## Genero BDL User Guide

- What's new in 3.10: 18

## General

- Introduction to Genero BDL: 29
- Other source of information: 29
- General terms used in this documentation: 28
- Documentation conventions: 26
- Syntaxes: 26
- Warnings, notes and tips: 27
- Code examples: 27
- Enhancement references: 27

## Installation

- Resources for upgrades: 38
- Software requirements: 39
  - Supported operating systems: 39
  - System packages: 39
  - Database client software: 40
  - C compiler for C extensions: 40
  - Java runtime environment: 40
  - IPv6 support with Genero: 41
- Installing Genero BDL: 41
- Upgrading Genero BDL: 42
- Install Genero Mobile for Android: 42
- Install Genero Mobile for iOS (single version): 43
- Install Genero Mobile for iOS (multiple versions): 44
- Platform specific notes: 45
  - HP-UX configuration notes: 45
  - IBM® AIX® configuration notes: 45
  - Mac® OS X® configuration notes: 46
  - Microsoft® Windows® configuration notes: 47
  - Web Services platform notes: 48
  - SUSE® Linux Enterprise: 48
  - Debian / Ubuntu Linux: 49
  - Red Hat Enterprise Linux: 49

## Upgrading

- New features of Genero BDL: 49
  - BDL 3.10 new features: 50
  - BDL 3.00 new features: 57
  - BDL 2.51 new features: 62
### Configuration

The FGLPROFILE file(s) ................................................................. 220
Understanding FGLPROFILE ..................................................... 221
FGLPROFILE entry syntax .......................................................... 222
List of FGLPROFILE entries ....................................................... 223
Environment variables ............................................................... 226
Setting environment variables on UNIX™ ................................ 226
Setting environment variables on Windows™ ............................ 227
Setting environment variables in FGLPROFILE (mobile) .......... 227
Operating system environment variables ................................. 228
Database client environment variables ......................................... 230
Genero environment variables ................................................... 230
Front-end connection ............................................................... 249
Database server connections .................................................... 249

### Language basics

Syntax features .............................................................................. 249
Lettercase insensitivity ................................................................. 250
Whitespace separators ............................................................... 250
Quotation marks ....................................................................... 250
Escape symbol ......................................................................... 251
Statement terminator ............................................................... 251
Comments ............................................................................... 251
Identifiers ................................................................................ 252
Preprocessor directives ............................................................ 253
Data types ................................................................................ 253
BIGINT ..................................................................................... 254
BYTE ..................................................................................... 255
BOOLEAN ............................................................................... 257
CHAR(size) ............................................................................. 257
DATE ...................................................................................... 259
DATETIME qual1 TO qual2 ....................................................... 260
DECIMAL(p,s) ....................................................................... 262
FLOAT ..................................................................................... 264
INTEGER ............................................................................... 264
INTERVAL qual1 TO qual2 ....................................................... 265
MONEY(p,s) ............................................................................ 267
SMALLFLOAT ........................................................................ 268
SMALLINT .............................................................................. 268
STRING .................................................................................. 269
TINYINT .................................................................................. 270
TEXT ...................................................................................... 271
VARCHAR(size) ....................................................................... 273
Type conversions ...................................................................... 274
When does type conversion occur? ...................................... 274
Data type conversion reference .............................................. 275
Handling type conversion errors .......................................... 280
Formatting numeric values ..................................................... 281
Formatting DATE values .......................................................... 284
Formatting DATETIME values ................................................ 285
### Advanced features

<table>
<thead>
<tr>
<th>Contents</th>
<th>vi</th>
</tr>
</thead>
</table>

- **Optimization**
  - Runtime system basics .......................................................... 401
  - Check runtime system memory leaks ...................................... 402
  - Optimize your programs .......................................................... 403

- **Localization**
  - Application locale ................................................................. 405
  - Localized strings .................................................................. 430

- **Runtime stack**
  - Passing simple typed values as parameter ............................. 444
  - Passing a record as parameter ............................................... 445
  - Passing a static array as parameter ....................................... 446
  - Passing a dynamic array as parameter ................................... 446
  - Passing a dictionary as parameter ........................................ 447
  - Passing objects as parameter ............................................... 448
  - Passing a TEXT/BYTE as parameter ...................................... 448
  - Returning simple typed values from functions ....................... 448
  - Returning dynamic arrays from functions ........................... 449
  - Returning dictionaries from functions ................................ 449
  - Returning TEXT/BYTE values from functions ....................... 450

- **Exceptions**
  - Understanding exceptions ..................................................... 451
  - Exception classes .................................................................. 451

- **Types**
  - Understanding type definition .............................................. 397
  - TYPE .................................................................................. 397
  - Using types in programs ....................................................... 398

- **Dictionary**
  - Understanding dictionaries .................................................. 393
  - DICTIONARY ...................................................................... 394
  - Dictionary methods .............................................................. 396

- **Arrays**
  - Understanding arrays .......................................................... 386
  - ARRAY ............................................................................. 387
  - Static arrays ....................................................................... 388
  - Dynamic arrays ................................................................... 389
  - Array methods ..................................................................... 391
  - Copying arrays .................................................................... 392

- **Records**
  - Understanding records .......................................................... 382
  - RECORD ........................................................................... 383
  - record.elem1 THRU record.elem2 ......................................... 385

- **Constants**
  - Understanding constants ....................................................... 379
  - CONSTANT ....................................................................... 380

- **Examples**
  - Dictionary methods .............................................................. 396
  - DICTIONARY in action .......................................................... 394
  - Understanding dictionaries .................................................. 393

- **Optimization**
  - Runtime system basics .......................................................... 401
  - Check runtime system memory leaks ...................................... 402
  - Optimize your programs .......................................................... 403

- **Localization**
  - Application locale ................................................................. 405
  - Localized strings .................................................................. 430

- **Runtime stack**
  - Passing simple typed values as parameter ............................. 444
  - Passing a record as parameter ............................................... 445
  - Passing a static array as parameter ....................................... 446
  - Passing a dynamic array as parameter ................................... 446
  - Passing a dictionary as parameter ........................................ 447
  - Passing objects as parameter ............................................... 448
  - Passing a TEXT/BYTE as parameter ...................................... 448
  - Returning simple typed values from functions ....................... 448
  - Returning dynamic arrays from functions ........................... 449
  - Returning dictionaries from functions ................................ 449
  - Returning TEXT/BYTE values from functions ....................... 450
  - Implicit data type conversion on the stack ......................... 450

- **Exceptions**
  - Understanding exceptions ..................................................... 451
  - Exception classes .................................................................. 451
<table>
<thead>
<tr>
<th>Contents</th>
</tr>
</thead>
</table>

- Exception actions................................................................. 452
- WHENEVER instruction.......................................................... 452
- TRY - CATCH block................................................................. 455
- Tracing exceptions................................................................. 456
- Default exception handling..................................................... 457
- Non-trappable errors............................................................. 457
- Examples....................................................................................... 457

- OOP support................................................................................. 460
  - Understanding classes and objects........................................ 460
  - DEFINE ... package.class.................................................... 460
  - Distinguish class and object methods...................................... 460
  - Working with objects............................................................ 461
  - What class packages exist?..................................................... 463

- XML support................................................................................. 463
  - DOM and SAX standards..................................................... 463
  - DOM and SAX built-in classes.............................................. 463
  - Limitations of XML built-in classes........................................ 464
  - Exception handling with XML classes................................. 464
  - Controlling the user interface with XML classes................... 465

- JSON support.............................................................................. 465
  - What is JSON?....................................................................... 465
  - JSON utility classes............................................................ 466
  - BDL/JSON conversion basics................................................. 466
  - BDL names and JSON element names.................................. 467
  - NULLs and empty structures.................................................. 468
  - BDL to JSON type conversion rules...................................... 470
  - JSON to BDL type conversion rules...................................... 471

- Globals......................................................................................... 472
  - Understanding global blocks................................................. 473
  - GLOBALS.............................................................................. 473
  - Rules for globals usage........................................................ 473
  - Database schema in globals.................................................. 474
  - Content of a globals file....................................................... 474
  - Examples................................................................................. 475

- Database schema....................................................................... 476
  - Understanding database schemas......................................... 476
  - SCHEMA.............................................................................. 477
  - Structure of database schema files........................................ 478
  - Database schema extractor options.................................... 486

- Programs...................................................................................... 491
  - Structure of a program......................................................... 491
  - Structure of a module.......................................................... 492
  - The MAIN block / function................................................... 493
  - Importing modules.............................................................. 496
  - Predefined constants........................................................... 502
  - Configuration options.......................................................... 504
  - Program registers............................................................... 516

- Program execution.................................................................... 519
  - Executing programs............................................................ 520
  - RUN..................................................................................... 521
  - EXIT PROGRAM................................................................. 524
  - BREAKPOINT...................................................................... 524

- Front calls.................................................................................. 525
  - Understanding front calls.................................................... 525
  - ui.Interface.frontCall.......................................................... 526
  - User-defined front calls...................................................... 528

### BDL 3.10 new features

Features added in 3.10 releases of the Genero Business Development Language.

#### Table 1: Core language

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>The DICTIONARY type, to define associative arrays / hash-maps.</td>
<td>See Dictionary on page 393, DICTIONARY as class on page 2262.</td>
</tr>
<tr>
<td>Overview</td>
<td>Reference</td>
</tr>
<tr>
<td>----------</td>
<td>-----------</td>
</tr>
<tr>
<td>New FUNCTION definition syntax, to declare exact function signature with parameter types in the parentheses, and return types in the RETURNS clause.</td>
<td>See FUNCTION definitions on page 353, Function parameters on page 355, Returning values on page 360.</td>
</tr>
<tr>
<td>Function references, to call functions only know at runtime.</td>
<td>See Function references on page 362, FUNCTION func-spec on page 364.</td>
</tr>
<tr>
<td>Invoking methods with an object reference returned from a method: LET s = s.substring(1,10).toLowerCase()</td>
<td>See Working with objects on page 461.</td>
</tr>
<tr>
<td>GUI log file name with process id (--start-guilog=&quot;myfile-%p.log&quot;).</td>
<td>See Front-end protocol logging on page 1021.</td>
</tr>
<tr>
<td>Source code coverage tool (FGLCOV/fglrun --merge-cov).</td>
<td>See Source code coverage on page 2056.</td>
</tr>
<tr>
<td>Program execution trace (fglrun --trace).</td>
<td>See Execution trace on page 2060.</td>
</tr>
<tr>
<td>Java SE 10 and 11 support.</td>
<td>See Java Inteface changes on page 112, Java software requirements on page 2072.</td>
</tr>
<tr>
<td>New DYNAMIC ARRAY methods copyTo(), search(), searchRange().</td>
<td>See DYNAMIC ARRAY.copyTo on page 2257, DYNAMIC ARRAY.search on page 2259, DYNAMIC ARRAY.searchRange on page 2260.</td>
</tr>
<tr>
<td>Defining the localized string lookup path when program starts.</td>
<td>See base.Application.reloadResources on page 2272.</td>
</tr>
<tr>
<td>Bit-wise operation and hexadecimal/binary string conversion on INTEGER values.</td>
<td>See The util.Integer class on page 2582.</td>
</tr>
<tr>
<td>Channel openFile() method can write to stderr.</td>
<td>See base.Channel.openFile on page 2278.</td>
</tr>
<tr>
<td>Variable definition attributes for JSON serialization: json_null, json_name.</td>
<td>See JSON support on page 465.</td>
</tr>
<tr>
<td>Resource files (.42f, etc) can now also be found in the directory where the MAIN module resides.</td>
<td>See Default resource file search path on page 124, FGLRESOURCEPATH on page 244.</td>
</tr>
<tr>
<td>VIM plugins can be used directly from FGLDIR/vimfiles.</td>
<td>See Code completion and syntax highlighting with VIM on page 2012.</td>
</tr>
<tr>
<td>Base64 to/from Hexadecimal string conversion methods.</td>
<td>See util.Strings.base64DecodeToHexString on page 2603, util.Strings.base64EncodeFromHexString on page 2604.</td>
</tr>
</tbody>
</table>
### Source documentation enhancements, to describe module variables, constants and user defined types.

See [Commenting a module constant on page 2015](#), [Commenting a module variable on page 2016](#), [Commenting a module type on page 2016](#).

**fglform** checks for unique TABINDEX values.

See [Unique TABINDEXes in a form on page 118](#).

### Table 2: User interface

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic dialog creation (equivalents of <strong>INPUT ARRAY</strong> and <strong>DIALOG</strong> blocks).</td>
<td>See <a href="#">Dynamic Dialogs on page 1903</a>, <a href="#">ui.Dialog.createInputArrayFrom on page 2371</a>, <a href="#">ui.Dialog.createMultipleDialog on page 2373</a>.</td>
</tr>
<tr>
<td>Click on cell in <strong>DISPLAY ARRAY</strong> with <strong>FOCUSONFIELD</strong> attribute.</td>
<td>See <a href="#">Field-level focus in DISPLAY ARRAY on page 1740</a>.</td>
</tr>
<tr>
<td>Get user's preferred language defined on the front-end platform.</td>
<td>See <a href="#">User's preferred language on page 425</a>.</td>
</tr>
<tr>
<td>New &quot;accordion&quot; value for the <strong>position</strong> style attribute of <strong>FOLDER</strong> containers, to render the children pages as a set of collapsible group boxes.</td>
<td>See <a href="#">Folder style attributes on page 1093</a>, <a href="#">FOLDER item type on page 1171</a>, <a href="#">Presentation styles changes on page 112</a>.</td>
</tr>
<tr>
<td>A set of ready-to-use web components are now provided in the Genero BDL package.</td>
<td>See <a href="#">Built-in Web Components on page 1875</a>, <a href="#">Web components changes on page 115</a>.</td>
</tr>
<tr>
<td><strong>gICAPI</strong> Web Component <strong>onFlushData</strong> and <strong>onStateChange</strong> methods to better control content change and form field state.</td>
<td>See <a href="#">gICAPI.onFlushData() on page 1841</a>, <a href="#">gICAPI.onStateChanged() on page 1847</a>.</td>
</tr>
<tr>
<td>New dialog methods to set text, image and comment of default action views.</td>
<td>See <a href="#">Configuring default action views dynamically on page 1651</a>.</td>
</tr>
<tr>
<td>Defining array cell attributes in dynamic dialogs with simple and two-dimensional dynamic arrays.</td>
<td>See <a href="#">ui.Dialog.setArrayAttributes on page 2397</a>.</td>
</tr>
<tr>
<td>Display values to form fields or screen arrays that are only known at runtime.</td>
<td>See <a href="#">ui.Form.displayTo on page 2357</a>.</td>
</tr>
<tr>
<td><strong>NOTEDITABLE</strong> can be specified for <strong>TEXTEDIT</strong> form fields.</td>
<td>See <a href="#">NOTEDITABLE attribute on page 1274</a>.</td>
</tr>
<tr>
<td>Use the <strong>DateEdit</strong> style attribute <strong>calendarType</strong> to define the type of calendar.</td>
<td>See <a href="#">DateEdit style attributes on page 1089</a>.</td>
</tr>
<tr>
<td>The <strong>UserInterface</strong> style attribute <strong>reverse</strong> can be used for Arabic languages support.</td>
<td>See <a href="#">Right-to-left languages support on page 426</a>.</td>
</tr>
<tr>
<td><strong>localStorage</strong> front calls to store key/value pairs on the front-end side.</td>
<td>See <a href="#">Local storage front calls on page 2543</a>, <a href="#">New localStorage frontcalls on page 125</a>.</td>
</tr>
</tbody>
</table>
### Overview

<table>
<thead>
<tr>
<th>Style attribute</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>rowActionTrigger (Table class)</td>
<td>See Defining the action for a row choice on page 1768.</td>
</tr>
<tr>
<td>STYLE attribute</td>
<td></td>
</tr>
<tr>
<td>DOUBLECLICK attribute now supported for SCROLLGRID lists, in .per file syntax and as DISPLAY ARRAY attribute.</td>
<td>See Defining the action for a row choice on page 1768.</td>
</tr>
<tr>
<td>ON CHANGE is now allowed in CONSTRUCT.</td>
<td>See ON CHANGE block on page 1384.</td>
</tr>
<tr>
<td>SCREEN can get a TAG attribute.</td>
<td>See SCREEN section on page 1193.</td>
</tr>
<tr>
<td>bold attribute in table cell attributes.</td>
<td>See ui.Dialog.setArrayAttributes on page 2397.</td>
</tr>
<tr>
<td>The Window style attribute thinScrollbarDisplayTime accepts a negative value, to hide the scrollbar.</td>
<td>See Window style attributes on page 1117.</td>
</tr>
<tr>
<td>Form item attribute INITIALPAGESIZE for SCROLLGRID elements.</td>
<td>See INITIALPAGESIZE attribute on page 1266.</td>
</tr>
<tr>
<td>The standard.openFiles frontcall can be used to let the user select multiple files on the front-end platform.</td>
<td>See The openFiles front call.</td>
</tr>
<tr>
<td>The Window style attributes actionPanelButtonSize and ringMenuButtonSize support the &quot;em&quot; unit (&quot;20em&quot;).</td>
<td>See Presentation styles changes on page 112, Window style attributes on page 1117.</td>
</tr>
<tr>
<td>AGGREGATE fields can be used with any item type (was limited to EDIT columns).</td>
<td>See Summary lines in tables on page 1767.</td>
</tr>
<tr>
<td>GDC auto-update front call (monitor.update) to install a new GDC automatically from a Genero program.</td>
<td>See monitor.update frontcall.</td>
</tr>
<tr>
<td>Input field hint specification with the PLACEHOLDER attribute.</td>
<td>See PLACEHOLDER attribute on page 1277.</td>
</tr>
<tr>
<td>Front call API allows RECORD and ARRAY specification in input and output parameters.</td>
<td>See ui.Interface.frontCall on page 526, webcomponent.call.</td>
</tr>
<tr>
<td>The ui.Dialog.cancel() method can be used to cancel a parent DIALOG from the SUBDIALOG code.</td>
<td>See ui.Dialog.cancel on page 2382.</td>
</tr>
<tr>
<td>New theme front calls allow the Genero application to set the theme, retrieve the theme in use, or list all available themes for an application using the Genero Browser Client.</td>
<td>See Theme front calls on page 2539.</td>
</tr>
<tr>
<td>Better control of row / cell highlighting for TABLE and SCROLLGRID containers.</td>
<td>See Row and cell highlighting in TABLE on page 1105, Row and cell highlighting in SCROLLGRID on page 1101, Row highlighting in TREE on page 1109.</td>
</tr>
<tr>
<td>Set the Table style attribute tableType to listView, to get Mobile list view rendering for tables.</td>
<td>See Controlling table rendering on page 1759, Table style attributes on page 1101.</td>
</tr>
</tbody>
</table>
### Overview

Set the Scrollgrid style attribute `customWidget` to `pagedScrollGrid`, to render the scrollgrid as a responsive tile list.

Set the Checkbox style attribute `customWidget` to `toggleButton`, to render the checkbox as a toggle switch.

The Button style attribute `alignment` can be used to define the content position in the widget.

The Window style attribute `windowState` can be set to `fullscreen` to display the window in fullscreen mode (GDC only).

---

**Table 3: SQL databases:**

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support of Microsoft® ODBC v13 and v17 for SQL Server with <code>dbmsnc_13</code> and <code>dbmsnc_17</code> ODI drivers. These drivers are available on Windows® and Linux® 64bits platforms, to connect to SQL Server 2016, 2017 and Azure SQL Database.</td>
<td>See Microsoft ODBC Driver for SQL Server on page 117.</td>
</tr>
<tr>
<td>Support for SAP HANA® 2.0 database with the new ODI driver <code>dbmhdb_2</code>.</td>
<td>See SAP HANA on page 978.</td>
</tr>
<tr>
<td>Support for IBM® DB2® LUW 11.x (with <code>dbmdb2_10</code>).</td>
<td>See Database driver specification (driver) on page 606.</td>
</tr>
<tr>
<td>Support for Oracle® 12c on macOS®.</td>
<td>See Mac OS X configuration notes on page 46 (Special consideration must be taken for libclntsh.so)</td>
</tr>
<tr>
<td>Support for PostgreSQL 9.6 and 10.</td>
<td>See Database driver specification (driver) on page 606.</td>
</tr>
<tr>
<td>Support for Oracle® MySQL 5.7 (<code>dbmmys_5_7</code>) and MySQL 8.0 (<code>dbmmys_8_0</code>).</td>
<td>See Oracle MySQL 5.7 and 8.0 support on page 122, Database driver specification (driver) on page 606.</td>
</tr>
<tr>
<td>Support for MariaDB 10.2 with the new ODI driver <code>dbmmdb_10_2</code>.</td>
<td>See Database driver specification (driver) on page 606, Prepare the runtime environment - connecting to the database on page 812.</td>
</tr>
<tr>
<td>Support for FreeTDS 1.00 (to connect to SQL Server up to version 2016)</td>
<td>See Prepare the runtime environment - connecting to the database on page 770.</td>
</tr>
<tr>
<td>The SNC driver selects automatically the char mode (<code>snc.widechar</code> FGLPROFILE parameter) depending on the application locale.</td>
<td>See Wide Char mode of SNC driver on page 125.</td>
</tr>
<tr>
<td>Special hints in C-style comments to control SQL statement execution.</td>
<td>See fglhint_* in SQL comments on page 123.</td>
</tr>
<tr>
<td>Defining ODBC connection string parameters for SQL Server with the &quot;datasource?options&quot; notation in the &quot;source&quot; connection parameter.</td>
<td>See Database source specification (source) on page 606, SQL connection identifier on page 622.</td>
</tr>
</tbody>
</table>
### Overview

| Specifying Oracle® DB schema and tablespace in temporary table emulations. | See Temp table emulation with Oracle DB on page 122. |
| Oracle® DB proxy authentication. | See Oracle DB Proxy Authentication on page 121. |
| Print SQL debug message only when SQL error occurs, and control SQL debug level from programs with fgl_sqldebug() | See Debugging SQL statements on page 542, fgl_sqldebug() on page 2176. |
| Converting MATCHES to PostgreSQL SIMILAR TO expressions. | See MATCHES and LIKE on page 916. |
| Faster SQL execution with PostgreSQL driver and new pre-fetch row count parameter in FGLPROFILE. | See PostgreSQL specific FGLPROFILE parameters on page 620. |
| SET LOCK MODE support with PostgreSQL driver. | See Concurrency management on page 890. |

### Table 4: Tools

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>The fpi command line tool can be used to show Genero BDL version information.</td>
<td>See fpi on page 1988.</td>
</tr>
<tr>
<td>The fglgar command line tool is now delivered with the FGLGWS package.</td>
<td>See fglgar on page 1985, Packaging web applications on page 2063.</td>
</tr>
<tr>
<td>fglcomp option -W to-err-file to write warnings to the .err file.</td>
<td>See fglcomp on page 1972.</td>
</tr>
<tr>
<td>fglcomp option --tag=string to write a custom string to the .42m pcode module.</td>
<td>See fglcomp on page 1972, 42m module information on page 2009.</td>
</tr>
</tbody>
</table>

### Table 5: Web Services

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support of Message Transmission Optimization Mechanism (MTOM), a method of efficiently sending binary data to and from Web services.</td>
<td>See Message Transmission Optimization Mechanism (MTOM) on page 3123, XMLOptimizedContent on page 3279, and fglwsdl on page 1980 (-hexb64AsString option)</td>
</tr>
<tr>
<td>The swaRef feature optimizes file transfer when the files are attachments and located on disk.</td>
<td>See swaRef (SOAP with attachments using wsi:swaRef) on page 3124.</td>
</tr>
<tr>
<td>Better support of Web Services on iOS mobile devices.</td>
<td>See Web Services on mobile devices on page 3312.</td>
</tr>
<tr>
<td>New methods clearHeaders() and removeHeader() remove headers from an HTTP multipart object.</td>
<td>See com.HTTPPart methods on page 2746.</td>
</tr>
<tr>
<td>New XML serializer options xml_ignoreunknownelements and xml_ignoreunknownattributes, to ignore unexpected elements or attributes.</td>
<td>See Serialization option flags on page 2890.</td>
</tr>
<tr>
<td>Overview</td>
<td>Reference</td>
</tr>
<tr>
<td>----------</td>
<td>-----------</td>
</tr>
<tr>
<td>The <code>XMLElementNillable</code> attribute provides an option to set all XML elements explicitly to null and to serialize them with <code>xsi:nil=&quot;true&quot;</code>, when the BDL variable is NULL.</td>
<td>See <code>XMLElementNillable</code> on page 3269, Web Services changes on page 106.</td>
</tr>
<tr>
<td>The <code>XMLNillable</code> attribute provides an option to set an XML node explicitly to null and to serialize it with <code>xsi:nil=&quot;true&quot;</code>, when the BDL variable is NULL but not optional.</td>
<td>See <code>XMLNillable</code> on page 3267, Web Services changes on page 106.</td>
</tr>
<tr>
<td>New built-in server-side methods for the <code>com.HTTPServiceRequest</code> class: <code>getURLHost()</code>, <code>getURLPort()</code>, <code>getURLPath()</code>, <code>getURLQuery()</code>, <code>findRequestCookie()</code>, and <code>setResponseCookie()</code>.</td>
<td>See The <code>HTTPServiceRequest</code> class on page 2688.</td>
</tr>
<tr>
<td>Methods added to assist with cookie management.</td>
<td></td>
</tr>
<tr>
<td>New methods for proxy management of the current <code>HTTPRequest</code>.</td>
<td>See The <code>HTTPRequest</code> class on page 2714.</td>
</tr>
<tr>
<td>The <code>xml.XSLTTransformer</code> class provides methods for transforming XML following the XSLT version 1.0 specification.</td>
<td>See The <code>XSLTTransformer</code> class on page 2962.</td>
</tr>
<tr>
<td>New methods to generate a password of a given size and based on a human readable password using Password-Based Key Derivation Function 2 (PBKDF2).</td>
<td>See The <code>PBKDF2</code> class on page 2992.</td>
</tr>
<tr>
<td>New methods allow you to save passwords as BCrypt results.</td>
<td>See The <code>BCrypt</code> class on page 2994.</td>
</tr>
<tr>
<td>A new REST demo has been added in <code>$FGLDIR/demo/WebServices/forum</code>. This demo uses REST services with JSON, text and binary data; manages authorization access via the new HTTP automatic cookie API; and uses the new BCrypt API to store a password in a database.</td>
<td>See the <code>readme.txt</code> provided with the demo.</td>
</tr>
<tr>
<td>The <code>enveloped-signature</code> method has an optional parameter to specify the node where the signature will be added.</td>
<td>See Transformation identifier on page 2939.</td>
</tr>
<tr>
<td><code>FGLPROFILE</code> entry to define regex-based URL specification for HTTP configuration.</td>
<td>See Web Services changes on page 106, Server configuration on page 3240.</td>
</tr>
<tr>
<td>New <code>fglwsdl</code> option <code>-fRPCNamespace</code> to produce BDL code supporting the <code>namespace</code> attribute for RPC parameters.</td>
<td>See Web Services changes on page 106, <code>fglwsdl</code> on page 1980.</td>
</tr>
<tr>
<td>New <code>fglpass</code> option <code>-gid</code> and <code>security.global.agent.gid=true</code> <code>FGLPROFILE</code> entry, to allow agent authentication to be performed with UNIX user group instead of user only.</td>
<td>See Web Services changes on page 106, <code>fglpass</code> on page 1983, Use the password agent on page 3118.</td>
</tr>
</tbody>
</table>
Table 6: Mobile apps (GMA 1.30 and GMI 1.30)

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>GMI and GMA include generic Cordova/PhoneGap plugin frontcalls to make use of the Cordova plugins.</td>
<td>See Cordova plugin front calls on page 2569.</td>
</tr>
<tr>
<td>GMI build tool options --install-plugins and --list-plugins, to manage Cordova plugins.</td>
<td>See gmibuildtool on page 1994 and Cordova plugins on page 3370.</td>
</tr>
<tr>
<td>GMA build tool option --build-cordova, to embed one or more Cordova plugins.</td>
<td>See gmabuildtool on page 1989 and Cordova plugins on page 3370.</td>
</tr>
<tr>
<td>GMA build tool command scaffold, to manage scaffold archives. This new command comes with the --list-plugins and --install-plugins options to handle plugins in the scaffold archive.</td>
<td>See gmabuildtool on page 1989 and Building Android apps with Genero on page 3317.</td>
</tr>
<tr>
<td>Stretchable SCROLLGRID lists are supported on mobile front-ends.</td>
<td>See SCROLLGRID item type on page 1179.</td>
</tr>
<tr>
<td>Predefined actions enterbackground and s enterforeground to detect app state change.</td>
<td>See Background/foreground modes on page 3299.</td>
</tr>
<tr>
<td>The GMIDIR environment variable allows you to install the GMI archive in a different directory than FGLDIR.</td>
<td>See Building iOS apps with Genero on page 3332.</td>
</tr>
<tr>
<td>GMI build tool option --extensions/libs, to specify the libraries to be used to build your iOS app.</td>
<td>See Building iOS apps with Genero on page 3332.</td>
</tr>
<tr>
<td>GMA build tool options --build-status-icon-* allow you to define the status notification bar icon.</td>
<td>See Building Android apps with Genero on page 3317, gmabuildtool on page 1989.</td>
</tr>
<tr>
<td>GMA build tool option --accept-licenses allows you to silently accept Android™ SDK licenses during updates of Android™ SDK.</td>
<td>See gmabuildtool on page 1989 and Building Android apps with Genero on page 3317.</td>
</tr>
<tr>
<td>GMA supports now the alignment style attribute for IMAGE.</td>
<td>See Image style attributes on page 1095.</td>
</tr>
<tr>
<td>GMI build tool option --install provides a method for installing without the need to snoop with instruments for the actual device name.</td>
<td>See gmibuildtool on page 1994 and Genero mobile development client for iOS on page 3295.</td>
</tr>
<tr>
<td>The style attribute reduceFilter controls the display of the the listview reduce filter on GMA clients.</td>
<td>See Table style attributes on page 1101.</td>
</tr>
<tr>
<td>GMA build tool option --build-force-scaffold-update, to recreate the app project directory from a fresh GMA scaffold directory.</td>
<td>See gmabuildtool on page 1989 and Genero Mobile for Android (GMA) 1.30 changes on page 108.</td>
</tr>
<tr>
<td>GMA build tool option --build-quietly, to force yes for any answer asked during the build process.</td>
<td>See gmabuildtool on page 1989 and Genero Mobile for Android (GMA) 1.30 changes on page 108.</td>
</tr>
<tr>
<td>The front call mobile.isForeground indicates if the app is in foreground mode.</td>
<td>See Front calls changes on page 114, isForeground on page 2556.</td>
</tr>

</table>

Related concepts
BDL 3.10 upgrade guide on page 106
These topics describe product changes you must be aware of when upgrading to version 3.10.

General

These topics provide an introduction to the Genero Business Development Language

- Documentation conventions on page 26
- General terms used in this documentation on page 28
- Other source of information on page 29
- Introduction to Genero BDL programming on page 29

Documentation conventions

Learn about documentation conventions regarding syntax, warnings, code examples, and enhancement references.

- Syntaxes on page 26
- Warnings, notes and tips on page 27
- Code examples on page 27
- Enhancement references on page 27

Syntaxes

The term *syntax* is global and indicates the way to use a product function.

For example, it can be used to describe a language instruction or a command-line tool:

```
CALL function ( [ parameter ]|, . . . ] )
[ RETURNING variable ]|, . . . ]
```

Language keywords are written in uppercase.

Variable elements in a syntax definition are written in *italics*.

Wildcard characters in syntax definitions are written in *italics*.

Wildcards in syntax definitions are marked with an underscore and used to indicate elements that can either repeat, be mandatory or optional:

**Table 7: Wildcard characters**

<table>
<thead>
<tr>
<th>Wildcards</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>[] e</code></td>
<td>Square brackets indicate an optional element in the syntax.</td>
</tr>
<tr>
<td>`[] e1</td>
<td>e2 ...`</td>
</tr>
<tr>
<td>`{} e1</td>
<td>e2 ...`</td>
</tr>
<tr>
<td><code>[]...</code></td>
<td>A sign made of square brackets with three dots indicate that the previous element can appear more than once.</td>
</tr>
<tr>
<td><code>, ...</code></td>
<td>A sign made of square brackets with a comma followed by three dots indicate that the previous element can appear more than once, and must be separated by a comma.</td>
</tr>
</tbody>
</table>
Warnings, notes and tips

Documentation notes focus on a technical fact you must be aware of.

**Important**
An important note describes a fact that needs to be considered, before using the related feature.

**Important:** When a DATE, DATETIME or INTERVAL constant cannot be initialized correctly, it is set to NULL.

Some Genero features are not supported on all back-end or front-end platforms. The following warnings about the limitation:

**Important:** This feature is not supported on mobile platforms.

**Important:** This feature is only for mobile platforms.

**Important:** This feature is experimental, the syntax/name and semantics/behavior may change in a future version.

Some Genero features are deprecated:

**Important:** This feature is deprecated, and may be removed in a future version.

**Notes**
Simple notes describe a fact you must be aware of, but does not represent any risk.

**Note:** This feature has been introduced in version 2.50.

**Tips**
Tip notes suggest an option or programming pattern to be used.

**Tip:** Use dynamic arrays instead of static arrays to save memory usage.

**Warnings**
Warning notes highlight an action that might cause something to break or otherwise be catastrophic.

**Warning:** Using a high cost value for the salt is very CPU consuming, and can really slow down the application depending on the system it is running.

**Code examples**
Code examples contain code that can be copied as-is.

Code examples appear in the documentation as follows:

```
MAIN
   DEFINE a1 ARRAY[100] OF INTEGER,
       a2 ARRAY[10,20] OF RECORD
       id INTEGER,
...
```

**Enhancement references**
In some parts of the documentation you can find enhancement reference notes with a number identifying the request in our internal database.

*Enhancement reference: BZ#1827*
General terms used in this documentation

This documentation uses several terms that must be clarified for a good understanding.

**Application**

The *application* defines all software components that compose the information system managing a given domain. Usually, the domains covered by programs written in BDL are business oriented.

**End user**

The *end user* is the person that uses the application; that person works on hardware called the workstation.

**Programs**

The *programs* are the software components that are developed and distributed by the supplier of the application. Programs typically implement business logic. Programs are executed by the runtime system. Program components are typically p-code modules, forms and additional resource files.

**Developer**

The *developer* is the person in charge of the conception and implementation of the application components.

**Application data**

*Application data* defines the data manipulated by the application. It is typically managed by one or more database systems. The application data has a volatile state when loaded in the runtime system, and it has a static state when stored in the database system.

**Database**

The *database* is a logical entity regrouping the application data. It is managed by the database system.

**Database system**

The *database system* is the software that manages data storage and searching; it is usually installed on the database server machine and is supported by a tier software vendor.

**Development database**

The *development database* is the database used in the application development environment.

**Production database**

The *production database* is the database used on production sites.

**Front end**

The *front end* is the software that manages the display and input of the user interface on the workstation machine. This component is historically called "the client". It is the software handling the presentation. There are different sort of front-ends available, for desktop workstations (GDC), for web-browsers (GAS), and on mobile devices (GMA/GMI).

**Runtime system**

The *runtime system* is the software that manages the execution of the programs, where the business logic is processed. The runtime system is also known as the Dynamic Virtual Machine (DVM - fgrun).

**User interface**

The *user interface* defines the parts of the programs that interact with the end user, including interactive elements like windows, screens, input fields, buttons and menus. It is managed by the front-end.

- Genero BDL concepts on page 31

**Overview of Genero BDL**

Genero Business Development Language (BDL) is a program language designed to write an interactive database application.

A Genero BDL application is a set of programs that handle the interaction between a user and a database. Programs communicate with the database server with Structured Query Language (SQL), and execute interactive instruction controlling application forms, to manage user input.
An important feature of the language is the ease with which you can design applications that allow the user to access and modify data in a database. The language syntax includes a set of SQL statements to manipulate the database, powerful interactive instructions that provide simple record input, read-only and read-write record list handling, as well as database query to search the database, by using forms supporting a large variety of graphical widgets.

The program sources are compiled to p-code modules, which can be interpreted on different platforms by the Dynamic Virtual Machine (the Runtime system).

- Separation of business logic and user interface on page 30
- Portability - write once, deploy anywhere on page 30

Separation of business logic and user interface
Genero BDL separates business logic and the user interface to provide maximum flexibility.

- Intensive use of XML standards ensures that user interface is well separated from the program logic.
- Forms define the user interface are designed in a simple-to-understand and simple-to-read syntax.
- The business logic is written in .4gl source code modules.
- High-level interactive instructions called dialogs let you write form controllers in a few lines of code.
- Action views (buttons, menu items, toolbar icons) in the form definition can trigger actions defined in the business logic.
- The user interface can be manipulated at runtime, for example to enable/disable fields and action views dynamically.

Related concepts
User interface on page 1008
These topics cover programming the user interface (UI) with the Genero Business Development Language.

Portability - write once, deploy anywhere
Genero application can be deployed for different kinds of display devices, operating systems and database servers, by using the same source code.

Application forms can be displayed with a graphical front-end device based on native desktop frameworks, in web browsers, as well as on simple dumb terminals. Genero programs can be executed on major Operating Systems such as UNIX™, Linux®, Windows® and Mac OS X® SQL can be performed by IBM® Informix®, or any other major database server such as Oracle® DB, IBM® DB2®, Microsoft™ SQL Server, PostgreSQL, Oracle® MySQL, SAP ASE.
Figure 2: Genero portability

- Programming tools on page 35
• Compiling a program on page 36
• Deploying application program files on page 37

**Genero programs**
Genero Business Development Language (BDL) is a programming language based on simple and readable syntax.

The program logic is written in text files with the .4gl file extension, called *program source modules*. Module sources are compiled (fglcomp) into p-code modules with the .42m file extension, that can be executed by the *runtime system* (fglrun). Application programs are build with a group of .42m modules.

**Related concepts**
Programs on page 491
Explains program structure basics and global instructions/registers.

**Integrated SQL support**
A set of SQL statements are part of the language syntax and can be used directly in the source code, as a normal procedural instruction.

The static SQL statements are parsed and validated at compile time. At runtime, these SQL statements are automatically prepared and executed. Program variables are detected by the compiler and handled as SQL parameters. Common SQL statements such as SELECT, INSERT, UPDATE or DELETE can be directly written in the source code, as part of the language syntax:

```main
DEFINE n INTEGER, s CHAR(20)
DATABASE stores
LET s = "Sansino"
SELECT COUNT(*) INTO n FROM customer WHERE custname = s
DISPLAY "Rows found: " || n
END MAIN
```

Dynamic SQL management allows you to execute SQL statements that are constructed at runtime. The SQL statement can use SQL parameters:

```main
DEFINE txt CHAR(20)
DATABASE stores
LET txt = "SET DATE_FORMAT = YMD"
PREPARE sh FROM txt
EXECUTE sh
END MAIN
```

Through the database drivers, the same program can open database connections to any of the supported databases.

**Related concepts**
SQL support on page 528
These topics cover SQL support in the Genero Business Development Language.

**XML support**
The language provides XML support through different classes, depending on your needs.

Genero XML support is provided in two forms:

• For basic XML tasks related to the user interface, use the built-in XML classes.
• For complex XML tasks, and Web Services functions, use the full-featured XML classes provided in the web services extension.
The user interface
The Genero user interface technology is based on the sharing of an abstract representation between the runtime system and the front-end.

When a program starts, the runtime system creates the abstract user interface (AUI) tree and passes this tree to the front-end. The front-end renders the abstract element as real graphical objects on the workstation.

When an interaction statement takes control of the application, the tree on the front-end is automatically synchronized with the runtime system tree. Runtime system and front-ends communicate with the front end protocol, through the computer network. The AUI tree and the protocol are using XML standards.

Figure 3: AUI tree synchronization
Resource files describe the appearance (decoration) of some of the graphic objects. Default resource files (default.4ad, default.4st) are provided and can be customized, or replaced with your own versions.

The elements of the AUI tree can be manipulated at runtime with built-in utilities.

Related concepts
User interface on page 1008
These topics cover programming the user interface (UI) with the Genero Business Development Language.

Language library
Several utility packages are provided to ease programming in different domains.

Utility functions and classes are available in different forms, including built-in classes, built-in functions, and loadable modules.

Related concepts
Library reference on page 2149
Reference for classes and functions provided as built-in or extension packages.

Windows and forms
Programs manipulate window and form objects to define display areas controlled by interactive statements.

The forms are defined in text-based form specification files (.per). These form files are transformed by the fglform compiler to produce the runtime form files (.42f) that are deployed in production environments. The resulting (.42f) files are XML documents that describe the form elements, enabling portability across display devices. The XML file can also be written directly, or it can be generated or modified from your program at runtime with XML utilities.

Related concepts
Form definitions on page 1031
This section describes how to define application forms and program resources related to the presentation layer.

**Interactive instructions**
Control application forms with interactive instructions that perform field input and action handling.

These *interactive instructions* allow the program to respond to user actions and data input. For example, the `INPUT BY NAME` block controls a set of form fields where the user can enter data:

```plaintext
DEFINE cust_rec RECORD LIKE customer.*
INPUT BY NAME cust_rec.*
    BEFORE FIELD cust_name
    ON ACTION print
END INPUT
```

Interactive instructions can be implemented as modal or parallel dialogs. *Modal dialogs* control a given window, and that window closes when the dialog is accepted or canceled. The window displays on top of any existing windows which are not accessible while the modal dialog executes. *Parallel dialogs* allow access to several windows simultaneously; the user can switch from one window to the other. Parallel dialogs are mainly used to implement split views on mobile platforms.

**Related concepts**
- Dialog instructions on page 1342
  This section describes the dialog instructions to control application forms and the concepts related to dialog implementation.

- Responding to user actions
  Clicking a form button or pressing a key triggers *actions* that can invoke the execution of program code called *action handlers*. Form elements that can trigger actions are called *action views*.

  Action handlers are defined in interactive statements with the `ON ACTION` clause. The code defined in action handler blocks is executed when an action is fired. Action objects are created and linked to action views when such `ON ACTION` handlers are seen by the runtime system. Common action handlers, such as `accept` (dialog validation) and `cancel` (dialog cancellation), are created automatically in accordance with the interactive instruction.

  By configuring *action defaults*, you define the default decoration attributes (text, image) and functional attributes (accelerator keys, context menu display) for the action views associated with actions.

- Dialog actions on page 1640
  Describes how to program action handling when the end user triggers an action on the front-end.

**Producing reports**
The language allows you to implement reports easily, producing different sort of output formats.

Page headers and footers, with page numbers, can be defined. Data can be grouped together, with group totals and subtotals shown. The output from a report can be sent to the screen, to a printer, to a file, or (through a pipe) to another program, and report output can even be redirected to an SAX filter in order to write XML data, that can be transformed into HTML, PDF or any other document format that can be generated from an XML source.

**Related concepts**
- Reports on page 1924

**Internationalization**
The language supports single-byte and multibyte internationalization.

The language supports single-byte such as ISO-8859-1, as well as multibyte character sets such as BIG5 or UTF-8.

Length semantics to define variables and manipulate character string data can be based on byte or character units.
Labels and messages can be separated from programs and forms, to customize your application for specific subsets of the user population, whether it is for a particular language or a particular business segment.

The source files (4gl, per, 4ad, and so on) can be written in a specific encoding. However, we recommend you to keep sources in ASCII, and store locale-dependent strings in external strings files (.str).

**Related concepts**

[Localization on page 405](#)

Localization support allows you to implement programs that follow specific language and cultural rules.

[Localized strings on page 430](#)

Localized strings provide a means of writing applications in which the text of strings can be customized on site.

**Web services support**

Implement Web services servers and clients with the Genero Web Services (GWS) library.

Web services are a standard way of communicating between applications over an intranet or Internet.

The Genero Web Services Extension (GWS) is an extension to the Genero Business Development Language. It installs within the Genero Business Development Language directory. The fglgws package includes both Genero Business Development Language and Genero Web Services.

The Genero Application Server is required to manage your Web services in a deployment environment. It is not required for Web services development, unless you are interested in testing deployment issues.

**Related concepts**

[Web services on page 3102](#)

Create a Web service client or server with Genero BDL.

**Extending the language**

You can extend the language using C or Java.

**Using C**

The language can be completed with *C extensions*. This allows you to implement specific function libraries in C, callable from the program modules. C extension libraries are typically used to interface with specific devices, such as barcode scanners or biometric identification devices.

**Using Java**

You can instantiate Java objects from your programs by using the *Java interface*. This allows you to take benefit of the huge class library of Java.

**Related concepts**

[C-Extensions on page 2109](#)

With *C-Extensions*, you can bind your own C libraries in the runtime system, to call C function from the application code.

[The Java interface on page 2071](#)

The *Java interface* allows you to import Java classes and instantiate Java objects in your programs.

**Programming tools**

Genero BDL includes several programming tools in addition to compilers.

A set of useful programming tools is provided, to help you in the application development process, for debugging, optimization and source documentation production.

**Related concepts**

[Programming tools on page 1967](#)
These topics cover programming with the Genero Business Development Language.

**Compiling a program**
You need to compile the source files in order to run the application.

A program can consist of a single source code module, but generally it will be organized in multiple modules, will involve form specification files and perhaps localized string files.

Database schema files are required when you define program data types and variables in terms of an existing database column or table, by using the `DEFINE ... LIKE` statement.

Before running your application with the runtime system, you need to use compilation tools in order to build the various runtime files.

**Figure 4: Genero compilation tools**

The compiled source code modules can be linked into a .42r program that can be executed by the Runtime System. Compiled modules can also be grouped together into a .42x library that can then be used to build .42r programs.

**Figure 5: Linking of compiled modules**
It is also possible to declare what modules are needed by the current module with the IMPORT FGL instruction, in order to define the dependency between .4gl modules. When using this language feature, it is no longer required to link modules together to build a program.

```
IMPORT FGL cust_module
MAIN
  DATABASE stores
  CALL cust_module.input_customer()
END MAIN
```

Importing modules is the preferred solution.

**Related concepts**

- **Programs** on page 491
  Explains program structure basics and global instructions/registers.

- **Form definitions** on page 1031
  This section describes how to define application forms and program resources related to the presentation layer.

- **Localization** on page 405
  Localization support allows you to implement programs that follow specific language and cultural rules.

** Deploying application program files**

To deploy an application, you must deploy all of the required runtime and resource files. Many (but not all) of these files are compiled from the source files.

**Figure 6: Deployment files**

These program files must be deployed at the user site:

- `.42r` - Programs files
- `.42m` - PCode modules
- `.42f` - Runtime form files
- `.42s` - Compiled localized string files
- `.4ad`, `.4st`, etc - XML resource files

**Runtime environment settings**

The `fglprofile` configuration file and environment variables can be used to change the behavior of programs.

These topics provide an look back at the new features introduced with each release of the Genero Business Development Language.

## Software requirements

Before installing, ensure that your system meets the minimum system requirements and additional software.

### Supported operating systems

Details of the supported operating systems for the Genero Business Development Language.

Genero Business Development Language is supported on a large range of operating systems, such as Linux®, IBM® AIX®, HP-UX, SUN Solaris, Mac OS X® and Microsoft™ Windows®.

You must install the software package corresponding to the operating system that you use. For the detailed list of supported operating systems, refer to the relevant installation guide or contact your support center.

For a detailed list of supported operating systems, refer to the *Supported platforms and databases* document (available on the Products download page of the Four Js Web site) or contact your support center. This document also informs you which operating systems will no longer be supported as of the next release.

### System packages

Some Genero BDL features need specific operating system packages.

#### Curses (or NCurses) library

On Unix-like platforms, the Genero runtime system (*fglrun*) needs the Curses library to be installed on the system. The Curses library is required for the text mode (for INFORMIXTERM=terminfo).

Depending on the operating system, *fglrun* will require *libcurses*, *libncurses*, *libncurses5*, or *libncursesw5*.

**Note:** For UTF-8 support in text mode, you need the *libncursesw5* package. Make sure that the Curses software package installed on your system includes this library. See *Platform specific notes* on page 45.

If the required Curses library is not installed, executing *fglrun* will report this kind of error:

```
fglrun: error while loading shared libraries:
```
libncursesw.so.5: cannot open shared object file: No such file or directory

Related concepts
TERMININFO terminal capabilities on page 1024

Database client software

To connect to a database server, the database client software must be installed on the system where you run the Genero BDL programs.

The Genero runtime system uses database drivers to connect to database servers, as a database client program. Database vendor-specific client software needs to be installed on the system where you run the Genero programs.

Genero database drivers are shipped as shared libraries and require the database vendor client software shared library such as Informix® Client SDK (with ESQL/C), Oracle® Client (with OCI), Microsoft® SQL Server ODBC. The database driver to be selected must correspond to the database client type and version.

For a detailed list of supported databases, database driver names, and operating systems on which those database drivers are supported, refer to the System Support matrix (available on the Products download page of the Four Js web site) or contact your support center. This matrix also informs you which database drivers will no longer be supported as of the next release.

Related information
Table 172: Database driver names on page 607

C compiler for C extensions

Ensure you have a C compiler and linker to compile your C-Extensions.

Applications using C extensions, need a C compiler and linker to build the C extension library that will be loaded by the runtime system.

C compiler On UNIX™ platforms

On UNIX® platforms, you need a cc compiler on the system where you create the C extension libraries. Note that some UNIX® systems do not have a C compiler installed by default.

C compiler On Microsoft™ Windows® platforms

On Windows® platforms, it is mandatory to install Microsoft® Visual C++ version corresponding to the installed Genero BDL package. The OS identifier of the Genero BDL package file name identifies the Visual C++ version to be used.

C compiler On Mac OS X™ platforms

On Mac® OS X platforms, it is mandatory to install Xcode® 6.1, on the system where you create the C extension libraries.

Related concepts
C-Extensions on page 2109

With C-Extensions, you can bind your own C libraries in the runtime system, to call C function from the application code.

Java runtime environment

Software requirements when using the Java Interface

In order to use the Java Interface in your application programs, you need the Java software installed and properly configured.

• Install a Java Development Kit on development sites (if you need to compile your own Java classes)
• Install a Java Runtime Environment on production sites (on the server where your programs are running)

**Note:** Over time, the Java platform has used different versioning systems, to distinguish a "Java developer version", from a "Java product version". For example, the Java developer version (JDK) 1.8 corresponds to the Java product version 8. With recent versions like Java 10, a unique version numbering convention is used.

The Java classes defined by Genero (com.fourjs.fgl.lang.*) are compiled with `javac -source 1.6 -target 1.6` options. Therefore, the minimum theoretical version is Java SE 6. However, depending on the platform, the minimum required Java version may be greater than version 6.

**Note:** As a general rule, always install the current long-term-support (LTS) Java version available on your platform, with JNI support. For example, Java SE 8 (released in March 2014) and Java SE 11 (released in September 2018) are LTS versions.

For a detailed list of supported JVMs, refer to the [Supported platforms and databases](#) document (available on the Products download page of the Four Js Web site) or contact your support center.

The version of the installed Java software can be shown with the command:

```
java --version
```

In order to execute Java byte code, the Genero runtime system uses the JNI interface. The JVM is loaded as a shared library and its binary format must match the binary format of the Genero runtime system. For example, a 64-bit Genero package requires a 64-bit JVM.

When implementing Java classes for Genero Mobile for Android™ (GMA), check the JDK version required by the Android™ SDK. For more information, see the [Android™ Studio web site](#).

**Related concepts**
The Java interface on page 2071
The Java interface allows you to import Java classes and instantiate Java objects in your programs.

**IPv6 support with Genero**
Network interface configuration for IPv6 support

**IPv6 basics**
IPv6 is the successor for IPv4, to increase the possible number of nodes of a computer network.

**IPv6 support for WS clients**
A Web Services client program can by default access a WS server using IPv6. For more details, see Configure a WS client to use IPv6 on page 3160.

**Note:** Web Services server programs work only in IPv4 to communicate with the GAS (since there is no need for IPv6 on a localhost). It’s up to the Web server to support IPv6 for the internet access of WS clients.

**Related concepts**
Web services on page 3102
Create a Web service client or server with Genero BDL.

**Installing Genero BDL**

This section provides Genero BDL installation instructions.

Different forms of installation programs are provided, as individual package or bundled with other Genero components. Refer to the appropriate installation guide for a detailed description of the installation procedure. Do not hesitate to contact your support center if you need help.

After installing a package, it is recommended that you:
1. Set the FGLDIR on page 240 environment variable to the BDL installation directory.
2. Add FGLDIR/bin to the PATH environment variable, in order to run compilers and runtime system tools from the command line.
3. Set the database client software environment (for example, INFORMIXDIR, etc)
4. Set access path to database client software DLLs (PATH), or UNIX® shared libraries (LD_LIBRARY_PATH, SHLIB_PATH, LIBPATH)
5. Depending on the database server you want to connect to, set up the correct database driver in FGLPROFILE. The default database driver is selected during the installation procedure.
6. Depending on what rendering mode you want to use (text mode or graphical mode), you will have to set environment variables such as FGLGUI on page 240, FGLSERVER on page 245, TERM, INFORMIXTERM.
7. If your application uses C-Extensions, a C compiler is required and you must recompile your C-Extensions as shared libraries.
8. If your application uses the Java Interface, setup the required JDK environment.

Install Genero Mobile for iOS (multiple versions) on page 44
To build and package Genero Mobile for iOS (GMI) applications, you must first install GMI. This topic explains how to install multiple GMI versions/packages in parallel into different GMIDIR directories.

Upgrading Genero BDL
Genero BDL upgrading requires several steps to consider.

After upgrading to a newer version, follow these next steps:

1. If the new version is a major upgrade (for example, from 2.20 to 2.21), recompile the sources and form files. While recompilation is not needed when migrating to maintenance release versions (for example, from 2.21.01 to 2.21.02), there is potentially some p-code optimization benefits to be gained from doing so.
2. If required, you may need to recreate the C-Extensions libraries. C extension libraries must be provided as dynamically loadable modules and a rebuild is generally not needed. However, if the C-Extension API header files have changed, consider recompiling your C sources. Check FGLDIR/include/f2c for C Extension API header file changes.

Related concepts
Upgrading on page 49
These topics talk about what steps you need to take to upgrade to the next release of Genero Business Development Language, and allows you to identify which features were added for a specific version.

Install Genero Mobile for Android™
To build and package Genero Mobile for Android™ (GMA) applications, you must first install GMA.

Before you begin:

Important: The GMA and Genero BDL X.YZ versions are interdependent. For example, GMA 1.30 is required to work with Genero BDL version 3.10, GMA 1.40 is required to work with Genero BDL 3.20.
• Download Genero Mobile for Android™ (GMA) from the Four Js Web site.
• Install Genero Business Development Language. See Installing Genero BDL on page 41 for more details.

1. Install the Java Development Kit (JDK).
   The minimum required version is 1.8.
2. Install Android™ SDK. Set the ANDROID_SDK_ROOT environment variable to the installation directory.
3. Install the GMA buildtool and the GMA binary archive.
   They are provided in the GMA distribution archive (fjs-gma-*.zip).
   a) Create a directory (gma-install-dir) for the GMA development tools.
   
   ```bash
   $ mkdir /opt/fourjs/gma-1.30
   ```
   b) Extract the content of the Genero Mobile for Android™ package (fjs-gma-*.zip) into this directory.
   
   ```bash
   $ unzip -q -o -d /opt/fourjs/gma-1.30 fjs-gma-*.zip
   ```
   c) Add the gma-install-dir directory to your PATH environment variable, in order to find the gmabuildtool command.
4. Execute the gmabuildtool updatesdk command.
   An internet connection is required.
   **Important:** Execute the gmabuildtool updatesdk command every time a new version of the GMA buildtool and GMA binary archive is installed.
5. If you plan to publish your app on Google Play, register to Google Play as a developer and create a Google Play project.
6. If you have installed Cordova plugins, you need to re-install the plugins with the --install-plugin option of gmabuildtool. For more details, see Installing Cordova plugins on page 3371.

  Genero provides a command-line tool to create applications for Android™ devices.

## Install Genero Mobile for iOS (single version)

To build and package Genero Mobile for iOS (GMI) applications, you must first install GMI. This topic explains how to install a unique GMI version/package into FGLDIR.

Before you begin:

**Important:** The GMI and Genero BDL X.YZ versions are interdependent. For example, GMI 1.30 is required to work with Genero BDL version 3.10, GMI 1.40 is required to work with Genero BDL 3.20, etc.

• Download the Genero Mobile for iOS (GMI) distribution archive from the Four Js Web site. GMI can only be installed on a Mac® OS X computer.
• Install Genero Business Development Language. See Installing Genero BDL on page 41 for more details.

Follow this procedure if you are using only one version of GMI for a Genero BDL installation.

**Important:** When re-installing a new GMI archive, remove all "build" directories created by the gmibuildtool.

1. Install Xcode®.
   The Xcode® version must support the iOS versions of your mobile devices.
   **Tip:** As a general rule, update the Xcode® and iOS to the latest versions
2. Define the FGLDIR environment variable with the Genero BDL installation directory.

   $ export FGLDIR=/opt/fourjs/fglgws-3.10

3. Extract the GMI distribution archive (fjs-fglgmi-*\.zip) into FGLDIR.
   The GMI distribution archive contains the GMI buidtool and the needed iOS libraries and helper scripts.

   $ unzip -q -o -d $FGLDIR fgl-fglgmi-*.zip

4. If you have installed Cordova plugins, you need to re-install the plugins with the --install-plugin option of gmibuildtool. For more details, see Installing Cordova plugins on page 3371.

Related concepts
Building iOS apps with Genero on page 3332
Genero provides a command-line tool to build applications for iOS devices.

Install Genero Mobile for iOS (multiple versions)
To build and package Genero Mobile for iOS (GMI) applications, you must first install GMI. This topic explains how to install multiple GMI versions/packages in parallel into different GMIDIR directories.

Before you begin:
Important: The GMI and Genero BDL X.YZ versions are interdependent. For example, GMI 1.30 is required to work with Genero BDL version 3.10, GMI 1.40 is required to work with Genero BDL 3.20, etc.

- Download the Genero Mobile for iOS (GMI) distribution archive from the Four Js Web site. GMI can only be installed on a Mac® OS X computer.
- Install Genero Business Development Language. See Installing Genero BDL on page 41 for more details.

If you need to test several versions of GMI against a single installation of Genero BDL, you will extract each GMI distribution archive to a separate directory. You can then quickly change the version of GMI used by resetting the GMIDIR and PATH environment variables.

Important: When re-installing a new GMI archive, remove all "build" directories created by the gmibuildtool.

1. Install Xcode®.
   The Xcode® version must support the iOS versions of your mobile devices.
   Tip: As a general rule, update the Xcode® and iOS to the latest versions

2. Create a directory for the GMI distribution archive.

   $ mkdir /opt/fourjs/gmi-1.30

3. Define the GMIDIR environment variable with the GMI installation directory.

   $ export GMIDIR=/opt/fourjs/gmi-1.30

4. Extract the GMI distribution archive (fjs-fglgmi-*\.zip) into GMIDIR.
   The GMI distribution archive contains the GMI buildtool and the needed iOS libraries and helper scripts.

   $ unzip -q -o -d $GMIDIR fgl-fglgmi-*.zip

5. Update PATH to include GMIDIR/bin.

   $ export PATH=$GMIDIR/bin:$PATH

6. If you have installed Cordova plugins, you need to re-install the plugins with the --install-plugin option of gmibuildtool. For more details, see Installing Cordova plugins on page 3371.

Genero provides a command-line tool to build applications for iOS devices.

Platform specific notes
These notes provide operating system specific information to use Genero BDL on the platform.

HP-UX configuration notes

Thread Local Storage in shared libraries
On HP-UX, the shared library loader cannot load libraries using Thread Local Storage (TLS), like Oracle® libclntsh. In order to use shared libraries with TLS, you must use the LD_PRELOAD_ONCE environment variable. For more details, search for "shl_load + Thread Local Storage" on the HP® support site.

PostgreSQL on HP-UX LP64
On HP-UX® LP64, it is recommended that the PostgreSQL database driver is linked with the libxnet.sl library if you want to use networking. You can force the usage of libxnet by setting the LD_PRELOAD_ONCE environment variable to /lib/pa20_64/libxnet.sl.

Java Interface
Check HP/UX platform notes when using the Java Interface on this operating system.

IBM® AIX® configuration notes

LIBPATH environment variable
The LIBPATH environment variable defines the search path for shared libraries. Make sure LIBPATH contains all required library directories, including the system library path /lib and /usr/lib.

Shared libraries archives
On AIX®, shared libraries are usually provided in .a archives containing the shared object(s). For example, the DB2® client library libdb2.a contains both the 32-bit (shr.o) and the 64-bit (shr_64.o) versions of the shared library. Not all products follow this rule; for example Oracle® 9.2 provides libclntsh.a with shr.o on 64-bit platforms, and Informix® provides both .a archives with static objects and .so shared libraries as on other platforms. The runtime system database drivers are created with the library archives or with the .so shared objects, based on the database type and version. No particular manipulation is needed to use any supported database client libraries on this platform.

The dump command
On IBM® AIX®, you can check the library dependencies with the dump command:

$ dump -Hv -X64 libstckp.so

Unloading shared libraries from memory
In production environments, AIX® loads shared libraries into the system shared library segment in order to improve program load time. Once a shared library is loaded, other programs using the same library are attached to that memory segment.
Once a shared library is loaded by the system, you cannot copy the executable file unless you unload the library from the system memory. This problem will occur when installing a new version of the software, even if it is installed in a different directory. Since shared libraries have the same name, AIX® will not allow multiple versions of the same library to load. Therefore, before installing a new version, make sure all shared libraries are unloaded from memory.

The `genkld` command prints the list of shared libraries currently loaded into memory. The `slibclean` command unloads a shared library from the system shared library segment.

**POSIX Threads and shared libraries**

When using a thread-enabled shared library like Oracle's `libclntsh`, the program using the shared object must be linked with thread support, otherwise you can experience problems (like segmentation fault when the runner program ends). IBM® recommends using the `xlc_r` compiler to link a program with pthread support.

By default, the runtime system provided for AIX® platforms is linked with pthread support.

**Java Interface**

Check [IBM® AIX® platform notes](#) when using the Java Interface on this operating system.

**Mac® OS X® configuration notes**

### DYLD_LIBRARY_PATH denied in OS X® 10.11

Starting with Mac® OS X® 10.11 (El Capitan), if the System Integrity Protection (SIP) is enabled, the `DYLD_LIBRARY_PATH` environment variable is no longer exported in sub processes. This variable defined the shared library search path for software components used by the Genero runtime system. This was required especially for database client libraries installed in directories other than `/usr/lib` and `/usr/local/lib` (the default location for shared libraries).

As `DYLD_LIBRARY_PATH` cannot be used, the proper workaround is to install all required shared libraries in `/usr/local/lib`. A good practice is to create the installation directory of the software component in `/usr/local/product/version`, and create symbolic links to the required shared libraries in `/usr/local/lib`.

To make sure that all required libraries can be found, check the dependencies on a Genero binary (typically, the ODI driver) with the `otool -L` and `otool -l` commands.

For example, with Oracle 12 Instant Client:

```bash
$ mkdir /usr/local/oracle/
$ mkdir /usr/local/oracle/instantclient_12_2

... install Oracle Instant Client in /usr/local/oracle/instantclient_12_2 ...

$ cd /usr/local/lib
$ ln -s /usr/local/oracle/instantclient_12_2/libclntsh.dylib.12.1
    libclntsh.dylib.12.1

... set Genero FGL environment ...

$ otool -L $FGLDIR/dbdriver/dbmora_12.dylib
... check dependencies and paths

$ otool -l $FGLDIR/dbdriver/dbmora_12.dylib
... check load sequences
```

**Important:** If Mac OSX includes a database client library in system directories such as `/usr/lib`, the system shared library will be found first, before user shared libraries located in `/usr/local/lib`. For example, Mac OSX comes with a PostgreSQL client library `/usr/lib/libpq.5.dylib -> libpq.5.6.dylib`. In this case, if you want to use a more recent PostgreSQL client library, you will have to patch the Genero ODI driver with the
install_lib_tool, using the -change option to use the @rpath prefix to libpq.5.dylib shared library entry, and add a search path with -add_rpath to specify target PostgreSQL lib directory:

```bash
$ cd $FGLDIR/dbdrivers
$ otool -L dbmpgs_9.dylib
...  original-path-to-postgresql-dir/libpq.5.dylib (compatibility ...  
...
$ install_name_tool
  -change original-path-to-postgresql-dir/libpq.5.dylib @rpath/libpq.5.dylib
  -add_rpath /Library/Postgresql/9.5.1/lib 
  dbmpgs_9.dylib
$ otool -L dbmpgs_9.dylib
...  @rpath/libpq.5.dylib (compatibility ...  
...
$ otool -l dbmpgs_9.dylib
...  check load sequences
```

**Java Interface**

Check [Mac OS X platform notes](#) when using the Java Interface on this operating system.

**Microsoft™ Windows® configuration notes**

**Microsoft™ Visual C++ version**

When using C-Extensions, you need Microsoft™ Visual C++ compiler to compile and link your C sources. Make sure you have installed the software package corresponding to the MSVC version installed on your system. The MSVC version is identified in the software package name.

**Checking binary dependencies**

Microsoft™ Visual C++ provides the dumpbin utility to extract information from a binary file.

Use the /dependents option to check for DLL dependencies:

```
C:\> dumpbin /dependents mylib.dll
Microsoft (R) COFF/PE Dumper Version 7.10.3077
Copyright (C) Microsoft Corporation. All rights reserved.
Dump of file mylib.dll
File Type: EXECUTABLE IMAGE
Image has the following dependencies:
isqlt09a.dll
MSVCR71.dll
KERNEL32.dll
Summary
1000 .data
1000 .rdata
```
Changing the stack size of fglrun

On Windows® platforms, the fglrun.exe binary has a predefined C stack size. In some rare cases (for example, when programs do deep recursion), the stack size of fglrun.exe binary needs to be changed to avoid a stack overflow. The stack size of fglrun can be changed permanently by patching the EXE file with the Microsoft™ Visual C++ editbin utility. Check the stack size by running the dumpbin utility on fglrun.exe as follows:

```bash
C:\> dumpbin /headers %FGLDIR%\bin\fglrun.exe
```

Search for the line containing "stack reserve" words in the OPTIONAL HEADER VALUES section:

```
OPTIONAL HEADER VALUES
... 100000 size of stack reserve
```

The stack size is displayed in hexadecimal value. So for example, a value 100,000 means 1,048,567 bytes = 1MB. In order to modify the stack size of fglrun.exe, run the editbin utility on fglrun.exe with the /stack option:

```bash
C:\> editbin /stack:1000000 %FGLDIR%\bin\fglrun.exe
```

See Microsoft™ Visual C++ documentation for more details.

C-Extensions on page 2109

With C-Extensions, you can bind your own C libraries in the runtime system, to call C function from the application code.

Web Services platform notes

Genero Web Services reference documentation contains a list of platform specific notes to consider. For more details, see Web Services platform specific notes.

SUSE® Linux Enterprise

Installing the Curses library on SUSE Linux Enterprise 15

On SUSE® Linux Enterprise 15 (SLES 15), the Curses library must be installed as follows:

```bash
# SUSEConnect -p sle-module-legacy/15/x86_64
# zypper install libncurses5
```

Note: On SUSE, the libncurses5 RPM package includes the libncursesw.so.5 library for UTF-8 support in text mode.

See also TERMINFO terminal capabilities on page 1024.
Debian / Ubuntu Linux

Installing the Curses library on Debian or Ubuntu

On Debian Linux 9 (and derived Linux brands like Ubuntu), the Curses library must be installed as follows:

```
# apt-get install libncurses5
# apt-get install libncursesw5
```

Note: On Debian, the `libncursesw.so.5` library for UTF-8 support in text mode is part of the `libncursesw5` package: The `libncurses5` package does not include the `libncursesw.so.5` library.

See also TERMINFO terminal capabilities on page 1024.

Red Hat Enterprise Linux

Installing the Curses library on RedHat Enterprise Linux

On Red Hat® Enterprise Linux® 7, the Curses library must be installed as follows:

```
# yum install ncurses-libs
```

Note: On Red Hat Enterprise Linux, the `ncurses-libs` RPM package includes the `libncursesw.so.5` library for UTF-8 support in text mode.

See also TERMINFO terminal capabilities on page 1024.

Upgrading

These topics talk about what steps you need to take to upgrade to the next release of Genero Business Development Language, and allows you to identify which features were added for a specific version.

<tr>
<td>New <strong>FUNCTION</strong> definition syntax, to declare exact function signature with parameter types in the parentheses, and return types in the <strong>RETURNS</strong> clause.</td>
<td>See FUNCTION definitions on page 353, Function parameters on page 355, Returning values on page 360.</td>
</tr>
</tbody>
</table>
### Overview

Function references, to call functions only know at runtime.

Invoking methods with an object reference returned from a method: LET s = s.subString(1,10).toLowerCase()

GUI log file name with process id (--start-guilog="myfile-$p.log").

Source code coverage tool (FGLCOV/fglrun --merge-cov).

Program execution trace (fglrun --trace).

Java SE 10 and 11 support.

New DYNAMIC ARRAY methods copyTo(), search(), searchRange().

Defining the localized string lookup path when program starts.

Bit-wise operation and hexadecimal/binary string conversion on INTEGER values.

Channel openFile() method can write to stderr.

Variable definition attributes for JSON serialization: json_null, json_name.

Resource files (.42f, etc) can now also be found in the directory where the MAIN module resides.

VIM plugins can be used directly from FGLDIR/vimfiles.

Base64 to/from Hexadecimal string conversion methods.

Source documentation enhancements, to describe module variables, constants and user defined types.

fglform checks for unique TABINDEX values.

</tr>
<tr>
<td>The <code>XMLNillable</code> attribute provides an option to set an XML node explicitly to null and to serialize it with <code>xsi:nil=&quot;true&quot;</code>, when the BDL variable is NULL but not optional.</td>
<td>See <code>XMLNillable</code> on page 3267, Web Services changes on page 106.</td>
</tr>
<tr>
<td>New built-in server-side methods for the <code>com.HTTPServiceRequest</code> class: <code>getURLHost()</code>, <code>getURLPort()</code>, <code>getURLPath()</code>, <code>getURLQuery()</code>, <code>findRequestCookie()</code>, and <code>setResponseCookie()</code></td>
<td>See The <code>HTTPServiceRequest</code> class on page 2688.</td>
</tr>
</tbody>
</table>
Overview

Methods added to assist with cookie management.

New Genero BDL helper functions: SplitUrl(), FindQueryStringValue(), and SplitQueryString().

New methods for proxy management of the current HttpServletRequest.

Genero Web Services accepts 2 new options to enable OCSP (Online Certificate Status Protocol).

The xml.XSLTTransformer class provides methods for transforming XML following the XSLT version 1.0 specification.

New methods to generate a password of a given size and based on a human readable password using Password-Based Key Derivation Function 2 (PBKDF2).

New methods allow you to save passwords as BCrypt results.

A new REST demo has been added in $FGLDIR/demo/WebServices/forum. This demo uses REST services with JSON, text and binary data; manages authorization access via the new HTTP automatic cookie API; and uses the new BCrypt API to store a password in a database.

The enveloped-signature method has an optional parameter to specify the node where the signature will be added.

FGLPROFILE entry to define regex-based URL specification for HTTP configuration.

New fglwsdl option -fRPCNamespace to produce BDL code supporting the namespace attribute for RPC parameters.

New fglpass option -gid and security.global.agent.gid=true FGLPROFILE entry, to allow agent authentication to be performed with UNIX user group instead of user only.

Detect window resizing or device orientation change with the windowresized predefined action. | See Adapting to viewport changes on page 1308.
Dialog methods to convert the program array row index to the visual index, and the opposite. | See ui.Dialog.arrayToVisualIndex on page 2381, ui.Dialog.visualToArrayIndex on page 2407.
Providing application image resources to Web Components with ui.Interface.filenameToURI(). | See Using image resources with the gICAPI web component on page 1855, ui.Interface.filenameToURI on page 2333.
The standard.openFile frontcall is now supported with GBC. | See standard frontcall support matrix.
The dictionariesDirectory parameter for the standard.feInfo frontcall can be used to get the directory where spell checker dictionary files can be uploaded. | See standard.feInfo frontcall.
The allowWebSelection style attribute can be used to enable items selection with a simple mouse drag. | See Table style attributes on page 1101.
The browserMultiPage style can be used to specify whether the RUN and RUN WITHOUT WAITING instructions will be executed in the same browser tab or in a new browser tab. | See UserInterface style attributes on page 1116.

Table 16: SQL databases

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
</table>
Support for PostgreSQL 9.4. | See Database driver specification (driver) on page 606. |
Support for SAP® ASE 16.x. | See Database driver specification (driver) on page 606. |
Maria DB support (V5.5 and V10): Use the dbmmys driver. | See MariaDB support on page 133. |
Support for Microsoft® SQL Server 2016 with SNC 11, ESM and FTM drivers. | See Microsoft SQL Server on page 769. |
## Overview

| Dynamic cursor built-in class `base.SqlHandle`. |
| SQL interruption is now supported with Oracle® MySQL. |
| MySQL VARCHAR(N) can be used when N is greater as 255. |
| MySQL DATETIME can store fractional seconds. |
| Native Oracle® NUMBER type (without precision/scale) can be extracted by `fgldbsch`. |
| Serial emulation based on triggers and sequences with SQL Server 2012 and +. |
| PostgreSQL connection string option specification in the `source` parameter. |

</tbody>
</table>
Release 68

Access the HTTP headers request and response in high level web services.

The standard API is enhanced with few new methods and a new class called HTTPPart to handle the different part in a HTTP request or response at client and server side.

The client side is able to generate stubs to support multiple part with Genero Web Services. Support for the server side is not yet provided.

Note: Starting with version 2.50.25, when generating client stubs managing multipart, you will get extra input and/or output variables called AnyInputParts and AnyOutputParts, defined as a DYNAMIC ARRAY of com.HTTPPart objects. These arrays may contain additional input and/or output HTTP parts not specified in the WSDL. You will have to adapt your client program, to handle those dynamic arrays in any functions calling such stubs. See Client stubs managing multipart changes on page 147.

FGLPROFILE HTTPS configuration details no longer needed to perform HTTPS communication. A default SSL/TLS configuration is now generated automatically.

Creating URL base that applies to multiple server applications by using a wildcard in the URL, allowing for a shared server configuration (such as authentication and HTTPS).

BDL 2.41 new features
Features added in 2.41 releases of the Genero Business Development Language.

Table 32: User interface

<tbody>
<tr>
<td>The NVL() operator allows you to write the equivalent of an IF expr IS NOT NULL THEN RETURN expr ELSE RETURN default END IF statement in a single scalar expression.</td>
<td>See NVL() on page 309.</td>
</tr>
</tbody>
</table>
## Overview

### The IIF() allows you to write the equivalent of an IF bool-expr THEN RETURN true-value ELSE RETURN false-value END IF statement in a single scalar expression.

See **IIF() on page 310**.

### A new global program option has been added, OPTIONS SHORT CIRCUIT, to instruct the runtime system to evaluate Boolean expressions by using the short-circuit evaluation (also called minimal evaluation) method.

See **OPTIONS (Compilation) on page 505** and **Controlling semantics of AND / OR operators on page 505**.

### Table 34: User interface

#### Overview

New ON INSERT, ON APPEND, ON UPDATE and ON DELETE interaction blocks are now allowed in DISPLAY ARRAY dialogs to implement list modification, as an alternative to the traditional INPUT ARRAY dialog. These new triggers simplify the programming of modifiable record lists.

The new find and findnext actions of DISPLAY ARRAY and INPUT ARRAY can be used by the user to search rows where a field value matches the value entered in the find dialog box.

The DISPLAY ARRAY dialog now supports a built-in seek feature to quickly find rows where a field value starts with the character typed by the user.

Define a summary line for TABLEs by using AGGREGATE form fields. Values can be automatically computed or can be calculated and displayed by program

Using the terminfo database for text terminal mode (FGLGUI=0) by setting INFORMIXTERM=terminfo.

#### Reference

See **DISPLAY ARRAY modification triggers on page 1750**.

See **Find function on page 1764**.

See **Keyboard seek on page 1765**.

See **AGGREGATE item definition on page 1223**.

See **Using a text terminal on page 1024**.

### Table 35: SQL databases

#### Overview

New database drivers are provided.

The fgIcomp compiler now supports SQL ... END SQL blocks for compliance with IBM® Informix® 4GL.

The Static SQL syntax has been extended to allow the FIRST, LIMIT, SKIP and MIDDLE SELECT projection clause options.

The CASE operator is now allowed in Static SQL statements.

#### Reference

List of new database drivers:

- dbmntz6x for IBM® Netezza® ODBC client
- dbmsncB0 for SQL Server 2012 Native client
- dbmesmB0 for SQL Server 2012, with Easysoft ODBC driver
- dbmpgs91x for PostgreSQL 9.1.x client

See **SQL ... END SQL on page 647**.

See **Static SQL statements on page 638**.
The syntax of DDL (Data Definition Language) statements in Static SQL now allows the IF NOT EXISTS and IF EXISTS clauses.

The transaction instruction set has been completed with SAVEPOINT and ROLLBACK WORK TO SAVEPOINT.

Control shadow column extraction with fgldbsch.

A new FGLPROFILE entry parameter has been added to control the ORACLE DATE fetch into CHAR/VARCHAR variables.

Support for the ROWVERSION data type of SQL Server (2008 and +) has been added.

See Static SQL statements on page 638.

See SAVEPOINT on page 634 and ROLLBACK WORK on page 635.

See fgldbsch on page 1978.

See DATE and DATETIME data types on page 857.

See SQL Server ROWVERSION data type on page 793.

<table>
<thead>
<tr>

<tr>
<td>Overview</td>
</tr>
<tr>
<td>The Genero Web Service engine has been enhanced to support a part of SOAP 1.2 protocol, restricted to the SOAP POST feature only. It does not support the SOAP 1.2 encoding feature, as it is prohibited by the WS-I Basic Profile 2.0.</td>
</tr>
<tr>
<td>To allow the SOAP 1.2 protocol in your Genero Web service application, call the setFeature() method of your web service to enable SOAP 1.2 support.</td>
</tr>
<tr>
<td>The same Web service can provide both the SOAP 1.1 and SOAP 1.2 protocol.</td>
</tr>
<tr>
<td>You can also specify the SOAP role of your Genero application if you pass the new SoapModuleURI option to the WebServiceEngine setOption() method in order to identify the headers the SOAP engine has to understand.</td>
</tr>
<tr>
<td>The Genero Web Service engine has been enhanced to support the WS-Addressing 1.0 specification. To enable WS-Addressing 1.0 specification in your Genero Web service application, call the setFeature() method of your web service with &quot;TRUE&quot; or &quot;REQUIRED&quot; as a parameter.</td>
</tr>
<tr>
<td>The Genero Web Service engine has been enhanced to support stateful services.</td>
</tr>
<tr>
<td>There are two kinds of stateful services:</td>
</tr>
<tr>
<td>• Based on WS-Addressing: independent from the transport protocol used to convey the state between the client and the server.</td>
</tr>
<tr>
<td>• Based on HTTP cookies: depends on the transport protocol to convey the state between the client and the server.</td>
</tr>
<tr>
<td>To create a stateful web service, call com.WebService.createStatefulWebService() with a simple BDL variable or a dedicated W3CEndpointReference record to handle the service state.</td>
</tr>
<tr>
<td>You can also take a look at WS-Addressing and at the following links for additional information: JAX-WS, Oracle and Stateful based on cookies.</td>
</tr>
</tbody>
</table>
Overview

The Genero Web Service engine has been enhanced to support SOAP faults in RPC and Document style services.

On the server side, you can define BDL variables that will be thrown as SOAP faults to a web service client using the SOAP 1.1 or SOAP 1.2 protocol.

The fglwsdl tool has also been enhanced to generate client and server stubs according to the SOAP fault described in the WSDL.

- Method createFault()
- Method addFault()
- Method SetFaultDetail()
- Tool fglwsdl

The Genero fglwsdl tool generates a new Endpoint record per service in the client stub to configure the client behavior at runtime without the need to modify the generated code.

This feature requires regeneration of the client stub and modification of the server location assignment if used in your application (See also Web Services changes on page 148).

The Genero fglwsdl tool has been enhanced to support WS-Addressing 1.0, the SOAP 1.2 protocol and to handle operation faults in SOAP 1.1 and SOAP 1.2.

The generated client and server stub will handle WS-Addressing 1.0, SOAP 1.2 protocol and manage soap faults as defined in the WSDL.

The following options have been added:

Options related to SOAP:
- -soap11: Generate only client and server stubs supporting the SOAP 1.1 protocol.
- -soap12: Generate only client and server stubs supporting the SOAP 1.2 protocol.
- -ignoreFaults: Do not generate soap faults.

Options related to WS-Addressing:
- -wsa <yes|no>: Force support of WS-Addressing 1.0. If yes, disable support of WS-Addressing 1.0. If no, otherwise support WS-Addressing 1.0 according to the definition in the WSDL.

Other options:
- -alias: Generate FGLPROFILE Logical names in place of URLs for all client stubs.
- -extDir: Add all schema files located in a directory and ending with .xsd as external schemas.
- -CA: Validate HTTPS certificate against a certificate authority list.

Reference

See Change WS client behavior at runtime on page 3149.

See fglwsdl on page 1980.
## Overview

The XML-Signature and XML Encryption API of the XML library have been enhanced with new built-in methods to ease compatibility with the WS-Security specification:

- Method `getSignatureMethod()`
- Method `getThumbprintSHA1()`
- Method `getSHA1()`

The XML library has been enhanced to support XML parsing from PIPE and saving to PIPE:

- Method `loadFromPipe()`
- Method `saveToPipe()`
- Method `readFromPipe()`
- Method `writeToPipe()`

The Genero Web Services service library has been enhanced to support global SSL/TLS security configuration in `FGLPROFILE` for HTTPS communication.

You can now define the SSL/TLS certificate and private key to be used for all secured connections with the following entries and still use a dedicated SSL/TLS configuration if needed for a particular server:

- Entry `security.global.certificate`
- Entry `security.global.privatekey`
- Entry `security.global.keysubject` (Windows only)
- Entry `security.global.protocol`

A universal unique identifier function, `CreateUUIDString()`, has been added to the COM library. This function generates a universal unique identifier in BDL.

The Genero Web services library has been enhanced with two new serializers:

- `xml.Serializer.DomToStax()` converts a Dom node to a Stax writer
- `xml.Serializer.StaxToDom()` converts a Stax reader to a Dom node

## Reference

See XML security classes on page 2891.

See Web services configuration on page 3236.

This method is desupported since 3.00, use `security.RandomGenerator.CreateUUIDString` on page 2972 as replacement.

**BDL 2.30 new features**
Features added in 2.30 releases of the Genero Business Development Language.

**Table 38: Core language**

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genero is now available on Mac OS-X™. You need at least Mac OS X version 10.5. The Operating System code for Mac OS X 10.5 64-bit is m64x105. Platform identifier is now displayed when using the -V option with command-line tools. The FGLPROFILE environment variable now accepts multiple file specification with an operating-system-specific path separator. The LOAD, UNLOAD and base.Channel class support the &quot;CSV&quot; delimiter specification to read/write files in Comma Separated Value format. Version 2.30.04 supports now the fglrun.arrayIgnoreRangeError entry which can be set to true to force the runtime system to return the first element of an array when the array index is out of bounds.</td>
<td>See Supported operating systems on page 39. See fglrun on page 1968. See LOAD on page 684, UNLOAD on page 687 and The Channel class on page 2273 See Arrays on page 386.</td>
</tr>
</tbody>
</table>
### Overview

The version 2.30.04 introduces the new `fglrun.mapAnyErrorToError` FGLPROFILE entry. This configuration parameter can be set to true to map the default action of the WHENEVER ANY ERROR exceptions to the action defined for the WHENEVER ERROR exception type.

### Reference

See [Exceptions](#) on page 451.

<table>
<thead>
<tr>
<th>Table 39: User interface</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Overview</strong></td>
</tr>
<tr>
<td>Drag &amp; Drop support in DISPLAY ARRAY for tables or tree views.</td>
</tr>
<tr>
<td>A new form item type called WEBCOMPONENT is provided to integrate external Java-Script-based widgets in your forms.</td>
</tr>
<tr>
<td>New <code>ui.Form</code> class method to make a specific form field visible, showing the parent containers automatically.</td>
</tr>
<tr>
<td>This method can also be used to bring a given folder page to the front, even if the field is not active (i.e. not driven by a dialog).</td>
</tr>
<tr>
<td>The ERROR and MESSAGE instructions get an additional STYLE attribute, to reference a presentation style and define the rendering with font, color, and position.</td>
</tr>
<tr>
<td>New style for TOOLBAR and TOPMENU elements. See Front-End documentation for more details about possible decoration attributes.</td>
</tr>
<tr>
<td>As with COMBOBOX, the items of a RADIOGROUP are now filled with the values of the INCLUDE attribute, if specified.</td>
</tr>
<tr>
<td>Identify the last clicked CANVAS item with the <code>drawGetClickedItemId()</code> function of <code>fgldraw.4gl</code>.</td>
</tr>
<tr>
<td>The <code>FIELD_TOUCHED()</code> operator and <code>ui.Dialog.getFieldTouched()</code> method accept now a simple star as parameter, in order to check all fields used by the dialog.</td>
</tr>
<tr>
<td>The JUSTIFY attribute is now supported for all form item types, in order to let you specify both the data justification in the field/cell and the alignment of the table column header.</td>
</tr>
<tr>
<td>The <code>ui.Dialog.setFieldActive()</code> method takes now a list of fields as parameter, with the &quot;dot-asterisk&quot; notation, like the <code>setFieldTouched()</code> method.</td>
</tr>
</tbody>
</table>
This new feature is part of the fix for bug #18224.

When modifying a tree during the dialog execution (for example, when implementing dynamic trees with ON EXPAND / ON COLLAPSE triggers), if you use the `ui.Dialog.insertRow()`, `ui.Dialog.deleteRow()` or `ui.Dialog.deleteAllRows()` methods to modify the node list, the internal tree structure was corrupted. The program array can be safely modified directly with array methods, but multi-range selection flags and cell attributes are not synchronized when doing this. Starting with 2.30.02, you can now use the `ui.Dialog.insertNode()`, `ui.Dialog.appendNode()` and `ui.Dialog.deleteNode()` methods to manipulate the node list and get additional data like row selection flags and cell attributes synchronized.

