT
BEFORE DIALOG
```
CALL DIALOG.setFieldActive( "cust.industry", FALSE )
...
END DIALOG

Consider centralizing field activation / deactivation in a setup function specific to the dialog, passing the DIALOG object as parameter.

Do not disable all fields of a dialog, otherwise the dialog execution stops (at least one field must get the focus during a dialog execution).

If you disable the current field having the focus, the dialog will execute the AFTER FIELD block of the current field and the BEFORE FIELD block on the next field in the tabbing order. This can unnecessarily fire validation code implemented in AFTER FIELD. As a general pattern, it is not recommended to disable a field in your dialog code when it is not the current field.

It is also possible to hide fields with the ui.Form.setFieldHidden() method of the form objects. The dialog considers hidden fields as disabled (there is no need to disable fields that are already hidden). But hiding form elements changes the space used in the window layout and the form may be displayed in an unexpected way. When hiding elements in containers prepared for that, such as tables, this doesn't happen.

**Identifying sub-dialogs in procedural DIALOG**

Sub-dialogs need to be identified by a name to distinguish the different contexts.

A procedural DIALOG block is a collection of sub-dialogs that act as controllers for different parts of a form. In order to program a procedural DIALOG block, there must be a unique identifier for each sub-dialog.

For example, to set the current row of a screen array with the DIALOG.setCurrentRow() method, you pass the name of the screen array to specify the sub-dialog to be affected. Sub-dialog identifiers are also used as a prefix to specify actions for the sub-dialog.

The following topics describe how to specify the names of the different types of DIALOG sub-dialogs:

- [Identifying an INPUT sub-dialog](#) on page 1492
- [Identifying a DISPLAY ARRAY sub-dialog](#) on page 1494
- [Identifying an INPUT ARRAY sub-dialog](#) on page 1496
- [Identifying a CONSTRUCT sub-dialog](#) on page 1493
- [The SUBDIALOG clause](#) on page 1496.

How are action views of the forms bound to action handlers in the program code?

**Defining the tabbing order**
Control the order of tabbing through the fields with the TABINDEX attribute.

When a dialog is executing, the end-user can jump from field to field with the keyboard by using the Tab and Shift-Tab keys.

**Note:** One can tab out of an INPUT ARRAY sub-dialog with Ctrl-Tab and Shift-Ctrl-Tab accelerators (in INPUT ARRAY, Tab and Shift-Tab loop in the fields of the current row).

The order in which the fields can be visited with the Tab key can be controlled with a program option and the TABINDEX form field attribute.

The FIELD ORDER dialog attribute defines the way tabbing order works (it can also be defined globally with OPTIONS FIELD ORDER *mode*). Tabbing order can be based on the dialog binding list (FIELD ORDER CONSTRAINED, the default) or it can be based on the form tabbing order (FIELD ORDER FORM). It is recommended that you use the FIELD ORDER FORM option, to use the tabbing order specified in the form file.

The TABINDEX field attribute allows tabbing order in the form to be defined for each form item. By default, the form compiler assigns a tabbing index for each form item based on the position of the item in the layout.

**Important:** TABINDEX values must be unique in a form.

Form elements that can get the focus are:

- Simple form fields controlled by INPUT or CONSTRUCT.
- Read-only lists controlled by DISPLAY ARRAY,
- Editable list cells controlled by INPUT ARRAY,
- Simple buttons controlled by a COMMAND interaction block.

If you use the keyboard to tab into a form element, the focus will go to the next (or previous) element that is visible and activated. In other words, if a form item is hidden or disabled, it is removed from the tabbing list.

The tabbing position of a read-only list driven by a DISPLAY ARRAY binding is defined by the TABINDEX of the first field.

When TABINDEX is set to zero, the form item is excluded from the tabbing list. However, the item with TABINDEX=0 can still get the focus with the mouse (or when you tap on it on a mobile device).

The NEXT FIELD instruction can also use the tabbing order, when executing NEXT FIELD NEXT and NEXT FIELD PREVIOUS.

If the form uses a TABLE container, the front-end resets the tab indexes when the user moves columns around. This way, the visual column order always corresponds to the input tabbing order. If the order of the columns in an editable list shouldn’t be changed, you can freeze the table columns with the UNMOVABLECOLUMNS attribute.

**Related concepts**

Dialog configuration with FGLPROFILE on page 1610
FGLPROFILE parameters can be used to configure dialog behavior.

**Which form item has the focus?**
Identify what element of the current form has the focus.

Sometimes it is important to know what form element has currently the focus. This is especially important when implementing a DIALOG block, that can control several parts of a form. For example, when several lists are driven by multiple DISPLAY ARRAY sub-dialogs, you may need to know what is the current list.

To get the name of the current form item, use the DIALOG.get_current_item() method. This method is the replacement of the former fgl_dialog_getfieldname() built-in function. It has been extended to return identifiers for fields, lists, or actions identifiers.

```plaintext
DIALOG ATTRIBUTES(UNBUFFERED)
DISPLAY ARRAY p_orders TO orders.*
```
... END DISPLAY
DISPLAY ARRAY p_items TO items.*
... END DISPLAY
... IF DIALOG.getCurrentItem() == "items" THEN
... END IF
... END DIALOG

It is also possible to detect when the focus enters or leaves a field or a group of fields by using control blocks such as BEFORE INPUT/DISPLAY or AFTER INPUT/DISPLAY.

Related concepts
The DISPLAY ARRAY sub-dialog on page 1494
The DISPLAY ARRAY sub-dialog is the controller to implement the navigation in a list of records, with option data modification actions.

ui.Dialog.getCurrentItem on page 2385
Returns the current item having focus.

Detection of focus changes on page 1632
Describes how to detect when the focus goes from field to field or to a read-only list.

The buffered and unbuffered modes on page 1618
The buffered and unbuffered mode control the synchronization of program variables and form fields.

Giving the focus to a form element
How to force the focus to move or stay in a specific form element using program code.

Use the NEXT FIELD instruction to force the focus to a specific field or screen record (list). The NEXT FIELD instruction expects a form field name.

In a DIALOG block, when the specified field is the first column identifier of a sub-dialog driven by a DISPLAY ARRAY block, the read-only list gets the focus. If the field name is not known at compile time, you can alternatively use the ui.Dialog.nextfield() method.

DIALOG ATTRIBUTES(UNBUFFERED)
  INPUT BY NAME p_cust ATTRIBUTES(NAME="cust")
  ... END DISPLAY
  DISPLAY ARRAY p_orders TO orders.*
  ... END DISPLAY
  ON ACTION go_to_header
    NEXT FIELD cust_num
  ON ACTION go_to_detail
    NEXT FIELD order_lineno
  ... END DIALOG

When a BUTTON exists in the form layout, it can get the focus if the DIALOG block defines a COMMAND clause as action handler. Currently there is no way to give the focus to a BUTTON by program.

DIALOG ATTRIBUTES(UNBUFFERED)
  ... COMMAND "print"
    CALL print_order()
  ... END DIALOG
In rare cases (especially when using folder tabs), it may be required to show a part of the form that is not controlled by the dialog, when there is no active field or button that can get the focus in that part of the form, and when the above techniques cannot work. In this case, in order to show temporarily a given part of the form that cannot get the focus, you use the `ui.Form.ensureFieldVisible` on page 2359 or `ui.Form.ensureElementVisible` on page 2358 methods.

```
DEFINE form ui.Form
...
DIALOG ATTRIBUTES(UNBUFFERED)
...
BEFORE DIALOG
  LET form = DIALOG.getForm()
...
ON ACTION show_image1
  CALL form.ensureElementVisible("image1")
...
END DIALOG
```

When using the `FOCUSONFIELD` attribute of `DISPLAY ARRAY`, you can set the focus to a specific cell by using the `NEXT FIELD` instruction on page 1389 instruction or the `ui.Dialog.nextField()` method, in conjunction with the `ui.Dialog.setCurrentRow()` method. For more details, see Field-level focus in `DISPLAY ARRAY` on page 1740.

**Related concepts**

  - How to execute user code in ON ACTION blocks when an action is fired.

**Detection of focus changes**

Detects how to detect when the focus goes from field to field or to a read-only list.

**Detecting focus changes in a singular INPUT or CONSTRUCT**

An singular `INPUT` or `CONSTRUCT` controls several fields that can get the focus and become current. In order to execute some code when a field gets (or loses) the focus, use the following control blocks:

- `BEFORE FIELD` (a specific field (or group of fields) gets the focus)
- `AFTER FIELD` (the field (or group of fields) loses focus)

**Detecting focus changes in a singular DISPLAY ARRAY**

A singular `DISPLAY ARRAY` controls rows of a list, that can get the focus and become current. In order to execute some code when a row gets (or loses) the focus, use the following control blocks:

- `BEFORE ROW` (a new row gets the focus inside a `DISPLAY ARRAY` or `INPUT ARRAY` list)
- `AFTER ROW` (a row inside a `DISPLAY ARRAY` or `INPUT ARRAY` list loses focus)

**Detecting focus changes in a singular INPUT ARRAY**

An singular `INPUT ARRAY` controls several fields and rows of a list, that can get the focus and become current. In order to execute some code when a field or a row gets (or loses) the focus, use the following control blocks:

- `BEFORE ROW` (a new row gets the focus inside a `DISPLAY ARRAY` or `INPUT ARRAY` list)
• **BEFORE FIELD** (a specific field (or group of fields) gets the focus)
• **AFTER FIELD** (the field (or group of fields) loses focus)
• **AFTER ROW** (a row inside a DISPLAY ARRAY or INPUT ARRAY list loses focus)

**Detecting focus changes in a DIALOG**

A DIALOG interaction block can handle different parts of a form simultaneously. In order to execute some code when a part of the form gets (or loses) the focus, use the following control blocks:

• **BEFORE INPUT** (a field of this INPUT or INPUT ARRAY sub-dialog gets the focus and none of its fields had focus before)
• **BEFORE CONSTRUCT** (a field of this CONSTRUCT sub-dialog gets the focus and none of its fields had focus before)
• **BEFORE DISPLAY** (this DISPLAY ARRAY sub-dialog gets the focus and none of its fields had focus before)
• **BEFORE ROW** (a new row gets the focus inside a DISPLAY ARRAY or INPUT ARRAY list)
• **BEFORE FIELD** (a specific field (or group of fields) gets the focus)
• **AFTER FIELD** (the field (or group of fields) loses focus)
• **AFTER ROW** (a row inside a DISPLAY ARRAY or INPUT ARRAY list loses focus)
• **AFTER DISPLAY** (this DISPLAY ARRAY sub-dialog loses the focus = focus goes to another sub-dialog)
• **AFTER CONSTRUCT** (this CONSTRUCT sub-dialog loses the focus = focus goes to another sub-dialog)

These triggers are also executed by **NEXT FIELD**.

**Related concepts**

**DIALOG control blocks** on page 1504

*Dialog control blocks* are predefined dialog triggers where you can implement specific code to control the interactive instruction.

**Enabling autocompletion**

Autocompletion allows a list of completion proposals to be displayed while the user is typing text into a field.

**Introduction to autocompletion**

Text input fields (like EDIT and BUTTONEDIT) can be defined with an autocompletion feature, by combining the COMPLETER form field attribute with program code providing the list of completion proposals in a dynamic array of strings, with the DIALOG.setCompleterItems() method, when the ON CHANGE trigger is fired for the autocompletion field.

**Defining a form field for autocompletion**

In order to enable autocompletion in a text form field, you must define the COMPLETER attribute:

```
EDIT f1 = FORMONLY.firstname, COMPLETER;
```

The COMPLETER attribute can be used for EDIT and BUTTONEDIT fields.

**Providing the front-end with a list of completion proposals**

The DIALOG.setCompleterItems() method must be used to provide the list of completion proposals during dialog execution:

```
DEFINE items DYNAMIC ARRAY OF STRING
-- fill the array with items
LET items[1] = "Ann"
LET items[2] = "Anna"
LET items[3] = "Annabel"
```
CALL DIALOG.setCompleterItems(items)

**Important:** Consider the execution time of the code creating the completion proposal list. For example, avoid long complex SQL queries that can take more than a few milliseconds to complete.

The `setCompleterItems()` method will raise error -8114 if the list of items contains more than 50 elements. The purpose of autocompletion is to provide a short list of completion proposals to the user. Note that this error is not trappable with exception handlers like `TRY/CATCH`, the code must avoid exceeding the limit.

**Detecting user input**

When implementing autocompletion, you must detect when the user modifies the field value, to adapt the list of items with the `setCompleterItems()` method.

In order to detect user input, define the `ON CHANGE` dialog control block, and call a custom function by passing the `DIALOG` object, and the value of the current field as parameter, to filter the completion proposal list accordingly:

```lisp
INPUT BY NAME rec.firstname
  ...
  ON CHANGE firstname
    CALL fill_proposals_firstname(DIALOG, rec.firstname)
```

For text fields defined with the `COMPLETER` attribute, the `ON CHANGE` trigger will be fired without leaving the field, each time the user types characters in. The event is fired after a short delay, to not overload the UI exchanges between the front-end and the runtime system.

**Note:** The item list for a field implementing autocompletion is not permanent: The program must re-define the autocompletion item list with `setCompleterItems()`, on every `ON CHANGE` event.

**Example**

The example below implements form field with autocompletion: Each time the `ON CHANGE` trigger is fired, the set of completion proposals is adapted to the current field value, to match names that start with the same characters typed by the user.

Form file (`compl.per`):

```plaintext
LAYOUT
  GRID
  { [f1] [f2] } END
END
ATTRIBUTES
  EDIT f1 = FORMONLY.field1, COMPLETER;
  EDIT f2 = FORMONLY.field2;
END
```

Program file (`compl.4gl`):

```plaintext
DEFINE all_names DYNAMIC ARRAY OF STRING
MAIN
  DEFINE rec RECORD
    field1 STRING,
    field2 STRING
  END RECORD
  CALL fill_names()
  OPEN FORM f FROM "compl"
  DISPLAY FORM f
  OPTIONS INPUT WRAP
```
INPUT BY NAME rec.* ATTRIBUTES(UNBUFFERED)
  ON CHANGE field1
    CALL fill_proposals(DIALOG, rec.field1)
END INPUT
END MAIN

FUNCTION fill_names()
  DEFINE i INTEGER
  LET i=0
  LET all_names[i:=i+1] = "Amanda"
  LET all_names[i:=i+1] = "Ann"
  LET all_names[i:=i+1] = "Anna"
  LET all_names[i:=i+1] = "Annabelle"
  LET all_names[i:=i+1] = "Barbara"
  LET all_names[i:=i+1] = "Barry"
  LET all_names[i:=i+1] = "Brice"
END FUNCTION

FUNCTION fill_proposals(dlg, curr_val)
  DEFINE dlg ui.Dialog, curr_val STRING
  DEFINE curr_set DYNAMIC ARRAY OF STRING,
      i, x INTEGER
  LET x=0
  FOR i=1 TO all_names.getLength()
    IF upshift(all_names[i]) MATCHES upshift(curr_val)||"*" THEN
      LET curr_set[x:=x+1] = all_names[i]
    END IF
  END FOR
  CALL dlg.setCompleterItems(curr_set)
END FUNCTION

Filling a COMBOBOX item list
The item list of COMBOBOX fields can be initialized at runtime.

Introduction to COMBOBOX fields
COMBOBOX fields are typically used when a field can hold a short predefined list of values. COMBOBOX fields are usually rendered with a drop-down list, from where the end user can choose a value.

Note: All items of a COMBOBOX list will be transmitted to the front-end. Therefore, the number of items that can be selected in a COMBOBOX fields should be limited to 20 to 50 items. If the selection list holds more items, consider using a BUTTONEDIT field, which opens a new window with a TABLE container.

COMBOBOX item lists can be defined in three different ways:
1. In the form definition file, as a static list of items with single values.
2. In the form definition file, as a static list of items with value/label pairs.
3. At runtime when the form is loaded, as single values or value/label pairs.

In this topic we will learn how to implement a COMBOBOX field that is filled dynamically.
For static item list definitions, see **COMBOBOX item type** on page 1166.

### Defining the COMBOBOX initialization function

In order to fill a COMBOBOX field when the form file is loaded, use the **INITIALIZER** attribute to define the name of the function that will be called to fill the item list:

```plaintext
COMBOBOX f1 = FORMONLY.city, INITIALIZER=fill_city;
```

The initialization function name is case-insensitive.

**Important:** When the form is displayed, make sure that the initialization function is available (i.e. the .42m module where the function is defined is loaded).

### Implementing the item list initialization function

The function defined with the **INITIALIZER** attribute takes a `ui.ComboBox` object as parameter.

To add items to the selection list of the COMBOBOX field, use the `addItem()` method of `ui.ComboBox`:

```plaintext
FUNCTION fill_city(cmb)  
  DEFINE cmb ui.ComboBox  
  CALL cmb.addItem(101,"Berlin")  
  CALL cmb.addItem(102,"Madrid")  
  CALL cmb.addItem(103,"London")  
  CALL cmb.addItem(104,"Paris")  
  CALL cmb.addItem(105,"Rome")  
END FUNCTION
```

**Note:** If you want to define a list of items with single values, specify only the first parameter of `addItem()`.

### Detecting COMBOBOX value change

In order to detect a value change in a COMBOBOX, define the **ON CHANGE** dialog control block. The **ON CHANGE** block will be immediately executed when the user selects a new item in the list. One can typically clear other fields related to the COMBOBOX field:

```plaintext
ON CHANGE city  
  LET rec.address = NULL
```

### NULL values in COMBOBOX fields

Pay attention to NULL value handling with COMBOBOX fields:

- By default, if the field allows nulls, the item list automatically gets a NULL item.
- Prefer to deny nulls with the **NOT NULL** attribute, and add a special item such as `(0,"<Undefined>")` to identify a non-specified-value.

### Example

The next example shows how to implement the function to fill the item list of a COMBOBOX field with a list of cities. When the COMBOBOX field is changed, the **ON CHANGE** block is fired and the address field is cleared:

Form file (`combobox.per`):

```plaintext
LAYOUT  
GRID  
{  
  City : [f1]  
  Address: [f2]  
}  
END
```
END

ATTRIBUTES
COMBOBOX f1 = FORMONLY.city, INITIALIZER=fill_city;
EDIT f2 = FORMONLY.address;
END

Program file (combobox.4gl):

MAIN

DEFINE rec RECORD
    city INTEGER,
    address VARCHAR(100)
END RECORD

OPEN FORM f1 FROM "combobox"
DISPLAY FORM f1

INPUT BY NAME rec.* ATTRIBUTES(UNBUFFERED)
    ON CHANGE city
    LET rec.address = NULL
END INPUT
END MAIN

FUNCTION fill_city(cmb)
    DEFINE cmb ui.ComboBox
    CALL cmb.addItem(101,"Berlin")
    CALL cmb.addItem(102,"Madrid")
    CALL cmb.addItem(103,"London")
    CALL cmb.addItem(104,"Paris")
    CALL cmb.addItem(105,"Rome")
END FUNCTION

Related concepts

COMBOBOX item type on page 1166
Defines a line-edit with a drop-down list of values.

Field-anchored windows

The Window style attribute "position" can be set to "field" in order to display the window under the current field.

The Window style attribute "position"

The "position" style attribute for Window elements can take several values, to control where the window will appear on the screen. It can for example be anchored to an existing window, or centered. For more details about the "position" attribute, see Window style attributes on page 1117.

In this topic, we will describe how to use the "field" value of the Window position style attribute, to display the window under the current field having the focus. This will result in a "drop-down" window, typically used to select a record in a list:
Defining your custom "dropdown" Window style

The "position" style attribute for Window elements must be defined under a Style element. We use the name "dropdown" to reference the style element in program source files.

Add the following XML elements to the default.4st file:

```xml
<Style name="Window.dropdown">
  <StyleAttribute name="position" value="field" />
  <StyleAttribute name="windowType" value="modal" />
  <StyleAttribute name="border" value="none" />
  <StyleAttribute name="windowSystemMenu" value="no" />
  <StyleAttribute name="actionPanelPosition" value="none" />
  <StyleAttribute name="ringMenuPosition" value="none" />
  <StyleAttribute name="statusBarType" value="none" />
</Style>
```

Note: Additional Window style attributes are required to get the expected rendering. For example, we remove the border, system menu, statusbar, action panel, etc, to get a minimal window frame. Note also that the windowType attribute must be "modal".

The zoom.per form

The zoom.per form defines a TABLE container, with the STYLE attribute set to "dropdown":

```perl
LAYOUT
TABLE t1 (STYLE="dropdown")
{
  [c1 | c2 ]
  [c1 | c2 ]
  [c1 | c2 ]
  [c1 | c2 ]
}
END
END
ATTRIBUTES
c1 = FORMONLY.col1;
c2 = FORMONLY.col2;
```
The main.per form

The main.per form defines a GRID container with two BUTTONEDIT fields, with an ACTION, that will fire the ON ACTION program code to open the zoom window:

```4gl
LAYOUT
GRID
{
    [f1] [f2]
}
END
END
ATTRIBUTES
BUTTONEDIT f1 = FORMONLY.field1, ACTION=zoom1, IMAGE="zoom";
BUTTONEDIT f2 = FORMONLY.field2, ACTION=zoom2, IMAGE="zoom";
END
```

The main.4gl program

The main.4gl module implements a simple INPUT with ON ACTION handlers calling a function that opens the zoom window.

Note that the OPEN WINDOW instruction uses the STYLE="dropdown" attribute:

```4gl
MAIN
    DEFINE rec RECORD
        field1 STRING,
        field2 STRING
    END RECORD

    OPEN FORM f1 FROM "main"
    DISPLAY FORM f1

    INPUT BY NAME rec.* ATTRIBUTES(UNBUFFERED)
        ON ACTION zoom1
            LET rec.field1 = open_zoom(rec.field1)
        ON ACTION zoom2
            LET rec.field2 = open_zoom(rec.field2)
    END INPUT

END MAIN

FUNCTION open_zoom(cv)
    DEFINE cv STRING
    DEFINE arr DYNAMIC ARRAY OF RECORD
        col1 INT,
        col2 STRING
    END RECORD
    DEFINE i INT
    FOR i=1 TO 100
        LET arr[i].col1 = i
        LET arr[i].col2 = SFMT("Item %1",i)
    END FOR
    OPEN WINDOW wz WITH FORM "zoom" ATTRIBUTES(STYLE="dropdown")
    LET int_flag = FALSE
    DISPLAY ARRAY arr TO sr.*
    AFTER DISPLAY
```

Action handling basics

This topic describes the basics of action views, action events, and action handlers.

In the user interface of the application, action views can produce action events, that will execute user code in the corresponding action handler defined in the current interactive instruction of the program.

Actions views are for example BUTTON form items.

Action handlers are ON ACTION or COMMAND dialog blocks that execute user code, in the current interactive dialog.

Action views are bound to action handlers by name.

If no action view is explicitly defined in the current form, the front end will create a "default action view" for the action. This is typically a button that appears in a specific area, located and decorated following the front end platform standards.

Actions can be configured with action attributes. These can be defined explicitly at the action view level (button in form), as dialog-specific action configuration (ON ACTION name ATTRIBUTES(...)), or with action defaults.

Special actions are supported, such as the interrupt action if the user cancels a running application procedure.

The ACTION DEFAULTS section defines local action view default attributes for the form elements.

Predefined actions

Genero predefines some action names for common operations of interactive instructions.

Predefined actions are different from user-defined action, in the sense that the name of a predefined action is reserved, and the action may have an ON ACTION handler, while user-defined actions have a specific name, and must be implemented with an ON ACTION handler.

There are two types of predefined actions:

- **Automatic actions**: actions that are automatically created and handled by the program dialog, like accept, cancel, insert.
- **Special actions**: actions with a special usage, that can be invoked asynchronously or automatically by the front-end, like interrupt, dialogtouched.

Default decoration attributes and keyboard shortcuts are defined with action defaults, like for user-defined actions.

Overwriting predefined actions with ON ACTION

If you define your own ON ACTION handler with the name of a predefined action, the default action processing is bypassed and the program code is executed instead.

The next code example defines an ON ACTION clause with the accept predefined action name:

```
INPUT BY NAME customer.*
  ON ACTION accept
  ...
END INPUT
```

In this case, the default behavior of the automatic accept action is not performed; the user code is executed instead.

Predefined actions enabled depending on the context

Some predefined actions (such as insert, append and delete in INPUT ARRAY) are enabled and disabled automatically by the dialog depending on the context (for example, when a static array used by the INPUT ARRAY is full, the insert and append actions get disabled).

Even when overwriting such actions with your own action handler, the runtime system will continue to enable and disabled the actions automatically.

Overwriting predefined actions is not recommended.

Related concepts

Syntax of INPUT ARRAY instruction on page 1426
The INPUT ARRAY supports data entry by users into a screen array and stores the entered data in an array of records.

**Binding action views to predefined actions**

As for user-defined actions, if you design forms with action views using predefined action names, they will automatically attach themselves to the actions of the interactive instructions.

It is also possible to define default images, texts, comments and accelerator keys in the action defaults resource file for the predefined actions.

**Automatic and local actions using the same name**

Some predefined actions exist as both automatic actions and as local actions (like editcopy). The automatic actions are created from the dialog context. If an automatic action has to be defined and if a local action exists with the same name, the automatic action takes precedence over the local action.

For example, if the dialog context requires an editcopy runtime action, the local editcopy action will not be handled by the front end. Identical action names are used for automatic and local action to bind with the same action view. For example, the same toolbar button created with the editcopy name will trigger the automatic action or the local action, depending on the context.

**Related concepts**

Dialog actions on page 1640

Describes how to program action handling when the end user triggers an action on the front-end.

**Default action views**

A default action view is created to render an action handler when no explicit action view exists for it.

If no explicit action view is defined, such as a toolbar button, a topmenu item or a simple button in the form layout, the front-end creates a default action view for each COMMAND or ON ACTION action handler, or implicit action such as insert/delete in INPUT ARRAY, in the current interactive instruction.

The rendering of default action views depends on the platform. On a desktop front-end, the default action views appear as buttons in the action frame in the right-hand side of the current window. On a mobile device, the default action views will follow the mobile user interface standards, which can be vendor specific. For more details about default action views on mobile, see Action views on mobile devices on page 1678.

When creating action handlers with ON KEY (or COMMAND KEY without a command name in a MENU), the default action view is invisible. If you define a text attribute in the action defaults, the default action view is made visible.

Control the default action view visibility by using the DEFAULTVIEW action attribute.
If one or more action views are defined explicitly for a given action, the front-end considers that the default view is not needed. Typically, if you define in the form a BUTTONEDIT field, a BUTTON, or a TOOLBAR item that triggers the action, you do not need an additional button in the action frame.

The presentation of default action views can be controlled with presentations style attributes for the Window AUI tree nodes.

Configuring actions
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

Action attributes define attributes for actions, including decoration such as text, icon, comment, as well as keyboard accelerator (ctrl-?, function keys), and also semantics such as current field validation control when an action is fired.

The action attributes can be defined in different ways:

1. Common action attributes can be centralized in a global action defaults file with the .4ad extension.
2. Form-specific action attributes can be defined in the ACTION DEFAULTS section of a form definition file.
3. Dialog-specific action attributes can be defined in programs with the ATTRIBUTES() clause of ON ACTION handlers.
4. Form-item specific action view attributes (decoration only) can be defined directly at the item level (labels, icons, comments).
5. Default action views can be configured dynamically with ui.Dialog.setAction*() methods.

Action attributes do not only define action view decoration; it is possible to define the semantics of an action, for example by using the VALIDATE action default attribute. Functional attributes take effect for a given action when the dialog implementing the action handler becomes active.

Action attributes are particularly important for rendering the default action view (when there is no explicit action view defined in the form). This is typically the case when no form is associated with the dialog.

Action attributes can be defined with action defaults. Common action defaults are defined in a global action defaults (.4ad) file, while form specific actions are define within the ACTION DEFAULTS section of form files.

If a dialog is not attached to a specific form such as an independent MENU, define the action attributes with the ATTRIBUTES clause of ON ACTION handlers, to render the default view and configure the action semantics. Attributes defined by ON ACTION action-name ATTRIBUTES() will only be applied to the default action view: The elements in the forms do not get decoration attributes defined by dialog action handlers.

The final decoration and functional attribute values are set in this order of precedence:

1. The attribute defined in the action view element definition itself (local form element decoration) - For default action views, the attributes are defined with ui.Dialog.setAction*() methods.
2. The attribute defined in the ATTRIBUTES clause of an ON ACTION handler.
3. The attribute defined for the action in the ACTION DEFAULTS section of the current form.
4. The attribute defined for the action in the global action defaults file (.4ad).

Note: The global action defaults can be loaded at runtime with ui.Interface.loadActionDefaults on page 2338, and the form-specific ACTION DEFAULTS section can be loaded with ui.Form.loadActionDefaults on page 2361. These solutions are typically used in a migration process, to get action views decoration without modifying existing .per forms.

The syntax for defining action attributes depends on the context where the action attributes are defined:
• In the .4ad file, the syntax follows XML standards, as defined in Action default attributes reference (.4ad) on page 1062.
• In the .per files, the syntax follows the form specification file attributes, as defined in ACTION DEFAULTS section on page 1189.
• In the .4gl files (in dialog action handlers), the syntax follows the language syntax, as defined in ON ACTION block on page 1369.

Example

Consider the following parts of code related to the same action definition, namely "print":

1. A BUTTON item defined in the form specification file:

```plaintext
ATTRIBUTES
    BUTTON b1: print, TEXT="Print item";
END
```

2. A dialog instruction with code defining the ON ACTION handler with an ATTRIBUTES clause:

```plaintext
DIALOG ...
    ...
    ON ACTION print
        ATTRIBUTES( ROWBOUND, IMAGE = "printer_2" )
    ...
```

3. The form ACTION DEFAULTS section defining:

```plaintext
form.per:
    ACTION DEFAULTS
        ACTION print (IMAGE="printer_1",
                        COMMENT="Print the order",
                        ACCELERATOR=Control-P,
                        CONTEXTMENU=NO)
    END
```

4. A global .4ad action defaults file defining:

```plaintext
<ActionDefaultList>
    <ActionDefault name="print" text="Print" image="smiley" />
</ActionDefaultList>
```

When the dialog executes, the "print" action will get the following functional attributes:

• acceleratorName = "control-p" - from the form ACTION DEFAULTS section
• rowBound = "yes" - from the dialog ON ACTION handler
• contextMenu = "no" - from the form ACTION DEFAULTS section

The form button (the action view) will get the following decoration attribute values:

• text = "Print item" - from the BUTTON form item
• image = "printer_2" - from the dialog ON ACTION handler
• comment = "Print the order" - from the form ACTION DEFAULTS section

Related concepts

Action defaults files on page 1061

### Using attributes of action defaults

#### Purpose of action defaults

*Action defaults* allow to define default attributes for common action. These defaults can be overwritten with form item attributes, or with dialog action handler attributes (only for default action views).

Centralize action attributes with action defaults, to avoid specifying them in all the source files that define the same action view and action handler. For example, you can specify the default text, image and keyboard accelerator for elements like push buttons, toolbar items, topmenu options.

Common action defaults are typically defined in a global action defaults (.4ad) file, while form specific actions are configured with form action defaults in the ACTION DEFAULTS section of the .per form specification file.

#### Global action defaults file

Global action defaults are defined in an XML file with the 4ad extension. By default, the runtime system searches for a file named default.4ad in several directories as described in the FGLRESOURCEPATH reference topic. If no file was found, standard action default settings are loaded from the FGLDIR/lib/default.4ad file.

**Important:** Global action defaults must be defined in a unique file; you cannot combine several 4ad files.

It is possible to use localized strings in action default attributes such as TEXT and COMMENT, by using LStr XML elements:

```xml
<ActionDefaultList>
  <ActionDefault name="yes" text="Yes">
    <LStr text="common.yes"/>
  </ActionDefault>
  ...
</ActionDefaultList>
```

**Note:** A global action defaults file can be loaded dynamically by program with the `ui.Interface.loadActionDefaults()` method. Use this solution if you need different global action defaults depending on the program. However, it is recommended that you consider using a single global default actions file, to get the same decoration and keyboard accelerators in all your programs.
Form specific action defaults

Action defaults can be defined at the form level in the ACTION DEFAULTS section. When action defaults are defined in the form file, action views get the attributes defined locally for this form:

```
ACTION DEFAULTS
  ACTION print (TEXT="Print",
              IMAGE="printer",
              COMMENT="Print the current record",
              ACCELERATOR=CONTROL-P)
END
```

It is possible to use localized strings in action default attributes such as TEXT and COMMENT:

```
ACTION print (TEXT=%"common.print")
```

**Note:** Form specific action defaults files can be loaded dynamically by program with the `ui.Form.loadActionDefaults()` method. Use this solution if you cannot change your .per form definition files to define ACTION DEFAULTS section: The `loadActionDefaults()` method of a form object is typically used in a generic form initializer function.

Action defaults are applied only once

Decoration attributes (like TEXT, IMAGE) of an action view will automatically be set with the value defined in the action defaults to all new action views of a new created form, if there is no explicitly value specified in the element definition for that attribute. Decoration action default attributes are applied only once, to newly created form elements: Dynamic changes are not reapplied to action views. For example, if you first load a toolbar, then you load a global action defaults file, the attributes of the toolbar items will not be updated with the last loaded action defaults. If you dynamically create action views (like TopMenu or ToolBar), the action defaults are not applied, so you must set all decoration attributes by hand.

Action defaults and sub-dialog actions

The action default attributes to be applied are selected following the name of the action. In some situations, the action view can be bound to an action handler by specifying a sub-dialog and/or field name prefix. For those views, the action defaults defined with the corresponding action name will be used to set the attributes with the default values. In other words, the prefix will be ignored. For example, if an action view is defined with the name `custlist.append`, it will get the action defaults defined for the `append` action.

Functional attributes

Functional attributes (like VALIDATE, ACCELERATOR) can only be defined in action defaults, or in ON ACTION dialog action handlers with the ATTRIBUTES clause. Functional attributes take effect for a given action when the dialog becomes active.

Related concepts

- `ui.Interface.loadActionDefaults` on page 2338
  Load the default action defaults file.
- `ui.Form.loadActionDefaults` on page 2361
  Load form action defaults.
- `ACTION DEFAULTS section` on page 1189
  The ACTION DEFAULTS section defines local action view default attributes for the form elements.
- `Dialog action handler attributes` on page 2341
  Action attributes can be specified at the dialog instruction level for default action views. These action attributes will overwrite the attributes defined in action defaults.
To define dialog-level action attributes for an action, add the `ATTRIBUTES()` clause to `ON ACTION`, with a comma-separated list of action default attributes:

```
ON ACTION print
    ATTRIBUTES (TEXT = "Print",
                COMMENT = "Print the current record",
                IMAGE = "printer",
                VALIDATE = NO)
```

It is possible to use localized strings in action attributes such as `TEXT` and `COMMENT`:

```
ON ACTION print
    ATTRIBUTES (TEXT = "%"common.print.label",
                COMMENT = "%"common.print.comment",
                ... )
```

Dialog-level action attributes are typically used when the dialog is not related to a specific form, for example with independent `MENU` dialogs.

If the current form defines explicit action views (buttons in layout, toolbar buttons, topmenu items) with the same name as the `ON ACTION` handler defining action attributes with the `ATTRIBUTES()` clause, the explicit action views will not get the action attributes defined by the `ON ACTION`.

**Related concepts**
- `ON ACTION block` on page 1369
- `Localized strings` on page 430

*Localized strings* provide a means of writing applications in which the text of strings can be customized on site.

**Configuring default action views dynamically**

Attributes of default action views can be changed dynamically during a dialog execution with `ui.Dialog.setAction*()` methods.

For example, to change the text and icon of the default action view bound to the "print" action:

```
CALL DIALOG.setActionText("print", "Print order")
CALL DIALOG.setActionImage("print", "printer")
```

The corresponding default action view will be decorated with the new text and icon.

**Note:** The attributes set with `ui.DIALOG.setAction*()` methods are volatile and last only for the duration of the current dialog.

**Related concepts**
- `ui.DIALOG.setActionImage` on page 2396
  Set the image of a default action view.
- `ui.DIALOG.setActionText` on page 2396
  Defining the text of a default action view.
- `ui.DIALOG.setActionComment` on page 2395
  Set the comment/hint of a default action view.
- `Hiding and showing default action views` on page 1667
  If needed, default action views can be hidden or shown.
- `Enabling and disabling actions` on page 1666
  By default, dialog actions are enabled. However, it is recommended that an action be disabled when not allowed in the current context.
- `Localized strings` on page 430
Localized strings provide a means of writing applications in which the text of strings can be customized on site.

**Text attribute shows default action view**

When creating actions with `ON KEY` (or `COMMAND KEY` without a command name in a `MENU`), the default action view (i.e. button in action frame) is invisible. However, if you define a `TEXT` action attribute for the corresponding key action, the default action view is made visible.

You can also control the visibility of the default action view with the `DEFAULTVIEW` action attribute.

Note that it is also possible to set key labels with form attributes (`KEY`) or with function calls (`FGL_SETKEYLABEL()`), this feature is supported for backward compatibility. Use action default text attributes in new developments.

**Related concepts**

- **Setting action key labels** on page 1676
  Labels can be defined to decorate buttons controlled by `ON KEY / COMMAND KEY` action handlers.

- **DEFAULTVIEW attribute** on page 1253
  The `DEFAULTVIEW` attribute defines if a default view (a button) must be displayed for a given action.

**Defining keyboard accelerators for actions**

Keyboard accelerators keys are attributes defining the keyboard shortcuts for actions.

Keyboard accelerators can be defined at several levels (global action defaults, form file action defaults, dialog instructions).

For example, in a `.per` form file `ACTION DEFAULTS` section:

```
ACTION DEFAULTS
   ACTION print (TEXT="Print", ACCELERATOR=Control-P)
END
```

**Note:** Up to four accelerator keys can be defined for the same action in action defaults. However, as a general pattern, define only one accelerator per action.

If no accelerators are defined for an action, the runtime system sets default accelerators for predefined actions, depending on the user interface mode. For example, the `accept` action will get the `Return` and `Enter` keys in GUI mode, but gets the `Escape` key in TUI mode.

If a user-defined action is defined with an accelerator that would normally be used for a predefined action, the runtime system does not set that accelerator for the predefined action. For example (in GUI mode), if you define an `ON ACTION quit` with an action default using the accelerator "Escape", the "cancel" predefined action will not get the "Escape" default accelerator. In this case, user settings take precedence over defaults.

**Note:** Text edition and navigation keys such as `[Home]` and `[End]` are usually local to the widget. Depending on the context, such common keys might be eaten by the graphical widget and will not invoke the action configured with the corresponding accelerator. For example, even if the "firstrow" action defines the `Home` accelerator, when using an `INPUT ARRAY`, the `[Home]` key will jump to the beginning of the edit field, not the first row of the list.

When using the `ON ACTION` clause in a dialog instruction, action accelerators are used in both GUI and TUI mode. However, for backward compatibility, this is not done in TUI mode when using the `ON KEY` clause.

The traditional `ON KEY` clause in a dialog like `INPUT` implicitly defines the `acceleratorName` attribute for the action, and the corresponding action default accelerator will be ignored. For example, when you define an `ON KEY (F10)` block, the first accelerator will be "F10", even if an action default defines an accelerator "F5" for the action "F10". However, you can set other accelerators with the `acceleratorName2`, `acceleratorName3` and `acceleratorName4` attributes in action defaults.

**Important:** In TUI mode, actions created with `ON KEY` do not get accelerators of action defaults; only actions defined with `ON ACTION` will get accelerators of action defaults.

In menus, the behavior is a bit different, see the `COMMAND and COMMAND KEY` clause of `MENU`. 
If you want to force an action to have no accelerator, you can use `none` as the accelerator name.

**Related concepts**

- **Predefined actions** on page 1641
  Genero predefines some action names for common operations of interactive instructions.

- **Keyboard accelerator names** on page 1673
  Reference for keyboard accelerator names to be used in ACCELERATOR* attributes, and in ON KEY / COMMAND
  KEY clauses in source dialog code.

**Action attributes list**

**ACCELERATOR action attribute**
The ACCELERATOR is an action attribute defining the primary accelerator key for an action.

**Syntax**

Syntax 1 (Dialog action handlers)

```plaintext
ACCELERATOR = "key"
```

Syntax 2 (ACTION DEFAULTS section in form files)

```plaintext
ACCELERATOR = key
```

Syntax 3 (Global .4ad action defaults file)

```plaintext
acceleratorName = "key"
```

1. `key` defines the accelerator key.

**Usage**

The ACCELERATOR attribute defines the keyboard combination that can be pressed by the user to send an action to the program.

Note that in dialog-specific action attributes, the ACCELERATOR must be specified as a string expression.

This attribute applies to the actions defined by the current dialog in the current window. It can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, or as dialog action attribute.

**Example**

```plaintext
-- As action handler attribute
ON ACTION print ATTRIBUTES(ACCELERATOR="control-p")

-- As action default
ACTION DEFAULTS
  ACTION print (ACCELERATOR=control-p)
END

-- In a global action defaults file
<ActionDefault name="print" acceleratorName="control-p" ... />
```

**Related concepts**

Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

**ACCELERATOR2 action attribute**
The ACCELERATOR2 is an action attribute defining the secondary accelerator key for an action.

**Syntax**

Syntax 1 (Dialog action handlers): N/A
Syntax 2 (ACTION_DEFAULTS section in form files)

```plaintext
ACCELERATOR2 = key
```

Syntax 3 (Global .4ad action defaults file)

```plaintext
acceleratorName2 = "key"
```

1. `key` defines the accelerator key.

**Usage**
The ACCELERATOR2 attribute defines the keyboard combination that can be pressed by the user to send an action to the program.

**Important:** This attribute is provided for specific cases, consider using only one accelerator per action.

**Related concepts**

- Keyboard accelerator names on page 1673
  Reference for keyboard accelerator names to be used in ACCELERATOR* attributes, and in ON KEY / COMMAND KEY clauses in source dialog code.
- Defining keyboard accelerators for actions on page 1652

  The ACCELERATOR2 is an action attribute defining the secondary accelerator key for an action.
- Configuring actions on page 1646
  Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

**ACCELERATOR3 action attribute**
The ACCELERATOR3 is an action attribute defining the third accelerator key for an action.

**Syntax**

Syntax 1 (Dialog action handlers): N/A
Syntax 2 (ACTION_DEFAULTS section in form files)