</tr>
</tbody>
</table>

Informix® SMALLFLOAT and FLOAT can now be stored in Oracle native BINARY_FLOAT / BINARY_DOUBLE types.

The LOAD, UNLOAD and base.Channel class support the "CSV" delimiter specification to read/write files in Comma Separated Value format.

Use the `fgl_db_driver_type()` built-in function to identify the target database type.

In order to identify the reason why a database driver cannot be loaded, when setting FGLSQLDEBUG you now get an additional debug message that contains the operating system error message (dlerror()).

The fgl dbsch tool can now extract database schema from SQLite. However, pay attention to the data types used in SQLite (V 3.6): This database supports some standard type names in the SQL syntax but in reality the types used to store data are very limited. For example, a DATE will be stored as an integer or string (i.e. there is no native DATE type). See SQLite documentation for more details.

The fgl dbsch tool will extract the schema based on the original type names used to create the table.

### Related concepts

### Overview

The XML library supports a new option, `xml_useutctime`, to serialize any BDL `DATE` and `DATETIME` using the UTC format requested in most WS-Security exchanges.

The XML library has been enhanced with two APIs in the `CryptoKey` class. Due to security issues, the usage of a direct shared symmetric or HMAC key is not recommended; operations are secure using a key derived from a common shared key instead. The XML library has been enhanced with two APIs in the `CryptoKey` class:

- Constructor `CreateDerivedKey()`
- Method `deriveKey()`

The COM library has been enhanced with two helper APIs in a new `Util` class. In most Web Service security exchanges, the application must be able to compute digest passwords and use random binary data to detect reply attacks (for instance). The COM library has therefore been enhanced with two helper APIs in a new `Util` class:

- Static method `CreateDigestString()`
- Static method `CreateRandomString()`

The StAX reader and writer classes have been enhanced with two new methods to set up the XML stream on a TEXT lob. It enables parsing of an XML document in StAX directly from a TEXT with the `readFromText()` method, and creating a new XML document saved directly as TEXT with the `writeToText()` method.

The Genero Web Services library has been enhanced to support XML wildcard attributes.

Such wildcard attribute can be set in a XML schema or in a WSDL via the `anyAttribute` tag. It allows additional attributes belonging to other XML schemas in a main XML schema. The additional attributes are not necessarily known by the main schema.

The `fglwsdl` tool has been enhanced to recognize the additional attribute and to generate a one-dimensional dynamic array with a new `XMLAnyAttribute` attribute, and the XML Serializer has been enhanced to handle the new `XMLAnyAttribute` during the serialization and deserialization process.

A new option called `xs_processcontents` is supported by the XML Serializer to generate the XML schema of such wildcard attributes with a `processContents` tag that defines the way a validator will handle them.

### Reference

See [Serialization option flags](#) on page 2890.

See [Derived keys](#) on page 2908.

These methods are desupported since 3.00, use `security.Digest.CreateDigestString` on page 2990 and `security.RandomGenerator.CreateRandomString` on page 2972.

See [The StaxWriter class](#) on page 2842 and [The StaxReader class](#) on page 2856.

See [Attributes to customize XML serialization](#) on page 3250 and [The Serializer class](#) on page 2877.
Overview

The package contains a new demo called SimplePKI that demonstrates the usage of XML-Encryption in Genero.

It allows several clients to register to a centralized PKI (Public Key Infrastructure) service that generates a unique RSA key-pair per user. The private key is returned to the user during the registration or login, using a derived symmetric key based on the user’s password to make it secure. Then any client is able to retrieve the public key of the registered users, and to encrypt XML data only readable by that user.

Note: This demo can easily be adapted in a real-world application if (for instance) all key-pair are stored in a database for persistence.

You can find the demo in the demo/WebServices/simplepki subdirectory or by running the demo application in your installation directory.

If the driver code crashes or stops the process with an assertion, you can easily identify the last SQL instruction that was executed.</td>
<td>See User authentication callback function on page 624.</td>
</tr>
</tbody>
</table>
The Genero Web Services XML Library has been improved to support the XML-Signature and XML-Encryption specifications defined by the W3C (also known as XML-Security).

The library enables BDL applications to handle public, private, symmetric or hmac keys and X509 certificates in order to sign XML documents or document fragments, and verify a XML signature against a certificate or key. It also enables the applications to encrypt XML nodes using symmetric keys, and decrypt them back using DOM manipulation. Combined with the COM library, any BDL application can now exchange any XML documents over the Internet in a completely secured manner.

The library provides classes for:

- Manipulating cryptography keys
- Handling X509 certificates for identification
- Encrypting and decrypting XML documents, document fragments, or symmetric keys
- Signing XML documents, document fragments, or any kind of data, and validating them against XML signatures

The Genero Web Services XML library provides APIs to encrypt and decrypt strings with symmetric or RSA public/private keys. These APIs can be used to encrypt/decrypt passwords directly in BDL applications.

The Genero Web Services provides support for the new BOOLEAN, TINYINT and BIGINT data types.

You can use these data types when writing your web service or to customize your BDL RECORDs for XML serialization. The fglwsdl tool has been enhanced to generate these new data types automatically when encountered in WSDL files or XML schemas.

**Note:** For compatibility issues, the fglwsdl tool allows code generation without these new data types by using the option `-legacyTypes`.

### Table 51: User interface

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
</table>
| The `ui.ComboBox` class has been extended with new methods: `getTextOf()` and `getIndexOf()`. A new FGLPROFILE entry has been added to force the current row to be shown automatically after a sort in a table: 

```
Dialog.currentRowVisibleAfterSort = 1
```

By default, the offset does not change and the current row may disappear from the window. When this new parameter is used, the current row will always be visible. | See The ComboBox class on page 2413  
See Dialog configuration with FGLPROFILE on page 1610 |

### Table 52: SQL databases

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
</table>
| Static SQL syntax now supports derived tables and derived column lists in the FROM clause. For example: 

```
SELECT * FROM  
(SELECT * FROM customer  
ORDER BY cust_num)  
AS t(c1,c2,c3,...)
```

See database server documentation for more details about this SQL feature. Informix® 11 does not support the full ANSI SQL 92 specification for derived columns, while other databases like DB2® do. For this reason, fglcomp allows the ANSI standard syntax. The `SET ISOLATION` statement now supports the new Informix® 11 clauses for the COMMITTED READ option: 

```
SET ISOLATION TO COMMITTED READ  
[LAST COMMITTED]  
[RETAIN UPDATE LOCKS]
```

When connecting to a non-Informix database, the LAST COMMITTED and RETAIN UPDATE LOCKS are ignored; other databases do not support these options, and have the same behavior as when these options are used with Informix® 11. The `CAST` operator can now be used in static SQL statements: 

```
CAST ( expression AS sql-data-type )
```

Only Informix® data types are supported after the AS keyword. | See SELECT on page 645  
See SET ISOLATION on page 637  
See Static SQL statements on page 638 |
In order to execute database administration tasks, you can now connect to Oracle as SYSDBA or SYSOPER with the `CONNECT` instruction:

```
CONNECT TO "dbname"
USER "scott/SYSDBA"
USING "tiger"
```

### Table 53: Web Services - Version 2.11.00

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Genero Web Services com library provides the <code>HTTPServiceRequest</code> class to perform low-level XML and TEXT over HTTP communication on the server side. This allows communication at a very low-level layer, to write your own type of web services.</td>
<td>See <a href="#">The <code>HTTPServiceRequest</code> class</a> on page 2688.</td>
</tr>
<tr>
<td>XML facet constraints attributes: the Genero Web Services XML library provides 12 new XML attributes to map to simple BDL variables. These attributes restrict the acceptable value-space for each variable in different ways such as:</td>
<td>See <a href="#">Attributes to customize XML serialization</a> on page 3250.</td>
</tr>
<tr>
<td>- a minimum or a maximum number of XML characters or bytes.</td>
<td></td>
</tr>
<tr>
<td>- a strict number of XML characters or bytes.</td>
<td></td>
</tr>
<tr>
<td>- a minimum inclusive or exclusive value depending on the data type.</td>
<td></td>
</tr>
<tr>
<td>- a maximum inclusive or exclusive value depending on the data type.</td>
<td></td>
</tr>
<tr>
<td>- an enumeration of authorized values.</td>
<td></td>
</tr>
<tr>
<td>- a number of digits and fraction digits.</td>
<td></td>
</tr>
<tr>
<td>- how white spaces have to be handled.</td>
<td></td>
</tr>
<tr>
<td>- a regular expression to match. <em>(See Section F of XML Schema Part 2)</em></td>
<td></td>
</tr>
</tbody>
</table>

The `fglwsdl` tool has been enhanced with the following three new options:

- `-disk`: to retrieve locally a WSDL or an XSD with all its dependencies from an URL on the disk
- `-nofacets`: to avoid the generation of the new facet constrain attributes (for compatibility)
- `-regex`: to validate a value against a regular expression as described in the XML Schema specification

### Table 54: Web Services - Version 2.11.04

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Genero Web Services library provides two new methods in the <code>WebOperation</code> class to create One-Way operations in services.</td>
<td>See <a href="#">The <code>WebOperation</code> class</a> on page 2668.</td>
</tr>
<tr>
<td>A One-Way operation means that the server accepts an incoming request, but doesn't return any response back to the client. There is one method called <code>CreateOneWayRPCStyle</code> to create an RPC Style operation, and another one called <code>CreateOneWayDOCStyle</code> to create a Document Style operation.</td>
<td></td>
</tr>
<tr>
<td>For instance, a One-Way operation can be used as a logger service, where a client sends a message to the server, but doesn't care about what the server is doing with it.</td>
<td></td>
</tr>
</tbody>
</table>
The `fglwsdl` tool has been enhanced with the following new options:

- `-b`: Generate code from a WSDL using the binding section instead of the service section
- `-autoNsPrefix`: Determine the prefix for variables and types based on the XML namespace they belong to
- `-nsPrefix`: Set the prefix for a variable or a type belonging to the given XML namespace

The following options have been changed:

- `-o`: If there are several services in one WSDL, they will be generated in the same file with the given base name instead of returning an error
- `-disk`: Retrieves and displays all dependencies to the current directory but there are no sub directories any longer.
- `-prefix`: Accepts patterns %s, %f and %p

The Genero Web Services library has been enhanced to support WSDL with circular references.

The Genero language doesn't provide a way to define variables or types that refer to themselves. However, to provide better interoperability and a way to handle such circular data, the `fglwsdl` tool now generates variables or types of `xml.DomDocument` type when circular references are detected during the processing of WSDL files. This gives the user the ability to manipulate the circular data by hand, using the XML DOM API.

### Related concepts

  These topics describe product changes you must be aware of when upgrading to version 2.11.

### BDL 2.10 new features

Features added in 2.10 releases of the Genero Business Development Language.

### Table 55: Core language

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>The <code>TRY/CATCH</code> block can handle exceptions raised by the runtime system.</td>
<td>See <strong>TRY - CATCH block</strong> on page 455</td>
</tr>
<tr>
<td><code>WHENEVER ... RAISE</code> instructs the runtime system that an uncaught exception will be handled by the caller of the function.</td>
<td>See <strong>WHENEVER instruction</strong> on page 452</td>
</tr>
<tr>
<td>NULL point exceptions can now be trapped as other exceptions: Error -8083 will be raised if you try to call an object method with a variable that does not reference an object (that contains NULL):</td>
<td>See <strong>OOP support</strong> on page 460</td>
</tr>
</tbody>
</table>

```
DEFINE x ui.Dialog
  -- x is NULL
CALL x.setFieldActive("fieldname",FALSE)
  -- raises -8083
```

In previous versions, the above code raised a fatal NULL pointer error.
The `base.Channel` class now provides a method to establish a client socket connection to a server, with the new `openClientSocket()` method.

For debugging purpose, get the stack trace of the program with the `base.Application.getStackTrace()` method.

Before version 2.10, it was only possible to assign a `TEXT` to a `TEXT` variable. It is now possible to assign `STRING`, `CHAR` and `VARCHAR` values to a `TEXT` variable.

The `fglrun -e` option now supports a comma-separated list of extensions, and `-e` can be specified multiple times:

```
fglrun -e ext1,ext2,ext3
    -e ext4,ext5 myprogram
```

Get an action event when the user modifies the value of a field, with the predefined `dialogtouched` action, to detect first user modifications.

The `parse()` and `toString()` methods are now available for a `om.DomNode` object.

A `om.DomDocument` object can be created with `createFromString()`.

The `TEXT` and `BYTE` data types now support the methods `readFile(fileName)` and `writeFile(fileName)`.

### Table 56: User interface

<table>
<thead>
<tr>
<th>Overview</th>

<tr>
<td>Before version 2.10, it was only possible to assign a <code>TEXT</code> to a <code>TEXT</code> variable. It is now possible to assign <code>STRING</code>, <code>CHAR</code> and <code>VARCHAR</code> values to a <code>TEXT</code> variable.</td>
<td>See [Type conversions](page 274)</td>
</tr>
</tbody>
</table>
### Overview

Presentation styles have been extended:

- The style attribute "position" for Windows™ can be set to "previous".
- TEXTEDIT now has the "textSyntaxHighlight" attribute (value can be "per", more to come...).
- All widgets can now use the "localAccelerators" global style attribute to interpret standard navigation and editor keys (like Home/End) without firing an action that uses the same keys as accelerators.

Get an action event when the user modifies the value of a field, with the predefined dialogtouched action, to detect first user modifications.

Use the validate="no" action default attribute to prevent data validation when executing an action.

Define a minimum width and height for forms with the MINWIDTH, MINHEIGHT attributes.

In INPUT ARRAY, avoid the automatic creation of a temporary row with the new AUTO APPEND = FALSE dialog attribute.

</tr>
<tr>
<td>• Serialization of BDL variables in XML</td>
</tr>
<tr>
<td>• Creation of XML Schemas corresponding to BDL variables</td>
</tr>
</tbody>
</table>
New classes have been added to the Genero Web Services COM library to facilitate low-level XML and TEXT over HTTP and TCP Client communication (com).

The Genero Web Services com library provides two classes, HTTPRequest and HTTPResponse, to perform low-level XML and TEXT over HTTP communications on the client side. Two more classes, TCPRequest and TCPResponse, are also provided to perform low-level XML and TEXT over TCP communications on the client side. This allows communication between applications using the core Web technology, taking advantage of the large installed base of tools that can process XML delivered plainly over HTTP or TCP, as well as SOAP over HTTP.

Specific streaming methods are also available to improve the communication by sending XML to the network even if the serialization process is not yet finished, as well as for the deserialization process.

It is also possible to prevent asynchronous requests from being blocked when waiting for a response, and to perform specific HTTP form encoded requests as specified in HTML4 or XForms1.0.

The fglwsdl tool now generates low-level and asynchronous client stubs from the WSDL.

The fglwsdl tool generates all client stubs with the low-level HTTPRequest and HTTPResponse classes of the com library to perform HTTP communications. The low-level generated stub also takes advantage of the streaming methods, if Document Style or RPC-Literal web services are performed. Streaming is not possible with RPC-Encoded web services, as nodes can have references to other nodes in the XML document, requiring the entire document in memory to perform serialization or deserialization.

The fglwsdl tool also generates two new BDL functions for each operation of a Web service. These two functions enable you to perform asynchronous web service operation calls by first sending the request, and retrieving the corresponding response later in the application. This allows you to prevent a BDL application from being blocked if the response of a web service operation takes a certain amount of time.

Genero Web Services provides an enhanced fglwsdl tool that is able to generate Genero data types from a XML schema. The data types can then be used in your application to be serialized or deserialized in XML. The resulting XML is a valid instance of that XML schema, and validation with a XML validator will succeed.

BDL 2.00 new features

Features added in 2.00 releases of the Genero Business Development Language.

Table 65: Core language

The runtime system (fglrun) now uses shared libraries for database drivers; there is no need to link anymore.

See Database driver specification (driver) on page 606.

The TYPE instruction allows to define your own data type structures.

See Types on page 397.

File management function library provided as loadable extension.

See The os.Path class on page 2640.

Mathematical function library provided as loadable extension.

See The util.Math class on page 2607.

C extension support has been extended with Informix-like C API functions.

No longer applicable as of Genero 2.51

The runtime system now shares several static elements among all processes, reducing the memory usage. The shared elements are: Data type definitions, string constants and debug information. For example, when a program defines a string containing a long SQL statement, all fglrun processes will share the same string, which is allocated only once.

See Runtime system basics on page 402.

The IMPORT instruction allows to declare a C extension module.

See IMPORT C-Extension on page 496.

New debugger commands (call, ignore).

See Debugger commands on page 2035.

The base.Channel class now has an isEof() method to detect end of file.

See Read and write simple lines on page 2287.

<tr>
<td>GWS now supports SOAP header management through the CreateHeader method in the Web Service class that is part of the Web Services library (com).</td>
<td>See The WebService class on page 2658.</td>
</tr>
</tbody>
</table>
### Overview

HTTPS support has been added on the client side. GWS supports secure communications through the use of encryption and standard X.509 certificates. Based on the OpenSSL engine, new security features allow a Web Services client to communicate with any secured server over HTTP or HTTPS.

A new tool is provided, `fglpass`, allowing you to encrypt a password from a standard X.509 certificate, and to decrypt a password you previously encrypted with a certificate.

Entries in the `FGLPROFILE` file are used to define the configuration for client security.

You can configure a GWS Client to connect via an HTTP proxy by adding an entry in the `FGLPROFILE` file.

You can define multiple Web Services in a single Genero DVM. When you start the Web Services engine, all registered Web Services are started.

You can remap the location of Genero Web Services using entries in the `FGLPROFILE` file, depending on the network configuration and the access rights management of the deployment site.

Serializing Genero data types: you can add optional attributes to the definition of data types. You can use these attributes to map the BDL data types in a Genero Web Services Client or Server application to their corresponding XML data types.

The `WSHelper.42m` library included in the `$FGLDIR/lib` directory of the Genero Web Services package file contains internal BDL functions to handle SOAP requests and errors.

It is recommended that it is linked into every Genero Web Services Server or Client program.

</tr>
<tr>
<td>Form DEFAULT SAMPLE instruction to define a default sample attribute for all form fields.</td>
<td>See INSTRUCTIONS section on page 1239</td>
</tr>
<tr>
<td>New form item attributes: SAMPLE, JUSTIFY, SIZEPOLICY ...</td>
<td>See SAMPLE attribute on page 1281, JUSTIFY attribute on page 1268, SIZEPOLICY attribute on page 1283</td>
</tr>
<tr>
<td>To hide form elements by default, that can be shown by the end user by option, use HIDDEN=USER as 'hidden to the user by default'.</td>
<td>See HIDDEN attribute on page 1260</td>
</tr>
<tr>
<td>Individual table columns now have new attribute UNMOVABLE to avoid moving.</td>
<td>See UNMOVABLE attribute on page 1291</td>
</tr>
<tr>
<td>WANTCOLUMNSANCHORED replaced by UNMOVABLECOLUMN and WANTCOLUMNSVISIBLE replaced by UNHIDABLECOLUMNS.</td>
<td>See UNMOVABLECOLUMNS attribute on page 1291, UNHIDABLECOLUMNS attribute on page 1290</td>
</tr>
<tr>
<td>Tables now accept a WIDTH and HEIGHT attribute to specify a size.</td>
<td>See WIDTH attribute on page 1302, HEIGHT attribute on page 1259</td>
</tr>
<tr>
<td>New RADIOGROUP attribute to define the orientation of the radio buttons: ORIENTATION.</td>
<td>See ORIENTATION attribute on page 1275</td>
</tr>
</tbody>
</table>
The **MENU COMMAND** clause now generates action names in lowercase. This means, when you define `COMMAND "Open"`, it will bind to all actions views defined with the name 'open'.

New `ui.Interface.loadTopMenu()` method to load a global `TOPMENU`.

The **ON CHANGE** block is now invoked when the user clicks on a `CHECKBOX`, `RADIOGROUP`, or changes the item in a `COMBOBOX`.

New `DIALOG` keyword to reference the current dialog as a `ui.Dialog` object. This can be used for example to enable/disable fields during the dialog execution.

The `ui.Form` built-in class has new methods to handle form elements. The hidden attribute is now also managed at the model level, this allows you to hide form fields by name, instead of using the decoration node.

```plaintext
CALL myform.setElementHidden("formonly.field1",2)
CALL myform.setFieldHidden("field1",2)
-- prefix is optional
```

New methods are provided in `ui.Interface` to control the MDI children.

In `INPUT ARRAY`, `CANCEL INSERT` now supported in `AFTER INSERT`, to remove the new added line when needed.

`TOOlBAR` and `TOPMENU` elements now have the hidden attribute so you can create them and hide the options the user is not supposed to see.

**Important:** Hiding a toolbar or topmenu option does not prevent the use of the accelerator of the action. Use `ui.Dialog.setActionActive()` to disable an action.

New option `NEXT FIELD CURRENT` to give control back to the dialog instruction without moving to another field.

<td>The <code>fglcomp</code> compiler now converts static SQL updates like:</td>
<td>See <a href="#">UPDATE</a> on page 642</td>
</tr>
</tbody>
</table>

```plaintext
UPDATE tab SET (c1,c2)=(v1,c2) ...
```

to a standard syntax:

```plaintext
UPDATE tab SET c1=v1, c2=v2 ...
```
On Windows™ platforms only, the ix drivers automatically set standard Informix®
environment variables with ifx_putenv(). Values are taken from the console
environment with getenv(). Additional variables can be specified with:

```
dbi.stdifx.environment.count = n
dbi.stdifx.environment.xx = "variable"
```

### Table 82: User interface

<table>
<thead>
<tr>
<th>Overview</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interactive instructions support the UNBUFFERED mode, to synchronise data model and view automatically: When you set a variable, the value is automatically displayed to the field, and when the user fires and action, the field value is automatically assigned to the corresponding program variable.</td>
<td>See <a href="#">The buffered and unbuffered modes</a> on page 1618.</td>
</tr>
<tr>
<td>DISPLAY ARRAY can now work in paged mode, to avoid loading a large array of rows, with the ON FILL BUFFER clause.</td>
<td>See <a href="#">Paged mode of DISPLAY ARRAY</a> on page 1743.</td>
</tr>
<tr>
<td>Centralize default attributes for actions in ACTION DEFAULTS.</td>
<td>See <a href="#">Configuring actions</a> on page 1646.</td>
</tr>
<tr>
<td>Client side settings can now be saved by application name, with a specific API. By default it is the name of the program.</td>
<td>See <a href="#">ui.Interface.setName</a> on page 2343.</td>
</tr>
<tr>
<td>New attribute APPEND ROW = TRUE/FALSE attribute for the INPUT ARRAY instruction, to control the creation of the default append action.</td>
<td>See <a href="#">INPUT ARRAY row modifications</a> on page 1748.</td>
</tr>
<tr>
<td>New attribute KEEP CURRENT ROW = TRUE/FALSE for the DISPLAY ARRAY and INPUT ARRAY instructions, to defines if the current row must remain highlighted when leaving the dialog. The default is FALSE.</td>
<td>See <a href="#">Handling the current row</a> on page 1736.</td>
</tr>
<tr>
<td>You can now define a TOOLBAR in form specification files.</td>
<td>See <a href="#">TOOLBAR section</a> on page 1192.</td>
</tr>
<tr>
<td>You can now define a TOPMENU in form specification files.</td>
<td>See <a href="#">TOPMENU section</a> on page 1190.</td>
</tr>
<tr>
<td>The <code>fgl_gethelp()</code> function returns the help text for the given help number.</td>
<td>See <a href="#">fgl_gethelp()</a> on page 2166.</td>
</tr>
<tr>
<td>The <code>fgl_set_arr_curr()</code> function changes the current row in DISPLAY ARRAY or INPUT ARRAY.</td>
<td>See <a href="#">Handling the current row</a> on page 1736.</td>
</tr>
<tr>
<td>Users can now send an interruption event to the program, to stop long running SQL queries, processing loops and reports.</td>
<td>See <a href="#">User interruption handling</a> on page 1612.</td>
</tr>
<tr>
<td>The <code>statusBarType</code> window style attribute to define the statusbar layout.</td>
<td>See <a href="#">Window style attributes</a> on page 1117.</td>
</tr>
<tr>
<td>The new FIELD ORDER FORM option can be used to follow the new TABINDEX attribute, to define the field tabbing order. FIELD ORDER FORM can also be used at the dialog level as dialog attribute.</td>
<td>See <a href="#">Defining the tabbing order</a> on page 1630.</td>
</tr>
<tr>
<td>For COMBOBOX form items, a default ITEMS list is created by fglform when an INCLUDE attribute is used.</td>
<td>See <a href="#">COMBOBOX item type</a> on page 1166.</td>
</tr>
<tr>
<td>The ON IDLE clause can be used to execute a block of instructions after a timeout.</td>
<td>See <a href="#">Get program control if user inactive</a> on page 1613.</td>
</tr>
</tbody>
</table>
New logical order of execution for \texttt{INPUT ARRAY} triggers:
\begin{enumerate}
\item \texttt{BEFORE INPUT}
\item \texttt{BEFORE ROW}
\item \texttt{BEFORE INSERT}
\item \texttt{BEFORE FIELD}
\end{enumerate}

New \texttt{ui.ComboBox} class to configure \texttt{COMBOBOX} fields at runtime.

\texttt{DISPLAY ARRAY} and \texttt{INPUT ARRAY} instructions now automatically use two predefined actions \texttt{nextrow} and \texttt{prevrow}, which allow binding action views for navigation.

\texttt{ON CHANGE} field trigger can be used to detect field modification. Useful for fields such as \texttt{CHECKBOX} and \texttt{COMBOBOX}.

Program icon definition with \texttt{ui.Interface.setImage()}. 

\texttt{LABEL} fields can now have a \texttt{FORMAT} attribute.

Front-end function calls allow to execute code on the front-end side with the \texttt{ui.Interface.frontCall()} method.

New \texttt{ui.Form} built-in class to handle forms.

New \texttt{ON ROW CHANGE} clause in \texttt{INPUT ARRAY}, executed when if at least one value in the row has been modified, and the user moves to another row or validates the dialog. The \texttt{ON ROW CHANGE} block is executed before the \texttt{AFTER ROW} block.

\texttt{MENU} instruction now supports \texttt{ON ACTION} clause, to write abstract menus as simple action handlers.

New 'help' predefined action, to start help viewer for \texttt{HELP} clauses in dialog instructions.

Upgrade Guides for Genero BDL
Provides information about product changes to be considered when migrating to a new version.

Important: Each upgrade guide is an incremental upgrade guide that covers only topics related to a specific version of Genero. It is important that you read all of the upgrade guides that sit between your existing version and the desired version.

- General BDL upgrade guide on page 105
- BDL 3.10 upgrade guide on page 106
- BDL 3.00 upgrade guide on page 127
- BDL 2.51 upgrade guide on page 138
- BDL 2.50 upgrade guide on page 143
- BDL 2.40 upgrade guide on page 148
- BDL 2.32 upgrade guide on page 152
General BDL upgrade guide

These topics describe general considerations when upgrading to a new version of Genero BDL.

1. **Runtime system and front-end compatibility** on page 105
2. **P-Code compatibility across versions** on page 105

**Runtime system and front-end compatibility**

For better compatibility and GUI related bug fixes, use front-end and runtime system with the equivalent version number.

Graphical User Interface new features and bug fixes usually require modifications inside the runtime system (`fglrun`) and front-ends (GDC, GBC, GMA, GMI).

When upgrading the runtime system to the latest version, we strongly recommend that you upgrade to the latest front-end version as well. For example, when upgrading to a runtime system 2.50.xx, upgrade front-ends to the latest available 2.50.xx version.

**P-Code compatibility across versions**

P-Code incompatibility (within .42m files) may be introduced from version to version.

Recompilation is only needed when the p-code becomes incompatible. When executing a program with and older p-code version as expected, `fglrun` will raise the error `-6201`.

Recompile your `.4gl` sources when upgrading to a new features release. Recompilation is not required when upgrading to a bug-fix release.

Feature and bug-fix releases are distinguished by the product version number. The product version number can be found by executing the `fglrun` command with the `-V` option.

The product version number has the following format: `M.FF.BB`, where `M` stands for the major release number, `FF` is a feature number, and `BB` is the bug-fix number. For example: `2.31.14`.

- A new feature release is identified by the `M.FF` part of the product version number.
- A bug-fix release is identified by the `BB` part of the product version number.

For example, you must recompile your sources when upgrading from 2.50 to 3.00, from 2.40 to 2.50, or from 2.51 to 2.52.

**Related concepts**

[Compiling source files](#) on page 1998
Describes how to build the runtime files from source files.

**BDL 3.10 upgrade guide**

These topics describe product changes you must be aware of when upgrading to version 3.10.

**Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Web Services changes on page 106

24. MariaDB 10.2 support on page 126
25. Fatal runtime error message on page 126
26. BUTTONEDIT and ON ACTION INFIELD on page 127

**Web Services changes**

There are changes in support of web services in Genero 3.10.

**The XMLElementNillable, XMLOptional, and XMLNillable attributes**

The management of XML serialization when serializing nillable has changed. These attributes define how a NULL value is interpreted in XML.

When using the XMLOptional on page 3266 attribute, the behavior of the XML serialization has changed; it no longer handles XML nillable.

The new XMLNillable on page 3267 attribute can be used to specify that the XML representation of a NULL value must be xsi:nil="true".

In order to get the same result as when using XMLOptional in prior versions, set both XMLOptional and XMLNillable.

Instead of specifying each element individually with XMLNillable, the XMLElementNillable on page 3269 attribute can be used with a BDL RECORD defined as TYPE or DEFINE to specify the XML representation for nillable in all elements in the record. This eases migration to the new XMLNillable behavior, because now you can get the same behavior as before defining database records by adding the XMLElementNillable attribute.
**Important:** If in versions prior to GWS 3.10 you had the following expected XML serialization behavior, you need to take action to avoid serializer errors:

- A variable that was expected to serialize an `xsi:nil` value, you must set the `XMLNillable` attribute on that variable.
- A record defined with `LIKE` for fields in a database table which may allow null values, you must set the `XMLElementNillable` attribute as in the example.

```bda
DEFINE var RECORD ATTRIBUTE(XMLElementNillable) LIKE customer.*
```

It is therefore recommended to do the following:

- Recompile the Genero Web Service server to create a new WSDL that supports the XML nillable feature.
- Regenerate all Genero Web Service client stubs from the newly-generated WSDL to get the support of XML nillable. Regenerate client stubs using the `fglwsdl` tool.

**Better support for Web Services API on iOS/GMI**

Most of the Web Services APIs are not available on iOS mobile devices.

There are still some exceptions, related to iOS restrictions. For details see [Web Services on mobile devices](#) on page 3312.

**Note:** In versions before 3.10, the iOS app displayed a pop-up dialog to cancel a long running HTTP request. Starting with 3.10, the pop-up dialog is no longer used; only the activity indicator displays, and the app goes into background mode, if the HTTP request fails to complete after several minutes. The program gets a runtime error -15553 if the user taps the app icons, to bring the app back to foreground mode.

**OpenID Single sign-on (SSO) protocol not supported**

Support of the OpenID Single sign-on (SSO) protocol has been dropped. This service based on Genero REST is no longer delivered in the Genero Web Services package under `$FGLDIR/web_utilities/services/openid`.

If you have previously used OpenID to authenticate users launching applications, you must now use an alternate method, such as OpenID Connect. See the [OpenID Connect SSO](#) topics in [Genero Application Server User Guide](#).

**Define server configuration based on regular expressions**

Starting with GWS 3.10.09, instead of using the `ws.myident.url` FGLPROFILE entry, you can now use a regular expression to identify several server URLs, by using the `ws.ident.regex.url` entry.

For more details, see [Web Services FGLPROFILE: Server configuration](#).

**fglwsdl option -fRPCNamespace to support namespaces in RPC parameters**

Starting with GWS 3.10.09, the `fglwsdl` tool supports the new option `-fRPCNamespace` to produce BDL code supporting the `namespace` attribute for RPC parameters.

For more details, see [fglwsdl](#) on page 1980.

**fglpass option -gid to allow agent authentication through a UNIX user group**

Starting with GWS 3.10.10, the `fglpass` tool can be used with the `-gid` to allow agent authentication for all users which belong to the group of the current user executing the `fglpass` command.

For more details, see [fglpass](#) on page 1983, [Use the password agent](#) on page 3118.

**Related concepts**

[Web services](#) on page 3102
Create a Web service client or server with Genero BDL.

**Genero Mobile for Android™ (GMA) 1.30 changes**
Modifications to consider when using the Genero Mobile for Android™.

**Note:** This topic describes feature changes in the GMA 1.30 product. See also the Mobile section in Genero BDL 3.10 New Features page.

**GMA 1.30 with FGLGWS 3.10**

**Important:** The GMA version 1.30 is built on FGLGWS 3.10 and therefore, strongly tied to this Genero BDL version.

**Desupport of GMA front-end application on Google Play**
The GMA front-end app is no longer available for download on Google Play.

In order to install the GMA front-end on your device, use the `gmabuiltool` as described in Genero mobile development client for Android on page 3294.

**ANDROID_SDK_ROOT replaces ANDROID_HOME**
When building apps with `gmabuildtool`, the ANDROID_HOME environment variable is deprecated.

To define the Android SDK installation directory, use ANDROID_SDK_ROOT instead.

If the `--android-sdk` option is not specified, the `gmabuildtool` will first use ANDROID_SDK_ROOT, then ANDROID_HOME as fallback.

Consider changing your environment settings to follow Android™ SDK specifications.

**Default directory for localized strings in GMA apps**
The .42s localized string files for the default language can be provided in the `appdir/defaults` directory.

Resource files such as .42s provided in `pwd` are always loaded by the runtime system. As GMA, `pwd` and `appdir` are the same, it was not possible to provide default strings files in `appdir`. It was required to provide localized string files for any language, in the corresponding `appdir/locale-code` directories.

For more details, see Localized string files on mobile devices on page 438 and Deploying mobile apps on page 3315.

**New --no-install-extras option**
By default, when updating the Android™ SDK with `gmabuildtool updatesdk`, the process installs also extra SDK modules.

The `--no-install-extras` option of `gmabuildtool updatesdk` can be used to skip installation of extra SDK modules when not needed.

**Unique package for all architectures**
The GMA bundle is now provided as a single package, supporting both ARM and x86 device architectures.

The `--build-types` option of `gmabuildtool build` is no longer available.

**Unique scaffolding archive**
Before GMA 1.30, two GMA binary archives where provided:

- `fjs-gma-*-android-scaffolding.zip`
- `fjs-gma-*-android-extension-project.zip`
Starting with GMA 1.30, the scaffolding and extension project have been merged in a single `fjs-gma-*--android-scaffolding.zip` archive.

For more details, see Executing Java code with GMA on page 2098.

**New scaffold command**
The `gmabuildtool scaffold` command has been added to manage scaffold archives.

In its initial version, the scaffold command provides the `--list-plugins` option, to show available plugins, and the `--install-plugins` option, to install plugins in the scaffold archive (for Cordova support).

**No more gma/temp directory**
The Genero Mobile Android™ project directory does not longer need the `gma/temp` directory to build an app.

Since GMA 1.30, the `--build-distribution` option of `gmabuildtool` is no longer available.

**gmabuildtool options use `--build-app-genero-program` as base directory by default**
Starting with GMA 1.30, the `gmabuildtool` options listed below use the application program files directory (`--build-app-genero-program` option) as base directory for their default values.

In previous versions, the default base directory was the current working directory. Note however, that the default value for the `--build-app-genero-program` option is still the current working directory.

- `-bp / --build-project`
- `-bih / --build-app-icon-hdpi`
- `-bim / --build-app-icon-mdpi`
- `-bixh / --build-app-icon-xhdpi`
- `-bixxh / --build-app-icon-xxhdpi`
- `-bsh / --build-status-icon-hdpi`
- `-bsm / --build-status-icon-mdpi`
- `-bsxh / --build-status-icon-xhdpi`

**GMA scaffolding archive usage (`--build-force-scaffold-update` option)**
During the manual installation procedure (to build GMA apps from the command line without GST), it was required to unzip the scaffolding zip archive in a dedicated directory (`gma-scaffold-project`), which could be referenced with the `--build-project` option of the `gmabuildtool build` command.

Starting with GMA 1.30, if not yet done, the APK build process will automatically unzip the original GMA scaffold archive (`gma-install-dir/artifacts`) into the `--build-project` directory. If needed, you can force a cleanup and update these scaffold files with the `--build-force-scaffold-update` option.

**New `--build-quietly` option**
The `--build-quietly` option of `gmabuildtool build` allows to build the APK silently, by answered yes to all questions asked during the build process.

**The IMAGE style attribute `alignment` is supported**
GMA 1.30 now supports the `alignment` style attribute for IMAGE form items.
For the possible values of this attribute, see Image style attributes on page 1095.

**Dangerous permissions no longer set by default**
Starting with GMA 1.30, the Android™ Dangerous Permissions such as `android.permission.WRITE_EXTERNAL_STORAGE` are no longer set by default when building an
APK. Such permissions must be specified explicitly with the `--build-app-permissions` option of `gmabuildtool`, depending on the frontcalls used by the app.

For more details, see Android permissions on page 3321.

**Push Notification: Firebase Cloud Messaging replaces Google Cloud Messaging**

Starting with GMA 1.30.18, the Firebase Cloud Messaging framework replaces Google Cloud Messaging to implement push notifications.

What you need to consider:

1. A new Firebase Cloud Messaging project must be created from the FCM console.
2. The package name of the FCM app must match the package name used to build your APK (with the `--build-app-package-name` option of `gmabuildtool`)
3. You must download the `google-services.json` configuration file and put it in the `appdir`.
4. The `sender-id` parameter of the `registerForRemoteNotifications`, `getRemoteNotifications` and `unregisterFromRemoteNotifications` frontcalls is no longer needed (all informations are in the `google-services.json` parameter file).
5. In the server application sending push notifications, replace the Google API key by the Server Key found in the Firebase Cloud Message project parameters.

For more details, see Push notifications on page 3345.

**Related concepts**

Building Android apps with Genero on page 3317

Genero provides a command-line tool to create applications for Android™ devices.

Genero Mobile for iOS (GMI) 1.30 changes

Modifications to consider when using Genero Mobile for iOS.

**Note:** This topic describes features changes in the GMI 1.30 product. See also the Mobile section in Genero BDL 3.10 New Features page.

**GMI 1.30 with FGLGWS 3.10**

**Important:** The GMI version 1.30 is built on FGLGWS 3.10 and therefore, strongly tied to this Genero BDL version.

**Default directory for localized strings in GMI apps**

The `.42s` localized string files for the default language can be provided in the `appdir/defaults` directory.

Resource files such as `.42s` provided in `pwd` are always loaded by the runtime system. As GMA, `pwd` and `appdir` are the same, it was not possible to provide default strings files in `appdir`. It was required to provide localized string files for any language, in the corresponding `appdir/locale-code` directories.

For more details, see Localized string files on mobile devices on page 438 and Deploying mobile apps on page 3315.

**Building GMI apps with C extensions**

Before GMI 1.30, in order to build an iOS app with C extensions, it was required to create your own `makefile` based on the generic `GMIDIR/lib/Makefile-gmi` file, to add your own C extension libraries or custom front calls with the `USEREXTENSION` variable:

```bash
...
GMI_OPTIONS = \
```
Starting with GMI 1.30, it is now possible to build your static library with the staticlib target of GMIDIR/lib/Makefile-gmi, and pass your library to the gmibuildtool with the --extension-libs option:

```
$ gmibuildtool ... -extension-libs "-lz libBPush.a" ...
```

For more details, see Building iOS apps with Genero on page 3332.

### Registering custom front calls in GMI

Before GMI 1.30, it was required to implement a `frontCalls()` function, in order to declare the Objective-C class implementing your custom front calls:

```swift
NSArray* frontCalls()
{
    return @[ [ExtensionFrontCall class] ];
}
```

Starting with GMI 1.30, upon startup, the GMI detects the extension by enumerating all descendants of the Frontcall classes.

Thus, there is no need to implement this function anymore.

For more details, see Implement front call modules for GMI on page 2139.

### Managing plugins in GMI

Starting with GMI 1.30, the gmibuildtool allows you to handle plugins with the `--install-plugins` and `--list-plugins` options.

For more details, see Cordova plugins on page 3370.

### C Extension changes

Modifications to consider when using C Extensions

#### Informix ESQL/C header files no longer distributed

Prior to version 3.10.11, Informix ESQL/C header files such as `decimal.h` were provided in FGLDIR/include/esql directory.

Starting with BDL 3.10.11, the Informix ESQL/C header files are no longer distributed in the BDL packages: Genero provides its own header files defining the C structures for DECIMAL, DATETIME, INTERVAL and TEXT/BYTE types.

Simply include the `fglExt.h` header file in your C extension source.

If you need additional type definitions that are not provided in Genero C Extension header files, install the latest Informix CSDK, and include the Informix header files before `fglExt.h`.

For more details, see Header files for ESQL/C typedefs on page 2110.

**C Extension API functions for bigint**

Genero BDL 2.51 has desupported C Extension stack functions, that were introduced again in 3.10 (also backported in 3.00.10).

The following C API functions are available again:

- popbigint(bigint *dst)
- pushbigint(bigint val)

The following C type definitions are available again:

- bigint: Defines a 8-byte signed integer

For more details, see Runtime stack functions on page 2114

**Related concepts**

- C-Extensions on page 2109

With C-Extensions, you can bind your own C libraries in the runtime system, to call C function from the application code.

**Java Interface changes**

There are changes in support of Java in Genero 3.10.

**Genero BDL supports Java SE 6 to Java SE 10 and 11**

Starting with version 3.10.14, Genero BDL supports now Java SE 10 and 11 when using the Java Interface.

**Important:** The minimal required version to use the BDL Java Interface is Java SE 6.

For more details, see Java software requirements on page 2072.

**Related concepts**

- The Java interface on page 2071

The Java interface allows you to import Java classes and instantiate Java objects in your programs.

**Presentation styles changes**

Modifications to consider when using presentation styles.

**Edit.dataTypeHint style attribute is deprecated**

Starting with Genero BDL 3.10, the Edit presentation style attribute dataTypeHint is deprecated.

Consider using the KEYBOARDHINT form attribute instead.

Reference: Edit style attributes on page 1092.

**Image.alignment style attribute**

The alignment style attribute for IMAGE form items is now supported by:

- GMA 1.30.01

For the possible values of this attribute, see Image style attributes on page 1095.

**TextEdit.customWidget style attribute**

With Genero BDL 3.10, the TextEdit presentation style customWidget is no longer required with the GBC frontend.

This style attribute was supported by GWC-HTML5, when using textFormat="html".

Reference: TextEdit style attributes on page 1109.
Note: Genero 3.10 introduces the `fgrichtext` web component, an alternative to the richtext option in TEXTEDIT fields, which is supported by all front-ends.

**Window.commentPosition style attribute is deprecated**

Since Genero BDL 3.10, the Window presentation style `commentPosition` is deprecated.

This style attribute is only supported by the GDC front-end.

Reference: Window style attributes on page 1117.

**Window.actionPanelButtonSize and Window.ringMenuButtonSize style attributes**

Starting with Genero BDL 3.10, the action panel and ring menu button sizes can be defined by specifying a size relative to the height of the current font, using the "em" unit, for example:

```xml
<StyleAttribute name="actionPanelButtonSize" value="20em" />
```

**Note:** The abstract values such as "small", "medium", "large" are supported for backward compatibility.

**Table.allowWebSelection with GBC**

To select table/tree content with the GBC front-end, by default, the user must press the CTRL key and do a click-and-drag.

Starting with GBC 1.00.28, you can use the "allowWebSelection" style attribute, to allow content selection from a table (or a treeview), with a simple click-and-drag (without pressing the CTRL key):

```xml
<StyleAttribute name="allowWebSelection" value="yes" />
```

**Note:** In GWC-HTML5, the "allowWebSelection" style attribute was supported for the Window elements, to allow the user to copy the content of disabled fields to the clipboard. Text selection and copy in disabled fields is allowed by default with GBC.

Reference: Table style attributes on page 1101, Tree style attributes on page 1106.

**Table.resizeFillsEmptySpace and Table.resizeFillsEmptySpace with GBC**

Starting with GBC 1.00.33, the `resizeFillsEmptySpace` style attribute can be used for Table and Tree elements:

```xml
<StyleAttribute name="resizeFillsEmptySpace" value="yes" />
```

Reference: Table style attributes on page 1101, Tree style attributes on page 1106.

**Window.tabbedContainer with GBC**

Since GBC 1.00.34, the `tabbedContainer` style attribute can be used to render hosted applications embedded in a tab container, as was done with GWC-HTML5:

```xml
<StyleAttribute name="tabbedContainer" value="yes" />
```

If the window of an application uses `tabbedContainer=yes`, every subsequent application is embedded in a tab container generated by GBC. When using this style attribute, the GBC side bar is replaced by Start menus on page 1918, which is mandatory when `tabbedContainer=yes`. 
Window.position value "center" with GBC

Starting with GBC 1.00.35, you can use the window position "center" for the position style attribute:

```
<StyleAttribute name="position" value="center" />
```

Note: Using the center position mimics HTML5 centering windows when setting the sizable style attribute to "no". The main difference with HTML5 is that centering was the default behavior with HTML5. With GBC, it has to be specified explicitly.

Window.sizable with GBC for modal windows

Since GBC 1.00.37, the "sizable" style attribute can also be used for modal windows:

```
<StyleAttribute name="sizable" value="no" />
```

Reference: Window style attributes on page 1117.

CheckBox.customWidget style attribute

Starting with GBC 1.00.38, the CheckBox presentation style attribute customWidget can be defined to "toggleButton", to get a toggle switch rendering:

```
<StyleAttribute name="customWidget" value="toggleButton" />
```

Reference: CheckBox style attributes on page 1087.

DateEdit.calendarType style attribute

Since GBC 1.00.45, the DateEdit presentation style attribute calendarType altered its behaviour for the value modal. When set to modal, the user must use the calendar to validate (or cancel) a date change, and clicking outside the calendar closes the calendar. Previous behavior included a greyed overlay when the calendar was opened as modal, and clicking outside the calendar did nothing.

Reference: DateEdit style attributes on page 1089.

Folder.position value "accordion"

Starting with GBC 1.00.47, you can use the value "accordion" for the position style attribute of FOLDER containers, to render the children pages as a set of collapsible group boxes.

Note: The "accordion" position is only supported by the GBC front-end.

Reference: Folder style attributes on page 1093.

Front calls changes

Modifications to consider when using front calls.

session. front call are desupported

The session.setVar and session.getVar front calls are no longer supported in Genero 3.10: The session front calls rely on the GAS "wa" protocol (html5Proxy). This protocol is only supported only by GWC-HTML5 client. html5Proxy is no longer delivered in Genero 3.10.

In order to store information on the front-end side, use the localStorage front calls. For more details, see New localStorage frontcalls on page 125.

standard.setWebComponentPath

The standard.setWebComponentPath front call is deprecated in Genero BDL 3.10. To deploy your web components, consider using the solutions described in Deploying the gICAPI web component files on page 1850.
standard.feInfo: outputMap
Starting with Genero BDL 3.10, the outputMap information can no longer be used with the standard.feInfo front call.

standard.cbSet supported by GBC
Since Genero BDL 3.10 (GDC 1.00.35), the GBC supports the standard.cbSet front call.

mobile.isForeground to check app foreground mode
Since Genero BDL 3.10.11 (GMA 1.30.10, GMI 1.30.11), the mobile.isForeground front call can be used to check if the app is in foreground mode.
For more details, see mobile.isForeground front call.

Related concepts
Front calls on page 525
Front call functions execute on the platform where the front-end is installed.
Web components on page 1825
This section describes how to use web components in your application.

Web components changes
Modifications to consider when using web components.

fglrrichtext: New implementation
Up to FGLGWS version 3.10.09 (WCG 1.00.11), the fglrichtext built-in web component was based on draft.js Rich Text Editor Framework.
Starting with FGLGWS 3.10.11 (WCG 1.00.12), the fglrichtext web component is implemented with the quilljs Rich Text Editor.
Available features and configuration options have changed.
For more details, see The fglrichtext web component on page 1875.

fglrrichtext: Support of emojis
Starting with FGLGWS version 3.10.13 (WCG 1.00.13), the emoji toolbar option allows users to include an emoji in the text of an fglrichtext web component.
Important: Since emojis are Unicode characters and not plain images, your application needs to use UTF-8. Emojis rendering will differ depending on the device you're running it on. You might need to install fonts that handle emoji characters as well if your device doesn't handle it.
For more details, see Configuring the toolbar on page 1877.

fglrrichtext: Defining a default font
Starting with FGLGWS version 3.10.16 (WCG 1.00.15), a default font family and font size can be specified for a fglrichtext web component with new properties.
For more details, see Specifying the default font on page 1880.

fglrrichtext: Localizing texts
Starting with FGLGWS version 3.10.16 (WCG 1.00.15), it is possible to localize the texts used by the fglrichtext web component.
Several properties have been added to the fglrichtext web component, to define the strings for each toolbar button tooltips, combobox items, and popup dialog labels.
For more details, see Localizing rich text component strings on page 1880.

**fglsvgcanvas: Mouse hovering events**

Starting with FGLGWS version 3.10.11 (WCG 1.00.12), the fglsvgcanvas built-in web component supports new properties to detect `onmouseover`/`onmouseout` mouse hovering SVG events, and trigger **ON ACTION** blocks. For more details, see The fglsvgcanvas web component on page 1891.

**fglsvgcanvas: title() and createChars() functions**

Starting with FGLGWS version 3.10.18 (WCG 1.00.16), the fglsvgcanvas library provides the `title()` function to create a title SVG element, and the `createChars()` function to create a text node. For more details, see fglsvgcanvas utility functions (IMPORT FGL fglsvgcanvas) on page 2211.

**fglgallery: Aspect ratio for image elements**

Using FGLGWS version 3.10.18 (WCG 1.00.16), image elements are now aligned properly by using the same size, in case if picture resources have different sizes.

By default, the images are displayed with a square (1:1) aspect ratio. To define a different aspect ratio, the fglgallery library provides the `setAspectRatio()` function. For more details see fglgallery image aspect ratio handling.

**fglgallery: Custom CSS file handling**

Starting with FGLGWS version 3.10.18 (WCG 1.00.16), to avoid missing resource errors in web viewers, the custom CSS file `FGLDIR/webcomponents/fglgallery/css/fglgallery-custom.css` is no longer included by default in the `fglgallery.html` file.

If you want to provide your own CSS file for fglgallery, uncomment the `<link />` line in `fglgallery.html`.

Note also that CSS names have changed, since the HTML content of fglgallery has been reviewed for images aspect ratio handling.

**Debugging web components with GDC**

Starting with GDC 3.10.24, the new command line option `--webengine-remote-debugging=<address>:<port>` can be used to define the debug port for QT WebEngine Developer Tools, like when using the `QTWEBENGINE_REMOTE_DEBUGGING` environment variable.

For more details, see Debugging a web component on page 1830.

**Related concepts**

Web components on page 1825

This section describes how to use web components in your application.

**Desupported database drivers**

Database drivers for old database client versions are removed in accordance with vendor de-support plans.

**Database drivers desupported in version 3.10:**

- SQL Server 2005 SQL Native Client (`dbmsnc_9`).
- Oracle® MySQL 5.1.x (`dbmmys_5_1`)

**Related concepts**

Database driver specification (driver) on page 606
(GDC) Local Actions
The concept of "Local Actions" is now deprecated.

Starting with Genero 3.10, the concept of "Local Actions" is deprecated.

Local Actions are available in the GDC front-end only, to bind local operations to action views.

For example, the typical copy/cut/paste operations can be bound to ToolBar items by using the editcopy, editcut, editpaste action names.

Local Actions can be considered as an over-engineered feature. Business applications do not have to implement basic copy/cut/paste editor actions. The user interface must focus on application functions (create new record, print order, etc).

Related concepts
Dialog actions on page 1640
Describes how to program action handling when the end user triggers an action on the front-end.

Toolbars on page 1327
Toolbars define a bar of buttons that appears at the top of application forms.

Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

Microsoft ODBC Driver for SQL Server
Support for Microsoft® ODBC Driver for SQL Server

Feature summary
Genero BDL 3.10 now supports Microsoft® ODBC Driver v13 and v17 for SQL Server, respectively with the dbmsnc_13 and dbmsnc_17 ODI drivers.

These ODI drivers are available on Windows® and Linux® platforms, to connect to:

- Microsoft SQL Server 2016,
- Microsoft SQL Server 2017,
- Microsoft Azure SQL Database.

Using Microsoft® ODBC on Windows® platforms
The new ODI drivers for Microsoft SQL Server can be used to connect from Windows platforms to Microsoft SQL Server 2016, 2017 and Azure DB.

The Windows ODI drivers for Microsoft ODBC for SQL Server need the following DLLs:

- The dbmsnc_13 ODI driver requires MSODBCSQL13.DLL.
- The dbmsnc_17 ODI driver requires MSODBCSQL17.DLL.

Note: Microsoft ODBC 11 for SQL Server (MSODBCSQL11.DLL) is not supported.

For backward compatibility, the dbmsnc_11 driver using Microsoft SQL Native Client 11 (SQLNCLI11.DLL) is still supported. However, it is recommended to upgrade to the dbmsnc_13 or dbmsnc_17 drivers using Microsoft ODBC for SQL Server.

Important:
With Genero BDL 3.10, the generic ODI driver named dbmsnc maps to the most recent SNC driver dbmsnc_17, requiring Microsoft ODBC 17 for SQL Server (MSODBCSQL17.DLL) in the ODBC data source definition. If you do not set up the ODBC data source configuration to use MSODBCSQL17.DLL, the SNC ODI driver will report an invalid ODBC driver error.

With Genero 3.00, you still have to use dbmsnc_11 to connect to SQL Server 2016. For a cross-version configuration of Genero, use explicit ODI driver names dbmsnc_11, dbmsnc_13 or dbmsnc_17, instead of the...
generic driver name "dbmsnc". This is required because dbmsnc maps to dbmsnc_17 in BDL 3.10 and dbmsnc maps to dbmsnc_11 in BDL 3.00.

**Using Microsoft® ODBC on Linux® platforms**

The new ODI drivers for Microsoft SQL Server can be used to connect from Linux platforms to Microsoft SQL Server 2016, 2017 and Azure DB.

The Linux ODI drivers for Microsoft ODBC for SQL Server are linked to the following shared libraries:

- The dbmsnc_13 ODI driver requires libmsodbcsql-13.so.
- The dbmsnc_17 ODI driver requires libmsodbcsql-17.so.

On Linux® platforms, the dbmsnc_nn drivers are directly linked to the corresponding libmsodbcsql-nn.so ODBC driver library. There is no need to install the unixODBC software. The SNC drivers will be able to connect to SQL Server, as long as the dynamic linker can find the Microsoft ODBC driver library. The libmsodbcsql-nn.so shared library is a symbolic link located in /usr/lib64, which points to the real ODBC 13 shared library.

**Azure SQL Database**

The ODI drivers for Microsoft ODBC for SQL Server can be used to connect to Microsoft Azure SQL Databases, from Windows or Linux platforms.

To establish a TCP connection to a server created through the Azure portal, you need to configure the firewalls on the server side and on your computer and network.

**Related concepts**

- [Database driver specification (driver)](#) on page 606

### Unique TABINDEXes in a form

The TABINDEX values must be unique in a given form file.

Starting with Genero 3.10, the TABINDEX attribute must be unique in a form layout:

```
LAYOUT
GRID
{
  [f1   ]
  [f2             ]
  [f3                 ]
}
END
END
ATTRIBUTES
EDIT f1 = FORMONLY.cust_id;
EDIT f2 = FORMONLY.cust_name, TABINDEX=2;
EDIT f3 = FORMONLY.cust_address, TABINDEX=2;
# TABINDEX has to be unique.
# See error number -6847.
END
```

**Related concepts**

- [Defining the tabbing order](#) on page 1630
  Control the order of tabbing through the fields with the TABINDEX attribute.

- [TABINDEX attribute](#) on page 1287
The **TABINDEX** attribute defines the tab order for a form item.

**Optional SCREEN RECORD size for lists**
A **SCREEN RECORD** definition can omit the number of rows of the corresponding list container.

Starting with Genero 3.10, a **SCREEN RECORD** definition can be defined without the size of the corresponding list container (**TABLE**, **SCROLLGRID**, **TREE** or static field list).

When specifying the size in **SCREEN RECORD**, it must match the exact number of rows of the corresponding list container, otherwise **fglform** will throw error **-2029**:

```
LAYOUT
GRID
{
<TABLE t1 >
[c1  |c2   ]
[c1  |c2   ]
<    |    >
}
END
END
ATTRIBUTES
c1 = FORMONLY.cust_id;
c2 = FORMONLY.cust_name;
END
INSTRUCTIONS
SCREEN RECORD sr_cust[10](FORMONLY.*);
# Screen record array 'sr' has different component sizes.
# See error number -2029.
END
```

**Related concepts**

- [Binding tables to arrays in dialogs](#) on page 1758
  Program arrays act as data model that are bound to form tables, when implementing list dialogs.
- [Defining tables in the layout](#) on page 1755
  Define table views in the **LAYOUT** section of the form definition file.

**Type checking with fglcomp compiler**

The **fglcomp** compiler is more strict regarding type checking.

Starting with Genero 3.10, the **fglcomp** compiler is now more strict when assigning complex types.

Any assignment potentially throwing runtime error **-1260** is subject to the new compiler error **-6631**.

**Note:** Assignments using primitive types such as **CHAR** to **INTEGER** are not checked, except for **DATETIME**, **INTERVAL**, **TEXT** and **BYTE** assignments, which are candidates for runtime error **-1260**.

Type checking errors are raised on:

- incompatible assignments in **LET** variable = value.
- passing incompatible values to functions (user functions, built-in functions, C extensions).
- returned types of functions when the **FUNCTION** is defined with the **RETURNS** clause.

Better type checks include:

- better predictions (for autocompletion in **vim** and Studio)
- being able to call methods on return values of methods.

For example, when assigning invalid object references to variables defined with a different class:

```
$ cat tcl.4gl
MAIN
    DEFINE sb base.StringBuffer
```
LET sb = "foo" -- illegal: assigns a String to a StringBuffer
END MAIN

With versions prior to 3.10, you get no compiler error, but an error at runtime:

$ fglcomp -V
fglcomp 3.10.14
...
$ fglcomp tcl
$ fglrun tcl
Program stopped at 'tcl.4gl', line number 3.
FORMS statement error number -1260.
It is not possible to convert between the specified types.

With version 3.10, you get now a compiler error:

$ fglcomp -V
fglcomp 3.10.03
...
$ fglcomp -M tcl

In the following example, the type returned by base.Channel.create() does not match the variable definition:

$ cat tc2.4gl
MAIN
  DEFINE sb base.StringBuffer
  LET sb = base.Channel.create() -- what's the return type of base.Channel.create()?
END MAIN

$ fglcomp -M tc2

This example tries to pass a STRING to a method whereas an om.DomNode is expected:

$ cat tc3.4gl
MAIN
  DEFINE doc om.DomDocument
  DEFINE n1, n2 om.DomNode
  LET doc = om.DomDocument.createFromString("<Foo><Bar/></Foo>")
  LET n1 = doc.getDocumentElement()
  LET n2 = doc.getDocumentElement().getFirstChild()
  LET n2 = n1.getFirstChild()
  CALL n1.removeChild(n2) -- legal: n2 is an om.DomNode
  CALL n1.removeChild("Bar") -- illegal: n2 is a STRING
END MAIN

$ fglcomp -M tc3.4gl

This example uses the return value of FGL-functions:

$ cat tc4.4gl
MAIN
  DEFINE s STRING
  LET s = function1() -- unchecked: return type unknown
  LET s = function2() -- illegal: returns a base.Channel
LET s = function3() -- legal: returns a STRING
END MAIN

FUNCTION function1()
  RETURN base.Channel.create()
END FUNCTION

FUNCTION function2() RETURNS base.Channel
  RETURN base.Channel.create()
END FUNCTION

FUNCTION function3() RETURNS STRING
  RETURN "foo"
END FUNCTION

$ fglcomp tc4.4gl
The compilation was not successful. Errors found: 1.
The file 'tc4.err' has been written.

$ cat tc4.err
MAIN
  DEFINE s STRING
  LET s = function1() -- unchecked: return type unknown
  LET s = function2() -- illegal: returns a base.Channel
    incompatible types, found: base.Channel, required: STRING.
    See error number -6631.
  LET s = function3() -- legal: returns a STRING
END MAIN
...

Related concepts
Data types on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

fglcomp on page 1972
The fglcomp tool compiles .4gl source files into .42m p-code modules.

Calling functions on page 358
Functions can be invoked, to execute the code they define.

Function references on page 362
Function can be referenced and invoked dynamically in a CALL instruction, or in an expression.

Oracle DB Proxy Authentication
Specifying a proxy user when connecting to Oracle® DB.

Oracle® DB supports proxy authentication, a feature that allows a given DB user "A" to connect with the credentials of another DB user "B" and to be seen as user "A" for the rest of the SQL session.

In order to link a proxy user to another user, issue the following command:

```
ALTER USER app_user GRANT CONNECT THROUGH proxy_user
```

An application can then connect with the credentials of proxy_user, and be identified as app_user during the SQL session.

See Oracle® DB documentation for more details about proxy authentication.

Starting with Genero 3.10, it is possible to specify a "proxy client" at connection time, by using the /PROXY_CLIENT:user_name suffix in the user name parameter of the CONNECT TO instruction.
In the example, the application connects with the proxy user credentials, and the proxy client is defined as `app_user`:

```sql
CONNECT TO "myserver"
    USER "proxy_user/PROXY_CLIENT:app_user"
    USING "proxy_pswd"
```

A subsequent `SELECT USER FROM dual` would return "APP_USER".

**Related concepts**
- [Database users](#)
- [Temp table emulation with Oracle DB](#)
- [Oracle DB specific FGLPROFILE parameters](#)
- [Oracle® MySQL 5.7 and 8.0 support](#)
- [ODI driver for Oracle® MySQL 8.0](#)

**Temp table emulation with Oracle DB**
Controlling the Oracle® schema and the tablespace for tables created by Informix® temporary table emulation.

In order to support Informix® CREATE TEMP TABLE and SELECT ... INTO TEMP statements, the Oracle® ODI driver converts the SQL text to Oracle® syntax. Two emulation methods are supported by Genero: "default" and "global" emulation. First method creates regular tables, while second method uses Oracle® global temporary tables. The emulation method used is defined by the following FGLPROFILE entry:

```plaintext
dbi.database.mydb.ifxemul.temptables.emulation = { "default" | "global" }
```

If your Genero application requires real Oracle® database users for each end user, you need to specify the common schema where application tables are defined, to access them without a schema prefix in SQL statements. You typically do this with the following FGLPROFILE entry:

```plaintext
dbi.database.mydb.ora.schema = "app_owner"
```

However, if your application programs create Informix-style temporary tables, each Oracle® DB user needs CREATE ANY TABLE and DROP ANY TABLE privileges to create the tables in the common schema. This is not suitable in an organization using a strong security policy.

The Oracle® tables created by the "default" emulation are by default created in the TEMPTABS tablespace, while global temporary tables are created in the TEMPTABS schema. Before Genero 3.10, it was not possible to control this.

Starting with Genero 3.10, it is possible to specify the schema and the tablespace where Oracle® tables are created for temporary table emulation:

```plaintext
dbi.database.dbname.ora.temptables.schema.source = { "login" | "command" }
dbi.database.dbname.ora.temptables.schema.command = "select-statement"
dbi.database.dbname.ora.temptables.tablespace = "tablespace-name"
```

These FGLPROFILE parameters apply to both default and global temporary table emulation methods. When using "default" emulation, you typically configure these entries to add the current user name as schema for the CREATE TABLE Oracle® statements and avoid granting CREATE/DROP ANY TABLE privileges to all users. With the "global" emulation, you can specify a common schema (different from the default TEMPTABS schema), to share the global temporary table among several database users.

**Related concepts**
- [Temporary tables](#)
- [Oracle DB specific FGLPROFILE parameters](#)
- [Oracle® MySQL 5.7 and 8.0 support](#)
- [ODI driver for Oracle® MySQL 8.0](#)
**Important:** MySQL 8.0 uses the version number .21 for the libmysqlclient.so library. The dbmmys generic driver name maps now to the dbmmys_8_0 driver, which is linked to libmysqlclient.so.21. In prior Genero versions, the generic driver name dbmmys was an alias for dbmmys_5_5 or dbmmys_5_7. When using MySQL versions older than 8.0, you need to use the exact driver name with the version number. See Database driver specification (driver) on page 606 for more details.

**ODI driver for Oracle® MySQL 5.7**

Genero BDL 3.10 supports Oracle® MySQL 5.7 with the dbmmys_5_7 driver.

**Important:** MySQL 5.7 uses the version number .20 for the libmysqlclient.so library. The dbmmys_5_7 driver is linked to libmysqlclient.so.20. With MySQL 5.7, you need to use the dbmmys_5_7 driver. See Database driver specification (driver) on page 606 for more details.

**Oracle® MySQL JSON data type**

MySQL 5.7 introduces the JSON data type to store and handle JSON documents.

This new type can be used in Genero BDL programs, by using TEXT data type:

```perl
MAIN
  DEFINE p_js TEXT
  LOCATE p_js IN MEMORY
  CONNECT TO "test1+driver='dbmmys'" USER "mysuser" USING "fourjs"
  EXECUTE IMMEDIATE "create table t1 ( pk int, js json )"
  LET p_js = '{"id": "9999", "name": "Tom Baker"}'
  INSERT INTO t1 VALUES ( 1, p_js )
  LET p_js = NULL
  SELECT js INTO p_js FROM t1 WHERE pk = 1
  DISPLAY p_js
END MAIN
```

When producing a database schema file from a MySQL 5.7+ database, the fgldbsch tool will convert JSON columns to TEXT.

**Related concepts**

- Oracle MySQL / MariaDB on page 811
- What is JSON? on page 465
- JSON (JavaScript Object Notation) is a well known lightweight data-interchange format for JavaScript.

**fgldbsch** on page 1978

The fgldbsch tool generates the database schema files from an existing database.

**fglhint_* in SQL comments**

Using SQL comment hints to control statement execution.

Starting with version 3.10, you can now specify fglhint_* keywords in C-style SQL comments, to give an indication to the database driver about the type of SQL statement to be executed.

**Note:** C-style SQL comments can only be used in dynamic SQL statements and SQL blocks.

For example, to force an INSERT statement to be treated as a regular SELECT returning a result set, use the fglhint_select hint in a C-style comment:

```perl
DECLARE c1 CURSOR
  FROM /* fglhint_select */ INSERT INTO table1 OUTPUT INSERTED,* SELECT * FROM customers"
```

**Important:** If you are using /* */ comments, these will now be parsed and any unknown keyword will be ignored: Comments such as /* INSERT */ or /* SELECT */ must be replaced by /* fglhint_insert */ and /* fglhint_select */ respectively.
Furthermore, Informix® emulation can be disabled with the fglhint_no_ifxemul hint.

**Related concepts**

- fglhint_* SQL comments on page 660
  Using special SQL comment hints to control statement execution.
- Static SQL statements on page 638
  Describes static SQL statements supported in the language.
- Dynamic SQL management on page 654
  Explains how to execute and manage SQL statements at runtime.

**SCROLLGRID content is checked by fglform**

When using a SCROLLGRID, fglform compiler checks that it does not hold other list containers.

Before version 3.10, fglform on page 1970 did not give an error when using TABLE, TREE or SCROLLGRID as sub-elements in a SCROLLGRID container, for example:

```
SCROLLGRID gr2
{
  <TABLE tb4   >
  [ab8        ]
}
END
```

This layout construction is illegal: It can not be rendered by the GUI and causes undefined front-end behavior or crash.

Starting with 3.10, fglform gives a compilation error `-6846`, if SCROLLGRID contains elements other than simple form fields or labels.

**Related concepts**

- SCROLLGRID container on page 1216
  Defines a scrollable grid view widget, in a grid-based layout.

**Default resource file search path**

Search rules for program resource files have been enhanced in 3.10.

**Default search in application directory**

Starting with version 3.10, if resource files such as `.42f` form files are not found in the current working directory, or in the directories specified in the FGLRESOURCEPATH environment variable, or in `FGLDIR/lib`, the runtime system also does a lookup in the directory where the `MAIN .42m` module or the `.42r` program file resides.

As a result, if all program files are in the directory where the main program module resides, there is no need to set FGLRESOURCEPATH.

For more details about resource file directory search, see FGLRESOURCEPATH on page 244.

**Form file path using absolute path**

If the file name specified in `OPEN FORM/OPEN WINDOW WITH FORM` is an absolute path, the runtime system must not search for the form in FGLRESOURCEPATH.

Before version 3.10, to load a form file specified with an absolute path in `OPEN FORM` or `OPEN WINDOW WITH FORM`, the runtime system tried to find the file by appending the absolute path to the directories defined by FGLRESOURCEPATH.

This could end up in loading unexpected resource files.

For example, with:

```
OPEN FORM f FROM "/dir/form"
```
The form "/dir/form" was searched in each element of FGLRESOURCEPATH.

Since version 3.10, FGLRESOURCEPATH is only used, if the file name is not an absolute path.

For more details, see The WITH FORM clause on page 1038.

**Related concepts**

Providing the image resource on page 1049
There are several things you need to know about providing an image resource in a Genero program.

os.Path.pathType on page 2652
Checks if a path is a relative path or an absolute path.

**Using os.Path.pathType() on Windows**

How to identify absolute file paths on Windows, whether using a drive letter or not.

Before version 3.10, on Windows® platforms, a file name starting with a directory-separator (slash or backslash) was not interpreted by os.Path.pathType() as an absolute name. As result, such files where considered as relative path and searched by concatenating the path to the elements defined in FGLLDPATH, FGLRESOURCEPATH, FGLIMAGEPATH.

Starting with version 3.10, a file name starting with a directory-separator or starting with a drive letter, is considered an absolute file path.

This change has also an impact on the os.Path.join on page 2651 method, which returns the second parameter only if it is identified as an absolute path.

**Related concepts**

FGLLDPATH on page 243
Defines the search paths to load program modules.

FGLRESOURCEPATH on page 244
Defines search path for resource files.

FGLIMAGEPATH on page 241
Defines the search paths for VM server image files.

os.Path.pathType on page 2652
Checks if a path is a relative path or an absolute path.

**New localStorage frontcalls**

New localStorage frontcalls replace GAS specific session.setVar and session.getVar calls.

The session module front calls setVar and getVar are deprecated. Starting with version 3.10, you can use the new localStorage front calls, supported by all Genero front-ends.

For more details, see Local storage front calls on page 2543.

**Related concepts**

Front calls on page 525
Front call functions execute on the platform where the front-end is installed.

**Wide Char mode of SNC driver**

The snc.widechar FGLPROFILE entry defaults to the right setting for the current application locale.

SQL Server performs better, when using the correct ODBC types in SQLBindParameter(), depending on the database columns types:

- When using CHAR/VARCHAR/TEXT SQL types (typically, when the application locale uses a single-byte encoding), the recommendation is that ODBC SQL types SQL_[VAR]CHAR (single-char ODBC SQL types) are used
- When using NCHAR/NVARCHAR/NTEXT SQL types (when the application locale uses a multi-byte encoding such as UTF-8), it is recommended to use the ODBC SQL types SQL_W[VAR]CHAR (these are wide-char ODBC SQL types)
The `dbi.database.dbname.snc.widechar` FGLPROFILE entry controls the ODBC SQL types used by the SNC driver.

Before version 3.10, the `snc.widechar` option was set to `true` by default, assuming that the application locale uses a multi-byte encoding like UTF-8. If the database columns are defined with CHAR/VARCHAR/TEXT types, this parameter had to be set to `false`.

Starting with 3.10, to simplify application configurations when using a single-byte encoding, the `snc.widechar` option defaults to the expected setting, based on the current application locale (assuming that the database column types fit the application locale):

- If the application locale defines a single-byte encoding (such as ISO8859-1), we assume that the database columns are defined with CHAR/VARCHAR/TEXT types to store single-byte characters, and the SNC driver will use SQL_[VAR]CHAR.
- If the application locale defines a multibyte encoding (such as UTF-8 or BIG5), we assume that the database columns are defined with NCHAR/NVARCHAR/NTEXT types to store UNICODE characters, and the SNC driver will use SQL_W_[VAR]CHAR.

**Note:** Set the `dbi.database.dbname.snc.widechar` to `false`, only if you are using a multibyte encoding such as BIG5, with CHAR/VARCHAR/TEXT column types in the database.

**Note:** Easysoft (ESM) and FreeTDS (FTM) drivers do not support the `snc.widechar` option: The SQL char type binding mode is automatic, depending on the current application locale, and it cannot be changed.

**Related concepts**
- CHAR and VARCHAR data types on page 780
- The FGLPROFILE file(s) on page 220
- FGLPROFILE environment variable defines Genero BDL configuration files
- Multibyte character sets (MBCS) on page 410

**MariaDB 10.2 support**
The new ODI driver `dbmmdb_10_2` is provided to connect to MariaDB 10.2.

MariaDB 10.2 comes with a new client library name `libmariadb.so`. In prior versions of MariaDB, the client library name was `libmysqlclient.so`.

Starting with Genero 3.10, MariaDB 10.2 is supported by using the new `dbmmdb_10_2` ODI driver. This driver is linked to `libmariadb.so.3`, the MariaDB 10.2 client library.

**Important:** The driver-specific FGLPROFILE entries must use the "mdb" code, for example:

```plaintext
dbi.database.test1.mdb.config = "'/opt/var/app/my.cnf"
```

To connect to older MariaDB version 10.0 and 10.1, you can still use the `dbmmys_5_5` ODI driver, linked to the `libmysqlclient.so.18` shared library, provided in MariaDB 10.0 and 10.1 distributions.

**Important:** The driver-specific FGLPROFILE entries must use the "mys" code, for example:

```plaintext
dbi.database.test1.mys.config = "'/opt/var/app/my.cnf"
```

**Related concepts**
- Database driver specification (driver) on page 606

**Related tasks**
- Prepare the runtime environment - connecting to the database on page 812

**Fatal runtime error message**
Fatal runtime errors are displayed to the end user.

Starting with Genero 3.10.11, fatal runtime errors that cannot be trapped (like -1110 "Form file (name) not found") are displayed in a pop-up window to the end user before the program ends.
Note: This new behavior is also available with older front-end versions.

It is now much easier to identify the reason of the fatal error. In prior versions, the program windows just disappeared without any error message and the only way to identify the problem was to inspect the fglrun output on the application server.

The end user can now take a screenshot and report the issue to the application provider.

Related concepts
Non-trappable errors on page 457
Some specific Genero runtime errors are not trappable.

BUTTONEDIT and ON ACTION INFIELD
With ON ACTION INFIELD, a BUTTONEDIT action is now always considered as a field-qualified action.

Before version 3.10, when implementing the action handler for a BUTTONEDIT action with ON ACTION action-name INFIELD field-name, it was mandatory to add the "field-name." prefix in the ACTION attribute, to make the button always active, even when the focus was not in the field:

```plaintext
-- Form file:
BUTTONEDIT f1 = customer.cust_city, ACTION = cust_city.zoom;

-- Program file:
ON ACTION zoom INFIELD cust_city
```

When specifying only the action name in the ACTION attribute, the BUTTONEDIT button was only enabled when the focus was in the field. However, this is not the expected behavior of a BUTTONEDIT button.

Starting with Genero 3.10, the expected behavior is now implicitly achieved, even when the field name is not specified in the ACTION attribute:

```plaintext
BUTTONEDIT f1 = customer.cust_city, ACTION = zoom;
```

For more details see Field-specific actions (INFIELD clause) on page 1669, BUTTONEDIT item type on page 1164.

BDL 3.00 upgrade guide
These topics describe product changes you must be aware of when upgrading to version 3.00.

Important: This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Web Services changes on page 128
2. Form definitions for mobile applications on page 130
3. Desupported database drivers on page 130
4. Oracle DB NUMBER type on page 131
5. Oracle DB scroll cursor emulation removal on page 131
6. MySQL VARCHAR size limit on page 131
7. MySQL DATETIME fractional seconds on page 132
8. PostgreSQL DATETIME type mapping change on page 133
9. MariaDB support on page 133
11. FGL_GETVERSION() built-in function on page 134
12. Built-in front-end icons desupport on page 134
13. Modifications in front calls on page 135
14. SERIAL emulation with SQL Server on page 135
15. Improved compilation time on page 135
16. Preprocessor changes on page 136
17. Current system time in UTC on page 137
18. Structured ARRAYs in list dialogs on page 138

**Web Services changes**
There are changes in support of web services in Genero 3.00.

**Migration to 3.00 on client side**
If migrating from a version 2.xx of a GWS client application to version 3.00, you need to regenerate all client stubs in your application using the `fglwsdl` tool.

**Important:** It is mandatory to regenerate the client stubs, to support fault response with HTTP error code of 200. For more information see SOAP fault handling in client stub on page 129.

See also Change client behavior at runtime.

**Default SSL/TLS protocol on server side**
The default for the FGLPROFILE entry `security.global.protocol` is now `SSLv23`, enabling all supported SSL/TLS protocols, including `TLSv1.2` as required by the Federal Law of USA. In prior versions, the default was `TLSv1 (v1.0)`. It is up to the web server administrator to restrict the SSL/TLS protocol to `TLSv1.2`.

For more details, see HTTPS and password encryption on page 3237

**Server socket read/write timeout on server side**
Before version 3.00, when a WS client did not send all the HTTP body (for instance, after connection has been accepted), by default the WS server would wait indefinitely, and this could end up in a denial of service.

The `com.WebServiceEngine` class supports now a new option called `server_readwritetimeout`, to define the server socket read/write timeout: If a timeout occurs, the WS server program will raise the BDL exception `-15553`. By default this timeout is defined as 5 seconds.

For more details, see WebServiceEngine options on page 2684.

**HTTPPart header default settings with com.HTTPPart.CreateAttachment()**
The `com.HTTPPart.CreateAttachment()` method now by default creates header fields based on the file name and file extension.

For more details, see com.HTTPPart.CreateAttachment on page 2748.

**File path returned by com.HTTPPart.getAttachment()**
Before version 3.00, the `com.HTTPPart.getAttachment()` method returned the path to a temporary file. Starting with Version 3.00, this method will now return the absolute path location of the received part file name, based on the "Content-Disposition" header.

For more details, see com.HTTPPart.getAttachment on page 2750.

**XForms characters in com.HTTPServiceRequest.readFormEncodedRequest()**
Starting with version 3.00, if the result string of the HTTP request contains `&` or `=` XForms special characters, these are escaped by doubling them.

For more details, see com.HTTPServiceRequest.readFormEncodedRequest on page 2704.

**Specific exception -15575 when GAS disconnects web service server**
The GWS methods listed below will raise an exception with a specific error code `-15575`, when the GAS disconnects properly the web service server. Before version 3.00, the generic error `-15565` was raised. A specific error code
allows you to distinguish fully a normal disconnection from other errors, in a TRY/CATCH block. See code examples in method reference pages:

- com.WebServiceEngine.GetHTTPServiceRequest on page 2678
- com.WebServiceEngine.HandleRequest on page 2679

**SOAP fault handling in client stub**

Web Services client stub generation has been changed to support fault response with HTTP error code of 200. The generated code supports SOAP fault with HTTP error code of 200 and 500. To enable this new feature in your client stub code, regenerate the stubs with the fglwsdl tool.

For more details, see [Client side SOAP fault handling](#).

**Optional multipart handling in client stub**

In the generated client stub code, all functions handling the SOAP request with multipart get an additional input parameter and/or return parameter as a DYNAMIC ARRAY OF com.HTTPPart, to pass and return optional parts.

When generating client stubs managing multipart, you get an extra input and/or output variable called "AnyInputParts" and "AnyOutputParts" that is a DYNAMIC ARRAY of com.HTTPPart objects. Those variables may contain additional input and/or output HTTP parts not specified in the WSDL. You will have to adapt your client program by handling those dynamic arrays in any Genero functions calling such stubs.

Request example prior to 3.00:

```genero
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
    DEFINE InputHttpPart_1 com.HTTPPart
    ...
    DEFINE InputHttpPart_n com.HTTPPart
    ...
    RETURN wsstatus
END FUNCTION
```

Request example 3.00 and greater, with extra input variable AnyInputParts:

```genero
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
    DEFINE InputHttpPart_1 com.HTTPPart
    ...
    DEFINE InputHttpPart_n com.HTTPPart
    DEFINE AnyInputParts DYNAMIC ARRAY OF com.HTTPPart
    ...
    RETURN wsstatus
END FUNCTION
```

**Note:** This change has also been backported in 2.50.25.

For more details, see [Multipart in the client stub](#) on page 3156.

**Removal of FGLWSNOINFO environment variable**

Before version 3.00, the GWS library displayed by default a message about certificates used by the program:

```
--
WS-INFO (Certificate authority) | Loading from Windows keystore
--
```

To avoid this message, it was possible to set the FGLWSNOINFO environment variable to TRUE.

Starting with version 3.00, this message is no longer displayed by the GWS library, and the FGLWSNOINFO is no longer required.
Desupported Web Services APIs

The methods listed in the following table are desupported in Genero 3.00.

Table 87: Table of desupported methods (with their alternative)

<table>
<thead>
<tr>
<th>Methods desupported as of 3.00</th>
<th>Alternative method to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.Util.CreateDigestString</td>
<td>security.Digest.CreateDigestString on page 2990</td>
</tr>
</tbody>
</table>

Form definitions for mobile applications

Genero version 3 supports grid-based layout with all front-ends, and introduces STACK layout.

Support for grid-based and stack-based layout

Before Genero version 3.00 (i.e., with Genero Mobile version 1.1), the GMI front-end could only support a stack-based layout and it was required to create different forms for iOS apps and other front-ends supporting grid-based layout. In fact, to get a stack-based layout, grid-based .per forms were automatically transformed on the fly when displayed on the GMI front-end.

Starting with Genero 3.00, all mobile front-ends support now grid-based layout and stack-based layout, and a new STACK layout container was introduced to define stack-based layout forms explicitly. Therefore, you can now use the same form definition for all mobile front-ends, by implementing the layout type of your choice. It is even possible to mix grid-based or stack-based forms in the same app.

Loading different forms based on front-end type

If you want to use a grid-based or stack-based form for the front-end, you can load the form with OPEN FORM (or OPEN WINDOW) and implement the layout type based on the front-end name returned by the ui.Interface.getFrontEndName() method:

```main
... 
OPEN FORM f1 FROM IF( ui.Interface.getFrontEndName()=="GMI", 
    "myform_stack", "myform_grid" )
    DISPLAY FORM f1
... 
END MAIN
```

Form rendering on page 1306
The section explains the layout rules to render forms on graphical front-ends.

Desupported database drivers

Database drivers for old database client versions are removed in accordance with vendor de-support plans.

Database drivers desupported in version 3.00:

- SAP ASE 15.x (dbmase_15). New SAP® ASE 16.x version is now supported.
- Oracle® Database 10.1 and 10.2 (dbmora_10)
  
  Note: This driver is no longer available for Linux® PowerPC 32/64 platforms, because Oracle® has desupported this platform.
- IBM DB2® UDB 9.x (dbmdb2_9)
Related concepts

Database driver specification (driver) on page 606

Oracle DB NUMBER type
The NUMBER/FLOAT Oracle® data type can now be extracted by fgldbsch to create .sch files.

Before Genero 3.00, columns using the native Oracle® NUMBER/NUMBER(p>32) type (with up to 38 significant digits), or the FLOAT(b) type (when (b/3)>32), were not allowed by the fgldbsch schema extractor. This restriction was applied to avoid the risk of overflow errors, if the Oracle® NUMBER/FLOAT column contains values that do not fit into a BDL DECIMAL(32, s) type.

Starting with Genero 3.00, fgldbsch can map NUMBER/FLOAT native Oracle® types to BDL DECIMAL(32) or DECIMAL(32, s) types, when specifying the flag B with the -cv option for these native types:

- NUMBER (floating point number) is extracted as DECIMAL(32)
- NUMBER(p>32) (scale defaults to 0) is extracted as DECIMAL(32,0)
- NUMBER(p>32, s) or NUMBER(*, s) is extracted as DECIMAL(32, s)
- FLOAT(b) is extracted as DECIMAL(b/3) or FLOAT

For more details about Oracle® type conversion rules and -cv type positions, run fgldbsch with the -cx ora option.

Note: This new behavior has been introduced to simplify integration with existing Oracle® databases, to extract .sch schema from databases using column types that have no exact equivalent BDL type. When designing new database tables, it is recommended that you only use DECIMAL(p, s), with p<=32 to achieve maximum portability.

When fetching numeric values with more than 32 significant digits into BDL decimals, values will be rounded for DECIMAL(32), or raise an overflow error -1226 for DECIMAL(32, s).

Related concepts

NUMERIC data types on page 854
Database schema on page 476
Defines database table structures with column type information to be reused in program variable definitions.

Oracle DB scroll cursor emulation removal
The scroll cursor emulation has been removed in the Oracle® DB driver.

Before Genero 3.00, it was possible to enable scrollable cursor emulation (with temporary files) by defining the following FGLPROFILE entry:

dbi.database.mydbname.ora.cursor.scroll.emul = true

This feature was supported to workaround an Oracle® DB bug in versions 8 and 9i. The bug no longer exist in recent Oracle® DB versions and therefore the default native scrollable cursor feature can be safely used.

If this FGLPROFILE entry is set, the runtime system will print a warning to stderr.

Related concepts

List of FGLPROFILE entries on page 223
This is a summary of supported FGLPROFILE entries.

Scrollable cursors on page 560
How scrollable cursors can be supported on different databases.

MySQL VARCHAR size limit
MySQL 5 VARCHAR columns can be used to store VARCHAR(N>255) values.

Before Genero 3.00, the Oracle® MySQL driver converted a VARCHAR(N>255) type to a MySQL TEXT type, because MySQL versions before 5.0.3 only allowed up to 255 characters for a VARCHAR column. MySQL TEXT type is a large object type with specific semantics and constraints, but it was the only available type to store character data above the 255 character limit. As a result, data type information was lost when extracting the database schema with fgldbsch from a MySQL database: When creating a table in a Genero BDL program, the original
Upgrading 132

VARCHAR(N>255) type was converted to TEXT (with a fixed size of 65535 characters), and then converted by fgldbsch back to a VARCHAR2(65535) type in the .sch file. The original size of the VARCHAR type was lost.