```plaintext
ACCELERATOR3 = key
```

Syntax 3 (Global .4ad action defaults file)

```plaintext
acceleratorName3 = "key"
```

1. `key` defines the accelerator key.

**Usage**
The ACCELERATOR3 attribute defines the keyboard combination that can be pressed by the user to send an action to the program.
Important: This attribute is provided for specific cases, consider using only one accelerator per action.

Related concepts

ACCELERATOR4 action attribute
The ACCELERATOR4 is an action attribute defining the fourth accelerator key for an action.

Syntax
Syntax 1 (Dialog action handlers): N/A
Syntax 2 (ACTION DEFAULTS section in form files)

```
ACCELERATOR4 = key
```

Syntax 3 (Global .4ad action defaults file)

```
acceleratorName4 = "key"
```

1. key defines the accelerator key.

Usage
The ACCELERATOR4 attribute defines the keyboard combination that can be pressed by the user to send an action to the program.

Important: This attribute is provided for specific cases, consider using only one accelerator per action.

Related concepts

COMMENT action attribute
The COMMENT attribute defines hint for the user about the action.

Syntax
Syntax 1 (Dialog action handlers and form action defaults)

```
COMMENT = \%"string"
```
Syntax 2 (Global .4ad action defaults file)

```
comment = "string"
(with optional LStr node for localized strings)
```

1. `string` is the text to display, with the `%` prefix it is a localized string.

**Usage**

Use the `COMMENT` attribute to define a description for the action. This text will typically be displayed as a hint for the corresponding action view.

Consider using localized strings with the `%"string-id"` syntax, if you plan to internationalize your application.

This action attribute can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, as dialog action attribute, or as action view attribute.

**Example**

```
-- As action handler attribute
ON ACTION print ATTRIBUTES(COMMENT="Prints current record")

-- As action default
ACTION DEFAULTS
   ACTION print (COMMENT="Print current order information")
END

-- In a form button, using a localized string id
BUTTON b1: print, COMMENT=%"actions.print.comment";

-- In a global action defaults file with a localized string id
<ActionDefault name="zoom" comment="Opens a zoom window" ... >
   <LStr comment="actions.zoom.comment" />
</ActionDefault>
```

**Related concepts**

*Localized strings* on page 430

*Localized strings* provide a means of writing applications in which the text of strings can be customized on site.

*COMMENT attribute* on page 1250

The `COMMENT` attribute defines a hint for the user about the form element.

*CONTEXTMENU action attribute*

The `CONTEXTMENU` attribute defines whether a context menu option must be displayed for an action.

**Syntax 1 (Dialog action handlers and form action defaults):**

```
CONTEXTMENU = ↓ AUTO ↓ YES ↓ NO ↓
```

**Syntax 2 (Global .4ad action defaults file):**

```
contextMenu = ↓ "yes" ↓ "no" ↓ "auto" ↓
```

**Usage**

`CONTEXTMENU` is an action attribute defining whether the context menu option must be displayed for an action.

**Important:** Actions to be displayed in a context menu must have a `TEXT` attribute. If the `TEXT` attribute is not defined or is empty, the action will not be shown in the context menu.
Possible values for CONTEXTMENU are:

1. NO indicates that no context menu option must be displayed for this action.
2. YES indicates that a context menu option must always be displayed for this action, if the action is visible.
3. AUTO means that the context menu option is displayed if no explicit action view is used for that action and the action is visible.

The default is YES.

Note: With some front-ends, the CONTEXTMENU=AUTO attribute will be interpreted as CONTEXTMENU=YES. Consider using CONTEXTMENU=NO or leave the default (CONTEXTMENU=YES).

This attribute applies to the actions defined by the current dialog in the current window. It can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, or as dialog action attribute.

Example

```plaintext
-- As action handler attribute
ON ACTION zoom ATTRIBUTES(CONTEXTMENU=YES)

-- As action default
ACTION DEFAULTS
  ACTION zoom (CONTEXTMENU=YES)
END

-- In a global action defaults file
<ActionDefault name="zoom" contextMenu="yes" ... />
```

Related concepts
CONTEXTMENU attribute on page 1250
The CONTEXTMENU attribute defines whether a context menu option must be displayed for an action.

ui.Dialog.setActionHidden on page 2395
Showing or hiding a default action view.

DEFAULTVIEW action attribute
The DEFAULTVIEW attribute defines if a default view (a button) must be displayed for a given action.

Syntax

Syntax 1 (Dialog action handlers and form action defaults)

```
DEFAULTVIEW = AUTO | YES | NO
```

Syntax 2 (Global .4ad action defaults file)

```
defaultView = "yes" "no" "auto"
```

Usage

DEFAULTVIEW is an action attribute defining whether the default action view (a button) must be displayed for an action.

Possible values for CONTEXTMENU are:

- NO indicates that no default action view must be displayed for this action.
- YES indicates that a default action view must always be displayed for this action, if the action is visible.
- AUTO means that a default action view is displayed if no explicit action view is used for that action and the action is visible.

The default is AUTO.
This attribute applies to the actions defined by the current dialog in the current window. It can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, or as dialog action attribute.

**Note:** The DEFAULTVIEW attribute does not apply to default action views displayed by a MENU instruction using the STYLE="dialog" or "popup" attribute: DEFAULTVIEW is related to the action panel of a window, pop-up and dialog menus have no relation to the action panel.

**Example**

```plaintext
-- As action handler attribute
ON ACTION zoom ATTRIBUTES(DEFAULTVIEW=YES)

-- As action default
ACTION DEFAULTS
    ACTION zoom (DEFAULTVIEW=YES)
END

-- In a global action defaults file
<ActionDefault name="zoom" defaultView="yes" ... />
```

**Related concepts**

- Default action views on page 1645
  A default action view is created to render an action handler when no explicit action view exists for it.
- ui.Dialog.setActionHidden on page 2395
  Showing or hiding a default action view.
- DEFAULTVIEW attribute on page 1253
  The DEFAULTVIEW attribute defines if a default view (a button) must be displayed for a given action.

**DISCLOSUREINDICATOR action attribute**
The DISCLOSUREINDICATOR attribute a drill-down decoration to an action.

**Syntax**

(only in MENU action handlers)

```plaintext
DISCLOSUREINDICATOR
```

**Usage**

DISCLOSUREINDICATOR is an action attribute defining whether a disclosure indicator must be shown for the default view (a button) of an action.

**Important:** This feature is only for mobile platforms.

A disclosure indicator gives a visual hint to the user, to show that the selection of the action will drill down in the application screens.

The DISCLOSUREINDICATOR attribute is typically used in a MENU instruction, for options that open a sub-menu.

The rendering of a disclosure indicator depends from the front-end platform standards. On iOS devices, buttons will show a typical > icon on the right.

This attribute can only be specified in a MENU dialog, as action attribute in the ATTRIBUTES () clause of ON ACTION handlers, and applies to the actions defined by the current dialog in the current window.

Note that form buttons can get a DISCLOSUREINDICATOR attribute, as an action view decoration.

**Example**

```plaintext
MENU ...
   ...
```
ON ACTION details ATTRIBUTES(DISCLOSUREINDICATOR)
   CALL show_customer_details(cust_rec.cust_no)
   ...

Related concepts

**Default action views** on page 1645
A default action view is created to render an action handler when no explicit action view exists for it.

**IMAGE action attribute**
The IMAGE attribute defines the image resource to be displayed for the action.

### Syntax

**Syntax 1 (Dialog action handlers and form action defaults)**

```
IMAGE = "resource"
```

**Syntax 2 (Global .4ad action defaults file)**

```
image = "resource"
```

1. `resource` defines the file name, path or URL to the image source.

### Usage:
The IMAGE attribute is used to define the image resource for the action view such a BUTTON, BUTTONEDIT or a TOOLBAR button.

For more details about image resource specification, see [Providing the image resource](#) on page 1049.

This action attribute can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, as dialog action attribute, or as action view attribute.

### Example

-- As action handler attribute
ON ACTION print ATTRIBUTES(IMAGE="printer")

-- As action default
ACTION DEFAULTS
   ACTION print (IMAGE="printer")
END

-- In a form buttonedit or button
BUTTONEDIT f001 = FORMONLY.field01, IMAGE = "zoom"
BUTTON b01: open_file, IMAGE = "buttons/fileopen"
BUTTON b02: accept, IMAGE = "http://myserver/images/accept.png"

Related concepts

**Using images** on page 1046
Describes how to use pictures in the forms of your application.

**IMAGE attribute** on page 1261
The IMAGE attribute defines the image resource to be displayed for the form item.

**ROWBOUND action attribute**
The ROWBOUND attribute defines if the action is related to the row context of a record list.

**Syntax**
(only in action handlers of record list dialog)

```plaintext
ROWBOUND
```

**Usage**
The ROWBOUND is typically used in a DISPLAY ARRAY or INPUT ARRAY dialog action handler, when the action depends on the row context. The actions marked with this attribute will be automatically enabled/disabled based on current row existence, and rendered in a special way depending on the front-end platform standards.

**Important:** This feature is only for mobile platforms.

The ROWBOUND attribute was mainly introduced for mobile applications, when using a TABLE container to get a list view: Actions marked with this attribute will be rendered in a native manner on the mobile device.

If a default action view is displayed for the action, it will be automatically hidden when no current row context is available.

This attribute can only be specified in a list handling dialog, as action attribute in the ATTRIBUTES() clause of ON ACTION handlers, and applies to the actions defined by the current dialog in the current window.

Default actions such as the delete action when using an ON DELETE modification trigger will automatically get the ROWBOUND attribute, to be available only when at least one row exists in the list. Therefore, the ROWBOUND attribute cannot be specified for such DISPLAY ARRAY modification triggers.

**Example**

```plaintext
DISPLAY ARRAY ...
   ...
   ON ACTION print ATTRIBUTES(ROWBOUND)
       CALL print_customer_info(arr_curr())
   ...
```

**Related concepts**

- Default action views on page 1645
  A default action view is created to render an action handler when no explicit action view exists for it.

- **TEXT action attribute**
The TEXT attribute defines the label associated to the action.

**Syntax**

**Syntax 1 (Dialog action handlers and form action defaults)**

```plaintext
TEXT = I%1"string"
```

**Syntax 2 (Global .4ad action defaults file)**

```plaintext
text = "string"
   (with optional LStr node for localized strings)
```

1. `string` defines the label for the action, with the `%` prefix it is a localized string.
Usage

The TEXT attribute is used to define the label associated to an action, for example for a CHECKBOX form field or a BUTTON action view.

Consider using localized strings with the \%\textcolor{red}{string-id}\% syntax, if you plan to internationalize your application.

This action attribute can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, as dialog action attribute, or as action view attribute.

Example

```
-- As action handler attribute
ON ACTION print ATTRIBUTES(TEXT="Print")

-- As form action default
ACTION DEFAULTS
  ACTION print (TEXT="Print")
END

-- As a CHECKBOX label
CHECKBOX cb01 = FORMONLY.checkbox01,
  TEXT="OK" ...
;

-- As a BUTTON label, using a localized string id
BUTTON b1: print, TEXT=\%"actions.print.label\%"

-- In a global action defaults file with a localized string id
<ActionDefault name="zoom" text="Zoom" ...
  <LStr text="actions.zoom.label" />
</ActionDefault>
```

Related concepts

Localized strings on page 430

Localized strings provide a means of writing applications in which the text of strings can be customized on site.

TEXT attribute on page 1288

The TEXT attribute defines the label associated with a form item.

VALIDATE action attribute

The VALIDATE action attribute defines the data validation level for a given action.

Syntax

Syntax 1 (Dialog action handlers and form action defaults)

```
VALIDATE = NO
```

Syntax 2 (Global .4ad action defaults file)

```
validate = "no"
```

Usage

When the VALIDATE action attribute is set to NO, it indicates that no data validation must occur for this action. However, current input buffer contains the text modified by the user before triggering the action.

This attribute applies to the actions defined by the current dialog in the current window. It can be specified as action default attribute in a global .4ad file, in the ACTION DEFAULTS section of form files, or as dialog action attribute.
Example

```
-- As action handler attribute
ON ACTION undo ATTRIBUTES(VALIDATE=NO)

-- As action default
ACTION DEFAULTS
  ACTION undo (VALIDATE=NO)
END

-- In a global action defaults file
<ActionDefault name="undo" validate="no" ... />
```

Related concepts

- Data validation at action invocation on page 1665
- The `validate` action attribute controls field validation when an action is fired.
- VALIDATE attribute on page 1294
- The `VALIDATE` action attribute defines the data validation level for a given action.

Defining action views in forms

How to define action views that will fire action events.

Actions views are form items that can be activated to fire an action event. The action event triggers user code in an ON ACTION block.

We distinguish action views defined explicitly in form files from default action views. A default action view will automatically appear when an action handler is implemented in the current dialog (if no explicit action view with the same name exists in the form). Default action view creation can be controlled with the DEFAULTVIEW action attribute.

To fire user code, action views are bound to action handlers by name.

Action view decoration attributes (IMAGE for icons, TEXT for label, COMMENT for hint) can be centralized in action defaults.

Action views can be items of form elements dedicated to action execution, such as TOOLBAR items (i.e. toolbar buttons) or TOPMENU options:

```
TOOLBAR
  ITEM accept
  ITEM cancel
  ...
END
```

Action views can be typical BUTTON items defined in the form LAYOUT:

```
LAYOUT
GRID
{
  [b1     ]
  ...
}
...
ATTRIBUTES
BUTTON b1 : print, IMAGE="printer";
...
```

Action views can be sub-elements of other elements, as when defining a BUTTONEDIT with an ACTION attribute:

```
LAYOUT
GRID
```
Action views can also be simple **IMAGE** items, when the **ACTION** attribute is specified:

```
LAYOUT
GRID
{
    [i1              ]
    ...
}
ATTIBUTES
IMAGE i1: image1, ACTION=show_details, IMAGE="mylogo";
...
```

Note that **IMAGE** fields can be defined as **TABLE** columns and define the **ACTION** attribute to trigger user code:

```
LAYOUT
GRID
{
    <TABLE t1          >
    [c1  |c2       |c3 ]
    [c1  |c2       |c3 ]
    [c1  |c2       |c3 ]
    ...
}
ATTIBUTES
...
IMAGE c3: FORMONLY.image, ACTION=delete;
...
```

For more details about image column actions see **Image columns firing actions** on page 1762.

The row selection in a **TABLE** (or **TREE**) will be considered an action view when defining the **DOUBLECLICK** attribute:

```
DISPLAY ARRAY arr TO sr.*
    ATTRIBUTES(UNBUFFERED, DOUBLECLICK=select)
    ...
END DISPLAY
```

Action views can also be graphical elements that are standard action triggers on the front-end platform, such as the **[x] cross button** of desktop windows, that will automatically bind to a "close" action, or the **FAB button** of Android, which can be configured to trigger a specific action.

**Related concepts**

- **Form specification files** on page 1132
- **ON ACTION block** on page 1369
Implementing dialog action handlers
How to execute user code in ON ACTION blocks when an action is fired.

Actions handlers are typically defined in dialog instructions with the ON ACTION interaction block. You must specify the name of the action after the ON ACTION keywords:

```plaintext
INPUT BY NAME ...
   ...
   ON ACTION print
     -- user code
   ...
```

Action handlers can also be defined with the COMMAND syntax in MENU and DIALOG instructions:

```plaintext
MENU ...
   ...
   COMMAND "Print" "Print the current record"
     -- user code
   ...
```

ON ACTION blocks provide better abstraction than COMMAND blocks by using simple action identifiers and leaving the decoration in the form files or action defaults files.

The ON ACTION block defines an action handler with a simple action name.

The COMMAND block defines an action handler with an action name, but it also defines decoration attributes, such as the label and comment. Keyboard accelerators and help topic numbers can also be defined.

**Note:** Action views controlled by ON ACTION handlers cannot get the focus. When using the COMMAND action handler, action views such as a BUTTON defined in the form layout can get the focus and are part of the tabbing item list.

Action handlers are bound to action views by name.

**Related concepts**
- Action handling basics on page 1640
  This topic describes the basics of action views, action events, and action handlers.
- ON ACTION block on page 1369
- COMMAND [KEY] block on page 1523

**Binding action views to action handlers**
How are action views of the forms bound to action handlers in the program code?

Action views (such as buttons) are bound to action handlers by the name attribute. Action handlers are defined in interactive instructions with an ON ACTION clause or COMMAND / ON KEY clauses.

For example, in the ATTRIBUTES section of the form, a button may be defined as follows:

```plaintext
BUTTON b1: show_help, TEXT="Show Help";
```

The corresponding action handler (code) in the program will use the "show_help" action name:

```plaintext
ON ACTION show_help
   CALL ShowHelp()
```

Other type of action views can for example be toolbar items:

```plaintext
TOOLBAR tb
   ITEM show_help ( TEXT="Show Help" )
   ...
```
Or BUTTONEDIT buttons (using the ACTION attribute to define the action name):

```plaintext
BUTTONEDIT f1 = customer.cust_city, ACTION = open_city_list;
```

The COMMAND / ON KEY clauses are typically used to write text mode programs. Such clauses define the name of the action and the decoration label. It is recommended that you use ON ACTION clauses instead, because they identify user actions with an abstract name. However, if required, you can use a COMMAND clause in a non-menu dialog to include the corresponding action view in the focusable form items.

In the ON ACTION action-name clause, the name of the action must be a valid identifier, preferably written in lowercase letters. In the abstract user interface tree (where the action views are defined), action names are case sensitive (as they are standard DOM attribute values). However, identifiers are not case sensitive in the language. The fglcomp compiler always converts the action identifiers of ON ACTION clauses to lowercase:

```plaintext
ON ACTION PrintRecord   -- will be compiled as "printrecord"
```

To avoid confusion, always use lowercase names for action names (for example, print_record instead of PrintRecord).

**Related concepts**

- Field-specific actions (INFIELD clause) on page 1669
  Using the INFIELD clause of ON ACTION provides automatic action activation when a field gets the focus.
- Defining action views in forms on page 1662
  How to define action views that will fire action events.
- Implementing dialog action handlers on page 1664
  How to execute user code in ON ACTION blocks when an action is fired.

**Data validation at action invocation**

The validate action default attribute controls field validation when an action is fired.

When using the UNBUFFERED mode of interactive instructions such as INPUT or DIALOG, if the user triggers an action, the current field data is checked and loaded in the target variable bound to the form field. For example, if the user types a wrong date (or only a part of a date) in a field using a DATE variable and then clicks on a button to invoke an action, the runtime system will display an invalid input error and will not execute the ON ACTION block corresponding to the button.

To prevent data validation for some actions, use the validate action default attribute. This attribute instructs the runtime not to copy the input buffer text into the program variable (requiring input buffer text to match the target data type).

```plaintext
ACTION DEFAULTS
  ...
  ACTION zoom ( ... VALIDATE = NO ... )
  ...
END
```

This is especially needed in DIALOG instructions; in singular dialogs like INPUT, predefined actions like cancel do not validate the current field value when UNBUFFERED mode is used.

The validate action default attribute can be set in the global action default file, or at the form level, with the VALIDATE attribute in a line of the ACTION DEFAULTS section.

**Related concepts**

- The buffered and unbuffered modes on page 1618
  The buffered and unbuffered mode control the synchronization of program variables and form fields.
- ACTION DEFAULTS section on page 1189
The **ACTION DEFAULTS** section defines local action view default attributes for the form elements.

### Enabling and disabling actions

By default, dialog actions are enabled. However, it is recommended that an action be disabled when not allowed in the current context.

Dialog actions are enabled to let the user invoke the action handler (ON ACTION/COMMAND) by clicking on the corresponding action view (button) or by pressing its accelerator key. In most situations, actions remain active during the whole dialog execution. However, to follow GUI standards, actions must be disabled when not allowed in the current context. For example, a print action is disabled if no record is currently shown in the form. After a database query, when the form is filled with a given record, the print action can be activated.

Depending on the front-end ergonomics, the visual result of disabling an action can be different. On desktop front-ends, the action views (buttons) are typically grayed, indicating that the action is there but cannot be triggered. On other front-ends such as some mobile devices, the action view might be hidden, for layout reasons (there is not much space on a mobile device screen).

During a dialog instruction, enable or disable an action with the `ui.Dialog.setActionActive()` method of the `ui.Dialog` built-in class. This method takes the name of the action (in lowercase letters) and a boolean expression (0 or FALSE, 1 or TRUE) as arguments.

```plaintext
BEFORE INPUT
CALL DIALOG.setActionActive( "zoom", FALSE )
```

Consider centralizing action activation / deactivation in a setup function specific to the dialog, passing the `DIALOG` object as the parameter. Centralizing the action activation defines the rules in a single location:

```plaintext
FUNCTION cust_dialog_setup(d)
    DEFINE d ui.Dialog
    DEFINE can_modify BOOLEAN
    LET can_modify = (cust_rec.is_new OR user_info.is_admin)
    CALL d.setActionActive("update", can_modify)
    CALL d.setActionActive("delete", can_modify)
    ...
END FUNCTION
```

Some **predefined dialog actions** such as insert / append / delete of `INPUT ARRAY` are automatically enabled/disabled base on the context. For example, if the maximum number of rows (`MAXCOUNT`) is reached in an `INPUT ARRAY`, insert and append actions are disabled.

When the action activation depends on the focus being in a specific field, consider using the `INFIELD` clause of `ON ACTION` to automatically disable an action if the focus leaves the specified field.

Inside a `DIALOG` block, actions can be defined a different levels, and may need to be identified with the sub-dialog prefix, when you invoke the `ui.Dialog.setActionActive()` method outside of the context of the sub-dialog. In the next example, the `check_row` action must be prefixed by the `s_ord` sub-dialog name, because `ui.Dialog.setActionActive()` is called from the `INPUT BY NAME` sub-dialog context, to disable an action from the `DISPLAY ARRAY` sub-dialog:

```plaintext
DIALOG ATTRIBUTES(UNBUFFERED)
    DISPLAY ARRAY a_ord TO s_ord.*
    -- sub-dialog-level action
    ON ACTION check_row
    ...
END DISPLAY
...
INPUT BY NAME rec.* ...
ON CHANGE consolidation
    -- Must use sub-dialog name to identify the check_row action:
    CALL DIALOG.setActionActive( "s_ord.check_row", FALSE )
...
```

Enabling and disabling dialog actions.

Hiding and showing default action views
If needed, default action views can be hidden or shown.

When an action is rendered with a default action view (for example, by a button on the action frame of a desktop front-end, or in the top action panel on a mobile front-end), it is sometimes required to hide the action button when the operation is not possible and there is not much space on the screen.

Important: Hiding an action will only make the default action view invisible, if there is a keyboard accelerator associated to the action, it can still fire the action. Consider disabling the action completely with setActive().

During a dialog instruction, shown or hide an action with the setActionHidden() method of the ui.Dialog built-in class. This method takes the name of the action (in lowercase letters) and a boolean expression (FALSE or TRUE) as arguments:

BEFORE INPUT
CALL DIALOG.setActionHidden( "zoom", TRUE )

Consider centralizing action visibility control in a setup function specific to the dialog, passing the DIALOG object as the parameter. Centralizing the action activation defines the rules in a single location:

FUNCTION cust_dialog_setup(d)
DEFINE d ui.Dialog
DEFINE can_modify BOOLEAN
LET can_modify = (cust_rec.is_new OR user_info.is_admin)
CALL d.setActionActive("update", can_modify)
CALL d.setActionHidden("update", IIF(can_modify,0,1))
CALL d.setActionActive("delete", can_modify)
CALL d.setActionHidden("delete", IIF(can_modify,0,1))
...
END FUNCTION

Pay attention to multi-level action definitions inside a DIALOG block: Inside a DIALOG block, actions must be hidden/shown with the ui.Dialog.setActionHidden() method by specifying a simple action name:

DIALOG ATTRIBUTES(UNBUFFERED)
...
BEFORE DIALOG
CALL DIALOG.setActionHidden( "print", TRUE )
...
ON ACTION query
-- query the database and fill the record
...
CALL DIALOG.setActionHidden( "print", (cust_id IS NULL) )
...
END DIALOG

**Sub-dialog actions in procedural DIALOG blocks**

This topic describes how action are differentiated with handlers defined in a procedural DIALOG block.

We distinguish *dialog actions* from *sub-dialog actions*: When the `ON ACTION` handler is defined at the same level as a `BEFORE DIALOG` control block, it is a dialog action, and the action name is a simple identifier as in singular interactive instructions:

```
action-name
```

When the `ON ACTION` handler is defined inside a sub-dialog, or if the action is an implicit action such as `insert` in `INPUT ARRAY`, it is a sub-dialog action, and the action name gets the name of the sub-dialog as the prefix to identify the sub-dialog action with a unique name:

```
sub-dialog-name.action-name
```

The `INPUT ARRAY` and `DISPLAY ARRAY` sub-dialogs are implicitly identified with the screen-record name defined in the form. For `INPUT` and `CONSTRUCT` sub-dialogs, the sub-dialog identifier can be specified with the `NAME` attribute.

The next example defines two 'check' action in different sub-dialog contexts, and a 'close' action at the dialog level:

```
DIALOG
  INPUT BY NAME ... ATTRIBUTES (NAME = "cust")
    ON ACTION check                   -- sub-dialog action "cust.check"
      ...
  END INPUT
  DISPLAY ARRAY arr_orders TO sr_ord.*
    ON ACTION check                   -- sub-dialog action "sr_ord.check"
      ...
  END DISPLAY
  BEFORE DIALOG
    ...
  ON ACTION close                      -- dialog action "close"
      ...
  END DIALOG
```

By using the sub-dialog identifier in form definition files, you can bind action views to specific sub-dialog actions. Action views bound to sub-dialog actions with qualified sub-dialog action names will always be active, even if the focus is not in the sub-dialog of the action. You typically use fully-qualified sub-dialog actions names for buttons in the form body or in tomenu options. However, it does not make much sense to use this technique for toolbar buttons, where buttons must be enabled/disabled based on the context.

```
TOOLBAR
  ...
  ITEM append
    ...
  END

TOPMENU
  ...
    GROUP orders (TEXT="Orders")
      COMMAND sr_ord.append
    ...
  END

LAYOUT
GRID
```
If you bind an action view with a simple action name (without the sub-dialog prefix), the action view will be attached to any sub-dialog action with the matching name. This is especially useful for common actions such as the implicit insert / append / delete actions created by INPUT ARRAY, when the dialog handles multiple editable lists. Bind toolbar buttons to these actions without the sub-dialog prefix; the buttons will apply to the current list that has the focus. The action views bound to sub-dialog actions without the sub-dialog qualifier will automatically be enabled or disabled when entering or leaving the group of fields controlled by the sub-dialog (i.e. typical navigation buttons in the toolbar will be disabled if the focus is not in a list).

If a sub-dialog action is invoked when the focus is not in the sub-dialog of the action, the focus will automatically be given to the first field of the sub-dialog, before executing the user code defined in the ON ACTION clause. This will trigger the same validation rules and control blocks as if the user had selected the first field of the sub-dialog by hand.

When using DIALOG.setActionActive() (or any method that takes an action name as parameter), you can specify the action name with or without a sub-dialog identifier. If you qualify the action with the sub-dialog identifier, the sub-dialog action is clearly identified. If you don't specify a sub-dialog prefix, the action will be identified based on the focus context - when the focus is in the sub-dialog of the action, non-qualified action names identify the local sub-dialog action; otherwise, they identify a dialog action if one exists with the same name. Disabling an action by the program with setActionActive(), will take precedence over the built-in activation rules (i.e. if the action is disabled by the program, the action will not be activated when entering the sub-dialog).

For action views bound to sub-dialog actions with qualifiers, the action defaults defined with the corresponding action name will be used to set the attributes with the default values. In other words, the prefix will be ignored. For example, if an action view is defined with the name "custlist.append", it will get the action defaults defined for the "append" action.

Toolbars define a bar of buttons that appears at the top of application forms.

Field-specific actions (INFIELD clause)
Using the INFIELD clause of ON ACTION provides automatic action activation when a field gets the focus.

The ON ACTION interaction block of INPUT, CONSTRUCT and INPUT ARRAY (as singular dialogs or sub-dialogs in DIALOG instruction), can be specified with the INFIELD field-name clause. With this clause, the action will only be active when the focus is on one of the fields. The same action name can be used for several fields.
Actions defined with the `INFIELD field-name` clause can be identified with the field name as prefix:

```
field-name.action-name
```

You can bind form action views with or without the field name prefix:

```
-- Form file:
EDIT f1 = customer.cust_name;
BUTTON b1 : cust_name.clear, ... ;   -- field-qualified action
BUTTON b2 : clear, ... ;           -- unqualified action

-- Program code:
ON ACTION clear INFIELD cust_name
...  
```

- Without the field name prefix, the action view is enabled and disabled automatically depending on the current field: The action view is enabled when the corresponding `INFIELD` field has the focus.
- When binding the action view with the fully-qualified name including the field name prefix, the action view will always be active, and the focus will jump to the first corresponding field, if the action is fired.

**Note:**
When using `ON ACTION action-name INFIELD field-name` for one or several `BUTTONEDIT` fields, the runtime system implicitly handles the `BUTTONEDIT` action as a field-qualified action, even if the `ACTION` attribute is defined without the field name:

```
BUTTONEDIT f1 = customer.cust_city, ACTION = zoom;
```

Is equivalent to:

```
BUTTONEDIT f1 = customer.cust_city, ACTION = cust_city.zoom;
```

Actions defined in sub-dialogs of the `DIALOG` instruction get the name of the sub-dialog as prefix. If `ON ACTION action-name INFIELD field-name` is used in a sub-dialog, the action object name is prefixed with the name of the sub-dialog, followed by the name of the field. The fully-qualified action name will be:

```
sub-dialog-name.field-name.action-name
```

When the field-specific action is invoked (for example by a button of the toolbar bound with the fully-qualified action name) and if the field does not have the focus, the runtime system first selects that field before executing the code of the `ON ACTION INFIELD` block. The field selection forces data validation and `AFTER FIELD` of the current field, followed by `BEFORE FIELD` of the target field associated to the action.

It's still possible to enable and disable field-specific action objects by the program using the `DIALOG.setActionActive()` method. When specifying a fully-qualified action name with the field name prefix, that field-specific action will be enabled or disabled. When disabled by the `setActionActive()` method, the corresponding action views will always be disabled, even if the field has the focus. If you do not specify a fully-qualified name in the method call, and if several actions are defined with the same action name in different sub-dialogs and/or using the `INFIELD` clause, the method will identify the action according to the current focus context. For example, if you define `ON ACTION zoom INFIELD cust_city` and `ON ACTION zoom INFIELD cust_addr`, when the focus is in `cust_city`, a call to `DIALOG.setActionActive("zoom", FALSE)` will disable the action specific to the `cust_city` field.

Fields can be enabled or disabled dynamically with the `DIALOG.setFieldActive()` method. If an `ON ACTION INFIELD` is declared on a field and if you enable/disable the field dynamically, then the field-specific action (and corresponding action views in the form) will be enabled or disabled accordingly.

For action views bound to field actions with qualifiers, the action defaults defined with the corresponding `action name` will be used to set the attributes with the default values. In other words, the prefix will be ignored. For example, if an
action view is defined with the name "cust_addr.check", it will get the action defaults defined for the "check" action.

**Related concepts**

- **Configuring actions** on page 1646
- **Topmenus** on page 1334
- **Toolbars** on page 1327

**Multilevel action conflicts**

Actions can be defined at two levels in a singular dialog, and three levels in the context of a DIALOG block:

- **Dialog level**
- **Sub-dialog level** (procedural DIALOG only)
- **Field level** (ON ACTION with INFIELD clause)

It is not good practice to use the same action name at different levels of a dialog: This makes action view bindings and action handling (i.e. enabling / disabling) very complex, because there are many possible combinations. Therefore, when using the same action name at different dialog levels, the fgcomp compiler will raise a warning -8409. However, it is legal to use the same action name for a given level of action handlers in a sub-dialogs or for field-actions. For example, using the "zoom" action name for multiple ON ACTION INFIELD handlers is a common practice.

When binding action views with full qualified names, the ON ACTION handler is clearly identified, and the corresponding user code will be executed. However, when you do not specify the complete prefix of a sub-dialog or field action, the runtime system searches for the best ON ACTION handler to be executed, according to the current focus context.

Take for example a DIALOG instruction defining three ON ACTION print handlers at the dialog, sub-dialog and field level:

```plaintext
DIALOG
  INPUT BY NAME ... ATTRIBUTES (NAME = "cust")
  ...
  ON ACTION print INFIELD cust_name -- field-level action (1)
  ...
  ON ACTION print -- sub-dialog-level action (2)
  ...
END INPUT
  ...
  ON ACTION print -- dialog-level action (3)
  ...
END DIALOG
```

The action views of the form will behave as follows:

- Action views bound with the name "print" will always be active, and invoke the ON ACTION print handler corresponding to the current focus context:
  - (1) is invoked if the focus is in the cust_name field.
  - (2) is invoked if the focus is in the cust sub-dialog, but not in cust_name field.
  - (3) is invoked if the focus is in another sub-dialog as cust sub-dialog.
- Action views bound with the name "cust.print" will always be active, even if the focus is not the cust sub-dialog, and invoke the ON ACTION print handler depending on the focus context:
  - (1) is invoked if the focus is in the cust_name field.
  - (2) is invoked if the focus is in the cust sub-dialog, but not in cust_name field.
• Action views bound with the name "cust.cust_name.print" will always be active, and invoke the ON ACTION print INFIELD cust_name handler after giving the focus to the cust_name field.

If the first field of a sub-dialog defines an ON ACTION INFIELD with the same action name as a sub-dialog action, and the focus is not in that sub-dialog when the user selects an action view bound with the name sub-dialog-name.action-name, the runtime system gives the focus to the first field of the sub-dialog. This field becomes the current field, and the runtime system executes the field-specific action handler instead of the sub-dialog action handler.

To avoid mistakes and complex combinations, it is recommended that you use specific action names for each dialog level.

Action display in the context menu
The CONTEXTMENU action default attribute allows you to control action visibility in the context menu.

Some front-ends can display a context menu, with all the active actions that are possible in the current form. Displaying all actions might not be adapted to your needs. To control if an action must be displayed in the context menu, set the CONTEXTMENU attribute in action defaults. Values for CONTEXTMENU can be YES, NO and AUTO.

```
ACTION DEFAULTS
  ...
  ACTION insert ( ... CONTEXTMENU = YES ... )
  ACTION append ( ... CONTEXTMENU = YES ... )
  ACTION delete ( ... CONTEXTMENU = YES ... )
  ...
  ACTION validate_order ( ... CONTEXTMENU = NO ... )
  ...
END
```

Related concepts
Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

Implementing the close action
The close action is a predefined action dedicated to close graphical windows (for example, with the X cross button).

Purpose of the close action
In graphical applications, windows can be closed by the user, for example by pressing Alt+F4 or by clicking the cross button in the upper-left corner of the window.

A predefined action named "close" is dedicated to this specific event.

When the end user closes a graphical window, the program gets a close action. It is then possible to execute user code in an ON ACTION close action handler, or leave the default behavior.

Note: The default action view (that is the button in the action frame) of the close action is hidden.

The close action in multiple dialogs
When executing a DIALOG instruction, the close action executes the ON ACTION close block, if defined. Otherwise, the close action is mapped to the cancel action if an ON ACTION cancel handler is defined.

If neither ON ACTION close, nor ON ACTION cancel are defined, nothing will happen if the user tries to close the window with the X cross button or an ALT+F4 keystroke.

The INT_FLAG register will not be set in the context of DIALOG.

The close action in singular dialogs
When an ON ACTION close handler is defined in an INPUT, INPUT ARRAY, CONSTRUCT, DISPLAY ARRAY or PROMPT interactive instruction, the handler code will be executed if the close action is fired.
If no explicit ON ACTION close handler is defined, the close action acts the same as the cancel predefined action. So by default when the user clicks the X cross button in a window, the interactive instruction stops and the INT_FLAG is set to 1.

If there is an explicit ON ACTION cancel block defined, INT_FLAG is set to 1 and the user code under ON ACTION cancel will be executed.

If the CANCEL=FALSE option is set, no cancel and no close action will be created, and you must write an ON ACTION close handler to proceed with the close action. In this case, the INT_FLAG register will not be set when the close action is invoked.

The close action in MENU dialogs

When an ON ACTION close handler is defined in a MENU statement, the handler code will be executed if the close action is fired.

If no explicit ON ACTION close action handler is defined, the code of the COMMAND KEY (INTERRUPT) or ON ACTION cancel will be executed, if defined.

If neither COMMAND KEY (INTERRUPT) nor ON ACTION cancel is defined:

- If the MENU uses the default rendering (as buttons in current window action frame) or with the attribute STYLE="dialog", nothing happens and the program stays in the MENU instruction.
- If the MENU is defined with the attribute STYLE="popup", there is no X cross button to click. However, the Escape key, or a click outside the popup menu will terminate the MENU dialog.

Regarding the INT_FLAG register, its value is unknown after a MENU instruction.

The close action on mobile devices

When displaying on a mobile device, the close action is rendered differently depending on the mobile platform:

- On Android™, the close action is mapped to the [Back] button (it is not rendered in the action panel)
- On iOS, there is no [Back] button concept and the close action is rendered as a regular action.

For more details, see Action views on mobile devices on page 1678.

Example

You typically implement a close action handler to open a confirmation dialog box as in the following example:

```
INPUT BY NAME cust_rec.*
...
ON ACTION close
  IF msg_box_yn("Are you sure you want to close this window?") == "y" THEN
    EXIT INPUT
  END IF
...
END INPUT
```

Related concepts

Predefined actions on page 1641

Genero predefines some action names for common operations of interactive instructions.

Keyboard accelerator names

Reference for keyboard accelerator names to be used in ACCELERATOR* attributes, and in ON KEY / COMMAND KEY clauses in source dialog code.

ON KEY Virtual keys

Virtual keys are the key names that can be used in program instructions such as ON KEY and COMMAND KEY.

An ON KEY block defines one to four different action objects that will be identified by the key name in lowercase (ON KEY(F5,F6) = creates Action f5 + Action f6). Each action object will get an acceleratorName attribute assigned. In GUI mode, action defaults are applied for ON KEY actions by using the
name of the key. You can define secondary accelerator keys, as well as default decoration attributes like button text and image, by using the key name as action identifier. The action name is always in lowercase letters.

Check carefully the ON KEY CONTROL-? statements because they may result in having duplicate accelerators for multiple actions due to the accelerators defined by action defaults. Additionally, it is recommended to avoid using ON KEY statements with ESC, TAB, UP, DOWN, LEFT, RIGHT, HELP, NEXT, PREVIOUS, INSERT, CONTROL–M, CONTROL–X, CONTROL–V, CONTROL–C, and CONTROL–A in GUI programs, because they are very likely to clash with default accelerators defined in the action defaults.

By default, ON KEY actions are not decorated with a default button in the action frame (i.e. default action view). You can show the default button by configuring a text attribute with the action defaults.

Table 357: Names of keys to be referenced in programs

<table>
<thead>

Related concepts

Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

Accelerator key names

Accelerators keys are attributes defining the keyboard shortcuts for actions.

Action accelerate keys are typically centralized with actions defaults attributes. For a complete usage description, see Defining keyboard accelerators for actions on page 1652.

Keyboard key names can be combined with key modifiers, to define key combinations such as [Ctrl] + [P].

Tip: To force an action to have no accelerator, specify "none" as the accelerator name.

Table 358: Keyboard key names

<table>
<thead>
<tr>
<th>Key Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>Special name indicating the runtime system must not set any accelerator for the action.</td>
</tr>
</tbody>
</table>
### Key Name | Description
--- | ---
0–9 | Decimal digit keys from [0] to [9]
A–Z | Letters keys from [A] to [Z]
F1–F35 | The functions keys like [F10]
BackSpace | The [BACKSPACE] key (do not confuse with [DELETE] key)
Delete | The [DELETE] key (navigation keyboard group)
Down | The [DOWN] key (arrow keyboard group)
End | The [END] key (navigation keyboard group)
Enter | The [ENTER] key (numeric keypad, see Note)
Escape | The [ESCAPE] key
Home | The [HOME] key (navigation keyboard group)
Insert | The [INSERT] key (navigation keyboard group)
Left | The [LEFT] key (arrow keyboard group)
Minus | The [-] minus sign key (Hyphen)
Next | The [PAGE UP] key (navigation keyboard group)
Prior | The [PAGE DOWN] key (navigation keyboard group)
Return | The [RETURN] key (alphanumeric keypad, see Note)
Right | The [RIGHT] key (arrow keyboard group)
Space | The [SPACEBAR] key
Tab | The [TAB] key
Up | The [UP] key (arrow keyboard group)

**Note:** The "Enter" accelerator key name represents the [ENTER] key available on the numeric keypad of standard keyboards, while "Return" represents the [RETURN] key of the alphanumeric keyboard. By default, the "accept" validation action is configured to accept both "Enter" and "Return" keys.

**Related concepts**

**Configuring actions** on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

**Predefined actions** on page 1641
Genero predefines some action names for common operations of interactive instructions.

**Accelerator key modifiers**

Key modifiers define keyboard control key combinations in accelerator key names.

The accelerator key names such as "F10" can be combined with key modifiers, by using a minus sign (Hyphen) as separator:

```
key-modifier - [ ] key-modifier - [ ] key-modifier - [ ] key-name
```

**Table 359: Names of key modifiers**

<table>
<thead>
<tr>

<td>The left or right [Alt] key.</td>
</tr>
</tbody>
</table>

For example:

Control-P
Shift-Alt-F12
Control-Shift-Alt-Z

**Related concepts**

**Accelerator key names** on page 1674
Accelerators keys are attributes defining the keyboard shortcuts for actions.

**Setting action key labels**
Labels can be defined to decorate buttons controlled by ON KEY / COMMAND KEY action handlers.

**Syntax**
Key label configuration can take place at different levels.

- FGLPROFILE definitions
  
  ```plaintext
  key.key-name.text = "label"
  ```

- Program-level key labels
  
  ```plaintext
  CALL fgl_setkeylabel( "key-name", "label" )
  ```

- Form level key labels (in KEYS section)
  
  ```plaintext
  KEYS key-name = [%]"label"
  [...] [END]
  ```

- Dialog level key labels
  
  ```plaintext
  CALL fgl_dialog_setkeylabel( "key-name", "label" )
  ```

- Form field level key labels (in field definition)
  
  ```plaintext
  KEY key-name = [%]"label"
  ```

1. `key-name` is the name of the key.
2. `label` is the text to be displayed in the default action view (button).

**Usage**
In GUI mode, ON KEY and COMMAND KEY action handlers in dialogs can be shown as form buttons when a label text is defined for the key: By defining a label for a key, the runtime system will automatically show a default button for the key action.

**Important:** Key label configuration is provided for backward compatibility. Consider using action configuration in new programs. However, key labels can be used to easily improve the graphical rendering of your application, without touching legacy code using ON KEY / COMMAND KEY in dialogs.

In the example, the function key F10 is used to show a detail window in this interactive dialog:

```plaintext
INPUT BY NAME myrecord.*
ON KEY (F10)
  CALL ShowDetail()
```
By default, if you do not specify a label for F10, no default action button is displayed for a function key or control key. Furthermore, if the text provided for the key label is empty or null, the default action button will not be displayed.

In order to get a default action view button for F10, define for example the KEY attribute in the form file, for the corresponding fields where this action can be fired:

```
ATTRIBUTES
...  
f07 = customer.cust_city, KEY F10 = "City list";
f08 = customer.cust_state, KEY F10 ="State list";
...
```

Table 360: Key names recognized by the runtime system

<table>
<thead>
<tr>
<th>Key Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>f1 to f255</td>
<td>Function keys.</td>
</tr>
<tr>
<td>control-a to control-z</td>
<td>Control keys.</td>
</tr>
<tr>
<td>accept</td>
<td>Predefined dialog validation action.</td>
</tr>
<tr>
<td>interrupt</td>
<td>Predefined dialog cancellation action. The action name is <em>cancel</em>, not <em>interrupt</em>.</td>
</tr>
<tr>
<td>insert</td>
<td>Predefined INPUT ARRAY dialog row insertion action.</td>
</tr>
<tr>
<td>append</td>
<td>Predefined INPUT ARRAY dialog row addition action.</td>
</tr>
<tr>
<td>delete</td>
<td>Predefined INPUT ARRAY dialog row deletion action.</td>
</tr>
<tr>
<td>help</td>
<td>Predefined help action.</td>
</tr>
</tbody>
</table>

Key labels can be defined at different levels. The order of precedence for key label definition is the following:

1. The label defined with the KEY attribute of the form field.
2. The label defined for the current dialog, using the FGL_DIALOG_SETKEYLABEL function.
3. The label defined in the KEYS section of the form specification file.
4. The label defined as default for a program, using the FGL_SETKEYLABEL function.
5. The label defined in the FGLPROFILE configuration file (key.key-name.text entries).

In Genero, you typically define action labels with action attributes. However, if key labels are defined, they will overwrite the text defined in action attributes for the corresponding key action. In BDS 3.xx versions, default key labels are defined in FGLDIR/etc/fglprofile. These defaults have been commented out in Genero to have action attribute text applied (In Genero, by default, fgl_getkeylabel() returns NULL for all keys). If you want to get the same default key labels as in BDS 3.xx, uncomment the key.* lines in FGLDIR/etc/fglprofile.

You can query the label defined at the program level with the FGL_GETKEYLABEL function and, for the current interactive instruction, with the FGL_DIALOG_GETKEYLABEL function.

**Related concepts**

- Configuring actions on page 1646
- Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

- FGLPROFILE environment variable defines Genero BDL configuration files
- COMMAND KEY() block on page 1368
- ON KEY block on page 1357
**Action views on mobile devices**
Action views are rendered following mobile specific standards.

**Action view rendering on mobile**
The top and/or bottom part of the app screen can be used to place action views (UI button controls).

Key functions of these areas:

- Make important actions prominent and accessible in a predictable way (such as **New** or **Search**).
- Support consistent navigation and view switching within apps.
- Reduce clutter by providing an action overflow for less-used actions.
- Provide a dedicated space for giving your app an identity with text and/or an image.

How actions are rendered on the mobile device depends on:

- The order of the **ON ACTION** statements in the current dialog of the running app.
- The type of platform (Android™/iOS).
- The type (phone/tablet) and orientation of the device.

Actions are mapped to the Android™ or iOS platform in a specific way, following the platform standard.

Actions can be programmatically **enabled** and **disabled**, and **hidden and shown**.

The text, image and other properties of the action can be controlled with **action attributes**.

**GUI elements to trigger actions on mobile devices**
Each mobile platform provides its own standard to display action triggers.

GMA and GMI follow respectively the Android™ and iOS standards:

- iOS navigation controller and toolbar pane on page 1679
- Android action bar on page 1685
- Android floating action button on page 1687

**Decorating action views on mobile**
Actions are typically decorated using the **IMAGE** or the **TEXT** action attribute. If these attributes are not defined or if the specified image resource is not available, the mobile front-end uses a default decoration. For some actions, the front-end always uses the platform-specific decoration. For example, on iOS devices, the "refresh" action always renders as a typical circular arrow icon.

Well-known actions use a default icon or text corresponding to the mobile platform GUI guidelines. As these follow the mobile OS standards, do not define your own text or icons for common actions such as "accept" or "cancel".

For a complete list of predefined action decorations, see:

- iOS default action views decoration on page 1684
- Android default action views decoration on page 1688

**Rendering close/cancel/accept actions on Android™ devices**
The physical back button on an Android™ device is considered a default action view for the "close", "cancel", or "accept" action in the current dialog:

- If a close action is defined, it is assigned to the back button.
- If the close action is not defined, but the cancel action is defined, it is assigned to the back button.
- If neither close nor cancel actions are defined, but the accept action is defined, it is assigned to the back button.

If accept or cancel cannot be assigned to the back button, a default action view appears in the action panel. For example, if all three actions (close, cancel and accept) exist and are active, the action panel shows a check mark for the accept action and a cross icon for the cancel action, while the back button fires the close action.
**Default action views rendering with MENU**

On mobile devices, the rendering of the MENU dialog depends on whether or not the current window has a form.

If a MENU is active and the current Window has no form, then the MENU is shown as a list of actions.

If a MENU is active and has a FORM, then the menu actions are rendered like all other dialog actions.

**iOS navigation controller and toolbar pane**

On iOS devices, apps can display a navigation controller and a toolbar pane.

The iOS navigation controller is made of a navigation bar, a optional menu icon and a common action pane (the current window/form title is displayed in the middle of these UI controls).

The iOS toolbar pane displays at the bottom of the screen to show application options.
Figure 81: iOS app interface
Navigation bar (1) The left side navigation bar provides a linear path through various screens. The accept, cancel or close action is rendered as the [<] back button, respectively in the order of precedence given here. If there is a previous form or window, then this button shows the title of the previous page. If there is not a form to return to, the "back" navigation button is not shown.

Menu icon (2) The three-bars icon is the menu icon. This icon appears when the current form defines a TOPMENU. The menu options are displayed in a listview, when the user taps on the menu icon.

Common action pane (3) The right-hand side is the common action pane. Default action views are displayed here, in the same order as the ON ACTION blocks of the current dialog.

Toolbar pane (4) When default action views are displayed, if there is not enough room in the common action pane (3), the remaining actions are displayed in the toolbar pane at the bottom of the screen. If there is not enough space to display all action views in the toolbar pane, an overflow icon appears on the right. Tap on the overflow icon to show the remaining action views.

Use a TOOLBAR in your form, to have full control on the toolbar pane: An action displayed as a TOOLBAR item in the toolbar pane will no longer display as default action view in the common action pane (3).

In the next screen shot, the iOS device is oriented in landscape mode. The app is the same, yet since there is enough space in the navigation bar, all default action views display in the common action pane.

![iOS app interface in landscape mode](image-url)

Figure 82: iOS app interface in landscape mode
To customize the application, define the colors of the iOS navigation bar and toolbar with the following Window-class style attributes:

- `iosTintColor`, for items in (1), (2), (3) and (4) (and for other form items)
- `iosNavigationBarTintColor`, for (1), (2) and (3).
- `iosToolBarTintColor`, for (4).

For example, by setting the following style attributes, the navigation bar will render as shown in the screen shot:

```xml
<Style name="Window">
  <StyleAttribute name="iosTintColor" value="darkRed" />
  <StyleAttribute name="iosNavigationBarTintColor" value="orange" />
  <StyleAttribute name="iosToolBarTintColor" value="orange" />
  <StyleAttribute name="iosTabBarTintColor" value="orange" />
</Style>
```
Figure 83: iOS (7) colored navigation bar
**iOS default action views decoration**

Common default action views get a decoration implicitly, following iOS standards.

On iOS devices, the decoration for well known actions can be a symbol or a text. When a text is used, it is internationalized. For example, the "accept" action translates to "Done" when the mobile language is English, "Fertig" in German and "OK" in French.

For the default action views of the common actions, the decoration will always follow the iOS standards, even if an attribute is explicitly specified for the action. For example, if you implement an ON ACTION save action handler with ATTRIBUTES(TEXT="Write", IMAGE="disk"), the action view renders with the "Save" text on an iOS device configured for the English language.

To bypass the iOS standard decoration and render default action views with text and images defined by the corresponding action attributes, use the `iosRenderSystemActions` presentation style attribute with the value "no".

**Table 361: Default rendering for common actions on iOS**

**Android™ action bar**

On Android devices, apps show an action bar.

The Android action bar displays in the top of the screen, with several elements having a specific purpose:

1. **The app icon (1)**
   - The app icon and the title of the current form display in the upper left corner.
   - The application title is defined by the TEXT attribute of the main window displayed by the application.
   - The icon that appears is either the icon set for the app in the packaging, or it is the image specified by the ui.Interface.setImage method. The application icons must be included in the deployment package (.apk) and follow the Android standards (several icon sizes are required).

2. **The view control (2)**
   - If your app implements different views controlled by a top-level navigator, this segment allows users to switch between views. For more details, see Navigator pane on
In an application handling multiple views in parallel, the view control item displays as a text button.

**Figure 84: Android View Control**

The right-hand side of the action bar shows the actions. The action buttons (3) show the most important actions of your app. Actions that do not fit in the action bar are moved to the action overflow, and an overflow icon appears on the right. Tap on the overflow icon to display the list of remaining action views. If the device has a physical Menu button, the overflow actions are accessible by pressing the physical Menu button and not from an action overflow icon.

Actions display in the order of the ON ACTION statements of the current dialog. If a toolbar is defined, the actions defined in the toolbar take priority and list prior to other actions, in the order they are defined in the toolbar.

If an image is available, it is displayed, otherwise the action text is shown. Depending on the space available (space used by the app icon, screen size, orientation, and so on), the number of actions and the device type,
Android displays either the icon or the icon and the text of the action.

**Android™ floating action button**

On Android™ devices, apps using material design show a **Floating Action Button (FAB)**.

The **Android™ floating action button** displays on the bottom right of the screen, and can be tapped to fire a specific action.

![Android_FAB](image)

**Figure 85: The floating action button (1)**

The material design guidelines include the concept of promoted actions, that can be triggered with the floating action button.

Define the list of actions that can be fired from the FAB button with **FAB configuration style attributes**:

```xml
<Style name="Window">
    <StyleAttribute name="materialFABActionList" value="accept,select,detail" />
</Style>
```

The order of the actions define which action is triggered when the FAB button is tapped, and several matching actions are active. With the above example, if the "accept" action is disabled, and the "select" and "detail" actions are active, a tap on the FAB button fires the "select" action.

The icon of the FAB button is defined by the **IMAGE attribute** of the corresponding action. If no **IMAGE attribute** is defined for the action, a default icon is selected from the built-in icons, according to the name of the action. See
Android default action views decoration on page 1688 for more details about action names to default Android™ built-in icon mapping.

Android™ default action views decoration

Common default action views get a decoration implicitly based on Android standards.

On Android™ devices, when the IMAGE and the TEXT action attributes are not defined for an action, the default action view gets an implicit decoration.

The default icon is selected from the name of the action. The symbol is chosen from the built-in images (i.e. Android™ material design icons), if it has the same name as the action. If no icon corresponds, the default action view will get no icon.

The text defaults to the name of the action, converted to uppercase. The text displays only if the Android™ system considers that the screen is large enough to display the texts. Typically, texts are shown on tablets, but not on smartphones with small/medium screens.

For example, when implementing a ON ACTION refresh handler, GMA will implicitly use the default icon with the name "refresh" (the typical circular refresh symbol), and, if there is enough room, display the text "REFRESH" on the right of the icon.

Position and rendering of default action views can be controlled with Android™ specific style attributes. For more details, see Default action view style attributes on page 1091.

Not also that some actions can be rendering as the Floating Action Button of material design, as described in Android floating action button on page 1687.

Default actions views displayed in the top control bar and in the overflow button will get a text but no icons, while the FAB material design button will get an icon but no text.

The next table shows the default icons that will be selected for common Genero BDL action names.

Note: This table does not list all possible built-in icons: More images are available from the Android material design icon library, and the GMA will select the icon from the action name. For example, an action with the name "audio" will get the Android music symbol icon:

User interface | 1730
List dialogs

List dialogs are dialogs controlling a list of records rendered in a list container such as TABLE, TREE or SCROLLGRID.

Genero provides the DISPLAY ARRAY and INPUT ARRAY list dialogs to control a list of records that are defined in a program array.

**Note:** The DISPLAY ARRAY and INPUT ARRAY dialogs can use dynamic or static arrays. Static arrays are supported for backward compatibility. Consider using dynamic arrays in new implementations.

A DISPLAY ARRAY handles by default a read-only list. However, you can implement modification triggers, to let the end user append, modify and delete rows.

An INPUT ARRAY dialog allows immediate data modification: The rows are editable by default.

The topics in this chapter are common to all list dialogs.

The form must define a list container to display the records, it can be one of the following:

- TABLE
- TREE
- SCROLLGRID

Eventually, the list dialog can control a plain grid with basic form fields. In this case, only one record will be displayed at a time, but list navigation is still available.

Related concepts

**Record list (DISPLAY ARRAY)** on page 1394
The DISPLAY ARRAY instruction provides record list navigation in an application form, with optional record modification actions.

**Editable record list (INPUT ARRAY)** on page 1425
The INPUT ARRAY instruction provides always-editable record list handling in an application form.

Array binding in list controllers

Program array elements are bound to screen arrays elements in the definition of the DISPLAY ARRAY or INPUT ARRAY list dialog.

Array elements are bound to screen array fields by position

A screen array groups a set of fields to define list container columns in a per form file.
When using a program array in DISPLAY ARRAY or INPUT ARRAY, the elements of the array are bound by position to the fields of the associated screen array.

In the form file:

```plaintext
 ... 
 INSTRUCTIONS 
 SCREEN RECORD sa ( 
     FORMONLY.col_pkey, 
     FORMONLY.col_name, 
     FORMONLY.col_details 
 ); 
 END 

In the program file (note the name of the record elements can be different from screen array element names):

```plaintext
DEFINE arr DYNAMIC ARRAY OF RECORD 
     pkey INTEGER, 
     name VARCHAR(50), 
     details VARCHAR(50) 
 END RECORD 
... 
DISPLAY ARRAY arr TO sa.* 
... 
END DISPLAY 

Tip: The order of the screen array elements must match the order of program array elements used by the list dialog. However, in the list container of the LAYOUT section, the order of the columns (field item tags) does not need to match the order of the fields in the screen array. To get the tabbing order defined by the form, you will however have to use OPTIONS FIELD ORDER FORM in the program.

Using PHANTOM fields to get the same columns as the database table

In most cases, the record list data comes from a database table. A program array can be easily defined with the same structure as its corresponding database table, by using a schema file and a DEFINE LIKE instruction:

```plaintext
SCHEMA stores 
DEFINE arr_cust DYNAMIC ARRAY OF RECORD LIKE customer.* 

However, you might not want to display all columns of the database table in the list container. To hide some columns, use PHANTOM field definition in the form. The screen array will hold all columns of the table and program array. It is then possible to bind the program array to the screen array: The number of elements in the program array and in the screen array will match.

```plaintext
... 
ATTRIBUTES 
EDIT c1 = FORMONLY.col_pkey;  -- Column in TABLE container 
EDIT c1 = FORMONLY.col_name;  -- Column in TABLE container 
PHANTOM FORMONLY.col_details; -- Not used in LAYOUT (only in screen array) 
END 
... 

Array sub-records can be bound to flat screen arrays

If additional fields are required to hold data that is not stored in the database table, it is possible to define the program array with a sub-record matching the database table structure, and define volatile data fields beside this record.

```plaintext
SCHEMA stores 
DEFINE arr DYNAMIC ARRAY OF RECORD 
     checked CHAR(1), 
```
sql_data RECORD LIKE items.*,
comment STRING
END RECORD

MAIN
...
INPUT ARRAY arr FROM sa.* ...
...
END MAIN

Here the "checked" and "comment" members are not part of the database table, while the "sql_data" element is defined LIKE the "items" table of the "stores" schema. All members defined in this dynamic array can be bound to a flat screen array.

**Complete example using additional fields and phantom fields**

In the next example, the program array is defined with more elements than the corresponding database table, and the form definition file uses phantom fields, to hide some database columns.

Form file:

```
LAYOUT
GRID
{
<TABLE t1                              >
[c1    |c2                     |c3     ]
[c1    |c2                     |c3     ]
[c1    |c2                     |c3     ]
[c1    |c2                     |c3     ]
<                                      >
}
END
END
ATTRIBUTES
EDIT c1 = FORMONLY.pkey, TITLE="PKey", NOENTRY;
EDIT c2 = FORMONLY.name, TITLE="Name";
CHECKBOX c3 = FORMONLY.checked, TITLE="Checked";
PHANTOM FORMONLY.details; -- Not used in layout
PHANTOM FORMONLY.comment; -- Not used in layout
END
INSTRUCTIONS
SCREEN RECORD sa{
    FORMONLY.checked, -- Note order is different to the layout
    FORMONLY.pkey,
    FORMONLY.name,
    FORMONLY.details,
    FORMONLY.comment
};
END
```

Program file:

```
TYPE t_type RECORD
    checked CHAR(1),
    sql_data RECORD -- Could be RECORD LIKE items.*
        pkey INTEGER,
        name VARCHAR(50),
        details VARCHAR(200)
    END RECORD,
    comment STRING
    END RECORD

DEFINE arr DYNAMIC ARRAY OF t_type
```
MAIN

OPTIONS INPUT WRAP, FIELD ORDER FORM
CALL create_db()
CALL fill_array()
OPEN FORM f1 FROM "form1"
DISPLAY FORM f1
INPUT ARRAY arr FROM sa.* ATTRIBUTES(WITHOUT DEFAULTS)
BEFORE ROW
    MESSAGE arr[arr_curr()].sql_data.details
END INPUT
END MAIN

FUNCTION create_db()
    DEFINE rec t_type
    CONNECT TO ":memory:+driver='dbmsqt'"

Related concepts

Binding tables to arrays in dialogs on page 1758
Program arrays act as data model that are bound to form tables, when implementing list dialogs.

Variable binding in DISPLAY ARRAY on page 1397
Variable binding in INPUT ARRAY on page 1429
Populating a DISPLAY ARRAY on page 1742
The program array must be filled with rows to populate the DISPLAY ARRAY dialog.

Controlling the number of rows
Methods are provided to set and get the total number of rows in a read-only or editable list of records.

Set the number of rows when using a static array
When using a static array in DISPLAY ARRAY or INPUT ARRAY, you must specify the actual number of rows with the SET_COUNT() built-in function or with the COUNT dialog attribute. Both of them are only taken into account when the interactive instruction starts.

DEFINE arr ARRAY[100] OF ...
... (fill the array with x rows)
CALL set_count(x)
DISPLAY ARRAY arr TO sa.*
When using multiple list subdialogs in a DIALOG block, the SET_COUNT() built-in function is unusable, as it defines the total number of rows for all lists. The only way to define the number of rows when using a static array in multiple dialogs is to use the COUNT attribute.

Consider using dynamic arrays instead of static arrays.

**Set the number of rows when using a dynamic array**

When using a dynamic array in DISPLAY ARRAY or INPUT ARRAY, the total number of rows is automatically defined by the array variable (array.getLength()).