Starting with Genero 3.00, when creating a table in a BDL program with CREATE TABLE, the MySQL driver leaves any VARCHAR(N) as is, even if the size is greater than 255.

Note: The MySQL driver does not distinguish MySQL server 5.0.x (5.0.2 / 5.0.3) versions. It assumes that we are connected to a server version 5.0.3 or above, supporting large VARCHAR types.

If your application is using VARCHAR(N) types with N>255 and your MySQL server version is 5.0.3 or above, it is recommended that you review your database creation scripts to use VARCHAR(N) instead of TEXT.

Note: The CHAR(N>255) types are still mapped to a MySQL TEXT type, because MySQL CHAR type has a limit of 255 characters. When designing a database, consider using CHAR only for short character string data storage (less than 50 characters), and use VARCHAR for larger character string data storage (name, address, comments).

Related concepts
CHAR and VARCHAR data types on page 818
Data types on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

TEXT and BYTE (LOB) types on page 827
Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

MySQL DATETIME fractional seconds
MySQL 5.6.4 TIME and DATETIME types support fractions of seconds that can be used to store DATETIME HOUR TO FRACTION(N) or DATETIME YEAR TO FRACTION(N).

Before Genero 3.00, the Oracle® MySQL driver converted DATETIME types as follows:

- DATETIME HOUR TO SECOND was converted to MySQL TIME.
- Other DATETIME types were converted to MySQL DATETIME.

Starting with Genero 3.00, when creating a table in a BDL program with the CREATE TABLE statement, if the MySQL server version is greater or equal to 5.6.4, the types are converted differently, as follows:

The SQL Translator of the MySQL driver makes the following conversions automatically for the DATETIME types:

- DATETIME HOUR TO MINUTE is converted to MySQL TIME (seconds set to 00).
- DATETIME HOUR TO SECOND is converted to MySQL TIME.
- DATETIME HOUR TO FRACTION (n) is converted to MySQL TIME (n).
- DATETIME YEAR TO MINUTE is converted to MySQL DATETIME (seconds set to 00).
- DATETIME YEAR TO SECOND is converted to MySQL DATETIME.
- DATETIME YEAR TO FRACTION (n) is converted to MySQL DATETIME (n).

This change has no impact if your application is using DATETIME HOUR TO SECOND or DATETIME YEAR TO SECOND. However, it is now possible to store DATETIME HOUR TO FRACTION(N) and DATETIME YEAR TO FRACTION(N) data. The DATETIME YEAR TO FRACTION(N) is typically used to implement data modification timestamps to track user changes.

Related concepts
DATE and DATETIME data types on page 822
Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

Data types on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

Date/time literals in SQL statements on page 571
Good practices for date and time handling in SQL.

**PostgreSQL DATETIME type mapping change**
Conversion of DATETIME type with fractional seconds to PostgreSQL TIME(N)/TIMESTAMP(N) was invalid and has been reviewed.

Before Genero 3.00, the PostgreSQL driver converted DATETIME types as follows:

- **DATETIME HOUR TO MINUTE** was converted to **TIMESTAMP(3) WITHOUT TIME ZONE**
- **DATETIME HOUR TO SECOND** was converted to **TIME(0) WITHOUT TIME ZONE**
- **DATETIME HOUR TO FRACTION(n)** was converted to **TIME(n+1) WITHOUT TIME ZONE**
- **DATETIME YEAR TO MINUTE** was converted to **TIMESTAMP(3) WITHOUT TIME ZONE**
- **DATETIME YEAR TO SECOND** was converted to **TIMESTAMP(3) WITHOUT TIME ZONE**
- **DATETIME YEAR TO FRACTION(n)** was converted to **TIMESTAMP(n+1) WITHOUT TIME ZONE**

Starting with Genero 3.00, when creating a table in a BDL program with CREATE TABLE, the types are converted in a different way:

- **DATETIME HOUR TO MINUTE** is converted to **TIME(0) WITHOUT TIME ZONE** (seconds set to 00).
- **DATETIME HOUR TO SECOND** is converted to **TIME(0) WITHOUT TIME ZONE**.
- **DATETIME HOUR TO FRACTION(n)** is converted to **TIME(n) WITHOUT TIME ZONE**.
- **DATETIME YEAR TO MINUTE** is converted to **TIMESTAMP(0) WITHOUT TIME ZONE** (seconds set to 00).
- **DATETIME YEAR TO SECOND** is converted to **TIMESTAMP(0) WITHOUT TIME ZONE**.
- **DATETIME YEAR TO FRACTION(n)** is converted to **TIMESTAMP(n) WITHOUT TIME ZONE**.

This bug fix introduces an incompatibility and can have an impact on applications using **DATETIME HOUR TO MINUTE**, **DATETIME HOUR TO FRACTION(n)** or **DATETIME YEAR TO FRACTION(n)**. If you are using one of these types, consider reviewing your database schema, to modify the column types according to the new SQL type conversion rules.

**Related concepts**

- **DATE and DATETIME data types** on page 900
- **Using portable data types** on page 553
  
Only a limited set of data types are really portable across several database engines.

- **Data types** on page 253
  
Selecting the correct data type assists you in the input, storage, and display of your data.

- **Date/time literals in SQL statements** on page 571
  
Good practices for date and time handling in SQL.

**MariaDB support**
The MariaDB database is now supported by Genero 3.00.

MariaDB is the open source brand of Oracle's MySQL that has been adopted by several major organizations.

The purpose of the MariaDB project is to be a drop-in replacement for MySQL.

MariaDB supported versions are 10.0 and higher.

To connect to MariaDB, use the MySQL database driver (dbmmys), and follow MySQL adaptation guide for configuration and SQL portability issues.

Depending on the libmysqlclient library compatibility, you might need to configure Genero to use a version-stamped driver. As of Genero version 3.00, the generic driver name "dbmmys" can be used to connect to MariaDB 10.0. See **Database driver specification (driver)** on page 606 for more details.

**Related concepts**

- **Oracle MySQL / MariaDB** on page 811
The FreeTDS driver can now be used for SQL Server versions > 2005.

Before Genero version 3.00, the FreeTDS driver could only be used to connect to SQL Server 2005. Starting with Genero 3.00 the dbmftm driver can connect to SQL Server 2008, 2012 and 2014.

With SQL Server version >= 2008, date/time types used to store DATE and DATETIME values are different to those used with SQL Server version 2005. See DATE and DATETIME data types on page 786 for more details.

Important: For SQL Server version 2008, 2012 and 2014, you must set TDS_Version=7.3 in odbc.ini. Using TDS version 8.0 introduces problems (tested with FreeTDS 0.95.5 to 0.95.19)

Related tasks
Prepare the runtime environment - connecting to the database on page 770

FGL_GETVERSION() built-in function
The FGL_GETVERSION() function now returns the product version number (for example: 3.00.00).

Prior to Genero 3.00, the fgl_getversion() on page 2169 built-in function returned the internal build number.

Starting with Genero 3.00, the function returns the product version number as a string, such as 3.00.00.

Related concepts
Built-in functions on page 2149
A built-in function is a predefined function that is part of the runtime system, or provided as a library function automatically loaded when a program starts. The built-in functions are part of the language.

Built-in front-end icons desupport
Image resources included in front-ends are desupported with Genero 3.00.

Starting with Genero 3.00, the icon files distributed in front-end packages are no longer provided (as before in the GDC-installation-dir/pics for example)

Common icons for buttons, toolbars, topmenus, and other items using icons can be centralized on the application side where the program executes. It is recommended that this feature be used to provide the same icons on different types of front-ends, or use specific icons, but from the same central icon directory. For more details, see Providing the image resource on page 1049.

Note that mobile front-ends will display default icons, for default action views, if no IMAGE attribute is specified for the action. See Action views on mobile devices on page 1678 for more details.

Related concepts
FGLIMAGEPATH on page 241
Defines the search paths for VM server image files.

Presentation styles changes
Deprecated and renamed presentation style attributes.

Starting with version 3.00:

The following presentation style attributes are desupported:

- CheckBox: customWidget

The following presentation style attributes are deprecated:

- Image: imageContainerType ( = "browser")
  Replace IMAGE fields using this style attribute with URL-based WEBCOMPONENT fields.
- ComboBox: comboboxCompleter
  Consider using the COMPLETER form field attribute instead.
Related concepts
Style attributes reference on page 1082
A presentation style attribute may be a common attribute that can be applied to any graphical element. Most presentation style attributes apply only to a specific graphical element.

Modifications in front calls
Describes changes applied to front calls.

Front call modifications in BDL version 3.00:
• Before version 3.00, the connectivity front call accepted a host name as parameter. Starting with version 3.00, this front call no longer uses a host name. It will only check the available network type. For more details, see the mobile.connectivity front call.

Related concepts
Front calls on page 525
Front call functions execute on the platform where the front-end is installed.

SERIAL emulation with SQL Server
The SERIAL and BIGSERIAL types can be emulated with triggers and sequences when using SQL Server 2012 and higher.

By default when using SQL Server, the SERIAL and BIGSERIAL types are emulated with IDENTITY columns. This native sequence generator is the fastest and preferred solution. However, it requires removing the serial column in all INSERT statements, which can lead to a large change in your legacy code.

Until version 3.00, it was possible to workaround this limitation by using the "regtable" serial emulation. But this solution required using a dedicated SERIALREG table that needed to be updated for each INSERT statement. This resulted in poor performances, when concurrent programs create rows in the same tables (locking issues in SERIALREG).

Starting with Genero 3.00, it is now possible to use a serial emulation based on triggers and sequences. Sequences were introduced in SQL Server version 2012, so you need at least a 2012 server in order to use this emulation:

```
dbi.database.mydb.ifxemul.datatype.serial.emulation = "trigseq"
```

Related concepts
SERIAL data types on page 788
List of FGLPROFILE entries on page 223
This is a summary of supported FGLPROFILE entries.

Auto-incremented columns (serials) on page 562
How to implement automatic record keys.

Improved compilation time
The fglcomp and fglform compilers have been reviewed to achieve faster compilation.

A Genero project can be very large, with thousands of .4gl source files to compile. Compilation time can be an issue when the whole set of sources needs to be compiled every day, or several times a day.

In Genero 3.00, the fglcomp on page 1972 compiler has been improved to deliver better performances. Depending on the content of the source file, the compiler can complete the process twice as fast.

Loading .sch database schema files has also been improved. Using huge schema files with several thousands lines is no longer an issue. This is especially useful when compiling forms that define fields based on database columns in a schema file.

Related concepts
fglform on page 1970
The fglform tool compiles form specification files into XML formatted files used by programs.

Database schema on page 476
Defines database table structures with column type information to be reused in program variable definitions.

**Preprocessor changes**
Several bugs have been fixed in the preprocessor, that can now result in a compilation error.

**String token expansion**
Before version 3.00, the following preprocessor syntax was used to expand a string macro parameter:

```c
&define T(x) DISPLAY "head_"#x"_tail"
-- macro usage:
T(body)
```

This produced the following result (after preprocessing):

```
"head_""body""_tail"
```

It was accepted by the compiler, because it was interpreted as a single string literal.

The new preprocessor now produces (as expected):

```
"head_" "body" "_tail"
```

However, this will now result in a compiler error, because this is not a valid string literal.

To solve an issue such as this and get the same result string as before version 3.00, use the `||` concatenation operator in the preprocessor macro and add (escaped) double quotes before and after the `#ident` placeholder:

```c
&define T(x) DISPLAY "head_" || #x || "_tail"
```

or, by using single quotes as border strings delimiters:

```c
&define T(x) DISPLAY 'head_' || #x || '_tail'
```

**Identifier concatenation**
Before version 3.00, the following type of macro:

```c
&define FOO() foo
-- macro usage:
FOO()bar
```

was producing a single identifier token (accepted by the compiler):

```
fooobar
```

But it will now produce two distinct identifier tokens (as expected):

```
foo bar
```

And this will result in a compilation error.

**Backslash in macro parameters**
Before version 3.00.00 it was possible to use the backslash to escape a comma in preprocessor macro parameters. This syntax is no longer allowed by the preprocessor, it is not a valid usage. To solve this issue, replace parameters by real string literals in the macro:

```c
-- bad coding
```
The ## paste operator

Before version 3.00.00, the ## paste operator was used to construct code with two elements that did not result in a valid token, for example:

```
&define FOO(name) rec_ ## [ x ]
FOO(x)
```

produced:

```
rec_[ x ]
```

This kind of preprocessor macro is no longer allowed in version 3.00.00 and will result in a compiler error:

```
x.4gl:2:1:2:1:error:(-8042) The operator '##' formed 'rec_[', an invalid preprocessing token.
```

The ## paste operator must be used to join two identifiers, to create a new identifier:

```
&define REC_PREFIX(name) rec_ ## name
LET REC_PREFIX(customer) = NULL
```

This will produce:

```
LET rec_customer = NULL
```

File inclusion search path

Before version 3.00, the compiler option -I was allowing you to specify a list of pathes separated by the OS path separator.

This behavior was unexpected and wrong: The -I option must define a single path (or directory).

Command lines using the followin (UNIX) notation:

```
fglcomp -I path1:path2 ...
```

must be reviewed by specifying each directory in a separate -I option:

```
fglcomp -I path1 -I path2 ...
```

Related concepts

Source preprocessor on page 2019
A typical preprocessor like in the C language.

Current system time in UTC

Use the util.Datetime.getCurrentAsUTC() method to get the current system date/time in UTC.

Starting with Genero version 3.00, you can use the util.Datetime.getCurrentAsUTC() method to get the current system time in UTC (Coordinated Universal Time).
This method has been added to solve the issue when using `util.Datetime.toUTC(CURRENT)` during the daylight saving time transition period in the fall, as described in `util.Datetime.toUTC` on page 2581.

**Structured ARRAYs in list dialogs**

ARRAYs with sub-records can be used in list dialogs, to simplify array definition based on database tables, requiring additional information at runtime.

Starting with Genero version 3.00, ARRAY variables defined with sub-records can be bound to DISPLAY ARRAY and INPUT ARRAY screen records.

This is especially useful when you need to define arrays from database tables, and handle additional row information at runtime, for example, to hold an image resource for each row, to be displayed with the IMAGECOLUMN attribute.

An array is usually defined with a flat list of members:

```
SCHEMA shop
DEFINE a_items DYNAMIC ARRAY OF RECORD LIKE items.*
...
```

With version 3.00, arrays structured with sub-records can now be used within a DISPLAY ARRAY or INPUT ARRAY dialog. The array members and the form fields used by the screen array are bound by position:

```
SCHEMA shop
DEFINE a_items DYNAMIC ARRAY OF RECORD
    item_data RECORD LIKE items.*,
    it_image STRING,
    it_count INTEGER
END RECORD
...
DISPLAY ARRAY a_items TO sr.*
...
```

For more details about program variable to form field binding in dialogs, see Binding variables to form fields on page 1620, Example 4: DISPLAY ARRAY with structured array on page 1423.

**BDL 2.51 upgrade guide**

These topics describe product changes you must be aware of when upgrading to version 2.51.

**Important**: This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Desupported database drivers on page 138
2. New database driver name specification on page 139
3. The FIELD form item type and .val schema file on page 140
4. TRY/CATCH and ERROR LOG on page 140
5. DATETIME types with SQLite on page 140
6. Desupport of C-Extension API functions on page 141

**Desupported database drivers**

Database drivers for old database client versions are removed in accordance with vendor desupport plans.

**Database drivers desupported in version 2.51:**

- Genero DB is no longer supported (`dbmads*`).
- Oracle® MySQL 4.1 and 5.0 (`dbmmys41x, dbmmys50x`)  
- PostgreSQL 8.3, 8.4 (`dbmora83x, dbmpgs84x`)  
- Oracle® Database 9.2 (`dbmora92x`)  
- IBM® DB2® UDB version 7.x and 8.x (`dbmdb27x, dbmdb28x`)
Note also that database driver naming convention has changed in 2.51, for more details see New database driver name specification on page 139.

**Related concepts**
- Microsoft SQL Server on page 769
- Database driver specification (driver) on page 606

**New database driver name specification**
Allows database driver specification without target database version information.

Starting with version 2.51, the database drivers follow a new file name convention, which allows you to specify a generic name based on the target database type without any database version information.

**Important:** Most database driver names have changed. You need to re-configure the "driver" entry in your FGLPROFILE settings (or database connection string parameters), to match the new driver names. If you are using the default driver (dbmdefault), there is no configuration change needed. To simplify upgrading, the runtime system identifies old driver names and converts them to new names. However, it is recommended that you consider using the generic driver name corresponding to the type of database your applications connect to. The error -6366 occurs if the runtime system is not able to load the specified database driver, or cannot identify an old driver name.

Before version 2.51, it was required to specify the exact database type and version, to match both the database client and the server version. For example, when using Oracle® 11.2 (server and client):

```plaintext
dbi.database.stores.driver = "dbmoraB2x"
```

Starting with 2.51, you can now, for example, specify a generic driver name without version, which can connect to any database server version supported by the DB vendor client/server protocol. The generic name defines a database driver for the latest database client version that is available on the platform:

```plaintext
dbi.database.stores.driver = "dbmora"
```

Each generic database driver name has also a human-readable alias, such as "informix" or "oracle".

```plaintext
dbi.database.stores.driver = "oracle"
```

To simplify driver specification, install the latest database client software that corresponds to the generic driver name, especially if it does not require a database server upgrade.

For some database client software, additional database drivers are still provided for older database client versions (if available on the platform). In such cases, the driver file name gets a version identifier.

For example:
- dbmora_11 (Oracle® 11g client)
- dbmmys_5_1 (Oracle® MySQL client 5.1.x)
- dbmsnc_10 (SQL Server Native Client 10 (SQLNCLI10.DLL))
- dbmsnc_9 (SQL Server Native Client 9 (SQLNCLI.DLL))

Such database drivers with version info are provided to follow db client library dependency rules, as defined by the database vendors. For example, on a Linux® platform, Oracle® MySQL version 5.1.x provides the db client library named libmysqlclient.so.16. In this file name, "16" is the version number that defines the shared library compatibility. The database driver that was compiled and linked in a compatible db client environment is dbmmys_5_1. This database driver is linked to libmysqlclient.so.16. Starting with Oracle® MySQL version 5.5.x, the db client library version number has been incremented to 18 (linked to libmysqlclient.so.18). The driver to be used with that library version is dbmmys_5_5, which was compiled and linked with a 5.5.x environment.

**Related concepts**
- Database driver specification (driver) on page 606
- List of FGLPROFILE entries on page 223
This is a summary of supported FGLPROFILE entries.

**The FIELD form item type and .val schema file**
Form files using the FIELD item type and/or .val attribute definitions must be reviewed.

Starting with version 2.51, the FIELD item type defining abstract fields in forms, based on .val schema file attributes is deprecated.

Furthermore, any non-I4GL attribute defined in the .val schema file must be avoided. Reading attributes in the .val is now only supported for compatibility with I4GL projects.

With Genero, it is recommended to define all form item attributes in the form definition file.

**Related concepts**
- Form specification files on page 1132
  Form specification files are the source files defining the layout and content of application forms.

**TRY/CATCH and ERROR LOG**
Errors are no longer logged when raised in a TRY/CATCH block.

Before version 2.51, exceptions occurring in a TRY/CATCH block were logged if the error log is initiated with the startlog() function. With version 2.51, if an exception is raised in a TRY/CATCH block, it will no longer be logged in the error log file. In other words, the TRY/CATCH block will behave like WHENEVER ERROR CONTINUE, regarding error logging.

Example:

```plaintext
CALL startlog("errors.txt")
... TRY
  INSERT INTO customer ...
CATCH
  -- Handle errors and write to error log with errorlog() if needed.
  IF SQLCA.SQLCODE == -8634 THEN
    ...
  END IF
END TRY
```

**Important:** In order to get this new behavior, the pcode is no longer compatible with older versions (<=2.50). All programs must be recompiled.

**Related concepts**
- Exceptions on page 451
  Describes exception (error) handling in the programs.

**DATETIME types with SQLite**
Better support for Informix® DATETIME types emulation within SQLite.

Before version 2.51, DATETIME SQL types where converted to SQLite types as follows:

- DATETIME HOUR TO SECOND type was translated to TIME (hh:mm:ss).
- DATETIME YEAR TO FRACTION and all other combinations (except HOUR TO SECOND) were translated to TIMESTAMP (YYYY-MM-DD hh:mm:ss.fff).

Since most DATETIME types were converted to TIMESTAMP, it was not possible to distinguish common date/time types such as DATETIME HOUR TO MINUTE or DATETIME YEAR TO MINUTE, especially when extracting the database schema with fgldbsch. Type information was lost and this prevented schema-base variable definitions with DEFINE LIKE.

Starting with version 2.51, common DATETIME SQL types are now mapped to different types in SQLite, to provide better support for these types. In fact, SQLite allows you to define table columns with custom types (you can use any type name). However, the number of tokens in the syntax is limited so it's not possible to use, for example, the tokens DATETIME YEAR TO SECOND directly. The Genero database driver uses this SQLite SQL language feature to
map Informix-style DATETIME types to specific custom types. For example, a DATETIME HOUR TO MINUTE becomes a SMALLTIME, a DATETIME YEAR TO FRACTION(2) becomes a DATETIME(2), etc. Furthermore, the data values inserted in the database now match exactly the precision of the original DATETIME type. For more details about date/time mapping and emulation, see DATE and DATETIME data types on page 931.

**Related concepts**
- SQLite on page 922
- fgldbsch on page 1978

The fgldbsch tool generates the database schema files from an existing database.

**Desupport of C-Extension API functions**

BIGINT and BOOLEAN stack functions and C API functions for C-Extensions are no longer supported.

**Note:** Starting with version 3.10 (also backported in 3.00.10), the popbigint() and pushbigint() function are again available.

Since version 2.51:

The C-Extension stack functions to handle BIGINT and BOOLEAN types have been removed:

**Table 88: Desupported FGL stack functions**

<table>
<thead>
<tr>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>popboolean()</td>
</tr>
<tr>
<td>popbigint()</td>
</tr>
<tr>
<td>pushboolean()</td>

With *C-Extensions*, you can bind your own C libraries in the runtime system, to call C function from the application code.

**BDL 2.50 upgrade guide**

These topics describe product changes you must be aware of when upgrading to version 2.50.

**Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Web Services changes on page 144
2. Desupported database drivers on page 145
3. TEXT/BYTE support with FTM/ESM database drivers on page 145
4. Presentation styles changes on page 145
5. Floating point to string conversion on page 146
6. Web Services changes
7. Implicit creation of certificates for HTTPS on page 147
8. PostgreSQL schema extraction needs namespace on page 147
9. Client stubs managing multipart changes on page 147

Web Services changes
There are changes in support of web services in Genero 2.50.

Client stubs managing multipart changes on client side

Important: This change has been backported from version 3.00

Starting with version 2.50.25, when generating client stubs managing multipart, you get an extra input and/or output variable called "AnyInputParts" and "AnyOutputParts" that is a DYNAMIC ARRAY of com.HTTPPart objects. Those variables may contain additional input and/or output HTTP parts not specified in the WSDL. You will have to adapt your client program by handling those dynamic arrays in any Genero functions calling such stubs.

Request example prior to 2.50.25:

```plaintext
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
    DEFINE InputHttpPart_1 com.HTTPPart
    ... 
    DEFINE InputHttpPart_n com.HTTPPart
    ... 
    RETURN wsstatus
END FUNCTION
```

Request example 2.50.25 and greater, with extra input variable AnyInputParts:

```plaintext
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
    DEFINE InputHttpPart_1 com.HTTPPart
    ... 
    DEFINE InputHttpPart_n com.HTTPPart
    DEFINE AnyInputParts DYNAMIC ARRAY OF com.HTTPPart
    ... 
    RETURN wsstatus
END FUNCTION
```

Web Services deprecated APIs

The methods listed in the following table are deprecated in version 2.50.

**Table 90: Table of deprecated methods (with their alternative)**

<table>
<thead>
<tr>
<th>Method deprecated as of 2.50</th>
<th>Alternative method to use</th>
<th>Alternative method to use as of 2.50</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.Util.CreateDigestString</td>
<td>security.Digest.CreateDigestString on page 2990</td>
<td></td>
</tr>
</tbody>
</table>

Related concepts

The HTTPPart class on page 2745
The com.HTTPPart class provides an interface to manage the HTTP attachment sent or received in HTTP.

Multipart in the client stub on page 3156
You can generate a client stub for a Web service that has multiple parts.

Dynamic arrays on page 389

Desupported database drivers
Database drivers for old database client versions are removed in accordance with vendor desupport plans.

Database drivers desupported in versions 2.50:

- SQL Server MDAC drivers (Code MSV, name: \*mssv\*):
  - On a Microsoft Windows® platform, use the SQL Server Native Client driver instead (Code SNC).
    - With the SNC drivers, set the dbi.database.dbname.snc.widechar FGLPROFILE entry to false when using CHAR/VARCHAR/TEXT in the SQL Server database. Note that this is only required for versions up to 3.00: Starting with version 3.10, the char mode of SNC driver is selected automatically, depending on the current application locale.
- Oracle® MySQL 5.4 (dbmmys54x)
- Oracle® Database 8.1 (dbmora81x)
- Oracle® Database 9.0 (dbmora90x)

Related concepts
Microsoft SQL Server on page 769
Oracle MySQL / MariaDB on page 811
Oracle Database on page 839

TEXT/BYTE support with FTM/ESM database drivers
FTM and ESM database drivers TEXT/BYTE type mapping has changed.

Since version 2.50, the TEXT and BYTE data types are now converted respectively to VARCHAR(MAX) and VARBINARY(MAX) data types, the recommended LOB types introduced in SQL Server 2005. Before version 2.50, the TEXT and BYTE data types were converted to TEXT and IMAGE data types, respectively, in SQL Server.

It is still possible to use SQL Server TEXT and IMAGE types, but if you create or alter tables in an FGL program, the VARCHAR(MAX) and VARBINARY(MAX) types will be used instead.

Related concepts
TEXT and BYTE (LOB) types on page 795

Presentation styles changes
Deprecated and renamed presentation style attributes.

Starting with version 2.50:

The following presentation style attributes are deprecated (still implemented, but not to be used):
- Window: backgroundImage
- TextEdit: textSyntaxHighlight

The next presentation style attributes have been replaced by a new style attribute, or have been renamed:
- CheckBox: nativeLook => customWidget (with same possible values)

  Important: In 3.00, the customWidget attribute is desupported.

Related concepts
Style attributes reference on page 1082
A presentation style attribute may be a common attribute that can be applied to any graphical element. Most presentation style attributes apply only to a specific graphical element.

**Floating point to string conversion**
The default formatting of a DECIMAL(P), SMALLFLOAT and FLOAT adapts to the significant digits of the value.

Floating point decimal types (like DECIMAL(5)) can store a large range of values, with a variable number of digits after the decimal point: For example, a DECIMAL(5) can store 12345 as well as 0.12345. See DECIMAL(p,s) on page 262 for more details about floating point decimal types.

With Genero 2.50, the conversion to string from a DECIMAL(P), FLOAT and SMALLFLOAT has been revised, to keep all significant digits and avoid data loss.

Before Genero 2.50, floating point decimals converted to strings were formatted with 2 decimal digits by default, which could lead to data loss. See following example using a DECIMAL(12):

```
MAIN
  DEFINE str STRING, dec12, dec12_bis DECIMAL(12)
  LET dec12 = 10.12999
  LET str = dec12
  DISPLAY str
  LET dec12_bis = str
  DISPLAY (dec12 == dec12_bis)
END MAIN
```

Prior to Genero 2.50, the above code displayed:

```
10.13
0
```

Starting with Genero 2.50, all significant digits are kept, which allows for proper decimal data serialization:

```
10.12999
1
```

Prior to Genero 2.50, floating point decimal values conversion of huge values could also lose digits in the whole part of the number; the width of the result was never longer than p + 2. Starting with Genero 2.50, all significant digits of a floating point decimal are kept in the result string:

<table>
<thead>
<tr>
<th>Values</th>
<th>Vers&lt;2.50</th>
<th>Vers&gt;=2.50</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.23456e123</td>
<td>1.23456e123</td>
<td>1.23456e123</td>
</tr>
<tr>
<td>1.23456e40</td>
<td>1.235e40</td>
<td>1.23456e40</td>
</tr>
<tr>
<td>123.456</td>
<td>123.46</td>
<td>123.456</td>
</tr>
<tr>
<td>123456.0</td>
<td>123456.0</td>
<td>123456.0</td>
</tr>
<tr>
<td>0.123456</td>
<td>0.12</td>
<td>0.123456</td>
</tr>
<tr>
<td>0.0123456</td>
<td>0.01</td>
<td>0.0123456</td>
</tr>
<tr>
<td>0.00123456</td>
<td>0.00</td>
<td>0.00123456</td>
</tr>
<tr>
<td>1.23456e-08</td>
<td>0.00</td>
<td>1.23456e-08</td>
</tr>
</tbody>
</table>

If you expect that any DECIMAL(P) to string conversion rounds to 2 digits, define the following FGLPROFILE entry:

```
fglrun.decToCharScale2 = true
```

**Note:** Do not use this configuration parameter unless you have migration issues. This configuration parameter applies only to DECIMAL(P) types, FLOAT and SMALLFLOAT conversions to string is not impacted.

**Related concepts**

Data type conversion reference on page 275
This topic lists type conversion rules for all data types.

**Implicit creation of certificates for HTTPS**
Certificates for HTTPS are now created implicitly when nothing is specified in FGLPROFILE.

Before version 2.50, certificates for HTTPS had to be specified explicitly in FGLPROFILE.

Starting with 2.50, no HTTPS certificate is defined in FGLPROFILE, when a web services program starts, the creation is implicit.

**Related concepts**
- [HTTPS configuration](#) on page 3132
- If no client certificate is provided, Genero Web Services (GWS) does the HTTPS request transparently.

**FGLPROFILE entries** on page 3237
The fglprofile entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

**PostgreSQL schema extraction needs namespace**
To extract a database schema from PostgreSQL, the `fgldbsch` tool now requires db namespace specification.

In version 2.50, the `fgldbsch` database schema extractor can only extract the schema from a PostgreSQL database if you specify the `-ow` option.

PostgreSQL distinguishes table owners from table schemas (in other words table namespaces). The real table namespace is defined by the `pg_class.relnamespace` column: it contains the oid of a namespace defined in `pg_namespace`.

For PostgreSQL, the `fgldbsch -ow` option will specify the namespace, instead of the owner of the table, because a db user can create several schemas/namespaces and use the same table name in those different namespaces. As result, filtering on user name can mix up table definitions from different schemas/namespaces.

When extracting a database schema from a PostgreSQL database, you must specify the namespace of tables with the `-ow` option. If no `-ow` option is specified and the `-un` option is specified, `fgldbsch` will use the login name of the `-un` option as namespace. If neither `-ow`, nor `-up` options are specified, `fgldbsch` will use the PostgreSQL "public" namespace/schema by default.

Since database tables are usually created in the "public" namespace, you typically specify this namespace with the `-ow` option:

```bash
fgldbsch -db test1 -dv dbmpgs -un pgsuser -up fourjs -v -ow public
```

**Related concepts**
- [Specifying the table owner](#) on page 488
- `fgldbsch` on page 1978
  
  The `fgldbsch` tool generates the database schema files from an existing database.

**Client stubs managing multipart changes**
You must update client programs that call client stubs managing multipart.

**Important:** This change has been backported from version 3.00

Starting with version 2.50.25, when generating client stubs managing multipart, you get an extra input and/or output variable called "AnyInputParts" and "AnyOutputParts" that is a DYNAMIC ARRAY of `com.HTTPPart` objects. Those variables may contain additional input and/or output HTTP parts not specified in the WSDL. You will have to adapt your client program by handling those dynamic arrays in any Genero functions calling such stubs.

Request example prior to 2.50.25:

```genero
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
  DEFINE InputHttpPart_1 com.HTTPPart
  ...
  DEFINE InputHttpPart_n com.HTTPPart
```

Request example after 2.50.25:

```genero
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
  DEFINE InputHttpPart_1 com.HTTPPart
  ...
  DEFINE InputHttpPart_n com.HTTPPart
  DEFINE AnyInputParts com.HTTPPart
  Define AnyOutputParts com.HTTPPart
```

```javascript
FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
  DEFINE InputHttpPart_1 com.HTTPPart
  ...
  DEFINE InputHttpPart_n com.HTTPPart
  DEFINE AnyInputParts com.HTTPPart
  Define AnyOutputParts com.HTTPPart
```
RETURN wsstatus
END FUNCTION

Request example 2.50.25 and greater, with extra input variable AnyInputParts:

FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n)
  DEFINE InputHttpPart_1 com.HTTPPart
  ...
  DEFINE InputHttpPart_n com.HTTPPart
  DEFINE AnyInputParts DYNAMIC ARRAY OF com.HTTPPart
  ...
  RETURN wsstatus
END FUNCTION

Related concepts
The HTTPPart class on page 2745
The com.HTTPPart class provides an interface to manage the HTTP attachment sent or received in HTTP.

Multipart in the client stub on page 3156
You can generate a client stub for a Web service that has multiple parts.

Dynamic arrays on page 389

BDL 2.40 upgrade guide
These topics describe product changes you must be aware of when upgrading to version 2.40.

Important: This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Web Services changes on page 148
2. Desupported database drivers on page 149
3. Program size option removal (fglrn -s) on page 149
4. Informix SERIAL emulation with SQL Server on page 149
5. SIZEPOLICY attribute removal for containers on page 150
6. The LVARCHAR type in IBM Informix databases on page 150
7. Right-trim collation for character types in SQLite on page 150
8. Message files support now 4-bytes integer message numbers on page 150
9. MySQL client library version change in MySQL 5.5.11 on page 151
10. New compiler warning to avoid action shadowing on page 151
11. Runtime error raised when report dimensions are invalid on page 151
12. Linker checks all referenced functions on page 152

Web Services changes
There are changes in support of web services in Genero 2.40.

Modification to server location at runtime on client side
Important:
It is recommended to regenerate all client stubs in your application using the fglwsdl tool.

If you have modified the server location at runtime via the generated global variable in your client application, you MUST apply following modification:

• Prior to version 2.40, you had something similar to the following:

LET Calculator_CalculatorPortTypeLocation = "http://host:port/Calculator"
Starting with version 2.40, you must have something similar to the following:

```plaintext
LET Calculator_CalculatorPortTypeEndPoint.Address.Uri = "http://host:port/Calculator"
```

See Change client behavior at runtime.

**Desupported database drivers**

Database drivers for old database client versions are removed in accordance with vendor de-support plans.

**Database drivers desupported in versions 2.40:**

- PostgreSQL versions 8.0, 8.1 and 8.2 (dbmpgs80x, dbmpgs81x, dbmpgs82x).
- Sybase Adaptive Server Anywhere (ASA) version 8 driver (dbmasa8x)

**Note:** The dbmasa8x driver was provided for the Sybase ASA desktop database engine (renamed Sybase SQL Anywhere when writing these lines). Since version 2.30, Genero Business Development Language supports a new driver to connect to SAP Adaptive Server Enterprise (ASE): dbmase.

**Related concepts**

- SAP ASE on page 945

**Program size option removal (fglrun -s)**

The -s option of fglrun is no longer available.

Before version 2.30 the -s option of fglrun on page 1968 was used to compute the size of program elements such as global and module variables, p-code and structured data types. Starting with version 2.30, this option reported a size of zero. With version 2.40 the -s option is now fully desupported.

The -s option was mainly implemented for internal use. Regarding the amount of memory used by a program, it is recommended that you consider the memory allocated dynamically at runtime: If you fill large dynamic arrays, or leave a lot of SQL cursors open without freeing them, the memory footprint of a program can be much larger than the actual size of static elements that may be reported by the -s option.

**Related concepts**

- Optimization on page 401

**Optimize your programs** on page 403

This section contains programming tips to optimize the execution of your application.

**Informix® SERIAL emulation with SQL Server**

SERIAL type emulation has been enhanced for SQL Server.

**Using SCOPE_IDENTITY() to get the last sequence**

Before version 2.40, the SQL Server drivers (SNC, MSV, ESM, FTM) used the @@IDENTITY expression to retrieve the last generated identity column, if the native serial emulation is configured. But @@IDENTITY is not recommended, because it can return an identity value generated for another table in a trigger of the main table.

Starting with 2.40, the SQL Server drivers use the SCOPE_IDENTITY() function, which returns the last number generated in the current scope (ignoring identity numbers generated in triggers).

**Regtable serial emulation trigger code change**

When using the "regtable" serial emulation, the code of the triggers has changed in version 2.40, using now the SET NOCOUNT ON instruction. Existing serial triggers created by prior versions must be reviewed, to have the same trigger body in all tables, otherwise an SQL error is raised when executing INSERT statements.

**Related concepts**

- SERIAL data types on page 788
SIZEPOLICY attribute removal for containers
The SIZEPOLICY attribute is no longer available for layout containers like TABLE / GRID.

Before version 2.40 it was possible to specify a SIZEPOLICY attribute for several types of form elements, including containers such as TABLE, GRID. The SIZEPOLICY attribute makes no sense in containers and is only meaningful for leaf nodes (widgets such as EDIT, COMBOBOX). The form compiler will now report a syntax error if the SIZEPOLICY attribute is used in the definition of elements that are not widgets.

Related concepts
SIZEPOLICY attribute on page 1283
The SIZEPOLICY attribute is a sizing directive based on the content of a form item.

The LVARCHAR type in IBM® Informix® databases
Native LVARCHAR type of Informix is now mapped by default to a large VARCHAR in schema file.

Starting with version 2.40, the fgldbsch database schema extractor converts now by default IBM® Informix® LVARCHAR(N) types to VARCHAR2(N) with type code 201. Before 2.40, you had to pass -cv AAAB... option to avoid a conversion error when generating the schema file.

The static SQL syntax has been enhanced, to support the LVARCHAR type name in DDL statements such as CREATE TABLE. The non-Informix® ODI drivers have been adapted to convert LVARCHAR type names to VARCHAR.

Two-Pass reports can now use VARCHAR types with a size greater than 255 bytes (the temporary table will be created with an LVARCHAR column). However, the index is created as well, and IBM® Informix® IDS (version 11 when writing these lines) has a size limitation for indexes. You may get an SQL error -517 if the VARCHAR variable used to group / order rows in the report routine exceeds ~350 bytes (see IDS SQL error -517 for details).

Related concepts
Database schema extractor options on page 486
The fgldbsch tool extracts the schema description for an existing database.

Command reference on page 1968
Command line tools provided for BDL.

Right-trim collation for character types in SQLite
CHAR and VARCHAR columns in SQLite need to be defined with a TRIM collation to ignore trailing spaces in comparisons.

Since version 2.40, the SQLite database driver adds the COLLATE RTRIM keywords after the CHAR(N) and VARCHAR(N) types in CREATE TABLE statements, when Informix® emulation is enabled (the default). This collation clause forces SQLite to use right-trim comparison rules instead of the default binary mode. The binary mode requires to have the same number of trailing spaces in both character values to be equal. By using COLLATE RTRIM clause, the trailing blanks are trimmed and thus ignored. it is recommended that you also use [VAR]CHAR(N) COLLATE RTRIM in database creation scripts.

Related concepts
SQLite on page 922

Message files support now 4-bytes integer message numbers
2-byte .msg message number limitation was removed.

Before version 2.40, message files entries were only defined with numbers in the range -32767 to 32767 (SMALLINT). This limitation is no longer true in 2.40; message numbers can now be in the range -2147483648 to 2147483647 (INTEGER).

Related concepts
Message files on page 1059
Message files centralize strings and larger texts identified by a number, that can be used in programs.

MySQL client library version change in MySQL 5.5.11

Shared library version number of the MySQL client library must match the library used to link the ODI driver.

Starting with Oracle® MySQL 5.5.11, the client library version number was changed from 16 to 18. In fact the libmysqlclient.so.16 file was renamed to libmysqlclient.so.18. From a cross-5.5.x compatibility point of view, this may not be the best thing to do, since the major shared library version has changed, client applications using the C API (such as Genero ODI MySQL drivers) need to be recompiled and re-linked in order to use the latest library.

In Genero version 2.40, the dbmmys55x ODI driver is linked with libmysqlclient.so.18 on the platforms where MySQL 5.5.11+ is available. That is: Linux®, Solaris and Mac OS X® platforms, when writing these lines. On other UNIX™ platforms such as HP, the client library is still libmysqlclient.so.16. This may change in future Genero versions, following the availability of MySQL 5.5.11+ versions.

Therefore, you must pay attention to the MySQL 5.5 version you have installed. You need to upgrade your MySQL 5.5 client software to match the client library used to build the dbmmys55x.so shared library. On Linux®, you can run the ldd command to check what libmysqlclient.so version is required. If it's not possible to upgrade your MySQL client software, please contact the support channel.

Related concepts
Oracle MySQL / MariaDB on page 811

New compiler warning to avoid action shadowing

Prevent the same action name at different levels of ON ACTION handlers in a dialog.

The fglcomp compiler of version 2.40 will now print warning -8409, if a dialog block defines ON ACTION handlers at different levels with the same action name.

It is not good practice to use the same action names at different levels of a dialog. For example, you can define several ON ACTION INFIELD handlers using the action name “zoom”, but do not define an ON ACTION zoom at the sub-dialog or dialog level.

If the warning occurs during compilation, modify your code in order to use specific action names at each level, and do not forget to rename the actions of the corresponding action views in the forms.

Related concepts
Multilevel action conflicts on page 1671

Command reference on page 1968
Command line tools provided for BDL.

Runtime error raised when report dimensions are invalid

Report page length checking error -4375 might occur at compile time or runtime.

Several fixes related to PAGE LENGTH error -4375 have been done in subsequent releases.

Below is the history of changes for this report definition error:

1. Version 2.40 fixes bug FGL-3035: A START REPORT instruction raises error -4375 at runtime, when the top/bottom margin sizes do not fit the page length. In this version, the error is not returned at compile time, because report dimensions can be specified with variables in START REPORT.
2. Version 2.50.00 fixes bug FGL-3711: The compiler also raises error -4375, if PAGE LENGTH is too short to cover the specified page header and trailer lengths.
3. Version 2.51.07 fixes bug FGL-651: FIRST PAGE HEADER blocks can have the same number of rows as the PAGE LENGTH.
4. Version 2.50.26 fixes bug FGL-4223: Reports with PAGE LENGTH = 1 TOP MARGING 0 BOTTOM MARGIN 0 are often used to produce reports without any page formatting. A page length of 1 denies printing in PAGE HEADER and PAGE TRAILER. However, it is possible to print any number of lines in FIRST PAGE HEADER and ON LAST ROW is possible.
Related concepts
Reports on page 1924

Linker checks all referenced functions
The linker checks definition of all functions referenced in all modules provided in the link command.

Starting with version 2.40, any reference to a function has to be resolved by the linker: When linking a 42r program, if an unused module references an undefined function, the linker (fglrun -l or fgllink) will stop with the error -1338. Before version 2.40, the undefined function was ignored.

Note: Complete function reference is only checked by the linker when creating a 42r program file. When creating a 42x library, there can be references to undefined functions.

In the example, the main.4gl module does not call any function, but the module used in the link line (module.4gl) defines an unused function (f1) calling an undefined function (f2):

main.4gl:

```
MAIN
  DISPLAY "In main..."
END MAIN
```

module.4gl:

```
FUNCTION f1() -- Unused in program
  DISPLAY "In f1..."
  CALL f2() -- Undefined
END FUNCTION
```

Compiling and linking:

```
$ fglcomp main.4gl
$ fglcomp module.4gl
$ fgllink -o prog.42r main.42m module.42m
ERROR(-1338):The function 'f2' has not been defined in any module in the program.
```

Related concepts
Linking programs on page 2004
Describes how to link .42m modules together to build a .42r program file.

BDL 2.32 upgrade guide
These topics describe product changes you must be aware of when upgrading to version 2.32.

Important: This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Front-end protocol compression disabled on page 152
2. SQLite driver no longer needs libiconv on Windows on page 153
3. Need for Informix CSDK to compile C extensions on page 153
4. FESQLC tool removal on page 153

Front-end protocol compression disabled
GUI communication does not require protocol compression on LAN networks.

Until version 2.32.00, front-end protocol compression was enabled by default, to speed up GUI communication on slow networks. However, on regular networks, compression is useless and can be disabled to save processing
resources. With version 2.32.00, the compression is now disabled by default. If needed, compression can be enabled with this FGLPROFILE entry:

```plaintext
gui.protocol.format = "zlib"
```

Note also that compression needs the zlib library to be present on the computer where fglrun executes. Starting with 2.32.00, the product package no longer includes the fallback zlib library ($FGLDIR/lib/libzfgl.so or %FGLDIR%\bin\libzfgl.dll). If no standard zlib is installed on your system, compression will not be possible.

**Related concepts**

- GUI protocol compression on page 1020
- The FGLPROFILE file(s) on page 220
- FGLPROFILE environment variable defines Genero BDL configuration files

**SQLite driver no longer needs libiconv on Windows®**

UTF-8 string data storage in SQLite requires conversion when the application is not UTF-8.

Starting with version 2.32, the SQLite driver (dbmsqt3xx) no longer needs the LIBICONV.DLL library on Windows® platforms to do charset conversion, when the application locale is not UTF-8.

**Related concepts**

- SQLite on page 922
- Localization on page 405

Localization support allows you to implement programs that follow specific language and cultural rules.

**Need for Informix® CSDK to compile C extensions**

Compiling C Extensions requires now the Informix CSDK.

**Note:** This upgrade note is related to C Extensions or ESQL/C Extensions, and can be ignored if your application does not use such extensions.

To compile C or ESQL/C extensions manipulating data types like DECIMAL, you need IBM® Informix® data type structure definitions such as dec_t, dtme_t, intrvl_t, as well as macros like DECLEN() or TU_ENCODE(). Before version 2.32, these C structure and macros where provided in the files of the FGLDIR/include/f2c directory.

The Genero BDL version 2.32 no longer provides the IBM® Informix® ESQL/C structure definitions in FGLDIR/include/f2c files, because we have identified that some of the definitions are platform specific. However, to compile your C extensions, you need these definitions if your extensions use complex data types such as DECIMAL, DATETIME/INTERVAL, BYTE/TEXT. The definitions are not required if you use standard C types such as int or char[].

Starting with version 2.32, you need to install an IBM® Informix® CSDK on your development machine in order to get the structure and macro definitions to compile your C extensions. The IBM® Informix® CSDK is only required on the development platform. It is not required to install the CSDK on the production machines, except of course if you want to connect to an IBM® Informix® database server.

**Related concepts**

- C-Extensions on page 2109

With C-Extensions, you can bind your own C libraries in the runtime system, to call C function from the application code.

**FESQLC tool removal**

The ESQL/C compiler (fesql) has been removed from the Genero BDL product.

Starting with version 2.32, the fesqlc compiler and linker is no longer part of the Genero BDL package.

Contact your support channel for more details.

**Related concepts**

- Command reference on page 1968
Command line tools provided for BDL.

**BDL 2.30 upgrade guide**

These topics describe product changes you must be aware of when upgrading to version 2.30.

**Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. GUI server auto start on page 154
2. Form compiler is more strict on page 154
3. ORACLE and INTERVAL columns on page 154
4. DIALOG.setCurrentRow() changes row selection flags on page 155
5. Schema extractor needs table owner on page 155
6. Windows installation for all users only on page 155
7. MenuAction close no longer created by default on page 155
8. Emulated scrollable cursor temp files in DBTEMP on page 156
9. Modifying tree view data during dialog execution on page 156

### GUI server auto start

FGLSERVER defaults the server defined by wsmap settings, when starting GUI server.

Before version 2.30, the runtime system was trying to connect to localhost:0 when FGLSERVER was not set, even if gui.server.autostart FGLPROFILE entries are defined.

This behavior has been identified as a bug (FGL-1583) and has been fixed, changing the way fglrun proceeds with the GUI connection when autostart settings are defined; with 2.30, the wsmap workstation mappings are now taken into account, so that FGLSERVER defaults to localhost:n, where n is the GUI server number found from the wsmap settings.

**Related concepts**

Automatic front-end startup on page 1022

### Form compiler is more strict

The .per grammar parser has been reviewed to deny invalid code.

In version 2.30, the internals of fglform have been reviewed to simplify the extension of the form syntax with new item types and attributes. This code review has removed some inconsistencies in the grammar parser; as a result, the form compiler is more strict regarding invalid syntaxes. Thus, you may experience compilation errors with forms that compiled with prior versions. Simply fix the invalid syntax in your forms and recompile.

**Related concepts**

fglform on page 1970

The fglform tool compiles form specification files into XML formatted files used by programs.

### ORACLE and INTERVAL columns

INTERVAL storage bug fix needs a review of existing databases in production.

Before 2.30.00 (build 1566), negative (and only negative) INTERVAL values were inserted incorrectly. This a critical bug.

For example, it was not possible to compare an INTERVAL value inserted by a program with an INTERVAL literal:

```sql
SELECT ... FROM table
WHERE interval_col = INTERVAL '-55555-11' YEAR(9) TO MONTH
```

The problem concerns database columns with the following interval types:

```
INTERVAL YEAR(p) TO MONTH
INTERVAL DAY(p) TO FRACTION(n)
```
(Other INTERVAL types are stored in a CHAR(50))

A simple INTERVAL to CHAR to INTERVAL conversion will fix the values:

```
UPDATE table SET interval_col = TO_CHAR(interval_col)
```

**Related concepts**

- **Interval expressions** on page 298
  - This section covers interval expression evaluation rules.
- **Interval literals** on page 292
  - Interval literals define an interval value in an expression.

**DIALOG.setCurrentRow() changes row selection flags**

Row selection flags are reset by a call to setCurrentRow().

Before version 2.30, the `DIALOG.setCurrentRow()` method did not modify the row selection flags.

Starting with version 2.30, the method resets row selection flags to false and marks the new current row as selected.

**Related concepts**

- **Multiple row selection** on page 1752
  - Multiple row selection allows the end user to select several rows within a list of records.

**Schema extractor needs table owner**

The `fgldbsch` schema extractor requires a `-ow` option to distinguish different database users/shemas.

Starting with version 2.30, the `fgldbsch` schema extractor will always use a table owner / schema to select tables from databases where several schemas can hold tables with the same name.

The table owner can be specified with the `-ow` option, and defaults to the user name passed with the `-un` option, or to the current database user if no `-up` option was given. The last case can occur when the database connection information is taken from the FGLPROFILE configuration file, or when the OS user authentication is used.

**Related concepts**

- **fgldbsch** on page 1978
  - The `fgldbsch` tool generates the database schema files from an existing database.

**Windows” installation for all users only**

Installation on Windows platforms is for all users.

Starting with version 2.30, the Windows® installer forces you to install the product for all users.

**Related concepts**

- **Installation** on page 38
  - This chapter contains installation and setup instructions.

**MenuAction close no longer created by default**

The close action is no longer created by default in MENU dialog.

Before version 2.30, a `close` MenuAction was created by default for MENU dialogs. This action node is no longer created, except if you have a COMMAND KEY(INTERRUPT) in the MENU, or if you have your own user action handler ON ACTION close, of course. You must take this change into account if you are manipulating the AUI tree with om classes in MENUs.

**Related concepts**

- **Ring menus (MENU)** on page 1358
  - The `MENU` instruction implements a list of options the end user can choose from.

- **The DomNode class** on page 2436
The `om.DomNode` class provides methods to manipulate a DOM node of a data tree.

**Emulated scrollable cursor temp files in DBTEMP**
Directory of scrollable cursor data storage can be defined with `DBTEMP`.

On UNIX™ platforms, starting with 2.30, the temporary files for emulated scrollable cursors will be created in the directory defined by the `DBTEMP` on page 238 environment variable when defined, otherwise `TMPDIR`, `TEMP` or `TMP` will be used. Using `DBTEMP` for database files conforms to `DBTEMP` usage for temporary files of `TEXT` and `BYTE` data storage.

**Related concepts**
- `TMPDIR`, `TMP`, `TEMP` on page 230
  Defines the directory for temporary files.
- `TEXT` on page 271
  The `TEXT` data type stores large text data.
- `BYTE` on page 255
  The `BYTE` data type stores any type of binary data, such as images or sounds.

**Modifying tree view data during dialog execution**
Use `ui.Dialog` methods to insert/append/delete treeview nodes.

Before version 2.30, it was possible to use the `insertRow()` / `appendRow()` / `deleteRow()` / `deleteAllRows()` dialog class methods to modify the tree array during the dialog execution. But these methods were not designed to handle tree data properly. An alternative was to use program array methods, but when modifying the program array directly, multi-range selection flags or cell attributes were not synchronized.

Starting with 2.30.02, you can now use the `insertNode()`, `appendNode()` and `deleteNode()` methods of the `ui.Dialog` class. You can still directly fill the program array before the dialog execution, but it is recommended to use dialog methods during the dialog execution.

**Related concepts**
- The `Dialog` class on page 2367
  The `ui.Dialog` class provides a set of methods to configure, query and control the current interactive instruction.
- Tree views on page 1789
  Describes how to implement tree views.

**Presentation styles changes**
Modifications to consider when using presentation styles.

**Form.resetFormSize style attribute**
Starting with Genero BDL 2.30, the Form presentation style `resetFormSize` can be used to control the window resizing behavior when doing successive `OPEN FORM / DISPLAY FORM`.

For more details, see Form style attributes on page 1094.

**Related concepts**
- Windows and forms on page 1032
  The section describes the concept of windows and forms in the language.

**BDL 2.21 upgrade guide**
These topics describe product changes you must be aware of when upgrading to version 2.21.

**Important**: This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Web Services changes on page 157
2. PostgreSQL 8.4 and INTERVAL type on page 157
3. `fglcomp --build-rdd` compiles the module on page 158
4. Unique and primary key constraint violation on page 158
5. IMPORT with list of C-Extensions on page 158
6. Initializing dynamic arrays to null on page 159
7. Strict screen record definition for tables on page 159

Web Services changes
There are changes in support of web services in Genero 2.21.

Operation publication restrictions on server side
If you use a variable as the name of the function to publish, you will get an error message at compile time.
For example:

```java
com.WebOperation.CreateRPCStyle(test,"Add",add_in,add_out)
```

Where `test` is a string variable, `add_in` and `add_out` are input and output records.
At compile time, you get the error message:

```
error:(-9054) Web service function must be a string
```

The function name in the parameter can only be a string literal not a string variable.

Since version 2.21, FGL has introduced the concept of PUBLIC/PRIVATE functions, there is a risk for a user
publishing private functions. Private functions are not always available at runtime.
As a workaround you can add a switch based on the function name value in order to call the appropriate publication
API with the name in a string literal as shown in the following sample:

```java
CASE function_name
  WHEN "Operation1"
    LET op = com.WebOperation.CreateDocStyle(
                   "Operation1","Operation1",op1_in,op1_out)
  WHEN "Operation2"
    LET op = com.WebOperation.CreateDocStyle(
                   "Operation2","Operation2",op2_in,op2_out)
  OTHERWISE
    DISPLAY "ERROR"
END CASE
```

In Java or in .NET you cannot publish a different number of operations for the same service, everything is done
at compile time. For instance, when you publish a Web service in Java, only the public methods are published as
operations of the service. There is no way to add or remove some methods at runtime. The only way you have is to
create another Java class.

Be aware that if you dynamically change the service operations names, you are creating a different service, which
might be confusing for the Web service client.

PostgreSQL 8.4 and INTERVAL type
The `dbmpgs84x` database driver requires your database schema use the INTERVAL type, rather than a CHAR(50)
type.

Version 2.21 introduced support for PostgreSQL 8.4 with the new database driver `dbmpgs84x`. This version of
PostgreSQL implements a native INTERVAL data type that is similar to the Genero Business Development Language
INTERVAL type.

When using the `dbmpgs84x` (and higher) driver, Informix-style INTERVAL types will be mapped / translated to
native PostgreSQL INTERVALs. Prior drivers will keep using the CHAR(50) replacement. If your application is
storing INTERVAL in a PostgreSQL database, you will have to modify you database schema to replace the existing
CHAR(50) column with the native INTERVAL data type of PostgreSQL 8.4. If you cannot migrate the database, you
can still use the older dbmpgs83x driver using CHAR(50) for INTERVALs, but that driver requires a PostgreSQL client version 8.3.

**Related concepts**
- *PostgreSQL* on page 887

**fglcomp --build-rdd compiles the module**

*fglcomp --build-rdd* now creates both the .42m and .rdd files.

Before version 2.21, *fglcomp --build-rdd* only produced the .rdd data definition file.

This option is now a compilation option. Both .42m and .rdd files are created at the same time.

**Related concepts**
- *fglcomp* on page 1972

The *fglcomp* tool compiles .4gl source files into .42m p-code modules.

**Command reference** on page 1968

Command line tools provided for BDL.

**Unique and primary key constraint violation**

Unique and primary key constraint violations mostly return error -268. However, error -269 may be checked too.

When a unique or primary key constraint is violated, the IBM® Informix® driver returns the error -268 in SQLCA.SQLCODE if the database uses transaction logging, and error -239 if the database uses no logging.

Regarding non-Informix drivers, all 2.21 drivers now return -268 when a unique constraint or primary key constraint is violated. Before 2.21, the Oracle and SQL Server / SAP ASE drivers returned error -239, which is only returned by IBM® Informix® databases without transaction logging. Returning error -268 for all drivers is the best choice in a context of transactional databases.

Check your code for -239 error code usage and replace by -268. If you still need to test error -239 (for example because you have IBM® Informix® databases without transactions), we recommend that you write a function testing different error codes to check unique constraint violation:

```sql
FUNCTION isUniqueConstraintError()
    IF (SQLCA.SQLCODE==-239 OR SQLCA.SQLCODE==-268)
    OR (SQLCA.SQLCODE==-346 AND SQLCA.SQLERRD[2]==-100)
    THEN
        RETURN TRUE
    ELSE
        RETURN FALSE
    END IF
END FUNCTION
```

**IMPORT with list of C-Extensions**

The IMPORT instruction for C extensions denies a comma-separated syntax.

Before version 2.21.00, the IMPORT instruction for C extensions was documented as allowing a comma-separated list of libraries:

```
IMPORT lib1, lib2
```

This compiled, but at runtime only the first library was found. Using elements of the other libraries raised a runtime error.

With 2.21.00 and the new .42m module importation support, the compiler is now more strict and denies the comma-separated syntax. You must specify every library, Java class or .4gl module in separate lines:

```
IMPORT lib1
IMPORT JAVA myclass
IMPORT FGL mymodule
```
Related concepts

Importing modules on page 496
Use the \texttt{IMPORT \ldots} instruction to import BDL, C or Java external modules in the current module.

Structure of a module on page 492
A module defines a set of program elements such as functions, report routines, types, constants and variables.

Initializing dynamic arrays to null
The \texttt{INITIALIZE TO NULL} instruction clears the dynamic array.

Starting with version 2.21.00, the \texttt{INITIALIZE TO NULL} instruction clears the dynamic arrays (i.e. \texttt{array.getLength()} returns 0). Before this version, all elements of the dynamic array were kept, and set to null. Since the old behavior was documented, this behavior change required a migration note. The new behavior is expected by most programmers.

Related concepts

\texttt{INITIALIZE} on page 372
The \texttt{INITIALIZE} instruction initializes program variables with NULL or default values.

Strict screen record definition for tables
The fglform compiler of version 2.21.00 now makes a strict checking of the fields used in the screen record definition for table containers.

It generates error \texttt{-6819} if the screen record do not use all columns used in the table. The order can be different, however.

Related concepts

\texttt{TABLE container} on page 1217
Defines a re-sizable table designed to display a list of records.

BDL 2.20 upgrade guide
These topics describe product changes you must be aware of when upgrading to version 2.20.

\textbf{Important:} This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Web Services changes on page 160
2. Sort is now possible during \texttt{INPUT ARRAY} on page 160
3. Cell attributes and buffered mode on page 160
4. Field methods are more strict on page 161
5. Strict variable identification in SQL statements on page 161
6. SQL Warnings with non-Informix databases on page 161
7. SERIALREG table for 64-bit serial emulation on page 162
8. Extracting the database schema with fgl dbsch on page 163
9. Database driver internal error changed from -768 to -6319 on page 163
10. Searching for image files on the application server on page 163
11. Strict action identification in dialog methods on page 164
12. Strict field identification in dialog methods on page 164
13. Form compiler checking invalid layout definition on page 164
14. Database schema compatibility on page 165
15. Predefined actions get automatically disabled depending on the context on page 165
16. \texttt{BEFORE ROW} no longer executed when array is empty on page 165
17. Controlling \texttt{INPUT ARRAY} temporary row creation on page 166
Web Services changes
There are changes in support of web services in Genero 2.20.

Migration to 2.20 on client side
If migrating a GWS client application to version 2.20, you need to regenerate all client stubs in your application using the fglwsdl tool.

Important:
This is mandatory. The regenerated code is based on low-level COM and XML APIs and is completely different from versions prior to 2.1x. If you do not regenerate your client stubs, you will not be able to execute the code.

Backward compatibility option --compatibility
When using a Genero 2.2x runner for the GWS client application, you must:
1. Regenerate the GWS client stubs using the --compatibility option of the fglwsdl tool, so the function prototypes will be compatible:

2. Compile the GWS client stubs and re-link the client application (.42r).

Renamed options
The http_invoketimeout and tcp_connectiontimeout options have been respectively renamed as readwritetimeout and connectiontimeout, as they are now available for either HTTP or TCP protocol. While the old option names remain for backward compatibility, using the new option names is strongly recommended.

Moved options
xml_ignoretimezone and xml_usetypedefinition options were part of the com.WebServiceEngine class. They have been moved to the xml.Serializer class, which groups functions on serialization.

Sort is now possible during INPUT ARRAY
Built-in sort is available in INPUT ARRAY.

Starting with version 2.20, the built-in sort is now available during INPUT ARRAY. If you want to avoid sorts in a table, use the UNSORTABLECOLUMNS attribute.

Related concepts
UNSORTABLECOLUMNS attribute on page 1293
The UNSORTABLECOLUMNS attribute indicates that the columns of the table cannot be selected by the user for sorting.

Editable record list (INPUT ARRAY) on page 1425
The INPUT ARRAY instruction provides always-editable record list handling in an application form.

Cell attributes and buffered mode
Must use the UNBUFFERED mode when setting cell attributes.

Before version 2.20, array cell attributes were synchronized quite often by the runtime system, and this was not very efficient. As a result, there was not much difference between using buffered or unbuffered mode; when changing cell attributes, the result was immediate even in buffered mode.

Starting with version 2.20, it is recommended that you use the UNBUFFERED mode when setting cell attributes; otherwise, the colors will not be synchronized on the front-end.
Related concepts
Cell color attributes on page 1751
List controllers can display every cell in a specific color.

The buffered and unbuffered modes on page 1618
The buffered and unbuffered mode control the synchronization of program variables and form fields.

Field methods are more strict
Dialog class methods are more strict regarding form field names.

Starting with Genero 2.20 (or when using multiple dialogs in 2.11.08 and higher), DIALOG class methods such as `setFieldActive()` need the correct field specification with the screen-record name prefix, if the field was explicitly bound with the `FROM` clause of `INPUT` or `INPUT ARRAY`.

In prior versions, the field was found by these methods even if the prefix was invalid. (Actually, the prefix was just ignored and only the fieldname was used.)

Related concepts
Identifying fields in dialog methods on page 2409

Strict variable identification in SQL statements
Program variable identification in static SQL statements is more strict in version 2.20 than older versions.

If you define a variable with the same name as a SQL object (i.e. table name, table alias), the fglcomp compiler will raise an error because it will consider the program variable first. For example, if the variable name matches the table or alias identifier, using `table.column` in the SQL statement will be resolved as `variable.member`, which does not exist.

The next code example will not compile because the program defines a variable using the same name as the table alias `c`:

```
MAIN
  DEFINE c INTEGER
  DATABASE stores
  SELECT COUNT(*) INTO c FROM customer c
  WHERE c.fname IS NULL
END MAIN
```

The code also fails to compile with IBM® Informix® 4gl 7.32, but it did compile with version of Genero Business Development Language.

To work around this, you must either rename the program variable, or explicitly identify SQL objects with the @ prefix in the SQL statement:

```
MAIN
  DEFINE c INTEGER
  DATABASE stores
  SELECT COUNT(*) INTO c FROM customer c
  WHERE @c.fname IS NULL
END MAIN
```

Recompile all your programs to find the conflicts.

SQL Warnings with non-Informix databases
SQL Warnings are now propagated for all database drivers, and can set the SQLCA.SQLAWARN, SQLSTATE and SQLERRMESSAGE registers.

Before version 2.20, is was impossible for a non-Informix driver to return SQL Warning information in SQLCA, SQLSTATE and SQLERRMESSAGE.
This new behavior will have no impact if you test SQL Errors with STATUS or SQLCA.SQLCODE, as these registers remain zero if an SQL Warning is raised. However, if you are using SQLSTATE to check for SQL Errors, you must now distinguish SQLSTATE of class 01: These are SQL Warnings, not SQL errors.

In this example, when connected to IBM® DB2®, the SQLSTATE register will get the value 01504 indicating that all rows of the table have been deleted. As a result, testing SQLSTATE against 00000 will evaluate to false, and run into the error handling block, which is unexpected:

```
MAIN
   DATABASE stores
   WHENEVER ERROR CONTINUE
   DELETE FROM customer
   IF SQLSTATE <> "00000" THEN
      -- handle error
   END IF
END MAIN
```

To check for successful SQL execution with or without warning, you can, for example, code:

```
MAIN
   DATABASE stores
   WHENEVER ERROR CONTINUE
   DELETE FROM customer
   IF NOT (SQLSTATE=="00000" OR SQLSTATE MATCHES "01*") THEN
      -- handle error
   END IF
END MAIN
```

**SERIALREG table for 64-bit serial emulation**

You must alter the SERIALREG table to do serial emulation on a BIGINT column.

The SERIALREG based serial emulation is defined by the following FGLPROFILE entry:

```
  dbi.database.<dbname>.ifxemul.datatype.serial.emulation = "regtable"
```

Version 2.20 introduces the **BIGINT** data type, which is a 64-bit signed integer. You can use BIGSERIAL or SERIAL8 columns with IBM® Informix®, and ODI drivers can emulate 64-bit serials in other database servers. However, if you are using serial emulation based on the SERIALREG table, you must redefine this table to change the LASTSERIAL column data type to a BIGINT. If the BIGINT data type is not supported by the database server, you can use a DECIMAL(20,0) instead:

```
CREATE TABLE serialreg (  
tablename VARCHAR2(50) NOT NULL,  
lastserial BIGINT NOT NULL,  
PRIMARY KEY ( tablename )  
)
```

**Important:** If you need to migrate an installed database using SERIALREG-based triggers, you will have to keep the current registered serials and use ALTER TABLE instead of CREATE TABLE. This example shows the ALTER TABLE syntax for SQL Server. Check the database server manuals for the exact syntax of the ALTER TABLE statement.

```
ALTER TABLE serialreg ALTER COLUMN lastserial BIGINT NOT NULL
```

Additionally, all existing SERIALREG-based triggers must be modified, in order to use BIGINT instead of INTEGER variables, otherwise you will get BIGINT to INTEGER overflow errors. For example, to modify existing triggers with SQL Server, you can use the ALTER TRIGGER statement, which can be easily generated from the database browser tool (there is a modify option in the context menu of triggers). After the existing trigger code was
generated, you must edit the code to replace the INTEGER data type by BIGINT in the variable declarations, and execute the ALTER TRIGGER statement.

**Extracting the database schema with fgldbsch**
The fgldbsch database schema extraction tool has been updated to map native database types to newly-added types.

Version 2.20 implements new data types such as BIGINT and BOOLEAN. The fgldbsch database schema extraction tool has been reviewed to map native database types to these new types when possible. Pay attention to these changes, when extracting a schema from your database.

For example, before version 2.20, fgldbsch converted an Oracle NUMBER(20,0) to a DECIMAL(20,0) by default. Now, since 2.20 provides the BIGINT native FGL type, it can be used to store a NUMBER(20,0) from Oracle.

You can get the previous behavior by using a conversion directive with the `-cv` option of fgldbsch.

To see the new conversion rules, run the fgldbsch tool with the `-ct` option.

**Related concepts**

**BIGINT** on page 254
The BIGINT data type is used for storing very large whole numbers.

**BOOLEAN** on page 257
The BOOLEAN data type stores a logical value, TRUE or FALSE.

**fgldbsch** on page 1978
The fgldbsch tool generates the database schema files from an existing database.

**Database driver internal error changed from -768 to -6319**
The internal error raised was changed to avoid conflicts with an IBM® Informix® SQL error code.

Prior to version 2.20, if an unexpected error occurred in a database driver, the driver could return error -768, which is a real IBM® Informix® SQL error that instructs the user to call the IBM® support center.

To avoid any mistake, 2.20 database drivers return now the error -6319 if an internal error occurs, which is a Genero Business Development Language specific error message that suggests you to set the FGLSQLDEBUG environment variable to get detailed debug messages.

**Related concepts**

**FGLSQLDEBUG** on page 245
Defines the debug level for tracing SQL instructions.

**Searching for image files on the application server**
For security reasons, the image file transfer mechanism has been slightly modified in version 2.20.

(This modification has also been back-ported in 2.11.14):

If FGLIMAGEPATH is set, the current working directory is no longer searched as in previous versions. You must explicitly add "." to the list of directories. By default, if FGLIMAGEPATH is not defined, the runtime system still searches the current directory.

If FGLIMAGEPATH is defined, the image files used in IMAGE form fields or in the IMAGE attribute must be located below one of the directories listed in the environment variable. This constraint does not exist if FGLIMAGEPATH is not set and has been relaxed in 2.21.00 for image fields displayed by program.

Starting with 2.21.00, images displayed by program to IMAGE fields are considered as valid files to be transferred to the clients without risk and do not follow the FGLIMAGEPATH security restrictions. Images are however searched for in the path list defined in FGLIMAGEPATH.

**Related concepts**

**FGLIMAGEPATH** on page 241
Defines the search paths for VM server image files.

**IMAGE attribute** on page 1261
The **IMAGE** attribute defines the image resource to be displayed for the form item. 

**IMAGE item type** on page 1174
Defines an area that can display an image resource.

**Strict action identification in dialog methods**
Actions referenced in methods of the dialog class must exist in the current dialog, or an error is raised.

Starting with version 2.20.00, dialog class methods like `ui.Dialog.setActionActive()` can now raise a runtime error `-8089` if the action name is invalid. Before version 2.20, the method ignored the invalid action name, which made it difficult for the programmer to debug.

**Related concepts**
`ui.Dialog.setActionActive` on page 2394
Enabling and disabling dialog actions.

**Strict field identification in dialog methods**
Fields referenced in methods of the dialog class must exist in the current dialog, or an error is raised.

Starting with version 2.20.05, dialog class methods like `ui.Dialog.setFieldTouched()` can now raise a runtime error `-1373` if the field specified does not match a field in the current dialog. Before version 2.20.05, these methods previously ignored the invalid field specification, making it difficult for the programmer to quickly find the mistake.

**Related concepts**
`ui.Dialog.setFieldTouched` on page 2403
Sets the modification flag of the specified field.

**Form compiler checking invalid layout definition**
It is better to identify form layout mistakes when the form is compiled, rather than at runtime.

Starting with version 2.20.05, the fglform compiler performs more layout checking than before. Thus, existing (invalid) forms that compiled with prior versions of Genero may no longer compile with 2.20.05. This strict checking is done to detect layout mistakes during form design, instead of having the front-ends render invalid forms in an unknown manner at run time.

For example, the following form definitions are invalid and will raise a compilation error with fglform:

```plaintext
SCHEMA FORMONLY
LAYOUT
GRID
{
  [f01:  |f02    ] -- HBox layout tags in lists are denied
  [f01:  |f02    ]
  [f01:  |f02    ]
  [f01:  |f02    ]
}
END
END

SCHEMA FORMONLY
LAYOUT
GRID
{
  [f01    ]  [f02    ] -- Misaligned field tags (vertical)
  [f01    ]  [f02    ]
  [f01    ]  [f02    ]
}
END
```
Database schema compatibility

fgldbsch extracts specific type for BOOLEAN.

Version 2.20.06 database schema extraction now generates a different type code for BOOLEAN, that introduces a compatibility issue with older versions of fglcomp and fgllform.

If database tables use data types that are equivalent to the BOOLEAN Informix® type, such as the BIT type in SQL Server, you must regenerate the .sch database schema file with the fgldbsch tool. If you keep using the schema generated by an older version such as 2.20.04, fglcomp or fgllform will raise the error -6634.

This problem will only occur if your database tables use the BOOLEAN (or native equivalent type). See SQL database guides on page 689 for more details about database specific boolean types.

Related concepts
Database schema on page 476
Defines database table structures with column type information to be reused in program variable definitions.

Predefined actions get automatically disabled depending on the context

Dialogs will automatically disable some predefined actions, if it makes no sense to trigger the action in the current context.

Starting with version 2.20, (or with version 2.10 when FGL_USENDIALOG=1), the dialogs will automatically disable some predefined actions if it makes no sense to trigger the action in the current context. For example, during an INPUT ARRAY, if there are no rows to remove, the predefined delete action will be disabled automatically.

Similarly, the insert and append actions get disabled when the array is full (this can happen with static arrays or when using the MAXCOUNT attribute). The predefined actions will also be disabled if you overwrite them with your own ON ACTION handler.

Related concepts
Predefined actions on page 1641
Genero predefines some action names for common operations of interactive instructions.

BEFORE ROW no longer executed when array is empty

In order to trigger the BEFORE ROW block when entering an array, the array must not be empty.

Before version 2.20, the BEFORE ROW block was always executed when entering a DISPLAY ARRAY or INPUT ARRAY dialog, even if the number of real data rows was zero. Starting with 2.20, when using an empty dynamic array or when using a static array and specifying zero data rows with a SET_COUNT(0) call or with the COUNT=0 attribute, the BEFORE ROW control block is no longer executed when the dialog starts.

The BEFORE ROW block will be executed when a new row is created in INPUT ARRAY. When entering an INPUT ARRAY with an empty array, a new temporary row is created by default, except if you use the AUTO APPEND = FALSE attribute.

Related concepts
BEFORE ROW block on page 1403
**Controlling INPUT ARRAY temporary row creation**
Down move after last row in INPUT ARRAY creates a new *temporary row*.

The INPUT ARRAY dialog and sub-dialog provides the APPEND ROW and AUTO APPEND attributes to control row creation at the end of a list (known as *temporary row creation*).

APPEND ROW controls explicit temporary row creation, while AUTO APPEND controls automatic temporary row creation.

Starting with version 2.20, moving down after the last row (with the mouse or keyboard) or leaving the last column of the last row with a TAB key are considered events that trigger automatic temporary row creation.

Before version 2.20, these cases were considered as events for an explicit temporary row creation. In other words, if you want to deny temporary row creation in such case, it is now done with AUTO APPEND = FALSE while in older versions it was controlled by APPEND ROW = FALSE.

**Related concepts**
Appending rows in INPUT ARRAY on page 1749
Rows appended at the end of an editable list are temporary until they are edited.

**BDL 2.11 upgrade guide**
These topics describe product changes you must be aware of when upgrading to version 2.11.

**Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero.
Check prior upgrade guides if you migrate from an earlier version.

1. Writing timestamp information in p-code modules on page 166

**Writing timestamp information in p-code modules**
A compilation timestamp is no longer automatically written to p-code files, when the source code is not modified.

Before release 2.10, the 42m p-code files were stamped with a compilation timestamp. This information changed after every compilation, even if the source code was not modified.

Since 2.10, the timestamp information is no longer written to p-code files by default, allowing 42m file comparison, checksum creation, or storage of 42m file in versioning tools. Version 2.11.05, provides the fglcomp on page 1972 --timestamp option to force a timestamp in p-code modules:

```
$ fglcomp --timestamp mymodule.4gl
$ fglrun -b mymodule.42m
2008-12-24 11:22:33 2.11.05-1169.84 /home/devel/stores/mymodule.4gl 15
```

**Related concepts**
Compiling source files on page 1998
Describes how to build the runtime files from source files.

**BDL 2.10 upgrade guide**
These topics describe product changes you must be aware of when upgrading to version 2.10.

**Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero.
Check prior upgrade guides if you migrate from an earlier version.

1. XML declaration added automatically on page 166
2. Using SQL Server 2008 date/time types on page 167

**XML declaration added automatically**
The XML declaration is added automatically when writing XML files.

An XML file must start with a "Prolog" or "XML Declaration" defining the XML version and character set used by the file:

```xml
<?xml version='1.0' encoding='ISO-8859-1' ?>
```
Starting with Genero version 2.10.05, the XML declaration is now added automatically when writing XML files.

Before 2.10.05, a workaround allowed you to write this header as a processing instruction, but this solution was subject to mistakes: the non-ASCII characters written to the XML file must match the encoding specification in the XML Declaration.

To avoid invalid character set definitions, the Genero BDL built-in classes now add the XML Declaration with the encoding attribute defined depending on the current locale used by the runtime system. The value written in the encoding attribute is defined by the charmap.alias file.

Related concepts
C-Extensions on page 2109
With C-Extensions, you can bind your own C libraries in the runtime system, to call C function from the application code.

The om package on page 2429
These topics cover the built-in classes for the om class

Using SQL Server 2008 date/time types
SQL Server 2008 introduces new SQL type to store date/time information.

Starting with Genero 2.10, SQL Server 2008 is now supported with the dbmsncA0 driver.

SQL Server 2008 introduces new data types to store date/time information, namely TIME(n), DATE, DATETIME2(n) and DATETIMEOFFSET(n). These data types offer better precision for data storage, as well as a one-to-one mapping for equivalent Genero BDL types (BDL DATE = SQL Server DATE).

When connected to SQL Server 2008 and higher, Genero database drivers for SQL Server use these new data type, when converting a CREATE TABLE / ALTER TABLE statement, and to store Genero BDL DATE and DATETIME information.

Therefore, upgrading to SQL Server 2008 requires planning the SQL Server database migration, in order to use the new date/time types provided in SQL Server 2008.

Note:
Up to Genero version 2.50, ODI drivers are built for a given database client and database server version. For example, dbmftm90 (using FreeTDS) is designed for SQL Server 2005, and will use old date/time types. Pay attention to the fact that drivers designed for an old SQL Server version (2005), can also work with a more recent SQL Server version (2008), but will act as if they were connected to SQL Server 2005 (using old date/time types).

Starting with Genero 3.00 (2.51 for Genero Mobile), ODI drivers can detect the database server version at runtime, and adapt the SQL conversions to the target server: Assuming that the FreeTDS version supports the required TDS protocol version to connect to the target server version, the dbmftm_0 ODI driver can connect to SQL Server 2005 or 2008, and adapt the date/time type usage to the targeted SQL Server version.

However, since Genero 3.10, SQL Server 2005 is no longer supported and only new SQL Server 2008 date/time types can be used.

For more details about BDL to SQL Server type mappings, see DATE and DATETIME data types on page 786 and Data type conversion table: Informix to SQL Server on page 779.

BDL 2.02 upgrade guide
These topics describe product changes you must be aware of when upgrading to version 2.02.

Important: This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Automatic HBox/VBox on page 168
**Automatic HBox/VBox**

fglform adds automatically HBox/VBox elements when needed.

Starting with version 2.02.01, the form compiler automatically adds HBox and VBox containers with splitter around stretchable form elements that are placed side-by-side.

When recompiling your forms with this new version of fglform on page 1970, the generated .42f can get additional HBox/VBox nodes even if you did not touch the .per source file.

**Related concepts**

Web Services changes
There are changes in support of Web services in Genero 2.00.

Using the 1.3x Web Services API

There is no need to create a special runner for Genero Web Services 2.x. Instead, the GWS 2.x library is imported into your applications. If you want to migrate your existing 1.x GWS Server application to 2.x, to avoid the need for a special runner, as well as to take advantage of any bug fixes, take the following steps:

1. Add the following statement at the top of any .4gl module where before you used GWS 1.3x functions:

   ```
   import com
   ```

2. Compile and re-link your GWS Server application (.42r).

   This imports the new GWS com library, and ensures that any GWS 1.3x functions that you have used will be compatible. Your existing Genero 1.3x Client applications, as well as third-party Client applications, will continue to work.

Using the new 2.00 Web Services API

If you want to take advantage of the new features and simplify future migrations, you can migrate your Genero Web Services (GWS) Server runner and also use the new GWS 2.x APIs. All the 1.3x publishing functions for all the operations in your application must be replaced with 2.x publishing functions. Since this does not change the interface, all existing Genero 1.3x client applications, as well as third-party client applications, will continue to work.

As 1.3x only supports RPC-Encoded style services, you must use the RPC style functions of the new 2.x APIs as the replacement functions, with setInputEncoded and setOutputEncoded set to true. And, you cannot add XML attributes to the records used as Web Service function parameters.

To replace the fgl_ws_server_publishfunction() statement in an existing GWS Server application; for example:

   ```
   CALL fgl_ws_server_publishfunction(
     "EchoInteger",
     "http://tempuri.org/webservices/types/in", "echoInteger_in",
     "http://tempuri.org/webservices/types/out", "echoInteger_out",
     "echoInteger")
   ```

1. Add this statement at the top of each module:

   ```
   import com
   ```

2. Define variables for the WebService and WebOperation objects:

   ```
   DEFINE serv  com.WebService
   DEFINE op    com.WebOperation  -- Operation of a WebService
   ```

3. Create the GWS Server object:

   ```
   LET serv = com.WebService.CreateWebService(
     "EchoInteger",
     "http://tempuri.org/webservices"
   )
   ```

4. Use the 2.x publishing functions for each operation:

   ```
   LET op = com.WebOperation.CreateRPCStyle(
     "echoInteger",
     "EchoInteger",
     echoInteger_in, echoInteger_out
   )
   CALL op.setInputEncoded(true)
   ```
CALL op.setOutputEncoded(true)
CALL serv.publishOperation(op,NULL)

5. Compile and re-link your GWS Server application (.42r)

GWS 2.x also allows your Server application (.42r) to contain multiple services. If you would like 2.x and 1.3x GWS to coexist in the same .42r executable, replace the existing publishing 1.3x functions.

Enhance the GWS server application to be WS-I compliant (recommended)

Important: You must be able to change all the client applications that access your migrated Genero Web Services (GWS) Server.

If you use the Literal styles now available in GWS 2.x for your Web service, your application will be WS-I compliant. However, the migration techniques still use the RPC/Encoded style (Only RPC/Encoded was supported in GWS 1.3x). If you can change all the client applications that access your migrated GWS Server, we recommend that you enhance the GWS Server application to be WS-I compliant.

1. Replace the publishing functions in the GWS Server application but omit the setInputEncoded and setOutputEncoded lines. The resulting style will be Literal.
2. The enhanced GWS Server will have a new RPC/Literal WSDL that must be used to regenerate the client stub with the fglwsl tool:

3. Compile that new client stub, and re-link it with the GWS client application. This operation must be repeated for each client application accessing that service.
4. Third party client applications must also be changed to use the new WSDL.

Runner creation is no longer needed

Starting with version 2.00, you no longer need to recompile/build a runner.

The runtime system architecture is now based on shared libraries (or DLLs on Windows®), and the database drivers are automatically loaded according to FGLPROFILE configuration parameters.

If you have C extensions, you must rebuild them as shared libraries.

Important: Database vendor client libraries (libclntsh, libcli, libpq, libaodbc) must be provided as shared objects (or DLL on Windows®).

Related concepts

C-Extensions on page 2109

With C-Extensions, you can bind your own C libraries in the runtime system, to call C function from the application code.

Desupported Informix® client environments

Upgrade IBM® Informix® Client Software Development Kit (CSDK) to the most recent version.

Always upgrade the IBM® Informix® Client Software Development Kit (CSDK) to the most recent version supported by Genero BDL.

The database interface of Genero Business Development Language (BDL) version 2.00 was redesigned to allow dynamic loading of database drivers. The following IBM® Informix® drivers and environments have been desupported with this redesign:

- ix210: Informix® ESQL/C 2.10
- ix410: Informix® ESQL/C 4.10
- ix501: Informix® ESQL/C 5.01
- ix711: Informix® ESQL/C 7.11
- ix720: Informix® ESQL/C 7.20
If required, old IBM® Informix® drivers can be re-enabled in a next Genero BDL version. However, we strongly recommend you to upgrade the IBM® Informix® Client Software Development Kit (CSDK) to the most recent version supported by Genero BDL.

**Related concepts**

[Installation](#) on page 38
This chapter contains installation and setup instructions.

**Desupported database drivers**
Database drivers for old database client versions are removed by following vendor desupport plans.

**Database drivers desupported in versions 2.00:**

- Adabas D 12 (dbmabd12)
- PostgreSQL 7 (dbmpgs7x)
- SQL Server 7 (dbmmmsv7x)

**Related concepts**

[Database driver specification (driver)](#) on page 606

**fglmkrtn tool removed**
The fglmkrtn tool has been removed, as database drivers are loaded dynamically.

Starting with version 2.00, database drivers are now always loaded dynamically. Thus the fglmkrtn tool has been removed from the distribution. This tool was provided in previous versions to create a fglrun runner with the correct database driver.

Refer to [Database connections](#) on page 600 for more details about database driver configuration.

**Related concepts**

[Database driver specification (driver)](#) on page 606

**fglinstall tool removed**
The fglinstall tool has been removed from the distribution. This tool was provided in previous versions to compile product message files, form files, and program modules provided in the distribution. The compiled versions of all these files are now included in the package.

**Related concepts**

[Command reference](#) on page 1968
Command line tools provided for BDL.

**Linking the utility functions library**
All utility functions are in the libfgl4js.42x library, up until 2.21.

Prior to version 2.00, some utility functions (canvas draw* and database db_* functions) were linked automatically to the 42r program when using fglrun -l or fgllink. These functions are implemented in the fgldraw.4gl and fgldbutl.4gl modules, which were linked in the libfgl.42x library and loaded automatically at runtime by fglrun.

Starting with version 2.00, all utility functions are now in the libfgl4js.42x library. So, if you use the draw* or db_* utility functions, you must now add the libfgl4js.42x library explicitly when using fglrun -l or fgllink, or you can use the fgl2p on page 1971 tool to link .42x programs. The fgl2p tool links the program with the libfgl4js.42x library by default.