```
DEFINE arr DYNAMIC ARRAY OF ...  
... (fill the array with x rows)  
DISPLAY ARRAY arr TO sa.*  
...  
END DISPLAY
```

However, special consideration has to be taken when using the paged mode of DISPLAY ARRAY. In this mode, the dynamic array only holds a page of the complete row set shown to the user: In paged mode, you must specify the total number of rows with the ui.Dialog.setArrayLength() method.

**Get the number of rows in a list**

To get the current number of rows in a DISPLAY ARRAY or INPUT ARRAY, use either the ui.Dialog.getArrayLength() or the ARR_COUNT() function.

The getArrayLength() method can be used inside or outside the context of the list dialog, as it takes the screen array as parameter to identify the list dialog. For example, when implementing a DIALOG block with two DISPLAY ARRAY subdialogs, you can query the number of rows of a list in the code block of another list controller:

```
DIALOG ... 
  DISPLAY ARRAY arr1 TO sa1.* 
  ON ACTION check 
    IF DIALOG.getArrayLength("sa2") > 1 THEN 
      ... 
    END IF 
  END DISPLAY 
  DISPLAY ARRAY arr2 TO sa2.* 
END DISPLAY 
END DIALOG
```

The ARR_COUNT() function must be used in the context of the DISPLAY ARRAY or INPUT ARRAY dialog, or just after executing such dialog. For example, it can be used just after an INPUT ARRAY dialog, to get the number of rows left in the list:

```
INPUT ARRAY arr FROM sa.*  
...  
END INPUT 
IF NOT int_flag THEN  
  FOR i=1 TO arr_count() 
    ... 
  END FOR 
END IF
```

The ARR_COUNT() function returns the number of rows for the last executed dialog, until a new list dialog is started.
Related concepts
ARRAY on page 387
An array defines a vector variable with a list of elements.

Populating a DISPLAY ARRAY on page 1742
The program array must be filled with rows to populate the DISPLAY ARRAY dialog.

Handling the current row
Query and control the current row in a read-only or editable list of records.

Get the current row
To query the current row of a list, use either the `ui.Dialog.getCurrentRow()` method or the `arr_curr()` built-in function, depending on the context.

The `getCurrentRow()` method can be used for a DISPLAY ARRAY or INPUT ARRAY dialog. The method takes the name of the screen array as the argument to identify the list.

For example, when implementing a DIAlOG block with two DISPLAY ARRAY subdialogs, you can query the current row of a list in the code block of the other list controller:

```plaintext
DIALOG ...
   DISPLAY ARRAY arr1 TO sa1.*
   ON ACTION check
      IF arr2[DIAlOG.getCurrentRow("sa2").value > 0 THEN
         ...
      END IF
   END DISPLAY
   DISPLAY ARRAY arr2 TO sa2.*
   END DISPLAY
END DIALOG
```

The `arr_curr()` function must be used in the context of the current DISPLAY ARRAY or INPUT ARRAY dialog, or just after executing such a dialog.

For example, when implementing modification triggers in a DISPLAY ARRAY dialog, the current row and the current screen line can be queried respectively with the `arr_curr()` and `scr_line()` functions:

```plaintext
DISPLAY ARRAY arr TO sa.*
ON UPDATE
   INPUT arr[arr_curr()].* WITHOUT DEFAULTS FROM sa[scr_line()].* ;
END DISPLAY
```

After the dialog execution, `arr_curr()` returns the current row index for the last executed dialog, until a new list dialog is started.

The row index returned by the `arr_curr()` function is constant in the context of a dialog block, even when removing rows from the array by program. A typical mistake is to reuse the `arr_curr()` index to get data from the new current row, after deleting the last row of the array.

In the next code example, the reuse of `arr_curr()` without checking for the new number of rows will automatically create a new program array element when accessing the element in the MESSAGE instruction:

```plaintext
ON ACTION dialog_delete_row
   CALL DIAlOG.deleteRow("sr",arr_curr())
   MESSAGE "Current item:", arr[arr_curr()].name
```

The above code works until you reach the last row: When last row is deleted, the MESSAGE instruction is automatically creating a new array element at the same index returned by `arr_curr()`.
Unlike `arr_curr()`, the `DIALOG.getCurrentRow()` method is synchronized with the actual number of rows in the array, as long as methods like `DIALOG.deleteRow()` are used:

```plaintext
ON ACTION dialog_delete_row
    CALL DIALOG.deleteRow("sr", DIALOG.getCurrentRow("sr"))
    MESSAGE "Current item:", arr[DIALOG.getCurrentRow("sr")]\[\].name
```

However, the code must also test if there are still rows in the list after deleting a row:

```plaintext
ON ACTION dialog_delete_row
    LET x = DIALOG.getCurrentRow("sr")
    CALL DIALOG.deleteRow("sr", x)
    LET x = DIALOG.getCurrentRow("sr")
    IF x > 0 THEN
        MESSAGE "Current item:", arr[x].name
    ELSE
        MESSAGE "No more rows in the list"
    END IF
```

### Set the current row

To set the current row in a list controlled by a `DISPLAY ARRAY` or `INPUT ARRAY`, use the `ui.Dialog.setCurrentRow()` method. This method takes the name of the screen array and the new row index as parameters:

```plaintext
DISPLAY ARRAY p_items TO sa.*
    ...
    ON ACTION next_empty
        LET row = findEmptyRow(p_items)
        CALL DIALOG.setCurrentRow("sa", row)
    ...
END DISPLAY
```

Calling the `DIALOG.setCurrentRow()` method will not execute control blocks such as `BEFORE ROW` and `AFTER ROW`, and will not set the focus. If you want to set the focus to the list, you must use the `NEXT FIELD` instruction. This works with `DISPLAY ARRAY` as well as `INPUT ARRAY`.

**Tip:** Use this method with care. Let the dialog handle normal navigation automatically, and jump to a specific row only in the context of an ON ACTION block.

The `fgl_set_arr_curr()` function can also be used. This function must be called in the context of the current list having the focus.

**Note:** `fgl_set_arr_curr()` triggers control blocks such as `BEFORE ROW` while `DIALOG.setCurrentRow()` does not trigger any control blocks.

In a `DISPLAY ARRAY` using `paged mode` with `COUNT=-1`, before calling `DIALOG.setCurrentRow(screen-array, row-index)`, call `DIALOG.setArrayLength(screen-array, count)` where `count >= row-index`. Otherwise, the `setCurrentRow()` call will have no effect, if the dialog has not yet seen `row-index` rows through `ON FILL BUFFER`.

### Converting visual index to/from program array index

When the end user sorts rows in a table, the program array index (`arr_curr()`) may differ from the visual row index (the row position as seen by the user).

The `ui.Dialog` class provides methods to convert between these contexts:

The `ui.Dialog.arrayToVisualIndex` on page 2381 method converts a program array index to a visual index. It can be used, for example, to display a typical list position message (Row: `current-row / total-rows`). The current row
(arr_curr() / getCurrentRow()) is a program array index that must be converted to a visual index. Note that you need to display such messages in the BEFORE ROW trigger and ON SORT trigger:

```plaintext
FUNCTION disp_row(d,n)
  DEFINE d ui.DIALOG, n STRING
  MESSAGE SFMT("Row: %1/%2", 
    d.arrayToVisualIndex(n,d.getCurrentRow(n)), 
    d.getArrayLength(n))
END FUNCTION
...
  DISPLAY ARRAY arr TO sr.*
  ...
  BEFORE ROW
    CALL disp_row(DIALOG,"sr")
  ON SORT
    CALL disp_row(DIALOG,"sr")
  ...
END DISPLAY
```

The `ui.Dialog.visualToArrayIndex` on page 2407 method converts a visual index to a program array index. It can be used for example to ask the user for a row position (visual index), and make that row current by using `DIALOG.setCurrentRow()` after converting to the program array index:

```plaintext
DEFINE i INTEGER
...
  DISPLAY ARRAY arr TO sr.*
  ...
  ON ACTION move_to
    PROMPT "Enter row index:" FOR i
    CALL DIALOG.setCurrentRow( "sr", DIALOG.visualToArrayIndex("sr", i))
  ...
END DISPLAY
```

List ordering on page 1764
List controllers implement a built-in sort. This feature can be disabled if not required.

Defining the action for a row choice
The row choice in the `DISPLAY ARRAY` dialog can be associated with a dedicated action.

Action fired by default by current row selection
When using a `DISPLAY ARRAY` dialog to control a list view like a `TABLE`, the physical event to choose a row has the following results, depending on the type of front-end:

• On the desktop (GDC) or web (GBC) front-end, by default, a mouse double-click changes the current row, and fires the "accept" action, if available. If the default accept action is fired, the dialog will end, except if the accept
action has been disabled or was overwritten by an ON ACTION accept handler. This default behavior applies to most record lists of desktop applications, where the main purpose is to let the user choose a row from the list.

- On a mobile device (GMA/GMI), there is no concept of double-click as with a mouse. By default, a tap on a row changes the current row only. This corresponds to a single mouse click on a desktop front-end, and therefore does not fire the "accept" action by default. If a tap must fire an action, define that action with the DOUBLECLICK attribute in the DISPLAY ARRAY dialog.

When using an INPUT ARRAY dialog, no row choice action ("accept") is possible by default. However, when setting the DOUBLECLICK attribute, a double click can be detected during INPUT ARRAY.

**Defining the name of the row choice action**

The action to be fired when a row choice occurs can be defined in the form file with the DOUBLECLICK attribute of the TABLE, TREE or SCROLLGRID containers, or with the DOUBLECLICK attribute of the DISPLAY ARRAY dialog:

```plaintext
DISPLAY ARRAY arr TO sr.*
    ATTRIBUTES(UNBUFFERED, DOUBLECLICK=select)
...```

The DISPLAY ARRAY attributes DOUBLECLICK, DETAILACTION and ACCESSORYTYPE were introduced for mobile apps, to be used together at dialog configuration level for list configuration.

**Note:** The DOUBLECLICK attribute in DISPLAY ARRAY takes precedence over the DOUBLECLICK attribute in the list container of a form file.

When defining a DOUBLECLICK action in the list container of the form file, or in a dialog attribute, you declare an explicit action view, and no default action view will be displayed for this action (you can force it with DEFAULTVIEW=YES).

**Using the DOUBLECLICK attribute with INPUT ARRAY**

With an INPUT ARRAY, field editing is implicit: A double click with the mouse is typically used to select text in an editable field. Therefore, unlike DISPLAY ARRAY, no accept action is fired by default when the user double-clicks on a cell during an INPUT ARRAY.

However, if the TABLE, TREE or SCROLLGRID list container defines the DOUBLECLICK attribute, the corresponding action is fired when a double click occurs, and a row choice action can be implemented in and INPUT ARRAY. This configuration is typically used when the list container has columns defined with non-editable fields like LABEL or EDIT using NOENTRY.

**Physical event triggering the row choice action**

For desktop and web UI applications, the physical event that fires the row choice action is the mouse double-click, which can be changed with the rowActionTrigger presentation style attribute for the Table, ScrollGrid and Tree classes.

For example, in web applications, the row choice is typically done by a simple mouse click. Define the simple-click physical event to fire the row choice action in your .4st style file as follows:

```xml
...<Style name="Table">
    <StyleAttribute name="rowActionTrigger" value="singleClick" />
</Style>
...```
Row choice action handler in programs

To handle row choice actions in the program code, define the DOUBLECLICK attribute for the DISPLAY ARRAY dialog, and the corresponding action handler block ON ACTION action-name:

```plaintext
DISPLAY ARRAY arr TO sr.*
    ATTRIBUTES(UNBUFFERED, DOUBLECLICK=select)
    ON ACTION select
        MESSAGE "myselect: ", arr_curr()
END DISPLAY
```

**Note:** If the DOUBLECLICK attribute is defined, it will only configure the action for the corresponding physical event. By default, the "accept" action is still available, and the [Ok] button or the [Return] key will still fire the accept action and leave the dialog. To avoid the default accept action, add ACCEPT=FALSE to the DISPLAY ARRAY attribute list.

Execution order of row change control blocks

During a DISPLAY ARRAY, if the selected row is not the current row, the AFTER ROW and BEFORE ROW control blocks execute before the ON ACTION block, in the following order:

1. AFTER ROW (for the previous current row)
2. BEFORE ROW (for the new current row)
3. ON ACTION double-click-action

Field-level focus in DISPLAY ARRAY

The DISPLAY ARRAY dialog supports cell-level focus with the FOCUSONFIELD.

Enabling focusable cells in DISPLAY ARRAY

When using a DISPLAY ARRAY dialog to control a list view, you can enable cell-level focus handling with the FOCUSONFIELD attribute.

**Important:** This feature is not supported on mobile platforms.

With a graphical front-end, this feature allows cell mouse clicks or tabbing between cells, instead of having the whole current row highlighted.

This feature can also be used in text mode (FGLGUI=0), to move in DISPLAY ARRAY fields with the keyboard using arrow keys or tab.

To enable field-level focus handling in a DISPLAY ARRAY, add the FOCUSONFIELD attribute in the dialog definition:

```plaintext
DISPLAY ARRAY arr TO sr.* ATTRIBUTES(FOCUSONFIELD)
```

Detecting cell focus changes

When the FOCUSONFIELD attribute is defined, BEFORE FIELD and AFTER FIELD blocks can be used, to detect field focus changes:

```plaintext
DISPLAY ARRAY arr TO sr.* ATTRIBUTES(FOCUSONFIELD)
    ...
    BEFORE FIELD cust_id
        MESSAGE "focus in cust_id, row = ", arr_curr()
    AFTER FIELD cust_id
        MESSAGE "focus left cust_id, row = ", arr_curr()
    BEFORE FIELD cust_name
```
Note that if defined, the AFTER ROW control block will execute after the AFTER FIELD block and the BEFORE ROW control block will execute before the BEFORE FIELD block. The code blocks execute in the following order:

1. AFTER FIELD (for the field that loses the focus)
2. AFTER ROW (for the previous current row)
3. BEFORE ROW (for the new current row)
4. BEFORE FIELD (for the field that gets the focus in the new row)

What is the current cell?

The current cell of DISPLAY ARRAY with FOCUSONFIELD attribute can be found by using the `ui.Dialog.getCurrentItem()` method:

```plaintext
DISPLAY ARRAY arr TO sr.* ATTRIBUTES(FOCUSONFIELD)
...  
  ON ACTION show_current_cell
    MESSAGE "Current cell = ", DIALOG.getCurrentItem()
```

Setting the current cell

To set the focus to a specific cell with program code, use the NEXT FIELD instruction, or the `ui.Dialog.nextField()` method, in conjunction with the `ui.Dialog.setCurrentRow()` method:

```plaintext
DISPLAY ARRAY arr TO sr.* ATTRIBUTES(FOCUSONFIELD)
...  
  ON ACTION top_left ATTRIBUTES(TEXT = "TOP LEFT")
    CALL DIALOG.setCurrentRow("sr", 1)
    NEXT FIELD first_field
  ON ACTION bottom_right ATTRIBUTES(TEXT = "BOTTOM RIGHT")
    CALL DIALOG.setCurrentRow("sr", sr.getLength())
    NEXT FIELD last_field
...  
END `DISPLAY`
```

Actions bound to the current row

Actions can be configured with the ROWBOUND attribute to depend from the current row.

When using a DISPLAY ARRAY or INPUT ARRAY dialog to control a table view, actions can get the ROWBOUND attribute in order to make the action only available when there is a current row in the list.

Important: This feature is only for mobile platforms.

The ROWBOUND attribute must only be used with TABLE and TREE containers (it does not make sense for SCROLLGRID and static lists in GRID containers).

This attribute is generally used in mobile applications, when a list view requires actions to be decorated in a row-specific way. For example, on Android™ devices, the actions with the ROWBOUND attribute will be available by selecting the three-dot button on the right of each list view cell.

In the next example, the DISPLAY ARRAY dialog implements three actions:

- The "refresh" action is not "rowbound", and will always be available (i.e. active/visible), even if the list is empty.
- The "check" action is rowbound, and will only be available if there is a (current) row in the list.
The "delete" action created by the ON DELETE modification trigger is implicitly "rowbounded".

```
DISPLAY ARRAY a_orders TO sr.* ATTRIBUTES(UNBUFFERED)
  ...
  ON ACTION refresh -- not rowbound
    CALL fetch_orders()
  ON ACTION check ATTRIBUTES(ROWBOUND)
    CALL check_order(arr_curr())
  ON DELETE -- implicitly rowbound
    CALL delete_order(arr_curr())
  ...
END`DISPLAY
```

Table views render in a specific way on mobile devices, in order to take advantage of mobile device ergonomics.

Populating a DISPLAY ARRAY
The program array must be filled with rows to populate the DISPLAY ARRAY dialog.

With DISPLAY ARRAY, either full list mode or paged mode is used to fill the form array. Consider using full list mode for short/medium result sets, and use paged mode for very large result sets.

Full list mode of DISPLAY ARRAY
In order to handle short/medium result sets, use the full list mode of DISPLAY ARRAY.

Understanding the full list mode

In full list mode, DISPLAY ARRAY uses a complete copy of the result set to be displayed in the form array. The full list mode is typically used for a short or medium row set (10 - 100 rows).

In full list mode, the DISPLAY ARRAY instruction uses a static or dynamic program array defined with a record structure corresponding to (or to a part of) a screen-array in the current form.

The program array is filled with data rows before DISPLAY ARRAY is executed, typically with a FOREACH loop when rows come from the database.

![Figure 86: Full list mode in DISPLAY ARRAY diagram](image-url)
Consider using a dynamic array instead of a static array: By using a dynamic array the program will only use the required memory resources, and the dialog will automatically detect the number of rows from the dynamic array (array.getLength())

**Full list mode example**

The following example implements a DISPLAY ARRAY in its simpler form: A dynamic array is filled with database rows and contains the whole result set to be displayed in the table:

```sql
MAIN
  DEFINE arr DYNAMIC ARRAY OF RECORD
  id INTEGER,
  fname CHAR(30),
  lname CHAR(30)
  END RECORD
DEFINE i INTEGER
DATABASE stores
OPEN FORM f1 FROM "custlist"
DISPLAY FORM f1
DECLARE c1 CURSOR FOR
  SELECT customer_num, fname, lname FROM customer
LET i=1
FOREACH c1 INTO arr[i].*
  LET i = i+1
END FOREACH
CALL arr.deleteElement(i)
DISPLAY ARRAY arr TO sa.* ATTRIBUTES(UNBUFFERED)
  BEFORE ROW
    MESSAGE "Moved to row ", arr_curr()
END DISPLAY
END MAIN
```

**Paged mode of DISPLAY ARRAY** on page 1743
In order to handle very large result sets, use the paged mode of DISPLAY ARRAY.

**Paged mode of DISPLAY ARRAY**
In order to handle very large result sets, use the paged mode of DISPLAY ARRAY.

**Understanding the paged mode**

The *paged mode* of DISPLAY ARRAY allows the program to display a very large number of rows, without copying all database rows into the program array.
This mode uses the **ON FILL BUFFER** data block to let the program populate the array with the current visible page of rows. This is a subset of the database query result set (**SELECT**), typically controlled by a scrollable cursor.

![Paged mode diagram](image)

**Figure 87: Paged mode diagram**

**Note:** **DISPLAY ARRAY** has following constraints when using the paged mode:

- By default, **row sorting** is not allowed: Implement an **ON SORT** trigger to handle list sorting.
- **Multi-range selection** is not supported, if the paged mode uses an undefined number of rows (**COUNT=-1**).
- To fill a **tree view** dynamically, use the **ON EXPAND / ON COLLAPSE** data blocks.

**Paged mode programming details**

In paged mode, the dynamic array holds a page of rows, not all rows of the result set. The data rows are provided through the **ON FILL BUFFER** block, by filling a dynamic array with the rows for the current visible page.

The **ON FILL BUFFER** clause is used to fill a page of rows in the dynamic array, from a row offset and the number of rows required in the page. The row offset is defined by the **FGL_DIALOG_GETBUFFERSTART()** built-in function, and the number of rows to provide is defined by the **FGL_DIALOG_GETBUFFERLENGTH()** built-in function.

**Note:** The **ON FILL BUFFER** is only triggered when all the user code is executed and the dialog gets the control back. This means that the fill clause is not immediately fired when calling **DIALOG.setArrayLength()**.

If the total number of rows is known before the dialog is started, specify it with the **COUNT** dialog attribute of **DISPLAY ARRAY**:

- The total number of rows can be changed during dialog execution with the **ui.Dialog.setArrayLength()** method.
- In singular **DISPLAY ARRAY** instructions, define the total number of rows of a paged mode with the **SET_COUNT()** built-in function or the **COUNT** attribute. Note that **SET_COUNT()** or **COUNT** are only taken into account when the dialog starts.
- If the total number of rows changes during the execution of the dialog, the only way to specify the number of rows is **DIALOG.setArrayLength()**.

If the total number of rows is not known before starting the **DISPLAY ARRAY** dialog, set **COUNT=-1** in **DISPLAY ARRAY** attributes. The dialog will then query for rows with **ON FILL BUFFER** until the end of the result set is reached. The end of the result set is detected:

- When the number of rows provided in **ON FILL BUFFER** is less than the number of rows required by the dialog.
• When you reset the total number of rows to a value higher than -1 with the \texttt{ui.Dialog.setArrayLength()} method.

\textbf{Note:} The dialog cannot support \textbf{multi-row selection} when the total number of rows is undefined.

The \texttt{DIALOG.setCurrentRow()} method can be used to move to a specific row in a paged mode DISPLAY ARRAY.

\textbf{Note:} Before calling \texttt{DIALOG.setCurrentRow(screen-array, row-index)}, be sure to provide the actual number of rows with \texttt{DIALOG.setArrayLength(screen-array, count)} where \texttt{count} \(\geq\) \texttt{row-index}. Otherwise, the \texttt{setCurrentRow()} call will have no effect, if the dialog has not yet seen \texttt{row-index} rows through \texttt{ON FILL BUFFER}.

If you use a tree view with a paged mode \texttt{DISPLAY ARRAY}, the program will raise an error at runtime: For tree views, the dialog needs the complete set of open nodes with parent/child relations to handle the tree view display. With the paged mode, only a short window of the dataset is known by the dialog.

A typical paged \texttt{DISPLAY ARRAY} implementation consists of a scroll cursor providing the list of records to be displayed. Scroll cursors use a static result set. If you want to display fresh data, you can implement an advanced paged mode by using a scroll cursor that provides the primary keys of the referenced result set, plus a prepared cursor to fetch rows on demand in the \texttt{ON FILL BUFFER} clause. In this case you may need to check whether a row still exists when fetching a record with the second cursor.

\textbf{Paged mode basic example}

The following example shows a \texttt{DISPLAY ARRAY} implementation using a scroll cursor to fill pages of records in \texttt{ON FILL BUFFER}, specifying an undefined number of rows (\texttt{COUNT=-1}).

```
MAIN
  DEFINE arr DYNAMIC ARRAY OF RECORD
    id INTEGER,
    fname CHAR(30),
    lname CHAR(30)
  END RECORD
END DISPLAY
```

```
DEFINE cnt, ofs, len, row, i INTEGER

DATABASE stores
OPEN FORM f1 FROM "custlist"
DISPLAY FORM f1
DECLARE c1 SCROLL CURSOR FOR
  SELECT customer_num, fname, lname FROM customer
OPEN c1

DISPLAY ARRAY arr TO sa.* ATTRIBUTES(COUNT=-1)
ON FILL BUFFER
  CALL arr.clear()
  LET ofs = fgl_dialog_getBufferStart()
  LET len = fgl_dialog_getBufferLength()
  LET row = ofs
  FOR i=1 TO len
    FETCH ABSOLUTE row c1 INTO arr[i].*
    IF SQLCA.SQLCODE!=0 THEN
      CALL DIALOG.setArrayLength("sa",row-1)
      EXIT FOR
    END IF
    LET row = row + 1
  END FOR
ON ACTION ten_first_rows_only
  CALL DIALOG.setArrayLength("sa", 10)
END DISPLAY
```
Paged mode with sorting feature

To implement row sorting in a \texttt{DISPLAY ARRAY} using paged mode, use the \texttt{ON SORT} trigger to detect a sort request, get the sort information with the \texttt{ui.Dialog.getSortKey} on page 2389 / \texttt{ui.Dialog.isSortReverse} on page 2391 methods, and re-execute the SQL query to sort rows accordingly with an \texttt{ORDER BY} clause. The \texttt{ON SORT} trigger will be fired before the \texttt{ON FILL BUFFER} trigger:

```
MAIN
   DATABASE test1
   OPEN FORM f1 FROM "custlist"
   DISPLAY FORM f1
   CALL show_list()
END MAIN

FUNCTION execute_sql(order_by)
   DEFINE order_by STRING
   DEFINE sql STRING
   IF order_by IS NULL THEN
       LET order_by = "ORDER BY fname"
   END IF
   LET sql = "SELECT customer_num, fname, lname FROM customer ", order_by
   DECLARE c1 SCROLL CURSOR FROM sql
   OPEN c1
END FUNCTION

FUNCTION show_list()
   DEFINE arr DYNAMIC ARRAY OF RECORD
      id INTEGER,
      fname VARCHAR(30),
      lname VARCHAR(30)
   END RECORD
   DEFINE ofs, len, row, i INTEGER,
      key STRING, rev BOOLEAN
   CALL execute_sql(NULL)
   DISPLAY ARRAY arr TO sa.* ATTRIBUTES(COUNT=-1)
   ON SORT
       LET key = DIALOG.getSortKey("sa")
       LET rev = DIALOG.isSortReverse("sa")
       IF key IS NULL THEN
           CALL execute_sql( NULL )
       ELSE
           -- Assuming that form field names match table column names
           CALL execute_sql( "ORDER BY " || key || IIF(rev," DESC"," ") )
       END IF
   ON FILL BUFFER
       CALL arr.clear()
       LET ofs = fgl_dialog_getBufferStart()
       LET len = fgl_dialog_getBufferLength()
       LET row = ofs
       FOR i=1 TO len
           FETCH ABSOLUTE row c1 INTO arr[i].*
           IF SQLCA.SQLCODE!=0 THEN
               CALL DIALOG.setArrayLength("sa",row-1)
               EXIT FOR
           END IF
       END FOR
       LET row = row + 1
   END FOR
END DISPLAY
```
Note that with the above example, the current row remains at the same position: When the table is sorted, the set of rows provided in the ON FILL BUFFER may not include the database row that was the current row before the sort.

To track the current row, store the primary key value of the current row before re-executing the query. After query execution, scan the cursor result set and perform a DIALOG.setCurrentRow() when the primary key of the current row is found. The current row might be outside the row set provided in ON FILL BUFFER. In order to make setCurrentRow() work properly, you have to count the total number of rows before the DISPLAY ARRAY:

```sql
...  
DEFINE cnt, ofs, len, row, i INTEGER,
   key STRING, rev BOOLEAN,
   row_count, curr_id, last_id INTEGER
...

SELECT COUNT(*) INTO row_count FROM customer

CALL execute_sql(NULL)
DISPLAY ARRAY arr TO sa.* ATTRIBUTES(COUNT=row_count)
   ON SORT
      LET row = DIALOG.getCurrentRow("sa")
      FETCH ABSOLUTE row c1 INTO last_id
      LET key = DIALOG.getSortKey("sa")
      LET rev = DIALOG.isSortReverse("sa")
      IF key IS NULL THEN
         CALL execute_sql( NULL )
      ELSE
         -- Assuming that form field names match table column names
         CALL execute_sql( "ORDER BY " || key || IIF(rev," DESC"," ") )
      END IF
      LET row=1
      WHILE TRUE
         FETCH c1 INTO curr_id
         IF SQLCA.SQLCODE==100 THEN
            ERROR "Last current row disappeared from result set!"
            EXIT PROGRAM 1
         END IF
         IF curr_id == last_id THEN
            CALL DIALOG.setCurrentRow("sa",row)
            EXIT WHILE
         END IF
         LET row = row+1
      END WHILE
   ON FILL BUFFER
...  
```

**INPUT ARRAY row modifications**

Controlling row creation and deletion in an editable record list.

The **INPUT ARRAY** instruction handles record list edition. This controller allows the user to directly edit existing rows and to create or remove rows with implicit actions.

The following implicit actions are created by default by the **INPUT ARRAY** dialog:

- **insert**: creates a new row before the current row. If there are no rows in the list, the action adds a new one.
- **append**: creates a new row after the last row of the list.
- **delete**: deletes the current row.

To prevent **INPUT ARRAY** from creating the implicit "insert", "append" and "delete" actions, set respectively the **INSERT ROW**, **APPEND ROW**, or **DELETE ROW** control attributes to **FALSE**. To prevent row addition, also set the **AUTO APPEND** attribute to **FALSE**.

```plaintext
...  
  INPUT ARRAY p_items FROM sa.*  
    -- Allow only row append and delete implicit actions.  
    ATTRIBUTES(AUTO APPEND=FALSE,  
               INSERT ROW=FALSE)  
...  
END INPUT  
...
```

Specific control blocks are available to take control when a row is created or deleted:

- **BEFORE INSERT** and **AFTER INSERT** control blocks can be used to control row creation. Cancel a row creation with **CANCEL INSERT** in **BEFORE INSERT** or **AFTER INSERT** blocks.
- **BEFORE DELETE** and **AFTER DELETE** control blocks can be used to control row deletion. Cancel row deletion with the **CANCEL DELETE** instruction in **BEFORE DELETE**.

Dynamic arrays and the **ui.Dialog** class provide methods such as **array.deleteElement()** or **ui.Dialog.appendRow()** to modify the list. When using these methods, the predefined triggers such as **BEFORE DELETE** or **BEFORE INSERT** are not executed. While it is safe to use these methods within a **DISPLAY ARRAY**, you must take care when using an **INPUT ARRAY**. For example, it is not recommended to call such methods in triggers like **BEFORE ROW**, **AFTER INSERT**, **BEFORE DELETE**.

Users can append **temporary rows** by moving to the end of the list, or when executing the append action. Appending temporary rows is different from inserting a row; an appended row is considered temporary until the user modifies a field while an inserted row remains in the list even if the user does not modify a field.

By default, when the last row is removed by a delete action, the **INPUT ARRAY** instruction will automatically create a new temporary row at the same position. The visual effect of this behavior can be misinterpreted - if no data were entered in the last row, you cannot see any difference. However, the last row is actually deleted and a new row is created, and the **BEFORE DELETE/AFTER DELETE/AFTER ROW/B EFORE ROW/B EFORE INSERT** control block sequence is executed. In order to avoid the creation of a new temporary row when the last row is deleted, set **AUTO APPEND = FALSE** attribute.

The insert, append or delete actions will be automatically disabled depending on the context: If the **INPUT ARRAY** is using a static array that becomes full, or if the **MAXCOUNT** attribute is reached, both insert and append actions will be disabled. The delete action is automatically disabled when **AUTO APPEND = FALSE** and there are no more rows in the array.

**Related concepts**

Attributes of the INPUT ARRAY clause of a DIALOG block.

The DIALOG control class on page 1611
This topic explains the purpose of the ui.DIALOG class.

Appending rows in INPUT ARRAY
Rows appended at the end of an editable list are temporary until they are edited.

In an INPUT ARRAY, a new row can be created at the end of the list. This new row is called "temporary" because it will be automatically removed if the user leaves the row without entering data. If data is entered by the user or by program (setting the touched flag), the temporary row becomes permanent.

A temporary row is promoted to a permanent row under certain conditions described in this topic. We distinguish also explicit temporary row creation from automatic temporary row creation.

**Note:** Temporary row creation is different from adding new rows with the DIALOG.appendRow() method; when appending a row by program, the row is considered permanent and remains in the list even if the user did not enter data in fields.

Explicit temporary row creation
Explicit temporary row creation takes place when the user decides to append a new row explicitly with the append action. If the list is empty, an insert action will have the same effect as an append action (a temporary row is created at position 1).

Automatic temporary row creation
By default, automatic temporary row creation takes place when AUTO APPEND is TRUE (default) and one of the following occurs:

- The user tries to move below the last row, with a Down keystroke or with the mouse.
- The user presses the Tab key when in the last field of the last row.
- The last row of the list is deleted by the user.
- The list has the focus and the last row of the list is deleted by program with DIALOG.deleteRow() or DIALOG.deleteAllRows().
- When the INPUT ARRAY is in a DIALOG block, the list has no rows and gets the focus (A new temporary row is created to let the user enter data immediately)

When is a temporary row removed?
The temporary row will be automatically removed if none of the fields has been touched (the modification flag is not set), and when leaving the list (INPUT ARRAY) or by moving upward in the list.

The row is "touched" when the user enters data in a field, or when the program simulates a user input with a DISPLAY TO / BY NAME instruction or with the DIALOG.setFieldTouched() method.

**Note:** When the modification flag is set by program, NOENTRY fields are ignored. However, fields dynamically disabled by DIALOG.setFieldActive() are taken into account.

Deny row append
Temporary row creation is useful because, in most cases, INPUT ARRAY is used to edit existing rows and append new rows at the end of the list. However, you might want to prevent row addition or at least avoid the automatic temporary row creation when the last row is deleted or when an empty list gets the focus.

To avoid explicit temporary row creation, prevent INPUT ARRAY from defining the implicit append action by setting the APPEND ROW attribute to FALSE in the ATTRIBUTE clause:

```plaintext
...  
    INPUT ARRAY p_items FROM sa.* ATTRIBUTES(APPEND ROW=FALSE)  
    ...  
```
When APPEND ROW or INSERT ROW attributes are set to FALSE, automatic temporary row can still occur when the user deletes the last row of the list or if the list is empty when the INPUT ARRAY is entered. To avoid automatic temporary row creation when only one of APPEND ROW=FALSE or INSERT ROW=FALSE, use AUTO APPEND=FALSE:

```
... INPUT ARRAY p_items FROM sa.* ATTRIBUTES(INSERT ROW=FALSE, AUTO APPEND=FALSE)
  ... END INPUT
...```

If both APPEND ROW and INSERT ROW attributes are set to FALSE, the dialog will prevent explicit temporary row creation and also automatic temporary row creation, as if AUTO APPEND = FALSE was used.

### Row creation control blocks for temporary rows

In order to control row creation, use the BEFORE INSERT and AFTER INSERT control blocks. The BEFORE INSERT trigger is invoked after a new row was inserted or appended, just before the user gets control to enter data in fields. Regarding temporary rows, the AFTER INSERT block is invoked if data has been entered and you leave the new row (for example, when the focus moves to another row or leaves the current list), or if the dialog is validated, for example with ACCEPT DIALOG in case of DIALOG (or ACCEPT INPUT in case of singular INPUT ARRAY). No AFTER INSERT block is invoked if the user did not enter data. The temporary row is automatically deleted.

In the BEFORE INSERT control block, you can tell if a row is a temporary appended one by comparing the current row (DIALOG.getCurrentRow() or ARR_CURR()) with the total number of rows (DIALOG.getArrayLength() or ARR_COUNT()). If the current row index equals the row count, you are in a temporary row.

### AFTER ROW and temporary rows

When a temporary row is automatically removed, the AFTER ROW block will be executed for the temporary row, but ui.Dialog.getCurrentRow() / ARR_CURR() will be one row greater than DIALOG.getArrayLength() / ARR_COUNT(). In this case, ignore the AFTER ROW event.

### Related concepts

**INPUT ARRAY ATTRIBUTES clause** on page 1500
Attributes of the INPUT ARRAY clause of a DIALOG block.

**Predefined actions** on page 1641
Genero predefines some action names for common operations of interactive instructions.

**The Dialog class** on page 2367
The ui.Dialog class provides a set of methods to configure, query and control the current interactive instruction.

**DISPLAY ARRAY modification triggers**
Using dedicated interaction blocks to allow the user to modify a read-only record list.

The DISPLAY ARRAY block implements by default a read-only list of records. The end user can navigate in the list, but cannot modify the rows.

The traditional way to implement an editable list of record is to use INPUT ARRAY. However, INPUT ARRAY uses ergonomics that may not correspond to the end user expectations. Basically, a list controlled by an INPUT ARRAY is always in "edit mode": the focus is in a field and the user can modify the current field. When moving up or down in the list, the edit cursor jumps to the upper or lower cell.
Other GUI applications use a different pattern, with read-only lists that can switch to edit mode when a specific action is fired. To implement such ergonomics, use the ON INSERT, ON APPEND, ON UPDATE, ON DELETE modification triggers to control row insertion, appending, modification and deletion in a DISPLAY ARRAY block.

Related concepts
ON APPEND block on page 1409
ON INSERT block on page 1410
ON UPDATE block on page 1412
ON DELETE block on page 1413
Example 3: DISPLAY ARRAY using modification triggers on page 1422

Cell color attributes
List controllers can display every cell in a specific color.

When using the DISPLAY ARRAY or INPUT ARRAY, you can assign specific colors to cells of a TABLE or TREE rows with the DIALOG.setArrayAttributes() or DIALOG.setCellAttributes() method.

Call the method in the dialog initialization clause, for example, in BEFORE DISPLAY for a singular DISPLAY ARRAY dialog.

The method takes an array as parameter. This array must have one of the following structures:

- A DYNAMIC ARRAY OF RECORD (with the same structure as the data array, but using the STRING data type)
- A DYNAMIC ARRAY WITH DIMENSION 2 OF STRING (to define attributes in dynamic dialog when the row structure is defined at runtime)
- A DYNAMIC ARRAY OF STRING (to define attributes for complete lines instead of individual cells)

Cell attributes are defined by using the TTY attributes such as "red reverse" for example. See method reference for all possible values.

Note: If cell attributes are changed during the dialog execution, use the UNBUFFERED mode to get automatic form synchronization. The unbuffered mode is not required if the cell attributes are defined before executing the dialog, and are left unchanged until the dialog ends.

Example
This is the list.per form file defining the table view:

```
LAYOUT TABLE {
   [c1     |c2       ]
}
END
END
ATTRIBUTES
   c1 = FORMONLY.key;
   c2 = FORMONLY.name;
END
INSTRUCTIONS
   SCREEN RECORD sr(FORMONLY.*);
END
```

This is the program code (main.4gl):

```
MAIN
   DEFINE arr DYNAMIC ARRAY OF RECORD
      key INTEGER,
      name VARCHAR(100)
   END RECORD
   DEFINE att DYNAMIC ARRAY OF RECORD
      key STRING,
```

name STRING
END RECORD
DEFINE I INT
FOR i=1 TO 10
    LET arr[i].key = i
    LET arr[i].name = "Item "||i
    LET att[i].key = "red reverse"
    LET att[i].name = IIF(i MOD 2,"blue","green")
END FOR
OPEN FORM f1 FROM "list"
DISPLAY FORM f1
DISPLAY ARRAY arr TO sr.* ATTRIBUTES(UNBUFFERED)
BEFORE DISPLAY
    CALL DIALOG.setCellAttributes(att)
ON ACTION att_modify_cell
    LET att[2].key = "red reverse"
ON ACTION att_clear_cell
    LET att[2].key = NULL
END DISPLAY
END MAIN

Related concepts
The buffered and unbuffered modes on page 1618
The buffered and unbuffered mode control the synchronization of program variables and form fields.

Multiple row selection
Multiple row selection allows the end user to select several rows within a list of records.

The DISPLAY ARRAY controller supports multiple row selection when the ON SELECTION CHANGE block is defined, or by enabling the feature with the ui.Dialog.setSelectionMode() method when the dialog starts. The setSelectionMode() method can also be used to enable or disable the multi-row selection during the dialog execution.

Important: This feature is not supported on mobile platforms.

When multi-row selection is enabled, the end user can select one or several rows with the standard keyboard and mouse click combinations. When the end user selects or de-selects rows, the ON SELECTION CHANGE block is fired, if defined. The program can then query the DIALOG.isRowSelected() method to check for selected rows.

DISPLAY ARRAY arr TO sr.*
...  
ON SELECTION CHANGE
    FOR i=1 TO DIALOG.getArrayLength("sr")
        DISPLAY SFMT("Row: %1 s=%2", i, DIALOG.isRowSelected("sr", i) )
    END FOR
ON ACTION enable_mrs
    CALL DIALOG.setSelectionMode( "sr", 1 )
ON ACTION disable_mrs
    CALL DIALOG.setSelectionMode( "sr", 0 )
...
END DISPLAY

Multiple row selection is GUI-specific and therefore cannot be used in TUI mode.

With multiple row selection, you must distinguish between two concepts: row selection and current row. In GUI mode, a selected row usually has a blue background, while the current row has a dotted focus rectangle. The current row may not be selected, or a selected row may not be the current row. When the default single-row selection is used, the current row is always selected automatically.
If the \texttt{ON SELECTION CHANGE} block is not required, use the \texttt{ui.Dialog.setSelectionMode()} method to enable multi-row selection for the dialog:

\begin{verbatim}
DISPLAY ARRAY arr TO sr.*
   BEFORE DISPLAY
     CALL DIALOG.setSelectionMode( "sr", 1 )
   ...
END DISPLAY
\end{verbatim}

Note that without the \texttt{ON SELECTION CHANGE} trigger, it is not possible to detect row selection changes when staying on the current row, since no \texttt{BEFORE ROW} / \texttt{AFTER ROW} trigger is fired in this case.

Row selection flags can be changed by program for a range of rows with the \texttt{DIALOG.setSelectionRange()} method.

The \texttt{DISPLAY ARRAY} dialog implements an implicit row-copy feature. The selected rows can be dragged to another dialog or external program, or the end-user can do an "editcopy" predefined action (Ctrl-C shortcut), to copy the selected rows to the front-end clipboard. The row-copy feature works also when multiple row selection is disabled, but only the current row will be dragged or copied to the front-end clipboard.

If you delete, insert or append rows in the program array with methods such as \texttt{array.deleteElement()}. selection information is not synchronized. To sync the selection flags with the data rows, use dialog methods like \texttt{DIALOG.insertRow()} (or \texttt{DIALOG.insertNode()} for tree-views).

**Behavior of \texttt{ui.Dialog} class methods with multiple row selection**

**Table 363: Effect of \texttt{ui.Dialog} class on selection flags when multi-range selection is enabled**

<table>

  - [Example 1: Simple list view](#) on page 1780

### Understanding tables views

Table views define the graphical element to display a list of records.

The end user can navigate in the list to select a row or edit rows, depending on the dialog controlling the table.

If the front-end platform standards allow it, the user can resize the table, sort rows, move/resize/hide columns, make multiple-row selections, search rows by criterion, and more.

**Figure 88: Form with Table View (desktop front-end)**
Tables views are controlled by a DISPLAY ARRAY or INPUT ARRAY instruction, using a form screen-array bound to a TABLE container.

When controlled by a DISPLAY ARRAY, the table view is by default read-only. However, you can implement modification triggers, to let the end user append, modify and delete rows.

When controlled by an INPUT ARRAY, the table view allows immediate data modification: The rows are editable.

Note that a table view can also be used with an INPUT or CONSTRUCT dialog.

You can customize the rendering and the behavior of table views with form attributes in the TABLE container, and in the program using the dialog implementation.

Related concepts
List dialogs on page 1731
Describes how to program dialogs controlling list containers.

Defining tables in the layout
Define table views in the LAYOUT section of the form definition file.