Starting with version 2.21, the libfgl.42x library is no longer provided.

**Related concepts**

[Utility functions](#) on page 2181
A utility function is a function provided in a separate library; it is not built in the runtime system.

Command reference on page 1968
Command line tools provided for BDL.

**Dynamic C extensions**
Dynamic C extensions are automatically loaded with `IMPORT` instructions.

Prior to version 2.00, you had to use `FGLPROFILE` entries to specify Dynamic C extensions to be loaded at runtime.

Starting with version 2.00, Dynamic C extensions are automatically loaded with `IMPORT` instructions. The `FGLPROFILE` entries are no longer used.

**Important:** Global variables (userData) can no longer be shared between the runtime system and the C extensions. You must use functions to pass global variable values.

There is no longer any need to define the `FGL_API_MAIN` macro in the extension interface file.

All C data type definitions are now centralized in the `fglExt.h` header file; header files such as `Date.h`, `MyDecimal.h` have been removed from the distribution.

**Related concepts**

C-Extensions on page 2109
With C-Extensions, you can bind your own C libraries in the runtime system, to call C function from the application code.

Example 4: Global variables on page 378

**WANTCOLUMNSANCHORED is desupported**
Use `UNMOVABLECOLUMNS` to specify that table columns cannot be moved around by the user.

Before version 2.00, the `WANTCOLUMNSANCHORED` attribute was undocumented but still supported by the language, to simplify migration from 1.20.

Starting with version 2.00, the `WANTCOLUMNSANCHORED` attribute is desupported; you must use `UNMOVABLECOLUMNS` to specify that table columns cannot be moved around by the user.

**Related concepts**

UNMOVABLECOLUMNS attribute on page 1291
The `UNMOVABLECOLUMNS` attribute prevents the user from moving columns of a table.

**PIXELWIDTH / PIXELHEIGHT are deprecated**
Use the `WIDTH` and `HEIGHT` attributes to specify the size of an image.

Before version 2.00, the `PIXELWIDTH` and `PIXELHEIGHT` attributes were used to specify the real size of an IMAGE form item.

Starting with version 2.00, you must use the `WIDTH attribute` on page 1302 and `HEIGHT attribute` on page 1259 to specify the size of an image:

In the `.per` form file:

```plaintext
IMAGE img1 = FORMONLY.image1, 
    HEIGHT = 100 PIXELS, 
    WIDTH = 100 PIXELS;
```

The `PIXELWIDTH` and `PIXELHEIGHT` attributes are still supported by the form compiler, but are deprecated and will be removed in a future version.

**Related concepts**

IMAGE item type on page 1174
Defines an area that can display an image resource.

**Prefetch parameters with Oracle**

Prefetch parameters allow an application to automatically fetch rows from the Oracle® database when opening a cursor.

Before version 2.00, the default prefetch parameters are 50 rows and 65535 bytes for the prefetch buffer. Some customers experienced a huge memory usage with those default values, when using a lot of cursors: It appears that the Oracle® client is allocating a buffer of prefetch.memory (64 Kbytes) for each cursor.

Starting with version 2.00, the default is 10 rows and 0 (zero) bytes for the prefetch buffer (memory), meaning that memory is not included in computing the number of rows to prefetch.

**Related concepts**

Database connections on page 600
Explains how to manage database connections in a program.

**Preprocessor directive syntax changed**

The preprocessor directives use an ampersand character (&) instead of a hash (#) character.

Before version 2.00, the preprocessor directives start with a (#) hash character, to be compliant with standard preprocessors (like cpp). This caused too many conflicts with standard language comments that use the same character:

```
#include "myheader.4gl"
# This is a comment
```

Starting with version 2.00, the preprocessor directives use an ampersand character (&):

```
&include "myheader.4gl"
FUNCTION debug( msg )
  DEFINE msg STRING
&ifdef DEBUG
    DISPLAY msg
&endif
END FUNCTION
```

The preprocessor is now integrated in the compiler, to achieve faster compilation.

**Important:** To simplify the migration, the # hash character is still supported when using the -p fgllpp option of the compiler. However, it is recommended that you review your source code and use the & character instead; # hash will be desupported in a future version.

**Related concepts**

Source preprocessor on page 2019
A typical preprocessor like in the C language.

**Static SQL cache is removed**

The Static SQL Cache has been removed.

Before version 2.00, the size of the static SQL cache is defined by an FGLPROFILE entry:

```
dbi.sql.static.optimization.cache.size = max
```

This entry was provided to optimize SQL execution without touching code using a lot of static SQL statements, especially when using non-Informix® databases where the execution of static SQL statements is slower than with Informix®. This is useful for fast migrations, but there were a lot of side effects and unexpected errors.

Starting with version 2.00, the Static SQL Cache has been removed for the reasons described. Programs continue to run without changing the code, but if you want to optimize program execution, you must use dynamic SQL (PREPARE + EXECUTE).
Related concepts
Dynamic SQL management on page 654
Explains how to execute and manage SQL statements at runtime.

SQL directive set removed
The SQL directive set specification has been removed.
Before version 2.00, it was possible to define SQL directive sets in `FGLPROFILE`:

```
dbi.sqldirset.set-name.directive.directive-name.\{deflist\substrg\} = "value"
```

With this feature, one could write SQL statement with database specific syntax, to be adapted at runtime depending on the target database type:

```
-- substrg directive:
dbi.sqldirset.ora.directive.trunc.substrg = "TRUNCATE\('$(1)\')"
"SELECT * FROM customer WHERE \{% trunc custname\} = ?"

-- ifdef directive:
dbi.sqldirset.ifx.directive.ifdef.deflist = "INFORMIX"
dbi.sqldirset.ora.directive.ifdef.deflist = "ORACLE,ANSI"
"SELECT * FROM
\{% ifdef INFORMIX \"t1, OUTER(t2)\"\}
\{% ifdef ORACLE \"t1, t2\"\}"
\{% ifdef ORACLE \"(+)\"\}"
```

Starting with version 2.00, SQL directive sets are no longer supported. Consider writing SQL statements with a syntax that is supported by all target database servers, or use dynamic SQL if you need to adapt the SQL syntax to the database type.

Related concepts
Dynamic SQL management on page 654
Explains how to execute and manage SQL statements at runtime.

Static SQL cache is removed on page 173
The Static SQL Cache has been removed.

Connection database schema specification
Oracle- and DB2-specific `FGLPROFILE` entries can be specified to define the database schema at runtime.
Before version 2.00, an `FGLPROFILE` entry was specified to define the database schema at runtime:

```
dbi.database.dbname.schema = "schema-name"
```

This entry was used to select the native database schema after connecting to the server, for Oracle® and DB2® only.

Starting with version 2.00, this entry is now specific to the Oracle® and DB2 database driver configuration parameters:

```
dbi.database.dbname.ora.schema = "schema-name"
dbi.database.dbname.db2.schema = "schema-name"
```

For other database servers, this configuration parameter is not defined.

**Important:** It is no longer possible to specify the "schema" parameter in the connection string (`dbname +schema='name'`).

Related concepts
Database connections on page 600
Explains how to manage database connections in a program.

**Schema extraction tool changes**
The fgldbsch schema extractor is recommended, and has been enhanced.

**Unique tool**
Version prior to 2.00 two schema extractors were provided: fglschema and fgldbsch on page 1978. The first one can only extract schemas from Informix® databases, while the second one can extract schemas from all supported databases.

Starting with version 2.00, the fgldbsch tool has been extended to support the old fglschema options, and fglschema has been replaced by a simple script calling fgldbsch. When you call fglschema, you actually call fgldbsch. We recommend that you use fgldbsch with its specific command line options.

**System tables**
In 2.0x, fgldbsch does not extract system tables by default. You must specify the `-st` option to get the system tables description in the schema files.

**Remote synonyms**
The original fglschema tool searched for remote synonyms with Informix® databases. The fgldbsch tool of version 2.00 does not search for remote synonyms.

**Public and private synonyms**
Since version 1.32.1b (build 620.313), fgldbsch does not extract private synonyms anymore. Only public synonyms are extracted. The .sch schema files do not contain table owners, and if two private synonyms have the same names, there is no way to distinguish them in the schema files. Therefore, to avoid any mistakes, private synonyms are not extracted anymore.

**Related concepts**
- Database schema on page 476
  Defines database table structures with column type information to be reused in program variable definitions.
- Database schema extractor options on page 486
  The fgldbsch tool extracts the schema description for an existing database.

**Global and module variables using the same name**
Program variable names must be different in global and module scope.

Since version 2.00, when you declare a module variable with the same name as a global variable, a compilation error must be thrown.

This is critical to avoid confusion with the variable usage:

```plaintext
GLOBALS
    DEFINE level INTEGER
END GLOBALS

GLOBALS "globals.4gl"
    DEFINE level INTEGER
FUNCTION func1()
    LET level = 123  -- is this the global or the module variable?
END FUNCTION
```

Before version 2.00, the compiler did not detect this and the module variable was used, but one might want to use the global variable instead!
If you have module variables defined with the same name as global variables, the compiler now raises the following error:

```
-4319: The symbol 'variable-name' has been defined more than once.
```

You can easily fix this by renaming the module variable. There is no risk in doing this modification, because in versions before 2.00, the module variable was used, not the global variable.

Remark: The compiler now also detects duplicate global variable declaration. Just remove the duplicated lines in your source.

**Related concepts**

*Globals* on page 472
Global variables can be shared among all modules of a program.

*Variables* on page 366
Explains how to define program variables.

*Importing modules* on page 496
Use the `IMPORT ...` instruction to import BDL, C or Java external modules in the current module.

**Connection parameters in FGLPROFILE when using Informix®**

The `dbi.database.*` connection parameters defined in FGLPROFILE are used by the Informix® driver

Before version 2.00, the `dbi.database.*` connection parameters defined in FGLPROFILE are ignored by the Informix® drivers.

Starting with version 2.00, the `dbi.database.*` connection parameters defined in FGLPROFILE are used by the Informix® driver, as well as other database vendor drivers. For example, if you connect to the database "stores", and you have the following entries defined, the driver tries to connect as "user1" with password "alpha":

```
  dbi.database.stores.username = "user1"
  dbi.database.stores.password = "alpha"
```

You typically get SQL errors -387 or -329 when the wrong database login or the wrong database name is used.

**Related concepts**

*Database connections* on page 600
Explains how to manage database connections in a program.

**Inconsistent USING clauses**

Having data types changing at each execute is no longer supported.

**Important: This issue applies to non-Informix databases only.**

Before version 2.00, it was possible to execute a prepared statement with the variable list changing at each `EXECUTE` statement:

```
DEFINE var1 DECIMAL(6,2)
DEFINE var2 CHAR(10)
DEFINE var3 DATE
PREPARE st1 FROM "INSERT INTO tab1 VALUES (?, ?, ?)"
EXECUTE st1 USING var1, var2, var3
EXECUTE st1 USING var2, var3, var1 -- different order = different data types
```

The database interface of version 2.00 has been rewritten for better performance. Having data types changing at each execute is no longer supported.

Error `-254` will be raised if different data types are used in subsequent `EXECUTE` statements (with the same statement name).
Related concepts

**Database transactions** on page 538
Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Usage of RUN IN FORM MODE**

RUN ... IN FORM MODE is recommended to run interactive applications.

Before version 2.00, **RUN ... IN FORM MODE** was recommended to run interactive applications.

Starting with version 2.00, **RUN ... IN FORM MODE** is recommended to run interactive applications. The **RUN** command is used as follows (in both GUI and TUI mode):

1. When starting an interactive program, either use **RUN ... IN FORM MODE** or, if the default mode is **LINE MODE**, use the **RUN** instruction without any option.
2. When starting a batch program that does not display any message, it is recommended that you use **RUN ... IN FORM MODE**.

For more details about the RUN options, see the **RUN** on page 521 instruction.

Related concepts

**Program execution** on page 519

**TTY and COLOR WHERE attribute**

All types of fields now allow TTY attributes and the conditional COLOR WHERE attribute.

Before version 2.00, only some field types like EDIT or TEXTEDIT provided support for TTY attributes (COLOR, REVERSE), and the conditional COLOR WHERE attribute.

Starting with version 2.00, all field types allow TTY attributes and the conditional COLOR WHERE attribute. This means that when using **ATTRIBUTES(tty-attribute)** in programs, all fields will now be affected.

For example, CHECKBOX and RADIOGROUP fields will now get a colored background, this was not the case in prior versions.

Related concepts

**COLOR attribute** on page 1248
The **COLOR** attribute defines the foreground color of the text displayed by a form element.

**BDL 1.33 upgrade guide**

These topics describe product changes you must be aware of when upgrading to version 1.33.

These topics describe product changes you must be aware of when upgrading to version 1.30.

**Important:** This is an incremental upgrade guide that covers only topics related to a specific version of Genero. Check prior upgrade guides if you migrate from an earlier version.

1. Action and field activation on page 178
2. Using HBox tags in forms on page 178
3. Width of ButtonEdit/DateEdit/ComboBox on page 181
4. Form fields default sample on page 183
5. Size policy for ComboBoxes on page 185
6. Action defaults at form level on page 187
7. Compiled string files (.42s) on page 187

**Action and field activation**
Dialog methods can be used to control action and field activation.

Version 1.30 provides dialog methods to control action and field activation:

- `ui.Dialog.setActionActive( action-name, TRUE/FALSE )`
- `ui.Dialog.setFieldActive( field-name, TRUE/FALSE )`

Previous versions allowed you to modify directly the ‘active’ attribute of the underlying DOM node in the AUI tree. This is now forbidden: it is mandatory to use the methods to enable/disable action or fields. The dialog will synchronize the ‘active’ attribute in the AUI tree based on the value passed to the methods and depending on the context (some actions or fields can be automatically disabled).

**Using HBox tags in forms**
HBox tags can be used to stack form items horizontally.

Version 1.30 supports now HBox tags to stack form items horizontally without being influenced by elements above or below.

In an HBox there is a free mix of Form Fields, labels, and Spacer Items possible.

A typical usage of an HBox tag is to have zipcode/city form fields side by side with predictable spacing in-between.

The "classic" layout would look like the following form definition:

```xml
<G "User Data(version 1.20)" >
  Last Name [l_name ]First Name[f_name ]
  Street [street ]
  City [city ]Zip Code[zip ]
  Phone(private)[phone ] At work [ ]
  Code [aa]-[ab]-[ac]
</G>
```

In Figure 7: HBox tag example screenshot on page 179 you will notice that the distance between "l_name" and "First Name" is smaller than between "First Name" and "f_name". How can this be? Two lines under, there is the "zip" field which affects this distance.
If we put HBox tags around the fields we want to group horizontally together, we get the predictable spacing between "l_name", "First Name" and "f_name".

```
<G "User Data in HBoxes stacked" >
Last Name  [l_nameh   :"First Name":f_nameh   ]
Street     [streeth]:
City       [cityh   :":Zip Code":ziph :]
Phone(private)[phoneh :":At work":phonewh :]
Code       [ba:"-":bb:"-":bc:]
</G>
```

Here "l_nameh", "First Name" and "f_nameh" are together in one HBox; the ":" colon acts as a separator between the 3 elements.

The width of an element is calculated from the space between "[" and "]": (width of \texttt{cityh} is 14), or from the space between ":" and ":" (width of \texttt{bb} is 2), or from the space between ":" and "]": (width of \texttt{f_nameh} is 16). The "zip" field in the version 1.20 example has a width of five and the "ziph" field has also a width of five.

In the second Groupbox in Figure 7: HBox tag example screenshot on page 179 you will notice that the HBox is smaller than the first one, even though it uses two characters more in the screen definition. The reason is that each HBox occupies only ONE cell in the parent grid, and the content in one HBox is independent of the content in another HBox. This relaxes the parent grid; it has to align only the edges of the HBoxes and the labels left of the HBoxes. The two extra characters in the Form file for the second Group come from the fact that the labels need quoting to distinguish them from field definitions. Of course, you could use a Label field if the two extra characters are unwanted (which is done in the third Groupbox).

The third Groupbox shows how the alignment in an HBox can be affected by putting empty elements (\texttt{::}) inside the HBox Tag:

```
<G "User Data in HBoxes right part right aligned" >
Last Name  [l_nameh2  ::lfirsth2:f_nameh2  ]
Street     [streeth2]:
City       [cityh2  ::=lzip:ziph2]
Phone(private)[phoneh2 ::latw:phonewh2 :]
Code       [ca: "-":cb: "-":cc]
</G>
```

Between "l_nameh2" and "lfirsth2" there are two ":" signs with a white space between them. This means: put a Spacer Item between \texttt{l_nameh2} and \texttt{lfirsth2}, which gets all the additional space if the HBox is bigger than the sum of \texttt{l_nameh2}, \texttt{lfirsth2} and \texttt{f_nameh2}. The number of spaces, however, has no effect. The spacer item between \texttt{cityh2} and \texttt{lzip} has the same force as the spacer between \texttt{l_nameh2} and \texttt{lfirsth2}.

You can treat a spacer item like a spring. The spacer item between \texttt{cityh2} and \texttt{lzip} presses \texttt{cityh2} to the left-hand side, and the rest of the fields to the right-hand side. In the "Code" line there is more than one spacer item; they share the additional space among them. (The "Code" HBox sample in the third line is only to show how spacer items work; we always advise using "Code" as in the second Groupbox, or to use a picture)

In general we advise using the approach shown in the second Groupbox: stack the items horizontally by replacing field ends with ":". This is the easy way to remove unwanted horizontal spacing.

**Figure 7: HBox tag example screenshot**
A big advantage in using elements in an HBox tag is that the fields get their real sizes depending on the `.per` definition.

```
LAYOUT
GRID
{
  <G g1 >
  [a    ] single Edit Field
  <G g2 >
  MMMMMMMM
  [b    ] The large label expands the Edit Field
  <G g3 >
  MMMMMMMM
  [c    :] The large label has no influence on the Edit width
}
END
END
ATTRIBUTES
EDIT a = formonly.a, sample="0", default="12345";
EDIT b = formonly.b, sample="0", default="12345";
```
EDIT c = formonly.c, sample="0", default="12345";
END

In the second Groupbox, the edit field is expanded to be as large as the label above; using an HBox prevents this.

![Figure 8: Use of HBox](image)

**Note:** in this example, we use a sample of "0" to display *exactly* five numbers.

**HBox Tags limitations**

HBox tags don't work for fields of Screen Arrays or Tables; you will get a form compiler error. The reason is that the current AUI structure does not allow this. The front end needs a Matrix element directly in a Grid or a ScrollGrid to perform the necessary positioning calculations for the individual fields.

**Width of ButtonEdit/DateEdit/ComboBox**

When using BUTTONEDIT/COMBOBOX/DATEDIT fields, it is recommended that you account for the width of the widget button in addition to the input area.

The problem with BUTTONEDIT, DATEEDIT and COMBOBOX in versions prior to 1.30 is that a field [b] got the width 3, the same width as an edit field with the same layout.

For example:

```
LAYOUT
GRID
{
  [e ]
  [b ]
}
END
END
ATTRIBUTES
EDIT e=formonly.e;
BUTTONEDIT b=formonly.b;
END
```

In this example, the outer (visual) width of both elements was the same, but the edit portion of "b" was much smaller, because the button did not count at all. (In practice this meant that on average only one and a half characters of "b" was visible). However, you could input 3 characters! This resulted in a BUTTONEDIT where only one character was visible and inputting more than one character was possible.
Starting with version 1.30, for the Button, the Form Compiler subtracts two character positions from the width of BUTTONEDIT/COMBOBOX/DATEEDIT. This is possible because now the form compiler differentiates the width of the widget from the width of the entry part.

In fact, there is no visual difference between version 1.20 and 1.30 regarding this example, but in version 1.30 you can only enter one character, which is visually more correct.

In the example the BUTTONEDIT aligns with the Edit; that's why the Edit part of the BUTTONEDIT is usually still a bit bigger than one character (this depends on the button size, but if a button edit is contained by an HBox, it will get the exact size of "width" multiplied by the average character pixel width.

To express the BUTTONEDIT/COMBOBOX/DATEEDIT layout more visually, it is possible to specify:

```
[e ]
[b- ]
```

the "-" sign marks the end of the edit portion and the beginning of the button portion (edit width="1", widget width="3").

The two characters are also subtracted for a BUTTONEDIT which is child of an HBox.

```
[b :]
```

gets also width="1", but no widget width, because the HBox stacks the elements horizontally without needing widget width definition.

The two extra characters are only used to show the real size relations more WYSIWYG, and to have the same calculation as in a field without an HBox parent.

```
[e1:e2:e3: ]
[b1 :b2 :b3 ]
```

shows that three BUTTONEDIT fields are much larger than three EDIT fields with the same width.

You can even write:

```
[e1:e2:e3: ]
[b1- :b2- :b3- ]
```

or:

```
[e1:e2:e3: ]
[b1-:b2-:b3-]
```

to use slim buttons and

```
[e1:e2:e3: ]
[b1- :b2- :b3- ]
```

if one uses large buttons to get the maximum WYSIWYG effect.

Please note that buttons do not grow if two characters "- " are expanded to three characters "- "; the button always computes its size from the image used, it's just reserves more space in the form to match the real size.

**Related concepts**

Form fields default sample on page 183
An algorithm is used to compute the field width when no SAMPLE attribute is specified.

**Form fields default sample**

An algorithm is used to compute the field width when no SAMPLE attribute is specified.

Starting with version 1.30, if no SAMPLE attribute is specified in the form files, the client uses an algorithm to compute the field widths: The client assumes a default SAMPLE of "M" for the first six characters and then "0" for the subsequent characters and applies this algorithm to all fields, with some exceptions like DATEEDIT fields.

The default algorithm tends to produce larger forms compared to forms used in BDS V3 and very first versions of Genero. Do not hesitate to modify the SAMPLE attribute in the form file, to make your fields shorter.

If you do not want to touch all your forms, a more tailored automatic solution would be to specify a `ui.form.setDefaultInitializer()` function, to set the SAMPLE depending on the AUI tag. In this example small UPSHIFT fields get a sample of "M"; all other fields get a sample of "0". This will preserve the original width for UPSHIFT fields. However, numeric and normal String fields will get the sample of "0" and make the overall width of the form smaller.

Program:

```plaintext
# this demo program shows how to affect the "sample" attribute in a
# ui.form.setDefaultInitializer function
# the main concern is to set a default sample of "0" and to
# correct the sample attribute for small UPSHIFT fields to "M"
# to be able to display full uppercase letter for fields with a small width

MAIN
  DEFINE three_char_upshift CHAR(3)

END

Figure 9: Sample usage in form

Related concepts
SAMPLE attribute  on page 1281
The SAMPLE attribute defines the text to be used to compute the width of a form field.

**Size policy for Combo Boxes**

You can use the SIZEPOLICY attribute for a COMBOBOX.

Starting with version 1.30 you can use the SIZEPOLICY attribute for COMBOBOXes.

COMBOBOX form items had a special behavior in versions prior to 1.30, because they adapted their size to the maximum item of the value list. On one hand, this is very convenient because the programmer doesn't have to find the biggest string in the value list, and to estimate how large it will be on the screen (with proportional fonts the string with the highest number of characters is not automatically the largest string). On the other hand, this behavior often led to an unpredictable layout if the programmer didn't reserve enough space for the COMBOBOX.

The SIZEPOLICY attribute gives better control of the result.

```
<G "Combo makes edit2 too big"                     >
  [edit1]                      
  [combo  ]                     
  [edit2  ]                     
...                         
ATTRIBUTES
EDIT edit1=formonly.edit1;
COMBOBOX combo=formonly.combo,
  ITEMS=((0,"Veeeeeeery Looooooooooooooong Item"),(1,"hallo")),
  DEFAULT=0;
EDIT edit2=formonly.edit2;
END
```

**Figure 10: Use of SIZEPOLICY**

In this case, the "combo" field gets very large as does "edit2", because it ends in the same grid column. It will confuse the end user if he can input only eight characters and the field is apparently much bigger. Two possibilities exist to surround this:

Use an HBox to prevent the edit2 from growing, and use HBoxes for all fields which start together with combo and are as large or bigger than combo:

```
<G "Edit2 in HBox doesn't grow" >
  [edit1]
  [combo  ]
  [edit2  ]
...  
```
Use the new SIZEPOLICY attribute, and set it to fixed to prevent combo from getting bigger than the initial six characters (6+Button):

```xml
<G "Combo has a fixed size">
  ...
  [combo  ]
  [edit2  ]
  ...
  ATTRIBUTES
  ...
  COMBOBOX combo=formonly.combo,
  
  ITEMS = ((0,"Veeeeeeeery Looooooooooooooooong Item"),(1,"hallo")),
  
  DEFAULT=0, SIZEPOLICY=FIXED ;
  ...
</G>
```

In this example the edit2 dictates the maximum size of combo, because even if the SIZEPOLICY is fixed, the elements are aligned by the Grid.

To prevent this and have exactly six characters (numbers) in the ComboBox, you need to de-couple combo from edit2 by using an HBox.

```xml
<G "Combo has a fixed size,sample 0,in HBox" 
  ...
  Combo [combo  :
  Edit2 [edit2  :
  ...
  COMBOBOX combo=formonly.combo,
  
  ITEMS = ((0,"12345678 Looooooooooooooooong Item"),(1,"hallo")),
  
  DEFAULT=0, SIZEPOLICY=FIXED, SAMPLE="0";
</G>
```
Now the wanted six numbers are displayed and combo does not grow to the size of edit2.

**Related concepts**

- **SIZEPOLICY attribute** on page 1283
  The SIZEPOLICY attribute is a sizing directive based on the content of a form item.

**Action defaults at form level**

You can define action defaults in forms.

Starting with version 1.30 it is now possible to define action defaults in forms. In previous versions you had to define a global action default file; this works for defining common global action attributes, but there is a need to define specific action attributes in some forms. A typical zoom window may have search and navigation actions, while data input windows need to define add/delete/update actions instead.

It is now possible to define an action default section in the form file, and you can also load action defaults with `ui.Form.loadActionDefaults` on page 2361.

**Related concepts**

- **ACTION DEFAULTS section** on page 1189
  The ACTION DEFAULTS section defines local action view default attributes for the form elements.

**Compiled string files (.42s)**

The file extension of compiled string files is new `.42s`.

Starting with version 1.30, compiled localized string files use now the file extension `.42s`.

Before version 1.30, the file extension was `.41s`.

See **Localized strings** on page 430.

---

**Planned desupport**

Features described in this topic will be deprecated or desupported in the next major release of the product.

**Important:** If you are using one of these features, consider reviewing your code now.

**Features that will be desupported in a future version**

Deprecated features no longer documented:

- Oracle® MySQL 5.5, MariaDB 10.0 and 10.1, and corresponding database driver (`dbmmys_5_5`).
- The PIXELWIDTH and PIXELHEIGHT form file attributes (use `WIDTH = n PIXELS / HEIGHT = n PIXELS` instead).
- The FIELD form item type that specified abstract form fields with attributes defined in the `.val` schema file.
- The Window.commentPosition style attribute (only supported by the GDC front-end).

Deprecation features still documented:
(GDC only) Local Actions.
- The GDC WinCOM, WinDDE and WinMail front call modules.
- The `standard.setWebComponentPath` front call.
- The `fglrun.mmapDisable=true` FGLPROFILE entry is deprecated.

Introduction to I4GL migration

IBM® Informix® 4GL and Genero BDL products

IBM® Informix® 4GL (I4GL) and Genero Business Development Language (BDL) are distinct development tools. The purpose of Genero BDL is to be as compatible as possible with I4GL, and it is very close. The success of Genero BDL depends on the ability to compile and run legacy 4gl code with minimum code changes. For text-mode applications, the migration steps are often reduced to recompile-and-run.
Genero BDL extends the I4GL language with advanced features, such as a Graphical User Interface and SQL access to non-Informix databases. This leads to some differences that you have to deal with, but these incompatibilities are minor compared to the added value.

In some rare cases, the Genero BDL team decided to take a different path to implement an I4GL feature, because we considered that the IBM® Informix® 4gl solution was not adaptable. For example, the dynamic arrays in I4GL and Genero BDL have different semantics.

This guide will help you identify the differences and find solutions to make the migration from IBM® Informix® 4gl easier.

**IBM® Informix® 4GL reference version**

Several versions of the IBM® Informix® 4GL language have been released. It started in the mid-80s with I4GL version 4.x; then came version 6.x in 1996. I4GL version 7.2 was released in 1998; then versions 7.31, 7.32, and finally the version: 7.50 came out.

There have been several bug fixes and enhancements over the life of I4GL, resulting in releases that slightly differ. Supporting strict compatibility with all versions of I4GL is not possible for Genero BDL.

The Genero BDL compatibility level with IBM® Informix® 4gl is achieved by comparing with the latest version of I4GL, which is version 7.50 at the time of this writing.

**Installation and setup topics**

**Using C extensions**

With IBM® Informix® 4GL, you can extend the fglgo runtime executable or link your binary programs with c4gl by adding your own C functions.

When migrating to Genero Business Development Language, the C-Extensions must be reviewed in order to provide them as shared libraries. Normally, C extensions modules must be specified in .4gl modules with the IMPORT instruction. To simplify migration, the runtime system loads the userextension shared library (or DLL) automatically, so you can group all your existing C functions in a unique shared library and use it without changing the source code of your programs.

**Related concepts**

C-Extensions on page 2109

With C-Extensions, you can bind your own C libraries in the runtime system, to call C function from the application code.

**Localization support in Genero**

To support language-specific and country-specific locales, as well as multibyte character sets like BIG5, IBM® Informix® 4GL uses the Informix® GLS library.

For locale support, Genero Business Development Language (BDL) does not use the Informix® GLS library, to be independent from Informix® GLS libraries. Genero uses the standard C library functions for character data handling, based on the POSIX setlocale() function.

I4GL uses the CLIENT_LOCALE environment variable to define the locale for the application. With Genero BDL, you must use the LANG/LC_ALL environment variables to specify the locale of the application. However, CLIENT_LOCALE is still needed to define the locale for the IBM® Informix® database client.

**Related concepts**

Localization on page 405

Localization support allows you to implement programs that follow specific language and cultural rules.

**Database schema extractor**

Before compiling .4gl or .per files, you must extract the database schema with the fgldbsch tool. This will produce an .sch file, and optionally, .val and .att files. The fgldbsch tool can extract database schemas from Informix®, and from other databases such as Oracle and SQL Server, but you must be aware of data type conversion rules.
Related concepts

**Database schema** on page 476
Defines database table structures with column type information to be reused in program variable definitions.

**Compiling 4GL to C**

The IBM® Informix® 4GL compilers include a p-code based runtime system called RDS as well as a C-compiled solution, the c4gl compiler. The RDS solution is typically used in a development environment, supporting a debugger, while the Informix® 4GL C compiler is traditionally used to maximize performance on production sites. However, the C compiled binaries need to be built on the same target platform as the production system.

Genero Business Development Language supports a p-code architecture, which is as fast as the C-compiled version of IBM® Informix® 4GL. Since p-code files are portable, you can develop your application on a platform that is different from the production platform, saving porting procedures and simplifying deployment tasks.

**User interface topics**

**Smooth migration with traditional UI mode**

IBM® Informix® 4GL (I4GL) and Genero Business Development Language (BDL) handle windows and form content rendering differently. I4GL is designed to write applications for for dumb terminals, while Genero BDL uses real GUI rendering, with resizable windows and proportional fonts. To simplify migration from TUI-style products, Genero BDL supports the traditional GUI mode.

**Related concepts**

**Traditional GUI mode** on page 1015

**Refreshing the user interface**

When a program executes an instruction displaying information to the user, IBM® Informix® 4GL (I4GL) refreshes the screen immediately.

For example, when doing successive `DISPLAY ... AT` instructions in a loop, I4GL will show screen changes for each `DISPLAY` instruction:

```
MAIN
  DEFINE i INTEGER
  FOR i=1 TO 5000000
    DISPLAY i AT 2,2
  END FOR
END MAIN
```

Genero Business Development Language (BDL) handles screen refreshing differently:

To optimize the display for graphical front-ends, the runtime system will only refresh the screen, when the user gets the control. This means, when an interactive instruction (a dialog) waits for a user interaction.

With the above code, when using FGLGUI=0 to run in text mode, the screen will not show the numbers.

In order to display the numbers to the end user, force the screen refresh with an `ui.Interface.refresh()` API call. Note that the user interface should be refreshed periodically rather than continuously, to avoid network clogging. This is the reason for the `(i MOD 100)==0` test:

```
MAIN
  DEFINE i INTEGER
  FOR i=1 TO 5000000
    DISPLAY i AT 2,2
    IF (i MOD 1000) == 0 THEN
      CALL ui.Interface.refresh()
    END IF
  END FOR
END MAIN
```
Important: Genero’s special refresh behavior (delaying the output until the runtime waits for a user interaction) does in most cases not introduce any display problem in legacy programs. Special attention is required, if some information must be visible immediately and the runtime continues with processing code. A typical example is a "Please wait..." message, displayed just before a long processing.

Related concepts
The dynamic user interface on page 1009
The dynamic user interface is the base concept of the Genero user interaction components.

SCREEN versus LAYOUT section
To design a form with IBM® Informix® 4GL, you organize labels and fields in the SCREEN section of a .per form file. Genero Business Development Language introduced a new LAYOUT section to place form elements. The new LAYOUT section allows more sophisticated form design than SCREEN.

When writing new programs for GUI applications, it is recommended that you use a LAYOUT section instead of SCREEN. However, the SCREEN section is still supported to be used to design TUI mode forms.

Figure 14: Form using a SCREEN section in TUI mode
The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

Migrating screen arrays to tables

With IBM® Informix® 4GL, a list of records can be displayed on the screen by using a static screen array in the SCREEN section of the form specification file, with a finite number of lines:

```plaintext
DATABASE stores
SCREEN
{
  Id       First name   Last name
  [f001    |f002        |f003        
  [f001    |f002        |f003        
  [f001    |f002        |f003        
  [f001    |f002        |f003        
  [f001    |f002        |f003        
  [f001    |f002        |f003        
}
END TABLES
  customer
END
ATTRIBUTES
  f001 = customer.customer_num ;
  f002 = customer.fname ;
  f003 = customer.lname ;
END
INSTRUCTIONS
  SCREEN RECORD sr_cust[6]( customer.* )
END
```
The display of the form specification file in GUI mode:

![Screen with table widget](image)

**Figure 16: Form displayed not using table widget**

With Genero Business Development Language, use a static screen array for applications displayed in dumb terminals, and for GUI applications you can for example use the TABLE container:

```
DATABASE stores
LAYOUT
TABLE
{
  Id       First name   Last name
  [f001    |f002        |f003        ]
  [f001    |f002        |f003        ]
  [f001    |f002        |f003        ]
  [f001    |f002        |f003        ]
  [f001    |f002        |f003        ]
  [f001    |f002        |f003        ]
}
END
END
TABLES
  customer
END
ATTRIBUTES
  f001 = customer.customer_num ;
  f002 = customer.fname ;
  f003 = customer.lname ;
END
INSTRUCTIONS
  SCREEN RECORD sr_cust( customer.* );
END
```

The display of the form specification file is a real table widget, which is resizable. The .4gl source is untouched.
**Figure 17: Form displayed as table widget**

**Related concepts**
- **TABLE container** on page 1217
  Defines a re-sizable table designed to display a list of records.

**Review TUI specific features**

Typical IBM® Informix® 4GL programs use the TUI mode and often exploit all the display possibilities of the language for dumb terminals. Some instructions are specific to TUI mode and should be reviewed when redesigning the application for GUI mode.

For example, data records can be displayed in a screen array with a `DISPLAY array[array-index].* TO screen-array[screen-line]` instruction, optionally with the `ATTRIBUTES()` clause to use some TTY attributes like colors, reverse and bold effects. When scrolling a list, I4GL actually uses the terminal scrolling capabilities to preserve the TTY attributes in each row. This applies only to the current rows visible on the screen, but it was a commonly used feature.

In order to display application screens on different types of front-ends, Genero Business Development Language (BDL) handles user interface elements in a more abstract way. Therefore, dumb terminal specifics as described above cannot be supported. A good replacement for `DISPLAY ... TO ... ATTRIBUTES()` in `DISPLAY ARRAY` or `INPUT ARRAY` is to use the `DIALOG.setArrayAttributes()` method.

Genero BDL supports TUI-specific instructions such as `DISPLAY AT`, `CLEAR SCREEN`, `CLEAR WINDOW`, as well as TTY attributes such as `BLUE`, `RED`, `REVERSE`, but it is recommended that you use those instructions for TUI programs only. The recommendation for new GUI programs is to use graphical user interface possibilities. For example, a good replacement for TTY attributes is to use presentation styles.

**Related concepts**
- **Presentation styles** on page 1065
  Use presentation styles to specify decoration attributes for window and form elements.

**The default SCREEN window**

When the first interactive instruction is reached in a Genero BDL program, a default window named SCREEN is created.
The default SCREEN window can be used to open one or more successive forms; it can also be closed, with the CLOSE WINDOW SCREEN instruction. If the default SCREEN window is not closed, and a new window is created with the OPEN WINDOW command, an empty default SCREEN window will be displayed.

When writing a GUI application, you typically open the main form in the SCREEN window, and display other forms with the OPEN WINDOW name WITH FORM instruction:

```
MAIN
  DEFER INTERRUPT
  OPTIONS INPUT WRAP
    ... OPEN FORM f_main FROM "custfrm"
    DISPLAY FORM f_main
  ...
END MAIN
```

The SCREEN window is not visible in TUI mode because program windows are rendered as simple boxes and SCREEN is created without borders. The size of the SCREEN window is 80x25 in TUI mode.

**Related concepts**

**OPEN WINDOW** on page 1034
Creates and displays a new window.

**Specifying WINDOW position and size**

When writing a program for TUI mode, the windows can be created with the OPEN WINDOW name AT x,y instruction, specifying an position on the screen; sometimes even the width and height of the window is specified, for example when you don’t use a form to create the window. Window position and size is allowed by Genero Business Development Language for TUI mode applications.

However, the window position and sizes are ignored in GUI mode. In GUI mode, the window position is defined by the window manager, and the size adapts to the form displayed. In this mode, the preferred way to display application forms is to use the OPEN WINDOW name WITH FORM instruction.

**Related concepts**

**OPEN WINDOW** on page 1034
Creates and displays a new window.

**Right justified field labels**

If the application forms define right-justified labels and use a proportional font in GUI mode, the text will no longer be aligned as on a dumb terminal. Form layout must be reviewed to replace any right-justified text with LABEL form items. Migration to GUI mode can also be easier achieved with the traditional mode, to leave TUI-style forms untouched.

**Example of right-justified static form labels**

```
DATABASE FORMONLY
SCREEN
{
  Customer id: [f01 ]
  Name: [f02 ]
  Zipcode: [f03 ]
  Address: [f04 ]
}
END
ATTRIBUTES
EDIT f01 = FORMONLY.cust_id;
EDIT f02 = FORMONLY.cust_name;
EDIT f03 = FORMONLY.cust_zipcode;
EDIT f04 = FORMONLY.cust_address;
```
Example of form label items with localized text

```
LAYOUT
GRID
{
  [101   f01       ]
  [102   f02       ]
  [103   f03       ]
  [104   f04       ]
}
END

ATTRIBUTES
LABEL l01: TEXT=%"customer.id";
LABEL l02: TEXT=%"customer.name";
LABEL l03: TEXT=%"customer.zipcode";
LABEL l04: TEXT=%"customer.address";
EDIT f01 = FORMONLY.cust_id;
EDIT f02 = FORMONLY.cust_name;
EDIT f03 = FORMONLY.cust_zipcode;
EDIT f04 = FORMONLY.cust_address;
END
```

Related concepts

**LABEL item definition** on page 1232
Defines a simple text area to display a read-only value, in a grid-based layout.

**Traditional GUI mode** on page 1015

Reduce multiple text screens

Applications designed for dumb terminals (TUI mode) use various techniques to ensure that all display fits in an 80x25 screen. This may mean iterating through a number of dialogs using different forms, only displaying certain columns in an record list, using abbreviations for labels, etc.

With a graphical user interface (GUI mode), windows are wider, re-sizable and can contain different sort of layout elements and widgets, displaying much more information than in a simple dumb terminal. For example, TABLE containers display record lists and have the ability to scroll horizontally so that you can show more than 78 characters of data.

It is recommended that you review dumb-terminal oriented programs to see how to take advantage of the GUI possibilities. However, avoid ending up with over-crowded screens that may be unreadable to the end user.

**Related concepts**

**TABLE container** on page 1217
Defines a re-sizable table designed to display a list of records.

Review application ergonomics

With IBM® Informix® 4GL, programs can only execute a single MENU, INPUT, CONSTRUCT, DISPLAY ARRAY or INPUT ARRAY instruction at a time. This may be sufficient for dumb-terminal applications, but is not adapted for a graphical user interface.

Genero Business Development Language (BDL) introduces the concept of multi-dialog, where multiple interactive instructions control several form areas at the same time. Typical GUI concepts such as Drag and Drop and Tree Views are supported as well. You may wish to review your code to take advantage of these features.
Subscripted form fields are not supported

IBM® Informix® 4GL forms can define subscripted fields with multiple field definition entries in the ATTRIBUTES section, each defining a piece of the data displayed by the field, as in this example:

```
DATABASE stores
SCREEN
{
   1234567890
   [f01       ]
   [f02       ]
}
END
ATTRIBUTES
f01 = customer.cust_name[1,10];
f02 = customer.cust_name[11,20];
END
```

In the ATTRIBUTES section, the name of the field is immediately followed by a subscript specification defining the piece of sub-data the screen tag displays and allows to input.

This feature is not supported at all by Genero BDL, all fields must be defined as a whole.

**Related concepts**

[LAYOUT section](#) on page 1194

The LAYOUT section defines the graphical alignment of the form by using a tree of layout containers.

### 4GL programming topics

**Dynamic arrays**

Both IBM® Informix® 4GL (I4GL) and Genero Business Development Language (BDL) implement static arrays with a fixed size. Static arrays cannot be extended:

```
DEFINE arr ARRAY[100] OF RECORD LIKE customer.*
```

I4GL introduced dynamic arrays in version 7.32. Unlike Genero BDL, I4GL requires explicitly to associate memory storage with a dynamic array by using the ALLOCATE ARRAY statement, and memory must be freed with DEALLOCATE ARRAY. I4GL dynamic arrays can be resized with the Resize ARRAY statement. I4GL dynamic arrays cannot be used in a interactive instructions such as DISPLAY ARRAY.

```
DEFINE arr DYNAMIC ARRAY OF RECORD LIKE customer.*
ALLOCATE ARRAY arr[10]
RESIZE ARRAY arr[100]
LET arr[50].cust_name = "Smith"
DEALLOCATE ARRAY arr
```

Genero BDL supports dynamic arrays in a slightly different way than I4GL. There are no allocation, resizing, or deallocation instructions, because the memory for element storage is automatically allocated when needed. Furthermore, you can use dynamic arrays with interactive instructions, making a DISPLAY ARRAY or INPUT ARRAY unlimited.

```
DEFINE arr DYNAMIC ARRAY OF RECORD LIKE customer.*
LET arr[50].cust_name = "Smith"
DISPLAY ARRAY arr TO sr.*
```

In Genero BDL, the main difference between static arrays and dynamic arrays is the memory usage; when you use dynamic arrays, elements are allocated on demand. With static arrays, memory is allocated for the complete array when the variable is created.
**Important:** The semantics of dynamic arrays is very similar to static arrays, but there are some small differences. Keep in mind that the runtime system automatically allocates a new element for a dynamic array when needed. For example, when a `DISPLAY arr[100] .*` is executed with a dynamic array, the element at index 100 is automatically created if it does not exist.

**Related concepts**

**Arrays** on page 386

Arrays (static or dynamic) allow to handle an ordered collection of elements.

---

**Debugger command syntax**

IBM® Informix® 4GL (I4GL) provides a program debugger. Genero Business Development Language provides a program debugger with a different set of commands as I4GL, compatible with the well-known gdb tool. This debugger can be used alone in command line mode, or with a graphical shell compatible with gdb, such as `ddd`:

```bash
ddd --debugger "fglrun -d myprog"
```

**Related concepts**

**Starting fglrun in debug mode** on page 2031

The runtime system can be started in debug mode with the `-d` option.

---

**Mismatching global variable definitions**

The c4gl C-code compiler of IBM® Informix® 4GL has a weakness that allows global variable declarations of the same variable with different data types. Each different declaration found by the c4gl compiler defines a distinct global variable, which can be used separately. This can actually be very confusing (the same global variable name can, for example, reference a `DATE` value in module A and an `INTEGER` value in module B).

IBM® Informix® 4GL RDS (fglpc / fglgo) does not allow multiple global variable declaration with different types. The fglgo runner raises error -1337 if this happens.

The next code example shows two .4gl modules defining the same global variable with different data types:

**Main.4gl:**

```4gl
GLOBALs
    DEFINE v INTEGER
END GLOBALS

MAIN
    LET v = 123
END MAIN
```

**Module.4gl:**

```4gl
GLOBALs
    DEFINE v DATE
END GLOBALS

FUNCTION test()
    LET v = TODAY
END FUNCTION
```

The fglcomp tool compiles both modules separately without problem, but when linking with fgllink, the linker raises error -1337.

You must review your code and use the same data type for all global variables having the same name.
Related concepts

Data types on page 253

Selecting the correct data type assists you in the input, storage, and display of your data.

Strict function signature checking

IBM® Informix® 4GL (I4GL) is not very strict regarding function signature. With I4GL, you can, for example, define a function in module A that returns three values, and call that function in module B with a returning clause specifying two variables:

Module A:

```gl
FUNCTION func()
  RETURN "abc", "def", "ghi"
END FUNCTION
```

Module B (main):

```gl
MAIN
  DEFINE v1, v2 VARCHAR(100)
  CALL func() RETURNING v1, v2
END MAIN
```

The c4gl compiler (7.32) compiles and links these modules without error, but at execution time you get the following runtime error:

```
Program stopped at "main.4gl", line number 3.
FORMS statement error number -1320.
A function has not returned the correct number of values expected by the calling function.
```

With Genero Business Development Language (BDL), the mistake will be detected at link time:

```
$ fgllink -o prog.42x main.42m module_a.42m
ERROR(-6200): Module 'main': The function module_a.func(0,3) will be called as func(0,2).
```

Similarly, I4GL does not detect an invalid number of parameters passed to a function defined in a different module:

Module A:

```gl
FUNCTION func( p )
  DEFINE p INTEGER
  DISPLAY p
END FUNCTION
```

Module B (main):

```gl
MAIN
  CALL func(1,2)
END MAIN
```

The c4gl compiler (7.32) compiles and links these modules without error, but at execution time, you get the following runtime error:

```
Program stopped at "main.4gl", line number 2.
FORMS statement error number -1318.
A parameter count mismatch has occurred between the calling function and the called function.
```
When using Genero BDL, the error will be detected at link time:

```
$ fgllink -o prog.42x main.42m module_a.42m
ERROR(-6200): Module 'main': The function module_a.func(1,0) will be called as func(2,0).
```

However, Genero BDL does not check function signatures when several RETURN instructions are found by the compiler. This is necessary in order to be compatible with I4GL. The next code example compiles and runs with both I4GL and BDL:

```
MAIN
  DEFINE v1, v2 VARCHAR(100)
  CALL func(1) RETURNING v1
  DISPLAY v1
  CALL func(2) RETURNING v1, v2
  DISPLAY v1, v2
END MAIN

FUNCTION func( n )
  DEFINE n INTEGER
  IF n == 1 THEN
    RETURN "abc"
  ELSE
    RETURN "abc", "def"
  END IF
END FUNCTION
```

However, this type of programming is not recommended.

**Related concepts**

- [Returning values](#) on page 360
  A function can return values with the RETURN instruction.

**STRING versus CHAR/VARCHAR**

Genero Business Development Language (BDL) introduces a new data type named STRING, which is similar to VARCHAR, but without a size limit. The STRING data type does not exist in IBM® Informix® 4GL. The STRING data type implementation is optimized for memory usage; unlike CHAR/VARCHAR, BDL will only allocate the memory needed to hold the actual character string value in a STRING variable.

A STRING variable is typically used within utility functions (for example, to hold the path to a file). Another typical usage is with CONSTRUCT, to hold the SQL condition. The STRING variable can then be completed to build the SQL text and passed to the PREPARE or DECLARE instruction.

However, because of SQL assignment and comparison rules, the STRING variables cannot be used as SQL parameters in the USING clause of EXECUTE or OPEN/FOREACH, not can it be used to receive fetched data with the FETCH instruction: For SQL statements, use CHAR or VARCHAR data types.

The STRING data type has a number of built-in methods e.g. `getLength()` that will are very useful and will reduce source code.

**Related concepts**

- [STRING](#) on page 269
  The STRING data type is a variable-length, dynamically allocated character string data type, without limitation.

**Review user-made C routines**

IBM® Informix® 4GL (I4GL) applications often need additional utility C routines implemented in C-Extensions, for example to access the file system and read the content of a directory, with the `os.Path` class. Writing C-Extensions is an important cost in cross-platform portability and maintenance.
Genero Business Development Language (BDL) provides a set of libraries that include functions and classes which can probably replace some of the routines written for I4GL application. For example, BDL implements typical file management functions to search directories and files.

If portability is a concern (for example if you want to move from a UNIX™ platform to a Microsoft™ Windows™ or Mac OS-X™ platform), review your C routines and check whether there is a replacement built into the language or in one of the libraries provided.

Genero BDL even allows to use to the huge Java class library with the Java Interface.

**Web Services support**

Starting with IBM® Informix® 4GL version 7.50, I4GL functions can be deployed as Web Services. The published functions can be subscribed from programs that run on a Web client in another programming language.

Web Services support was introduced in Genero Business Development Language before I4GL 7.50 was released. Each implementation is quite different, but the basic principles are the same: publishing 4gl functions as Web Services, by handling WS requests and supporting easy input and output parameter conversions between WS data formats and 4gl program variables.

**Related concepts**

[Web services](#) on page 3102
Create a Web service client or server with Genero BDL.

**File I/O statements and APIs**

*Enhancement reference: BZ#19156*

IBM® Informix® 4GL version 7.50.xC4 introduced file manipulation instructions to access files on the operating system running the application. These instructions can be used to open, read, write, seek and close files:

```main
DEFINE fd1, fd2 INTEGER, v1, v2 VARCHAR(10)
OPEN FILE fd1 FROM "/tmp/file1" OPTIONS (READ, FORMAT="CSV")
OPEN FILE fd2 FROM "/tmp/file2" OPTIONS (WRITE, APPEND, CREATE, FORMAT="CSV")
READ FROM fd1 INTO v1, v2
SEEK ON fd2 TO 0 FROM LAST INTO v1
WRITE TO fd2 USING v1, v2
CLOSE FILE fd1
CLOSE FILE fd2
END MAIN
```

Genero Business Development Language (BDL) implements file I/O support with the base.Channel built-in class. This class implements file access, but it can also open streams to subprocesses (i.e. pipes) and sockets.

**Related concepts**

[The Channel class](#) on page 2273
The base.Channel class is a built-in class providing basic input/output functions.

**OPEN USING followed by FOREACH**

In earlier versions of IBM® Informix® 4GL (I4GL), the FOREACH instruction had no a USING clause to pass SQL parameters to the prepared statement. SQL Parameters could be specified in a OPEN USING instruction, and were re-used by the next FOREACH instruction:

```main
PREPARE st1 FROM "SELECT * FROM tab WHERE col>?"
DECLARE cu1 CURSOR FOR st1
OPEN cu1 USING var
FOREACH cu1 INTO rec.*
  DISPLAY rec.*
END FOREACH
```
This feature is supported by Genero Business Development Language, but can lead to defects with some versions of the Informix® database client. Review your code to avoid the `OPEN` statement by moving the `USING` clause to the `FOREACH` instruction.

**Related concepts**

**FOREACH (result set cursor)** on page 670
Processes a series of data rows returned from a database cursor.

---

### Migrating from Four Js BDS to Genero BDL

Product changes you must be aware of when migrating from Four Js BDS 3.xx to the most recent Genero Business Development Language version.

Installation and setup topics

License controller
With Four Js Business Development Suite (BDS), you must license the product with the `licencef4gl` command line tool. Starting with Genero Business Development Language, the command line tool to license the product is `fglWrt`. Run `fglWrt` with the `-h` option for the possible options.

Runner linking is no longer needed
With Four Js Business Development Suite (BDS), you need to create the `fglrn` binary with the `fglmkrun` tool, by specifying the type of the database driver and C extensions libraries to be linked with the runtime system. Since Genero Business Development Language version 2.00, you do not more need to link the runtime system.

The database drivers are provided as shared libraries ready to use; you just need to specify the driver to be loaded.

However, C extensions must be provided shared libraries for Genero BDL. To easy migration, the runtime system loads automatically the `userextension` share library (or DLL).

Related concepts
- Database connections on page 600
  Explains how to manage database connections in a program.
- C-Extensions on page 2109
  With C-Extensions, you can bind your own C libraries in the runtime system, to call C function from the application code.

Localization support
IBM® Informix® 4GL (I4GL) and Four Js Business Development Suite (BDS) use the Informix® GLS library for localization support (i.e. to support non-ASCII character sets such as BIG5). This implies a strong dependency to the proprietary GLS library.

Genero Business Development Language (BDL) does not use the GLS library; Genero BDL uses the standard C library functions for character set handling, based on the `setlocale()` POSIX conformant function.

While I4GL/BDS need the `CLIENT_LOCALE` environment variable to define the locale for the application, you must now use the `LANG/LC_ALL` environment variables to specify the locale of the Genero application. Note, however, that `CLIENT_LOCALE` is still needed when connecting to an Informix® database.

In Four Js BDS, you could select the locale library with the `fglmode` tool, to select either GLS or ASCII mode. This tool is no longer needed in Genero.

Related concepts
- Localization on page 405
  Localization support allows you to implement programs that follow specific language and cultural rules.

Database schema extractor
Before compiling .4gl or .per files with Four Js Business Development Suite (BDS) or with Genero Business Development Language (BDS), you need to extract the database schema as a .sch file.

In DBS, the name of the schema extraction tool `fglschema`, while Genero BDL provides the `fgldbsch` tool. The `fglschema` tool could only extract schemas from Informix® databases; `fgldbsch` can extract database schemas from Informix®, and from other databases like Oracle® DB, SQL Server, DB2®, PostgreSQL and Oracle® MySQL. The `fglschema` tool is still supported in Genero BDL for backward compatibility, but `fglschema` actually calls `fgldbsch`.

Note that Genero BDL allows you to centralize new widget types and attributes in the .val file.

Related concepts
- Database schema on page 476
Defines database table structures with column type information to be reused in program variable definitions.

**C-Code compilation is desupported**

Four Js Business Development Suite (BDS) fglcomp compiled to both P-Code or C-Code. The compiler of Genero Business Development Language does not support C-Code generation. Only P-Code generation is supported by Genero BDL.

If you experience performance problems when comparing Genero BDL to Four Js BDS, please contact your local support center.

**Desupported environment variables**

This table lists the Four Js Business Development Suite (BDS) environment variables that are no longer supported (or replaced) in Genero Business Development Language:

**Table 91: Desupported environment variables**

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description of the BDS environment variable</th>
<th>Genero equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>FGLDBS</td>
<td>FGLDBS defines the type and version of the database driver, used when linking fglrun with fglmkrun.</td>
<td>Database drivers are loaded dynamically by fglrun.</td>
</tr>
<tr>
<td>FGLCC</td>
<td>FGLCC defines the name of the C compiler.</td>
<td>The fglrun tool does not need to be created, it's fully dynamic.</td>
</tr>
<tr>
<td>FGLLIBSQL</td>
<td>FGLLIBSQL defines the list of database client software libraries to be used to link fglrun with fglmkrun.</td>
<td>Database drivers are loaded dynamically by fglrun.</td>
</tr>
<tr>
<td>FGLLIBSYS</td>
<td>FGLLIBSYS defines the list of system libraries to be used to link fglrun with fglmkrun.</td>
<td>The fglrun tool does not need to be created, it's fully dynamic.</td>
</tr>
<tr>
<td>FGLSHELL</td>
<td>FGLSHELL defined the name of the fglrun program, for example when using tools like fglschema.</td>
<td>The name of the runtime system tool is fglrun and does not need to be changed.</td>
</tr>
</tbody>
</table>

**Desupported FGLPROFILE entries**

Genero Business Development Language comes with redesigned software components and features. Some FGLPROFILE entries have been desupported. This section describes what configurations settings are no longer supported, and point to Genero equivalent features if they exist.

**Related concepts**

FGLPROFILE: VM configuration on page 213
FGLPROFILE: GUI configuration on page 205

**User interface topics**

**Smooth migration with traditional UI mode**

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for mode details.

**Front-end compatibility**

When migrating to Genero Business Development Language (BDL), you must use one of the Genero Front Ends; the WTK, WebFE and JavaFE front-ends are not compatible with the Genero fglrun runtime system. Note also that the
UNIX™ version of Genero does not include the fglX11d front-end any longer. You must use the GDC front-end on UNIX™.

**FGLGUI is 1 by default**

In Four Js Business Development Suite (BDS), when the FGLGUI environment variable is not set, the application starts in TUI mode (FGLGUI=0).

With Genero BDL, the default is GUI mode (FGLGUI=1). Therefore, when migrating from Informix® 4GL, it is recommended that you set FGLGUI=0 to run the application in text mode as a first step.

**Related concepts**

FGLGUI on page 240

Defines the user interface mode to be used by the program.

**FGLPROFILE: GUI configuration**

This table shows Four Js Business Development Suite (BDS) FGLPROFILE entries related to GUI configuration which are desupported in Genero Business Development Language.

<table>
<thead>
<tr>

FGLPROFILE environment variable defines Genero BDL configuration files

**Key labels versus action defaults**

In Four Js Business Development Suite (BDS), labels can be defined for keys such as accept, F10 or Control-Z. With this feature, it is possible to easily decorate ON KEY or COMMAND KEY blocks with a button in the action panel.

With Genero Business Development Language (BDL), interaction statements can define actions with the ON ACTION blocks. These action handlers are more abstract than ON KEY: You identify an action by a name, while decoration is defined in form files (ACTION DEFAULTS section) or in global configuration files (.4ad file).
When adapting your code for Genero, you are free to use the traditional ON KEY blocks or the new ON ACTION blocks. Genero still supports the key label settings as in Four Js BDS. However, key label settings will overwrite action defaults settings. Additionally, if the name of the key specified in the ON KEY clause does not only contain alphanumeric characters (such as Control-Z), it will not be possible to define action defaults attributes for these action handlers, as action names must be simple identifiers. This is also true for Menu COMMAND labels, for example with COMMAND "Exit program".

Migrating form field widgets

To get combo-boxes or check-boxes in Four Js Business Development Suite (BDS). per forms defined fields with the WIDGET attribute. To ease migration, the WIDGET attribute and the corresponding form field widgets are still supported in Genero Business Development Language (BDL), but these are now deprecated. Using new BDL form item types is recommended instead.

<table>

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for mode details.

Front-end configuration tools
Four Js Business Development Suite (BDS) provided WTK front-end and X11 front-end specific configuration tools called "Configuration Manager" / confdesi. These tools define widget aspect (color, borders, fonts).

In Genero Business Development Language, the form items can be decorated with presentation styles for all sorts of front-ends.

Related concepts
Presentation styles on page 1065
Use presentation styles to specify decoration attributes for window and form elements.

Function key mapping
With Four Js Business Development Suite (BDS), when the user pressed a key modifier plus a function key (like Shift-F4 or Ctrl-F6), the key combination was mapped to a regular function key F(nn+offset), because Shift and Control key modifiers are not handled in the 4GL language.

The number of function keys of the keyboard was defined by the gui.key.add_function FGLPROFILE entry. For example, when this entry is set to 12 (the default), a Shift-F4 was received as F16 (4 + 12) in the program, to be handled with the ON KEY (F16) clause.

This feature and FGLPROFILE entry is still supported when using the traditional mode.

When using the standard GUI mode, special consideration needs to be taken regarding function keys above F12.

Function keys from F1 to F12 are common keys found on the keyboard and do not need any particular configuration regarding accelerators: The ON KEY clause defines an action object identified by the key name (in lowercase) and the first accelerator attribute defined with the same name. For example, ON KEY (F10) creates an action f10, with accelerator F10.

However, if the program uses ON KEY (Fnn) clauses where nn is above 12, in order to have Shift-F(nn-12) key combinations working, you need to define this accelerator in the corresponding action default entry.

**Important:** Since the ON KEY (Fnn) clause defines an automatic shortcut key with the first accelerator attribute, it overwrites the value of acceleratorName attribute defined in the action defaults. In order to associate the actual Shift-F(nn-12) key combination for the action fnn, you must use the second accelerator attribute. For example: ON KEY (F14) creates an action f14, with first accelerator F14. Specify acceleratorName2="Shift-F2" in the .4ad action defaults file, to define the Shift-F2 key combination for the f14 action.

**The fgl_init4gl() function**

Four Js Business Development Suite (BDS) provided a few utility functions in the libfgl4js.42x library. This library had to be initialized with a call to fgl_init4js():

```c
MAIN
    ... 
    CALL fgl_init4js()
    ... 
END MAIN
```

Genero Business Development Language still supports the fgl_init4js() function, but only for backward compatibility. Calling this function has no effect in Genero.

**Static versus Dynamic Arrays**

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for more details.

**Debugger syntax changed**

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for more details.

**fgl_system() function**

The fgl_system() function is still supported in Genero Business Development Language, but it does not raise a terminal window on the front-end as with Four Js Business Development Suite (BDS). However, some front-ends implement a workaround for this feature, based on the detection of special strings displayed to stdout by fglrun. See front-end documentation for more details.

**Related concepts**

fgl_system() on page 2177
Runs a command on the application server.

**The Channel:: methods**

Genero Business Development Language provides file, socket and process I/O with the Channel built-in class, while Four Js Business Development Suite (BDS) has the Channel:: functions. You must review your code and replace Channel:: calls with the new API.

**Related concepts**

The Channel class on page 2273
The base.Channel class is a built-in class providing basic input/output functions.

**STRING versus CHAR/VARCHAR**

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for more details.

**Review user-made C routines**

This topic also concerns IBM® Informix® 4GL migration, see the I4GL Migration page for more details.

**Variable identification in SQL statements**

This topic applies also to older Genero Business Development versions, see the Genero 2.20 Migration page for more details.

**Default action of WHENEVER ANY ERROR**

With old Four Js Business Development Suite (BDS) versions like 2.10, expression evaluation errors such as a division by zero stop the program with an error message. Genero Business Development Language behaves like
IBM® Informix® 4GL and recent BDS versions like 3.55: By default, the WHENEVER ANY ERROR action is to CONTINUE the program flow. You can change this behavior by setting the next FGLPROFILE entry to true:

\[
\text{fglrun.mapAnyErrorToError = true}
\]

**Related concepts**

- Exceptions on page 451
- Describes exception (error) handling in the programs.

**Database driver features**

The following ODI driver features are no longer supported in Genero:

- Static SQL cache
- SQL directive sets

**Frequently asked questions**

The FAQ lists those questions frequently asked when migrating an existing 4GL application to Genero.

- FAQ001: Why do I have a different display with Genero than with BDS V3? on page 215

- FAQ010: Why do I get error -6366 “Could not load database driver drivername”? on page 220

**FAQ001: Why do I have a different display with Genero than with BDS V3?**

**Explanation**

Genero Business Development Language (BDL) introduces major graphical user interface enhancements that sometimes require code modification. With BDS V3, application windows created with the OPEN WINDOW instruction were displayed as static boxes in the main graphical window. In the GUI mode of Genero, application windows are displayed as independent, re-sizeable graphical windows.

**Solution:**

Review the program logic to reduce the number of windows created by the programs. Replace MENU created in specific windows by TOPMENU elements in your forms.

**Related concepts**

- OPEN WINDOW on page 1034
FAQ002: Why does an empty window always appear?

Description
An additional empty window appears when I explicitly create a window with the OPEN WINDOW instruction.

```
MAIN
   OPEN WINDOW w1 AT 1,1 WITH FORM "form1"
   MENU "Example"
      COMMAND "Exit"
      EXIT MENU
   END MENU
   CLOSE WINDOW w1
END MAIN
```

Explanation
In the new standard GUI mode, all windows are displayed as real front-end windows, including the default SCREEN window. When an application starts, the runtime system creates this default SCREEN window, as in version 3. This is required because some applications use the SCREEN window to display forms (they do not use the OPEN WINDOW instruction to create new windows). To facilitate BDS V3 to Genero migration, the runtime system must keep the default SCREEN window creation; otherwise, existing applications would fail if their code was not modified.

Solution
You can either execute a CLOSE WINDOW SCREEN at the beginning of the program, to close the default window created by the runtime system, or use the OPEN FORM + DISPLAY FORM instructions, to display the main form in the default SCREEN window.

Example
```
MAIN
   OPEN FORM f FROM "form1"
   DISPLAY FORM f
   MENU "Example"
      COMMAND "Exit"
      EXIT MENU
   END MENU
END MAIN
```

FAQ003: Why do some COMMAND KEY buttons no longer appear?

Description
When creating a MENU with COMMAND KEY(keyname) "option" clause, the button for keyname is no longer displayed:

```
MAIN
   MENU "Example"
      COMMAND "First"
      EXIT PROGRAM
      COMMAND KEY (F5) "Second"
      EXIT PROGRAM
```
**Explanation**

In BDS Version 3, when using the `MENU` instruction, several buttons are displayed for each clause of the type `COMMAND KEY (keyname) "option"`: one for the menu option, and others for each associated key.

When using Genero, for a named `MENU` option defined with `COMMAND KEY`, the buttons of associated keys are no longer displayed (F5 in our example), because there is already a button created for the named menu option. The so-called "hidden menu options" created by a `COMMAND KEY (keyname)` clause (F6 in our example) are not displayed as long as you do not associate a label, for example with the `FGL_SETKEYLABEL()` function.

**Related concepts**

`fgl_setkeylabel()` on page 2173  
Sets the default label associated to a key.

**FAQ004: Why aren't the elements of my forms aligned properly?**

**Description**

In my forms, I used to align labels and fields by character, for typical terminal display. But now, when using the new `LAYOUT` section, some elements are not aligned as expected. In this example, the beginning of the field `f001` is expected in the column near the end of the digit-based text of the first line, but the field is actually displayed just after the label "Name:".

```
DATABASE FORMONLY

LAYOUT FORMONLY
GRID {
   01234567890123456789
   Name:             [f001       ]
}   END
END

ATTRIBUTES
   f001 = formonly.field1 TYPE CHAR;
END
```

**Explanation**

By default, Genero displays form elements with proportional fonts, using layout managers to align these elements inside the window. In some cases, this requires a review of the content of form screens when using the new layout management, because the layout is based on new alignment rules which are more abstract and automatic than the character-based grids in Version 3.

In most cases, the `fglform` compiler is able to analyze the layout section of `.per` form specification file to produce an acceptable presentation, but sometimes you will have to tweak the form files to give hints for the alignment of elements.

**Solution**

In this example, the field `f001` alignment is based on the label appearing on the same line. By adding one space before the field position, the form compiler will understand that the field must be aligned to the text in the first line:

```
DATABASE FORMONLY
```

```
LAYOUT FORMONLY
GRID {
   01234567890123456789
   Name: [f001]   
}   END
END

ATTRIBUTES
   f001 = formonly.field1 TYPE CHAR;
END
```
In the next example, the fields are automatically aligned to the text in the first line:

```sql
DATABASE FORMONLY
LAYOUT
GRID {
  Name:             [f001       ]
} END
END
ATTRIBUTES
  f001 = formonly.field1 TYPE CHAR;
END
```

**Related concepts**
- [LAYOUT section on page 1194](#)
- The **LAYOUT** section defines the graphical alignment of the form by using a tree of layout containers.

**FAQ005: Why doesn't the ESC key validate my input?**

**Description**
The traditional ESC (escape) key does not validate an `INPUT`, it cancels the dialog instead.

**Explanation**
To follow platform standards (like Microsoft™ Windows® for example), the ESC key is the standard key to cancel the current interactive statement.

**Solution**
You can change the accelerator keys for the 'accept' action with action defaults. However, is not recommended to change the defaults, because ESC is the standard key used to cancel a dialog in GUI applications.

**Related concepts**
- [Configuring actions on page 1646](#)
  Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

**FAQ006: Why doesn't the Ctrl-C key cancel my input?**

**Description**
The traditional Ctrl-C key does not cancel an `INPUT` statement.
**Explanation**

To follow platform standards (like Microsoft® Windows® for example), the Ctrl-C key is used as the standard key to copy the current selected text to the clipboard, for cut and paste.

**Solution**

You can change the accelerator keys for the 'cancel' action with action defaults. However, it is not recommended to change the defaults, because ESC is the standard key used to cancel a dialog in GUI applications.

**Related concepts**

- Configuring actions on page 1646
- Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with action attributes.

**FAQ007: Why do the gui.* FGLPROFILE entries have no effect?**

**Description**

The gui.* and some other FGLPROFILE entries related to graphics no longer have effect.

**Explanation**

These entries are related to the old user interface. They are no longer supported. In BDS version 3, the gui.* entries were interpreted by the front end. As the user interface has completely been redesigned in Genero, some gui.* entries have been removed.

**Solution:**

Review all FGLPROFILE entries used in your current application and verify if there is a replacement.

**Related concepts**

- FGLPROFILE: GUI configuration on page 205

**FAQ008: Why do I get invalid characters in my form?**

**Description**

The application starts, connects to the database and seems to work properly, but strange symbols (rectangles, question marks) are displayed in the forms for non-ASCII characters. The ASCII characters display properly.

**Explanation**

This is certainly a character set configuration error.

**Solution**

You have probably defined a wrong runtime system locale to the database client locale.

**Related concepts**

- Localization on page 405
  - Localization support allows you to implement programs that follow specific language and cultural rules.

**FAQ009: Why do large static arrays raise a stack overflow?**

**Description**

When using very large static arrays (DEFINE a1 ARRAY[10000] OF ...), I get a stack overflow on Windows® platforms.
**Explanation**
The runtime system uses the default stack size defined by the C compiler. Because function static arrays are allocated on the C stack, using very large static arrays in functions can result in a stack overflow error.

**Solution**
Review the program and use dynamic array instead of static arrays.

**Related concepts**
Dynamic arrays on page 389

**FAQ010: Why do I get error -6366 "Could not load database driver drivername"?**

**Description**
Error **-6366** occurs when the runtime system fails to load the specified database driver.

**Explanation**
The database driver shared object (.so or .DLL) or a dependent library could not be found.

**Solution**
Make sure that the specified driver name does not have a spelling mistake. If the driver name is correct, there is probably an environment problem. Make sure that the database client software is installed on the system (Genero does not communicate directly with the database server, you need the client library). Check the UNIX™ LD_LIBRARY_PATH environment variable or the PATH variable on Windows®. These must point to the database client libraries. Another common error is the installation of a database client software of a different object type to the Genero runtime system. For example, if you install a 32 bit Genero version, you must install a 32 bit version of the database client software, the 64 bit version will not work.

**Related concepts**
Database client software on page 40
To connect to a database server, the database client software must be installed on the system where you run the Genero BDL programs.

**Configuration**
These topics cover configuration options of the Genero Business Development Language.

FGLPROFILE environment variable defines Genero BDL configuration files

- Understanding FGLPROFILE on page 221
- FGLPROFILE entry syntax on page 222
- List of FGLPROFILE entries on page 223
Understanding FGLPROFILE

The runtime system uses one or more configuration files in which you can define options and parameters to change the behavior of the programs.

Loading FGLPROFILE files

There are three different levels to specify a configuration file, and these files are loaded in the following order:

1. First, the runtime system reads the default configuration file provided in FGLDIR/etc/fglprofile. This file contains all supported entries, identifies the possible values for an entry, and documents default values. It is recommended that you not modify this default configuration file.

2. Then, if the FGLPROFILE environment variable is set, the runtime system reads entries from the files specified by this environment variable. A list of files can be provided with FGLPROFILE. Files must be separated by the operating system specific path separator.

   Note: On mobile devices, it is not possible to define environment variables. To specify a custom FGLPROFILE file for a mobile application, you must deploy a file with the name "fglprofile" in the appdir directory, along with the other application program files (.42m, .42f, and so on). Only one custom FGLPROFILE file can be deployed for a given mobile application.

3. After loading and merging the two previous levels, the runtime system checks whether the fglrun.defaults entry is set. This entry defines the program-specific profile directory. If this directory contains a file with the same name as the current program (without a .42r extension), the runtime system reads the entries from that file.

   Note: If the value of fglrun.defaults starts with $envvar, the specified environment variable is expanded to its value in order to build the path. For example, if the value is "$MYVAR/standard", and MYVAR contains /opt/app/config, and the program name is custinfo.42m (or custinfo.42r), the runtime system will try to read the file /opt/app/config/standard/custinfo.

The runtime system merges the different configuration files found at the three levels. If the same entry is defined in several files, the last loaded entry wins. This means that the order of precedence is:

1. Program-specific configuration file (if fglrun.defaults is defined in one of the other levels).
2. Configuration files defined by the FGLPROFILE environment variable, or appdir/fglprofile, for mobile applications.
3. The default configuration file FGLDIR/etc/fglprofile.

The default FGLPROFILE file

It is recommended that you NOT change the default configuration file in FGLDIR/etc/fglprofile. This file will be overwritten by a new installation and your changes will be lost. It is recommended that you make a copy and define your private configuration file using the FGLPROFILE environment variable.

FGLPROFILE file name

For non-mobile apps, there is no specific naming convention for FGLPROFILE configuration files. You can use a file name without an extension, or the .txt extension for simple text file.

On mobile devices, the name of the custom FGLPROFILE file must be "fglprofile", and must be deployed under the appdir directory.

FGLPROFILE file encoding

The character encoding of FGLPROFILE files must match the application locale.

Defining your own FGLPROFILE entries

User-defined entries can be read with the FGL_GETRESOURCE() built-in function.

Related concepts

FGLDIR on page 240
Defines the installation directory of Genero Business Development Language.

FGLPROFILE on page 243
Defines the configuration files to be used by the runtime system.

Application locale on page 405
The application locale defines the language and codeset for your application.

fgl_getresource() on page 2168
Returns the value of an FGLPROFILE entry.

FGLPROFILE entry syntax
Description of the syntax of FGLPROFILE entries.

Syntax

```plaintext
# comment
↓ entry-definition
```

where entry-definition is:

```plaintext
entry = value
```

where entry is:

```plaintext
ident [.ident [.ident] [...] [...]]
```

and value is:

```plaintext
[-][digit [.digit] [.digit]]
" alphanum [.alphanum] "
{true | false}
```

1. comment is a line of text that is started by a # hash.
2. entry identifies the name of the entry. This can be a dot-separated list of identifiers.
3. value is a numeric value, a string literal, or a boolean value (true/false).

Usage

An FGLPROFILE entry is a line in the configuration file associating a parameter name to a value that can be specified as a numeric, string or boolean.

Important: The encoding of FGLPROFILE files must match the application locale of the program. For more details about locale definition, see Application locale on page 405.

The entries are defined by a name composed of a list of identifiers separated by a dot character.

Note: FGLPROFILE entry names are case insensitive. In order to avoid any confusion, it is recommended to write FGLPROFILE entry names in lower case.

If an entry is defined several times in the same file, the last entry found in the file is used. No error is raised.

The value can be a numeric literal, a string literal, or a boolean (true/false).

Numeric values are composed by an optional sign, followed by digits, followed by an optional decimal point and digits:

```plaintext
my.numeric.entry = -1566.57
```
String values must be delimited by single or double quotes. The escape character is backslash, \t \n \r \f are interpreted as TAB, NL, CR, FF. Double the backslash to write a backslash character (\\):

```javascript
my.string.entry = "C:\data\test1.dbf"
```

Boolean values must be either the `true` or `false` keyword:

```javascript
my.boolean.entry = true
```

**Example**

```makefile
# Last modification: 2013-03-12/mike
report.aggregatezero = true
gui.connection.timeout = 100
dbi.database.stores.source = "C:\data\test1.dbf"
dbi.database.stores.prefetch.rows = 200
```

```

C shell:

```
setenv VAR=value
```

For more details, refer to the documentation for your UNIX™ system.

**Setting environment variables on Windows™**

On Windows™ platforms, environment variables can be set by one of the following methods:

- In a command window, with the `SET` command.
- In the registry, for the current user in `HKEY_CURRENT_USER` or a global setting in `HKEY_LOCAL_MACHINE`.

For more details, refer to the documentation of your Windows™ system.

On Windows™, double quotes do not have the same meaning as on UNIX™ systems. For example, if you set a variable with the command `SET VAR="abc"`, the value of the variable will be "abc" (with double quotes), and not abc.

When using Informix®, some variables related to the database engine must be set using the SETNET32 utility.

**Setting environment variables in FGLPROFILE (mobile)**

When executing applications on mobile devices, you can configure environment settings with FGLPROFILE entries. Setting an environment variable with an FGLPROFILE entry is equivalent to setting the environment variable before running the fglrun VM process on a server.

**Note:** Environment variables set in an FGLPROFILE file are only read when the deployed application runs on the mobile device. They are not read during development mode (that is when the VM runs on the development machine and the mobile client displays on the device). The FGLPROFILE environment variable settings are only for the VM component and are ignored by the GMA/GMI front-end component.

FGLPROFILE environment variables settings can be used to define DBDATE and DBFORMAT, if the default regional settings on the mobile must be ignored for date and numeric value formatting. Note that defining DBMONEY will have no effect, because DBFORMAT is defined automatically by the GMI or GMA front-end component before starting the VM component. Since DBFORMAT takes precedence over DBMONEY, setting DBMONEY in FGLPROFILE is pointless.

**Important:** C-runtime library variables such as LANG/LC_ALL cannot be set with FGLPROFILE entries, because the C-runtime library is (and must be) initialized before reading FGLPROFILE files.

The syntax is:

```
mobile.environment.env_name = "env_value"
```

where:

1. *env_name* is the name of the environment variable to be set.
2. *env_value* is the value for the *env_name* environment variable.

For example:

```
mobile.environment.MY_ENV_VAR = "my value"
```

The value specified in a *mobile.environment* entry can contain $NAME placeholders, that will be replaced by the actual value of the NAME environment variable. The NAME environment variable will typically be set by the front-end component, before starting the runtime system component, for example to define FGLDIR and FGLAPPDIR values.
If the environment variable contains directory or file paths, use the UNIX® path notation with / slashes as directory name separator, and the : colon as path separator.

This example defines the FGLIMAGEPATH environment variable for the mobile app, using FGLAPPDIR and FGLDIR predefined environment variables:

```
mobile.environment.FGLIMAGEPATH = "$FGLAPPDIR/myimages:$FGLAPPDIR/icons/myimage2font.txt:$FGLDIR/lib/image2font.txt"
```

**Note:** During development (when executing programs on a server), consider defining environment variables such as FGLAPPDIR in the shell environment, along with the other environment variables that are defined with mobile.environment entries, as these are only read when executing on mobile devices.

### Operating system environment variables

This section describes some well-known system environment variables that are used by Genero software components.

- **LC_ALL (or LANG)** on page 228
- **LD_LIBRARY_PATH** on page 228
- **PATH** on page 229
- **TERM** on page 229
- **TERMCAP** on page 229
- **TERMINFO** on page 230
- **TMPDIR, TMP, TEMP** on page 230

**LC_ALL (or LANG)**

Defines the current application locale on UNIX™ platforms.

The LC_ALL (or LANG) environment variable defines language, territory and codeset for programs running on UNIX™ platforms.

The codeset defined in LC_ALL is used by the runtime system to handle character strings.

It is important to set this variable properly to the character set used by your application.

If LC_ALL is not defined, LANG is used instead.

Read the UNIX™ man page of the `setlocale()` C function for more details about this variable.

**Related concepts**

- **Localization** on page 405
  - Localization support allows you to implement programs that follow specific language and cultural rules.

**LD_LIBRARY_PATH**

Defines search paths to find shared libraries on UNIX™ platforms.

The LD_LIBRARY_PATH environment variable defines the list of search paths for shared libraries loaded by the dynamic linker on UNIX™ platforms.

On some operating systems, the environment variable defining the shared library search path may have a different name.

- On a system where a 32-bit and a 64-bit environment coexist, you may need to set `LD_LIBRARY_PATH_64` to execute the 64-bit programs.
- On HP/UX, set `SHLIB_PATH`.
- On AIX®, set `LIBPATH`. 
On Mac OS X®, the usage of DYLD_LIBRARY_PATH is discouraged. Therefore, shared libraries that are not part of the Genero runtime system (such as database client libraries) must be found in the standard system directories (/usr/lib, /usr/local/lib)

**PATH**
Defines the list of search paths to find executable files.

The PATH environment variable defines the list of search paths for executable files.

On UNIX™ platforms, PATH defines the search path list for executable programs.

On Windows™ platforms, PATH defines the search path for programs and DLLs.

The path separator is a colon (:) on UNIX™ and a semicolon (;) on Windows™.

**TERM**
Defines the type of terminal on UNIX™ platforms.

The TERM variable is used by UNIX™ and Genero applications to identify the terminal type when running in TUI mode.

By default or when INFORMIXTERM equals termcap, Genero reads terminal capabilities from the file defined by the TERMCAP environment variable. When INFORMIXTERM is set to terminfo, Genero reads terminal capabilities from the terminfo database of the system.

TERMCAP is the older implementation of terminal capabilities database. Therefore, it is not recommended to set INFORMIXTERM=terminfo.

It is important to define this variable properly to match the text terminal hardware or the terminal emulation you are using.

**Related concepts**
TERMCAP on page 229
Defines the termcap terminal capabilities database on UNIX™ platforms.

INFORMIXTERM on page 248
Defines terminal control library to be used.

Using a text terminal on page 1024
This section covers topics about text terminal configuration when using the TUI mode (when the FGLGUI environment variable is set to zero).

TERMCAP
Defines the termcap terminal capabilities database on UNIX™ platforms.

**Usage**
For UNIX™ platforms, TERMCAP is an environment variable that defines the terminal capabilities file. This variable must be used in conjunction with TERM, when INFORMIXTERM is set to termcap, or when INFORMIXTERM is not set.

If the TERMCAP variable is not defined, Genero tries to open /etc/termcap. If no /etc/termcap file exists, the runtime system uses $FGLDIR/etc/termcap. You can add more terminal definitions in this file.

TERMCAP is the older implementation of terminal capabilities database. It is recommended that you set INFORMIXTERM=terminfo.

It is important to define terminal capabilities properly for your text terminal hardware or the terminal emulation you are using. Especially function keys (F1, F16) and display attributes (bold, reverse, colors) may not work if the escape sequences do not correspond to the terminal used.

For more details about the TERMCAP environment variable, please refer to your UNIX™ operating system manual.

**Related concepts**
TERM on page 229
Defines the type of terminal on UNIX™ platforms.

**INFORMIXTERM** on page 248
Defines terminal control library to be used.

**Using a text terminal** on page 1024
This section covers topics about text terminal configuration when using the TUI mode (when the FGLGUI environment variable is set to zero).

**TERMINFO**
Defines the *terminfo* terminal capabilities database.

On UNIX™ platforms, the TERMINFO environment variable points to the terminal capabilities database. This variable must be used along with TERM, when INFORMIXTERM is set to *terminfo*.

Setting this environment variable is generally not necessary. The default is defined by the UNIX™ system, it can be for example /etc/terminfo, /usr/lib/terminfo, or /lib/terminfo.

It is important to define terminal capabilities properly for your text terminal hardware, or the terminal emulation you are using. In particular, function keys (F1, F16) and display attributes (bold, reverse, colors) may not work if the escape sequences do not correspond to the terminal used.

For more details about the TERMINFO environment variable, please refer to your UNIX™ operating system manual.

**Related concepts**

**TERM** on page 229
Defines the type of terminal on UNIX™ platforms.

**INFORMIXTERM** on page 248
Defines terminal control library to be used.

**Using a text terminal** on page 1024
This section covers topics about text terminal configuration when using the TUI mode (when the FGLGUI environment variable is set to zero).

**TMPDIR, TMP, TEMP**
Defines the directory for temporary files.

The TMPDIR, TEMP and TMP environment variables define the directory where temporary files are created by the operating system and by some other software (TMPDIR is typically used on UNIX™ platforms, TEMP and TMP are used on Windows™).

On desktop and server platforms, consider using **DBTEMP** to define the temp file directory for runtime system temporary files.

On mobile devices, there is no need to define the TMPDIR (or DBTEMP) environment variable: The runtime system will automatically use the appropriate temporary directory within the app sandbox file system.

**Database client environment variables**

Programs connecting to a database server use a database driver that in turn uses a database client library. The database client software usually needs configuration settings that are defined with environment variables. Database client environment variable define information such as installation directory of the client software, localization settings, temporary directory, and more.

Refer to the database client software documentation for the required environment variable settings.

**Related concepts**

**Database client environment** on page 602
To connect to a database server, Genero BDL programs use vendor’s database client software.

**Genero environment variables**

This section lists and describes in detail all Genero specific environment variables.
**DBCENTURY**

Specifies the expansion for the century in `DATE` and `DATETIME` values.

The `DBCENTURY` environment variable specifies how to expand abbreviated one- and two-digit *year* specifications within `DATE` and `DATETIME` values, especially during field input.

**Important:** The `DBCENTURY` environment variable is also used by the IBM® Informix® database client and server to make date to string conversions.

Default value is "R" (prefix the entered value with the first two digits of the current year).

Values are case sensitive; only the four uppercase letters are valid.

**Table 96: DBCENTURY valid values**

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Algorithm for Expanding Abbreviated Years</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>Use the past, future, or current year closest to the current date.</td>
</tr>
<tr>
<td>F</td>
<td>Use the nearest year in the future to expand the entered value.</td>
</tr>
<tr>
<td>P</td>
<td>Use the nearest year in the past to expand the entered value.</td>
</tr>
</tbody>
</table>
Symbol | Algorithm for Expanding Abbreviated Years
---|---
R | Prefix the entered value with the first two digits of the current year.

If a year is entered as a single digit, it is first expanded to two digits by prefixing it with a zero; DBCENTURY then expands this value to four digits.

Three-digit years are not expanded.

Years before 99 AD (or CE) require leading zeros (to avoid expansion).