Designing table views
When using a grid-based layout, the table rows and columns are defined within an area delimited by curly brackets. Columns are defined with item tags and form fields. Every column tag must be properly aligned. You typically use a pipe character to separate the column tags.

A table definition using the TABLE layout item:
Alternatively, you can define `<TABLE>` layout tags inside a `GRID` container, beside other layout tags:

```
GRID
{
<GROUP g1>
[f1]  
[f2]  
<  
<TABLE t1>
[c1]  |c2  |c3  
[c1]  |c2  |c3  
[c1]  |c2  |c3  
<  
}
END
```

**Important:** Avoid Tab characters (ASCII 9) inside the curly-brace delimited area. If used, Tab characters are replaced with 8 blanks at compilation with `fglform`.

The position of the item tags is detected by the form compiler to build the table. Column item types (widget to be used) and behavior are defined with form items in the `ATTRIBUTES` section:

```
ATTRIBUTES
EDIT c1 = customer.cust_id;
EDIT c2 = customer.cust_name;
EDIT c3 = customer.cust_address;
END
```

When using a stack-based layout, table views are defined with the `TABLE` stack item inside a `STACK` container. In this case, position/size and behavior are defined at a single place:

```
LAYOUT
STACK
    TABLE t1(UNMOVABLECOLUMNS)
    EDIT customer.cust_id;
    EDIT customer.cust_name;
    EDIT customer.cust_address;
    END
END
END
```

**Controlling the size of the table**

In a grid-based container, the default width and height of a table are defined by the columns and the number of lines used in the table layout respectively. In a stack-based container,

You can overwrite the default table by specifying the `WIDTH` and `HEIGHT` attributes.

```
TABLE t1 ( WIDTH = 5 COLUMNS, HEIGHT = 10 LINES )
```

**Defining column titles**

The `TABLE` layout item definition can contain column titles as well as the tag identifiers for each column's form fields. The `fglform` form compiler can associate column titles in the table layout with the form field columns if they are aligned properly.

**Note:** At least two spaces are required between column titles.
Alternatively, you can set the column titles of a table container by using the TITLE attribute in the definition of the form fields. This allows you to use localized strings for the column titles.

```plaintext
TABLE
{
  [c1 | c2       | c3 ]
  [c1 | c2       | c3 ]
  [c1 | c2       | c3 ]
}
END

ATTRIBUTES
EDIT c1 = customer.cust_id, TITLE=%"label.cust_id";
EDIT c2 = customer.cust_name, TITLE=%"label.cust_name";
EDIT c3 = customer.cust_address, TITLE=%"label.cust_address";
END
```

Similarly, in a stack item TABLE container, columns can get a TITLE attribute:

```plaintext
LAYOUT
STACK
  TABLE t1(UNMOVABLECOLUMNS)
    EDIT customer.cust_id, TITLE=%"label.cust_id";
    EDIT customer.cust_name, TITLE=%"label.cust_name";
    EDIT customer.cust_address, TITLE=%"label.cust_address";
  END
END
END
```

**Height of table rows**

The height of table rows can be defined with a grid-based layout by adding empty tags underneath column tags (this makes sense only when using widgets that can get a height such as TEXTEDIT or IMAGE).

```plaintext
LAYOUT
TABLE
{
  [c1 | c2         ]
  [    |            ]
  [    |            ]
}
END
END
END

ATTRIBUTES
EDIT c1=FORMONLY.key;
TEXTEDIT c2=FORMONLY.thetext;
END
```

In the above example, the second column is defined as a TEXTEDIT item type, that can get a height as a number of grid cells. The height is defined by the number of item tags of the table row in the layout section (height=3 in our example)
Related concepts

**TABLE container** on page 1217
Defines a re-sizable table designed to display a list of records.

**Binding tables to arrays in dialogs**
Program arrays act as data model that are bound to form tables, when implementing list dialogs.

**Identifying list views in program dialogs**
In list dialogs such as the **INPUT ARRAY** or **DISPLAY ARRAY**, the screen array identifies the record list element in the current form to be bound to the program array used by the dialog.

In the next example, the **INPUT ARRAY** uses the **custlist** screen array of the form, and binds the **custarr** program array with:

```
INPUT ARRAY custarr FROM custlist.*
```

The screen array members are associated to the program array record members by position. The order and number of the screen array elements matter as they are bound by position to the members the program array. The position of the **TABLE** columns, however, can differ from the members of the screen array and program array.

To omit columns in the **TABLE** layout, yet include them in the definition of the screen array, and define the columns as **PHANTOM** fields in the form definition file. The program array can then be defined from the database table definition with the **DEFINE LIKE** instruction:

```
DEFINE custarr DYNAMIC ARRAY OF RECORD LIKE customer.*
```

Note that the array is usually defined with a flat list of members with ARRAY OF RECORD / END RECORD. However, the array can be structured with sub-records and still be used with a list dialog. This is especially useful when you need to define arrays from database tables, and additional information needs to be managed at runtime (for example to hold image resource for each row, to be displayed with the **IMAGECOLUMN** attribute):

```
SCHEMA shop
DEFINE a_items DYNAMIC ARRAY OF RECORD
    item_data RECORD LIKE items.*,
    it_image STRING,
    it_count INTEGER
    END RECORD
...
DISPLAY ARRAY a_items TO sr.*
...
```

**Defining screen arrays in grid-based layout TABLES**
When using a grid-based layout, the **TABLE** container is bound to a screen array defined in the **INSTRUCTION** section, by the name of the form fields used in the screen array definition.

The column data type and additional column properties are defined in the **ATTRIBUTES** section as form fields:

```
LAYOUT ...
TABLE ...
  [c1 | c2 | c3 ]
  [c1 | c2 | c3 ]
  [c1 | c2 | c3 ]
  [c1 | c2 | c3 ]
END ...
```
Each form field of the table must be grouped in the INSTRUCTIONS section in a SCREEN RECORD definition.

```
SCREEN RECORD custlist( cust_num, cust_name, cust_cdate );
```

### Defining screen arrays in stack-based layout TABLEs

When using a stack-based layout, the TABLE stack item gets a identifier, which defines the screen array to be used in programs:

```
LAYOUT STACK
  TABLE custlist (STYLE="regular")
    EDIT customer.cust_num;
    EDIT customer.cust_name,
    EDIT customer.cust_cdate;
  END
END
END
```

This identifier is mandatory for TABLE stack items.

### Related concepts

**Array binding in list controllers** on page 1731

Program array elements are bound to screen arrays elements in the definition of the DISPLAY ARRAY or INPUT ARRAY list dialog.

### Controlling table rendering

Table rendering can be controlled by the use of presentation styles and table attributes.

### Table width

By default, the width of a TABLE container is defined by the number of visible columns in its layout.

**Note:** Table column fields defined as HIDDEN will not contribute to computing the default table width.

In this example, the table is defined with three visible columns, which in turn define individual field widths. The sum of the field widths defines the default table width.

```
GRID
{<TABLE t1 >
[c1  |c2       |c3  
...
```

To specify explicitly the width of a table, use the WIDTH attribute:

```
TABLE t1 : table1, WIDTH = 80 COLUMNS, ... ;
```

**Note:** The COLUMNS unit is in the sense of the layout as shown in grid columns.
Table height

The height of a TABLE container is by default defined by the number of rows in its layout. In the example, the default table height will be three rows:

```
GRID
{
 <TABLE t1       >
 [c1 |c2 |c3 ]
 [c1 |c2 |c3 ]
 [c1 |c2 |c3 ]
 <   >
 ...
```

To specify explicitly the height of a table, use the **HEIGHT** attribute:

```
TABLE t1 : table1, HEIGHT = 10 LINES, ... ;
```

**Note:** The LINES unit is in the sense of the layout as shown in grid lines.

Defining a table with fixed height

By default, tables can be resized in height and behave as a stretchable element in the graphical window.

Use the **WANTFIXEDPAGESIZE** form file attribute to prevent table resizing:

```
TABLE t1 : table1, WANTFIXEDPAGESIZE, ... ;
```

Current row / current cell rendering

In a TABLE container, the highlighting of the current row (or current cell, when focus granularity is at the cell level) can be controlled with style attributes.

**Note:** The current row / current cell style attributes apply also to stretchable SCROLLGRID containers.

For more details, see Row and cell highlighting in TABLE on page 1105.

Making table columns unmovable

When the Table style attribute **tableType** is set to **frozenTable**, you can define a number of fixed columns on the left and right, respectively with the **leftFrozenColumns** and **rightFrozenColumns** style attributes:

```
<Style name="Table.custom_style">
 <StyleAttribute name="tableType" value="frozenTable"/>
 <StyleAttribute name="leftFrozenColumns" value="2"/>
 <StyleAttribute name="rightFrozenColumns" value="1"/>
</Style>
```

**Note:** With some front-ends (GBC), frozen columns can also be used in Treeviews.

See the reference topics Table style attributes on page 1101, Tree style attributes on page 1106.

Mobile-style list view rendering

TABLE containers can be rendered with a mobile list view look and feel, by setting the **tableType** style attribute to "listView":

```
<Style name="Table.custom_style">
 <StyleAttribute name="tableType" value="listView"/>
</Style>
```
For the complete list of style attributes, see Table style attributes on page 1101.

**Current row visibility after dialog execution**

When the dialog controlling the table has finished, the current row may be deselected, depending on the KEEP CURRENT ROW dialog attribute.

**Related concepts**

TABLE container on page 1217
Defines a re-sizable table designed to display a list of records.

**Displaying column images**

You can use PHANTOM fields and the IMAGECOLUMN attribute to display images in a column, to the left of the column value.

To display an image on the left of the column value in table views, define a PHANTOM field to hold the image name, and bind it to a parent column with the IMAGECOLUMN attribute.

```
LAYOUT TABLE
{
  [c1 |c2 |
  [c1 |c2 |
  [c1 |c2 |
}
END
END
ATTRIBUTES
PHANTOM FORMONLY.file_icon;
EDIT c1 = FORMONLY.file_name, IMAGECOLUMN=file_icon;
EDIT c2 = FORMONLY.file_size;
...
END
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.*);
END
```

The program code can then display the specified image with each row.

```
DEFINE arr DYNAMIC ARRAY OF RECORD
   file_icon STRING,
   file_name STRING,
   file_size INTEGER
END RECORD
...
FOR x=1 TO max_files
   CASE file_type(arr[x].file_name)
      WHEN "file" LET arr[x].file_icon = "file"
      WHEN "dir"  LET arr[x].file_icon = "folder"
   END CASE
END FOR
...
DISPLAY ARRAY arr TO sr.*
...
END DISPLAY
```

When images come from the database, these are typically fetched into BYTE variables. If the BYTE variable is located in a file (LOCATE IN FILE), it can be bound to the IMAGECOLUMN field: The runtime system will automatically
display the image data. Note, however, that each BYTE element of the array must be located in a distinct file. This can be done as follows:

```
DEFINE arr DYNAMIC ARRAY OF RECORD
    pic_num INTEGER,
    pic_data BYTE,
    pic_when DATETIME YEAR TO SECOND
END RECORD
...
DECLARE c1 CURSOR FOR SELECT * FROM mypics
LET i=1
LOCATE arr[i].pic_data IN FILE
FOREACH c1 INTO arr[i].*
    LOCATE arr[i:=i+1].pic_data IN FILE
END FOREACH
CALL arr.deleteElement(i)
...
```

Depending on the data source, you might want to use a program array structured with sub-records, to define database table related data from row information used at runtime only, as described in Variable binding in DISPLAY ARRAY on page 1397:

```
SCHEMA shop
DEFINE a_items DYNAMIC ARRAY OF RECORD
    item_data RECORD LIKE items.*,
    it_image STRING,
    it_count INTEGER
END RECORD
```

**Related concepts**

Runtime images on page 1052
Explains how to display pictures at runtime.

Image columns firing actions
Columns in tables displaying images can trigger action events, when the user selects the image.

TABLE and TREE containers can define columns as IMAGE field, to display pictures or icons. By default, these table cells are not clickable. When you define an ACTION attribute for a table column defined as IMAGE, the action event will fire when the image is selected (with a mouse click, for example). Note that this does not apply to the IMAGECOLUMN concept, which is rather a column decoration.

Important: When selecting an image, the current row may change as when selecting a new row in the table.

The following example defines a TABLE with two IMAGE columns, and attaches the update and delete actions:

```
LAYOUT TABLE
{
    [c1   |c2                 |i1|i2]
    [c1   |c2                 |i1|i2]
    [c1   |c2                 |i1|i2]
}
END
END
ATTRIBUTES
EDIT c1 = FORMONLY.id, TITLE="Id", NOENTRY;
EDIT c2 = FORMONLY.name, TITLE="Name";
IMAGE i1 = FORMONLY.i_modify, ACTION=update;
IMAGE i2 = FORMONLY.i_delete, ACTION=delete;
END
INSTRUCTIONS
SCREEN RECORD sr(FORMONLY.*);
In the program code, use a dialog instruction to implement the action handlers for the image actions. For example, you can define a `DISPLAY ARRAY` with `ON UPDATE` and `ON DELETE` list modification triggers that will respectively create the update and delete actions:

```
DISPLAY ARRAY arr TO sr.*
  ON UPDATE
    -- user code
  ON DELETE
    -- use code
END DISPLAY
```

**Built-in table features**

Several implicit list handling features are provided by table views.

**Columns layout**

By default, a user can position, hide, show, and resize columns in `TABLE` and `TREE` containers.

**Important:** This feature is not supported on mobile platforms.

**Resizing columns**

By default, columns can be resized. On desktop front-ends, the user can drag the right edge of a column header to increase or decrease the width of the column.

To prevent column resizing for all columns in a table, add the `UNSIZABLECOLUMNS` attribute to the `TABLE` or `TREE` container.

To prevent column resizing for an individual column, add the `UNSIZABLE` attribute to the form field definition for that column.

**Hiding/showing columns**

By default, the user can control the visibility of columns. On desktop front-ends, a user right-clicks on a column header to get a context menu that allows the show/hide columns.

To disable the column visibility option for all columns in a table, add the `UNHIDABLECOLUMNS` attribute to the `TABLE` or `TREE` container.

To disable the column visibility option for an individual column, add the `UNHIDABLE` attribute to the form field definition for that column.

To hide a column initially but allow column visibility, set the `HIDDEN` attribute with the value `USER` in the form field definition for that column. This hides the column by default, and allows the user to show the column if needed.

**Changing column positions**

By default, columns can be moved around. On desktop front-ends, a user can rearrange columns by dragging the column header to a the left or to the right.

To disable this option, add the `UNMOVABLECOLUMNS` attribute to the `TABLE` or `TREE` container.

To disable this option for an individual column, add the `UNMOVABLE` attribute to the form field definition for that column.
**List ordering**
List controllers implement a built-in sort. This feature can be disabled if not required.

When a DISPLAY ARRAY or INPUT ARRAY block is combined with a TABLE container, the row sorting feature is implicitly available. Row sorting is supported on TREE containers with DISPLAY ARRAY dialogs only.

**Important:** This feature is not supported on mobile platforms.

To sort rows in a list, the user must click on a column header of the table. Clicking on a table column header triggers a GUI event that instructs the runtime system to reorder the rows displayed in the list container.

In fact, the rows are only sorted from a visual point of view; the data rows in the program array (the model) are left untouched. Therefore, when rows are sorted, the visual position of the current row might be different from the current row index in the program array.

To sort rows, the runtime system uses the standard collation order of the system, following the current locale settings. As result, the rows might be ordered a bit differently than when using the database server to sort rows (with an ORDER BY clause of the SELECT statement), since database servers can define their own collation sequences to sort character data.

The built-in sort is enabled by default. To prevent sorting in a TABLE or TREE containers, defined the UNSORTABLECOLUMNS attribute at the list container level, or set the UNSORTABLE attribute at the column/field level. As rows can be created and modified during an INPUT ARRAY instruction, you may want to use the UNSORTABLECOLUMNS attribute for tables controlled by INPUT ARRAY.

To execute code after a sort was performed, use the ON SORT interaction block in the dialog, for example to display the current row position with `ui.Dialog.arrayToVisualIndex` on page 2381.

The sorting feature is disabled when using the paged mode of DISPLAY ARRAY, because not all result set rows are known by the runtime system in this mode. However, it is possible to detect a sort request from the user with the ON SORT trigger. You can then re-execute the SQL query with a new sort order. For more details, see Populating a DISPLAY ARRAY on page 1742.

When an application window is closed, the selected sort column and order is stored by the front-end in the user settings database of the system (for example, on Windows® platforms it’s the registry database). The sort will be automatically re-applied the next time the window is created. This way, the rows will appear sorted when the program restarts. The saved sort column and order is specific to each list container.

**Related concepts**
- **Record list (DISPLAY ARRAY)** on page 1394
  The DISPLAY ARRAY instruction provides record list navigation in an application form, with optional record modification actions.
- **Editable record list (INPUT ARRAY)** on page 1425
  The INPUT ARRAY instruction provides always-editable record list handling in an application form.
- **Paged mode of DISPLAY ARRAY** on page 1743
  In order to handle very large result sets, use the paged mode of DISPLAY ARRAY.
- **Full list mode of DISPLAY ARRAY** on page 1742
  In order to handle short/medium result sets, use the full list mode of DISPLAY ARRAY.

**Find function**
List controllers implement a built-in find. This feature can be disabled if not required.

The DISPLAY ARRAY and INPUT ARRAY block blocks support the built-in find feature by default.

**Important:** This feature is not supported on mobile platforms.

This feature works with any list container (TABLE, TREE, SCROLLGRID).

The built-in find creates the implicit "find" and "findnext" actions. These actions can be decorated, enabled and disabled as regular actions.
**Note:** If the dialog defines an explicit **ON ACTION find** or **ON ACTION findnext**, the default built-in find is disabled.

When the user triggers the "find" action (default accelerator is Ctrl-F), the dialog opens a pop-up window to enter a search value and search options. On validation with the OK button, the dialog starts to search a row where a field value matches the value entered in the find dialog. The "find" action starts the search from the current row (and in the field after the current field, if the dialog is an INPUT ARRAY).

After a "find" action, the user can trigger the "findnext" action (default accelerator is Ctrl-G), in order to continue the search, without opening the find dialog again (the current search value will be reused).

By default, any table column is scanned, but the user can select a specific column in the find dialog box, as long as a column title is available. Case-sensitive or insensitive search as well as wraparound options are also available.

**Important:** Only rows in memory can be searched. When using the **paged-mode** (**ON FILL BUFFER**), the built-in search is disabled. When implementing **dynamic tree views**, the built-in find will only search the tree nodes available in the program array.

The value entered in the find dialog is compared to type of columns, except columns using the type **TEXT** or **BYTE**. The comparison is based on the formatted value. For example, a **MONEY** column will display values formatted with the currency symbol. To match values in that column, the user must enter exactly the same value (that is with the currency symbol and the correct decimal separator).

Only text widgets displaying values are searched. Columns using widgets such as images, radio-groups, checkboxes are not searched. Furthermore, the find function ignores **PHANTOM** fields, hidden fields and fields defined with the **INVISIBLE** attribute.

With **COMBOBOX** fields, the find searches in the visible values of combobox items.

When the dialog is an **INPUT ARRAY** and no specific search column is selected in the find dialog, the search scans each cell. The search starts in the current row, after the current field. If no cell value matches in the current row, the search continues on the first field of the next row.

**Tip:** The built-in find feature is also available in **text mode**. In graphical mode, the default keyboard accelerator is Ctrl-F. When using text mode, the accelerator is the / slash key.

**Keyboard seek**

The keyboard seek feature allows a user to find a row in a read-only list, by typing characters.

When a **DISPLAY ARRAY** is used with a list, the keyboard seek feature is automatically implemented. A user may type alphabetic characters on the keyboard to have the runtime system automatically seek the next row having a character field that contains a value starting with the typed characters. The seek search restarts from the current row when the user types new characters on the keyboard.

**Important:** This feature is not supported on mobile platforms.

This feature works with any list container (**TABLE, TREE, SCROLLGRID**).

Numeric, date/time and large data (**TEXT/BYTE**) columns are ignored. Only character columns are searched, fields using widgets like image, radio-group or checkbox are ignored. Furthermore, the seek function ignores **PHANTOM** fields, hidden fields and fields defined with the **INVISIBLE** attribute.

The user can rapidly type several characters on the keyboard, to search for a value that starts with the typed characters. After a given timeout (less than a second), the seek buffer is cleared and a new search filter can be taken into account.

The seek search is case-insensitive.

If no row is found from the typed characters, the [Not found] error -8105 is displayed automatically.

If an alphabetic character is used as action accelerator, the built-in seek feature is disabled, because the accelerator must fire the corresponding action.
Only rows in memory can be searched. When using page-mode (ON FILL BUFFER), the built-in seek is disabled. When implementing dynamic tree views, the built-in seek will only search the tree nodes available in the program array.

By default, any character column of the list is scanned. But if the list gets sorted, the runtime system considers that the sort column is the most important and searches only in that column.

**Reduce filter**
The reduce filter allows a user to limit the row set in the list by using a filter.

**Understanding the reduce filter**
When using a DISPLAY ARRAY with a TABLE or SCROLLGRID container, and if the front-end supports filter search facility, the user can enter a criterion in that search field, to show only the rows matching the content of the filter.

The reduce filter is typically used on mobile devices, for full-screen list views.