If the database server and the client system have different settings for DBCENTURY, the client system setting takes precedence for abbreviations of years in dates entered through the application. Expansion is sensitive to the time of execution and to the accuracy of the system clock-calendar. You can avoid the need to rely on DBCENTURY by requiring the user to enter four-digit years or by setting the CENTURY attribute in the form specification of DATE and DATETIME fields.

**Related concepts**

- Formatting DATE values on page 284
- Date, numeric and monetary formats on page 424

This section describes how Genero BDL handles date, time, numeric and monetary formats.

**DBDATE**

Defines the default display and input format for DATE values.

The DBDATE environment variable defines the default display and input format for DATE values.

**Important:** The DBDATE environment variable is also used by the IBM® Informix® database client and server to make date to string conversions.

DBDATE defines the order of the month, day, and year time units within a string representing a date with numeric month and day such as "24/04/2014".

Values of DBDATE must be a restricted combination of symbols representing the position of the year (Yn), month (M) and day (D), the separator and some optional configuration options. For example, DMY4/ defines a date format with the day unit at the first position, followed by the month and the year (on 4 digits): "dd/mm/yyyy".

The separator always goes at the end of the format string (for example, DMY2/). If no separator or an invalid character is specified, the slash ( / ) character is the default. Specifying a 0 (zero) as separator indicates that no separator is used.

The default value of DBDATE depends on the type of platform: On desktop/server platforms, the default setting for DBDATE is: MDY4/. On mobile platforms, DBDATE defaults to the regional settings defined on the device.

**Table 97: Valid DBDATE symbols**

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning in DBDATE format string</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>Day of month as one or two digits</td>
</tr>
<tr>
<td>M</td>
<td>Month as one or two digits</td>
</tr>
<tr>
<td>Y2</td>
<td>Year as two digits</td>
</tr>
<tr>
<td>Y3</td>
<td>Year as three digits (Ming Guo format only)</td>
</tr>
<tr>
<td>Y4</td>
<td>Year as four digits</td>
</tr>
<tr>
<td>/</td>
<td>Default time-unit separator for the default locale</td>
</tr>
<tr>
<td>C1</td>
<td>Ming Guo format modifier (years as digits)</td>
</tr>
<tr>
<td>-</td>
<td>Hyphen time-unit separator</td>
</tr>
</tbody>
</table>
The combinations must follow a specific order:

```
{DM | MD} {Y2 | Y3 | Y4} {/ | - | .} 0 \[C1]
{Y2 | Y3 | Y4} {DM | MD} {/ | - | .} 0 \[C1]
```

When a form field and its corresponding variable are defined with the `DATE` type, values will be displayed depending on the DBDATE format, except if a `FORMAT` attribute is defined.

The DBDATE format is also used to automatically convert a character string to/from a `DATE` value in programs.

Note that DBDATE takes also effect when fetching `DATE` values from the database into `CHAR`/`VARCHAR` program variables. However, it is not recommended to fetch date information into string variables, it is recommended that you use `DATE` or `DATETIME` variables instead.

The C1 modifier can be used at the end of the DBDATE value in order to use Ming Guo date format with digit-based years. When using C1, you can use one of the Y4, Y3 or Y2 symbols for the year.

A Gregorian date format can look like "DMY4/", while a Ming Guo date format would look like "Y3MD/C1".

Date formatting specified in a `USING` clause or `FORMAT` attribute overrides the formatting specified in DBDATE.

**Related concepts**

- Formatting `DATE` values on page 284
  Date values must be formatted when converted to strings.

- Date, numeric and monetary formats on page 424
  This section describes how Genero BDL handles date, time, numeric and monetary formats.

- Using the Ming Guo date format on page 425
  Genero BDL can be configured to use the The Ming Guo calendar.

**DBDELMITER**

Defines the value separator for unload data files.

The DBDELMITER environment variable defines the value delimiter for `LOAD` and `UNLOAD` instructions.

If DBDELMITER is not defined, the default delimiter is a (|) pipe.

Do not use backslash or hex digits (0-9, A-F, a-f).

DBDELMITER defines also the default delimiter for the `base.Channel` in/out API.

**DBEDIT**

Defines the editor program for `TEXT` fields in TUI mode.

The DBEDIT environment variable defines the editor program to modify the values of form fields defined with the `TEXT` data type, when running programs on dumb terminals.

**DBFORMAT**

Defines currency symbol, decimal and thousands separator for input and display of numeric values.

The DBFORMAT environment variable defines the input and display format for numeric values.

**Important:**

- When defined, the DBFORMAT environment variable takes precedence over `DBMONEY`.
- The DBFORMAT environment variable is also used by the IBM® Informix® database client and server to make date to string conversions.
• When using a graphical front-end, the decimal separator of the numeric keypad will produce the character defined by the DBFORMAT (or DBMONEY) environment variables.

The value of a DBFORMAT variable must use the following syntax:

\[ \text{front:thousands:decimal:back} \]

1. \textit{front} is the leading currency symbol, can be an asterisk ( * ).
2. \textit{thousands} is a character that you specify as a valid thousands separator, can be an asterisk ( * ).
3. \textit{decimal} is a character that you specify as a valid decimal separator.
4. \textit{back} is the trailing currency symbol, can be an asterisk ( * ).

DBFORMAT takes precedence over DBMONEY.

If neither DBMONEY, nor DBFORMAT are defined, the default numeric formatting depends on the type of platform where the runtime system executes:

- On desktop/server platforms, the default numeric format defines the ( , ) comma as thousands separator, the ( . ) dot as decimal separator, and the ( $ ) dollar sign as front currency symbol for MONEY values. This corresponds to \texttt{DBMONEY="\$ ", or DBFORMAT="\\$:, ,: ".}
- On mobile platforms, the numeric format defaults to the regional settings defined on the device. Normally, there is no need to modify these defaults.

DBFORMAT can be set to define the input and display format for values of these types:

- \texttt{MONEY} (thousands separator, decimal separator and currency symbol)
- \texttt{DECIMAL} (thousands separator, decimal separator)
- \texttt{SMALLFLOAT} (thousands separator, decimal separator)
- \texttt{FLOAT} (thousands separator, decimal separator)
- \texttt{SMALLINT} (thousands separator)
- \texttt{INTEGER} (thousands separator)
- \texttt{BIGINT} (thousands separator)

DBFORMAT can specify the leading and trailing currency symbols (but not their default positions within a monetary value) and the decimal and thousands separators. The decimal and thousands separators defined by DBFORMAT apply to both monetary and other numeric data.

The instructions affected by the setting in DBFORMAT include (but are not restricted to) these items:

- \texttt{USING} operator.
- \texttt{FORMAT} field attribute.
- \texttt{DISPLAY} or \texttt{PRINT} statement (default formatting of numeric values).
- \texttt{LET} statement, where a \texttt{CHAR}, \texttt{VARCHAR} or \texttt{STRING} variable is assigned a monetary or number value.
- \texttt{LOAD} and \texttt{UNLOAD} statements that use ASCII files (or whatever the locale regards as a \texttt{flat} file) to pass data to or from the database.

The asterisk ( * ) specifies that a symbol or separator is not applicable; it is the default for any \textit{front}, \textit{thousands}, or \textit{back} term that you do not define.

If you specify more than one character for \textit{decimal} or \textit{thousands}, the values in the \textit{decimal} or \textit{thousands} list cannot be separated by spaces (nor by any other symbols). However, only the first character will be used to display numeric or currency values, when converting strings to numbers and when entering values in form fields.

Any printable character that your locale supports is valid for the thousands separator or for the decimal separator, except 0–9 digits, <>,,, |, ?, !, =, [ and ].

The same character cannot be both the thousands and decimal separator. A blank space (ASCII 32) can be the thousands separator (and is conventionally used for this purpose in some locales). The asterisk ( * ) symbol is valid as the decimal separator, but is not valid as the thousands separator.
Enclosing the DBFORMAT specification in a pair of single quotation marks is recommended to prevent the shell from attempting to interpret (or execute) any of the DBFORMAT characters.

The setting in DBFORMAT affects how formatting masks of the FORMAT attribute and USING operator are interpreted. In formatting masks of FORMAT and USING, these symbols are not literal characters but are placeholders for what DBFORMAT specifies:

- The dollar ($) sign is a placeholder for the front currency symbol.
- The comma (,) is a placeholder for the thousands separator.
- The period (.) is a placeholder for the decimal separator.
- The at (@) sign is a placeholder for the back currency symbol.

This table illustrates the results of different combinations of DBFORMAT setting and format string on the same value.

**Table 98: Results of combinations of DBFORMAT setting and format string on the same value**

<table>
<thead>
<tr>
<th>Value</th>
<th>Format String</th>
<th>DBFORMAT</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234.56</td>

<tr>
<td>1234.56</td>
<td>#,###.##&amp;</td>
<td>:::::DM</td>
<td>1.234,56DM</td>
</tr>
</tbody>
</table>

When the user enters numeric or currency values in fields, the runtime system behaves as follows:

- If a symbol is entered that was defined as a decimal separator in DBFORMAT, it is interpreted as the decimal separator.
- For MONEY fields, it disregards any front (leading) or back (trailing) currency symbol and any thousands separators that the user enters.
- For DECIMAL fields, the user must enter values without currency symbols.

When the runtime system displays or prints values:

- The DBFORMAT-defined leading or trailing currency symbol is displayed for MONEY values.
- If a leading or trailing currency symbol is specified by the FORMAT attribute for non-MONEY data types, the symbol is displayed.
- The thousands separator is not displayed unless it is included in a formatting mask of the FORMAT attribute or of the USING operator.

When MONEY values are converted to character strings by the LET statement, both automatic data type conversion and explicit conversion with a USING clause insert the DBFORMAT-defined separators and currency symbol into the converted strings.

For example, suppose DBFORMAT is set as follows:

```
*:::,SFr
```

The value 1234.56 will print or display as follows:

```
1234,56SFr
```
Here \( \text{SFr} \) stands for the Swiss Franc currency symbol. Values input by the user into a screen form are expected to contain commas, not periods, as their decimal separator because DBFORMAT has \(*:.:.,:\text{SFr}\) as its setting in this example.

**Related concepts**

- Formatting DATE values on page 284
  Date values must be formatted when converted to strings.
- Date, numeric and monetary formats on page 424
  This section describes how Genero BDL handles date, time, numeric and monetary formats.
- Type conversions on page 274
  Explains data type conversion rules of the language.
- FORMAT attribute on page 1257
  The FORMAT attribute defines the data formatting for numeric and date time fields, for input and display.

**DBMONEY**

Defines currency symbol and decimal separator for input and display of numeric values, when DBFORMAT is not defined.

The DBMONEY environment variable defines the currency symbol and the decimal separator for numeric values.

**Important:**

- When defined, the DBFORMAT environment variable takes precedence over DBMONEY.
- The DBMONEY environment variable is also used by the IBM® Informix® database client and server to make date to string conversions.

The value of a DBMONEY variable must use the following syntax:

```
front{. | ,}back
```

1. `front` is a character string representing a leading currency symbol that precedes the value.
2. `back` is a character string representing a trailing currency symbol that follows the value.

If neither DBMONEY, nor DBFORMAT are defined, the default numeric formatting depends on the type of platform where the runtime system executes:

- On desktop/server platforms, the default numeric format defines the (, ) comma as thousands separator, the ( . ) dot as decimal separator, and the ( $ ) dollar sign as front currency symbol for MONEY values. This corresponds to DBMONEY="$.", or DBFORMAT="$.:,:".
- On mobile platforms, the numeric format defaults to the regional settings defined on the device. Normally, there is no need to modify these defaults.

DBMONEY can only define the currency symbol and decimal separator characters must be specified in this environment variable. If you want to define the thousands separator, use the DBFORMAT environment variable instead. However, if only DBMONEY is used, an implicit thousands separator is selected.

The currency symbol in DBMONEY can be up to seven characters long and can contain any character except a comma or a period. It can be non-ASCII characters if the current locale supports a code set that defines the non-ASCII characters you use.

The DBMONEY environment variable can be set to define the input and display format for values of the following types:

- MONEY (thousands separator, decimal separator and currency symbol)
- DECIMAL (thousands separator, decimal separator)
- SMALLFLOAT (thousands separator, decimal separator)
- FLOAT (thousands separator, decimal separator)
- SMALLINT (thousands separator)
- INTEGER (thousands separator)
• **BIGINT** (thousands separator)

Numeric values will be displayed in forms and reports based on this environment variable.

**DBMONEY** will also be used for implicit data conversion between numeric values and character strings.

The position of the currency symbol (relative to the decimal separator) indicates whether the currency symbol appears before or after the **MONEY** value. When the currency symbol is positioned in **DBMONEY** before the decimal separator, it is displayed before the value ($1234.56). When it is positioned after the decimal separator, it is displayed after the value (1234.56F).

The runtime system recognizes the period (.) and the comma (,) as decimal separators. All other characters are considered to be part of the currency symbol. For example, ", FR" defines a **MONEY** format with the comma as decimal separator and the string " FR" (including the space) as the currency symbol.

Because only its position within a **DBMONEY** setting indicates whether a symbol is the **front** or **back** currency symbol, the decimal separator is required. If you use **DBMONEY** to specify a **back** symbol, for example, you must supply a decimal separator (a comma or period). Similarly, if you use **DBMONEY** to change the decimal separator from a period to a comma, you must also supply a currency symbol.

To avoid ambiguity in displayed numbers and currency values, do not use the thousands separator of **DBFORMAT** as the decimal separator of **DBMONEY**. For example, specifying comma as the **DBFORMAT** thousands separator dictates using the period as the **DBMONEY** decimal separator.

When using a graphical front-end, the decimal separator of the numeric keypad will produce the character defined by this environment variable.

**Related concepts**

**DBFORMAT** on page 233

Defines currency symbol, decimal and thousands separator for input and display of numeric values.

**DBPATH**

Defines the paths to search for Genero program resource files.

For IBM® Informix® 4GL compatibility, **DBPATH** is used by the runtime system to find resource files such as form definitions.

**Important**: The **DBPATH** environment variable is also used by the IBM® Informix® SE engine and SQLite, to define the path list to find database files. Genero has introduced the **FGLRESOURCEPATH** environment variable to not interfere with the database **DBPATH** settings. Consider dedicating **DBPATH** for database configurations, and use the **FGLRESOURCEPATH** to define program resource path list.

**DBPATH** must contain a list of paths, separated by the operating system specific path separator.

The path separator is platform specific (";" on UNIX™ platforms and ";" on Windows® platforms).

See **FGLRESOURCEPATH** for more details about resource files search path.

**DBPRINT**

Defines the print device to be used by reports.

The **DBPRINT** environment variable specifies the print device to be used by reports defined TO **PRINTER**.

On UNIX™ systems, the **DBPRINT** environment variable typically contains the printer queue command (such as lp).

When defining **DBPRINT=FGLSERVER**, the report is sent to the printer configured in the Genero Desktop Client (GDC).

**Related concepts**

**Reports** on page 1924

**DBSCREENDUMP**

Defines the output file name for text screen shots.

The **DBSCREENDUMP** environment variable defines the output file name for text screen shots when pressing Ctrl-P.
When using the TUI mode, if the user pressed the Ctrl-P key, the runtime system will dump the current screen into the file defined by this variable.

Unlike DBSCREENOUT, the output of DBSCREENDUMP includes the escape sequences of TTY attributes, which makes it less readable.

**Related concepts**

**DBSCREENOUT**
Defines the output file name for text screen shots.

The DBSCREENOUT environment variable defines the output file name for text screen shots when pressing Ctrl-P.

When using the TUI mode, if the user pressed the Ctrl-P key, the runtime system will dump the current screen into the file defined by this variable.

Unlike DBSCREENDUMP, the output of DBSCREENOUT excludes the escape sequences of TTY attributes.

**Related concepts**

**DBSCREENDUMP**
Defines the output file name for text screen shots.

**DBTEMP**
Defines the directory for temporary files.

The DBTEMP environment variable defines the directory for temporary files created by the runtime system.

If the DBTEMP variable is not defined, the runtime system uses the temporary directory as defined on the operating system. Depending on the platform, the TMPDIR, TMP, TEMP environment variables, or the default system temp directory will be used.

**Important:** The DBTEMP environment variable is also used by the IBM® Informix® database client and server for temporary files.

The temporary directory is used to create temporary files for:

1. **TEXT** or **BYTE** data located in a temporary file (LOCATE IN FILE without file name specification).
2. Temporary files of **emulated scrollable cursors** when the database engine does not support this feature.
3. Temporary file name generation with `os.Path.makeTempName()`.
4. Temporary files created by the Web Services API, such as `com.HTTPResponse.getFileResponse` on page 2740.

On mobile devices, do not set DBTEMP environment variable: The runtime system will automatically use the appropriate temporary directory within the app sandbox file system.

**FGL_LENGTH_SEMANTICS**
Defines the length semantics to be used in programs.

Define the FGL_LENGTH_SEMANTICS environment variable to specify byte or character length semantics, by setting the value to **BYTE** or **CHAR**, respectively.

If the variable is not set, byte length semantics will be used by default.

When using a single-byte character set such as ISO-8859-1, use byte length semantics (the default). If the application character set is UTF-8, it is recommended that you use char length semantics.

**Related concepts**

**Length semantics settings** on page 414
**FGLAPPPDIR**
Contains the path to the application directory when executing on a mobile device.

When executing on mobile devices, the FGLAPPPDIR environment variable is an automatic environment variable that contains the path to the appdir directory, containing application program files (.42m, .42f, and other resources).

This variable is typically used to define environment variables with mobile.environment FGLPROFILE entries, relative to the mobile appdir where application program files and resources are located.

**Note:** During development (when executing programs on a server), consider defining the FGLAPPPDIR in the shell environment, along with the other environment variables that are defined with mobile.environment entries, as these are only read when executing on mobile devices.

**Related concepts**
- Directory structure for GMI apps on page 3330
- Directory structure for GMA apps on page 3315

**FGLAPPSERVER**
Defines the listening TCP port of the Web service in development context.

The FGLAPPSERVER environment variable defines the TCP port on which the web service server will be started.

If the FGLAPPSERVER environment variable is not set, the default TCP port is 80.

During development, define this environment variable before starting the web service server program, to let web service clients connect directly to the runtime system. You typically defined FGLAPPSERVER to the port 8090.

In production, Genero Application Server (GAS) is used to deploy web services servers. The GAS will automatically set FGLAPPSERVER. Do not manually set FGLAPPSERVER when GAS is involved.

**Related concepts**
- The WebServiceEngine class on page 2675
- The com.WebServiceEngine class provides an interface to manage the Web Services engine.

**FGLCOV**
Enables coverage data collection.

The FGLCOV environment variable can be used to enable coverage data collection while executing programs.

When the FGLCOV variable is set, fglrun produces module.42m.cov files.

For more details, see Source code coverage on page 2056.

**FGLDBPATH**
Defines the path to database schema files for compilers.

The fglcomp on page 1972 and fglform compilers need database schema files to compile source modules and forms.

The path to the database schema files can be specified with FGLDBPATH.

If FGLDBPATH is not defined, the current directory is the default path for the database schema files. You can provide a list of paths, separated by the operating system specific path separator. FGLDBPATH is only used in development.
FGLDBPATH must contain a list of paths, separated by the operating system specific path separator. The path separator is ":" on UNIX™ platforms and ";" on Windows® platforms.

**Related concepts**

Database schema on page 476
Defines database table structures with column type information to be reused in program variable definitions.

**FGLDIR**
Defines the installation directory of Genero Business Development Language.

The FGLDIR environment variable defines the installation directory of the runtime system and compilers of Genero.

When executing on a mobile device, the FGLDIR environment variable is automatically set by the front-end component, before starting the runtime system component. As result, it is possible to use the $FGLDIR keyword in FGLPROFILE environment variable settings when executing on mobile devices.

**Related concepts**

PATH on page 229
Defines the list of search paths to find executable files.

**FGLGUI**
Defines the user interface mode to be used by the program.

The FGLGUI environment variable indicates whether the applications are run in TUI or GUI mode.

**Table 99: FGLGUI values**

<table>
<thead>
<tr>
<th>FGLGUI</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (zero)</td>
<td>The application executes in TUI (text) mode.</td>
</tr>
<tr>
<td>1 (default)</td>
<td>The application executes in GUI (graphical) mode and needs a front-end to display application windows.</td>
</tr>
</tbody>
</table>

**Related concepts**

Genero user interface modes on page 1013
User interface modes allow you to adapt the application form rendering to different types of displays.

**FGLGUIDEBUG**
Defines the debug level in GUI mode.

The FGLGUIDEBUG environment variable defines the debug level, when the GUI mode is used by the program.

By setting FGLGUIDEBUG to 1, the runtime system will display AUI protocol exchanges in the stderr output of the console running the program on the server.

The runtime system displays detailed information about user interface events that occur during program execution.

**Important:** This debug log is to be used in development context only. The output format can change in next product releases.

**Related concepts**

FGLGUI on page 240
Defines the user interface mode to be used by the program.

**FGLIMAGEPATH**
Defines the search paths for VM server image files.

**FGLIMAGEPATH basics**

The FGLIMAGEPATH environment variable is used by the runtime system, to find image resources on the server where the program executes, when the image name specified in the form element is not an URL that can be directly resolved and fetched by the front-end.

Image resources found through FGLIMAGEPATH will be transmitted to the front-end for display.

FGLIMAGEPATH defines a list of directories and/or image-to-font-glyph mapping files: If a path of FGLIMAGEPATH is a directory, it will be used for image file and font file lookup. If the element is a file name, it will be used as an image-to-font-glyph mapping file.

**FGLIMAGEPATH setting on mobile devices**

When executing on a mobile device, the environment variables must be defined with `mobile.environment` FGLPROFILE entries. The FGLAPPDIR and FGLDIR environment variables are automatically defined by the front-end component, and can be referenced with the `$FGLAPPDIR` and `$FGLDIR` placeholders, when defining FGLIMAGEPATH in FGLPROFILE:

```
mobile.environment.FGLIMAGEPATH
  = "$FGLAPPDIR/myimages:$FGLAPPDIR/icons/myimage2font.txt:$FGLDIR/lib/image2font.txt"
```

For more details about environment variable settings for mobile apps, see Setting environment variables in FGLPROFILE (mobile) on page 227.

**Default behavior when FGLIMAGEPATH is not defined**

If the FGLIMAGEPATH environment variable is not defined, the runtime system will by default:

- Find image resource files in the current working directory where the BDL program executes.
  
  **Note:** When executing the app on an iOS device, instead of searching the current working directory, image resources are by default found in the appdir directory.

- Use `FGLDIR/lib/image2font.txt` along with `FGLDIR/lib/FontAwesome.ttf`, for image to font glyph mapping (to get default icons).

**Order of precedence in FGLIMAGEPATH**

It is possible to mix several image file directories with several image-to-font-glyph mapping files in FGLIMAGEPATH:

The list of mapping files and directories defines the order of precedence to resolve conflicts, when several image names can resolve to several image resources.

For example, if a form element defines an image as "smiley", and if FGLIMAGEPATH is defined as:

```
/opt/myapp/images:/opt/myapp/image2font.txt
```

If the `/opt/myapp/images` directory contains an image file "smiley.png", and the `/opt/myapp/image2font.txt` file contains a mapping for "smiley", the "smiley.png" file from `/opt/myapp/images` will be selected by the runtime system.

If FGLIMAGEPATH is defined as follows:

```
/opt/myapp/image2font.txt:/opt/myapp/images
```
The mapping for smiley to font glyph would take precedence.

**FGLIMAGEPATH syntax**

FGLIMAGEPATH must contain a list of paths, separated by the operating system specific path separator. The path separator is ":" on UNIX™ platforms and ";" on Windows® platforms.

For example, on UNIX:

```
$ export FGLIMAGEPATH="/var/myapp/myimages:$FGLDIR/lib/image2font.txt"
```

**Image-to-font-glyph mapping**

Image names can be mapped to font glyphs when at least one file path is specified in FGLIMAGEPATH. The runtime system distinguishes file paths (as image-to-font-glyph mapping files), from directory paths (as locations to file plain image files and font files).

**Important:** The directory and file name to the font file must be specified in FGLIMAGEPATH, except if the font file is located in the same directory as the mapping file.

A default mapping file ("image2font.txt") and its corresponding font file ("FontAwesome.ttf") are provided in FGLDIR/lib. If FGLIMAGEPATH is not defined, the runtime system will use these files, to make the image name to font glyph mapping. If FGLIMAGEPATH is defined, the default mapping file will not be used. To get default Genero BDL icons, add $FGLDIR/lib/image2font.txt explicitly to your FGLIMAGEPATH path list.

**Important:** When providing your own customized font file, it must be a valid TTF file. For example, changing the file name is not sufficient to turn it into a different font: In order to produce a valid TTF file, use font management tools such as FontForge (http://fontforge.github.io/en-US/) or Fontello (http://fontello.com). Furthermore, to target Microsoft® Internet Explorer (version 11), you will need to patch the generated TTF file to remove embedding limitations from TrueType fonts, by setting the fsType field in the OS/2 table to zero. This modification can be done with freeware tools like ttembed.

The image-to-font-glyph mapping file must have the following syntax:

```
image-name=font-file:hexa-ordinal][:color-spec]
```

where:

1. **image-name** - is the name of the image to be mapped to a font character.
2. **font-file** - is the file name containing the font definitions.
3. **hexa-ordinal** - is the font glyph position in the font file, in hexadecimal notation.
4. **color-spec** - is the color to be used, in RGB hexadecimal format or as color alias as defined in presentation style colors. This field is optional: If not specified, the glyph will be displayed in a default color used by the front-end platform.

Lines starting with the # hash character are considered as comment lines and ignored.

For example:

```
# Common icons
camera=FontAwesome.ttf:f030
file=FontAwesome.ttf:f0f6:#8B0000
smiley=FontAwesome.ttf:f118:yellow
# Traffic lights
circle-red=FontAwesome.ttf:f111:red
circle-orange=FontAwesome.ttf:f111:orange
circle-green=FontAwesome.ttf:f111:green
```
**FGLIMAGEPATH and gICAPI web components**

For applications executing on a server and displaying on GDC/GMA/GMI front-ends in client/server mode (not through the GAS), the recommended solution is to locate gICAPI web component assets in `appdir/webcomponents`. Like image resources, the web component files will be automatically transferred to the front-end when connected in direct mode.

For backward compatibility, if the web component files are not located in the recommended directory, FGLIMAGEPATH can be used to define search paths for web component files. It is not recommended to use FGLIMAGEPATH to find web component files. For more details, see Deploying the gICAPI web component files on page 1850.

Note however that FGLIMAGEPATH must be used in direct mode, to find application image resources displayed inside a gICAPI web component. In such case, you need to add search paths for application images in FGLIMAGEPATH, and use the `ui.Interface.filenameToURI()` method to specify the image resource inside the web component. For more details, see Using image resources with the gICAPI web component on page 1855.

**Related concepts**
- Providing the image resource on page 1049
- There are several things you need to know about providing an image resource in a Genero program.

**FGLLDPATH**

Defines the search paths to load program modules.

The FGLLDPATH environment variable defines the search paths to load C extensions and `.42m` modules.

**Note:** The FGLLDPATH variable is used at link time and at run time.

A program can be composed by several p-code modules (`.42m`) and can use C extensions. When linking and when executing the program, the runtime system must known where to search for these modules. You can use the FGLLDPATH environment variable to define the search paths to load C extensions and p-code modules.

FGLLDPATH must contain a list of paths, separated by the operating system specific path separator. The path separator is `:` on UNIX™ platforms and `;` on Windows® platforms.

The directories are searched in the following order:

1. The current working directory.
2. The directory where the program file resides (the `.42m` module containing `MAIN` or the `.42r` program file).
3. A path defined in the FGLLDPATH environment variable.
4. The FGLDIR/lib directory.

**Note:** FGLLDPATH is also used by the debugger to find program sources. For more details, see FGLSOURCEPATH on page 245.

**Related concepts**
- FGLDIR on page 240
- Defines the installation directory of Genero Business Development Language.

- Importing modules on page 496
- Use the `IMPORT ...` instruction to import BDL, C or Java external modules in the current module.

**FGLPROFILE**

Defines the configuration files to be used by the runtime system.

**Usage**

The FGLPROFILE environment variable defines a list of configuration files to be used by the runtime system.

If FGLPROFILE is not set, the runtime system reads entries from the default configuration file located in `FGLDIR/etc/fglprofile`.

FGLPROFILE can define one unique configuration file, or a list of files to be loaded sequentially.
FGLPROFILE must contain a list of file paths, separated by the operating system specific path separator. The path separator is ";" on UNIX™ platforms and ";" on Windows® platforms.

**Note:** On mobile devices, it is not possible to define environment variables. To specify a custom FGLPROFILE file for a mobile application, you must deploy a file with the name "fglprofile" in the appdir directory, along with the other application program files (.42m, .42f, and so on). Only one custom FGLPROFILE file can be deployed for a given mobile application.

**Related concepts**
The FGLPROFILE file(s) on page 220  
FGLPROFILE environment variable defines Genero BDL configuration files

**FGLRESOURCEPATH**  
Defines search path for resource files.

**FGLRESOURCEPATH definition**  
The FGLRESOURCEPATH environment variable is used to define the search paths for program resource files:

1. Form definition files (.42f),  
2. Message files (.iem),  
3. Action defaults files (.4ad),  
4. Presentation styles files (.4st),  
5. Start menu files (.4sm),  
6. Toolbar files (.4tb),  
7. Topmenu files (.4tm),  
8. Localized strings files (.42s).

When the specified resource file is not an absolute path, the runtime system searches in directories in the following order:

1. The current working directory.  
2. A path defined in the FGLRESOURCEPATH (or DBPATH) environment variable.  
3. The FGLDIR/lib directory.  
4. The directory where the program file resides (the .42m module containing MAIN or the .42r program file).

The path separator is platform specific (";"); on UNIX™ platforms and ";" on Windows® platforms).

**Note:** On mobile platforms, localize string files are found by default in the language sub directories of the app directory. For more details, see Loading localized strings at runtime on page 437.

**FGLRESOURCEPATH versus DBPATH**  
For compatibility with Informix® 4GL, DBPATH is used by default to search for resource files such as form files and XML files used by the program. However, DBPATH is also used by the Informix® database software to locate databases: Informix® Dynamic Server uses DBPATH to let you specify fallback servers if INFORMIXSERVER is not available, and former Informix® Standard Engine needs DBPATH to find .dbs database files. This can be a problem when connecting from a machine where path format is not the same as on the remote database server: It is not possible to mix UNIX™ and DOS path formats in DBPATH. To work around this Informix® limitation, FGLRESOURCEPATH can be used instead of DBPATH to specify the directories of program resource files. You are then free to define DBPATH as Informix® requires.

**Related concepts**
DBPATH on page 237  
Defines the paths to search for Genero program resource files.  
IBM Informix Dynamic Server on page 603
**FGLSERVER**

Defines the graphical front-end form the application.

In GUI mode, FGLSERVER defines the host name and port of the graphical front end the runtime system will connect to in order to display application forms.

The values for the FGLSERVER environment variable must be specified with the following syntax:

```
{hostname|ip-address}[[:server-num]]
```

1. *hostname* is the name of a machine on the network.
2. *ip-address* is the IP V4 address (Ex: 10:0:0:105).
3. *server-num* identifies the front end.

The *server-num* parameter defines the front end server number (first is 0, second is 1, and so on). This defines implicitly the TCP port number the front end is listening to, as an offset for the base port 6400. For example, FGLSERVER=cobra:1 will use the TCP port 6401 (6400 + 1). This parameter is optional, when not specified, it defaults to zero (port 6400).

**Related concepts**

- [Genero user interface modes](#) on page 1013
- [Automatic front-end startup](#) on page 1022
- [Front-end connection](#) on page 249

To execute a Genero program with a graphical user interface, you need to specify the front-end (i.e. the graphical server) to the runtime system.

**FGLSOURCEPATH**

Defines the path to program source files.

The debugger needs to access the source files to display program code. By default, the current directory and the directories defined by FGLLDPATH are used to find source files.

The FGLSOURCEPATH environment variable is provided to distinguish execution directories (containing .42m files), from source directories (containing .4gl files), when the sources are not located in the same directory as the pcode files.

FGLSOURCEPATH must contain a list of paths, separated by the operating system specific path separator. The path separator is `:``` on UNIX™ platforms and `;``` on Windows™ platforms.

**UNIX™ example:**

```
$ FGLSOURCEPATH="/usr/app/source:/home/scott/sources"
$ export FGLSOURCEPATH
```

**Windows™ example:**

```
C:\> set FGLSOURCEPATH=C:\app\sources;C:\scott\sources
```

**Related concepts**

- [Integrated debugger](#) on page 2029

Describes the command-line debugger you can use to find bugs in your programs.

**FGLSQLDEBUG**

Defines the debug level for tracing SQL instructions.

If FGLSQLDEBUG is set to a value greater than zero, you get a debug trace in the standard error channel for every SQL instruction executed by the program.

**Important:** Sensitive and personal data may be written to the output. Make sure that the log output is written to files that can only be read by application administrators.
FGLSQLDEBUG can be used on a production site in order to identify a problem related to SQL statements. However, the SQL debug log can produce a lot of data and must be used with care.

**Note:** The output format of FGLSQLDEBUG is for debug purpose only and may change in future product releases.

Alternatively, you can use the `fgl_sqldebug()` function to set the SQL debug level by program.

**Related concepts**

- [Debugging SQL statements](#) on page 542
- Set the FGLSQLDEBUG environment variable to print SQL debug info.

**FGLTRACE_FUNCTIONS**

Defines the list of functions to be followed by the program execution trace.

The FGLTRACE_FUNCTIONS environment variable defines the list of functions to be traced with the program execution trace option.

By default, the trace starts with the **MAIN** function and all functions of the program are traced.

In order to limit the trace to a given set of functions, define the FGLTRACE_FUNCTIONS environment variable with space-separated list of function names. The functions can be prefixed by a module name:

```
{ function-name
  module-name.function-name
  
  ...
}
```

1. *module-name* is the name of a .42m module.
2. *function-name* is the name of a function.

**Important:** Unlike FGLTRACE_EXCLUDE, functions in FGLTRACE_FUNCTIONS can be specified with or without the module prefix. For example, if you want to include the `check_order()` function of the `orders.4gl` module, you can specify "`orders.check_order`" or "`check_order`" in FGLTRACE_FUNCTIONS.

For example, to enable the trace log in the "invoice_report_1” function (without specifying a module), and to enable the trace in the "add_customer" function, defined in the "custmod" module:

On UNIX™:

```
$ FGLTRACE_FUNCTIONS="invoice_report_1 custmod.add_customer"
$ export FGLTRACE_FUNCTIONS
```

On Windows™:

```
C:\> set FGLTRACE_FUNCTIONS=invoice_report_1 custmod.add_customer
```

**Note:** FGLTRACE_FUNCTIONS has a higher priority than FGLTRACE_EXCLUDE. The trace is enabled for a function listed in FGLTRACE_FUNCTIONS, when is it called from a function excluded by FGLTRACE_EXCLUDE.

**Related concepts**

- [Execution trace](#) on page 2060
  Print a function call stack of your program.

**FGLTRACE_EXCLUDE**

Defines the list of functions to be excluded from the program execution trace.

The FGLTRACE_EXCLUDE environment variable defines the list of patterns to identify functions (and class methods) that must be excluded from the call stack trace.

By default, all functions are traced, starting from the MAIN function, or from the functions listed in FGLTRACE_FUNCTIONS.
In order to exclude functions you don't want to trace, define the FGLTRACE_EXCLUDE environment variable with space-separated list of patterns:

```plaintext
exclude-pattern [...]
```

1. *exclude-pattern* is a string with wildcards like in a MATCHES expression:
   - The * wildcard represents 0 to n characters.
   - The ? wildcard represent a single character.
   - The [ ] wildcards can be used to define a single character in the specified range (use a ^ starting caret for negation).

**Important:** Unlike FGLTRACE_FUNCTIONS, user functions in FGLTRACE_EXCLUDE must be specified with their module prefix. For example, if you want to exclude the `check_order()` function of the `orders.4gl` module, use the qualified name "orders.check_order" in FGLTRACE_EXCLUDE.

The FGLTRACE_EXCLUDE environment variable is typically used to exclude build-in functions and classes such as `base.Array.*`. Tracing build-in functions can produce a huge log and is not always relevant. For example, if the program uses the `base.Array.getLength()` method, the trace will report each call to the method, as in `FOR i=1 TO arr.getLength()`.

**Tip:** To exclude all global built-in functions such as `fgl_getenv()`, use the `<builtin>.*` exclusion pattern.

For example, to exclude all methods from the build-in dynamic array class, from the `util.JSON` class, all om.* package calls and all functions of `mymodule` with the format `debug_[0-9]??`, define the variable as follows:

**On UNIX™**:

```bash
$ FGLTRACE_EXCLUDE="<builtin>.* base.Array.* util.JSON.* om.*
mymodule.debug_[0-9]??"
$ export FGLTRACE_EXCLUDE
```

**On Windows™**:

```bash
C:\> set FGLTRACE_EXCLUDE=<builtin>.* base.Array.* util.JSON.* om.*
mymodule.debug_[0-9]??
```

**Related concepts**

**Execution trace** on page 2060
Print a function call stack of your program.

**FGLWRTUMASK**
Defines the umask to be used by the license manager.

The FGLWRTUMASK environment variable is used by the fglWrt license manager to create the FGLDIR/lock directory.

This variable defines the umask to create the FGLDIR/lock directory.

The default is 000, which creates a directory with rwxrwxrwx file permissions.

**Related concepts**

**Installation** on page 38
This chapter contains installation and setup instructions.

**FGLWSDEBUG**
The FGLWSDEBUG environment variable enables web services library debugging.

Set the FGLWSDEBUG environment variable to turn on debug information display in the web services library.

**Important:** Sensitive and personal data may be written to the output. Make sure that the log output is written to files that can only be read by application administrators.
**Note:** This debug log is to be used in development context only. The output format can change in future product releases.

**Table 101: FGLWSDEBUG variable values**

<table>
<thead>
<tr>
<th>Value</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No data displayed; debug turned off.</td>
</tr>
<tr>
<td>1</td>
<td>Display socket errors.</td>
</tr>
<tr>
<td>2</td>
<td>Display HTTP bodies of incoming and outgoing requests (the XML content)</td>
</tr>
<tr>
<td>3</td>
<td>Display all information about incoming and outgoing requests (HTTP headers + HTTP bodies)</td>
</tr>
</tbody>
</table>

**Related concepts**

- **Debugging** on page 3106
- **GMIDIR**
  Defines the installation directory of Genero Mobile for iOS.
  The GMIDIR environment variable defines the installation directory of the Genero Mobile for iOS archive, used to build iOS apps with the `gmibuildtool`.
  When building apps with `gmibuildtool`, GMIDIR is used to find the GMI libraries and resource files.
  By default, if GMIDIR is not defined, the location for GMI libraries is found from the location of the `gmibuildtool`. For example, if `gmibuildtool` is found in `/opt/genero/gmi-1.20/bin/gmibuildtool`, GMIDIR will be defined as `/opt/genero/gmi-1.20`.

- **Building iOS apps with Genero** on page 3332
  Genero provides a command-line tool to build applications for iOS devices.

**INFORMIXTERM**

Defines terminal control library to be used.

The INFORMIXTERM environment variable indicates what terminal capabilities database must be used by the runtime system when running a program in TUI mode on a dumb terminal.

Possible values of INFORMIXTERM are `terminfo` and `termcap`. If the variable is not set, it defaults to `termcap`.

When set to `termcap` (the default), the runtime system reads terminal capabilities from the file defined by the TERMCAP environment variable.

When set to `terminfo`, the runtime system reads terminal capabilities from the terminfo database of the system (ncurses).

**Related concepts**

- **TERM** on page 229
  Defines the type of terminal on UNIX™ platforms.
- **TERMCAPE** on page 229
Defines the *termcap* terminal capabilities database on UNIX™ platforms.

**Front-end connection**

To execute a Genero program with a graphical user interface, you need to specify the front-end (i.e. the graphical server) to the runtime system.

In development mode, the target front-end is defined with the `FGLSERVER` on page 245 environment variable. However, there are various technologies to render a Genero application, depending on the front-end platform (PC, mobile device, web browser).

Details about front-end configuration for the runtime system can be found in User interface basics on page 1008.

**Database server connections**

Before running a Genero program using a database, you must configure the connection parameters to access the database server.

There are different solutions to define database connection parameters, consider using and indirect database connection configuration, by using an abstract database name in programs, and define the real database source, driver with `FGLPROFILE` entries.

The database configuration details can be found the SQL support chapter of this manual.

**Syntax features**

Genero BDL is an English-like programming language, easy to write and read.

- **Lettercase insensitivity** on page 250
- **Whitespace separators** on page 250
Lettercase insensitivity

Genero Business Development Language (BDL) is case insensitive, making no distinction between uppercase and lowercase letters, except within quoted strings.

Use pairs of double (" ) or single (’ ) quotation marks in the code to preserve the lettercase of character literals, filenames, and names of database entities.

You can mix uppercase and lowercase letters in the identifiers that you assign to language entities, but any uppercase letters in identifiers are automatically shifted to lowercase during compilation.

It is strongly recommended that you define a naming convention for your projects. For example, you can use underscore notation (get_user_name). If you plan to use the Java notation (getUserName), do not forget that Genero BDL is case insensitive (get_username is the same identifier as getUserName).

Tip: For better readability, and to be consistent with SQL syntax conventions, consider writing BDL language keywords in UPPERCASE, and other language elements like identifiers in lowercase:

```plaintext
INPUT BY NAME cust_rec.* ATTRIBUTES(UNBUFFERED)
```

With Genero BDL you can import and use Java classes and objects in BDL code. Genero BDL is case-sensitive regarding Java elements.

Related concepts

The Java interface on page 2071

The Java interface allows you to import Java classes and instantiate Java objects in your programs.

Whitespace separators

Genero Business Development Language (BDL) is free-form, like C or Pascal, and generally ignores TAB characters, LINEFEED characters, comments, and extra blank spaces between statements or statement elements. You can freely use these whitespace characters to enhance the readability of your source code.

Blank (ASCII 32) characters act as delimiters in some contexts. Blank spaces must separate successive keywords or identifiers, but cannot appear within a keyword or identifier. Pairs of double (" ) or single (’ ) quotation marks must delimit any character string that contains a blank space (ASCII 32) or other whitespace character, such as LINEFEED or RETURN.

Quotation marks

In the Genero BDL language, string literals are delimited by single (’ ) or double (" ) quotation marks.

```
'Valid character string'
"Another valid character string"
```

Do not mix double and single quotation marks as delimiters of the same string. The following is not a valid character string:

```
'Not A valid character string"
```

To include literal quotation marks within a quoted string, precede each literal quotation mark with the backslash (\), or else enclose the string between a pair of the opposite type of quotation marks:

```
MAIN
```
DISPLAY "Type 'Y' if you want to reformat your disk."
DISPLAY 'Type "Y" if you want to reformat your disk. '
DISPLAY 'Type ''Y'' if you want to reformat your disk.'
END MAIN

A string literal can be written on multiple lines. The compiler merges lines by removing the newline character.

In the SQL language, the standard specifications recommend that you use single quotes for string literals and double quotes for database object identifiers like table or column names. When accessing a non-Informix database, double quotation marks might not be recognized as database object name delimiters. As a general rule, use single quoted string literals in SQL statements, and use non-quoted, lowercase database object identifiers.

**Related concepts**

*Text literals* on page 289

Text literals define a character string in an expression.

**Escape symbol**

The Genero Business Development Language (BDL) compiler treats a backslash ( \ ) as the default escape symbol, and treats the immediately following symbol as a literal, except for special characters such as \r or \t.

See the *string literals reference* for the complete list.

To specify anything that includes a literal backslash, enter double ( \ \ ) backslashes wherever a single backslash is required. Similarly, use \\\\ to represent a literal double backslash.

**Statement terminator**

Genero Business Development Language (BDL) requires no statement terminators, but you can use the semicolon ( ; ) as a statement terminator in some cases.

For example, you can add a semicolon statement terminator for `PREPARE` and `PRINT` statements.

**Comments**

For clarity and to simplify program maintenance, it is recommended that you document your code by including comments in your source files.

A source comment is text in the source code to assist human readers, but which BDL ignores.

You can use comment indicators during development to disable instruction temporarily, without removing them from your source code modules.

A source comment can be specified by any of the following:
• A pair of minus signs (--) indicates a comment that terminates at the end of the current line. This comment indicator conforms to the ANSI standard for SQL.
• The hash (#) symbol indicates a comment that terminates at the end of the current line.
• A starting left-brace ( { ) starts a comment. It can be followed by any character (including line breaks). The comment ends when the closing right-brace ( } ) symbol is found.

```c
MAIN
  -- DISPLAY "This line will be ignored."
  # DISPLAY "This line will be ignored."
  {
    DISPLAY "This line will be ignored."
    DISPLAY "This line will be ignored."
  }
  DISPLAY "Hello, World"
END MAIN
```

Within a quoted string, the compiler interprets comment indicators as literal characters, rather than as comment indicators.

You cannot use curly brackets ( { } ) to nest comments within comments.

Comments cannot appear in the form section defining a layout grid, such as SCREEN, TABLE, TREE, or GRID.

The # symbol cannot indicate comments in an SQL statement block nor in the text of a prepared statement.

You cannot specify consecutive minus signs (--) in arithmetic expressions, as BDL interprets what follows as a comment. Instead, use a blank space or parentheses to separate consecutive arithmetic minus signs.

Do not follow the -- comment indicator with the sharp (#) symbol, unless you intend to compile the same source file with the Informix® 4GL product. The --# specific comment indicator is used to distinguish Informix® 4GL code from Genero BDL code. This conditional code compilation technique can be inverted by enclosing code blocks between --# { and --# } comments:

```c
MAIN
  --# DISPLAY "Ignored by I4GL, but compiled with BDL."
  --#{
    DISPLAY "Ignored by BDL, but compiled with I4GL."
  --#}
END MAIN
```

To summarize:
• Code lines starting with --# are compiled with Genero BDL, but ignored by Informix® 4GL.
• Code blocks surrounded with --#{ and --#} are compiled with Informix® 4GL, but ignored by Genero BDL.

**Identifiers**

A Genero Business Development Language (BDL) identifier is a character string that is declared as the name of a program entity.

An identifier must conform to the following rules:

• It must include at least one character, without any limitation in size.
• Only ASCII letters, digits, and underscore (_) symbols are valid.
• Blanks, hyphens, and other non-alphanumeric characters are not allowed.
• The initial character must be a letter or an underscore.
• Common identifiers are not case sensitive, so my_Var and MY_Var both denote the same identifier. However, in some cases, identifiers are case sensitive (like action names in the AUI tree). It is recommended to always write identifiers in lower case to avoid mistakes.

Within non-English locales, BDL identifiers can include non-ASCII characters in identifiers, if those characters are defined in the code set of the current locale. In multibyte East Asian locales that support languages whose written
form is not alphabet-based (such as Chinese, Japanese, or Korean), an identifier does not need to begin with a letter. It is however recommended to program in ASCII.

Related concepts
User interface basics on page 1008
This section introduces to the foundation of the Genero user interface.
Localization on page 405
Localization support allows you to implement programs that follow specific language and cultural rules.

Preprocessor directives
Genero Business Development Language (BDL) supports preprocessing instructions, which allow you to write macros and conditional compilation rules.

```
#include "myheader.4gl"
FUNCTION debug( msg )
  DEFINE msg STRING
 ifdef DEBUG
   DISPLAY msg
 endif
END FUNCTION
```

Note: Use the preprocessor with care, and only when there is no native language solution. Do not overcrowd your source code with preprocessing directives, that would make the code unreadable and unmaintainable.

Related concepts
Source preprocessor on page 2019
A typical preprocessor like in the C language.

Data types
Selecting the correct data type assists you in the input, storage, and display of your data.

Data type | Description
--- | ---
**TINYINT** | 1 byte signed integer
**TEXT** | Large text data (plain text)
**VARCHAR \[n\[,r\]\]** | Variable size character strings

**Related concepts**
- **Type conversions** on page 274
  - Explains data type conversion rules of the language.
- **Variables** on page 366
  - Explains how to define program variables.
- **Compiling source files** on page 1998
  - Describes how to build the runtime files from source files.

**BIGINT**
The **BIGINT** data type is used for storing very large whole numbers.

**Syntax**

```plaintext
BIGINT
```

**Usage**
The storage of **BIGINT** variables is based on 8 bytes of signed data (= 64 bits).
**BIGINT** variables can be initialized with **integer literals**:

```plaintext
MAIN
  DEFINE i BIGINT
  LET i = 9223372036854775600
  DISPLAY i
END MAIN
```

When assigning a whole number that exceeds the **BIGINT** range, the overflow error -1284 will be raised.

**BIGINT** variables are initialized to zero in functions, modules and globals.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see **Handling type conversion errors** on page 280.

**Related concepts**
- **INTEGER** on page 264
  - The **INTEGER** data type is used for storing large whole numbers.
- **SMALLINT** on page 268
  - The **SMALLINT** data type is used for storing small whole numbers.
- **TINYINT** on page 270
The TINYINT data type is used for storing very small whole numbers.

**BYTE**

The BYTE data type stores any type of binary data, such as images or sounds.

**Syntax**

```
BYTE
```

**Usage**

A BYTE or TEXT variable is a handle for a large object (LOB), that is stored in a file or in memory. Such data type is a complex type that cannot be used like INTEGER or CHAR basic types: It is designed to handle a large amount of data and has different semantics as simple types. The main difference with simple data types, is the fact that you must specify the storage with the LOCATE instruction, before using BYTE and TEXT variables.

The maximum size of data that can be handled by BYTE and TEXT variable is theoretically 2^31 bytes (~2.14 Gigabytes), but the practical limit depends from the disk or memory resources available to the process.

BYTE and TEXT variable must be initialized with the LOCATE instruction before usage. The LOCATE instruction basically defines where the large data object has to be stored (in a named file, in a temporary file, or in memory). This instruction will actually allow you to fetch a LOB into memory or into a file, or insert a LOB from memory or from a file into the database. When located in a temporary file (IN FILE), the temp directory can be defined by the DBTEMP environment variable.

```
DEFINE t TEXT
LET t = "aaaa" -- invalid, t is not located
LOCATE t IN MEMORY
LET t = "aaaa" -- valid, now t is located in memory
```

With BYTE and TEXT types, you can insert/update/fetch large objects of the database. The native database type to be used depends from the type of database server. After defining the storage with LOCATE, load/assign its value and use it directly in the SQL statements, or fetch data from LOB columns of the database, like simple data types:

```
DEFINE t1, t2 TEXT
...
CREATE TABLE mytable ( id INT, data TEXT )
...
LOCATE t1 IN MEMORY
CALL t1.readFile("lob.4gl")
INSERT INTO mytable VALUES ( 1, t1 )
LOCATE t2 IN FILE
SELECT data INTO t2 FROM mytable WHERE id=1
...
```

BYTE and TEXT types implement the readFile() and writeFile() methods to read/write the whole large object data from/to files. These methods can be used to easily interface with other software components:

```
DEFINE t TEXT
LOCATE t IN MEMORY
CALL t.readFile("orig.txt")
CALL t.writeFile("copy.txt")
```

For more details about LOB types methods, see **BYTE data type as class** on page 2245 and **TEXT data type as class** on page 2253.
When initializing a BYTE or TEXT variable to NULL (INITIALIZE var TO NULL), if the variable is located in a file, the file is truncated (file size will be zero). If the variable is located in memory, the data in memory will be truncated. A subsequent usage of the variable (for example, FETCH INTO or LET assignment) is still possible:

```sql
DEFINE b BYTE
LOCATE b IN FILE "picture.png"
INITIALIZE b TO NULL
-- The file "picture.png" is now empty.
```

Resources allocated to a BYTE or TEXT variable can be deallocated with the FREE instruction.

**Note:** When the TEXT or BYTE variable is already located, a new LOCATE will free the allocated resource: If the prior LOCATE was using the IN FILE clause, the temporary file is dropped, if the prior LOCATE was using IN MEMORY, the memory is freed.

A FREE will remove the file if the LOB variable is located in a (named or temporary) file. When located in memory, the FREE instruction will deallocate the memory. After freeing the resources of a LOB variable, it must be re-located with a LOCATE instruction:

```sql
DEFINE b BYTE
LOCATE b IN FILE
CALL b.readFile("picture.png") -- ok
FREE b
CALL b.readFile("picture.png") -- Invalid, b is not located.
LOCATE b IN MEMORY
CALL b.readFile("picture.png") -- ok
```

**Important:**

TEXT and BYTE are reference types. This implies that assigning two variables (LET, passing a variable as parameter to a function, returning a result from a function) does not copy the value (Only the handle is copied. As a result, modifying the data with a TEXT/BYTE variable assigned from another TEXT/BYTE variable will in fact modify the same LOB data. Furthermore, the storage resource (file or memory) that was used by the assigned variable becomes unreferenced and is lost:

```sql
DEFINE b1, b2 BYTE -- Could be TEXT: same behavior
LOCATE b1 IN FILE "mydata" -- reference file directly
LOCATE b2 IN MEMORY -- use memory instead of file
CALL b2.readFile("mydata") -- read file content into memory
# FREE b2 -- this should be done to free memory before LET
LET b2 = b1 -- Now b2 points directly to the file (like b1)
INITIALIZE b1 TO NULL -- truncates reference file
DISPLAY IIF( b2 IS NULL, "b2 is null", "b2 is not null")
-- Displays "b2 is null"
```

In the next (invalid) code example, we try to save the value of the img BYTE variable in a temporary variable (tmp), with the typical programming pattern to save the value before modification. In fact the LET tmp=img assignment does not copy the data of the LOB like for simple data types (STRING, VARCHAR, DECIMAL), only the reference (i.e. handle) to the data is copied:

```sql
-- WARNING: THIS IS AN INVALID CODE EXAMPLE
DEFINE img, tmp BYTE
LOCATE img IN MEMORY
CALL img.readFile("picture1.png")
LOCATE tmp IN MEMORY
LET tmp = img -- Expecting to save the current data, but now
-- both variables reference the same data...
CALL img.readFile("picture2.png")
LET img = tmp -- Does not restore the old value: Same data.
```

If you need to clone a large object, use the `writeFile()` / `readFile()` methods.
**Related concepts**

**TEXT** on page 271

The **TEXT** data type stores large text data.

---

**BOOLEAN**

The **BOOLEAN** data type stores a logical value, TRUE or FALSE.

**Syntax**

```
BOOLEAN
```

**Usage**

Boolean data types have two possible values: TRUE (integer 1) and FALSE (integer 0).

Variables of this type can be used to store the result of a boolean expression:

```
DEFINE result BOOLEAN
LET result = ( length("abcdef") > 0 )
```

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 280.

Boolean variables are typically used to store the result of a boolean expression:

```
FUNCTION checkOrderStatus( cid )
    DEFINE oid INT, b BOOLEAN
    LET b = ( isValid(oid) AND isStored(oid) )
    IF NOT b THEN
        ERROR "The order is not ready."
    END IF
END FUNCTION
```

Note that the database vendor specific implementation of the boolean SQL type may not correspond exactly to the Genero **BOOLEAN** type. For example, IBM® Informix® SQL boolean type accepts the 't' and 'f' values, while the **BOOLEAN** Genero type expects 0/FALSE and 1/TRUE integer values only. You can however use a **BOOLEAN** variable in SQL statements: IBM® Informix® will handle the conversion, and for other databases, the db drivers handle the conversion. Note also that the **TRUE**/**FALSE** constants are Genero language constants: The SQL syntax of the database may not support these keywords, for example in an statement such as `INSERT INTO mytable (key,bcol) VALUES (455,TRUE)`. For more details, see SQL portability on page 545.

---

**CHAR(size)**

The **CHAR** data type is a fixed-length character string data type.

**Syntax**

```
CHAR[ACTER] (size)
```

1. **size** defines the maximum length of the character string, in byte or char units (depending on the character length semantics)
2. The maximum size of a **CHAR** type is 65534.
3. If no **size** is specified, it defaults to 1.

**Usage**

The **CHAR** type is typically used to store fixed-length character strings such as short codes (XB124), phone numbers (650-23-2345), vehicle identification numbers.
CHAR and CHARACTER are synonyms.

The size can be expressed in bytes or characters, depending on the length semantics used in programs. For more details about character length semantics, see Length semantics settings on page 414.

When size is not specified, the default length is 1.

CHAR variables are initialized to NULL in functions, modules and globals.

Text literals can be assigned to character string variables:

```
MAIN
  DEFINE c CHAR(10)
  LET c = "abcdef"
END MAIN
```

When assigning a non-NULL value, CHAR variables are always blank-padded:

```
MAIN
  DEFINE c CHAR(10)
  LET c = "abcdef"
  DISPLAY "[", c ,"]"   -- displays [abcdef    ]
END MAIN
```

Trailing blanks of a CHAR value are not significant in comparisons:

```
MAIN
  DEFINE c CHAR(5)
  LET c = "abc"
  IF c == "abc" THEN    -- evaluates to TRUE
    DISPLAY "equals"
  END IF
END MAIN
```

Numeric and date-time values can be directly assigned the character strings:

```
MAIN
  DEFINE c CHAR(50), da DATE, dec DECIMAL(10,2)
  LET da = TODAY
  LET dec = 345.12
  LET c = da, " : ", dec
END MAIN
```

When you insert character data from CHAR variables into CHAR columns in a database table, the column-value is blank-padded to the size of the column. Likewise, when you fetch CHAR column values into CHAR variables, the program variable is blank-padded to the size of the variable.

```
MAIN
  DEFINE c CHAR(10)
  DATABASE test1
  CREATE TABLE table1 ( k INT, x CHAR(10) )
  LET c = "abc"
  INSERT INTO table1 VALUES ( 1, c )
  SELECT x INTO c FROM table1 WHERE k = 1
  DISPLAY "[", vc ,"]"     -- displays [abc  ]
END MAIN
```

In SQL statements, the behavior of the comparison operators when using CHAR values may vary from one database to the other. However, most database engines ignore trailing blanks when comparing CHAR values. For more details, see SQL portability on page 545.
**Related concepts**

**VARCHAR(size)** on page 273

The **VARCHAR** data type is a variable-length character string data type, with a maximum size.

**STRING** on page 269

The **STRING** data type is a variable-length, dynamically allocated character string data type, without limitation.

**DATE**

The **DATE** data type stores calendar dates with a Year/Month/Day representation.

**Syntax**

```
DATE
```

**Usage**

Storage of **DATE** variables is based on a 4 byte integer representing the number of days since 1899/12/31.

The value range is from 0001-01-1 (-693594) to 9999-12-31 (2958464).

**DATE** variables are initialized to zero (=1899/12/31) in functions, modules and globals.

Several built-in functions and operators specific to the **DATE** type are available, such as **MDY()** and **TODAY().** For more details, see **Date and time operators** on page 330.

Data type conversions, input and display of **DATE** values are ruled by environment settings, such as the **DBDATE** and **DBCENTURY** enviroment variables. Dates can be formatted with the **USING** operator. For more details, see **Formatting DATE values** on page 284.

**Note:** As date-to-string conversion is based on an environment settings, it is not recommended that you hard code strings representing dates:

```
LET date_var = "24/12/1998"      -- DBDATE dependant code
LET date_var = MDY(12,24,1998)   -- Portable code
```

To add or subtract a given number of days to a **DATE**, simply use a + or – arithmetic operator followed by an integer expression representing a number of days:

```
MAIN
DEFINE d DATE
LET d = TODAY
LET d = d + 10       -- Add 10 days
LET d = d - 20       -- Substract 20 days
DISPLAY "d = ", d USING "yyyy-mm-dd"
END MAIN
```

The difference of two dates returns the number of days:

```
MAIN
DEFINE d1, d2 DATE
LET d1 = MDY(12,24,1998)
LET d2 = MDY(5,11,2010)
DISPLAY "d2 - d1 = ", (d2-d1)
END MAIN
```

**DATE** values can be converted directly from/to **DATETIME** values:

```
MAIN
DEFINE d DATE,
   dt DATETIME YEAR TO FRACTION(3)
```
In order to add or subtract a number of months to a DATE, use the UNITS operator:

```plaintext
MAIN
DEFINE d0, d date
LET d0 = MDY(01, 31, 2015)
LET d = d0 + 1 UNITS MONTH; DISPLAY d
LET d = d0 - 1 UNITS MONTH; DISPLAY d
LET d = d0 - 2 UNITS MONTH; DISPLAY d
END MAIN
```

Note: In fact, the UNITS operator will produce an INTERVAL. Then the DATE value is converted to a DATETIME, to add or subtract the INTERVAL value. Finally the DATETIME is converted to a DATE, in order to assign the result to the target variable.

Related concepts

**DATETIME qual1 TO qual2** on page 260

The DATETIME data type stores date and time data with time units from the year to fractions of a second.

### DATETIME qual1 TO qual2

The DATETIME data type stores date and time data with time units from the year to fractions of a second.

**Syntax**

```
DATETIME YEAR TO FRACTION [ ( scale ) ]
| DATETIME YEAR TO SECOND
| DATETIME YEAR TO MINUTE
| DATETIME YEAR TO HOUR
| DATETIME YEAR TO DAY
| DATETIME YEAR TO MONTH
| DATETIME YEAR TO YEAR
| DATETIME MONTH TO FRACTION [ ( scale ) ]
| DATETIME MONTH TO SECOND
| DATETIME MONTH TO MINUTE
| DATETIME MONTH TO HOUR
| DATETIME MONTH TO DAY
| DATETIME MONTH TO MONTH
| DATETIME DAY TO FRACTION [ ( scale ) ]
| DATETIME DAY TO SECOND
| DATETIME DAY TO MINUTE
| DATETIME DAY TO HOUR
| DATETIME DAY TO DAY
| DATETIME HOUR TO FRACTION [ ( scale ) ]
| DATETIME HOUR TO SECOND
| DATETIME HOUR TO MINUTE
| DATETIME HOUR TO HOUR
| DATETIME MINUTE TO FRACTION [ ( scale ) ]
| DATETIME MINUTE TO SECOND
| DATETIME MINUTE TO MINUTE
| DATETIME SECOND TO FRACTION [ ( scale ) ]
| DATETIME SECOND TO SECOND
| DATETIME FRACTION TO FRACTION [ ( scale ) ]
```

1. *scale* defines the scale of the fractional part, it can be 1, 2, 3, 4 or 5.
**Usage**

The `DATETIME` data type stores an instance in time, expressed as a calendar date and time-of-day.

The qualifiers following the `DATETIME` keyword define the precision of the `DATETIME` type. While many sort of datetime types can be defined with all possible qualifier combinations, only a limited set of `DATETIME` types are typical used in applications:

- `DATETIME HOUR TO MINUTE, DATETIME HOUR TO SECOND, DATETIME HOUR TO FRACTION(scale)`: To hold a time value.
- `DATETIME YEAR TO MINUTE, DATETIME YEAR TO SECOND, DATETIME YEAR TO FRACTION(scale)`: To hold a date with time value.

`DATETIME YEAR TO DAY` is equivalent to `DATE`, consider used `DATE` instead.

When the `FRACTION` qualifier is specified without a precision, the precision defaults to 3.

`DATETIME` arithmetic is based on the `INTERVAL` data type, and can be combined with `DATE` values:

<table>
<thead>
<tr>
<th>Left Operand Type</th>
<th>Operator</th>
<th>Right Operand Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DATETIME</code></td>
<td>-</td>
<td><code>DATETIME</code></td>
<td><code>INTERVAL</code></td>
</tr>
<tr>
<td><code>DATETIME</code></td>
<td>-</td>
<td><code>DATE</code></td>
<td><code>INTERVAL</code></td>
</tr>
<tr>
<td><code>DATETIME</code></td>
<td>-</td>
<td><code>INTERVAL</code></td>
<td><code>DATETIME</code></td>
</tr>
<tr>
<td><code>DATETIME</code></td>
<td>+</td>
<td><code>INTERVAL</code></td>
<td><code>DATETIME</code></td>
</tr>
</tbody>
</table>

`DATETIME` variables are initialized to `NULL` in functions, modules and globals.

The `CURRENT` operator provides current system date/time:

```plaintext
DEFINE dt DATETIME YEAR TO SECOND
LET dt = CURRENT
```

`DATETIME` variables can be assigned with `datetime literals`, by using the `DATETIME(q1 TO q2)` notation:

```plaintext
DEFINE dt DATETIME YEAR TO SECOND
LET dt = DATETIME(2014-02-21 13:45:34) YEAR TO SECOND
```

`DATETIME` variables can be assigned from string literals, by using the format `YYYY-MM-DD hh:mm:ss.fffff`, or the ISO 8601 format sub-set (with the T separator between the date and time part, and with optional `+-nn` UTC indicator or timezone offset):

```plaintext
DEFINE dt DATETIME YEAR TO FRACTION(5)
LET dt = "2012-10-05 11:34:56.99999"
LET dt = "2012-10-05T11:34:56.99999+02:00"
```

When converting a `DATETIME` to a string, the format `YYYY-MM-DD hh:mm:ss.fffff` is used.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 280.

A `DATETIME` value can be converted to a different `DATETIME` (or `DATE`) with a different precision by using the `EXTEND()` operator:

```plaintext
MAIN
DEFINE dt1 DATETIME YEAR TO MONTH
DEFINE dt2 DATETIME YEAR TO FRACTION(5)
LET dt1 = CURRENT
LET dt2 = EXTEND(dt1, YEAR TO FRACTION(5))
```
Datetime conversion functions are provided in the `util.Datetime` class, for example to convert local datetime to UTC datetime values:

```plaintext
IMPORT util
MAIN
  DEFINE dt DATETIME YEAR TO FRACTION(5)
  LET dt = "2012-10-05 11:34:56.99999"
  DISPLAY util.Datetime.toUTC( dt )
END MAIN
```

**Related concepts**

- **DATE** on page 259
  The `DATE` data type stores calendar dates with a Year/Month/Day representation.

- **INTERVAL qual1 TO qual2** on page 265
  The `INTERVAL` data type stores spans of time as Year/Month or Day/Hour/Minute/Second/Fraction units.

**DECIMAL(p,s)**

The `DECIMAL` data type is provided to handle large numeric values with exact decimal storage.

**Syntax**

```plaintext
DECIMAL [ ( precision[, scale] ) ]
```

1. `precision` defines the number of significant digits (limit is 32, default is 16).
2. `scale` defines the number of digits to the right of the decimal point.
3. When no `scale` is specified, the data type defines a floating point number.
4. When no `(precision, scale)` is specified, it defaults to `DECIMAL(16)`.

**Usage**

Use the `DECIMAL` data type when you need to store values that have a fixed number of digits on the right and left of the decimal point (`DECIMAL (p, s)`), or to store a floating point decimal with an exact number of significant digits (`DECIMAL (p)`).

`DEC`, `DECIMAL` and `NUMERIC` are synonyms.

`DECIMAL` variables are initialized to NULL in functions, modules and globals.

When using `DECIMAL (p, s)` with a precision and scale, you define a decimal for fixed point arithmetic, with `p` significant digits and `s` digits on the right of the decimal point. For example, `DECIMAL(8, 2)` can hold the value 123456.78 (8 (p) = 6 digits on the left + 2 (s) digits on the right of the decimal point).

When using `DECIMAL (p)` with a precision but no scale, you define a floating-point number with `p` significant digits. For example, `DECIMAL(8)` can store 12345678, as well as 0.12345678.

**Note:** In most database implementations, the decimal data type always has a fixed number of decimal digits. Use `DECIMAL` types with precision and scale to implement portable code, and avoid mistakes if default sizes apply when precisions and/or scale are omitted in SQL statements. For example, with Oracle®, a `NUMBER (p)` is equivalent to a `DECIMAL (p, 0)` in BDL, not `DECIMAL (p)`.

When using `DECIMAL` without a precision and scale, it defaults to `DECIMAL (16)` , a floating-point number with a precision of 16 digits.

```plaintext
MAIN
  DEFINE d1 DECIMAL(10,4)
  DEFINE d2 DECIMAL(10,3)
  LET d1 = 1234.4567
  LET d2 = 1234.567
```
DECIMAL values can be converted to strings based on the DBFORMAT (or DBMONEY) environment variable (defines the decimal separator) setting.

**Value ranges**

The largest absolute value that a DECIMAL\((p, s)\) can store without errors is \(10^{p-s} - 10^s\). The stored value can have up to 30 significant decimal digits in its fractional part, or up to 32 digits to the left of the decimal point.

When using DECIMAL\((p, s)\) the range of values is defined by the \(p\), the number of significant digits. For example, a variable defined as DECIMAL\((5, 3)\) can store values in the range \(-9.999\) to \(9.999\). The smallest positive non zero value is \(0.001\).

When using DECIMAL\((p)\) the magnitude can range from \(-N*10^{-124}\) to \(N*10^{124}\), where \(N\) can have up to \(p\) significant digits and be \(0 < N < 10\). For example, a variable defined as DECIMAL\((5)\) can store values in the range \(-9.9999e-124\) to \(9.9999e+124\). The smallest positive non zero value is \(9.9999e-130\).

**Exceptions**

When the default exception handler is used, if you try to assign a value larger than the decimal definition (for example, 12345.45 into DECIMAL\((4, 2)\)), no out of range error occurs, and the variable is assigned with NULL. If WHENEVER ANY ERROR is used, it raises error -1226. If you do not use WHENEVER ANY ERROR, the STATUS variable is not set to -1226.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 280.

**Computation and rounding rules**

When computing or converting decimal values, the "round half away from zero" rule will apply: If the fraction of the value \(v\) is exactly 0.5, then \(r = v + 0.5\) if \(v\) is positive, and \(r = v - 0.5\) if \(v\) is negative. For example, when the result must be rounded to a whole number, 23.5 gets rounded to 24, and -23.5 gets rounded to -24.

In the next example, the division result of 11 / 3 gives the infinite decimal value 3.666666... (with an infinite decimal part). However, this value cannot be stored in a fixed point decimal type. When stored in a DECIMAL\((10, 2)\), the value will be rounded to 3.67, and when multiplying 3.67 by 3, the result will be 11.01, instead of 11:

```
MAIN
  DEFINE v DECIMAL(10,2)
  LET v = 11 / 3
  DISPLAY "1. v = ", v USING "---.&.&&&&&&&&"  !
  LET v = v * 3
  DISPLAY "2. v = ", v USING "---.&.&&&&&&&&"
END MAIN
```

Output:

```
1. v = 3.67000000
2. v = 11.01000000
```

**High-precision math functions**

A couple of precision math functions are available, to be used with DECIMAL values. These functions have a higher precision as the standard C library functions based on C double data type, which is equivalent to FLOAT:

- FGL_DECIMAL_TRUNCATE()
- FGL_DECIMAL_SQRT()
• FGL_DECIMAL_EXP()
• FGL_DECIMAL_LOGN()
• FGL_DECIMAL_POWER()

Related concepts
MONEY(p,s) on page 267
The MONEY data type is provided to store currency amounts with exact decimal storage.

FLOAT
The FLOAT data type stores values as double-precision floating-point binary numbers with up to 16 significant digits.

Syntax

FLOAT 

1. FLOAT and DOUBLE PRECISION are synonyms.
2. The precision can be specified, but it has no effect in programs.

Usage
The storage of FLOAT variables is based on 8 bytes of signed data (=64 bits), this type is equivalent to the double data type in C.

Note: This data type it is not recommended for exact decimal storage; use the DECIMAL type instead.

FLOAT variables are initialized to zero in functions, modules and globals.

FLOAT values can be converted to strings based on the DBFORMAT (or DBMONEY) environment variable setting. Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 280.

Related concepts
DECIMAL(p,s) on page 262
The DECIMAL data type is provided to handle large numeric values with exact decimal storage.

INTEGER
The INTEGER data type is used for storing large whole numbers.

Syntax

INTEGER

1. INT and INTEGER are synonyms.

Usage
The storage of INTEGER variables is based on 4 bytes of signed data (= 32 bits).
The value range is from -2,147,483,647 to +2,147,483,647.

INTEGER variables can be initialized with integer literals:

MAIN
   DEFINE i INTEGER
   LET i = 1234567
   DISPLAY i
END MAIN
When assigning a whole number that exceeds the INTEGER range, the overflow error -1215 will be raised.

INTEGER variables are initialized to zero in functions, modules and globals.

The INTEGER type can be used to define variables storing values from SERIAL columns.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 280.

Related concepts

BIGINT on page 254
The BIGINT data type is used for storing very large whole numbers.

SMALLINT on page 268
The SMALLINT data type is used for storing small whole numbers.

TINYINT on page 270
The TINYINT data type is used for storing very small whole numbers.

INTERVAL qual1 TO qual2

The INTERVAL data type stores spans of time as Year/Month or Day/Hour/Minute/Second/Fraction units.

Syntax 1: year-month class interval

| INTERVAL YEAR[(precision)] TO MONTH |
| INTERVAL YEAR[(precision)] TO YEAR |
| INTERVAL MONTH[(precision)] TO MONTH |

Syntax 2: day-time class interval

| INTERVAL DAY[(precision)] TO FRACTION[(scale)] |
| INTERVAL DAY[(precision)] TO SECOND |
| INTERVAL DAY[(precision)] TO MINUTE |
| INTERVAL DAY[(precision)] TO HOUR |
| INTERVAL DAY[(precision)] TO DAY |
| INTERVAL HOUR[(precision)] TO FRACTION[(scale)] |
| INTERVAL HOUR[(precision)] TO SECOND |
| INTERVAL HOUR[(precision)] TO MINUTE |
| INTERVAL HOUR[(precision)] TO HOUR |
| INTERVAL MINUTE[(precision)] TO FRACTION[(scale)] |
| INTERVAL MINUTE[(precision)] TO SECOND |
| INTERVAL MINUTE[(precision)] TO MINUTE |
| INTERVAL SECOND[(precision)] TO FRACTION[(scale)] |
| INTERVAL SECOND[(precision)] TO SECOND |
| INTERVAL FRACTION TO FRACTION[(scale)] |

1. **precision** defines the number of significant digits of the first qualifier, it must be an integer from 1 to 9. For YEAR, the default is 4. For all other time units, the default is 2. For example, YEAR(5) indicates that the INTERVAL can store a number of years with up to 5 digits.

2. **scale** defines the scale of the fractional part, it can be 1, 2, 3, 4 or 5.

Usage

The INTERVAL data type stores a span of time, the difference between two points in time. It can also be used to store quantities that are measured in units of time, such as ages or times.
The INTERVAL data type falls into two classes. These are mutually exclusive because year and month are not fixed-length units of time, and therefore incompatible with INTERVAL data types whose time units are smaller than month:

- **Year-Time** intervals store a span of years, months or both.
- **Day-Time** intervals store a span of days, hours, minutes, seconds and fraction of seconds, or a contiguous subset of those units.

INTERVAL variables are initialized to NULL in functions, modules and globals.

INTERVAL variables can be assigned from interval literals, by using the INTERVAL(q1 TO q2) notation:

```sql
DEFINE iv INTERVAL DAY(5) TO SECOND
LET iv = INTERVAL(-7634 14:23:55) DAY(5) TO SECOND
```

INTERVAL variables can be assigned from string literals, by using the format `YYYY-MM` or `DD hh:mm:ss.fffff`, depending on the interval class:

```sql
DEFINE iv INTERVAL DAY(5) TO SECOND
LET iv = "-7634 14:23:55"
```

INTERVAL variables defined with a single time unit can be assigned from integer values, by using the UNITS operator:

```sql
DEFINE iv INTERVAL SECOND(5) TO SECOND
LET iv = 567 UNITS SECOND
```

The INTERVAL type is used for DATETIME computation.

Depending on the data type of the operands, DATETIME or DECIMAL, the arithmetic operations give different resulting types:

**Table 104: Arithmetic operands for the INTERVAL, DATETIME, and DECIMAL data types**

<table>
<thead>
<tr>
<th>Left Operand Type</th>
<th>Operator</th>
<th>Right Operand Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTERVAL</td>
<td>*</td>
<td>DECIMAL</td>
<td>INTERVAL</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>/</td>
<td>DECIMAL</td>
<td>INTERVAL</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>-</td>
<td>INTERVAL</td>
<td>INTERVAL</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>+</td>
<td>INTERVAL</td>
<td>INTERVAL</td>
</tr>
<tr>
<td>DATETIME</td>
<td>-</td>
<td>INTERVAL</td>
<td>DATETIME</td>
</tr>
<tr>
<td>DATETIME</td>
<td>+</td>
<td>INTERVAL</td>
<td>DATETIME</td>
</tr>
<tr>
<td>DATETIME</td>
<td>-</td>
<td>DATETIME</td>
<td>INTERVAL</td>
</tr>
</tbody>
</table>

The next example shows how to use INTERVAL with DATETIME variables:

```sql
MAIN
DEFINE iym1, iym2 INTERVAL YEAR TO MONTH,
   dt1, dt2 DATETIME YEAR TO MINUTE,
   diff INTERVAL DAY(5) TO MINUTE
LET iym1 = "2342-4"
LET iym2 = "-55-11"
DISPLAY iym1 + iym2
LET dt1 = CURRENT
LET dt2 = "2010-12-24 00:00"
LET diff = dt1 - dt2
DISPLAY diff
LET diff = INTERVAL(-7634 14:23) DAY(5) TO MINUTE
```
For example, in the expression above `DISPLAY iym1 + iym2`, both values are from the same `INTERVAL` class, that is both are year-month, and the result of the `DATETIME+INTERVAL` calculation is a `DATETIME` value:

Result: `DATETIME 2286-05 YEAR TO MONTH`

`INTERVAL` values can be negative.

In order to check if an `INTERVAL` is negative, use the `UNITS` operator, to produce an interval constant for the comparison. Using numeric constants will not work:

```main
DEFINE start, end DATETIME YEAR TO SECOND
DEFINE diff INTERVAL SECOND(9) TO SECOND
LET start = CURRENT + 100 UNITS SECOND
LET end   = CURRENT - 200 UNITS SECOND
LET diff = end - start
IF diff < 0 THEN
    DISPLAY "this will not display!"
END IF
IF diff < 0 UNITS SECOND THEN
    DISPLAY "negative interval"
ELSE
    DISPLAY "positive interval"
END IF
END MAIN
```

Data type conversion can be controlled by catching the runtime exceptions. For more details, see `Handling type conversion errors` on page 280.

**Related concepts**

**DATE** on page 259
The `DATE` data type stores calendar dates with a Year/Month/Day representation.

**DATETIME qual1 TO qual2** on page 260
The `DATETIME` data type stores date and time data with time units from the year to fractions of a second.

**MONEY(p,s)**
The `MONEY` data type is provided to store currency amounts with exact decimal storage.

**Syntax**

`MONEY [ (precision[, scale]) ]`

1. `precision` defines the number of significant digits (limit is 32, default is 16).
2. `scale` defines the number of digits to the right of the decimal point.
3. When no `scale` is specified, it defaults to 2.
4. When no `(precision, scale)` is specified, it defaults to `MONEY(16, 2)`.

**Usage**
The `MONEY` data type is provided to store currency amounts. Its behavior is similar to the `DECIMAL` data type, with some important differences:

A `MONEY` variable is displayed with the currency symbol defined in the `DBFORMAT` (or `DBMONEY`) environment variable.
When the `scale` is not specified for the `MONEY` type, the default is 2. A `MONEY` without `precision` and `scale` defaults to `MONEY (16, 2)`.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 280.

See DECIMAL(p,s) on page 262 to learn other facts about the `MONEY (p, s)` data type.

**SMALLFLOAT**

The `SMALLFLOAT` data type stores values as single-precision floating-point binary numbers with up to 8 significant digits.

**Syntax**

```plaintext
SMALLFLOAT
```

1. `SMALLFLOAT` and `REAL` are synonyms.

**Usage**

The storage of `SMALLFLOAT` variables is based on 4 bytes of signed data ( =32 bits), this type is equivalent to the `float` data type in C.

**Note:** This data type it is not recommended for exact decimal storage; use the `DECIMAL` data type instead.

`SMALLFLOAT` variables are initialized to zero in functions, modules and globals.

`SMALLFLOAT` values can be converted to strings based on the `DBFORMAT` (or `DBMONEY`) environment variable setting.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 280.

**Related concepts**

DECIMAL(p,s) on page 262

The `DECIMAL` data type is provided to handle large numeric values with exact decimal storage.

**SMALLINT**

The `SMALLINT` data type is used for storing small whole numbers.

**Syntax**

```plaintext
SMALLINT
```

**Usage**

The storage of `SMALLINT` variables is based on 2 bytes of signed data ( = 16 bits ).

The value range is from -32,767 to +32,767.

`SMALLINT` variables can be initialized with `integer literals`:

```plaintext
MAIN
   DEFINE i SMALLINT
   LET i = 1234
   DISPLAY i
END MAIN
```

When assigning a whole number that exceeds the `SMALLINT` range, the overflow error `-1214` will be raised.
SMALLINT variables are initialized to zero in functions, modules and globals.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 280.

Related concepts

INTEGER on page 264
The INTEGER data type is used for storing large whole numbers.

BIGINT on page 254
The BIGINT data type is used for storing very large whole numbers.

TINYINT on page 270
The TINYINT data type is used for storing very small whole numbers.

**STRING**

The STRING data type is a variable-length, dynamically allocated character string data type, without limitation.

**Syntax**

```plaintext
STRING
```

**Usage**

The STRING data type is typically used to implement utility functions manipulating character string with unknown size, and in some special cases, in SQL statements.

STRING variables are initialized to NULL in functions, modules and globals.

The behavior of a STRING variable is similar to the VARCHAR data type, except that there is no theoretical size limit.

STRING variables can be initialized from string literals:

```plaintext
MAIN
    DEFINE s STRING
    LET s = "abcdef"
END MAIN
```

Variables declared with the STRING data type can be used to call STRING-type methods such as `getLength()` or `toUpperCase()`. For more details, see STRING data type as class on page 2246:

```plaintext
MAIN
    DEFINE s STRING
    LET s = "abc"
    DISPLAY s.toUpperCase()
END MAIN
```

STRING variables have significant trailing blanks (i.e. "abc  " is different from "abc"). However, in comparisons, trailing blanks do not matter:

```plaintext
MAIN
    DEFINE s STRING
    LET s = "abc  " -- a b c + 2 white spaces
    DISPLAY "1: s.length:", s.getLength()
    DISPLAY ", [", s, "]" -- displays "[abc  ]"
    DISPLAY IIF(s=="abc","Equals",NULL)
END MAIN
```

Unlike CHAR and VARCHAR, a STRING can hold a value of zero length without being NULL. For example, if you trim a string variable with the `trim()` method and if the original value is a set of blank characters, the result is an
empty string. But testing the variable with the IS NULL operator will evaluate to FALSE. Using a VARCHAR with the CLIPPED operator would give a NULL string in this case:

```
MAIN
  DEFINE s STRING
  LET s = " "  -- 5 spaces
  LET s = s.trim()
  DISPLAY "s = [", s, "] len=", s.getLength()
  DISPLAY IIF(s IS NULL, "NULL", "not NULL")
END MAIN
```

```
outputs:
s = [] len= 0
not NULL
```

STRING typed variables can be used in some special cases to hold SQL character string data, when the size of the SQL data string is not known (string expressions, large strings like JSON documents). In order to store character string data stored in a database, consider using the CHAR or VARCHAR types instead of STRING.

In STRING methods, positions and length parameters (or return values) can be expressed in bytes or characters, depending on the length semantics used in programs. For more details, see Length semantics settings on page 414

**Related concepts**
- STRING data type methods on page 2247
- CHAR(size) on page 257
  - The CHAR data type is a fixed-length character string data type.
- VARCHAR(size) on page 273
  - The VARCHAR data type is a variable-length character string data type, with a maximum size.

**TINYINT**

The TINYINT data type is used for storing very small whole numbers.

**Syntax**

```
TINYINT
```

**Usage**

The storage of TINYINT variables is based on 1 byte of signed data ( = 8 bits ).

The value range is from -128 to +127.

TINYINT variables can be initialized with integer literals:

```
MAIN
  DEFINE i TINYINT
  LET i = 101
  DISPLAY i
END MAIN
```

When assigning a whole number that exceeds the TINYINT range, the overflow error -8097 will be raised.

TINYINT variables are initialized to zero in functions, modules and globals.

The TINYINT variables cannot be NULL.

Data type conversion can be controlled by catching the runtime exceptions. For more details, see Handling type conversion errors on page 280.
Related concepts

**SMALLINT** on page 268
The **SMALLINT** data type is used for storing small whole numbers.

**INTEGER** on page 264
The **INTEGER** data type is used for storing large whole numbers.

**BIGINT** on page 254
The **BIGINT** data type is used for storing very large whole numbers.

**TEXT**

The **TEXT** data type stores large text data.

**Syntax**

```plaintext
TEXT
```

**Usage**

A **BYTE** or **TEXT** variable is a handle for a large object (LOB), that is stored in a file or in memory. Such data type is a complex type that cannot be used like **INTEGER** or **CHAR** basic types: It is designed to handle a large amount of data and has different semantics as simple types. The main difference with simple data types, is the fact that you must specify the storage with the **LOCATE** instruction, before using **BYTE** and **TEXT** variables.

The maximum size of data that can be handled by **BYTE** and **TEXT** variable is theoretically $2^{31}$ bytes (~2.14 Gigabytes), but the practical limit depends from the disk or memory resources available to the process.

**BYTE** and **TEXT** variable must be initialized with the **LOCATE** instruction before usage. The **LOCATE** instruction basically defines where the large data object has to be stored (in a named file, in a temporary file, or in memory). This instruction will actually allow you to fetch a LOB into memory or into a file, or insert a LOB from memory or from a file into the database. When located in a temporary file (**IN FILE**), the temp directory can be defined by the **DBTEMP** environment variable.

```plaintext
DEFINE t TEXT
LET t = "aaaa" -- invalid, t is not located
LOCATE t IN MEMORY
LET t = "aaaa" -- valid, now t is located in memory
```

With **BYTE** and **TEXT** types, you can insert/update/fetch large objects of the database. The native database type to be used depends from the type of database server. After defining the storage with **LOCATE**, load / assign its value and use it directly in the SQL statements, or fetch data from LOB columns of the database, like simple data types:

```plaintext
DEFINE t1, t2 TEXT
...  
CREATE TABLE mytable ( id INT, data TEXT )
...  
CALL t1.readFile("lob.4gl")
INSERT INTO mytable VALUES ( 1, t1 )
LOCATE t2 IN FILE
SELECT data INTO t2 FROM mytable WHERE id=1
...  
```

**BYTE** and **TEXT** types implement the **readFile()** and **writeFile()** methods to read/write the whole large object data from/to files. These methods can be used to easily interface with other software components:

```plaintext
DEFINE t TEXT
LOCATE t IN MEMORY
CALL t.readFile("orig.txt")
```
CALL t.writeFile("copy.txt")

For more details about LOB types methods, see BYTE data type as class on page 2245 and TEXT data type as class on page 2253.

When initializing a BYTE or TEXT variable to NULL (initialize var to NULL), if the variable is located in a file, the file is truncated (file size will be zero). If the variable is located in memory, the data in memory will be truncated. A subsequent usage of the variable (for example, FETCH INTO or LET assignment) is still possible:

```
DEFINE b BYTE
LOCATE b IN FILE "picture.png"
INITIALIZE b TO NULL
-- The file "picture.png" is now empty.
```

Resources allocated to a BYTE or TEXT variable can be deallocated with the FREE instruction.

**Note:** When the TEXT or BYTE variable is already located, a new LOCATE will free the allocated resource: If the prior LOCATE was using the IN FILE clause, the temporary file is dropped, if the prior LOCATE was using IN MEMORY, the memory is freed.

A FREE will remove the file if the LOB variable is located in a (named or temporary) file. When located in memory, the FREE instruction will deallocate the memory. After freeing the resources of a LOB variable, it must be re-located with a LOCATE instruction:

```
DEFINE b BYTE
LOCATE b IN FILE
CALL b.readFile("picture.png") -- ok
FREE b
CALL b.readFile("picture.png") -- Invalid, b is not located.
LOCATE b IN MEMORY
CALL b.readFile("picture.png") -- ok
```

**Important:**

TEXT and BYTE are reference types. This implies that assigning two variables (LET, passing a variable as parameter to a function, returning a result from a function) does not copy the value (Only the handle is copied. As a result, modifying the data with a TEXT/BYTE variable assigned from another TEXT/BYTE variable will in fact modify the same LOB data. Furthermore, the storage resource (file or memory) that was used by the assigned variable becomes unreferenced and is lost:

```
DEFINE b1, b2 BYTE -- Could be TEXT: same behavior
LOCATE b1 IN FILE "mydata" -- reference file directly
LOCATE b2 IN MEMORY -- use memory instead of file
CALL b2.readFile("mydata") -- read file content into memory
# FREE b2 -- this should be done to free memory before LET
LET b2 = b1 -- Now b2 points directly to the file (like b1)
INITIALIZE b1 TO NULL -- truncates reference file
DISPLAY IIF( b2 IS NULL, "b2 is null", "b2 is not null")
-- Displays "b2 is null"
```

In the next (invalid) code example, we try to save the value of the img BYTE variable in a temporary variable (tmp), with the typical programming pattern to save the value before modification. In fact the LET tmp=img assignment does not copy the data of the LOB like for simple data types (STRING, VARCHAR, DECIMAL), only the reference (i.e. handle) to the data is copied:

```
-- WARNING: THIS IS AN INVALID CODE EXAMPLE
DEFINE img, tmp BYTE
LOCATE img IN MEMORY
CALL img.readFile("picture1.png")
LOCATE tmp IN MEMORY
LET tmp = img -- Expecting to save the current data, but now
```
-- both variables reference the same data...
CALL img.readFile("picture2.png")
LET img = tmp -- Does not restore the old value: Same data.

If you need to clone a large object, use the writeFile() / readFile() methods.

It is possible to assign TEXT variables to/from VARCHAR, CHAR and STRING variables.

**Related concepts**

**BYTE** on page 255
The BYTE data type stores any type of binary data, such as images or sounds.

**VARCHAR(size)**
The VARCHAR data type is a variable-length character string data type, with a maximum size.

**Syntax**

```
VARCHAR (size, reserve)
```

1. `size` defines the maximum length of the character string, in byte or char units (depending on the character length semantics)
2. The maximum size of a VARCHAR type is 65534.
3. When no `size` is specified, it defaults to 1.
4. `reserve` is ignored; Its inclusion in the syntax is permitted for compatibility with the SQL data type.

**Usage**
The VARCHAR type is typically used to store variable-length character strings such as names, addresses and comments.

The `size` can be expressed in bytes or characters, depending on the length semantics used in programs. For more details about character length semantics, see **Length semantics settings** on page 414.

When `size` is not specified, the default length is 1.

VARCHAR variables are initialized to NULL in functions, modules and globals.

**Text literals** can be assigned to character string variables:

```pascal
MAIN
  DEFINE c VARCHAR(10)
  LET c = "abcdef"
END MAIN
```

VARCHAR variables store trailing blanks (trailing blanks are displayed or printed in reports, and stored in database columns):

```pascal
MAIN
  DEFINE vc VARCHAR(10)
  LET vc = "abc " -- a b c + 2 white spaces
  DISPLAY "[", vc ,"]" -- displays [abc ]
END MAIN
```

Trailing blanks of a VARCHAR value are not significant in comparisons:

```pascal
MAIN
  DEFINE vc VARCHAR(10)
  LET vc = "abc " -- a b c + 2 white spaces
  IF vc == "abc " THEN -- evaluates to TRUE
    DISPLAY "equals"
```
Numeric and date-time values can be directly assigned the character strings:

```
MAIN
  DEFINE vc VARCHAR(50), da DATE, dec DECIMAL(10,2)
  LET da = TODAY
  LET dec = 345.12
  LET vc = da, " : ", dec
END MAIN
```

When you insert character data from VARCHAR variables into VARCHAR columns in a database table, the trailing blanks are kept. Likewise, when you fetch VARCHAR column values into VARCHAR variables, trailing blanks are kept.

```
MAIN
  DEFINE vc VARCHAR(10)
  DATABASE test1
  CREATE TABLE table1 ( k INT, x VARCHAR(10) )
  LET vc = "abc  "         -- two trailing blanks
  INSERT INTO table1 VALUES ( 1, vc )
  SELECT x INTO vc FROM table1 WHERE k = 1
  DISPLAY "[", vc ,"]"     -- displays [abc  ]
END MAIN
```

In SQL statements, the behavior of the comparison operators when using VARCHAR values differs from one database to the other. IBM® Informix® is ignoring trailing blanks, but most other databases take trailing blanks of VARCHAR values into account. For more details, see SQL portability on page 545.

- STRING on page 269

**Type conversions**
Explains data type conversion rules of the language.
- When does type conversion occur? on page 274
- Data type conversion reference on page 275
- Handling type conversion errors on page 280
- Formatting numeric values on page 281
- Formatting DATE values on page 284
- Formatting DATETIME values on page 285
- Formatting INTERVAL values on page 287

**When does type conversion occur?**
In Genero BDL, data type conversion is implicit when possible.

The runtime system performs data conversion implicitly without objection, as long as the data conversion is valid. A date value can be converted to a character string, but a character string can only be converted to a date if the string represents a valid date in the current date format settings (DBDATE).

Implicit data type conversion can for example occur in the following cases:
- In a LET assignment,
• In an expression, when operands are not of the same data type,
• In DISPLAY instructions, or PRINT instructions in reports,
• In dialogs, when values must be converted to strings to be displayed in form fields,
• When passing and returning values to/from a function,
• When serializing numeric values in UNLOAD, JSON methods, etc.

In the next code example, implicit data type conversion occurs

1. When assigning the result of the DECIMAL expression to the VARCHAR variable v,
2. When assigning a VARCHAR value to the DECIMAL variable d,
3. When passing the DECIMAL value d to function func(), expecting a VARCHAR,
4. When returning the VARCHAR value from the func() function,
5. When displaying the DECIMAL value (formatting rules apply).

```
MAIN
    DEFINE v VARCHAR(50),
           d DECIMAL(10,2)
    LET v = 1234.50 * 2   -- 1.
    LET d = v             -- 2.
    LET d = func(d)       -- 3. and 4.
    DISPLAY d             -- 5.
END MAIN

FUNCTION func(v)
    DEFINE v VARCHAR(50)
    DISPLAY v
    RETURN v   -- 4.
END FUNCTION
```

Runtime stack on page 443
The runtime stack is used to pass/return values to/from functions.

Data type conversion reference
This topic lists type conversion rules for all data types.

Boolean type conversions
A BOOLEAN value is an integer value 1 or 0 and thus can be converted to/from any other numeric type of the language.

When converting a numeric value to a BOOLEAN, any value different from 0 becomes TRUE, otherwise (zero) is FALSE.

```
DEFINE hasContent BOOLEAN, s STRING
LET s = "abc"
LET hasContent = s.getLength()
```

When converting a string (CHAR, VARCHAR or STRING) to BOOLEAN, the string will be converted to a number first, then the number-to-boolean conversion applies. If the string value cannot convert to a numeric value (for example, "abc"), the boolean value becomes NULL.

When converting a BOOLEAN to a string, the result will be "1" or "0" string values, depending on the boolean value.

Large object type conversions
A TEXT value can be converted to/from CHAR, VARCHAR or STRING.

The BYTE type cannot be converted to/from any other type.
Integers to decimal types

TINYINT, SMALLINT, INTEGER and BIGINT values can be converted to SMALLFLOAT, FLOAT, DECIMAL or MONEY as long as the decimal type is defined with sufficient digits to hold the whole number.

If the integer value exceeds the range of the receiving data type, an overflow error occurs.

Decimal to integer types

When converting a SMALLFLOAT, FLOAT DECIMAL or MONEY to a TINYINT, SMALLINT, INTEGER or BIGINT, the fractional part of the decimal value is truncated.

```
MAIN
  DEFINE d DECIMAL(10,2),
     i INTEGER
  LET d = 123.45
  LET i = d
  DISPLAY i   -- displays 123
END MAIN
```

If the decimal value exceeds the range of the receiving integer data type, an overflow error occurs.

Decimal to decimal types

Converting between SMALLFLOAT, FLOAT DECIMAL or MONEY types is allowed as long as the receiving type is defined with sufficient digits to hold the whole part of the original value.

If the original value contains more fractional digits than the receiving data type supports, low-order digits are discarded.

```
MAIN
  DEFINE d1 DECIMAL(10,2),
         d2 DECIMAL(5,1)
  LET d1 = 123.45
  LET d2 = d1
  DISPLAY d2    -- displays 123.5
END MAIN
```

Decimal to character types

Converting SMALLFLOAT, FLOAT, DECIMAL or MONEY values to CHAR, VARCHAR and STRING implies numeric formatting.

Numeric formatting is controlled by the DBMONEY and DBFORMAT environment variables.

The resulting string is left-aligned (for lossless conversions) or right-aligned (for visual conversions), depending on the conversion context; and the decimal part is kept depending on the numeric type.

```
MAIN
  DEFINE m MONEY(8,2),
         s VARCHAR(10)
  LET m = 123.45
  LET s = m   -- Lossless conversion "$123.45"
  DISPLAY m   -- Visual conversion "$123.45"
END MAIN
```

Fixed point decimals (DECIMAL (p, s)) are converted to strings that can fit in a CHAR (p+2): The string is built with up to p significant digits + 1 character for the sign + 1 character for the decimal point. The result of a DECIMAL (p, s) to string conversion is never longer than p + 2 characters. For example, a DECIMAL (5, 2) can produce “-999.99” (5 + 2 = 7c).
Floating point decimals (DECIMAL (p)) are converted to strings that can fit in a CHAR (p+7): The string is built with up to p significant digits + 1 character for the sign + 1 character for the decimal point + the length of the exponent of needed ("e+123"). The result of a DECIMAL (p) to string conversion is never longer than p + 7. For example, a DECIMAL (5) can produce "-1.2345e-123" (5 + 7 = 12c).

DECIMAL to string conversion depends on the context in which the conversion occurs:

1. **Visual conversion**: The result of this conversion will typically be presented to the end user. This conversion happens in DISPLAY, MESSAGE, ERROR, PRINT. The result of a visual conversion is right aligned (padded with leading blanks). This padding results in the same length for any value for a given decimal precision. The length of the result is the maximum possible length as described previously (p+2 for DECIMAL(p,s), p+7 for DECIMAL(p)).

Visual conversion examples for DECIMAL(5,2):

<table>
<thead>
<tr>
<th>Values</th>
<th>1234567</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot; 0.00&quot;</td>
</tr>
<tr>
<td>-999.99</td>
<td>&quot;-999.99&quot;</td>
</tr>
<tr>
<td>12.3</td>
<td>&quot; 12.30&quot;</td>
</tr>
<tr>
<td>12.34</td>
<td>&quot; 12.34&quot;</td>
</tr>
</tbody>
</table>

Visual conversion examples for DECIMAL(5):

<table>
<thead>
<tr>
<th>Values</th>
<th>123456789012</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;0.0&quot;</td>
</tr>
<tr>
<td>-99999</td>
<td>&quot;-99999.0&quot;</td>
</tr>
<tr>
<td>12.3</td>
<td>&quot;12.3&quot;</td>
</tr>
<tr>
<td>12.34</td>
<td>&quot;12.34&quot;</td>
</tr>
<tr>
<td>12.345</td>
<td>&quot;12.345&quot;</td>
</tr>
<tr>
<td>1.23e7</td>
<td>&quot;12300000.0&quot;</td>
</tr>
<tr>
<td>1e100</td>
<td>&quot;1e100&quot;</td>
</tr>
</tbody>
</table>

2. **Form field conversion**: This conversion concerns decimal numbers presented in form-fields. The result of this conversion is in best case the same as (1). The result of the conversion depends on the width of the form-field. If the width of the form-field is smaller than the perfect length, automatic rounding and exponential notation might be used.

3. **Lossless conversion**: Such conversion happens when assigning numbers to string variables (LET), passing numbers as parameters to functions expecting strings, returning numbers from functions to strings, serializing numbers (UNLOAD, XML or JSON APIs). These conversions must avoid the loss of significant digits. When using floating point decimals, this leads to a variable length of the resulting string. A conversion must be reversible: decimal to string to decimal must give the original value. If the target variable is shorter then the maximum possible length, then automatic rounding will occur.

Lossless conversion examples of DECIMAL(5,2):

<table>
<thead>
<tr>
<th>Values</th>
<th>1234567</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;0.00&quot;</td>
</tr>
<tr>
<td>-999.99</td>
<td>&quot;-999.99&quot;</td>
</tr>
<tr>
<td>12.3</td>
<td>&quot;12.30&quot;</td>
</tr>
<tr>
<td>12.34</td>
<td>&quot;12.34&quot;</td>
</tr>
</tbody>
</table>

Lossless conversion examples of DECIMAL(5):

<table>
<thead>
<tr>
<th>Values</th>
<th>123456789012</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>&quot;0.0&quot;</td>
</tr>
<tr>
<td>-99999</td>
<td>&quot;-99999.0&quot;</td>
</tr>
<tr>
<td>12.3</td>
<td>&quot;12.3&quot;</td>
</tr>
</tbody>
</table>
Automatic rounding occurs if the target string variable is shorter than the maximum possible length of the DECIMAL type. Such conversion might lose significant digits: The runtime system tries to round the value, to fit into the target variable.

<table>
<thead>
<tr>
<th>Values</th>
<th>Different target sizes</th>
</tr>
</thead>
<tbody>
<tr>
<td>123456</td>
<td>12345</td>
</tr>
<tr>
<td>12345</td>
<td>1234</td>
</tr>
<tr>
<td>1234</td>
<td></td>
</tr>
</tbody>
</table>

Automatic switch to the exponential notation will occur if the integer part of the decimal value does not fit into the target string variable. For example, if the source variable is a DECIMAL(12) and the target variable is a CHAR(9):

<table>
<thead>
<tr>
<th>Values</th>
<th>123456789</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234567</td>
<td>&quot;1234567.0&quot;</td>
</tr>
<tr>
<td>12345678</td>
<td>&quot;12345678&quot;</td>
</tr>
<tr>
<td>123456789</td>
<td>&quot;123456789&quot;</td>
</tr>
<tr>
<td>1234567890</td>
<td>&quot;1.2346e10&quot;</td>
</tr>
<tr>
<td>12345678901</td>
<td>&quot;1.2346e11&quot;</td>
</tr>
</tbody>
</table>

The exponential notation will also be used if the absolute value of a floating point decimal is less than 1e-8 (0.00000001).

Default formatting of floating point decimals has been revised with Genero 2.50. If DECIMAL(P)-to-string conversion must round to 2 digits, use the fglrun.decToCharscale2 FGLPROFILE entry:

```
fglrun.decToCharscale2 = true
```

**Note:** Do not use the decToCharscale2 configuration parameter, unless you have migration issues.

Formatting a FLOAT is the same as DECIMAL(16). Any FLOAT value with up to 15 digits is exact. There is no precision loss when converting an exact FLOAT back and forth to/form a string. Some FLOAT values require 16, in some rare cases 17 digits for an exact string representation. 16 and 17 digits are not always exact: "8.000000000000001" and "8.000000000000002" represent the same float value.

Formatting a SMALLFLOAT is the same as DECIMAL(7). Any SMALLFLOAT value with up to 6 digits is exact. There is no precision loss when converting an exact SMALLFLOAT back and forth to/form a string. Some SMALLFLOAT values require 7, in some rare cases 8 digits for an exact string representation. 7 and 8 digits SMALLFLOAT are not always exact: "0.0009999901" and "0.0009999902" represent the same SMALLFLOAT value.

**Character to decimal types**

A CHAR, VARCHAR and STRING value can be converted to a TINYINT, SMALLINT, INTEGER, BIGINT, SMALLFLOAT, FLOAT, DECIMAL or MONEY value as long as the character string value represents a valid number.

If the original value contains more significant digits or more fractional digits than the receiving data type supports, low-order digits are discarded.

```main
DEFINE d DECIMAL(10,2)
LET d = "-123.45"
DISPLAY d -- displays -123.45
LET d = "1234567890123.45"
DISPLAY d -- displays null
```
Date time to character types

Converting DATE, DATETIME and INTERVAL values to CHAR, VARCHAR and STRING implies date time formatting.

DATE formatting is controlled by the DBDATE environment variable.

When converting a DATETIME to a string, the YYYY-MM-DD hh:mm:ss.fffff standard format is used.

When converting an INTERVAL to a string, either YYYY-MM or DD hh:mm:ss.fffff standard formats are used, depending on the interval class.

If the conversion result is longer than the receiving variable, the resulting character string is null.

Character to date time types

Converting a CHAR, VARCHAR or STRING value to a DATE, DATETIME or INTERVAL is possible as long as the character string defines a well formatted date time or interval value.

When converting a character string to a DATE, the string must follow the date format defined by the DBDATE environment variable.

When converting a string to a DATETIME, the format must be YYYY-MM-DD hh:mm:ss.fffff or follow the ISO 8601 format sub-set (with the T separator between the date and time part, and with optional UTC indicator or timezone offset).

Converting DATE to/from DATETIME types

When converting a DATETIME to another DATETIME with a different precision, truncation from the left or right can occur. If the target type has more fields than the source type, the year, month and day fields are filled with the current date.

When converting a DATE to a DATETIME, the datetime fields are filled with year, month and day from the date value and time fields are set to zero.
When converting a DATETIME to a DATE, an implicit EXTEND( datetime-value, YEAR TO DAY ) is performed.

```main
MAIN
  DEFINE da DATE,
    dt1 DATETIME YEAR TO SECOND,
    dt2 DATETIME HOUR TO MINUTE
  LET da = MDY(12,24,2012)
  LET dt1 = da
  DISPLAY dt1   -- displays 2012-12-24 00:00:00
  LET dt2 = "23:45"
  LET dt1 = dt2
  DISPLAY dt1   -- displays <current date> 00:00:00
END MAIN

Unsupported type conversions

Other data type conversions not mentioned in this topic are not allowed and will result in a runtime error.

Related concepts

Data types on page 253

Selecting the correct data type assists you in the input, storage, and display of your data.

Handling type conversion errors

Runtime errors can be handled on type conversion failures.

By default, in cases of type conversion or overflow errors, the program continues, the target variable is set to NULL and the global STATUS variable is not set.

In order to detect data conversion and overflow errors, use the WHENEVER ANY ERROR statement.

This code example shows use of the WHENEVER ANY ERROR statement:

```main
MAIN   -- DBDATE set to Y4MD-
  DEFINE v VARCHAR(50), d DATE
  LET v = "2012-99-99"      -- invalid date string
  LET d = v
  DISPLAY status, "/", NVL(d,"NULL")   -- displays 0/NULL
  WHENEVER ANY ERROR CONTINUE
  LET d = v
  DISPLAY status, "/", NVL(d,"NULL")   -- displays -1205/NULL
  WHENEVER ANY ERROR STOP
  LET d = "2012-11-23"  -- valid date, ok
  DISPLAY status, "/", NVL(d,"NULL")   -- displays 0/2012-11-23
  LET d = v   -- program execution stopped with error -1205
END MAIN
```

The code above will produce the following output:

```
0/NULL
-1218/NULL
Program stopped at 'x.4gl', line number 10.
FORMS statement error number -1218.
String to date conversion error.
```

Conversion and overflow errors are implicitly trapped in TRY/CATCH blocks.

In this example, the INTERVAL variable is not large enough to hold the result of d2 - d1:

```main
MAIN
  DEFINE d1, d2 DATETIME YEAR TO FRACTION(5)
  DEFINE i INTERVAL SECOND(2) TO SECOND
```
LET d1 = "2015-11-06 17:40:21.436"
LET d2 = "2015-11-06 10:40:21.436"
TRY
    LET i = d2 - d1
    CATCH
        DISPLAY STATUS, " / ", err_get(STATUS)
END TRY
END MAIN

Above code will produce the following output:

-1265 / Overflow occurred on a datetime or interval operation.

Predefined global registers can be used in programs to detect errors, signals and events.

Related reference

Genero BDL errors on page 2998
System error messages sorted by error number.

Formatting numeric values

Numeric values must be formatted when converted to strings.

When does numeric formatting take place?

Numeric formatting occurs when converting a number to a string with the USING operator, for example in a LET, DISPLAY or PRINT instruction, and when displaying numeric values in form fields defined with the FORMAT attribute.

Numeric values can be of type such as INTEGER, FLOAT, DECIMAL, MONEY, etc.

This example formats a DECIMAL(10,2) value with the USING operator:

MAIN
    DEFINE d DECIMAL(10,2)
    LET d = -123456.78
    DISPLAY d USING "-,---,--&.&& @"
END MAIN

Front currency symbol, thousands separator, decimal separator and back currency symbol are defined with the DBFORMAT (or DBMONEY) environment variable. For example, if DBFORMAT is defined as "@:.@.@@ @", the previous code example will produce the following output:

-123,456.78 E

Default formatting occurs when USING or FORMAT are not used, and a numeric value has to be converted to a character string, for example when passing a DECIMAL (p, s) to a function expecting a VARCHAR (n). For more details about default formatting, see Data type conversion reference on page 275.

This topic describes the syntax of the format-string in the USING "format-string" operator and FORMAT = "format-string" form field attribute.

Formatting symbols for numbers

When formatting numeric values, the format-string of the USING operator or FORMAT attribute consists of a set of place holders that represent digits, currency symbols, thousands and decimal separators. For example, "###.###" defines three places to the left of the decimal point and exactly two to the right, plus a "back" currency symbol at the end of the string.
**Note:** The **USING** operator or **FORMAT** attribute are required to display the thousands separator defined in **DBFORMAT**.

The **format-string** must use normalized placeholders described in Table 105: Format-string symbols for Numeric data types on page 282. The placeholders will be replaced by digits, blanks or by the elements defined in the **DBFORMAT** (or **DBMONEY**) environment variables. Any other character will be interpreted as a literal, and can be used at any place in the format string.

If the numeric value is too large to fit in the number of characters defined by the format, the result string is filled with a set of star characters (********), indicating an overflow. Note that this includes the +/- sign.

**Note:** If the numeric values can be negative numbers, specify one additional -(minus) placeholder for the sign. Otherwise, if the value is negative and not enough placeholders are defined, overflow star characters will be displayed.

The minus sign (-), plus sign (+), parentheses ( () ), and dollar sign ($) float. This means that when you specify multiple leading occurrences of one of these characters, the result string gets only a single character immediately to the left of the first digit.

**Table 105: Format-string symbols for Numeric data types**

<table>
<thead>
<tr>
<th>Placeholder</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>The star placeholder fills with asterisks any position that would otherwise be blank.</td>
</tr>
<tr>
<td>&amp;</td>
<td>The ampersand placeholder is used to define the position of a digit, and is replaced by a zero if that position would otherwise be blank.</td>
</tr>
<tr>
<td>#</td>
<td>The hash placeholder is used to define the position of a digit, it is used to specify a maximum width for the resulting string. The # is replaced by a blank, if no digit is to be displayed at that position.</td>
</tr>
<tr>
<td>&lt;</td>
<td>Consecutive &quot;less than&quot; characters cause left alignment and define digit positions. Displays a minus sign if the value is negative, or a blank if the value is positive. When you group several minus signs in the format string, a single minus sign floats immediately to the left of the first digit.</td>
</tr>
<tr>
<td>-</td>
<td>Displays a minus sign if the value is negative, or a plus sign if the value is positive. When you group several plus signs in the format string, a single plus sign floats immediately to the left of the first digit.</td>
</tr>
<tr>
<td>+</td>
<td>Displayed as left parenthesis for negative numbers. It is used to display &quot;accounting parentheses&quot; instead of a minus sign for negative numbers. Consecutive left parentheses display a single left parenthesis to the left of the first digit.</td>
</tr>
<tr>
<td>(</td>
<td>Displayed as right parenthesis for negative numbers. This wildcard character is used in conjunction with a open brace to display &quot;accounting parentheses&quot; for negative numbers.</td>
</tr>
<tr>
<td>)</td>
<td>The comma placeholder is used to define the position for the thousand separator defined in <strong>DBFORMAT</strong>. The thousand separator will only be displayed if there is a number on the left of it.</td>
</tr>
<tr>
<td>, (comma)</td>
<td>The period placeholder is used to define the position for the decimal separator defined in <strong>DBFORMAT</strong>. You can only have one decimal separator in a number format string.</td>
</tr>
<tr>
<td>. (period)</td>
<td>The dollar sign is the placeholder for the front currency symbol defined in <strong>DBFORMAT</strong>. Related concepts

Formatting DATE values on page 284
Date values must be formatted when converted to strings.

Formatting DATETIME values on page 285
Date-time values must be formatted when converted to strings.

Data types on page 253

Selecting the correct data type assists you in the input, storage, and display of your data.

Formatting DATE values

Date values must be formatted when converted to strings.

When does DATE formatting take place?

Date formatting occurs when converting a DATE to a string with the USING operator, for example in a LET, DISPLAY or PRINT instruction, and when displaying date values in form fields defined with the FORMAT attribute.

This example formats a DATE value with the USING operator:

```
MAIN
    DEFINE d DATE
    LET d = MDY(12,24,2014)
    DISPLAY d USING "mmm ddd yyyy"
END MAIN
```

This code example produces the following output:

```
Dec Wed 2014
```

Default formatting occurs when USING or FORMAT are not used, and a date value has to be converted to a character string, for example when passing a DATE to a function expecting a VARCHAR(n). Default date formatting is based on the date format defined with the DBDATE environment variable. For more details about default formatting, see Data type conversion reference on page 275.

This topic describes the syntax of the format-string in the USING "format-string" operator and FORMAT = "format-string" form field attribute.

Formatting symbols for DATE values

When formatting DATE values, the format-string of the USING operator or FORMAT attribute consists of a set of place holders that represent date parts as described in the following table:

Table 107: Format-string symbols for DATE values

<table>
<thead>
<tr>
<th>Placeholder</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dd</td>
<td>Day of the month as a 2-digit integer.</td>
</tr>
<tr>
<td>ddd</td>
<td>Three-letter English-language abbreviation of the day of the week. For example: Mon, Tue.</td>
</tr>
<tr>
<td>mm</td>
<td>Month as a 2-digit integer.</td>
</tr>
<tr>
<td>mmm</td>
<td>Three-letter English-language abbreviation of the month. For example: Jan, Feb.</td>
</tr>
<tr>
<td>yy</td>
<td>Year, as a 2-digits integer representing the 2 trailing digits.</td>
</tr>
<tr>
<td>yyy</td>
<td>Year as a 3-digit number (Ming Guo format only)</td>
</tr>
<tr>
<td>yyyy</td>
<td>Year as a 4-digit number.</td>
</tr>
<tr>
<td>c1</td>
<td>Ming Guo format modifier, see Using the Ming Guo date format on page 425.</td>
</tr>
</tbody>
</table>

Any character different from the date-formatting placeholders is interpreted as a literal and will appear as-is in the resulting string.

The calendar used for date formatting is the Gregorian calendar. The c1 placeholder is a formatting symbol used to adapt the date to the Ming Guo calendar.
Table 108: Date formatting examples

<table>
<thead>
<tr>
<th>Format String</th>
<th>Date value</th>
<th>Result string</th>
</tr>
</thead>
<tbody>
<tr>
<td>dd/mm/yyyy</td>
<td>2011-10-24</td>
<td>24/10/2011</td>

Genero BDL can be configured to use the The Ming Guo calendar.

Formatting DATETIME values

Date-time values must be formatted when converted to strings.

When does DATETIME formatting take place?

Datetime formatting occurs when converting a DATETIME to a string, for example in a LET, DISPLAY or PRINT instruction, and when displaying datetime values in form fields.

By default, DATETIME values are formatted in the ISO format:

```
yyyy-mm-dd hh:mm:ss.fffffff
```

A DATETIME value can be formatted with the `util.Datetime.format()` method:

```
IMPORT util
MAIN
  DEFINE dt DATETIME YEAR TO SECOND
  LET dt = CURRENT
  DISPLAY util.Datetime.format(dt, "%Y-%m-%d %H:%M:%S")
END MAIN
```

This code example produces the following output:

```
2015-12-23 11:45:33
```

Converting strings to DATETIME values

When a string represents a datetime value is ISO format, it can be directly converted to a DATETIME:

```
DEFINE dt DATETIME YEAR TO FRACTION(5)
LET dt = "2015-12-24 11:34:56.82373"
```

If you need to convert a string that does not follow the ISO format, use the `util.Datetime.parse()` method, by specifying a format string:

```
DEFINE dt DATETIME YEAR TO MINUTE
LET dt = util.Datetime.parse( "2014-12-24 23:45", "%Y-%m-%d %H:%M" )
```

Formatting symbols for DATETIME values

When formatting DATETIME values, the `format-string` of the `util.Datetime.parse()` and `util.Datetime.format()` methods consists of a set of place holders that represent the different parts of a datetime value (year, month, day, hour, minute, second and fraction).
s shows the formatting symbols for DATETIME expressions. Any character different from the placeholders described in this table is interpreted as a literal and will appear as-is in the resulting string.

The calendar used for date formatting is the Gregorian calendar.

**Table 109: Format-string symbols for DATETIME values**

<table>
<thead>
<tr>
<th>Placeholder</th>
<th>Description</th>

</tr>
<tr>
<td>%n</td>
<td>A newline character</td>
</tr>
<tr>
<td>%p</td>
<td>The locale’s equivalent of AM or PM</td>
</tr>
<tr>
<td>%r</td>
<td>The 12-hour clock time. In the POSIX locale equivalent to %H : %M : %S %p</td>
</tr>
<tr>
<td>%R</td>
<td>Equivalent to %H : %M</td>
</tr>
<tr>
<td>%s</td>
<td>The seconds (00-59)</td>
</tr>
<tr>
<td>%t</td>
<td>A tab character</td>
</tr>
<tr>
<td>%T</td>
<td>Equivalent to %H : %M : %S</td>
</tr>
<tr>
<td>%x</td>
<td>The date, using the locale’s date format.</td>
</tr>
<tr>
<td>%X</td>
<td>The time, using the locale’s time format.</td>
</tr>
<tr>
<td>%w</td>
<td>The ordinal number of the day of the week (0-6), with Sunday = 0.</td>
</tr>
<tr>
<td>%Y</td>
<td>The year within century (0-99)</td>
</tr>
<tr>
<td>%Y</td>
<td>The year, including the century (for example, 1991)</td>
</tr>
</tbody>
</table>
Table 110: Datetime formatting examples

<table>
<thead>
<tr>
<th>Format String</th>
<th>Datetime value</th>
<th>Result string</th>
</tr>
</thead>
<tbody>
<tr>
<td>%d/%m/%Y %H:%M</td>
<td>2011-10-24 11:23:45</td>
<td>24/10/2011 11:23</td>
</tr>
<tr>
<td>(%a.) %b. %d, %Y</td>
<td>1999-09-23</td>
<td>(Thu.) Sep. 23, 1999</td>
</tr>
</tbody>
</table>

**Formatting INTERVAL values**

Interval values must be formatted when converted to strings.

**When does INTERVAL formatting take place?**

Interval formatting occurs when converting an INTERVAL to a string, for example in a LET, DISPLAY or PRINT instruction, and when displaying interval values in form fields.

By default, INTERVAL values are formatted in the ISO format, and depending on the interval class and type.

For example, an INTERVAL YEAR(4) TO MONTH will be formatted as:

\[
\text{\textbackslash{[}+ | - \textbackslash{]}yyyy-mm}
\]

For an INTERVAL DAY(n) TO FRACTION(5), the default format is:

\[
\text{\textbackslash{[}+ | - \textbackslash{]}ddd dd hh:mm:ss.fffff}
\]

An INTERVAL value can be formatted with the `util.Interval.format()` method:

```sql
IMPORT util
MAIN
  DEFINE iv INTERVAL DAY(6) TO MINUTE
  LET iv = "-157 11:23"
  DISPLAY util.Interval.format(iv, "%d %H:%M")
END MAIN
```

This code example produces the following output:

\[-157 11:23\]

**Converting strings to INTERVAL values**

When a string represents a interval value is ISO format, it can be directly converted to a INTERVAL:

```sql
DEFINE iv INTERVAL HOUR(6) TO FRACTION(5)
LET iv = "20234:34:56.82373"
```

If you need to convert a string that does not follow the ISO format, use the `util.Interval.parse()` method, by specifying a format string:

```sql
DEFINE iv INTERVAL DAY(6) TO FRACTION(5)
LET iv = util.Interval.parse( "-7467 + 23:45:34.12345", "%d + %H:%M:%S%f5" )
```

**Formatting symbols for INTERVAL values**

When formatting INTERVAL values, the `format-string` of the `util.Interval.parse()` and `util.Interval.format()` methods consists of a set of place holders that represent the different parts of a interval value (year, month, day, hour, minute, second and fraction).
Table 111: Format-string symbols for INTERVAL values on page 288 shows the formatting symbols for INTERVAL expressions. Any character different from the placeholders described in this table is interpreted as a literal and will appear as-is in the resulting string.

Table 111: Format-string symbols for INTERVAL values

<table>
<thead>
<tr>
<th>Placeholder</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%Y</td>
<td>Years (0-999999999)</td>
</tr>
<tr>
<td>%m</td>
<td>Months (0-999999999 if highest INTERVAL qualifier is MONTH(n), 0-11 otherwise)</td>
</tr>
<tr>
<td>%d</td>
<td>Days (0-999999999)</td>
</tr>
<tr>
<td>%H</td>
<td>Hours (0-999999999 if highest INTERVAL qualifier is HOUR(n), 00-23 otherwise)</td>
</tr>
<tr>
<td>%M</td>
<td>Minutes (0-999999999 if highest INTERVAL qualifier is MINUTE(n), 00-59 otherwise)</td>
</tr>
<tr>
<td>%S</td>
<td>Seconds (0-999999999 if highest INTERVAL qualifier is SECOND(n), 00-59 otherwise)</td>
</tr>
<tr>
<td>%F[n]</td>
<td>The fractional part of a second, where n specifies the number of digits in the fractional part (1 to 5)</td>
</tr>
<tr>
<td>%t</td>
<td>A tab character</td>
</tr>
<tr>
<td>%n</td>
<td>A newline character</td>
</tr>
</tbody>
</table>

Table 112: Interval formatting examples

</tbody>
</table>

**Literals**

Describes the syntax of literals (constant values) to be used in sources.

- **Integer literals** on page 288
- **Numeric literals** on page 289
- **Text literals** on page 289
- **Datetime literals** on page 291
- **Interval literals** on page 292

**Integer literals**

Integer literals define a whole number in an expression.

**Syntax**

```
[+|−]digi[t_...]
```

1. *digit* is a digit character from '0' to '9'.

**Usage**

Integer literals are in base-10 notation, without blank spaces and commas and without a decimal point.
Integer literals can be used to specify values for `DECIMAL(P,0), BIGINT, INTEGER, SMALLINT` and `TINYINT` data types.

### Example

```
MAIN
  DEFINE n INTEGER
  LET n = 1234567
END MAIN
```

### Related concepts

- [Integer expressions](#) on page 296
  
This section covers integer expression evaluation rules.

### Numeric literals

Numeric literals define values with a decimal part in an expression.

#### Syntax

```
[+|-]digit[...] . digit[...] [e|E] [+|-] digit[...]
```

1. `digit` is a digit character from '0' to '9'.
2. Note that the decimal separator is always a dot, independently from DBMONEY.
3. The E notation can be used to specify the exponent.

#### Usage

Numeric/decimal literals in base-10 notation, without blank spaces and commas, with a decimal part after a dot.

Numeric literals can be used to specify values for `DECIMAL(P,S), MONEY(P,S), FLOAT` and `SMALLFLOAT` data types.

### Example

```
MAIN
  DEFINE n DECIMAL(10,2)
  LET n = 12345.67
  LET n = -1.23456e-10
END MAIN
```

### Related concepts

- [Numeric expressions](#) on page 296
  
This section covers numeric expression evaluation rules.

### Text literals

Text literals define a character string in an expression.

#### Syntax 1 (using double quotes)

```
" char [...] "
```

#### Syntax 2 (using single quotes)

```
' char [...] '
```

1. `char` is any character supported in the current locale, or a `\` backslash escape character as described below:
• `\`: the backslash character.
• `"`: double-quote character.
• `'`: single-quote character.
• `\n`: newline character.
• `\r`: carriage-return character.
• `\0`: null character.
• `\f`: form-feed character.
• `\t`: tab character.
• `\xNN`: ASCII character defined by the hexadecimal code `NN`.

**Usage**

A text literal (or character string literal) defines a character string constant containing valid characters in the current application character set.

The application character set is defined by the current locale.

A text literal can be written on multiple lines, the compiler merges lines by removing the newline character.

An empty string (``) is equivalent to `NULL`.

The escape character is the backslash character (`\`).

When using single quotes as delimiters, double quotes can be used as is inside the string, while single quotes must be doubled or escaped with a backslash:

```display`
DISPLAY '  2 double quotes: " "  2 single quotes: '' '
```

```display` as:
2 double quotes: " "  2 single quotes: ' '
```

When using double quotes as delimiters, single quotes can be used as is inside the string, while double quotes must be doubled or escaped with a backslash:

```display`
DISPLAY "  2 double quotes: " "  2 single quotes: ' ' "
```

```display` as:
2 double quotes: " "  2 single quotes: ' '
```

Special characters can be specified with backslash escape symbols. Use for example `\n` to insert a new-line character in a string literal:

```display`
DISPLAY "First line
Second line"
```

The `\xNN` hexadecimal notation allows you to specify control characters in a string literal. Only ASCII codes (<=0x7F) are allowed.

**Example**

```main`
MAIN
DISPLAY "Some text in double quotes"
DISPLAY 'Some text in single quotes'
DISPLAY "Include double quotes: " " " "
DISPLAY 'Include single quotes: " " "
DISPLAY 'Insert a newline character here: \n and continue with text.'
DISPLAY "This is a text
on multiple
lines."
    You can insert a newline with back-slash at the end of the line."
IF "" IS NULL THEN
    DISPLAY 'Empty string is NULL'
END IF
```
Related concepts

Localized strings on page 430
Localized strings provide a means of writing applications in which the text of strings can be customized on site.

String expressions on page 297
This section covers string expression evaluation rules.

Localization on page 405
Localization support allows you to implement programs that follow specific language and cultural rules.

Datetime literals

Datetime literals define date/time value in an expression.

Syntax

```
DATETIME ( dtrep ) qual1 TO qual2\(scale\)
```

where `qual1` can be one of:

- YEAR
- MONTH
- DAY
- HOUR
- MINUTE
- SECOND
- FRACTION

and `qual2` can be one of:

- YEAR
- MONTH
- DAY
- HOUR
- MINUTE
- SECOND
- FRACTION
- FRACTION(1)
- FRACTION(2)
- FRACTION(3)
- FRACTION(4)
- FRACTION(5)

1. `dtrep` is the datetime value representation in normalized format (YYYY-MM-DD hh:mm:ss.fffff).
2. `scale` defines the number of significant digits of the fractions of a second.
3. `qual1` and `qual2` qualifiers define the precision of the `DATETIME` literal.

Usage

A datetime literal is specified with the `DATETIME()` notation, and is typically used in interval or datetime expressions, or to assign a `DATETIME` variable.

In order to get the current date and time, use the `CURRENT` operator.

Example

```
MAIN
   DEFINE d1 DATETIME YEAR TO SECOND
   DEFINE d2 DATETIME HOUR TO FRACTION(5)
```
LET d1 = DATETIME( 2002-12-24 23:55:56 ) YEAR TO SECOND
LET d2 = DATETIME( 23:44:55.34532 ) HOUR TO FRACTION(5)
END MAIN

### Related concepts

**Datetime expressions** on page 298

This section covers date-time expression evaluation rules.

#### Interval literals

Interval literals define an interval value in an expression.

**Syntax 1: year-month class interval**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTERVAL (inrep) YEAR[p] TO MONTH</td>
<td>INTERVAL(345-5) YEAR TO MONTH</td>
</tr>
<tr>
<td>INTERVAL (inrep) YEAR[p] TO YEAR</td>
<td>INTERVAL(345-5) YEAR TO YEAR</td>
</tr>
</tbody>
</table>

**Syntax 2: day-time class interval**

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTERVAL (inrep) DAY[p] TO FRACTION[s]</td>
<td>INTERVAL(34562:22:33) DAY TO SECOND</td>
</tr>
<tr>
<td>INTERVAL (inrep) DAY[p] TO SECOND</td>
<td>INTERVAL(34562:22:33) DAY TO SECOND</td>
</tr>
<tr>
<td>INTERVAL (inrep) MINUTE[p] TO FRACTION[s]</td>
<td>INTERVAL(34562:22:33) MINUTE TO MINUTE</td>
</tr>
<tr>
<td>INTERVAL (inrep) MINUTE[p] TO SECOND</td>
<td>INTERVAL(34562:22:33) MINUTE TO SECOND</td>
</tr>
<tr>
<td>INTERVAL (inrep) SECOND[p] TO FRACTION[s]</td>
<td>INTERVAL(34562:22:33) SECOND TO SECOND</td>
</tr>
<tr>
<td>INTERVAL (inrep) SECOND[p] TO SECOND</td>
<td>INTERVAL(34562:22:33) SECOND TO SECOND</td>
</tr>
<tr>
<td>INTERVAL (inrep) FRACTION TO FRACTION[s]</td>
<td>INTERVAL(34562:22:33) FRACTION TO FRACTION</td>
</tr>
</tbody>
</table>

1. inrep is the representation of the interval value in normalized format (YYYY-MM or DD hh:mm:ss.fffff, depending on the interval class).

#### Usage

An interval literal is specified with the `INTERVAL()` notation, and is typically assigned in interval or datetime expressions, or to assign an `INTERVAL` variable.

#### Example

```
MAIN
  DEFINE i1 INTERVAL YEAR TO MONTH
  DEFINE i2 INTERVAL HOUR(5) TO SECOND
  LET i1 = INTERVAL( 345-5 ) YEAR TO MONTH
  LET i2 = INTERVAL( 34562:22:33 ) HOUR(5) TO SECOND
END MAIN
```

### Related concepts

Expressions

Shows the possible expressions supported in the language.

- **Understanding expressions** on page 293
- **Boolean expressions** on page 294
- **Integer expressions** on page 296
- **Numeric expressions** on page 296
- **String expressions** on page 297
- **Date expressions** on page 297
- **Datetime expressions** on page 298
- **Interval expressions** on page 298

Understanding expressions

This is an introduction to language expressions.

What is an expression?

An expression is a sequence of operands, operators, and parentheses that the runtime system can evaluate as a single value. Operands are program variables, constants, functions returning a single value and literal values. Operators are used for arithmetic or string manipulation, and the parentheses are used to overwrite precedence of operators.

Language and SQL expressions

Expressions in SQL statements are evaluated by the database server, not by the runtime system. The set of operators that can appear in SQL expressions resembles the set of language operators, but they are not identical. A program can include SQL operators, but these are restricted to SQL statements. Similarly, most SQL operands are not valid in program expressions. The SQL identifiers of databases, tables, or columns can appear in a LIKE clause or field name in program instructions, provided that these SQL identifiers comply with the naming rules of language. Here are some examples of SQL operands and operators that cannot appear in other language expressions:

- SQL identifiers, such as column names
- The SQL keywords USER and ROWID
- Built-in or aggregate SQL functions that are not part of the language
- The BETWEEN and IN operators
- The EXISTS, ALL, ANY, or SOME keywords of SQL expressions

Conversely, you cannot include language-specific operators in SQL expressions. For example:

- Arithmetic operators for exponentiation (***) and modulus (MOD)
- String operators ASCII, COLUMN, SPACE, SPACES, and WORDWRAP
- Field operators FIELD_TOUCHED(), GET_FLDBUF(), and INFIELD()
- The report operators LINENO and PAGENO

Parentheses in expressions

Parentheses are used as in algebra, to override the default order of precedence of operators. In mathematics, this use of parentheses represents the "associative" operator. It is, however, a convention in computer languages to regard this use of parentheses as delimiters rather than as operators. (Do not confuse this use of parentheses to specify operator precedence with the use of parentheses to enclose arguments in function calls or to delimit other lists.)

In this example, the variable y is assigned the value of 2.

```plaintext
LET y = 15 MOD 3 + 2
```
In this example, \( y \) is assigned the value of 0 because the parentheses change the sequence of operations.

```plaintext
LET y = 15 MOD (3 + 2)
```

**Related concepts**

- **Operators** on page 299
  This section describes basic syntax elements that can appear in expressions.
- **Literals** on page 288
  Describes the syntax of literals (constant values) to be used in sources.

### Boolean expressions

This section covers boolean expression evaluation rules.

A boolean expression is an expression that uses the AND/OR/NOT boolean operators.

The result of a boolean expression is a boolean value.

A boolean value is typically used in an IF block, WHILE block, or the WHEN in a CASE block.

Boolean expressions are a combination of AND/OR/NOT logical operators and comparison operators such as \( == \), \( >= \) or \( != \).

**Note:** The language provides the `TRUE` and `FALSE` predefined constants to initialize boolean variables or return boolean values from functions.

There are three kinds of boolean expressions:

- \( expr \) AND \( expr \)
- \( expr \) OR \( expr \)
- NOT \( expr \)

The \( (expr) \) operands of boolean expressions are boolean values.

If one of the operands is NULL, the result is NULL.

**Note:** The syntax and semantics of boolean expressions in Genero BDL programs is not the same as Boolean conditions in SQL, as SQL statements are executed by the database engine.

The following example shows a simple boolean expression using the AND operator:

```plaintext
IF a AND b THEN
  DISPLAY "Both a and b are TRUE"
END IF
```

In the next example, a boolean expression uses two comparison expressions:

```plaintext
IF (a == b) AND (a == c) THEN
  DISPLAY "a, b and c are equal"
END IF
```

The NOT operator will negate a boolean expression:

```plaintext
IF NOT a THEN
  DISPLAY "a is FALSE"
END IF
```

Use a **BOOLEAN** variable to store the result of a boolean expression:

```plaintext
MAIN
  DEFINE b BOOLEAN
  LET b = ( "a" == "b" ) -- result is FALSE
```
Important: It is bad practice to use non-boolean operands in boolean expressions, as in the following example:

```plaintext
DEFINE var STRING, cnt INTEGER
IF var AND cnt>0 THEN
    ...
END IF
```

Good practice (for character strings for example) is to do the following:

```plaintext
IF LENGTH(var)>0 AND cnt>0 THEN
```

or:

```plaintext
IF var IS NOT NULL AND cnt>0 THEN
```

If the operand is not of type boolean, it has to be converted to a boolean. If a conversion is required:

- Any numeric value evaluates to FALSE, if and only if the value is 0.
- Any character string value (STRING, CHAR, VARCHAR) follows the next rules:
  - If the string starts with a digit, then this conversion evaluates to FALSE, if and only if the string to integer conversion returns 0.
  - If the string does not start with a digit, then this conversion evaluates to FALSE if and only if the string has a length of 0.

**Note:** Consider using the expression `LENGTH(string)>0` or `string IS NOT NULL`, to check that a string contains characters, or convert the string to a numeric variable and then test the numeric value.

- **DATE** values can be converted to integers. `MDY(12,31,1899) = 0` and evaluates to FALSE. Any other date value is different from zero and evaluates to TRUE.
- Any other data type produces a conversion error and raises the runtime error -1260.

Below a more complex example of boolean expressions:

```plaintext
MAIN
    DEFINE r BOOLEAN, c INTEGER
    LET c = 4
    LET r = ( c!=5 ) AND ( c==2 OR c==4 )
    IF ( r AND canReadFile("config.txt") ) THEN
        DISPLAY "OK"
    END IF
END MAIN
```

If an expression that returns NULL is the operand of the **IS NULL** operator, the value of the boolean expression is TRUE:

```plaintext
MAIN
    DEFINE r INTEGER
    LET r = NULL
    IF r IS NULL THEN
        DISPLAY "TRUE"
    END IF
END MAIN
```

Boolean expressions in **CASE**, **IF**, or **WHILE** statements evaluate to FALSE, if any element of the comparison is NULL, except for operands of the **IS NULL** and the **IS NOT NULL** operator.
If you include a boolean expression in a context where the runtime system expects a number, the expression is evaluated, and is then converted to an integer by the rules TRUE=1 and FALSE=0.

```main
DEFINE r INTEGER
LET c = 4
LET r = 4 + (1==0)  -- result is 4.
END MAIN
```

**Related concepts**

*Type conversions* on page 274

Explains data type conversion rules of the language.

### Integer expressions

This section covers integer expression evaluation rules.

An integer expression evaluates to a whole number.

```main
DEFINE r, c INTEGER
LET c = 4
LET r = c * ( 2 + c MOD 4 ) / getRowCount("customers")
END MAIN
```

The operands of an integer expression can be:

- An integer literal.
- A variable or constant of type TINYINT, SMALLINT, INTEGER or BIGINT.
- A function returning a single integer value.
- A boolean expression.
- The result of a DATE subtraction, as a number of days.

If an integer expression includes an operand whose value is not an integer data type, the runtime system attempts to convert the value to an integer following the data conversion rules.

If an element of an integer expression is NULL, the expression is evaluated to NULL.

**Related concepts**

*Type conversions* on page 274

Explains data type conversion rules of the language.

### Numeric expressions

This section covers numeric expression evaluation rules.

A numeric expression evaluates to a decimal value.

```main
DEFINE r, c DECIMAL(10,2)
LET c = 456.22
LET r = c * 2 + ( c / 4.55 )
END MAIN
```

The operands of a numeric expression can be one of:

- An integer literal.
- A decimal literal.
- A variable or constant of numeric data type.
- A function returning a single numeric value.
- A boolean expression.
• The result of a **DATE** on page 259 subtraction, as a number of days.

If a number expression includes an operand whose value is not a numeric data type, the runtime system attempts to convert the value to a number following the data conversion rules.

If an element of a number expression is **NULL**, the expression is evaluated to **NULL**.

**Related concepts**
Type conversions on page 274
Explains data type conversion rules of the language.

**String expressions**
This section covers string expression evaluation rules.

A string expression includes at least one character string value and evaluates to a string data type value.

```plaintext
MAIN
DEFINE r, c VARCHAR(100)
LET c = "abcdef"
LET r = c[1,3] || ": " || TODAY USING "YYYY-MM-DD" || " " || length(c)
END MAIN
```

The data type of string expression result is **STRING**.

At least one of the operands in a string expression must be one of:

• A **character string literal**.
• A **variable** or **constant** of **CHAR, VARCHAR, STRING** or **TEXT** data type.
• A **function** returning a single character value.

Other operands whose values are not character string data types are converted to strings by following the data conversion rules.

If an element of a string expression is **NULL**, the expression is evaluated to **NULL**.

An empty string ("") is equivalent to **NULL**.

**Related concepts**
Type conversions on page 274
Explains data type conversion rules of the language.

**Date expressions**
This section covers date expression evaluation rules.

A date expression evaluates to a **DATE** data type value.

```plaintext
MAIN
DEFINE r, c DATE
LET c = TODAY + 4
LET r = ( c - 2 )
END MAIN
```

The operands of a date expression can be one of:

• A **character string literal** that can be evaluated to a date based on the **DBDATE** environment variable.
• A **variable** or **constant** of type **DATE**.
• A **function** returning a single date value.
• A unary + or − sign associated with an **integer expression** representing a number of days.
• The **TODAY** constant.
• A **CURRENT** expression with **YEAR TO DAY** qualifiers.
• An **EXTEND** expression with **YEAR TO DAY** qualifiers.
If a date expression includes an operand whose value is not a date data type, the runtime system attempts to convert the value to a date value following the data conversion rules.

If an element of an date expression is NULL, the expression is evaluated to NULL.

**Related concepts**

*Type conversions* on page 274
Explains data type conversion rules of the language.

### Datetime expressions

This section covers date-time expression evaluation rules.

A datetime expression evaluates to a **DATETIME** data type.

```plaintext
MAIN
  DEFINE r, c DATETIME YEAR TO SECOND
  LET c = CURRENT YEAR TO SECOND
  LET r = c + INTERVAL( 234-02 ) YEAR TO MONTH
END MAIN
```

The operands of a datetime expression can be one of:

- A datatime literal.
- A character string literal representing a datetime with the format **YYYY-MM-DD hh:mm:ss.fffff**.
- A variable or constant of **DATETIME** type.
- A function returning a single datetime value.
- A unary + or − sign associated with an interval expression.
- A **CURRENT** expression.
- An **EXTEND** expression.

If a datetime expression includes an operand whose value is not a datetime data type, the runtime system attempts to convert the value to a datetime value following the data conversion rules.

If an element of an integer expression is NULL, the expression is evaluated to NULL.

**Related concepts**

*Type conversions* on page 274
Explains data type conversion rules of the language.

### Interval expressions

This section covers interval expression evaluation rules.

An interval evaluates to an **INTERVAL** data type.

```plaintext
MAIN
  DEFINE r, c INTERVAL HOUR TO MINUTE
  LET c = "12:45"
  LET r = c + ( DATETIME(14:02) HOUR TO MINUTE - DATETIME(10:43) HOUR TO MINUTE )
END MAIN
```

The operands of an interval expression must be one of:

- An interval literal.
- A character string literal representing an Interval with the format **YYYY-MM-DD hh:mm:ss.fffff**.
- An integer expression using the **UNITS** operator.
- A variable or constant of **INTERVAL** type.
- A function returning a single interval value.
- The result of a **DATETIME** subtraction.
If an interval expression includes an operand whose value is not an interval data type, the runtime system attempts to convert the value to an interval value following the data conversion rules.

If an element of an integer expression is **NULL**, the expression is evaluated to **NULL**.

**Related concepts**
Type conversions on page 274
Explains data type conversion rules of the language.

---

**Operators**

This section describes basic syntax elements that can appear in expressions.

There are different sort of basic syntax elements such as operators for arithmetics, string and comparison, predefined variables and registers like SQLSTATE, and utility operators like SFMT() or TODAY.

Elements of an expressions are evaluated by following precedence rules, from highest to lowest, as described in the order of precedence list. Use () parentheses to instruct the runtime system to evaluate the expression in a different way than the default order of precedence.

- Order of precedence on page 299
- Operator usage context on page 301
- List of expression elements on page 301

**Related concepts**
Expressions on page 293
Shows the possible expressions supported in the language.

Order of precedence on page 299
The order of precedence defines in which order the elements of an expression are evaluated.

Parentheses () on page 324
Parentheses () force the evaluation of an expression before other operators.

**Order of precedence**

The order of precedence defines in which order the elements of an expression are evaluated.

The following list describes the precedence order of expression elements.

For example, the MOD operator has a higher precedence as the * operator. When computing an expression like ( 33 MOD 2 * 5 ), the runtime system first evaluates (33 MOD 2) = 1 and then evaluates (1 * 5) = 5. The order of evaluation can be changed this by using parentheses: ( 33 MOD (2 * 5) ) = 3.

### IS NULL

The IS NULL operator checks for NULL values.

#### Syntax

```plaintext
expr IS NULL
```

1. `expr` can be any expression supported by the language.

#### Usage

The IS NULL operator can be used to test whether the left-hand expression is NULL.

This operator applies to most data types, except complex types like BYTE and TEXT.

#### Example

```plaintext
MAIN
  DEFINE n INTEGER
  LET n = NULL
  IF n IS NULL THEN
    DISPLAY "The variable is NULL."
  END IF
END MAIN
```

#### Related concepts

- **Expressions** on page 293
  Shows the possible expressions supported in the language.
- **NULL** on page 502
  The NULL constant is provided as the "nil" value.
- **NVL()** on page 309
The `NVL()` operator returns the second parameter if the first argument evaluates to `NULL`.

**LIKE**
The `LIKE` operator returns `TRUE` if a string matches a given mask.

**Syntax**

```sql
expr [NOT] LIKE mask [ESCAPE "char"]
```

1. `expr` is any character string expression.
2. `mask` is a character string expression defining the filter.
3. `char` is a single char specifying the escape symbol.

**Usage**
The `mask` can be any combination of characters, including the `%` and `_` wildcards:
- The `%` percent character matches any string of zero or more characters.
- The `_` underscore character matches any single character.

The `ESCAPE` clause can be used to define an escape character different from the default backslash. It must be enclosed in single or double quotes.

A backslash (or the escape character specified by the `ESCAPE` clause) makes the operator treat the next character as a literal character, even if it is one of the special symbols in the `mask` list. This allows you to search for `%`, `_`, or `\` characters.

Do not confuse with the `LIKE` clause of the `DEFINE` instruction. `LIKE` operators used in SQL statements are evaluated by the database server. This may have a different behavior than the `LIKE` operator of the language.

If you need to escape a wildcard character, keep in mind that a string constant must also escape the backslash character. As a result, if you want to pass a backslash to the `LIKE` operator (by using backslash as default escape character), you need to write four backslashes in the original string constant.

The next table shows some examples of string constants used in the source code and their equivalent `LIKE` pattern:

<table>
<thead>
<tr>
<th>Original String Constant</th>
<th>Equivalent LIKE pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;%&quot;</td>
<td>%</td>
<td>Matches any character in a non-empty string.</td>
</tr>
<tr>
<td>&quot;_&quot;</td>
<td>_</td>
<td>Matches a single character.</td>
</tr>
<tr>
<td>&quot;abc%&quot;</td>
<td>abc%</td>
<td>Starts with abc.</td>
</tr>
<tr>
<td>&quot;*abc&quot;</td>
<td>%abc</td>
<td>Ends with abc.</td>
</tr>
<tr>
<td>&quot;%abc%&quot;</td>
<td>%abc%</td>
<td>Contains abc.</td>
</tr>
<tr>
<td>&quot;abc__&quot;</td>
<td>abc__</td>
<td>Strings equals abc followed by two additional characters.</td>
</tr>
<tr>
<td>&quot;%&quot;</td>
<td>%</td>
<td>Contains a single star character (the % wildcard is escaped)</td>
</tr>
<tr>
<td>&quot;%abc\%def%&quot;</td>
<td>%abc%def%</td>
<td>Contains abc followed by a backslash followed by def (the backslash is escaped)</td>
</tr>
</tbody>
</table>

**Example**

```sql
MAIN
  IF "abcdef" LIKE "a%e_" THEN
    DISPLAY "The value matches."
```
Related concepts

Expressions on page 293
Shows the possible expressions supported in the language.

DEFINE on page 367
A variable contains volatile information of a specific data type.

TRUE on page 503
TRUE is a predefined constant to be used in boolean expressions.

MATCHES
The MATCHES operator returns TRUE if a string matches a given mask.

Syntax

\[ expr \ [\text{NOT}\] \text{MATCHES} \ mask \ [\text{ESCAPE} \ "char" \ ] \]

1. \( expr \) is any character string expression.
2. \( mask \) is a character string expression defining the filter.
3. \( char \) is a single char specifying the escape symbol.

Usage

The \( mask \) can be any combination of characters, including the *, ?, [ , ], – and ^ wildcards:

- The * star character matches any string of zero or more characters.
- The ? question mark matches any single character.
- The [ ] brackets match any enclosed character.
- Inside [ ], the – (hyphen) between characters means a range of characters.
- Inside [ ], the ^ An initial caret matches any character that is not listed.

The ESCAPE clause can be used to define an escape character different from the default backslash. It must be enclosed in single or double quotes.

A backslash (or the escape character specified by the ESCAPE clause) makes the operator treat the next character as a literal character, even if it is one of the special symbols in the \( mask \) list. This allows you to search for wildcard characters such as *, ?, [ , ] or \.

If you need to escape a wildcard character, keep in mind that a string constant must also escape the backslash character. As a result, if you want to pass a backslash to the MATCHES operator (by using backslash as default escape character), you need to write four backslashes in the original string constant.

The next table shows some examples of string constants used in the source code and their equivalent MATCHES pattern:

</tr>
</tbody>
</table>

**Example**

```plaintext
MAIN
  IF "55f-plot" MATCHES "55[a-z]-*" THEN
    DISPLAY "Item reference format is correct."
  END IF
END MAIN
```

**Related concepts**

- **Expressions** on page 293
  Shows the possible expressions supported in the language.
- **DEFINE** on page 367
  A variable contains volatile information of a specific data type.
- **TRUE** on page 503
  TRUE is a predefined constant to be used in boolean expressions.

**Equal to (==)**
The == operator checks for equality of two expressions or for two record variables.

**Syntax 1: Expression comparison**

`expr == expr`

**Syntax 2: Record comparison**

`record1.* == record2.*`

1. `expr` can be any expression supported by the language.
2. `record1` and `record2` are records with the same structure.

**Usage**
The == operator evaluates whether two expressions or two records are identical.

A single equal sign (=) can be used as an alias for the == operator.

When comparing expressions using the first syntax, the result of the operator is FALSE when one of the operands is NULL. This first syntax applies to most data types, except complex types like BYTE and TEXT.

When comparing two records using the second syntax, the runtime system compares all corresponding members of the records. If a pair of members are different, the result of the operator is FALSE. When two corresponding members are NULL, they are considered as equal. This second syntax allows you to compare all members of records, but records must have the same structure.
Example

```plaintext
MAIN
   DEFINE n INTEGER
   LET n=512
   IF n==512 THEN
      DISPLAY "The variable equals 512."
   END IF
END MAIN
```

Related concepts

Expressions on page 293
Shows the possible expressions supported in the language.

Records on page 382
Records allow structured program variables definitions.

TRUE on page 503
TRUE is a predefined constant to be used in boolean expressions.

FALSE on page 503
FALSE is a predefined constant to be used in boolean expressions.

NULL on page 502
The NULL constant is provided as the "nil" value.

Different from (!=)
The != operator checks for non-equality of two expressions or for two record variables.

Syntax 1: Expression comparison

```plaintext
expr != expr
```

Syntax 2: Record comparison

```plaintext
record1.* != record2.*
```

1. <> is a synonym for !=
2. expr can be any expression supported by the language.
3. record1 and record2 are records with the same structure.

Usage

The != operator evaluates whether two expressions or two records are different.

A less-than sign followed by a greater-than sign (<> ) can be used as an alias for the != operator.

When comparing expressions with the first syntax, the result of the operator is FALSE when one of the operands is NULL. This syntax applies to most data types except complex types like BYTE and TEXT.

When comparing two records with the second syntax, the runtime system compares all corresponding members of the records. If one pair of members are different, the result of the operator is TRUE. When two corresponding members are NULL, they are considered as equal. This second syntax allows you to compare all members of records, but records must have the same structure.

Example

```plaintext
MAIN
   DEFINE n INTEGER
   LET n==512
   IF n!=32 THEN
```
DISPLAY "The variable is not equal to 32."
END IF
END MAIN

Related concepts
Expressions on page 293
Shows the possible expressions supported in the language.

Records on page 382
Records allow structured program variables definitions.

TRUE on page 503
TRUE is a predefined constant to be used in boolean expressions.

FALSE on page 503
FALSE is a predefined constant to be used in boolean expressions.

NULL on page 502
The NULL constant is provided as the "nil" value.

Lower (<)
The < operator is provided to test whether a value or expression is lower than another.

Syntax

expr < expr

Usage
Applies to most data types, except complex types such as BYTE and TEXT.

If one of the operands is NULL, the comparison expression evaluates to FALSE.

Example

MAIN
    DEFINE n INT
    LET n = 45
    IF n < 100 THEN
        DISPLAY "The variable is lower than 100."
    END IF
END MAIN

Related concepts
Expressions on page 293

TRUE on page 503
TRUE is a predefined constant to be used in boolean expressions.

FALSE on page 503
FALSE is a predefined constant to be used in boolean expressions.

NULL on page 502
The NULL constant is provided as the "nil" value.

**Lower or equal (<=)**
The <= operator is provided to test whether a value or expression is lower than or equal to another.

**Syntax**

```plaintext
expr <= expr
```

**Usage**

Applies to most data types, except complex types such as BYTE and TEXT.

If one of the operands is NULL, the comparison expression evaluates to FALSE.

**Example**

```plaintext
MAIN
  DEFINE n INT
  LET n = 100
  IF n <= 100 THEN
    DISPLAY "The variable is lower than or equal to 100."
  END IF
END MAIN
```

  FALSE is a predefined constant to be used in boolean expressions.
- **NULL** on page 502
  The NULL constant is provided as the "nil" value.

**Greater (>)**
The > operator is provided to test whether a value or expression is greater than another.

**Syntax**

```plaintext
expr > expr
```

**Usage**

Applies to most data types, except complex types such as BYTE and TEXT.

If one of the operands is NULL, the comparison expression evaluates to FALSE.

**Example**

```plaintext
MAIN
  DEFINE n INT
  LET n = 200
  IF n > 100 THEN
    DISPLAY "The variable is greater than 100."
  END IF
END MAIN
```

TRUE is a predefined constant to be used in boolean expressions.

FALSE on page 503
FALSE is a predefined constant to be used in boolean expressions.

NULL on page 502
The NULL constant is provided as the "nil" value.

Greater or equal (>=)
The >= operator is provided to test whether a value or expression is greater than or equal to another.

Syntax

expr >= expr

Usage

Applies to most data types, except complex types such as BYTE and TEXT.

If one of the operands is NULL, the comparison expression evaluates to FALSE.

Example

MAIN
  DEFINE n INT
  LET n = 100
  IF n >= 100 THEN
    DISPLAY "The variable is greater than or equal to 100."
  END IF
END MAIN

FALSE is a predefined constant to be used in boolean expressions.

NULL on page 502
The NULL constant is provided as the "nil" value.

NVL()
The NVL() operator returns the second parameter if the first argument evaluates to NULL.

Syntax

NVL( main-expr, subst-expr )

1. main-expr and subst-expr are any expression supported by the language.
Usage

The `NVL()` operator evaluates the first argument, and returns the result if the value is not null, otherwise it returns the second argument. This allows you to write the equivalent of the following `IF` statement, in a simple scalar expression:

```sql
IF main-exp IS NOT NULL THEN
    RETURN main-exp
ELSE
    RETURN subst-exp
END IF
```

Example

```sql
MAIN
    DEFINE var VARCHAR(100)
    LET var = arg_val(1)
    DISPLAY "The argument value is: ", NVL(var, "NULL")
END MAIN
```

Related concepts

- **Expressions** on page 293

- **IF** on page 350
  The `IF` instruction executes a group of statements conditionally.
- **NULL** on page 502
  The `NULL` constant is provided as the "nil" value.
- **IIF()**
  The `IIF()` operator returns the second or third parameter depending on the boolean expression given as first argument.

Syntax

```sql
IIF( bool-expr, true-expr, false-expr)
```

1. `bool-expr` is a boolean expression.
2. `true-expr` and `false-expr` are language expressions.

Usage:

The `IIF()` operator evaluates the first argument, the returns the second argument if the first argument is true, otherwise it returns the third argument. This allows you to write the equivalent of the following `IF` statement, in a simple scalar expression:

```sql
IF bool-expr THEN
    RETURN true-expr
ELSE
    RETURN false-expr
END IF
```

Example

```sql
MAIN
    DEFINE var VARCHAR(10)
    LET var = arg_val(1)
    DISPLAY IIF(var == "A", "Accepted", "Rejected")
END MAIN
```

NULL on page 502
The NULL constant is provided as the "nil" value.

Logical operators
Logical operators include NOT, AND and OR.

Table 117: Logical operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NOT</strong> on page 311</td>
<td>The NOT operator performs a logical negation to invert a boolean expression.</td>
</tr>
<tr>
<td><strong>AND</strong> on page 312</td>
<td>The AND operator is the logical intersection operator.</td>
</tr>
<tr>
<td><strong>OR</strong> on page 312</td>
<td>The OR operator is the logical union operator.</td>
</tr>
</tbody>
</table>

**NOT**
The NOT operator performs a logical negation to invert a boolean expression.

**Syntax**

```
NOT bool-expr
```

1. `bool-expr` is a boolean expression.

**Usage**
The NOT operator is typically used to invert the value of a boolean expression.

If the operand is NULL, the negation expression evaluates to NULL.

**Example**

```
MAIN
  IF NOT ( 256 == 257 ) THEN
    DISPLAY "This line should display"
  END IF
END MAIN
```

Related concepts

Boolean expressions on page 294

Expressions on page 293
Shows the possible expressions supported in the language.

IF on page 350
The IF instruction executes a group of statements conditionally.

NULL on page 502
The NULL constant is provided as the "nil" value.

**AND**
The AND operator is the logical intersection operator.

**Syntax**

```
bool-expr AND bool-expr
```

1. *bool-expr* is a boolean expression.

**Usage**

If one of the operands is NULL, the logical expression evaluates to FALSE.

By default, the runtime system evaluates both operands on the left and right side of the AND keyword. This is the traditional behavior of the Genero language, but in fact the right operand does not need to be evaluated if the first operand evaluates to FALSE. This method is called *short-circuit evaluation*, and can be enabled by adding the `OPTIONS SHORT CIRCUIT` clause at the beginning of the module.

**Example**

```main
MAIN
  IF 256!=257 AND 257==257 THEN
    DISPLAY "This line should display"
  END IF
END MAIN
```

**Related concepts**

  This section covers boolean expression evaluation rules.

- **Expressions** on page 293
  Shows the possible expressions supported in the language.

- **IF** on page 350
  The IF instruction executes a group of statements conditionally.

**OR**
The OR operator is the logical union operator.

**Syntax**

```
bool-expr OR bool-expr
```

1. *bool-expr* is a boolean expression.

**Usage**

If one of the operands is NULL, the logical expression evaluates to FALSE.

By default, the runtime system evaluates both operands on the left and right side of the OR keyword. This is the traditional behavior of the Genero language, but in fact the right operand does not need to be evaluated if the first operand evaluates to TRUE. This method is called *short-circuit evaluation*, and can be enabled by adding the `OPTIONS SHORT CIRCUIT` clause at the beginning of the module.
Example

```plaintext
MAIN
  IF TRUE OR FALSE THEN
    DISPLAY "This line should display"
  END IF
END MAIN
```

Arithmetic operators

Arithmetic operators allow you to complete numeric operations, such as addition and subtraction.

**Table 118: Arithmetic operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Addition (+)</td>
<td>The + operator adds a number to another.</td>
</tr>
<tr>
<td>Subtraction (-)</td>
<td>The – operator subtracts a number from another.</td>
</tr>
<tr>
<td>Multiplication (*)</td>
<td>The * operator multiplies a number with another.</td>
</tr>
<tr>
<td>Division (/)</td>
<td>The / operator divides a number by another.</td>
</tr>
<tr>
<td>Exponentiation (**)</td>
<td>The ** operator calculates an exponentiation.</td>
</tr>
<tr>
<td>MOD</td>
<td>The MOD operator calculates the modulus.</td>
</tr>
</tbody>
</table>

**Addition (+)**
The + operator adds a number to another.

**Syntax**

```
numExpr1 + numExpr2
```

1. `numExpr` is a numeric expression.

**Usage**

Use the + operator to add two numeric values.

If one of the operands is NULL, the arithmetic expression evaluates to NULL.

**Example**

```plaintext
MAIN
  DISPLAY 100 + 200
END MAIN
```

**Related concepts**

- **Numeric expressions** on page 296
This section covers numeric expression evaluation rules.

**Subtraction (-)**
The - operator subtracts a number from another.

**Syntax**

```
num-expr - num-expr
```

1. `num-expr` is a numeric expression.

**Usage**

Use the - operator to subtract a numeric value from another numeric value.

If one of the operands is NULL, the arithmetic expression evaluates to NULL.

**Example**

```
MAIN
  DISPLAY 100 - 200
END MAIN
```

**Related concepts**

*Numeric expressions* on page 296

This section covers numeric expression evaluation rules.

**Multiplication (*)**
The * operator multiplies a number with another.

**Syntax**

```
num-expr * num-expr
```

1. `num-expr` is a numeric expression.

**Usage**

Use the * operator to multiply a numeric value to another numeric value.

If one of the operands is NULL, the arithmetic expression evaluates to NULL.

**Example**

```
MAIN
  DISPLAY 100 * 200
END MAIN
```

**Related concepts**

*Numeric expressions* on page 296

This section covers numeric expression evaluation rules.

**Division (/)**
The / operator divides a number by another.

**Syntax**

```
num-expr / num-expr
```
1. *num-exp* is a numeric expression.

**Usage**

Use the `/` operator to divide a numeric value by another numeric value.

If one of the operands is NULL, the arithmetic expression evaluates to NULL.

**Example**

```
MAIN
  DISPLAY 100 / 200
END MAIN
```

**Related concepts**

Numeric expressions on page 296

This section covers numeric expression evaluation rules.

**Exponentiation (**)**

The `**` operator calculates an exponentiation.

**Syntax**

```
num-exp ** int-exp
```

1. *num-exp* is a numeric expression.

**Usage**

The `**` operator returns a value calculated by raising the left-hand operand to a power corresponding to the integer part of the right-hand operand.

If the right operand is a number with a decimal part, it is rounded to a whole integer before computing the exponentiation.

**Example**

```
MAIN
  DISPLAY 2 ** 8
  DISPLAY 10 ** 4
END MAIN
```

**Related concepts**

Numeric expressions on page 296

This section covers numeric expression evaluation rules.

**MOD**

The `MOD` operator calculates the modulus.

**Syntax**

```
int-exp MOD int-exp
```

1. *int-exp* is an integer expression.

**Usage**

The `MOD` operator returns the remainder, as an integer, from the division of the integer part of two numbers.

If the right operand is a number with a decimal part, it is rounded to a whole integer before computing the modulus.
Example

```
MAIN
   DISPLAY 256 MOD 16
   DISPLAY 26 MOD 2
   DISPLAY 27 MOD 2
END MAIN
```

<td>The LSTR() operator returns a localized string.</td>
</tr>
<tr>
<td>SFMT() on page 323</td>
<td>The SFMT() operator replaces place holders in a string with values.</td>
</tr>
</tbody>
</table>

**ASCII()**
The ASCII() operator produces an ASCII character.

**Syntax**

```
ASCII ( int-expr )
```

1. `int-expr` is an integer expression, in the range 0-255 or 0-127, depending on the current locale.

**Usage**
The ASCII() operator returns the character corresponding to the ASCII code passed as a parameter, in the current encoding of the application locale.

The possible values of the integer parameter passed to ASCII() depends on the locale settings:

- For single byte encodings (like ISO8859-1), the argument must be in the range of 0 to 255.
• For UTF-8, using char length semantics, the argument must be any valid 16bit code point (in the range 0-65535).
• For any other locale setting (any multibyte character set, or UTF-8 using byte length semantics), the argument must be in the range 0 to 127.

The ASCII() function can be also used to produce special characters such as escape (ASCII(27)), newline (ASCII(10)), horizontal tab (ASCII(9)).

When the argument is zero, ASCII() has a different behavior, depending on the context:

• ASCII(0) only displays the NULL character within the PRINT statement.
• If you specify ASCII(0) in other contexts, it returns a blank space.

Example

```small
MAIN
  DISPLAY ASCII(65), ASCII(66), ASCII(7)
END MAIN
```

Related concepts

PRINT on page 1952
Formats and prints a row of data in a report routine.

NULL on page 502
The NULL constant is provided as the "nil" value.

COLUMN
The COLUMN operator generates blanks.

Syntax

```plaintext
COLUMN position
```

1. position is the column position (starts at 1).

Usage

The COLUMN operator is typically used in report routines to align data in PRINT statements and move the character position forward within the current line. This operator makes sense when used in an expression with the comma append operator: Spaces will be generated depending on the number of characters that have been used in the expression, before the COLUMN operator.

The COLUMN operator can be used outside report routines, in order to align data to be displayed with a proportional font, typically in a TUI context. For example, the next lines will always display the content of the lastname variable starting from column 30 of the terminal, no matters the number of characters contained in the firstname variable. The example defines VARCHAR variables, since CHAR variables are blank-padded, we would need to use the CLIPPED operator:

```small
DEFINE firstname, lastname VARCHAR(50)
```
DISPLAY firstname, COLUMN(30), lastname

The pos operand must be a non-negative integer that specifies a character position offset (from the left margin) no greater than the line width (that is, no greater than the difference (right margin - left margin). This designation moves the character position to a left-offset, where 1 is the first position after the left margin. If current position is greater than the operand, the COLUMN specification is ignored.

Example

PAGE HEADER
  PRINT "Number", COLUMN 12,"Name", COLUMN 35,"Location"
ON EVERY ROW
  PRINT customer_num, COLUMN 12, fname, COLUMN 35,city

Related concepts

PRINT on page 1952
Formats and prints a row of data in a report routine.

CHAR(size) on page 257
The CHAR data type is a fixed-length character string data type.

VARCHAR(size) on page 273
The VARCHAR data type is a variable-length character string data type, with a maximum size.

CLIPPED on page 321
The CLIPPED operator removes trailing blanks of a string expression.

Concatenate (||)
The || operator makes a string concatenation.

Syntax

expr || expr

1. expr can be a character, numeric or date time expression.

Usage

The || operator is the concatenation operator that produces a string expression from the expression elements on both sides of the operator.

This operator has a high precedence; it can be used in parameters for function calls. The precedence of this operator is higher than LIKE and MATCHES, but less than arithmetic operators. For example, a || b + c is equivalent to (a || (b+c)).

If any of the members of a concatenation expression is NULL, the result string will be NULL.

Example

MAIN
  DISPLAY "Length: " || length( "ab" || "cdef" )
END MAIN

Related concepts

LIKE on page 303
The LIKE operator returns TRUE if a string matches a given mask.

MATCHES on page 304
The MATCHES operator returns TRUE if a string matches a given mask.

NULL on page 502
The NULL constant is provided as the "nil" value.

**Append (,)** on page 319
The , (comma) appends an expression to a string.

**Syntax**

```
char-exp, expr
```

**Usage**

The comma operator formats and concatenates expressions together.

This operator can only be used in some instructions such as `LET`, `PRINT`, `MESSAGE`, `ERROR` and `DISPLAY` instructions.

As an alternative, use the `||` concatenation operator.

Use the comma concatenation operator when data needs to be formatted for printing and display.

**Example**

```
MAIN
  DISPLAY "Today:", TODAY, " and a number: ", 12345.67
END MAIN
```

**Related concepts**

**LET** on page 376
The LET statement assigns values to variables.

**DISPLAY (to stdout)** on page 1343
The DISPLAY instruction displays text in line mode to the standard output channel.

**Concatenate (||)** on page 318
The `||` operator makes a string concatenation.

**Substring ([s,e])**
The `[ ]` (square brackets) extract a substring.

**Syntax**

```
char-variable [ start \ L, end \ L ]
```

1. *char-variable* must be a character data type variable.
2. *start* defines the position of the first character of the substring to be extracted.
3. *end* defines the position of the last character of the substring to be extracted.
4. If *end* is not specified, only one character is extracted.

**Usage**

The `[ ]` (square brackets) notation following a `CHAR` or `VARCHAR` variable extracts a substring from that character variable.

The *start* and *end* arguments can be expressed in bytes or characters, depending on the length semantics used in your programs.

**Important:** Substring expressions in SQL statements are evaluated by the database server. This may have a different behavior than the substring operator of the language.
Example

```sql
MAIN
  DEFINE s CHAR(10)
  LET s = "abcdef"
  DISPLAY s[3,4]
END MAIN
```

Related concepts

Length semantics settings on page 414
CHAR(size) on page 257
The CHAR data type is a fixed-length character string data type.
VARCHAR(size) on page 273
The VARCHAR data type is a variable-length character string data type, with a maximum size.

USING
The USING operator converts date and numeric values to a string based on a formatting mask.

Syntax

```sql
expr USING format
```

1. `expr` is a language expression.
2. `format` is a string expression that defines the formatting mask to be used.

Usage

The USING operator applies a formatting string to the left operand.

The left operand must be a valid date, integer or decimal number. Note that DATETIME and INTERVAL expressions cannot be formatted with the USING operator.

The format string can be any valid string expression using formatting characters as described in Formatting numeric values on page 281 and Formatting DATE values on page 284.

The USING operator has a low order of precedence: if you use operators with a higher precedence, the resulting string might not be what you are expecting.

For example, the `||` concatenation operator is evaluated before USING. As a result:

```sql
LET x = a || b USING "format"
```

will first concatenate `a` and `b`, then apply the USING format.

To solve this issue, use parentheses around the USING expression:

```sql
LET x = a || (b USING "format")
```

Example

```sql
MAIN
  DEFINE d DECIMAL(12,2)
  LET d = -12345678.91
  DISPLAY d USING "$-##,###,##&.&&"
  DISPLAY TODAY USING "yyyy-mm-dd"
END MAIN
```

Related concepts

DBFORMAT on page 233
Defines currency symbol, decimal and thousands separator for input and display of numeric values.

**DBMONEY** on page 236
Defines currency symbol and decimal separator for input and display of numeric values, when DBFORMAT is not defined.

**Using the Ming Guo date format** on page 425
Genero BDL can be configured to use the The Ming Guo calendar.

**Length semantics settings** on page 414
This section covers string expression evaluation rules.

**DATE** on page 259
The DATE data type stores calendar dates with a Year/Month/Day representation.

**DATETIME qual1 TO qual2** on page 260
The DATETIME data type stores date and time data with time units from the year to fractions of a second.

**INTERVAL qual1 TO qual2** on page 265
The INTERVAL data type stores spans of time as Year/Month or Day/Hour/Minute/Second/Fraction units.

**Concatenate (||)** on page 318
The || operator makes a string concatenation.

**CLIPPED**
The CLIPPED operator removes trailing blanks of a string expression.

**Syntax**

```
expr CLIPPED
```

1. *expr* is a language expression.

**Usage**

This operator removes all trailing spaces of a string expression.

The CLIPPED operator is typically used to remove the trailing blanks of a CHAR value, which would be printed otherwise.

**Example**

```
MAIN
    DISPLAY "Some text   " CLIPPED
END MAIN
```

**Related concepts**

**CHAR(size)** on page 257
The CHAR data type is a fixed-length character string data type.

**ORD()**
The ORD () operator returns the code point of a character in the current locale.

**Syntax**

```
ORD( source STRING )
```

1. *source* is a string expression.
Usage
The value returned by `ORD()` is the code point in the current locale of the character passed as argument. Only the first character of the argument is evaluated.
When using UTF-8 with character length semantics, the `ORD()` operator returns the UNICODE code point of the character.
`ORD` returns `NULL` if the argument passed is not valid.

Related concepts
Defining the application locale on page 412
This section describes the settings defining the application locale, changing the behavior of the compilers and runtime system.
`fgl_keyval()` on page 2170
Returns the key code of a logical or physical key.
`ASCII()` on page 316
The `ASCII()` operator produces an ASCII character.

SPACES
The `SPACES` operator returns a character string with blanks.

Syntax

```
int-expr SPACES
```

1. `int-expr` is an integer expression.
2. `SPACE` (without S) is an alias for this operator.

Usage
The `SPACE` operator is typically used in reports to print spaces to align data in the report output.

Example

```
MAIN
  DISPLAY 20 SPACES || "xxx"
END MAIN
```

Related concepts
Reports on page 1924
`Integer expressions` on page 296
This section covers integer expression evaluation rules.

LSTR()
The `LSTR()` operator returns a localized string.

Syntax

```
LSTR(str-expr)
```

1. `str-expr` is a string expression.

Usage
The `LSTR()` operator returns a localized string corresponding to the identifier passed as parameter.
Normally localized strings are automatically replaced when using the `%"ident"` notation in the source code. When the localized string identifier is not known at compile time, use the `LSTR()` function.

**Example**

```lisp
MAIN
  DISPLAY LSTR ("str"|123) -- loads string 'str123'
END MAIN
```

**Related concepts**

*Localized strings* on page 430

*Localized strings* provide a means of writing applications in which the text of strings can be customized on site.

**SFMT()**

The `SFMT()` operator replaces place holders in a string with values.

**Syntax**

```
SFMT(str-expr, param1, param2, ...)
```

1. `str-expr` is a string expression.
2. `param` is any valid expression used to replace parameter place holders (`%n`).
3. At least one parameter is required.

**Usage**

The `SFMT()` operator can be used with parameters that will be automatically set in the string at the position defined by parameter placeholders. The parameters used with the `SFMT()` operator can be any valid expressions. Numeric and date/time expressions are evaluated to strings depending on the current format settings (`DBDATE`, `DBMONEY`).

A placeholder a is special marker in the string, that is defined by the percent character followed by the parameter number. For example, `%4` represents the parameter `#4`. You are allowed to use the same parameter placeholder several times in the string. If you want to use the percent sign in the string, you must escape it with `%%`.

Predefined placeholders can be used to insert information about last runtime system error that occurred. Note that these are only available in the context of a runtime error trapped with a `WHENEVER ERROR GOTO / CALL` handler:

**Table 120: Predefined placeholders for runtime system error information**

<table>
<thead>
<tr>
<th>Predefined parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%(ERRORFILE)</td>
<td>Name of the module where last runtime error occurred.</td>
</tr>
<tr>
<td>%(ERRORLINE)</td>
<td>Line number in the module where last runtime error occurred.</td>
</tr>
<tr>
<td>%(ERRNO)</td>
<td>Last operating system error number.</td>
</tr>
<tr>
<td>%(STRERROR)</td>
<td>Last operating system error text.</td>
</tr>
</tbody>
</table>

**Example**

```lisp
MAIN
  DEFINE n INTEGER
  LET n = 234
  DISPLAY SFMT("Order #%1 has been %2.",n,"deleted")
END MAIN
```

In this example, `%1` is replaced by the value of the variable `n`, while `%2` is replaced by the string "deleted", resulting in: *Order #234 has been deleted.*
**Related concepts**

*String expressions* on page 297
This section covers string expression evaluation rules.

**DBDATE** on page 232
Defines the default display and input format for DATE values.

**DBMONEY** on page 236
Defines currency symbol and decimal separator for input and display of numeric values, when DBFORMAT is not defined.

**WHENEVER instruction** on page 452
Use the WHENEVER instruction to define how exceptions must be handled for the rest of the module.

**Associative syntax operators**
Associative syntax operators allow you to group together objects.

**Table 121: Associative syntax operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parentheses ( () ) on page 324</td>
<td>Parentheses ( () ) force the evaluation of an expression before other operators.</td>
</tr>
<tr>
<td>Membership (object.member) on page 325</td>
<td>Separator for object members.</td>
</tr>
<tr>
<td>Variable parameter list ( [ ] ) on page 325</td>
<td>Variable parameter list delimiters.</td>
</tr>
</tbody>
</table>

**Parentheses ( () )**
Parentheses ( () ) force the evaluation of an expression before other operators.

**Syntax**

```
(expr [ ... ])
```

1. *expr* is a language expression.

**Usage**

Parentheses can be used to change the order in which expression elements are evaluated, to bypass the precedence of operators.

Parentheses can also be used to ease the readability of the code in a complex expression.

**Example**

```
MAIN
  DEFINE n INTEGER
  LET n = ( ( 3 + 2 ) * 2 )
  IF n=10 AND ( n<>0 OR n>=20 ) THEN
    DISPLAY "OK"
  END IF
END MAIN
```

**Related concepts**

*Order of precedence* on page 299
The order of precedence defines in which order the elements of an expression are evaluated.

*Expressions* on page 293
Membership (object.member)
Separator for object members.

Syntax

\[ setname.element \]

Usage

The period expression element specifies that its right-hand operand is a member of the set whose name is its left-hand operand.

This notation is used to reference RECORD members, object and class methods, as well as module elements.

Example

```gdml
IMPORT FGL customer_module
...
MAIN
  DEFINE rec RECORD
      n INTEGER,
      c CHAR(10)
  END RECORD
  DEFINE form ui.Form
  LET rec.n = 12345
  LET rec.c = "abcdef"
  ...
  CALL form.setElementHidden("page1")
  ...
  CALL customer_module.check(345)
  ...
END MAIN
```

Related concepts

- **Records** on page 382
  Records allow structured program variables definitions.

- **Built-in packages** on page 2244
  These topics cover the built-in classes provided by the Genero Business Development Language.

- **Importing modules** on page 496
  Use the IMPORT ... instruction to import BDL, C or Java external modules in the current module.

Variable parameter list ( [ ] )
Variable parameter list delimiters.

Syntax

\[ [ variable [, ...] ] \]

Usage

The square brace notation in function parameters defines a variable list of arguments for a built-in function or a built-in class method.

The elements of a variable parameter list are program variables which are passed by reference. As result, the called function can modify the content of the passed variables, to return values in output parameters.
It is not possible to define user functions with variable parameter lists.

For real usage examples, see the read and write methods of the `base.Channel` class.

**Example**

```
MAIN
   DEFINE id INTEGER, name STRING,
       count INTEGER, stat INTEGER
   LET id = 12345
   LET name = "Forman"
   -- Warning: This is a fake call, the function does not exist!
   -- Here, id and name are passed as input values, while count
   -- and stat are used as output parameters...
   CALL built_in_function( [id,name], [count, stat] )
END MAIN
```

**Related concepts**

Read and write formatted data on page 2286

**SQL related operators**

SQL related operators allow you to retrieve the SQL state and the SQL error message.

**Table 122: SQL related operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQLSTATE on page 326</td>
<td>The <code>SQLSTATE</code> variable returns the code corresponding to the last SQL error.</td>
</tr>
<tr>
<td>SQLERRMESSAGE on page 327</td>
<td>The <code>SQLERRMESSAGE</code> variable holds the error message corresponding to the last SQL error.</td>
</tr>
</tbody>
</table>

**SQLSTATE**

The `SQLSTATE` variable returns the code corresponding to the last SQL error.

**Syntax**

```
SQLSTATE
```

**Usage**

The `SQLSTATE` predefined variable returns the ANSI/ISO SQLSTATE code when an SQL error occurred.

The `SQLSTATE` error code is a standard ANSI specification, but not all database engines support this feature. Check the database server documentation for more details.

The variable is `NULL` if the last SQL statement was successful.

**Example**

```
MAIN
   DATABASE stores
   WHENEVER ERROR CONTINUE
   SELECT foo FROM bar
   DISPLAY SQLSTATE
END MAIN
```

**Related concepts**

SQL execution diagnostics on page 529
If an SQL statement execution fails, error description can be found in the `SQLCA.SQLCODE`, `SQLSTATE`, `STATUS` and `SQLERRMESSAGE` predefined registers.

**SQLERRMESSAGE**
The `SQLERRMESSAGE` variable holds the error message corresponding to the last SQL error.

**Syntax**

```java
SQLERRMESSAGE
```

**Usage**
The `SQLERRMESSAGE` predefined variable returns the error message if an SQL error occurred. The variable is `NULL` if the last SQL statement was successful.

**Example**

```java
MAIN
  DATABASE stores
  WHENEVER ERROR CONTINUE
  SELECT foo FROM bar
  DISPLAY SQLERRMESSAGE
END MAIN
```

**Related concepts**

SQL execution diagnostics on page 529
If an SQL statement execution fails, error description can be found in the `SQLCA.SQLCODE`, `SQLSTATE`, `STATUS` and `SQLERRMESSAGE` predefined registers.

**Data type operators**
Data type operators allow you cast a data type or create an instance of a data type.

**Table 123: Data type operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CAST</strong> on page 327</td>
<td>The <code>CAST</code> operator converts a Java object to the user-defined type or Java class specified.</td>
</tr>
<tr>
<td><strong>INSTANCEOF</strong> on page 328</td>
<td>The <code>INSTANCEOF</code> checks the class of an object.</td>
</tr>
</tbody>
</table>

**CAST**
The `CAST` operator converts a Java object to the user-defined type or Java class specified.

**Syntax**

```java
CAST( obj AS type )
```

1. `obj` is a Java object.
2. `type` is a user-defined type or a Java class.

**Usage**
The `CAST()` operator is required when you want to assign an object reference to variable defined with a user-defined type or Java class which requires narrowing reference conversion.
Example

In this example, when assigning a `java.lang.StringBuffer` reference to a `java.lang.Object` variable, widening reference conversion occurs and no `CAST()` operator is needed, but when assigning an `java.lang.Object` reference to a `java.lang.StringBuffer` variable, you must cast the object reference to a `java.lang.StringBuffer`:

```plaintext
IMPORT JAVA java.lang.Object
IMPORT JAVA java.lang.StringBuffer
MAIN
   DEFINE sb1, sb2 java.lang.StringBuffer
   DEFINE o java.lang.Object
   LET sb1 = StringBuffer.create()
   LET o = sb1 -- Widening Reference Conversion does not need CAST()
   LET sb2 = CAST( o AS java.lang.StringBuffer ) -- Narrowing
      -- Reference Conversion needs CAST()
END MAIN
```

In order to cast an `fgl.FglRecord` object to a regular `RECORD`, you need to specify a user-defined type (TYPE definition):

```plaintext
IMPORT JAVA com.fourjs.fgl.lang.FglRecord
TYPE mytype RECORD f1, f2 INTEGER END RECORD
MAIN
   DEFINE r mytype
   DEFINE jr fgl.FglRecord
   LET jr = r
   LET r = CAST(jr AS mytype)
      -- This is denied:
      --   CAST(jr AS RECORD f1, f2 INTEGER END RECORD)
END MAIN
```

Related concepts

The INSTANCEOF operator on page 2097

The Java interface on page 2071

The Java interface allows you to import Java classes and instantiate Java objects in your programs.

INSTANCEOF

The INSTANCEOF checks the class of an object.

Syntax

```plaintext
expr INSTANCEOF type
```

1. `expr` can be any expression supported by the language.
2. `type` is a structured user defined type or a Java class.

Usage

The INSTANCEOF operator evaluates to `TRUE` if the object reference is of the type or class specified.

The INSTANCEOF operator is used to check if an expression (usually, an object reference) is one of the type or class specified by `type`.

Example

```plaintext
IMPORT JAVA java.lang.Object
IMPORT JAVA java.lang.StringBuffer
IMPORT JAVA java.lang.Number
MAIN
   DEFINE o java.lang.Object
```
DEFINE sb java.lang.StringBuffer
LET sb = StringBuffer.create()
LET o = sb
DISPLAY sb INSTANCEOF java.lang.StringBuffer  -- shows 1
DISPLAY o INSTANCEOF java.lang.StringBuffer  -- shows 1
DISPLAY o INSTANCEOF java.lang.Number  -- shows 0
END MAIN

Related concepts

The Java interface allows you to import Java classes and instantiate Java objects in your programs.

Assignment operators
An assignment operator allows you to assign a variable with an expression.

Table 124: Assignment operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Assignment (:=) on page 329</td>
<td>The := operator assigns a variable with an expression and returns the result.</td>
</tr>
</tbody>
</table>

Assignment (:=)
The := operator assigns a variable with an expression and returns the result.

Syntax

variable := expr

Usage

The := assignment operator puts a value in the left-hand variable and the resulting value can again be used in an expression.

Do not confuse with the LET instruction.

The := assignment operator has the lowest precedence, it can be used at many places and can simplify coding.

Example

In the next example, the := operator is used to increment the array index before usage:

MAIN
   DEFINE arr DYNAMIC ARRAY OF STRING,
       idx INTEGER
   LET idx = 0
   LET arr[idx:=idx+1] = "One"
   LET arr[idx:=idx+1] = "Two"
   LET arr[idx:=idx+1] = "Three"
END MAIN

Related concepts
LET on page 376
The LET statement assigns values to variables.

**Date and time operators**
Date and time operators allow you to work with date and time values.

**Table 125: Date and time operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT</td>
<td>The CURRENT operator returns the current system date and time.</td>
</tr>
<tr>
<td>EXTEND()</td>
<td>The EXTEND() operator adjusts a date time value depending on the qualifier.</td>
</tr>
<tr>
<td>DATE()</td>
<td>The DATE() operator converts an expression to a DATE value.</td>
</tr>
<tr>
<td>TIME()</td>
<td>The TIME() operator returns a time part of the date time expression.</td>
</tr>
<tr>
<td>TODAY</td>
<td>The TODAY operator returns the current calendar date.</td>
</tr>
<tr>
<td>YEAR()</td>
<td>The YEAR() operator extracts the year of a date time expression.</td>
</tr>
<tr>
<td>MONTH()</td>
<td>The MONTH() operator extracts the month of a date time expression.</td>
</tr>
<tr>
<td>DAY()</td>
<td>The DAY() operator extracts the day of the month of a date time expression.</td>
</tr>
<tr>
<td>WEEKDAY()</td>
<td>The WEEKDAY() operator extracts the day of the week of a date time expression.</td>
</tr>
<tr>
<td>MDY()</td>
<td>The MDY() operator creates a date from month, day and year units.</td>
</tr>
<tr>
<td>UNITS</td>
<td>The UNITS operator converts an integer to an interval.</td>
</tr>
</tbody>
</table>

**CURRENT**
The CURRENT operator returns the current system date and time.

**Syntax**

```
CURRENT \qual1 TO \qual2 \(\scale\)
```

1. `\qual1`, `\qual2` and `\scale` define the date time qualifier.

**Usage**
The CURRENT operator returns the system date/time in the current local timezone.

This operator can be used to assign the current system date and time to a DATETIME variable.

Use optional datatime qualifiers to specify the precision of the returned value. The possible qualifiers are the same as in a DATETIME data type definition.

If the datatime qualifiers are not specified after the CURRENT keyword, the precision defaults to YEAR TO FRACTION(3) precision.

**Example**

```
MAIN
```
## Related concepts

**DATETIME qual1 TO qual2** on page 260

The DATETIME data type stores date and time data with time units from the year to fractions of a second.

**EXTEND()**

The EXTEND() operator adjusts a date time value depending on the qualifier.

### Syntax

```plaintext
EXTEND ( dt-expr, qual1 TO qual2 [scale]
```

1. `dt-expr` is a date / time expression.
2. `qual1`, `qual2` and `scale` define the date time qualifier.

### Usage

The EXTEND() operator is used to convert a date time expression to a DATETIME value with a different precision. The default qualifier is `YEAR TO DAY`.

The possible qualifiers are the same as in a DATETIME data type definition.

The expressions passed as first parameter must be a valid datetime value. If it is a character string, it must consist of valid and unambiguous time-unit values and separators, but with these restrictions:

- It cannot be a character string in date format, such as "12/12/99".
- It cannot be an ambiguous numeric datetime value, such as "05:06" or "05".
- It cannot be a time expression that returns an INTERVAL value.

### Example

```plaintext
MAIN
    DISPLAY EXTEND ( TODAY, YEAR TO FRACTION(4) )
END MAIN
```

### Related concepts

**DATETIME qual1 TO qual2** on page 260

The DATETIME data type stores date and time data with time units from the year to fractions of a second.

**INTERVAL qual1 TO qual2** on page 265

The INTERVAL data type stores spans of time as Year/Month or Day/Hour/Minute/Second/Fraction units.

**DATE()**

The DATE() operator converts an expression to a DATE value.

### Syntax

```plaintext
DATE (expr)
```

1. `expr` is the expression to be converted to a date.

### Usage

DATE() converts a character string, an integer or datetime expression to a DATE value.
When `expr` is a character string expression, it must properly formatted by following the datetime format settings like `DBDATE`.

If `expr` is an integer expression, it is used as the number of days since December 31, 1899.

If you supply no operand, it returns a character representation of the current date in the format "weekday month day year".

**Example**

```
MAIN
   DISPLAY DATE ( 34000 )
   DISPLAY DATE ( "12/04/1978" )
   DISPLAY DATE ( CURRENT )
END MAIN
```

**Related concepts**

- **DATE** on page 259
  The `DATE` data type stores calendar dates with a Year/Month/Day representation.

- **DBDATE** on page 232
  Defines the default display and input format for `DATE` values.

- **String expressions** on page 297
  This section covers string expression evaluation rules.

- **Date expressions** on page 297
  This section covers date expression evaluation rules.

- **Integer expressions** on page 296
  This section covers integer expression evaluation rules.

**TIME()**
The `TIME()` operator returns a time part of the date time expression.

**Syntax**

```
TIME [ (datetime-expr) ]
```

1. `datetime-expr` is a datetime expression.

**Usage**

`TIME()` converts the time-of-day portion of its datetime operand to a character string.

This operator converts a date time expression to a character string representing the time-of-day part of its operand.

The format of the returned string is always "hh:mm:ss".

If you supply no operand, it returns a character representation of the current time. You can use the `CURRENT` operator to get a datetime result of the current system time.

**Example**

```
MAIN
   DISPLAY TIME ( CURRENT )
END MAIN
```

**Related concepts**

- **Datetime expressions** on page 298
  This section covers date-time expression evaluation rules.

- **CURRENT** on page 330
The `CURRENT` operator returns the current system date and time.

**TODAY**
The `TODAY` operator returns the current calendar date.

**Syntax**

```
TODAY
```

**Usage**

`TODAY` returns the current system date as a `DATE` value, in the current local timezone.

This operator can be used to assign the current system date to a `DATE` variable.

The `TODAY` operator is the `DATE` equivalent for the `CURRENT` operator used for `DATETIME`.

**Example**

```
MAIN
  DISPLAY TODAY
END MAIN
```

**Related concepts**

- `DATE` on page 259
  The `DATE` data type stores calendar dates with a Year/Month/Day representation.
- `CURRENT` on page 330
  The `CURRENT` operator returns the current system date and time.

**YEAR()**
The `YEAR()` operator extracts the year of a date time expression.

**Syntax**

```
YEAR ( expr )
```

1. `expr` is a date / time expression.

**Usage**

Returns an integer corresponding to the year portion of its operand.

**Example**

```
MAIN
  DISPLAY YEAR ( TODAY )
  DISPLAY YEAR ( CURRENT )
END MAIN
```

**Related concepts**

- `DATE` on page 259
  The `DATE` data type stores calendar dates with a Year/Month/Day representation.
- `MONTH()` on page 334
  The `MONTH()` operator extracts the month of a date time expression.
- `DAY()` on page 334
  The `DAY()` operator extracts the day of the month of a date time expression.
- `WEEKDAY()` on page 335
The \texttt{WEEKDAY()} operator extracts the day of the week of a date time expression.

\texttt{MDY()} on page 335
The \texttt{MDY()} operator creates a date from month, day and year units.

\textbf{MONTH()}

The \texttt{MONTH()} operator extracts the month of a date time expression.

**Syntax**

\texttt{MONTH ( \textit{expr} )}

1.  \textit{expr} is a date / time expression.

**Usage**

Returns a positive whole number between 1 and 12 corresponding to the month of its operand.

**Example**

\begin{verbatim}
MAIN
  DISPLAY MONTH ( TODAY )
  DISPLAY MONTH ( CURRENT )
END MAIN
\end{verbatim}

**Related concepts**

\texttt{DATE} on page 259
The \texttt{DATE} data type stores calendar dates with a Year/Month/Day representation.

\texttt{YEAR()} on page 333
The \texttt{YEAR()} operator extracts the year of a date time expression.

\texttt{DAY()} on page 334
The \texttt{DAY()} operator extracts the day of the month of a date time expression.

\texttt{WEEKDAY()} on page 335
The \texttt{WEEKDAY()} operator extracts the day of the week of a date time expression.

\texttt{MDY()} on page 335
The \texttt{MDY()} operator creates a date from month, day and year units.

\textbf{DAY()}

The \texttt{DAY()} operator extracts the day of the month of a date time expression.

**Syntax**

\texttt{DAY ( \textit{expr} )}

1.  \textit{expr} is a date / time expression.

**Usage**

Returns a positive whole number between 1 and 31 corresponding to the day of the month of its operand.

**Example**

\begin{verbatim}
MAIN
  DISPLAY DAY ( TODAY )
  DISPLAY DAY ( CURRENT )
END MAIN
\end{verbatim}
Related concepts

The `DATE` data type stores calendar dates with a Year/Month/Day representation.

The `YEAR()` operator extracts the year of a date time expression.

The `MONTH()` operator extracts the month of a date time expression.

The `WEEKDAY()` operator extracts the day of the week of a date time expression.

The `MDY()` operator creates a date from month, day and year units.

Syntax

```
WEEKDAY(expr)
```

1. `expr` is a date / time expression.

Usage

Returns a positive whole number between 0 and 6 corresponding to the day of the week implied by its operand.

The integer 0 (Zero) represents Sunday.

Example

```
MAIN
  DISPLAY WEEKDAY( TODAY )
  DISPLAY WEEKDAY( CURRENT )
END MAIN
```
2. \( expr2 \) is an integer representing the day (from 1 to 28, 29, 30 or 31 depending on the month).
3. \( expr3 \) is an integer representing the year (four digits).

**Usage**

The `MDY()` operator builds a date value with 3 integers representing the month, day and year.

The result is a `DATE` value.

This function is sensitive to the `C1` modifier of the `DBDATE` environment variable, defining a Ming Guo date format.

**Example**

```gdl
MAIN
  DISPLAY MDY ( 12, 3+2, 1998 )
END MAIN
```

**Related concepts**

- [DATE](#) on page 259
  - The `DATE` data type stores calendar dates with a Year/Month/Day representation.
- [YEAR()](#) on page 333
  - The `YEAR()` operator extracts the year of a date time expression.
- [MONTH()](#) on page 334
  - The `MONTH()` operator extracts the month of a date time expression.
- [DAY()](#) on page 334
  - The `DAY()` operator extracts the day of the month of a date time expression.
- [WEEKDAY()](#) on page 335
  - The `WEEKDAY()` operator extracts the day of the week of a date time expression.
- [Using the Ming Guo date format](#) on page 425
  - Genero BDL can be configured to use the The Ming Guo calendar.

**UNITS**

The `UNITS` operator converts an integer to an interval.

**Syntax**

\[ expr \text{ UNITS } qual[,scale] \]

where `qual` can be one of:

- `YEAR`
- `MONTH`
- `DAY`
- `HOUR`
- `MINUTE`
- `SECOND`
- `FRACTION(1-6)`

1. \( expr \) is an integer expression.

**Usage**

The `UNITS` operator converts an integer expression to an `INTERVAL` value expressed in a single unit of time that you specify after the `UNITS` keyword.

For the qualifiers `YEAR`, `MONTH`, `DAY`, `HOUR` and `SECOND`, if the left-hand expression evaluates to a decimal number, any fractional part is discarded before the `UNITS` operator is applied. However, when using `UNITS`
FRACTION, the expression can be a decimal number where the integer part is interpreted as a number of seconds, and the decimal part as the fraction of a second:

```
MAIN
    DEFINE iv INTERVAL SECOND(9) TO FRACTION(5)
    LET iv = 76242.77999 UNITS FRACTION
    DISPLAY iv -- Displays " 76242.77999"
END MAIN
```

The UNITS operator can be used to compare INTERVAL values. For example, to check if an INTERVAL SECOND(9) TO SECOND is negative:

```
FUNCTION is_negative( iv INTERVAL SECOND(9) TO SECOND )
    RETURN (iv < 0 UNITS SECOND )
END FUNCTION
```

UNITS has a higher precedence than any arithmetic or boolean operator. As a result, a left-hand arithmetic expression that uses a UNITS operator must be enclosed in parentheses. For example, \(10 + 20\) UNITS MINUTES will be evaluated as \(10 + (20\) UNITS MINUTES\) and give a conversion error. It must be written \((10 + 20)\) UNITS MINUTES to get the expected result.

Because the difference between two DATE values is an integer count of days rather than an INTERVAL data type, you might want to use the UNITS operator to convert such differences explicitly to INTERVAL values:

```
MAIN
    DEFINE d DATE
    LET d = TODAY + 200
    DISPLAY (d - TODAY) UNITS DAY
END MAIN
```

### Related concepts

**INTERVAL qual1 TO qual2** on page 265
The INTERVAL data type stores spans of time as Year/Month or Day/Hour/Minute/Second/Fraction units.

**DATETIME qual1 TO qual2** on page 260
The DATETIME data type stores date and time data with time units from the year to fractions of a second.

**Integer expressions** on page 296
This section covers integer expression evaluation rules.

**EXTEND()** on page 331
The EXTEND() operator adjusts a date time value depending on the qualifier.

### Dialog handling operators

Dialog handling operators allow you to handle variables in a DIALOG statement.

**Table 126: Dialog handling operators**

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_FLDBUF() on page 338</td>
<td>The GET_FLDBUF() operator returns as character strings the current values of the specified fields.</td>
</tr>
<tr>
<td>INFIELD() on page 338</td>
<td>The INFIELD() operator checks for the current screen field.</td>
</tr>
<tr>
<td>FIELD_TOUCHED() on page 339</td>
<td>The FIELD_TOUCHED() operator checks if fields were modified during the dialog execution.</td>
</tr>
</tbody>
</table>
GET_FLDBUF()

The GET_FLDBUF() operator returns as character strings the current values of the specified fields.

Syntax

```
GET_FLDBUF ( [group.].field [ , ... ] )
```

1. `group` can be a table name, a screen record, a screen array or FORMONLY.
2. `field` is the name of the screen field.

Usage

The GET_FLDBUF() operator is used to get the value of a screen field before the input buffer is copied into the associated variable.

**Note:** Use of this operator is recommended only in dialogs allowing field input (INPUT, INPUT ARRAY, CONSTRUCT). The behavior is undefined when used in DISPLAY ARRAY.

The GET_FLDBUF() operator takes the field names as identifiers, not as string expressions:

```
LET v = GET_FLDBUF( customer.custname )
```

If multiple fields are specified between parentheses, use the RETURNING clause:

```
CALL GET_FLDBUF( customer.* ) RETURNING rec_customer.*
```

When used in a INPUT ARRAY instruction, the runtime system assumes that you are referring to the current row.

The values returned by this operator are context dependent; it must be used carefully. If possible, use the variable associated to the input field instead.

When using the UNBUFFERED mode, program variables are automatically assigned, and the GET_FLDBUF operator is not required in most cases.

Example

```
INPUT BY NAME ...
   ...
   ON KEY(CONTROL-Z)
      LET v = GET_FLDBUF( customer.custname )
      IF check_synonyms(v) THEN
         ...
```

Related concepts

The buffered and unbuffered modes on page 1618
The buffered and unbuffered mode control the synchronization of program variables and form fields.

Editable record list (INPUT ARRAY) on page 1425
The INPUT ARRAY instruction provides always-editable record list handling in an application form.

ui.Dialog.getFieldBuffer on page 2386
Returns the input buffer of the specified field.

INFIELD()

The INFIELD() operator checks for the current screen field.

Syntax

```
INFIELD ( [group.].field )
```

1. `group` can be a table name, a screen record, a screen array or FORMONLY.
2. *field* is the name of the field in the form.

**Usage**

INFIELD checks for the current field in a CONSTRUCT, INPUT or INPUT ARRAY dialog. When used in an INPUT ARRAY instruction, the runtime system assumes that you are referring to the current row. For a generic coding equivalent, use the DIALOG.getCurrentItem() method.

**Example**

```plaintext
INPUT ...
  IF INFIELD( customer.custname ) THEN
    MESSAGE "The current field is customer's name."
  ...
```

**Related concepts**

Which form item has the focus? on page 1630

Identify what element of the current form has the focus.

Query by example (CONSTRUCT) on page 1461

The CONSTRUCT instruction implements database query criteria input in an application form.

Record input (INPUT) on page 1373

The INPUT instruction provides single record input control in an application form.

Editable record list (INPUT ARRAY) on page 1425

The INPUT ARRAY instruction provides always-editable record list handling in an application form.

**FIELD_TOUCHED**

The FIELD_TOUCHED() operator checks if fields were modified during the dialog execution.

**Syntax**

```plaintext
FIELD_TOUCHED ( 
  { [group.]field.*
  | group.*
  | *
  | [ , ... ] )
```

1. *group* can be a table name, a screen record, a screen array or FORMONLY.
2. *field* is the name of the field in the form.

**Usage**

FIELD_TOUCHED returns TRUE if the value of a screen field (or multiple fields) has changed since the beginning of the interactive instruction. The operator accepts a list of explicit field names, and supports the *[group.]* notation in order to check multiple fields in a single evaluation. When passing a simple asterisk (*) to the operator, the runtime system will check all fields used by the current dialog.

When used in an INPUT ARRAY instruction, the runtime system assumes that you are referring to the current row. The FIELD_TOUCHED operator can only be used inside an INPUT, INPUT ARRAY and CONSTRUCT interaction block.

For more details about the FIELD_TOUCHED operator usage and the understand the "touched flag" concept, refer to the definition of the DIALOG instruction.
Do not confuse the `FIELD_TOUCHED` operator with `FGL_BUFFERTOUCHED` built-in function; which checks a different field modification flag, that is reset when entering the field. The global touched flag controlled by `FIELD_TOUCHED` is reset when the dialog starts or when `DIALOG.setFieldTouched()` is used.

**Example**

```plaintext
INPUT ...
AFTER FIELD custname
    IF FIELD_TOUCHED( customer.custname ) THEN
        MESSAGE "Customer name was changed."
    END IF
... 
AFTER INPUT
    IF FIELD_TOUCHED( customer.* ) THEN
        MESSAGE "Customer record was changed."
    END IF
...
```

**Related concepts**

- [Input field modification flag](#) on page 1623
  - Each input field controlled by a dialog instruction has a modification flag.
- `ui.Dialog.getFieldTouched` on page 2387
  - Returns the modification flag for a field.
- `ui.Dialog.setFieldTouched` on page 2403
  - Sets the modification flag of the specified field.

**Flow control**

Definition of language elements and instructions that control the flow of a program.

- CALL on page 340
- RETURN on page 343
- CASE on page 344
- CONTINUE block-name on page 346
- EXIT block-name on page 347
- FOR on page 348
- GOTO on page 349
- IF on page 350
- LABEL on page 351
- SLEEP on page 351
- WHILE on page 352

**CALL**

- The `CALL` instruction invokes a specified function or method.

**Syntax**

```
CALL built-in-function
    | built-in-class.class-method
    | module. | variable-of-built-in-class.object-method
    | extension-class.class-method
    | module. | variable-of-extension-class.object-method
    | cext-module. | cext-function
    | java-class.java-class-method
    | variable-of-java-class.java-object-method
```
1. *built-in-function* is a built-in function.
2. *built-in-class* is a built-in class.
3. *class-method* is a method invoked by class name.
4. *module* is an imported module.
5. *variable-of-built-in-class* is a variable defined from a built-in class.
7. *extension-class* is a class from an extension package.
8. *variable-of-extension-class* is a variable defined from an extension-class.
9. *cext-module* is an imported C extension module.
10. *cext-function* is a C function defined in a cext-module.
11. *java-class* is a imported Java class.
12. *java-class-method* is a method of a java-class invoked by class name.
13. *variable-of-java-class* is a variable defined from a java-class.
15. *user-function* is a function defined in one of the modules of the program.
16. *function-reference* is a variable referencing a function.
17. *parameter-name* is the name of a function parameter, as specified in the function definition. The parameter name is optional.
18. *parameter-value* can be any valid expression, including object references of built-in classes or Java classes.
19. *variable* is a variable receiving a value returned by the function.

**Usage**

The **CALL** instruction invokes the function or class/object method specified and passes the program flow control to that function/method. After the called function is executed, the flow control goes back to the caller, the runtime system executing the next statement that appears after the **CALL** instruction.

Function arguments can be any expression supported by the language. Use a double-pipe operator `||` to pass the concatenation of character string expressions as a parameter.

```
CALL my_function( TODAY, 20*0.5435, 'abc'||'def'||var1 )
```

The **RETURNING** clause assigns values returned by the function to variables in the calling routine. The **RETURNING** clause is only needed when the function returns parameters.

```
MAIN
  DEFINE var1 CHAR(15)
  DEFINE var2 CHAR(15)
  CALL foo() RETURNING var1, var2
  DISPLAY var1, var2
END MAIN

FUNCTION foo()
  DEFINE r1 CHAR(15)
  DEFINE r2 CHAR(15)
  LET r1 = "return value 1"
  LET r2 = "return value 2"
  RETURN r1, r2
```
If the function returns a unique parameter, the function can be used in an expression and can be directly assigned to a variable with `LET var = function(...)` statement.

```plaintext
MAIN
    DEFINE var1 CHAR(10)
    DEFINE var2 CHAR(2)
    LET var1 = foo()
    DISPLAY "var1 = " || var1
    CALL foo() RETURNING var2
    DISPLAY "var2 = " || var2
END MAIN

FUNCTION foo()
    RETURN "Hello"
END FUNCTION
```

The value of a receiving variable may be different from the value returned by the function, following the data conversion rules.

```plaintext
MAIN
    DEFINE s STRING
    LET s = div(10,2)
END MAIN

FUNCTION div(x,y)
    DEFINE x,y INTEGER
    RETURN x / y
END FUNCTION
```

If the `IMPORT FGL` instruction is used to import a module, `function` can be prefixed with the name of the module followed by a dot (i.e. `module.function`). The module prefix is required to fully-qualify the function in case of conflicts (i.e. when functions with the same name are defined in several modules).

```plaintext
-- main.4gl
IMPORT FGL module1
IMPORT FGL module2
MAIN
    CALL module1.show("aaa")
    CALL module2.show("aaa")
END MAIN

-- module1.4gl
FUNCTION show(s)
    DEFINE s STRING
    DISPLAY s
END FUNCTION

-- module2.4gl
FUNCTION show(s)
    DEFINE s STRING
    DISPLAY s
END FUNCTION
```

The symbol following the `CALL` keyword can be a program variable that references a function.

This allows you to invoke functions dynamically, when the actual function to be called is only known at runtime:

```plaintext
TYPE t_func_ref FUNCTION (p1 INT, p2 INT) RETURNS INT
```
DEFINE fr t_func_ref,
   r INT

LET fr = FUNCTION add  -- Function with the same signature as t_func_ref
CALL fr(100,200) RETURNING r

LET fr = FUNCTION sub  -- Function with the same signature as t_func_ref
CALL fr(100,200) RETURNING r

Explains data type conversion rules of the language.

Importing modules on page 496
Use the IMPORT ... instruction to import BDL, C or Java external modules in the current module.

RETURN
The RETURN instruction gives the control of execution back to the caller, eventually by returning values on the stack.

Syntax

```
RETURN [ value [ , . . . ] ]
```

1. `value` can be any valid expression, an object reference or complex type reference such as a dynamic array reference.

Usage
The RETURN instruction transfers the control back from a function with optional return values.

Record members can be returned with the . * or THRU notation. Each member is returned as an independent variable.

Consider using the fully typed function definition syntax, with a RETURNS clause in the function header, to get better compilation control of your code. When using the RETURNS clause, the compiler will check that the function body contains RETURN instructions that match the number of return values as specified in the function definition.

A function may have several RETURN points (not recommended in structured programming) but they must all return the same number of values.

The number of returned values must correspond to the number of variables listed in the RETURNING clause of the CALL statement invoking this function.

A function cannot return a static array, but can return the reference of a dynamic array or dictionary.

Example

```
MAIN
   DEFINE fname, lname VARCHAR(30)
   LET lname = lastname(943)
   DISPLAY lname
DEFINE fname, lname VARCHAR(30)
   LET lname = lastname(943)
   DISPLAY lname
   CALL fullname(235) RETURNING fname, lname
   DISPLAY fname, lname
END MAIN

FUNCTION lastname(id INTEGER) RETURNS STRING
```
CASE id
    WHEN 943
        RETURN "McTiger"
    OTHERWISE
        RETURN NULL
END CASE
END FUNCTION

FUNCTION fullname(id INTEGER) RETURNS(STRING, STRING)
CASE id
    WHEN 235
        RETURN "Lee", "Park"
    OTHERWISE
        RETURN NULL, NULL
END CASE
END FUNCTION

Related concepts
Returning values on page 360
A function can return values with the RETURN instruction.

CALL on page 340
The CALL instruction invokes a specified function or method.

Expressions on page 293
Shows the possible expressions supported in the language.

Type conversions on page 274
Explains data type conversion rules of the language.

CASE
The CASE instruction specifies statement blocks that must be executed conditionally.

Syntax 1
CASE expression-1
    WHEN expression-2
        \_ statement \_ EXIT CASE \_
        \[\ldots\]
        \_ OTHERWISE \_ \_ statement \_ \_ EXIT CASE \_
        \[\ldots\]
END CASE

Syntax 2
CASE
    WHEN boolean-expression
        \_ statement \_ EXIT CASE \_
        \[\ldots\]
        \_ OTHERWISE \_ \_ statement \_ \_ EXIT CASE \_
        \[\ldots\]
END CASE

1. *expression-1* is any expression supported by the language.
2. *expression-2* is an expression that is tested against *expression-1*.
3. *expression-1* and *expression-2* should have the same data type.
4. **boolean-expression** is any boolean expression supported by the language.
5. **statement** is any instruction supported by the language.

**Usage**

In a CASE flow control block, the first matching WHEN block is executed. If there is no matching WHEN block, then the OTHERWISE block is executed. If there is no matching WHEN block and no OTHERWISE block, the program execution continues with the next statement following the END CASE keyword.

The EXIT CASE statement transfers the program control to the statement following the END CASE keyword. There is an implicit EXIT CASE statement at the end of each WHEN block and at the end of the OTHERWISE block. The OTHERWISE block must be the last block of the CASE instruction.

A null expression is considered as false: When doing a CASE expr ... WHEN [NOT] NULL using the syntax 1, it always evaluates to FALSE. Use syntax 2 as CASE ... WHEN expr IS NULL to test if an expression is null.

Make sure that expression-2 is not a boolean expression when using the first syntax. The compiler will not raise an error in this case, but you might get unexpected results at runtime.

If there is more than one expression-2 matching expression-1 (syntax 1), or if two boolean expressions (syntax 2) are true, only the first matching WHEN block will be executed.

**Example**

```plaintext
MAIN
  DEFINE v CHAR(10)
  LET v = "C1"
  -- CASE Syntax 1
  CASE v
    WHEN "C1"
      DISPLAY "Value is C1"
    WHEN "C2"
      DISPLAY "Value is C2"
    WHEN "C3"
      DISPLAY "Value is C3"
    OTHERWISE
      DISPLAY "Unexpected value"
  END CASE
  -- CASE Syntax 2
  CASE
    WHEN ( v="C1" OR v="C2" )
      DISPLAY "Value is either C1 or C2"
    WHEN ( v="C3" OR v="C4" )
      DISPLAY "Value is either C3 or C4"
    OTHERWISE
      DISPLAY "Unexpected value"
  END CASE
END MAIN
```

**Related concepts**

- [NULL](#) on page 502
The NULL constant is provided as the "nil" value.

**CONTINUE block-name**

The CONTINUE block-name instruction resumes execution of a loop or dialog statement.

**Syntax**

```
CONTINUE
   FOR
   FOREACH
   WHILE
   MENU
   CONSTRUCT
   INPUT
   DIALOG
```

**Usage**

The CONTINUE block-name instruction transfers the program execution from a statement block to another location in the compound statement that is currently being executed.

CONTINUE block-name can only be used within the statement block specified by block-name. For example, CONTINUE FOR can only be used within a FOR ... END FOR statement block.

The CONTINUE FOR, CONTINUE FOREACH, or CONTINUE WHILE keywords cause the current FOR, FOREACH, or WHILE loop (respectively) to begin a new cycle immediately. If conditions do not permit a new cycle, however, the looping statement terminates.

The CONTINUE CONSTRUCT, CONTINUE INPUT and CONTINUE DIALOG statements cause the program to skip all subsequent statements in the current control block. The screen cursor returns to the most recently occupied field in the current form, giving the user another chance to enter data in that field.

The CONTINUE MENU statement causes the program to ignore the remaining statements in the current MENU control block and re-display the menu. The user can then choose another menu option.

CONTINUE INPUT is valid in INPUT and INPUT ARRAY statements.

**Example**

```
MAIN
   DEFINE i INTEGER
   LET i = 0
   WHILE i < 5
      LET i = i + 1
      DISPLAY "i=" || i
      CONTINUE WHILE
      DISPLAY "This will never be displayed!"
   END WHILE
END MAIN
```

  The NULL constant is provided as the "nil" value.

- **WHILE** on page 352
The **WHILE** statement executes a block of statements until the specified condition becomes false.

### **EXIT** block-name

The **EXIT** block-name instruction transfers control out of the current program block.

#### Syntax

```
EXIT
CASE
FOR
FOREACH
WHILE
MENU
CONSTRUCT
REPORT
DISPLAY
INPUT
DIALOG
```

#### Usage

The **EXIT** block-name instruction transfers control out of a control structure (a block, a loop, a **CASE** statement, or an interface instruction).

The **EXIT** block-name instruction must be used inside the control structure specified by **block-name**. For example, **EXIT FOR** can only appear inside a **FOR ... END FOR** iteration block.

**EXIT DISPLAY** exits the **DISPLAY ARRAY** instruction and **EXIT INPUT** exits an **INPUT** or an **INPUT ARRAY** block.

**EXIT CONSTRUCT** exits current **CONSTRUCT** block.

**EXIT DIALOG** exits current **DIALOG** block.

To exit a function, use the **RETURN** instruction. To terminate a program, use the **EXIT PROGRAM** instruction.

#### Example

```plaintext
MAIN
  DEFINE i INTEGER
  LET i = 0
  WHILE TRUE
      DISPLAY "This is an infinite loop. How would you get out of here?"
      LET i = i + 1
      IF i = 100 THEN
          EXIT WHILE
      END IF
  END WHILE
  DISPLAY "Done."
END MAIN
```

#### Related concepts

**RETURN** on page 343

The **RETURN** instruction gives the control of execution back to the caller, eventually by returning values on the stack.

**EXIT PROGRAM** on page 524
The EXIT PROGRAM instruction terminates the execution of the program.

FOR
The FOR instruction executes a statement block a specified number of times.

Syntax

```plaintext
FOR counter = start TO finish [STEP value ] 
  ↓ statement
  ↓ EXIT FOR
  ↓ CONTINUE FOR ↓
END FOR
```

1. `counter` is the loop counter and must be an integer variable.
2. `start` is an integer expression used to set an initial counter value.
3. `finish` is any valid integer expression used to specify an upper limit for `counter`.
4. `value` is any valid integer expression whose value is added to `counter` after each iteration of the statement block.
5. When the `STEP` keyword is not given, `counter` increments by 1.
6. `statement` is any instruction supported by the language.
7. If `value` is less than 0, `counter` is decreased. In this case, `start` should be higher than `finish`.

Usage
The FOR instruction block executes the statements up to the `END FOR` keyword a specified number of times, or until `EXIT FOR` terminates the FOR statement. The `CONTINUE FOR` instruction skips the next statements and continues with the next iteration.

On the first iteration through the loop, the counter is set to the initial expression at the left of the `TO` keyword. For all further iterations, the value of the increment expression in the `STEP` clause specification (1 by default) is added to the counter in each pass through the block of statements. When the sign of the difference between the values of counter and the finish expression at the right of the `TO` keyword changes, the runtime system exits from the FOR loop.

The FOR loop terminates after the iteration for which the left- and right-hand expressions are equal. Execution resumes at the statement following the `END FOR` keywords. If either expression returns NULL, the loop cannot terminate, because the boolean expression "left = right" cannot become TRUE.

A `value` that equals 0 causes an unending loop unless there is an adequate `EXIT FOR` statement.

Using NULL for `start`, `finish` or `value` is treated as 0. There is no way to catch this as an error.

If `statement` modifies the value of `counter`, you might get unexpected results at runtime. In this case, it is recommended that you use a WHILE loop instead.

It is highly recommended that you ensure that `statement` does not modify the values of `start`, `finish` or `value`.

Example

```plaintext
MAIN
  DEFINE i, i_min, i_max INTEGER
  LET i_min = 1
  LET i_max = 10
  DISPLAY "Count from " || i_min || " to " || i_max
  DISPLAY "Counting forwards..."
  FOR i = i_min TO i_max
    DISPLAY i
  END FOR
  DISPLAY "... and backwards."
  FOR i = i_max TO i_min STEP -1
    DISPLAY i
  END FOR
```
Related concepts

Numeric expressions on page 296
This section covers numeric expression evaluation rules.

INTEGER on page 264
The INTEGER data type is used for storing large whole numbers.

EXIT block-name on page 347
The EXIT block-name instruction transfers control out of the current program block.

GOTO
The GOTO instruction transfers program control to a labeled line within the same program block.

Syntax

GOTO label-id

1. label-id is the name of the LABEL statement to jump to.

Usage

A GOTO statement continues program execution in the line following the LABEL instruction using the label-id identifier specified in the GOTO instruction.

The LABEL jump point can be defined before or after the GOTO statement.

The LABEL and GOTO statements must use the label-id within a single MAIN, FUNCTION, or REPORT program block.

The : colon after the GOTO keyword is optional.

GOTO statements can reduce the readability of your program source and result in infinite loops. It is recommended that you use FOR, WHILE and CASE statements instead.

The GOTO statement can be used in a WHENEVER statement to handle exceptions.

Example

MAIN
DEFINE exit_code INTEGER
DEFINE l_status INTEGER

WHENEVER ANY ERROR GOTO _error
DISPLAY 1/0
GOTO _noerror

LABEL _error:
LET l_status = STATUS
DISPLAY "The error number ", l_status, " has occurred."
LECT "Description: ", err_get(l_status)
LET exit_code = -1
GOTO _exit

LABEL _noerror:
LET exit_code = 0
GOTO _exit

LABEL _exit:
EXIT PROGRAM exit_code
Related concepts

LABEL on page 351
The LABEL instruction declares a jump point that can be reached by a GOTO.

WHENEVER instruction on page 452
Use the WHENEVER instruction to define how exceptions must be handled for the rest of the module.

IF

The IF instruction executes a group of statements conditionally.

Syntax

```plaintext
IF condition THEN
    statement
    [...] 
ELSE
    statement
    [...] 
END IF
```

1. `condition` is a boolean expression.
2. `statement` is any instruction supported by the language.

Usage

If `condition` is TRUE, the runtime system executes the block of statements following the THEN keyword, until it reaches either the ELSE keyword or the END IF keywords and resumes execution after the END IF keywords.

If `condition` is FALSE, the runtime system executes the block of statements between the ELSE keyword and the END IF keywords. If ELSE is absent, it resumes execution after the END IF keywords.

By default, the runtime system evaluates all part of the condition. The semantics of boolean expressions can be controlled by the OPTIONS SHORT CIRCUIT compiler directive, to reduce expression evaluation when using AND / OR operators.

A NULL expression is considered as FALSE. Use the IS NULL keyword to test if an expression is null.

Example

```plaintext
MAIN
    DEFINE name CHAR(20)
    LET name = "John Smith"
    IF name MATCHES "John*" THEN
        DISPLAY "The name starts with [John]!"
    ELSE
        DISPLAY "The name is " || name || "."
    END IF
END MAIN
```

Related concepts

Boolean expressions on page 294
This section covers boolean expression evaluation rules.

Controlling semantics of AND / OR operators on page 505
The **OPTIONS SHORT CIRCUIT** defines the semantics of **AND/OR** operators.

**LABEL**

The **LABEL** instruction declares a jump point that can be reached by a **GOTO**.

**Syntax**

```
LABEL label-id:
```

1. `label-id` is a unique identifier in a **MAIN**, **REPORT**, or **FUNCTION** program block.
2. The `label-id` must be followed by a colon (`:`).

**Usage**

The **LABEL** instruction declares a statement label, making the next statement one to which a **GOTO** statement can transfer program control.

**Example**

```
MAIN
   DISPLAY "Line 2"
   GOTO line5
   DISPLAY "Line 4"
   LABEL line5:
   DISPLAY "Line 6"
END MAIN
```

**Related concepts**

**GOTO** on page 349

The **GOTO** instruction transfers program control to a labeled line within the same program block.

**SLEEP**

The **SLEEP** instruction causes the program to pause for the specified number of seconds.

**Syntax**

```
SLEEP seconds
```

1. `seconds` must be an integer expression.

**Usage**

The **SLEEP** instruction is typically invoked to let the end user read a message displayed on a character terminal.

With graphical applications, the **SLEEP** command is seldom used.

When `seconds` is lower than zero or is null, the program continues immediately with the next statement.

**Example**

```
MAIN
   DISPLAY "Please wait 5 seconds..."
   SLEEP 5
   DISPLAY "Thank you."
END MAIN
```

**Related concepts**

**Integer expressions** on page 296
This section covers integer expression evaluation rules.

**WHILE**

The WHILE statement executes a block of statements until the specified condition becomes false.

**Syntax**

```
WHILE condition
    ↓ statement ↓ EXIT WHILE ↓ CONTINUE WHILE ↓
[...]
END WHILE
```

1. *condition* must be a boolean expression.
2. *statement* is any instruction supported by the language.

**Usage**

As long as the *condition* specified after a WHILE keyword is TRUE, all statements inside the WHILE ... END WHILE block are executed. After executing the last statement of the block, the runtime system again evaluates the condition, and if it is still TRUE, continues with the first statement in the block.

The loop stops when the condition becomes FALSE or when an EXIT WHILE is reached.

Use the CONTINUE WHILE instruction to skip the next statements and continue with the loop.

To avoid unending loops, make sure that the condition will become FALSE at some point, or that an EXIT WHILE statement will be executed.

**Example**

```
MAIN
    DEFINE cnt INTEGER
    LET cnt = 1
    WHILE cnt <= 100
        DISPLAY "Iter: " || cnt
        LET cnt = cnt + 1
        IF int_flag THEN
            EXIT WHILE
        END IF
    END WHILE
END MAIN
```

### Functions

Describes user defined functions.

- **Understanding functions** on page 353
- **FUNCTION definitions** on page 353
- **Function parameters** on page 355
- **Scope of a function** on page 356
- **Local symbol definition** on page 357
- **Calling functions** on page 358
- **Returning values** on page 360
- **Function references** on page 362
- **FUNCTION func-spec** on page 364
- **Examples** on page 364

---

#### Understanding functions

This is an introduction to functions.

Functions are named program blocks containing a set of statements to be executed when the function is invoked with a **CALL** statement, or when the function is used in an expression, or when the function is registered in a callback mechanism like **WHENEVER ERROR CALL**.

A function is defined in a program module, and is by default visible to all modules (a function is global by default), but it can also be declared as private to the module where it is defined.

To write generic code, it is possible to hold a function reference in a program variable. The variable can then be assigned with any function reference that is declared with the same function signature as the type used to define the variable.

**Related concepts**

**CALL** on page 340
The **CALL** instruction invokes a specified function or method.

**Expressions** on page 293
Shows the possible expressions supported in the language.

**WHENEVER instruction** on page 452
Use the **WHENEVER** instruction to define how exceptions must be handled for the rest of the module.

#### FUNCTION definitions

A **FUNCTION** definition defines a named procedure with a set of statements.

**Syntax 1 (legacy syntax):**

```plaintext
[PUBLIC|PRIVATE] FUNCTION function-name ( parameter-name [,....] )
  [parameter-definition [..]]
  [local-declaration [..]]
  [instruction]
  [[ RETURN expression [,....] ]
    [....]
] END FUNCTION
```

1. *function-name* is the function identifier.
2. *parameter-name* is the name of a formal argument of the function.
3. parameter-definition is a DEFINE instruction for a parameter.
4. local-declaration is a DEFINE, CONSTANT or TYPE instruction.
5. instruction is a language statement to be executed when the function is invoked.
6. expression is a value to be returned by the function.

Syntax 2 (fully typed):

```
[PUBLIC|PRIVATE] FUNCTION function-name (  
  parameter-name data-type  
  ↓ ATTRIBUTES ( attribute ↓ = "value" ↓ [, . . .] ↓ ) ↓  
  ↓ )  
↓ RETURNS ↓ data-type ↓ ( data-type ↓ [, . . .] ↓ ) ↓ ↓  
↓ local-declaration ↓ [, . . .] ↓  
↓ instruction  
↓ ↓ RETURN expression ↓ [, . . .] ↓  
↓ ↓  
END FUNCTION
```

1. function-name is the function identifier.
2. parameter-name is the name of a formal argument of the function.
3. data-type can be a built-in data type, a user defined type, a built-in class, an imported package class, or a Java class.
4. attribute is an attribute to extend the variable definition with properties.
5. value is the value for the variable attribute, it is optional for boolean attributes.
6. local-declaration is a DEFINE, CONSTANT or TYPE instruction.
7. instruction is a language statement to be executed when the function is invoked.
8. expression is a value to be returned by the function.

Example of function definition using legacy syntax

The following example shows a function definition using the legacy syntax, with parameter definition in the function body:

```
FUNCTION split(str, len)  
  DEFINE str STRING, len INT  
  RETURN str.subString(1, len),  
  str.subString(len+1, str.getLength())  
END FUNCTION
```

This syntax does not define a function with a complete signature.

Example of function definition with complete function type

By specifying data types in the parameter list, you define a function with a complete function type.

This syntax allows better compilation checking:

```
FUNCTION split(str STRING, len INT) RETURNS (STRING, STRING)  
  RETURN str.subString(1, len),  
  str.subString(len+1, str.getLength())  
END FUNCTION
```

Braces after the RETURNS clause are not required, when the function returns a single value:

```
FUNCTION count_items(sid INT) RETURNS INT  
  DEFINE cnt INT
```
The next example defines a function, that does not return values:

```sql
FUNCTION append(name STRING)
  DISPLAY "Do something with name..."
END FUNCTION
```

**Example of function without parameters and without return values**

In this example, the function has no parameters and does not return values:

```sql
FUNCTION clean_debug_log()
  CALL os.Path.delete("log.txt")
END FUNCTION
```

**Related concepts**

- **Variables** on page 366
  Explains how to define program variables.

- **Expressions** on page 293
  Shows the possible expressions supported in the language.

- **Function references** on page 362
  Function can be referenced and invoked dynamically in a CALL instruction, or in an expression.

- **Calling functions** on page 358
  Functions can be invoked, to execute the code they define.

**Function parameters**

Functions can take parameters, to specialize their behavior.

The `FUNCTION` block defines the body and the type (i.e. declaration) of a function. The function declaration specifies the name of the function and the identifiers of its formal arguments (if any).

The data type of each formal argument of the function must be specified by a `DEFINE` statement that immediately follows the argument list.

```sql
FUNCTION check_address(zipcode, street, city)
  DEFINE zipcode CHAR(5),
          street VARCHAR(100),
          city VARCHAR(50)
  DEFINE found BOOLEAN -- local function variable
  ...
END FUNCTION
```

The type of the function parameters can also be specified inside the parentheses, for better code readability:

```sql
FUNCTION check_address(zipcode CHAR(5), street VARCHAR(100), city VARCHAR(50))
  DEFINE found BOOLEAN -- local function variable
  ...
END FUNCTION
```

Like other identifiers, function names are case-insensitive. However, always consider using the same naming convention when defining and invoking functions.

**Note:** If the function name is also the name of a built-in function, an error occurs at link time, even if the program does not reference the built-in function.
If no argument is needed in a function call, an empty argument list must still be supplied, enclosed between the parentheses:

```plaintext
FUNCTION begin_work()
    ...
END FUNCTION
```

**Related concepts**

**Data types** on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

**Variables** on page 366
Explains how to define program variables.

**Scope of a function**

A functions can be isolated to control its visibility to other modules.

A `FUNCTION` block cannot appear within the `MAIN` block, in a `REPORT` block, or within another `FUNCTION` block. A function must be declared at the root level in the source code:

```plaintext
MAIN
    ...
END MAIN

FUNCTION myfunc(...) 
    ...
END FUNCTION

REPORT myrep(...) 
    ...
END REPORT
```

By default, functions are `PUBLIC`; They can be called by any other module of the program.

If a function is only used by the current module, you can hide that function to other modules, to make sure that it will not be called by mistake.

To keep a function local to the module, add the `PRIVATE` keyword before the function header.

Private functions are only hidden to external modules, all function of the current module can still call local private functions.

```plaintext
PRIVATE FUNCTION check_number(n)
    ...
END FUNCTION
```

For better code readability, you can use the `PUBLIC` keyword for functions that are global and visible to all modules:

```plaintext
PUBLIC FUNCTION initialize()
    ...
END FUNCTION
```

When not using the module prefix, function symbols are global to all modules and must be unique. However, with the `IMPORT FGL` method, you can use the module prefix when invoking a function and simplify function naming conventions, since different modules can the define functions with the same name:

```plaintext
-- Module svgutils.4gl:
PUBLIC FUNCTION initialize()
    ...
END FUNCTION
```
Related concepts

Importing modules on page 496
Use the `IMPORT ...` instruction to import BDL, C or Java external modules in the current module.

Local symbol definition

Symbols defined inside a function body are only visible to the function.

Inside the body of a function, you can define language elements that will only be visible for the function code:

- local constants with the `CONSTANT` instruction,
- local user-defined types with the `TYPE` instruction,
- local variables with the `DEFINE` instruction.

```plaintext
FUNCTION check_customer( cust_id INTEGER )
    CONSTANT c_max = 1000 -- local constant
    TYPE t_cust RECORD LIKE customer.* -- local type
    DEFINE found BOOLEAN -- local variable
    ...
END FUNCTION
```

Function arguments and local symbols must use different names, it is not possible to define a local variable with the same name as a function parameter:

```plaintext
FUNCTION func_a(x INTEGER)
    DEFINE x INTEGER
    The symbol 'x' has been defined more than once.
    See error number -4319.
    LET x = 1
END FUNCTION
```

```plaintext
FUNCTION func_b(x)
    DEFINE x INTEGER
    DEFINE x INTEGER
    The symbol 'x' has been defined more than once.
    See error number -4319.
    LET x = 1
END FUNCTION
```

Local function symbols are not visible in other program blocks. Global or module variable can use the same name as a local variable: The global or module variable is not visible within the function scope of the local variable:

```plaintext
DEFINE x INTEGER   -- Declares a module variable

FUNCTION func_a()
    DEFINE x INTEGER   -- Declares a local variable
    LET x = 123       -- Assigns local variable
END FUNCTION
```
FUNCTION func_b()
    LET x = 123 -- Changes the module variable
END FUNCTION

However, for better code readability, it is recommended that you consider using different names for global, module and local function symbols.

Runtime stack on page 443
The runtime stack is used to pass/return values to/from functions.

Calling functions
Functions can be invoked, to execute the code they define.

A function can be invoked in different ways:
1. with the CALL statement,
2. in an expression, when the function returns a unique value,
3. with a callback mechanism like WHENEVER ERROR CALL or the INITIALIZER attribute.

Note: The symbol used to identify the function to be called can be a static function name, or a variable referencing a function.

For basic data types such as INTEGER, arguments are passed by value (the value is copied on the stack) and records, while dynamic arrays and objects are passed by reference (a handle to the original data is copied on the stack and this allows modification of the original data inside the function).

In the following code example, the variable x defined in the MAIN block will not be modified by the function:

MAIN
    DEFINE x INTEGER
    LET x = 123
    CALL myfunc(x)
    DISPLAY x -- displays 123
END MAIN

FUNCTION myfunc(x)
    DEFINE x INTEGER
    LET x = x + 1
When a function returns a single value, it can be invoked in an expression:

```plaintext
MAIN
  DISPLAY ( 500 + add(50, 5) )
END MAIN

FUNCTION add(x, y) RETURNS INTEGER
  DEFINE x, y INTEGER
  RETURN (x + y)
END FUNCTION
```

The actual argument in a call to the function need not be of the declared data type of the formal argument. The runtime system will do the appropriate data type conversions. If data type conversion is not possible, a runtime error occurs. Note however that for historical reasons, Genero BDL data type conversion is quite permissive. The following example will not raise an error, because the string value is silently converted to a `NULL INTEGER`:

```plaintext
MAIN
  CALL add("aaaaa")
END MAIN

FUNCTION add(x)
  DEFINE x INTEGER
  DISPLAY "x = ", x
END FUNCTION
```

A function can invoke itself recursively:

```plaintext
MAIN
  CALL recursive(1)
END MAIN

FUNCTION recursive(x)
  DEFINE x INTEGER
  DISPLAY "x = ", x
  IF x<10 THEN
    CALL recursive(x+1)
  END IF
END FUNCTION
```

A function can be referenced by a variable, and be invoked through this variable in a `CALL` instruction, or in an expression:

```plaintext
TYPE t_func_ref FUNCTION (p1 INT, p2 INT) RETURNS INT
DEFINE fr t_func_ref
LET fr = FUNCTION add   -- Function with the same signature as t_func_ref
DISPLAY fr(100, 200)
```

Related concepts

**CALL** on page 340
The `CALL` instruction invokes a specified function or method.

**Expressions** on page 293
Shows the possible expressions supported in the language.

**Type conversions** on page 274
Explains data type conversion rules of the language.

**Runtime stack** on page 443
The runtime stack is used to pass/return values to/from functions.

Function references on page 362
Function can be referenced and invoked dynamically in a CALL instruction, or in an expression.

**Returning values**

A function can return values with the RETURN instruction.

**Definining the returned types in a function declaration**

Function definitions can specify the list of data types returned by the function with the RETURNS clause.

**Note:** The RETURNS clause in the function header is not mandatory. However, it is recommended, to define the complete function signature, and take advantage of better code checking by the compiler.

If the function returns a single value, specify the data type after the RETURNS clause:

```sql
FUNCTION get_count() RETURNS INT
...
END FUNCTION
```

**Note:** When the function returns a single value/type, it is also possible to enclose the type in parentheses:

```sql
FUNCTION get_count() RETURNS (INT)
```

But for convenience, the parentheses are optional when only one return type is used.

If the function returns a several values, you must specify the data types after the RETURNS clause inside parentheses:

```sql
FUNCTION get_address() RETURNS ( CHAR(5), VARCHAR(100), INTEGER )
...
END FUNCTION
```

The RETURNS types specification can use base data types such as INTEGER, user-defined types, and classes.

```sql
SCHEMA stores
TYPE t_cust DYNAMIC ARRAY OF RECORD LIKE customer.*
...
FUNCTION get_cust_list() RETURNS t_cust
...
END FUNCTION
```

**Returning from the function**

Use the RETURN instruction in the body of the function, to push a list of values on the stack, and return to the caller.

The RETURN instruction takes an optional comma-separated list of expressions:

```sql
FUNCTION get_address() RETURNS ( CHAR(5), VARCHAR(100), INTEGER )
DEFINE zipcode CHAR(5),
             street VARCHAR(100),
             city INTEGER
...
RETURN zipcode, street, city
END FUNCTION
```

The next example shows a function returning a single value:

```sql
FUNCTION get_count()
...
RETURN count
```
If a function does not need to return a value, the `RETURN` instruction can be used without arguments:

```sql
FUNCTION show_notfound()
    IF SQLCA.SQLCODE==0 THEN
        RETURN
    END IF
    ...
END FUNCTION
```

**Using functions in expressions**

Functions returning a simple value can be used in expressions:

```sql
LET c = get_count()
```

**Returning a list of values**

Functions returning multiple values must be invoked with a `CALL` instruction using the `RETURNING` clause. Values specified in RETURN statement must correspond in number and position to the RETURNING clause of the CALL instruction, and must be of the same or of compatible data types, to the variables in the RETURNING clause of the CALL statement. An error results if the list of returned values in the RETURN statement conflicts in number or in data type with the RETURNING clause of the CALL statement that invokes the function.

```sql
MAIN
    DEFINE zipcode CHAR(5),
        street VARCHAR(100),
        city VARCHAR(50)
    CALL get_address() RETURNING zipcode, street, city
END MAIN

FUNCTION get_default_address()
    RETURN "00000", "<undefined>", "<undefined>"
END FUNCTION
```

**Returning complex structures**

When returning simple built-in types like `INTEGER`, values are copied on stack and copied to the caller variables.

When returning a `RECORD` structure, all values are expanded on the stack:

```sql
TYPE t_rec RECORD
    pkey INT,
    name VARCHAR(20)
END RECORD

MAIN
    DEFINE r1 t_rec
    CALL get_rec() RETURNING r1.*
    DISPLAY r1.*
END MAIN

FUNCTION get_rec()
    DEFINE r t_rec
    LET r.pkey = 999
    LET r.name = "Mike"
    RETURN r.*
END FUNCTION
```
When returning complex types such as objects or dynamic arrays, the reference of the element are copied on the stack (this means that you can create an object inside a function, and return its reference in the RETURN statement):

```plaintext
MAIN
    DEFINE c base.Channel
    LET c = open_file("myfile.txt")
    ...
END MAIN

FUNCTION open_file(filename)
    DEFINE filename STRING
    DEFINE c base.Channel
    TRY
        LET c = base.Channel.create()
        CALL c.openFile(filename, "r")
        RETURN c
    CATCH
        RETURN NULL
    END TRY
END FUNCTION
```

**Related concepts**

**RETURN** on page 343
The RETURN instruction gives the control of execution back to the caller, eventually by returning values on the stack.

The CALL instruction invokes a specified function or method.

**Records** on page 382
Records allow structured program variables definitions.

**Type conversions** on page 274
Explains data type conversion rules of the language.

**Runtime stack** on page 443
The runtime stack is used to pass/return values to/from functions.

**Function references**
Function can be referenced and invoked dynamically in a CALL instruction, or in an expression.

**Purpose of function references**
A function reference points to a function definition, that can be called at runtime. The actual function is not known at compile time, only the function type (number and type of parameters and return values) is known.

This feature allows you to manipulate functions dynamically, for example to implement generic module, that can be configured with callback functions.

Function references are based on function types. Referenced functions must be defined with the syntax defining parameter types in parentheses (and the RETURNS clause, if the functions return values), For more details, see [FUNCTION syntax](#).

**Function types**
A function type identifies the number and types of parameters and return values of a function:

```plaintext
FUNCTION(p1 INT, p2 INT) RETURNS INT
```

A function type can be used as other types, to declare simple variables, members of a structured RECORD, or arrays.
User-type definition for function references
To simplify function reference usage, you can define a user-type with the TYPE instruction, using the function type that will match functions to be called by reference:

```
TYPE callback_function FUNCTION(p1 INT, p2 INT) RETURNS INT
```

This type can be used as other types, to declare simple variables, members of a structured RECORD, or arrays.

For more details about user-defined type definitions, see Types on page 397.

Variable definition for function references
When the user-type for the function reference is available, declare a program variable to hold such function reference:

```
DEFINE callback callback_function
```

For more details about variable definitions, see Variables on page 366.

Get the FUNCTION reference
To get the reference of a function, use the FUNCTION keyword followed by the name of the function to be referenced. The function must be defined in the current module, or in a module imported with IMPORT FGL.

```
LET callback = FUNCTION add
```

In the above example, the function "add()" must be defined with the same function type as the "callback" variable.

For more details, see FUNCTION func-spec on page 364.

Invoking a function with the CALL statement
Functions referenced in a variable can be invoked with the CALL instruction, by using the variable.

The referenced function will be called as in a regular function call:

```
CALL callback(100,200) RETURNING result
```

Using function references in expressions
Variables referencing functions can be used in expressions, like in this example:

```
LET get_count_func = FUNCTION get_total_items()
LET c = get_count_func()
LET get_count_func = FUNCTION get_total_elements()
LET c = c + get_count_func()
```

Passing function references as function parameters
Like other values, function references can be passed as function parameters:

```
CALL process( FUNCTION add, FUNCTION sub, callback )
...
FUNCTION process( f1 callback_function, f2 callback_function, f3 callback_function )
   DISPLAY f1(100,200) + f2(200,50) + f3(150,300)
END FUNCTION
```
Related concepts
Flow control on page 340
Definition of language elements and instructions that control the flow of a program.

**FUNCTION func-spec**
The `FUNCTION` keyword provides the reference to the specified function.

**Syntax**

```
FUNCTION _[module-name.]_function-name
```

1. `module-name` is the name of an imported module.
2. `function-name` is the name of a function defining in the current module or in an imported module.

**Usage**
The `FUNCTION` keyword instructs the compiler to use the next symbol as the name of a `FUNCTION`, rather than the name of a variable (the language allows the declaration of variables and functions with the same name in the same module).

The function specification following the `FUNCTION` keyword can be a single function name or a function name prefixed by a module name.

This expression is typically used to assign a variable defined with a type referencing a function. It can also be used as parameter in a function call, but it cannot be combined with other expressions.

**Example**

```groovy
IMPORT FGL mymodule

TYPE callback_function FUNCTION(p1 INT, p2 INT) RETURNS INT

FUNCTION add(p1 INT, p2 INT) RETURNS INT
    RETURN p1 + p2
END FUNCTION

... DEFINE v callback_function
    LET v = FUNCTION add -- Assign function reference to the variable
... CALL process( FUNCTION add, ... ) -- Function reference passed as parameter
... LET v = FUNCTION mymodule.sub -- Using a module prefix
```

Related concepts
Function references on page 362
Function can be referenced and invoked dynamically in a `CALL` instruction, or in an expression.

**Examples**
Function definition examples.

**Example 1: Function fetching customer number**
The example shows a typical function definition returning an `INTEGER`.

```groovy
FUNCTION findCustomerNumber(name VARCHAR(50)) RETURNS INTEGER
    DEFINE num INTEGER
    CONSTANT sqltxt = "SELECT cust_num FROM customer WHERE cust_name = ?"
```

**Example**

```
IMPORT FGL mymodule

TYPE callback_function FUNCTION(p1 INT, p2 INT) RETURNS INT

FUNCTION add(p1 INT, p2 INT) RETURNS INT
    RETURN p1 + p2
END FUNCTION

... DEFINE v callback_function
    LET v = FUNCTION add -- Assign function reference to the variable
... CALL process( FUNCTION add, ... ) -- Function reference passed as parameter
... LET v = FUNCTION mymodule.sub -- Using a module prefix

```
Example 2: Private function definition

This example shows how to define a private function.

This function will not be visible to other modules because it is declared as `PRIVATE` for the module:

```
PRIVATE FUNCTION checkLength( name VARCHAR(50) )
  DEFINE ok BOOLEAN
  IF length(name) == 0 THEN
    LET ok = FALSE
  ELSE
    LET ok = TRUE
  END IF
  RETURN ok
END FUNCTION
```

Example 3: Using function references

This example shows how to invoke functions dynamically by reference.

The module "compute.4gl":

```
PUBLIC TYPE compute_function FUNCTION(p1 INT, p2 INT) RETURNS INT
PRIVATE DEFINE cf compute_function
PUBLIC FUNCTION set_function( f compute_function )
  LET cf = f
END FUNCTION
PUBLIC FUNCTION compute(i1 INT, i2 INT) RETURNS INT
  DEFINE r INT
  IF cf IS NULL THEN
    DISPLAY "ERROR: Define the function with set_function(FUNCTION <name>))"
    EXIT PROGRAM 1
  END IF
  LET r = cf(i1, i2)
  DISPLAY SFMT("compute(%1, %2) = %3", i1, i2, r)
  RETURN r
END FUNCTION
PUBLIC FUNCTION add(p1 INT, p2 INT) RETURNS INT
  RETURN p1 + p2
END FUNCTION
PUBLIC FUNCTION sub(p1 INT, p2 INT) RETURNS INT
  RETURN p1 - p2
END FUNCTION
```

The main program:

```
IMPORT FGL compute
MAIN
```
Variables

Explains how to define program variables.

- Understanding variables on page 366
- DEFINE on page 367
- Declaration context on page 368
- Structured variables on page 369
- Database column types on page 369
- User defined types on page 370
- Initialization values on page 371
- Definition attributes on page 372
- INITIALIZE on page 372
- LOCATE (for TEXT/BYTE) on page 373
- FREE (for TEXT/BYTE) on page 375
- LET on page 376
- VALIDATE on page 377
- Examples on page 378

Understanding variables

This is an introduction to variables.

A variable is a program element that can hold volatile data. The following list summarizes variables usage:

- Variables are declared in programs with the DEFINE instruction.
- After definition, variables get default values according their type.
- The scope of a variable can be global, local to a module, or local to a function.
- When defined at the module level, a variable can be declare it as PRIVATE or PUBLIC.
- You can define structured variables with records, and with arrays.
- Default values (or NULL) can be assigned with the INITIALIZE instruction.
- Direct value assignment is done with the LET instruction.
- Database validation rules can be applied with the VALIDATE instruction.
- Variables can be used as SQL parameters or fetch buffers in SQL statements.
- Interactive instructions use program variables as model to hold the data.
- Variables can be defined with attributes by using the ATTRIBUTES() clause.

Related concepts

- Using program variables in static SQL on page 639
  Static SQL syntax supports the usage of program variables as SQL parameters.
- Binding variables to form fields on page 1620
  Some dialogs need program variables to store form field values.
- Variable binding in INPUT on page 1377
- Definition attributes on page 372
Variables can be defined with meta-data information.

**DEFINE**

A variable contains volatile information of a specific data type.

**Syntax**

```
[PUBLIC|PRIVATE]
DEFINE identifier [, ...] type-definition
   [, ...]
```

where `type-definition` is:

```
   data-type
   LIKE [dbname:]tabname.colname
   attributes-list
```

or `type-definition` is a function type definition:

```
FUNCTION function-name { 
   parameter-name data-type [, ...] attributes-list [, ...] 
   )
   RETURNS data-type ( data-type [, ...] )
```

where `attribute-list` is:

```
ATTRIBUTES ( attribute = "value" [, ...] )
```

1. `identifier` is the name of the variable or record member.
2. `data-type` can be a built-in data type, a record definition, an array definition, a dictionary definition, a user defined type, a built-in class, an imported package class, or a Java class.
3. `dbname` identifies a specific database schema file.
4. `tabname.colname` references a column defined in the database schema file.
5. `attribute` is an attribute to extend the variable definition with properties.
6. `value` is the value for the variable attribute, it is optional for boolean attributes.
7. `mdy-date-literal` is an MDY(\(\text{mm}, \text{dd}, \text{yyyy}\)) specification.
8. `key` identifies a dictionary entry.

**Usage**

A *variable* is a named location in memory that can store a single value, or an ordered set of values. Variables can be global to the program, module-specific, or local to a function.

Any program variable needs to be declared with a `DEFINE` statement before it is used.

A variable is typically defined with a *data type*.

The variable name must follow the convention of *identifiers*.

By default, module-specific variables are private; They cannot be used by an other module of the program. In order to improve code re-usability by data encapsulation, we recommend you keep module variables private, except if you want to share large data (like arrays) between modules. To make a module variable public, add the `PUBLIC` keyword before `DEFINE`. When a module variable is declared as public, it can be referenced by another module by using the `IMPORT` instruction.

When defining variables with the `LIKE` clause, the data types are taken from the database schema file at compile time. Make sure that the schema file of the database schema during development corresponds to the database schema
of the production database; otherwise the variables defined in the compiled version of your modules will not match
the table structures of the production database. For more details, see Database column types on page 369.

To write well-structured programs, avoid global variables. If you need persistent data storage during a program's
execution, use variables local to the module and give access to them with functions, or make the module variables
PUBLIC to other modules. For more details, see Declaration context on page 368.

Variables can be defined with the ATTRIBUTES() clause, to specify meta-data information for the variable. For
more details, see Definition attributes on page 372.

Variables can be defined to hold a function reference. Best practice is to declare a user-defined type with the function
type, then define the variables using the user type.

**Related concepts**
Records on page 382
Records allow structured program variables definitions.

Arrays on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

**Declaration context**
A variable can be declared in different contexts, which defines its visibility.

The DEFINE on page 367 statement declares the identifier of one or more variables, that will be visible to other
program blocks depending on the declaration context of the variables. The scope of reference of a variable defines
where it can be referenced in the program. Depending on the location of the variable definition, memory will be
allocated when the program starts, or during the program execution.

The context of a variable declaration in the source module determines where a variable can be referenced by other
language statements, and when storage is allocated for the variable in memory. The DEFINE statement can appear in
three contexts:

1. **Within a FUNCTION, MAIN, or REPORT program block**, DEFINE declares local variables, and causes memory to
   be allocated on the runtime stack when the function is called. These DEFINE declarations of local variables must
   precede any procedural statements within the same program block. The scope of reference of a local variable is
   restricted to the same program block. The variable is not visible elsewhere. Functions can be called recursively,
   and each recursive entry creates its own set of local variables. The variable is unique to that invocation of its
   program block. Each time the block is entered, a new copy of the variable is created.

2. **Outside any FUNCTION, REPORT, or MAIN program block**, the DEFINE statement declares module variables.
   Module variables have a persistent state during program execution. Memory for module variables is allocated
   when the module is loaded. Module variable declarations (DEFINE) must appear before any program blocks. By
default, the scope of reference is the whole module (module variables are private to the module), but it can be
   extended to the whole program when the variable is declared with the PUBLIC qualifier.

3. **Inside a GLOBALS block**, the DEFINE statement declares global variables that are visible to the whole program.
   Global variables have a persistent state during program execution. Memory for global variables is allocated
   when the program starts. Multiple GLOBALS blocks can be defined for a given module. Use one module to declare all
   global variables and reference that module within other modules by using the GLOBALS "filename.4gl"
   statement as the first statement in the module, outside any program block.

A compile-time error occurs if you declare the same name for two variables that have the same scope. You can,
however, declare the same name for variables that differ in their scope. For example, you can use the same identifier
to reference different local variables in different program blocks.

You can also declare the same name for two or more variables whose scopes of reference are different but
overlapping. Within their intersection, the compiler interprets the identifier as referencing the variable whose scope is
smaller, and therefore the variable whose scope is a superset of the other is not visible.

If a local variable has the same identifier as a global variable, then the local variable takes precedence inside the
program block in which it is declared. Elsewhere in the program, the identifier references the global variable.
A module variable can have the same name as a global variable that is declared in a different module. Within the module where the module variable is declared, the module variable takes precedence over the global variable. Statements in that module cannot reference the global variable.

A module variable cannot have the same name as a global variable that is declared in the same module.

If a local variable has the same identifier as a module variable, then the local identifier takes precedence inside the program block in which it is declared. Elsewhere in the same source-code module, the name references the module variable.

If a variable needs to be persistent during program execution, instead of using global variables, consider defining that variable in the module it belongs to, by specifying the PUBLIC or PRIVATE modifiers, depending on the scope you want to give to your variable, for other modules.

**Related concepts**
- Example 1: Local function variables on page 378
- Example 2: PRIVATE module variables on page 378
- Example 3: PUBLIC module variables on page 378
- Example 4: Global variables on page 378

**Structured variables**

Variables can be declared with a composite data type, based on simple data types.

To declare a structured variable, use the RECORD or DYNAMIC ARRAY keywords.

For example:

```plaintext
MAIN
  DEFINE myrec RECORD
    id INTEGER,
    name VARCHAR(100)
  END RECORD
  DEFINE myarr DYNAMIC ARRAY OF RECORD
    id INTEGER,
    name VARCHAR(100)
  END RECORD
  LET myarr[2].id = 52
END MAIN
```

**Related concepts**
- Records on page 382
- Records allow structured program variables definitions.

**Arrays** on page 386
- Arrays (static or dynamic) allow to handle an ordered collection of elements.

**Database column types**

Simple variables and record structures can be defined from database columns types.

Variables defined with the LIKE keyword get the same data type as the table column of a database schema.

**Important**: Database schema files are generated with the fgl dbsch tool. Column data types are read from the schema file during compilation. Make sure that your schema files correspond exactly to the production database.

For example:

```plaintext
SCHEMA stores
DEFINE cust_name LIKE customer.cust_name
MAIN
  DEFINE rec_cust RECORD LIKE customer.*
  ...
```
A SCHEMA statement must define the database name identifying the database schema files to be used.

Alternatively, specify the database schema file followed by a colon, before the table name. This allows you to use several database schemas at the same time:

```
DEFINE rec_city      RECORD LIKE base:city.*
DEFINE rec_country   RECORD LIKE base:country.*
DEFINE rec_customer  RECORD LIKE orders:customer.*
DEFINE rec_item      RECORD LIKE stock:item.*
```

At runtime, a program typically connects to a single database source. Using multiple database schemas is a programming feature.

The database schema files must exist and must be located in one of the directories specified in the FGLDBPATH environment variable.

When using database views, the column cannot be based on an aggregate function like `SUM()`.

If `LIKE` references a `SERIAL` column, the variable will be defined with the `INTEGER` data type. If `LIKE` references an `INT8`, `SERIAL8` or `BIGSERIAL` column, the variable will be defined with the `BIGINT` data type.

The table qualifier must specify `owner` if `table.column` is not a unique column identifier within its database, or if the database is ANSI-compliant and any user of your application is not the owner of `table`.

**Related concepts**

*Data types* on page 253

Selecting the correct data type assists you in the input, storage, and display of your data.

*LIKE* on page 303

The `LIKE` operator returns `TRUE` if a string matches a given mask.

**User defined types**

User defined types help to centralize the definition of complex structured data types.

A user defined type is created with the `TYPE` keyword. The next code example defines a type as a dynamic array of a record, with the structure of a database table as defined in the `mydbschema.sch` schema file:

```
SCHEMA mydbschema
...
TYPE t_custlist DYNAMIC ARRAY OF RECORD LIKE customer.*
```

Variables can then be defined with the "custlist" user defined type:

```
DEFINE cl t_custlist
```

The scope of a type can be global, local to a module or local to a function.

Variables can be defined with a type defined in the same scope, or in a higher level of scope.

A typical usage is to declare user-defined types as `PUBLIC` in a module, so they can be reused in other modules:

The `myutils.4gl` module defines the user type:

```
PUBLIC TYPE t_item_info RECORD
  id INTEGER,
  description VARCHAR(100),
  creation DATE,
  mandatory BOOLEAN,
...
END RECORD
...
In the module importing the utility module, define variables using the type name, with utility module as prefix:

```plaintext
IMPORT FGL myutils  
...  
DEFINE itemlist DYNAMIC ARRAY OF myutils.t_item_info  
...
```

**Related concepts**

*Types* on page 397

Types can be defined by the programmer to centralize the definition of complex/structured variables.

**Initialization values**

Variables are initialized differently depending on the data type.

When a variable is defined, it is automatically initialized by the runtime system to a default value. The default value the variable is assigned with depends on the data type.

**Table 127: data type specific default values for variables**

<table>
<thead>
<tr>
<th>Data type</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR</td>
<td>NULL</td>
</tr>
<tr>
<td>VARCHAR</td>
<td>NULL</td>
</tr>
<tr>
<td>STRING</td>
<td>NULL</td>
</tr>
<tr>
<td>INTEGER</td>
<td>Zero</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>Zero</td>
</tr>
<tr>
<td>FLOAT</td>
<td>Zero</td>
</tr>
<tr>
<td>SMALLFLOAT</td>
<td>Zero</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>NULL</td>
</tr>
<tr>
<td>MONEY</td>
<td>NULL</td>
</tr>
<tr>
<td>DATE</td>
<td>1899-12-31 (= Zero in number of days)</td>
</tr>
<tr>
<td>DATETIME</td>
<td>NULL</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>NULL</td>
</tr>
<tr>
<td>TEXT</td>
<td>NULL, must use LOCATE</td>
</tr>
<tr>
<td>BYTE</td>
<td>NULL, must use LOCATE</td>
</tr>
</tbody>
</table>

**Related concepts**

*Data types* on page 253

Selecting the correct data type assists you in the input, storage, and display of your data.

*LOCATE (for TEXT/BYTE)* on page 373
The LOCATE statement specifies where to store data of TEXT and BYTE variables.

**Definition attributes**

Variables can be defined with meta-data information.

**Basics**

To specify metadata information when defining a variable, use the ATTRIBUTES clause:

```sql
DEFINE myvar INTEGER ATTRIBUTES
```

**JSON serialization attributes**

To define JSON serialization options, use variable definition attributes such as json_null and json_name:

```sql
DEFINE rec RECORD
    cust_id INTEGER ATTRIBUTES(json_null="null"),
    cust_name INTEGER ATTRIBUTES(json_name="Customer Name"),
    ...
    orderlist DYNAMIC ARRAY ATTRIBUTES(json_null="undefined") OF RECORD
    ...
    END RECORD,
    ...
END RECORD
```

List of supported JSON attributes for variable definitions:

- json_null (values can be "null" or "undefined")
- json_name

For more details about JSON serialization attributes see BDL names and JSON element names on page 467.

**XML serialization attributes**

Variable attributes are also used when defining variables for XML-based Web Services:

```sql
DEFINE data RECORD ATTRIBUTES(XMLName="Demo"),
    val1 INTEGER ATTRIBUTES(XMLName= "Value1"),
    val2 STRING ATTRIBUTES(XMLName= "Value2"),
    attr INTEGER ATTRIBUTES(XMLAttribute,XMLName= "MyAttr")
END RECORD
```

For more details about XML attributes, see Attributes to customize XML serialization on page 3250.

**Related concepts**

**DEFINE** on page 367

A variable contains volatile information of a specific data type.

**INITIALIZE**

The INITIALIZE instruction initializes program variables with NULL or default values.

**Syntax**

```sql
INITIALIZE target [,...]
  ↓ TO NULL
  ↓ LIKE [table.*]table.column
```
1. `target` is the name of the variable to be initialized.
2. `table.column` can be any column reference defined in the database schema files.

**Usage**

The `INITIALIZE` instruction assigns `NULL` or default values to variables.

The argument of the `INITIALIZE` instruction can be a simple variable, a record (with `. *` notation), a record member, a range of record members specified with the `THRU` keyword, an array or an array element.

The `TO NULL` clause initializes the variable to `NULL`.

When initializing a static array `TO NULL`, all elements will be initialized to null. When initializing a dynamic array `TO NULL`, all elements will be removed (i.e. the dynamic array is cleared).

The `LIKE` clause initializes the variable to the default value defined in the database schema validation file. This clause works only by specifying the `table.column` schema entry corresponding to the variable.

To initialize a complete `RECORD`, you can use the star to reference all members:

```
INITIALIZE record.* LIKE table.*
```

You cannot initialize variables defined with a complex data type (like `TEXT` or `BYTE`) to a non-NULL value.

**Example**

```
SCHEMA stores
MAIN
    DEFINE cr RECORD LIKE customer.*
    DEFINE a1 ARRAY[100] OF INTEGER
    INITIALIZE cr.cust_name TO NULL
    INITIALIZE cr.cust_name THRU cr.cust_address TO NULL
    INITIALIZE cr.* LIKE customer.*
    INITIALIZE a1 TO NULL
    INITIALIZE a1[10] TO NULL
END MAIN
```

**Related concepts**

**DEFINE** on page 367
A variable contains volatile information of a specific data type.

**Initialization values** on page 371
Variables are initialized differently depending on the data type.

**LOCATE (for TEXT/BYTE)**

The `LOCATE` statement specifies where to store data of `TEXT` and `BYTE` variables.

**Syntax 1: Locate in memory**

```
LOCATE target IN MEMORY
```

**Syntax 2: Locate in a specific file**

```
LOCATE target IN FILE filename
```
**Syntax 3: Locate in a temporary file**

LOCATE target IN FILE

1. *target* is the name of a TEXT or BYTE variable to be located.
2. *filename* is a string expression defining the name of a file.

**Usage**

Before using TEXT and BYTE large objects, the data storage location must be specified with the LOCATE instruction. After defining the data storage, the variable can be used as input parameter or as a fetch buffer in SQL statements, as well as in interaction statements and reports.

The first syntax using the IN MEMORY clause specifies that the large object data must be located in memory.

The second syntax using the IN FILE *filename* clause specifies that the large object data must be located in a specific file.

The third syntax using the IN FILE clause specifies that the large object data must be located in a temporary file. The location of the temporary file can be defined with the DBTEMP environment variable. If DBTEMP is not defined, the default temporary directory dependents from the platform used.

The **FREE** instruction can be used to free the resources allocated to the large object variable.

**Note:** When the TEXT or BYTE variable is already located, a new LOCATE will free the allocated resource: If the prior LOCATE was using the IN FILE clause, the temporary file is dropped, if the prior LOCATE was using IN MEMORY, the memory is freed.

**Example**

The following code example defines two TEXT variables. The first located in memory and the second located in a named file. The variables are then used in SQL statements:

```sql
MAIN
  DEFINE ctext1, ctext2 TEXT
  DATABASE stock
  LOCATE ctext1 IN MEMORY
  LOCATE ctext2 IN FILE "/tmp/data1.txt"
  CREATE TABLE lobtab ( key INTEGER, col1 TEXT, col2 TEXT )
  INSERT INTO lobtab VALUES ( 123, ctext1, ctext2 )
END MAIN
```

The next code example illustrates the storage semantics of BYTE and TEXT, by fetching large objects from the database into an array. Each member of the array needs to get an individual storage location, before the data is actually fetched into the LOB handler of the array element. By using LOCATE IN FILE, a temporary file will be created for each large object:

```sql
TYPE t_arr DYNAMIC ARRAY OF RECORD
  id INTEGER,
  cmt TEXT
END RECORD

MAIN
  DEFINE arr t_arr,
    t TEXT
  DATABASE test1
  LOCATE t IN MEMORY
  CREATE TEMP TABLE tt1 ( id INTEGER, cmt TEXT )
  LET t = "aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa"
  INSERT INTO tt1 VALUES ( 1, t )
  LET t = "bbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbbb"
```

INSERT INTO ttl VALUES ( 2, t )

CALL fill_array(arr)

END MAIN

FUNCTION fill_array(arr)
  DEFINE arr t_arr,
       i INTEGER

  CALL arr.clear()
  DECLARE c1 CURSOR FOR SELECT * FROM ttl
  LET i=1
  LOCATE arr[i].cmt IN FILE
  FOREACH c1 INTO arr[i].*
    LOCATE arr[i:=i+1].cmt IN FILE
  END FOREACH
  CALL arr.deleteElement(i)
  FOR i=1 TO arr.getLength()
    DISPLAY arr[i].*
  END FOR

END FUNCTION

Related concepts
FREE (for TEXT/BYTE) on page 375
The FREE statement releases resources allocated to the specified variable.

FREE (for TEXT/BYTE)
The FREE statement releases resources allocated to the specified variable.

Syntax
FREE target

1. target is the name of a TEXT or BYTE variable to be freed.

Usage
When followed by a variable name, the FREE statement releases resources allocated to store the data of TEXT and BYTE variables.

If the TEXT/BYTE variable was located in memory, the runtime system releases the memory. If the variable was located in a file, the runtime system deletes the file.

For variables declared in a local scope of reference, the resources are automatically freed by the runtime system when returning from the function or MAIN block.

After freeing a TEXT or BYTE variable, it must be re-configured with a new LOCATE call.

Temporary files of large object are automatically deleted when the program ends.

Example
MAIN
  DEFINE ctext TEXT
  DATABASE stock
  LOCATE ctext IN FILE "/tmp/data1.txt"
  SELECT col1 INTO ctext FROM lobtab WHERE key=123
  FREE ctext
The `LOCATE` statement specifies where to store data of `TEXT` and `BYTE` variables.

**TEXT** on page 271
The `TEXT` data type stores large text data.

**BYTE** on page 255
The `BYTE` data type stores any type of binary data, such as images or sounds.

**LET**
The `LET` statement assigns values to variables.

**Syntax**

```
LET target = expr [, ...]
```

1. `target` is the name of the variable to be assigned.
2. `expr` is any valid expression supported by the language.

**Usage**
The `LET` statement assigns a value to a variable, or a set of values to all members of a `RECORD` by using the `.*` notation.

The runtime system applies data type conversion rules if the data type of `expression` does not correspond to the data type of `target`.

When assigning a numeric of date/time value to a character string variable, the values are formatted for display (for example, the numeric data is right-aligned).

When specifying a comma-separated list of expressions for the right operand, the `LET` statement concatenates all expressions together. Unlike the `||` operator, if an expression in the comma-separated list evaluates to `NULL`, the concatenation result will not be null, except if all expressions to the right of the equal sign are null.

The target variable can be record followed by dot + star (`record.*`), to reference all record members of the record. In this case, the right operand must also be a record using this notation, and all members will be assigned individually.

Variables defined with a complex data type (like `TEXT` or `BYTE`) can only be assigned to `NULL`.

**Example**

```
SCHEMA stores
MAIN
  DEFINE c1, c2 RECORD LIKE customer.*
  -- Single variable assignment
  LET c1.customer_num = 123
  -- Complete RECORD assignment
  LET c1.* = c2.*
END MAIN
```
Arrays (static or dynamic) allow to handle an ordered collection of elements.

**NULL** on page 502
The NULL constant is provided as the "nil" value.

**Type conversions** on page 274
Explains data type conversion rules of the language.

**Assignment (:=)** on page 329
The := operator assigns a variable with an expression and returns the result.

**TEXT** on page 271
The TEXT data type stores large text data.

**BYTE** on page 255
The BYTE data type stores any type of binary data, such as images or sounds.

---

**VALIDATE**
The VALIDATE instructions checks a variable value based on database schema validation rules.

**Syntax**
```
VALIDATE target [,..] LIKE
  ↓
 table.*
  ↓
 table.column
```
1. `target` is the name of the variable to be validated.
2. If `target` is a record, you can use the star notation to validate all members in the record.
3. `table.column` can be any column reference defined in the database schema.

**Usage**
The VALIDATE statement tests whether the value of the specified variable is within the range of values for a corresponding column in .val database schema file referenced by a SCHEMA clause. If the value does not match any value defined in the INCLUDE attribute of the corresponding column, the runtime system raises error -1321.

The argument of the VALIDATE instruction can be a simple variable, a record, or an array element. If the target is a record, you can use the dot + star (.* ) notation to reference all record members in the validation, or specify a range of record members with the THRU clause.

**Example**
```
SCHEMA stores
MAIN
  DEFINE cname LIKE customer.cust_name
  LET cname = "aaa"
  VALIDATE cname LIKE customer.cust_name
END MAIN
```

**Related concepts**
- **Database schema** on page 476
  Defines database table structures with column type information to be reused in program variable definitions.
- **Records** on page 382
Records allow structured program variables definitions.

Examples
Variable definition usage examples.

**Example 1: Local function variables**
This example shows how to define local function variables.

```
FUNCTION myfunc()
  DEFINE i INTEGER
  FOR i=1 TO 10
    DISPLAY i
  END FOR
END FUNCTION
```

**Example 2: PRIVATE module variables**
This example shows how to define a private module variable.

```
PRIVATE DEFINE s VARCHAR(100)
FUNCTION myfunc()
  DEFINE i INTEGER
  FOR i=1 TO 10
    LET s = "item #" || i
  END FOR
END FUNCTION
```

**Example 3: PUBLIC module variables**
This example shows how to declare public and private module variables.

The module "mydebug.4gl":

```
PUBLIC DEFINE level INTEGER,
  logfile STRING
PRIVATE DEFINE count INTEGER

FUNCTION message(m)
  DEFINE m STRING
  IF level THEN
    -- Write message to debug_logfile
    DISPLAY m
  END IF
  LET count = count + 1
END FUNCTION
```

The main module:

```
IMPORT FGL mydebug

MAIN
  LET mydebug.level = 4
  LET mydebug.logfile = "myfile.log"
  CALL mydebug.message("Some debug info...")
END MAIN
```

**Example 4: Global variables**
This example shows how to define and use global variables.
The module "myglobs.4gl":

```plaintext
GLOBALS
  DEFINE userid CHAR(20)
  DEFINE extime DATETIME YEAR TO SECOND
END GLOBALS
```

The module "mylib.4gl":

```plaintext
GLOBALS "myglobs.4gl"
DEFINE s VARCHAR(100)
FUNCTION myfunc()
  DEFINE i INTEGER
  DISPLAY "User Id = " || userid
  FOR i=1 TO 10
    LET s = "item #" || i
  END FOR
END FUNCTION
```

The main module:

```plaintext
GLOBALS "myglobs.4gl"
MAIN
  LET userid = fgl_getenv("LOGNAME")
  LET extime = CURRENT YEAR TO SECOND
  CALL myfunc()
END MAIN
```

**Constants**

The definition of constants allows to centralize common static values.

- Understanding constants on page 379
- CONSTANT on page 380
- Examples on page 382

**Understanding constants**

This is an introduction to constant definition.

A constant defines a read-only value identified by a name. A constant is similar to a variable, except that its value cannot be modified by program code.

Constants as typically used to define common invariable values that will be used at several place in a program:

```plaintext
CONSTANT PI DECIMAL(12,10) = 3.1415926,
  MAX_SIZE INT = 10000,
  ERRMSG = "PROGRAM ERROR: %1" -- type defaults to STRING
```

A good practice is to define constants that belong to the same domain in a single .4gl module, define the constant as PUBLIC, and import the module where the constants are needed.

**Related concepts**

Data types on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

Variables on page 366
Explains how to define program variables.

**Importing modules** on page 496

Use the **IMPORT** ... instruction to import BDL, C or Java external modules in the current module.

---

**CONSTANT**

The **CONSTANT** instruction defines a program constant.

**Syntax**

```
[PRIVATE|PUBLIC] CONSTANT constant-definition [, ...]
```

where **constant-definition** is:

```
identifier [ data-type ] = literal
```

1. *identifier* is the name of the constant to be defined.
2. *data-type* can be any built-in data type, except complex types like **TEXT** or **BYTE**.
3. *literal* must be an integer, decimal, string, or date/time literal, or an **MDY()** expression.
4. *literal* cannot be **NULL**.

**Usage:**

Constants define final static values that can be used in other instructions.

Constants can be defined with global, module, or function scope.

By default, module constants are private; They cannot be used by an other module of the program. To make a module constant public, add the **PUBLIC** keyword before **CONSTANT**. When a module constant is declared as public, it can be referenced by another module by using the **IMPORT** instruction.

When declaring a constant, the data type specification can be omitted. The literal value automatically defines the data type:

```
CONSTANT c1 = "Drink"  -- Declares a STRING constant
CONSTANT c2 = 4711     -- Declares an INTEGER constant
```

However, in some cases, you may need to specify the data type:

```
CONSTANT c1 SMALLINT = 12000 -- Would be an INTEGER by default
```

Constants can be used in variable, records, and array definitions:

```
CONSTANT n = 10
DEFINE a ARRAY[n] OF INTEGER
```

Constants can be used at any place in the language where you normally use literals:

```
CONSTANT n = 10
FOR i=1 TO n
  ...
```

Constants can be passed as function parameters, and returned from functions.

Define public constants in a module to be imported by others:

```
PUBLIC CONSTANT pi = 3.14159265
```
For date time constants, the value must be specified as an MDY(), DATETIME or INTERVAL literal:

```
CONSTANT my_date DATE = MDY(12,24,2011)
CONSTANT my_datetime DATETIME YEAR TO SECOND
    = DATETIME(2011-12-24 11:22:33) YEAR TO SECOND
CONSTANT my_interval INTERVAL HOUR(5) TO FRACTION(3)
    = INTERVAL(-54351:50:24.234) HOUR(5) TO FRACTION(3)
```

A constant cannot be used in the ORDER BY clause of a static SELECT statement, because the compiler considers identifiers after ORDER BY as part of the SQL statement (i.e. column names), not as constants:

```
CONSTANT pos = 3
-- Next line will produce an error at runtime
SELECT * FROM customers ORDER BY pos
```

Automatic data type conversion can take place in some cases:

```
CONSTANT c1 CHAR(10) = "123"
CONSTANT c2 CHAR(10) = "abc"
DEFINE i INTEGER
FOR i = 1 TO c1 -- Constant "123" is converted to 123 integer
    ...
FOR i = 1 TO c2 -- Constant "abc" is converted to zero!
    ...
```

Character constants defined with a string literal that is longer than the length of the data type are truncated:

```
CONSTANT s CHAR(3) = "abcdef"
DISPLAY s -- Displays "abc"
```

The compiler throws an error when an undefined symbol is used in a constant declaration:

```
CONSTANT s CHAR(c) = "abc"
-- Compiler error: c is not defined.
```

The compiler throws an error when a variable is used in a constant declaration:

```
DEFINE c INTEGER
CONSTANT s CHAR(c) = "abc"
-- Compiler error: c is a variable, not a constant.
```

The compiler throws an error when you try to assign a value to a constant:

```
CONSTANT c INTEGER = 123
LET c = 345
-- Runtime error: c is a constant.
```

The compiler throws an error when the symbol used is not defined as an integer constant:

```
CONSTANT c CHAR(10) = "123"
DEFINE s CHAR(c)
-- Compiler error: c is a not an integer constant.
```

You typically define common special characters with constants:

```
CONSTANT c_esc  = '\x1b'
CONSTANT c_tab  = '\t'
CONSTANT c_cr   = '\r'
CONSTANT c_lf   = '\n'
```
CONSTANT c_crlf = '\r\n'

Related concepts

Literals on page 288
Describes the syntax of literals (constant values) to be used in sources.
Importing modules on page 496
Use the IMPORT ... instruction to import BDL, C or Java external modules in the current module.

Examples
CONSTANT usage examples.

Example 1: Defining and using constants
This example shows how to define constants.

CONSTANT
c1 = "Drink",       # Declares a STRING constant
c2 = 4711,         # Declares an INTEGER constant
n = 10,            # Declares an INTEGER constant
x SMALLINT=1       # Declares a SMALLINT constant
DEFINE a ARRAY[n] OF INTEGER

MAIN
CONSTANT c1 = "Hello"
DEFINE i INTEGER
FOR i=1 TO n
...
END FOR
DISPLAY c1 || c2  # Displays "Hello4711"
END MAIN

Records
Records allow structured program variables definitions.
• Understanding records on page 382
• RECORD on page 383
• record.elem1 THRU record.elem2 on page 385
• Examples on page 385

Understanding records
This is an introduction to records.
A record defines a structured variable, where each member can be defined with a specific data type. Records can contain other records, or arrays.

DEFINE person RECORD
   id INTEGER,
   name VARCHAR(100),
   birth DATE
END RECORD

Records are typically used to store the values of a database row. Records can be defined based on the column types of a database table as defined in a database schema.
Records are used in interactive instructions like `INPUT` to control forms, and record are also used in `INSERT` and `UPDATE` SQL instructions, to update the database table.

SCHEMA stores
```plaintext
DEFINE cust RECORD customer.*
-- cust is defined with the column of the customer table
```

### Related concepts

- **Flow control** on page 340
  Definition of language elements and instructions that control the flow of a program.

### RECORD

Records define structured variables.

#### Syntax 1 (explicit record definition)

```plaintext
RECORD
  ↓ ATTRIBUTES( attribute ↓ = "value" ↓ ↓,↓,↓,↓ ) ↓
  ↓ member ↓
  ↓ data-type ↓
  ↓ LIKE ↓ dbname:tabname.colname ↓
  ↓ ↓ ATTRIBUTES( attribute ↓ = "value" ↓ ↓,↓,↓,↓ ) ↓
END RECORD
```

#### Syntax 2 (database column based record)

```plaintext
RECORD
  ↓ ATTRIBUTES( attribute ↓ = "value" ↓ ↓,↓,↓,↓ ) ↓
  LIKE ↓ dbname:tabname.* ↓
```

1. `member` is an identifier for a record member / field.
2. `data-type` is a data type, a record definition, a user defined type, an array definition, a built-in class, an imported package class, or a Java class.
3. `dbname` identifies a specific database schema file.
4. `tabname.colname` references a column defined in the database schema file.
5. `tabname.*` references the structure of a complete table defined in the database schema file.
6. `attribute` is an attribute to extend the record or record member definition with properties.
7. `value` is the value for the record definition attribute, it is optional for boolean attributes.

### Usage

A record defines an ordered set of variables called members.

Each record member is defined with a specific type or in turn, structured type.
Records whose members correspond in number, order, and data type compatibility to a database table can be useful for transferring data from the database to the screen, to reports, or to functions.

In the first form (Syntax 1), record members are defined explicitly:

```
DEFINE rec RECORD
  cust_id INT,
  cust_name VARCHAR(50),
  cust_address VARCHAR(100),
  ...
END RECORD
```

In the second form (Syntax 2), record members are created implicitly from the table definition found in the database schema file specified by the SCHEMA instruction:

```
SCHEMA stock
  ...
DEFINE rec RECORD LIKE customer.*
```

Important: When using the LIKE clause, the data types are taken from the database schema file during compilation. Make sure that the database schema file of the development database corresponds to the production database, otherwise the records defined in the compiled version of your programs will not match the table structures of the production database. Statements like SELECT * INTO record.* FROM table would fail.

In the rest of the program, record members are accessed by a dot notation (record.member). The notation record.member refers to an individual member of a record. The notation record.* refers to the entire list of record members. The notation record.first THRU record.last refers to a consecutive set of members. (THROUGH is a synonym for THRU):

```
DISPLAY rec.*
```

Records can be passed as function parameters, and can be returned from functions. However, when passing records to functions, you must keep in mind that the record is expanded as if each individual member would have been passed as parameter:

```
CALL myfunction(rec.*)
```

It is possible to assign and compare records having the same structure, by using the dot star notation:

```
LET rec2.* = rec3.*
...
IF rec1.* == rec2.* THEN
  ...
END IF
```

When comparing records, all members will be compared. If two members are NULL, the result of this member comparison results in TRUE.

Records can be defined with the ATTRIBUTES() clause, to specify meta-data information for the record. This feature is especially used when defining records for XML-based Web Services. For more details about XML attributes, see Attributes to customize XML serialization on page 3250.

Related concepts
Arrays on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

Variables on page 366
Explains how to define program variables.

Database schema on page 476
Defines database table structures with column type information to be reused in program variable definitions.

Data types on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

Functions on page 353
Describes user defined functions.

record.elem1 THRU record.elem2
The THRU keyword can be used to specify a range of members of a record.

Syntax

\[
record.first-member \ \text{THRU} \ \text{THROUGH} \ \text{THRU} \ record.last-member
\]

1. \( record \) defines the record to be used.
2. \( first-member \) defines the member of the record starting the group of variables.
3. \( last-member \) defines the member of the record ending the group of variables.
4. \( \text{THROUGH} \) is a synonym for \( \text{THRU} \).

Usage
The THRU keyword can be used in several instructions such as INITIALIZE, VALIDATE, LOCATE, to specify a list of record members.

Example

SCHEMA stores
MAIN
  DEFINE cust LIKE customer.*
  INITIALIZE cust.cust_name THRU customer.cust_address TO NULL
END MAIN

Related concepts
INITIALIZE on page 372
The INITIALIZE instruction initializes program variables with NULL or default values.

LOCATE (for TEXT/BYTE) on page 373
The LOCATE statement specifies where to store data of TEXT and BYTE variables.

VALIDATE on page 377
The VALIDATE instructions checks a variable value based on database schema validation rules.

Examples

RECORD usage examples.

Example 1: Defining a record with explicit member types
This example shows a simple record definition with built-in types.

MAIN
  DEFINE rec RECORD
      id INTEGER,
      name VARCHAR(100),
      birth DATE
  END RECORD
  LET rec.id = 50
  LET rec.name = 'Scott'
  LET rec.birth = TODAY
  DISPLAY rec.*
Example 2: Defining a record with a database table structure
This example shows how to define a record with members using the same types as database columns.

```
SCHEMA stores
DEFINE cust RECORD LIKE customer.*
MAIN
    DATABASE stores
        SELECT * INTO cust.* FROM customer WHERE customer_num=2
    DISPLAY cust.*
END MAIN
```

Example 3: Assigning an comparing records
This example shows how to use records with comparison and assignment operators.

```
SCHEMA stores
TYPE t_cust RECORD LIKE customer.*
MAIN
    DEFINE cust1, cust2 t_cust
    ...
    INITIALIZE cust1.* TO NULL
    ...
    LET cust2.* = cust1.*
    ...
    IF cust1.* != cust2.* THEN
        DISPLAY "Records are different!"
    END IF
    ...
END MAIN
```

Arrays
Arrays (static or dynamic) allow to handle an ordered collection of elements.

- Understanding arrays on page 386
- ARRAY on page 387
- Static arrays on page 388
- Dynamic arrays on page 389
- Array methods on page 391
- Copying arrays on page 392
- Examples on page 392

Understanding arrays
This is an introduction to arrays.

Arrays can store a one-, two- or three-dimensional set of elements.

The language supports three kind of array types:

- Static arrays - introduced in early versions of the language.
- Dynamic arrays - to be used in new developments.
- Java arrays - to define a Java array, to interface with Java classes.

For static and dynamic arrays, elements can be of simple built-in types such as INTEGER, VARCHAR(n), RECORD structured types, or user-defined types. A BDL array can also be defined with built-in classes, imported module classes (from the Web Services extensions for example), or Java classes.
Arrays can be used to define a list of records that will be controlled by dialog instructions such as DISPLAY ARRAY and INPUT ARRAY.

**Related concepts**

Dictionary on page 393
A dictionary holds an unordered collection of elements accessed by a key.

Using Java arrays on page 2094

**ARRAY**

An array defines a vector variable with a list of elements.

**Syntax 1: Static array definition**

```
ARRAY [ size [, size ] ]
\downarrow ATTRIBUTES( attribute \downarrow = "value" \downarrow [, ...] ) \downarrow
OF data-type
```

**Syntax 2: Dynamic array definition**

```
DYNAMIC ARRAY
\downarrow ATTRIBUTES( attribute \downarrow = "value" \downarrow [, ...] ) \downarrow
\downarrow WITH DIMENSION rank \downarrow
OF data-type
```

**Syntax 3: Java array definition**

```
ARRAY [ ] OF java-type
```

1. *size* can be an integer literal or an integer constant. The upper limit is 65535.
2. *rank* can be an integer literal of 1, 2, or 3. Default is 1.
3. *data-type* can be a data type, a record definition, a user defined type, a built-in class, an imported package class, or a Java class.
4. *java-type* must be a Java class or a simple data type that has a corresponding primitive type in Java, such as INTEGER (int), FLOAT (double).
5. *attribute* is an attribute to extend the array definition with properties.
6. *value* is the value for the array definition attribute, it is optional for boolean attributes.

**Usage**

An array defines an ordered set of elements.

The type of the array elements can be of a simple type or structured records.

Consider using dynamic arrays instead of static arrays.

Java-style arrays will only be useful to interface with Java calls.

Static and dynamic arrays can be defined with the ATTRIBUTES () clause, to specify meta-data information for the variable. This feature is especially used when defining variables for XML-based Web Services. For more details about XML attributes, see Attributes to customize XML serialization on page 3250.

**Related concepts**

Data types on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

Using Java arrays on page 2094
Variables on page 366
Explains how to define program variables.

**Static arrays**

Static arrays have a predefined and limited size.

**Defining static arrays**

Static arrays can store a one-, two- or three-dimensional array of variables, all of the same type. An array member can be any type except another array (ARRAY ... OF ARRAY).

```plaintext
MAIN
DEFINE custlist ARRAY[100] OF RECORD
   id INTEGER,
   name VARCHAR(50)
END RECORD
LET custlist[50].id = 12456
LET custlist[50].name = "Beerlington"
END MAIN
```

**Multi-dimentional static arrays**

The multi-dimensional array syntax (ARRAY[i,j,k]) specifies static arrays defined with an explicit size for all dimensions. Static arrays have a size limit. The biggest static array size you can define is 65535.

A single array element can be referenced by specifying its coordinates in each dimension of the array.

Avoid using large static arrays; All elements of static arrays are allocated and initialized when the program starts, even if the array is not used.

```plaintext
MAIN
DEFINE a1 ARRAY[100] OF INTEGER
LET a1[50] = 12456
LET a1[5000] = 12456  -- Runtime error!
END MAIN
```

**Element types**

The elements of a static array variable can be defined as a structured record:

```plaintext
MAIN
DEFINE arr ARRAY[50] OF RECORD
   key INTEGER,
   name CHAR(10),
   address VARCHAR(200),
   contacts ARRAY[50] OF VARCHAR(20)
END RECORD
LET arr[1].key = 12456
LET arr[1].name = "Scott"
LET arr[1].contacts[1] = "Bryan COX"
LET arr[1].contacts[2] = "Mike FLOWER"
END MAIN
```

**Passing static arrays to functions**

Static arrays are passed by value to functions. This is not recommended, as all array members will be copied on the stack.

A static array cannot be returned from a function.

Consider using dynamic arrays if you need to pass/return a list of elements to/from functions.
Using array methods
Array methods can be used on static arrays; However these methods are designed for dynamic arrays and are not appropriate for static arrays.

Related concepts
Array methods on page 391
Native BDL arrays and Java arrays can be used to invoke built-in methods.

Controlling out of bound in static arrays

Controlling out of bounds index error
By default, when an array index is out of range, fglrun raises error -1326. This is only the case for static arrays. When using a dynamic array, new elements are allocated if the index is greater than the actual array size.

Raising an index out of bounds error is normal for static arrays. However, in some situations, code must execute without error and evaluate expressions using indexes that are greater than the size of the array, especially with boolean expressions in IF statements:

```
IF index <= max_index OR arr[index] == some_value THEN
    ...
END IF
```

In this example, as all parts of a boolean expression need to be evaluated, the runtime system must get the value of the `arr[index]` element.

You can use an FGLPROFILE entry to control the behavior of the runtime system when an array index is out of bounds for a static array:

```
fglrun.arrayIgnoreRangeError = true
```

When this FGLPROFILE entry is set to true, the runtime system will return the first element of the array if the index is <=0 or greater than the size of the array and continue with the normal program flow.

Unless existing code is relying on this behavior, it is better to let the default get array out of bounds errors when the index is invalid.

You may also want to use the compiler directive to control boolean expression evaluation, with the OPTIONS SHORT CIRCUIT instruction.

Related concepts
Controlling semantics of AND / OR operators on page 505
The OPTIONS SHORT CIRCUIT defines the semantics of AND/OR operators.

Dynamic arrays

Defining dynamic arrays
Dynamic arrays are defined with the DYNAMIC ARRAY syntax and specify an array with a variable size. Dynamic arrays have no theoretical size limit. The elements of dynamic arrays are allocated automatically by the runtime system, based on the indexes used.

```
MAIN
    DEFINE a1 DYNAMIC ARRAY OF INTEGER
    LET a2[5000] = 12456  -- Automatic allocation for element 5000
END MAIN
```
Element types

The elements of a dynamic array variable are typically defined as a structured record:

```main
DEFINE arr DYNAMIC ARRAY OF RECORD
   key INTEGER,
   name VARCHAR(30),
   address VARCHAR(200),
   contacts DYNAMIC ARRAY OF VARCHAR(20)
END RECORD
LET arr[1].key = 12456
LET arr[1].name = "Scott"
LET arr[1].contacts[1] = "Bryan COX"
LET arr[1].contacts[2] = "Mike FLOWER"
END MAIN
```

Automatic element allocation

When a dynamic array element does not exist, it is automatically allocated before it is used. For example, when you assign an array element with the `LET` instruction by specifying an array index greater than the current length of the array, the new element is created automatically before assigning the value. This is also true when using a dynamic array in a `FOREACH` loop or when dynamic array elements are used as r-values, for example in a `DISPLAY`.

```main
DEFINE a DYNAMIC ARRAY OF INTEGER
LET a[50] = 33 -- Extends array size to 50 and assigns 33 to element #50
DISPLAY a[100] -- Extends array size to 100 and displays NULL
END MAIN
```

Important:

Pay attention to automatic element allocation in dynamic arrays. The following code example creates an additional element because at each iteration, the runtime system must allocate a new element to fetch the row from the database. As result, you need to remove the last element of the array after the `FOREACH` loop:

```define arr DYNAMIC ARRAY OF RECORD
   key INTEGER,
   name VARCHAR(30)
END RECORD,
x INTEGER
DECLARE c1 CURSOR FOR SELECT ckey, cname FROM mytable
LET x=1
FOREACH c1 INTO arr[x].*
   LET x=x+1
END FOREACH
CALL arr.deleteElement(x)

-- A more elegant way to fetch rows into an array:
TYPE my_type RECORD LIKE mytable.*
DEFINE arr DYNAMIC ARRAY OF my_type,
   rec my_type,
   x INTEGER
DECLARE c1 CURSOR FOR SELECT * FROM mytable
LET x=1
FOREACH c1 INTO rec.*
   LET arr[x:=x+1].* = rec.*
END FOREACH
```
Passing and returning dynamic arrays to functions

Dynamic arrays are passed (or returned) by reference to/from functions.

The dynamic array can be modified inside the called function, and the caller will see the modifications.

```plaintext
MAIN
  DEFINE a DYNAMIC ARRAY OF INTEGER
  CALL fill(a)
  DISPLAY a.getLength() -- shows 2
END MAIN

FUNCTION fill(x)
  DEFINE x DYNAMIC ARRAY OF INTEGER
  CALL x.appendElement()
  CALL x.appendElement()
END FUNCTION
```

Using multidimensional dynamic arrays

Multidimensional dynamic arrays can be defined by using the WITH DIMENSION syntax.

Array methods can be used on multidimensional arrays with the brackets notation:

```plaintext
MAIN
  DEFINE a2 DYNAMIC ARRAY WITH DIMENSION 2 OF INTEGER
  DEFINE a3 DYNAMIC ARRAY WITH DIMENSION 3 OF INTEGER
  LET a2[50,100] = 12456
  LET a2[51,1000] = 12456
  DISPLAY a2.getLength() -- shows 51
  DISPLAY a2[50].getLength() -- shows 100
  DISPLAY a2[51].getLength() -- shows 1000
  LET a3[50,100,100] = 12456
  LET a3[51,101,1000] = 12456
  DISPLAY a3.getLength() -- shows 51
  DISPLAY a3[50].getLength() -- shows 100
  DISPLAY a3[51].getLength() -- shows 101
  DISPLAY a3[50,100].getLength() -- shows 100
  DISPLAY a3[51,101].getLength() -- shows 1000
  CALL a3[50].insertElement(10) -- inserts at 50,10
  CALL a3[50,10].insertElement(1) -- inserts at 50,10,1
END MAIN
```

Related concepts

Array methods on page 391
Native BDL arrays and Java arrays can be used to invoke built-in methods.

Array methods

Native BDL arrays and Java arrays can be used to invoke built-in methods.

For example, to clear a dynamic array, use the clear() method:

```plaintext
DEFINE arr DYNAMIC ARRAY OF ...
CALL arr.clear()
```

For the list of native array methods, see DYNAMIC ARRAY methods on page 2256.

For the list of Java array methods, see Java Array type methods on page 2266.
Copying arrays

Arrays can be copied to other arrays in different ways.

The . * notation

The compiler allows the . * notation to assign an array to another array with the same structure.

Static array elements are copied by value (except objects and LOB members), while elements of dynamic arrays are copied by reference.

This means that after assigning a dynamic array with the . * notation, if you modify an element in one of the arrays, the change will be visible in the other array. You must pay attention to this behavior if you are used to the . * notation for simple records:

```
MAIN
  DEFINE left, right DYNAMIC ARRAY OF RECORD
    key INTEGER
  END RECORD
  LET left[1].key = 123
  LET right.* = left.*
  DISPLAY right[1].key    -- shows 123
  LET right[1].key = 456
  DISPLAY left[1].key    -- shows 456
END MAIN
```

The copyTo() method

A dynamic array can be copied to another dynamic array with the copyTo() method. The source and destination array must be defined with the same type:

```
DEFINE source, destination DYNAMIC ARRAY OF RECORD
  key INT,
  name STRING
END RECORD
CALL source.copyTo( destination )
```

Examples

Array usage examples.

**Example 1: Using static and dynamic arrays**

This example illustrates the syntax difference of static and dynamic arrays.

```
MAIN
  DEFINE a1 DYNAMIC ARRAY OF INTEGER
  DEFINE a2 DYNAMIC ARRAY WITH DIMENSION 2 OF INTEGER
  DEFINE a3 ARRAY[10,20] OF RECORD
    id INTEGER,
    name VARCHAR(100),
    birth DATE
  END RECORD
  LET a1[5000] = 12456
  LET a2[5000,300] = 12456
  LET a3[5,1].id = a1[50]
  LET a3[5,1].name = 'Scott'
  LET a3[5,1].birth = TODAY
END MAIN
```
Example 2: Filling a dynamic array with rows
This example shows how to fetch database rows into a dynamic array.

Automatic allocation of dynamic array element in the FOREACH statement creates an additional element that needs to be deleted after the loop:

```
SCHEMA stores

MAIN
  DEFINE custarr DYNAMIC ARRAY OF RECORD LIKE customer.*
  DEFINE index INTEGER

DATABASE stores

  DECLARE curs CURSOR FOR SELECT * FROM customer
  LET index = 1
  FOREACH curs INTO custarr[index].*
    LET index = index+1
  END FOREACH
  CALL custarr.deleteElement(custarr.getLength())

  DISPLAY "Number of rows found: ", custarr.getLength()
  FOR index=1 TO custarr.getLength()
    DISPLAY custarr[index].*
  END FOR

END MAIN
```

Dictionary
A dictionary holds an unordered collection of elements accessed by a key.

- Understanding dictionaries on page 393
- DICTIONARY on page 394
- DICTIONARY in action on page 394
- Dictionary methods on page 396
- Examples on page 396

Understanding dictionaries
This is an introduction to dictionaries.

Dictionaries can store an unordered collection of elements, that will be accessed by key, rather than by index as in arrays.

Dictionaries are used to implement a hash map (a.k.a. associative array).

The keys must be character string:

```
DEFINE dict DICTIONARY OF INTEGER
LET dict["abcdef"] = 999
```

Dictionary elements can be of simple built-in types such as INTEGER, VARCHAR(n), RECORD structured types, or user-defined types. A dictionary can also be defined with built-in classes, imported module classes (from the Web Services extensions for example), or Java classes.

Related concepts
Arrays on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

**DICTIONARY**

A dictionary defines an associative array (hash-map) of elements.

**Syntax**

```
DICTIONARY
   ↓ ATTRIBUTES( attribute ↓ = "value" ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ ↓ →
```  

1. *data-type* can be a data type, a record definition, a user defined type, a built-in class, an imported package class, or a Java class.
2. *attribute* is an attribute to extend the dictionary definition with properties.
3. *value* is the value for the dictionary definition attribute, it is optional for boolean attributes.

**Usage**

A dictionary defines an associative array of unordered elements, accessed by a key.

The elements of the dictionary can be of a simple type, or structured records.

The dictionary subscript syntax consists of a character string expression (the key), specified between square brackets.

The result of the subscript syntax can be used as l-value (as target variable in assignments):

```
LET dict["abcdef"] = "the value"
```

or as r-value (in expressions):

```
DISPLAY dict["abcdef"]
```

**Related concepts**

- **Data types** on page 253
  Selecting the correct data type assists you in the input, storage, and display of your data.

- **Variables** on page 366
  Explains how to define program variables.

**DICTIONARY in action**

**Defining dictionaries**

Dictionaries are defined with the **DICTIONARY** syntax. Dictionaries have no theoretical size limit.

The elements of dictionaries are allocated automatically by the runtime system. Dictionary elements are accessed by key:

```
MAIN
  DEFINE dict DICTIONARY OF DECIMAL(10,2)
  LET dict["bananas"] = 10540.45
  LET dict["apples"] = 3487.55
  LET dict["oranges"] = 234.10
  DISPLAY dict.getLength() -- Shows 3
END MAIN
```
**Element keys**

In a dictionary, elements are identified by a key. Similar to an array index, a key allows access to the element it references.

A key must be a hashable character string with a given length. For example, "Mike Hurn", "AXF98234".

Obviously, keys must be unique.

Keys are used in dictionary subscripts. The key value must be enclosed in square brackets:

```
LET dict[ "the key" ].member = value
```

The `DICTIONARY` class provides following methods related to keys:

- To check if a key exists, use the `contains()` method.
- To delete an element, use the `remove()` method.
- To get all keys of a dictionary, use the `getKeys()` method.

**Element types**

The elements of a dictionary variable are typically defined with simple data types, with a structured record, or with a user-defined type:

```TYPE t_contact RECORD
  name VARCHAR(30),
  address VARCHAR(100),
  birth DATE
END RECORD
```

```MAIN
DEFINE contact DICTIONARY OF t_contact
LET contact["EFC456"].name = "Mike Campbell"
LET contact["EFC456"].address = "5, Big tree St."
LET contact["EFC456"].birth = MDY(10,23,1999)
DISPLAY contact["EFC456"].*
END MAIN```

**Automatic element allocation**

When a dictionary element does not exist, it is automatically allocated before it is used.

For example, when you assign a dictionary element with the `LET` instruction by specifying a key that does not exist yet, the new element is created automatically before assigning the value.

Dictionary elements are also automatically created in a `FOREACH` loop or when dictionary elements are used as r-values, for example in a `DISPLAY`.

Consider using the `contains()` method, to check if a given element key is already existing.

```MAIN
DEFINE dict DICTIONARY OF INTEGER
LET dict["id1"] = 33  -- Created automatically
DISPLAY dict["id2"]  -- Created automatically
IF dict.contains("id3") THEN
  DISPLAY dict["id3"]  -- Not displayed as it does not exist
END IF
END MAIN```

**Passing and returning dictionaries to functions**

Dictionaries are passed (or returned) by reference to/from functions.
The dictionary can be modified inside the called function, and the caller will see the modifications.

```
MAIN
  DEFINE dict DICTIONARY OF INTEGER
  CALL fill(dict)
  DISPLAY dict.getLength() -- shows 2
END MAIN

FUNCTION fill(x)
  DEFINE x DICTIONARY OF INTEGER
  LET x["ABC"] = 123
  LET x["DEF"] = 456
END FUNCTION
```

**Related concepts**

**DICTIONARY methods** on page 2263

**Dictionary methods**

Dictionary variables can be used to invoke built-in methods.

For example, to clear a dictionary, use the `clear()` method:

```
DEFINE dict DICTIONARY OF ...
CALL dict.clear()
```

For the list of dictionary methods, see **DICTIONARY methods** on page 2263.

**Examples**

Dictionary usage examples.

**Example 1: Simple DICTIONARY usage**

Fill a DICTIONARY and show existing elements.

```
MAIN
  DEFINE dict DICTIONARY OF RECORD
      name VARCHAR(50),
      born DATE
  END RECORD
  DEFINE keys DYNAMIC ARRAY OF STRING
  DEFINE i INT

  INITIALIZE dict TO NULL

  -- 1) put some values into the dictionary
  LET dict["Mike"].name = "Mike"
  LET dict["Mike"].born = mdy(12, 23, 1998)
  --
  LET dict["Cliff"].name = "Cliff"
  LET dict["Cliff"].born = mdy(02, 11, 2001)

  -- 2) manipulate an element
  LET dict["Cliff"].born = mdy(4, 10, 1961)

  -- 3) get key list and display all elements
  LET keys = dict.getKeys()
  FOR i = 1 TO keys.getLength()
    DISPLAY i, " ", dict[keys[i]].*
  END FOR

  -- 4) check that an element exists
  DISPLAY dict.contains("Cliff")
```
Types

Types can be defined by the programmer to centralize the definition of complex/structured variables.

- Understanding type definition on page 397
- TYPE on page 397
- Using types in programs on page 398
- Examples on page 399

Understanding type definition

This is an introduction to types.

The TYPE instruction declares a user-defined type, which can be based on:

- Primitive data types (INTEGER, VARCHAR(n)),
- Records (RECORD ... END RECORD, RECORD ... LIKE tabname.*),
- Arrays (DYNAMIC ARRAY OF ...),
- Dictionaries (DICTIONARY OF ...),
- Function types (FUNCTION name(type,...) RETURNS ...)

Once declared, a type can be referenced in the declaration of program variables, or in other types.

Types are typically defined to avoid the repetition of complex structured types.

Tip: User-defined types improve code readability by centralizing data structure definitions. Consider using PUBLIC TYPE definitions to share types across modules with IMPORT FGL.

Related concepts
Variables on page 366
Explains how to define program variables.

TYPE

Types define a synonym for a base or structured data type.

Syntax:

```
[PUBLIC|PRIVATE] TYPE identifier type-definition [, ...]
```

where type-definition is:

```
{ data-type
  LIKE [dbname:]tabname.colname
  \ attributes-list \ }
```

or type-definition is a function type definition:

```
FUNCTION function-name {
  parameter-name data-type \ attributes-list \ }
```
where attribute-list is:

```
ATTRIBUTES ( attribute \= "value" \, \ldots )
```

1. **identifier** is the name of the type to be defined.
2. **data-type** can be a built-in data type, a record structure, an array definition, a dictionary definition, a built-in class, an imported package class, or a Java class.
3. **dbname** identifies a specific database schema file.
4. **tabname.colname** references a column defined in the database schema file.
5. **attribute** is an attribute to extend the type definition with properties.
6. **value** is the value for the type attribute, it is optional for boolean attributes.

**Usage**

User-defined types enforce reusability and simplify programming, by centralizing data structure definitions at a single place.

When defining types with the **LIKE** clause, the data types are taken from the database schema file at compile time. Make sure that the schema file of the database schema during development corresponds to the database schema of the production database; otherwise the types defined in the compiled version of your modules will not match the table structures of the production database.

Types referencing data types can use the **ATTRIBUTES()** clause, to specify meta-data information for the type member. This feature is especially used when defining types for XML-based Web Services. For more details about XML attributes, see **Attributes to customize XML serialization** on page 3250.

Function reference types can be used to define program variables, that will hold a function reference. See **Function references** on page 362 for more details.

**Related concepts**

- **Data types** on page 253
  Selecting the correct data type assists you in the input, storage, and display of your data.
- **Records** on page 382
  Records allow structured program variables definitions.
- **Arrays** on page 386
  Arrays (static or dynamic) allow to handle an ordered collection of elements.

**Using types in programs**

Define a type as a synonym for an existing data type, or as a shortcut for records and array structures.

After declaring a type, it can be used as a normal data type to define variables.

```
TYPE t_customer RECORD
  cust_num INTEGER, 
  cust_name VARCHAR(50),
  cust_addr VARCHAR(200)
END RECORD
...
DEFINE c1 t_customer
...
DEFINE o1 RECORD
  order_num INTEGER,
  customer t_customer,
  ...
END RECORD
```
The scope of a type is the same as for variables and constants. Types can be global, module-specific, or local to a function.

A good practice is to define types that belong to the same domain in a single .4gl module, and import that module in the modules where the types are needed.

By default, module-specific types are private; They cannot be used by an other module of the program. To make a module type public, add the PUBLIC keyword before TYPE. When a module type is declared as public, it can be referenced by another module by using the IMPORT FGL instruction:

```
-- customers.4gl
PUBLIC TYPE t_ord RECORD
  ord_id INTEGER,
  ord_date DATE,
  ord_total DECIMAL(10,2)
END RECORD
PUBLIC TYPE t_cust RECORD
  cust_id INTEGER,
  cust_name VARCHAR(50),
  orders DYNAMIC ARRAY OF t_ord,
END RECORD
...

-- main.4gl
IMPORT FGL customers
MAIN
  DEFINE custlist DYNAMIC ARRAY OF t_cust
  ...
END MAIN
```

Types can also used to declare a function signature, in order to define program variables that reference functions with that signature:

```
TYPE callback_function FUNCTION(p1 INT, p2 INT) RETURNS INT
DEFINE v callback_function
  ...
  LET v = FUNCTION add
  ...
```

**Related concepts**

- **Variables** on page 366
  Explains how to define program variables.

- **Importing modules** on page 496
  Use the IMPORT ... instruction to import BDL, C or Java external modules in the current module.

- **Function references** on page 362
  Function can be referenced and invoked dynamically in a CALL instruction, or in an expression.

**Examples**

- **TYPE (user types) usage examples.**

  **Example 1: Defining a type with a record structure**
  The example shows how to define a user type as a RECORD.

  ```
  TYPE t_customer RECORD
    cust_num INTEGER,
  ```
Example 2: Defining a type an using it in another module

This example shows how to use a type defined in another module.

The module "type_order.4gl":

```plaintext
PUBLIC TYPE rpt_order RECORD
  order_num INTEGER,
  store_num INTEGER,
  order_date DATE,
  cust_num INTEGER,
  fac_code CHAR(3)
END RECORD
```

The main program:

```plaintext
IMPORT FGL type_order

MAIN
  DEFINE o type_order.rpt_order
  CONNECT TO "custdemo"
  DECLARE order_c CURSOR FOR
    SELECT orders.*
    FROM orders ORDER BY cust_num
  START REPORT order_list
  FOREACH order_c INTO o.*
  OUTPUT TO REPORT order_list(o.*)
  END FOREACH
  FINISH REPORT order_list
END MAIN

REPORT order_list(ro)
  DEFINE ro rpt_order
  FORMAT
  ON EVERY ROW
    PRINT ro.order_num, , ro.order_date
END REPORT
```

Example 3: Defining a type with a function type

This example shows how to define a user type from a function type.

```plaintext
TYPE t_func_ref FUNCTION (p1 INT, p2 INT) RETURNS INT
```

Runtime system basics

This section contains topics about Genero BDL runtime system basic concepts.

Dynamic module loading

A Genero Business Development Language program is made of several .42m modules. Modules are linked together, or the dependency is defined with the IMPORT FGL instruction.

Except when using the debugger, modules are loaded dynamically when a module element (i.e. symbol) is required by the caller. For example, when executing a CALL instruction, the runtime system checks if the module of the function is already in memory. If not, the module is first loaded, then module variables are instantiated, and then the function is called.

Running programs are not affected by file replacements and will continue to run with an image of the module file that was originally loaded. However, replacing program modules during execution should be used with care: Since .42m modules are loaded dynamically on demand (when a symbol of the module is referenced), some modules may not yet be loaded, even if the program instance is already started. When replacing a module while programs are running, invalid symbol errors can occur if the module to be loaded does not correspond to the rest of the program modules that were loaded before the file replacements. See following scenario:

1. Program starts with V1 of main.42m, needing V1 of module libutil.42m (loaded later on demand).
2. Administrator upgrades application and installs main.42m and libutil.42m version V2.
3. Program running with V1 copy of main.42m calls a function from libutil.42m; runtime loads V2 of that module, while V1 is expected.

When live application updates are mandatory, consider installing new program and resource files (V2) in a different directory as the currently running version (V1), and use the FGLLDPATH and FGLRESOURCEPATH environment variables to point to the new files when starting a new (V2) program instance.

Note that on Windows™ platforms, program files currently in use cannot be overwritten, because of Windows™ OS memory mapping limitations. You need to turn off memory mapping with the FGLPROFILE entry fglrun.mmapDisable.

Elements shared by multiple programs

The (.42m) p-code module instructions and other elements such as constants are shared among several programs running on the same machine.

Localized string resource files (.42s) are also shared among all fglrun processes running on a computer.

These files are loaded with the system memory mapping facility, which allows multiple processes to access the same unique memory area.

Related concepts

Programs on page 491
Explains program structure basics and global instructions/registers.

Localized strings on page 430
Localized strings provide a means of writing applications in which the text of strings can be customized on site.

Elements shared by multiple modules

By definition, global variables are visible to all modules of a program, and thus shared among all modules of the program. While global variables are an easy way to share data among multiple modules, it is not recommended that you use too many global variables.

The data type definitions are only defined once in memory and shared by all modules of a program instance. By data type definition we mean the type descriptions, not the data itself. This applies only to the equivalent data types used in different modules.
**Objects private to a program**

Program objects such as global variables, module variables as well as resources used by the user interface and SQL connections and cursors, are private to a program.

This implies that each of these objects requires private memory to be allocated. If memory is an issue, do not allocate unnecessary resources. For example, don’t create windows / load forms or declare / prepare cursors until these are really needed by the program. When the resource is not longer needed, consider freeing them (CLOSE WINDOW, FREE cursor).

**Check runtime system memory leaks**

The Genero BDL runtime system can produce a garbage collection status when a program ends.

To improve the quality of the runtime system, `fglrun` supports the `-M` / `–m` options to count the creation of built-in class objects and some internal objects. This allows you to check for memory leaks in the runtime system: The runtime system counts the object creations and destructions for each class. The right-most column of the output is the difference between created and destroyed objects, it must show a zero for all type of objects.

The options described here are provided for debugging purpose only. The output format is subject to change. These options can also be removed in a next version of the product.

```
$ fglrun -M stores.42r
FunctionI        :       10 -      10 =      0
Module           :        3 -       3 =      0
...              
FieldType        :       19 -      19 =      0
```

The `-M` option displays memory counters at the end of the program execution.

The `-m` option checks for memory leaks, and displays memory counters at the end of the program execution if leaks were found.

Each line shows the number of objects allocated, and the number of objects freed. If the difference is not zero, there is a memory leak.

If you are doing automatic regression tests, we recommend that you run all your programs with `fglrun -m` to check for memory leaks in the runtime system.

**Optimize your programs**

This section contains programming tips to optimize the execution of your application.

**Finding program bottlenecks**

The best way to find out why a program is slow (and also, to optimize an already fast-running program), it to use the profiler.

This tool is included in the runtime system, and generates a report that shows what function in your program is the most time-consuming.

Additionally, you might want to identify part of code of your programs that are never executed, or executed very often, by using the coverage tool.

**Optimizing SQL statements**

SQL statement execution is often the code part of the program that consumes a lot of processor, disk and network resources. Therefore, it is critical to pay attention to SQL execution.

Advice for this can be found in [SQL Programming](#).
Passing small CHAR parameters to functions

Function parameters of most data types are passed by value (i.e. the value of the caller variable is copied on the stack, and then copied back into a local variable of the called function.) When large data types are used, this can introduce a performance issue.

For example, the following code defines a logging function that takes a CHAR(2000) as parameter:

```plaintext
FUNCTION log_msg( msg )
  DEFINE msg CHAR(2000)
  CALL myLogChannel.writeLine(msg)
END FUNCTION
```

If you call this function with a string having 19 bytes:

```plaintext
CALL log_msg( "Start processing..." )
```

When doing this call, the runtime system copies 19 characters on the stack, calls the function, and then copies the value into the local variable. Since the values in CHAR variables must always have a length matching the variable definition size, the runtime system fills the remaining 1981 positions with blanks. As result, each time you call this function, a 2000 characters long variable is created on the stack.

By using a VARCHAR(2000) (or a STRING) data type in this function, you optimize the execution because no trailing blanks need to be added.

Compiler removes unused variables

When declaring a large static array without any reference to that variable in the rest of the module, you will not see the memory grow at runtime. The compiler has removed its definition from the 42m module.

To get the defined variable in the 42m module, you must at least use it once in the source (for example, with a LET statement). Note that memory might only be allocated when reaching the lines using the variable.

Saving memory by splitting modules

Program modules (42m) are loaded dynamically on demand. If a program only needs some independent functions of a given module, all module resources will be allocated just to call these functions. By independent, we mean functions that do not use module objects such as variables defined outside function or SQL cursors. To avoid unnecessary resource allocation, you can extract these independent functions into another module and save a lot of memory at runtime.

If you are using 42x libraries, it is recommended that you create libraries with the 42m modules that belong to the same functionality group. For example, group all accounting modules together in an accounting library. By doing this, programmers using the 42x libraries are not dependent from module reorganizations.

Libraries are supported for backward compatibility, it is recommended that you consider using the IMPORT FGL instruction to define module dependency and get modules loaded dynamically when needed.

Saving memory by using STRING variables

The CHAR and VARCHAR data types are provided to hold string data from a database column. When you define a CHAR or VARCHAR variable with a length of 1000, the runtime system must allocate the entire size, to be able to fetch SQL data directly into the internal string buffer.

For character string data that is not stored in the database, consider using the STRING data type. The STRING type is similar to VARCHAR, except that you don't need to specify a maximum length and the internal string buffer is allocated dynamically as needed. Thus, by default, a STRING variable initially requires just a bunch of bytes, and grows during the program life time, with a limitation of 65534 bytes.

Use of a STRING variable is typically recommended when building SQL statements dynamically, for example from a CONSTRUCT instruction. You may also use the STRING type for utility function parameters, to hold file names for example.
After a large STRING variable is used, it should be cleared with a LET or a INITIALIZE TO NULL instruction. However, this is only needed for STRING variables declared as global or module variables. The variables defined in functions will be automatically destroyed when the program returns from the function.

Use of the base.StringBuffer build-in class is recommended when a great deal of string manipulation and modification is required. String data is not copied on the stack when an object of this class is passed to a function, or when the string is modified with class methods. This can have a big impact on performance when very large strings are processed.

**Saving memory by using dynamic arrays**

The language supports both static arrays and dynamic arrays. For compatibility reasons, static arrays must be allocated in their entirety. This can result in huge memory usage when big structures are declared, such as:

```
DEFINE my_array ARRAY[100,50] OF RECORD
  id CHAR(200),
  comment1 CHAR(2000),
  comment2 CHAR(2000)
END RECORD
```

If possible, replace such static arrays with dynamic arrays:

```
DEFINE my_array DYNAMIC ARRAY OF RECORD
  id CHAR(200),
  comment1 CHAR(2000),
  comment2 CHAR(2000)
END RECORD
```

However, be aware that dynamic arrays have a slightly different behavior than static arrays.

**Localization**

Localization support allows you to implement programs that follow specific language and cultural rules.

Programs execute in a specific application locale. Beside the support of a locale specification which defines the character set used by programs, the internationalization of an application requires all strings in the sources that are subject to translation to be extracted and centralized. Localized strings are used to keep application messages and form labels in external resource files, which can be provided in different languages.

- Application locale on page 405
- Localized strings on page 430

**Application locale**

The application locale defines the language and codeset for your application.

The application locale defines:

- The language (for messages),
- The country or territory (for currency symbols and date formats),
- The code set (for character set encoding).

A program needs to be able to determine its locale and act accordingly, to support different languages and character sets.

**Important:**

The same code point can represent distinct glyphs in different characters sets. Even if the glyphs/characters seem to display properly on the screen, an invalid locale configuration in one of the software components will result in invalid characters in your database system.
Take for example a client application configured to display glyphs (font) for CP437. If the application gets a 0xA2 (decimal 162) code point, it displays an o-acute character. Now imagine that the DB client is configured with character set CP1252. In this character set, the code point 0xA2 is actually the cent currency sign. As a result, if the user enters the o-acute char (0xA2 in CP437) in the database, it will actually be interpreted as cent sign (0xA2 in CP1252) by the database server. When fetching that character back to the client, the database server returns the 0xA2 code point, which displays correctly as o-acute on the CP437 configured client, and the end user sees what was entered before. But with a different client application configured properly with CP1252 as DB client codeset, the end user will see the cent currency sign instead of the o-acute character.

Understanding locale settings
This is an introduction to application locale definition.

It is critical to understand how the different components of a program handle locale settings. Each component (i.e. runtime system, database server, database client software, front-end, and terminal emulator) have to be configured properly to get the correct character set conversions through the whole chain. The chain starts on the end-user workstation with front-end windows and ends in the database storage files.

Figure 20: The Locale Settings schema on page 407 shows the different components of a Genero Business Development Language process.

The yellow rectangles show where locale configuration parameters have to be set:

1. The source files are encoded in a given character set. When compiling sources (fglcomp, fglform), the compilers use the OS locale (LANG/LC_ALL) to encode the resulting program files (.42m, .42f). For more details, see Defining the application locale on page 412.
   **Important:** When compiling, make sure that the LANG/LC_ALL environment variables match the encoding of the source files.

2. At runtime (fglrun), the OS locale (LANG/LC_ALL) for the runtime system must match the code set of the program files (.42m, .42f). For more details, see Defining the application locale on page 412.
   **Important:** At runtime, make sure that the LANG/LC_ALL environment variables match the encoding of the program files.

3. The locale of the database client must match the locale of the runtime system. Each database vendor uses it's own locale configuration system. For more details, see Database client settings on page 419.
   **Important:** At runtime, make sure that the database client locale matches the application locale (i.e. LANG/LC_ALL).

4. The locale of the database server defines the encoding for data on the server side. This encoding can be different from the database client locale (one can for example store the data in UTF-8, while client programs use ISO-8859-15), but it is usually the same character set. See database vendor documentation for more details.

5. When using the TUI mode, the terminal emulator must be configured with the character set corresponding to the application locale (2).
Figure 20: The Locale Settings schema

The typical mistake is to forget to set the runtime system locale (LANG/LC_ALL), or the database client software locale.

A character string is just a set of bytes; The same code might represent different characters in different code sets. Therefore, systems cannot detect that the current locale is correct, and won't raise any error, except when a set of bytes does not represent a valid code point in the current codeset. For example, the Latin letter é with acute (UNICODE: U+00E9) will be encoded as 0xE9/233 in CP1252, but in CP437 it will be encoded with 0x82/130. The codes 233 or 130 are valid characters in both code sets. If the database uses CP1252, 233 will represent an é and 130 will represent a curved quote. If the client application uses CP437, the é will be encoded as 130, stored as a curved quote, then fetched from the database as is and displayed back as é in the CP437 code page. As result, the end user cannot see that the character stored in the database is actually wrong, until another properly configured DB client application queries the database.

Note: Pay attention that on recent UNIX™ systems, the default OS locale is UTF-8 by default. If your application has been developed on an older system, it is probably using a single-byte character set like ISO-8859-15 or CP1252, and program need to be executed in this locale, not in the UTF-8 locale.

It is also important to identify database server character set (in other words what code set characters are stored in the database). Usually the database character set is defined when creating a database entity.
The best way to test if the characters inserted in the database are correct is to use the database vendor SQL interpreter and select rows inserted from a BDL program. The rows most hold non-ASCII data to check if the code of the characters is correct. Some databases support the ASCII() or better, the UNICODE() SQL function to check the code of a character. Use such function to determine the value of a character in the database field. If the character code does not correspond to the expected value in the character set of the database server, there is a configuration mistake somewhere.

If you run a BDL application in TUI mode (or a batch program doing DISPLAYs), you must properly configure the code set in the terminal window (X11 xterm, Windows® CMD, putty, etc). If the terminal code set does not match the runtime system locale, you will get invalid characters displayed on the screen. On Windows® platforms, the OEM code page of the CMD window can be queried/changed with the chcp command. On a Gnome terminal, go to the menu "Terminal" - "Set Character Encoding".

**Related concepts**

- **Defining the application locale** on page 412
  This section describes the settings defining the application locale, changing the behavior of the compilers and runtime system.

- **Database client settings** on page 419
  This section describes the settings defining the locale for the database client.

- **Locale and character set basics** on page 409
  This section is an introduction to locale and character set basics.

**Quickstart guide for locale settings**

This is a quick step-by-step guide to properly configure locale settings for your Genero application.

**Tip:** This is a quickstart guide for locale settings. It is highly recommended that you read the complete set of articles regarding localization.

1. The **application locale** is defined by the character set used in your source files (.4gl, .per, .str). The same character set will be used in the compiled files (.42m, .42f, .42s).

2. Set the operating system locale corresponding to the application locale.
   - **On UNIX**-based systems (including Mac® OS-X®), define the LANG (or LC_ALL) environment variable. Use `locale -a` command to check if the locale exists on the machine. If not, it must be installed. If not set, LANG defaults to POSIX (ASCII).
   - **On Windows® platforms**, check if the regional settings for non-UNICODE applications match the application locale. If the regional settings do no match, you can define the LANG environment variable with a locale name supported by Microsoft® C Runtime Library, such as French_France.1252, or set `LANG=.fglutf8` for the UTF-8 character set.
   - **On Android™ and iOS mobile devices**, the application locale is always UTF-8 and the length semantics is CHAR. This cannot be changed.

3. When using UTF-8 as character encoding, define the **length semantics** with the `FGL_LENGTH_SEMANTICS={BYTE|CHAR}` environment variable. On server platforms, Genero uses Byte Length Semantics by default for compatibility reasons. It's highly recommended to set `FGL_LENGTH_SEMANTICS=CHAR` to use Character Length Semantics. On mobile platforms, character length semantics is the default (this means that `FGL_LENGTH_SEMANTICS` does not need to be defined when running on a mobile device, it defaults to CHAR, and cannot be set to BYTE).

4. Set the **database client locale** with a character set corresponding to the application locale. For example, with Informix®, this is defined with the CLIENT_LOCALE environment variable. The actual name of the database client locale may be different from the application locale name. But remember that the **application and database client** character sets must match.

5. Check the length semantics used by the database. For example, with Oracle, it is recommended that you set the database option `NLS_LENGTH_SEMANTICS='CHAR'`, if the application uses CLS (typically with UTF-8).
6. With UTF-8, use the proper SQL character data type to store UTF-8 data: This data type can be different depending on the type of database server. For more details, see SQL character type for Unicode/UTF-8 on page 556.

7. Set the **front-end locale and font**. By front-end, we mean the program the end user interacts with. This can be a Genero front-end or a terminal emulator like Gnome-term, Putty, or a Windows® Console. When using a Genero front-end, the front-end character set is defined by the type of the front end, and the conversion from/to application character set is automatic, but you may need to select a font that is different from the system default. If you want to execute a TUI application in a terminal emulator, you must be sure that the terminal is configured to display the correct character set. This is for example defined with the `chcp` command on Windows®, or in the "Set Character Encoding" menu option of a Gnome-term.

8. Define the date, numeric and monetary formats with the DBDATE, DBMONEY, DBFORMAT environment variables. On server platforms such as UNIX™ and Windows®, these default to US formats (month/day/year for dates, the dot as decimal separator and $ as currency symbol). On mobile platforms, these default to the regional settings defined on the device.

**Locale and character set basics**

This section is an introduction to locale and character set basics.

Before starting with application/database design, configuration and settings, you must know some basics concerning language and character sets on computers. In this section, we attempt to describe these basics, but we strongly recommend you to carefully read the operating system and database server manuals covering localization or character set handling. You can also find a lot of information about character sets and character encoding on the internet.

- Why do I need to care about the locale and character set? on page 409  
- Characters, code points, character sets, glyphs and fonts on page 410  
- The ASCII character set on page 410  
- Single-byte character sets (SBCS) on page 410  
- Double-byte character sets (DBCS) on page 410  
- Multibyte character sets (MBCS) on page 410  
- Character size unit and length semantics on page 411  
- The UNICODE Standard on page 411  
- When do I need a UNICODE character set? on page 411  
- What is the standard for UNICODE encoding? on page 412  
- What is my current character set? on page 412

### Why do I need to care about the locale and character set?

If you don't know what you are doing with character sets, the end user might get strange characters displayed on the screen, and will probably not be able to input non-ASCII characters. In the worst case, as character set conversion can be symmetric for single-byte character sets, the end user might see correct characters on the workstation, but on the back-end you can get invalid characters in the database files. By upgrading to a newer OS, Genero Business
Development Language runtime or database system, or if a character set mapping utility was used somewhere in the chain, you can even get mixed character encoding in the database files.

**Related concepts**

Understanding locale settings on page 406

This is an introduction to application locale definition.

**Characters, code points, character sets, glyphs and fonts**

In computers, a character is the unit of information corresponding to a symbol of a natural language. This can be a letter, a digit, a punctuation mark, a mathematical or even musical symbol. To represent a character in memory or in a file, computers must encode the character in a specific numeric value called code point. This code point uniquely identifies a character in a given character set. Mapping a character to a code point is called character encoding. The same code point might represent a different character in several character sets. The glyph is the graphical representation of the character. In other words, it's the way the character is drawn on the screen or on a printer. Computers implement the glyph of characters with fonts, by mapping a code point to a bitmap image or drawing instructions based on math formulas or vector graphics.

**The ASCII character set**

ASCII stands for the American Standard Code for Information Interchange. ASCII is a well-known character encoding based on the English alphabet. Characters are encoded in a single byte, using the 7 lower bits only. Up to 127 characters, printable and non-printable (like control characters), are defined in ASCII. Nearly all other character sets (using 8 bits or multiple bytes) define the first 127 characters as the ASCII character set. Aliases for ASCII include ISO646-US, ANSI_X3.4-1968, IBM367, cp367, and more.

**Single-byte character sets (SBCS)**

A single-byte character set defines the encoding for characters on a unique byte. The size of a character is always one byte.

Example of single-byte character sets include ISO-8859-1, MS code page CP1252.

Genero Business Development Language supports single-byte character sets.

**Related concepts**

Length semantics settings on page 414

**Double-byte character sets (DBCS)**

A double-byte character set defines the encoding for characters on two bytes. The size of a character is always two bytes.

Example of double-byte character sets include UCS-2, used by SQL Server in NCHAR and NVARCHAR columns. Note that UTF-16 is not a (fixed) double-byte character set: You can have characters encoded on 2 or 4 bytes. UCS-2 is actually a subset of UTF-16.

Note that Genero Business Development Language does not support double-byte character sets.

**Related concepts**

Length semantics settings on page 414

**Multibyte character sets (MBCS)**

A multibyte character set defines the encoding for characters on a variable number of bytes. The size of a character can be one (usually ASCII chars), two, three or more bytes, depending on the character set.

Example of multibyte character sets are BIG5, EUC-JP, and UTF-8. BIG5 and EUC-JP characters can be one or two bytes long, while UTF-8 characters can be 1, 2, 3 or 4 bytes long (usually a maximum of 3 is sufficient).

Genero Business Development Language supports multibyte character sets.

**Related concepts**

Length semantics settings on page 414
Single-byte character sets (SBCS) on page 410
Double-byte character sets (DBCS) on page 410

**Character size unit and length semantics**

When programming an application for a Latin-based language such as English, a single-byte character set can be used, and the logical size, storage size and print width of characters is the same. For example, in ISO-8859-1, the ê character takes one logical position, has a storage size of one byte and a print width of one.

When programming an international application using multiple languages and a multibyte character set encoding, you must distinguish three size units:

1. The size in **character unit**, to count or position logical characters used in a string. For example, the strings abc and âêé have both a length of 3, in character units.
2. The size in **byte unit**, used to encode the character in a given character set. For example, a Latin ê acute character will use a unique byte in the ISO-8859-1 character set, but needs two bytes in UTF-8.
3. The size in **width unit**, used in formatting and alignments. The width is the length of the glyph/font of characters, especially in a fixed font. For example, a Latin character will take one width unit, while an Asian ideogram will take 2 width units.

Working with byte units in a multibyte character set can be difficult: You need to calculate sizes, lengths and substring offsets in a number of bytes, when the natural way is to count in characters.

Length semantics define the unit to be used for character data type definition, character string lengths and positions.

With **Byte Length Semantics**, a length is expressed in bytes, while **Character Length Semantics** counts in characters.

**Related concepts**

Length semantics settings on page 414

**The UNICODE Standard**

UNICODE is a standard specification to map all possible characters to a numeric value, in order to cover all possible languages in a unique character set. UNICODE defines the mapping of characters to integer codes, but it does not define the exact implementation (that is the encoding) for a character.

Several character sets are based on the UNICODE standard, such as UTF-7, UTF-8, UTF-16, UTF-32, UCS-2, and UCS-4. Each of these character sets use a different encoding method. For example, with UTF-8, the letter Æ is encoded with two bytes as 0xC3 and 0xB6, while the same character will be encoded 0x00C6 with UTF-16.

When Microsoft™ Windows® users talk about UNICODE, they typically mean UCS-2 or UTF-16, while UNIX™ users typically mean UTF-8.

**Related concepts**

Length semantics settings on page 414

When do I need a UNICODE character set? on page 411

**When do I need a UNICODE character set?**

With internationalization, people want to use different languages within the same application; for example, to have Chinese, Japanese, English, French and German addresses of customers in their database. UNICODE is a character encoding specification that defines characters for all languages. More and more databases use an UNICODE character set on the database server, because it "standardizes" all data from different client applications. If needed, the client application can then use a different character set like ISO-8859-1 or BIG5: The database software takes care of character set conversions. However, if the end user needs to deal with different languages, all components of the system (from database backend to GUI front-end) must work in UNICODE.

The UNICODE character set supported by Genero Business Development Language is UTF-8. Double-byte based UNICODE character sets such as UCS-2 or UTF-16 are not supported. The database server can however store character data in another UNICODE character set, as long as the database client is able to handle to conversion to/from UTF-8 for the Genero runtime system.
Related concepts
The UNICODE Standard on page 411

What is the standard for UNICODE encoding?
UNICODE is the standard for internationalization, but not all platforms/systems use the same UNICODE character set / encoding.
Recent UNIX™ distributions define UTF-8 as the default character set locale, XML files are UTF-8 by default, while Microsoft™ Windows® standard is UTF-16 (NTFS) / UCS-2 (SQL Server).

Related concepts
The UNICODE Standard on page 411

What is my current character set?
On a UNIX™ box, you have the LANG / LC_ALL environment variables to define the locale. Each process / terminal can set its own locale. By default this is en_US.utf8 on recent UNIX™ systems. You can query for available locales with the locale -a command. Some systems come with only a few locales installed, you must then install an additional package to get more languages. You must also define the correct character set in the terminal (xterm or gnome-term), otherwise non-ASCII characters will not display properly.

On Windows® platforms, for non-UNICODE (that means non-UTF-16/UCS-2) applications, you have ACP and OEMCP code pages. ACP stands for ANSI Code Page and were designed by Microsoft™ for GUI applications specifically, while OEMCP defines old code pages for MS/DOS console applications. You can select the default ACP/OEMCP code pages for non-UNICODE application in the language and regional settings panel of Windows® (make sure you define the settings for non-UNICODE applications, this is done in the "Advanced" panel on Windows® XP). Code page can be changed in each console window with the chcp command. With Genero Business Development Language, you can use the LANG environment variable on Windows® to define the character set for BDL. However, it is strongly recommended to use the default Windows® system locale and avoid setting LANG on Windows®.

Defining the application locale
This section describes the settings defining the application locale, changing the behavior of the compilers and runtime system.

• Language and character set settings on page 412
• Length semantics settings on page 414
• Collation ordering settings on page 419
• Numeric and currency locale settings on page 419
• Date and time locale settings on page 419

Language and character set settings

Purpose of application locale definition
The locale settings matters at compile time and at runtime. At runtime, the locale changes the behavior of the character handling functions, such as UPSHIFT and DOWNSHIFT. It also changes the handling of the character strings, which can be single byte or multibyte encoded. Compilation errors will occur if the source files contain characters that do not exist in the encoding defined by the current locale.
Always check that the local environment variable matches the locale of your Genero application, during development and at runtime:

$ fglrun -i mbc
Charmap      : UTF-8
Multibyte    : yes
Stateless    : yes
Length Semantics : CHAR
Mobile platforms

On iOS and Android™ mobile platforms, the locale is automatically defined to be UTF-8. This cannot be changed. The language conventions and system messages are defined by the device settings.

Windows® platforms

On Windows® platforms, if you don't specify the LANG environment variable, the language and character set defaults to the system locale which is defined by the regional settings for non-Unicode applications. For example, on a US-English Windows®, this defaults to the 1252 code page. You typically leave the default on Windows® platforms (it is not recommended to set the LANG variable, unless your application uses a different character set to the Windows® system locale).

On Windows® platforms, the syntax of the LANG variable is:

```
language[_-territory[.codeset]]
| .codeset
```

For example:

```
C:\> set LANG=English_USA.1252
```

UNIX™ platforms

On UNIX™-based platforms, The LC_ALL (or LANG) environment variable defines the global settings for the language used by the application.

With the LANG environment variable (or LC_ALL, on UNIX™), you define the language, the territory (aka country) and the codeset (aka character set or code page) to be used. The format of the value is normalized as follows, but may be specific on some operating systems:

```
language_territory.codeset
```

For example:

```
$ LC_ALL=en_US.iso88591; export LC_ALL
```

What are possible locales on my platform?

Usually OS vendors define a specific set of values for the language, territory and codeset. For example, on a UNIX™ platform, you typically have the value "en_US.ISO8859-1" for a US English locale, while Microsoft™ Windows® requires the "English_USA.1252" value. For more details about supported locales, refer to the operating system documentation.

A list of available locales can be found on UNIX™ platform by running the locale -a command. You may also want to read the man pages of the locale command and the setlocale function. On Windows® platforms, search the Microsoft™ MSDN documentation for "Language and Country/Region Strings".

UNICODE support (UTF-8)

To support multiple languages in your application, you must use UNICODE. The encoding supported by Genero for UNICODE applications is UTF-8.

On UNIX™ platforms, UTF-8 locales are natively supported with LANG/LC_ALL.
On Windows® platforms, UTF-8 is not well supported by the operating system: Defining the LANG environment variable to code page 65001 will not work. To workaround this limitation, Genero implements UTF-8 support on Windows® by setting the LANG environment variable to the value `.fgutf8`:

```
C:\> set LANG=.fgutf8
```

Length semantics settings

Understanding length semantics

The length semantics of character string data matters when using a multibyte character set. Length semantics involves data type length specification for database column and program variable definitions, as well as string manipulations (for string lengths, character positions, offsets and substring ranges).

In a single-byte characters set like ISO-8859-1, a character is encoded on one byte. The length of a string can be counted in bytes or characters, the unit does not matter. In other words, the length semantics is identical in bytes or characters, with a single byte encoding. However, with a multibyte character set like UTF-8 or BIG5, a character can be encoded on several bytes. In such case, the unit regarding length semantics matters, because the number of bytes of a character string can be different from the number of characters.

For multibyte characters sets, the language supports Byte Length Semantics (BLS) and Character Length Semantics (CLS) specification. BLS or CLS usage depends on the current character set of the application. BLS is typically used with a character set such as BIG5, because for historical reasons programmers are used to counting 2 bytes for each Asian ideogram. For UTF-8, which is a variable size encoding, the recommendation is to use CLS instead. CLS simplifies data type definition and string handling when using UTF-8.

Programming areas concerned by length semantics are illustrated in the following code example:

```sql
SCHEMA shop

# CREATE TABLE mytable (  
#     k INT,  
#     vc VARCHAR(10)  
#     -- what is the unit for the column size and how many  
#     -- characters can be stored in this column?  
# )

MAIN

DEFINE buf, tmp VARCHAR(50)  -- what is the unit for the size?
DEFINE rec RECORD LIKE mytable  -- what is the size of vc member?
DEFINE str STRING, len INT

DATABASE shop

SELECT LENGTH(vc) INTO len -- What unit use string functions in SQL?
    FROM mytable WHERE k = 45

LET buf = "abcdef..."  -- How many chars can this variable hold?

DISPLAY length(buf)  -- In what unit is the length expressed?

LET tmp = buf[1,5]  -- What is the unit for char positions?

LET str = buf

DISPLAY str.getLength() -- What is the unit for the length?
DISPLAY str.getIndexOf("def") -- What is the unit for the offset?
```
Using Byte Length Semantics

Byte Length Semantics must be used if the current locale defines a multibyte character set different from UTF-8.

*Important:*

- Byte Length Semantics is the default on UNIX™ and Windows® platforms.
- Byte Length Semantics cannot be set on mobile platforms.

With BLS, the size of CHAR/VARCHAR program variables is expressed in byte units. In a single-byte character set like ISO-8859-1, every character is encoded on a unique byte, so the number of bytes equals the number of characters. When using BLS with a multibyte character set, you must be aware of the storage size in byte units: Character encoding requires more than one byte, so the number of bytes to store a multibyte string is greater than the number of characters. For example, in a BIG5 encoding, one Chinese character needs 2 bytes, so if you want to hold a BIG5 string with a maximum of 10 Chinese characters, you must define a CHAR(20). When using UTF-8, characters can take one or several bytes which can use two or three times more storage space than character count. You need to choose the right expansion factor to define CHAR or VARCHAR variables in byte units.

```
-- Using Byte Length Semantics
DEFINE var VARCHAR(10)  -- Can store 10 bytes / 10 single-byte chars.
```

In order to use BLS, you can define the `FGL_LENGTH_SEMANTICS` environment variable to "BYTE", or just leave it unset, if BLS is the default on your platform. For example, on UNIX™:

```
$ FGL_LENGTH_SEMANTICS="BYTE"
$ export FGL_LENGTH_SEMANTICS
```

Using Char Length Semantics

Character Length Semantics is used with multibyte character sets such as UTF-8: Migrating to UTF-8 by using CLS will allow you to leave the source code untouched, even when doing complex string/substring manipulations.

The database typically also uses UTF-8 and CLS. If the database uses UTF-8 and only supports BLS, programs can still use CLS with UTF-8.

*Important:* Char Length Semantics is the default on iOS and Android™ mobile platforms, and cannot be changed (Byte Length Semantics cannot be used on mobile: only UTF-8 character set is allowed).

With CLS, the size of a CHAR/VARCHAR program variable is expressed in character units, and the number of bytes needed to store these characters is allocated automatically. A VARCHAR(10) variable will hold 10 characters, of any byte length. Furthermore, language functions and class methods dealing with character string length and positions will use character units.

```
-- Using Character Length Semantics
DEFINE var VARCHAR(10)  -- Can store 10 chars in UTF-8, or any encoding.
LET var = "Forêt"  -- 5 chars, that take 6 bytes in UTF-8
DISPLAY length(var)  -- Displays a length of 5 (characters)
DISPLAY ",[4,5],"  -- Displays [êt]
```

To enable Char Length Semantics, define the `FGL_LENGTH_SEMANTICS` environment variable to "CHAR". For example, on UNIX™:

```
$ FGL_LENGTH_SEMANTICS="CHAR"
$ export FGL_LENGTH_SEMANTICS
```
Length Semantics in SQL

On the database server side, the length semantics used for character data types varies from one vendor to another. Some databases use BLS, other use CLS, and other support both semantics.

Important: The length semantics used by the Genero runtime (defined by FGL_LENGTH_SEMANTICS) should match the length semantics used by the database server: If a database column is defined as a CHAR of 10 bytes, the corresponding BDL program variable should also be defined as a CHAR of 10 bytes (using FGL_LENGTH_SEMANTICS=BYTE, the default). If the database column is defined as a CHAR of 10 characters, the variable should be defined as a CHAR of 10 characters (using FGL_LENGTH_SEMANTICS=CHAR).

This table shows the character data type length semantics of supported database servers:

**Table 128: Character data type length semantics of supported database servers**

BLS (ASCII-7) / CLS (UNICODE)

Other SQL elements like functions and operators are affected by the length semantic. For example, Informix® LENGTH() function always returns a number of bytes, while Oracle's LENGTH() function returns a number of characters (use LENGTHB() to get the number of bytes with Oracle).

It is important to understand properly how the database servers handle multibyte character sets. Check your database server reference manual. In most documentations you will find a "Localization" chapter which describes those concepts in detail.

### Extracting database schemas

Database schema files (.sch) are used to resolve column data types when compiling .4gl modules and .per form files. This file contains size information for CHAR and VARCHAR types. It is important to identify the unit used by the database columns, to properly define CHAR/VARCHAR variables in programs and fields in forms.

Most database engines (like Oracle DB, SQL Server, PostgreSQL, SQLite) provide catalog tables with column size information in character units. In this case, the fgl dbsch tool extracts the column sizes in character units, without further conversion. If the column sizes is provided in bytes by catalog tables, fgl dbsch will try to detect character length semantic usage in the database and apply a reduction factor to convert the number of bytes to chars.

As a result - independently from the length semantics used in your programs - the CHAR/VARCHAR type sizes in the schema file are always expressed in character units. When using Byte Length Semantics, this makes no difference in a single-byte locale, because one character occupies a single byte. In a multibyte encoding (UTF-8) with BLS, this method guarantees that the program variable will not hold more ASCII characters than the database column can hold. When using Character Length Semantics with a multibyte character set, the size in characters will define character type variables in the same unit.

For example, with BLS, a VARCHAR(10 (bytes or chars)) column will define a VARCHAR(10 (bytes)) in programs. With CLS, a VARCHAR(10 (chars)) column will define a VARCHAR(10 (chars)) in programs.

### Moving from single-byte to UTF-8

Migration to Unicode (UTF-8) is facilitated with Char Length Semantics:

1. Verify that your database uses Char Length Semantics.
2. Convert your sources and string files from your single-byte locale to UTF-8 (iconv).
3. Enable Char Length Semantics with FGL_LENGTH_SEMANTICS=CHAR.
4. Compile and run your programs untouched.

### Related concepts

Multibyte character sets (MBCS) on page 410
Single-byte character sets (SBCS) on page 410
**Collation ordering settings**

The runtime system supports a sorting functionality in tables. To sort the data rows, the runtime systems uses the standard C library functions to order character strings.

The environment variable `LC_COLLATE` can be used to control sort order in Genero. You can for example define this variable as "C" or "POSIX" to get a binary sort order.

When using `LC_COLLATE`, set the `LANG` environment variable to define the global locale, if you use `LC_ALL`, it will overwrite all other `LC_*` variables defined.

**Related concepts**

`LC_ALL (or LANG)` on page 228
Defines the current application locale on UNIX™ platforms.

**Numeric and currency locale settings**

The environment variables `LC_MONETARY` and `LC_NUMERIC` are ignored. To perform decimal to/from string conversions, the runtime system uses the `DBMONEY` or `DBFORMAT` environment variables. These variables define hundreds / decimal separators and currency symbols for `MONEY` data types.

**Related concepts**

`Date, numeric and monetary formats` on page 424
This section describes how Genero BDL handles date, time, numeric and monetary formats.

`DBFORMAT` on page 233
Defines currency symbol, decimal and thousands separator for input and display of numeric values.

`DBMONEY` on page 236
Defines currency symbol and decimal separator for input and display of numeric values, when `DBFORMAT` is not defined.

**Date and time locale settings**

The environment variable `LC_TIME` is ignored. To perform date to/from string conversions, the runtime system uses by default the `DBDATE` environment variable.

**Related concepts**

`Date, numeric and monetary formats` on page 424
This section describes how Genero BDL handles date, time, numeric and monetary formats.

**Database client settings**

This section describes the settings defining the locale for the database client.

Each database software has its own client character set configuration.

**Important:** In order to properly send/receive character string data to/from the database server, the database client locale and application locale settings must match.

**Table 129: Database client settings defining the character set locale**

<table>
<thead>
<tr>
<th>Database Client</th>

See database vendor documentation for more details.

**Related concepts**

[SQL character type for Unicode/UTF-8](#) on page 556

This section explains database server specifics regarding Unicode / UTF-8 support with character string SQL types.

**Front-end locale configuration**

The host operating system on the front-end workstation must be able to handle the character set and fonts.

For instance, a Western-European Windows® is not configured to handle Arabic applications. If you start an Arabic application, some graphical problems may occur (for instance the title bar won't display Arabic characters, but unwanted characters instead).

The GUI front-end software must support the conversion of the runtime system character set to/from the character set used internally by the client, and must be configured with the correct font to display the characters used by the
application. For example, the default font for a front-end installed on an English Windows® system might not be able to display Japanese characters. You must then change the font in the front-end configuration panel. Refer to the front-end documentation to see how character set conversion and fonts can be configured.

When using a TUI program in a terminal emulator such as Putty, XTerm or even the Windows® Console, make sure the terminal is configured properly to display the characters of the application locale. For example, on a Windows® Console you can use the `chcp` command to change the current code page.

**Writing programs**
The language locale used when writing source code defines the runtime locale, except when developing in ASCII.

**Development and runtime character set must match**
When writing a form or program source file, you use a specific character set. This character set depends upon the text editor or operating system settings you are using on the development platform. For example, when writing a string constant in a .4gl module, containing Arabic characters, you probably use the ISO-8859-6 character set. The character set used at runtime (during program execution) must match the character set used to write programs.

At runtime, a Genero program can only work in a specific character set. However, by using localized strings, you can start multiple instances of the same compiled program using different locales. For a given program instance the character set used by the strings resource files must correspond to the locale. Make sure the string identifiers use ASCII only.

**Byte length semantics and substring expressions**
When using Byte Length Semantics (BLS), all character positions in strings are actually byte positions. In a multibyte environment, if you don’t pay attention to this, you can end up with invalid characters in strings. For example, an expression using a subscript operator \[x, y\] might refer to a byte position which is in fact in the middle of a multibyte character. If possible, use Character Length Semantics (CLS) with a multibyte locale to avoid such problems, or use only STRING methods to parse character strings.

**Related concepts**
- Defining the application locale on page 412
- Length semantics settings on page 414
- Language and character set settings on page 412
- Localized strings on page 430

Localized strings provide a means of writing applications in which the text of strings can be customized on site.

**Runtime system messages**
This section describes how to translate default English .msg message files in a different language.

Runtime system error messages are provided in .iem message files. The system message files use the same technique as user defined message files. The default message files (.msg) are located in the FGLDIR/msg/en_US directory.

For backward compatibility with IBM® Informix® 4GL, some of these system error messages are used by the runtime system to display messages during a dialog instruction. For example, end users may get the error message `-1309 "There are no more rows in the direction you are going"` when scrolling an a DISPLAY ARRAY list in TUI mode.

If your application language is not English, you will need to translate some of the system messages to a specific locale and language. If your application language is English, you might just want to customize the default messages.

Here are some examples of system messages that can appear at runtime:
Table 130: Examples (subset) of system messages for localized strings

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1204</td>
<td>Invalid year in date.</td>
</tr>
<tr>
<td>-1304</td>
<td>Error in field.</td>
</tr>
<tr>
<td>-1305</td>
<td>This field requires an entered value.</td>
</tr>
<tr>
<td>-1306</td>
<td>Please type again for verification.</td>
</tr>
<tr>
<td>-1307</td>
<td>Cannot insert another row - the input array is full.</td>
</tr>
<tr>
<td>-1309</td>
<td>There are no more rows in the direction you are going.</td>
</tr>
</tbody>
</table>

To use your own customized system messages, do this:

1. Create a new directory under $FGLDIR/msg, using the same name as your current locale. For example, if LANG=fr_FR.ISO8859-1, you must create $FGLDIR/msg/fr_FR.ISO8859-1.
2. Copy the original system message source files (.msg) from $FGLDIR/msg/en_US to the locale-specific directory.
3. Edit the source files with the .msg suffix and translate the messages.
4. Recompile the message files with the fglmkmsg tool to produce .iem files. Make sure you have set the correct locale!
5. Run a program to check if the new messages are used.

With this technique, you can deploy multiple message files in different languages and locales in the same FGLDIR/msg directory.

You can use the fglmkmsg tool with the -r option to revert a .iem file to a source .msg file.

There is no need to translate all messages of the .msg files: Most of the error messages are unexpected during a program execution and therefore can stay in English. The messages subject of translation can be found in the 4glusr.msg and rds.msg files.

The locale can be set with different environment variables (see setlocale manual pages for more details). To identify the locale name, the runtime system first looks for the LC_ALL value, then LC_CTYPE and finally LANG.

Pay attention to locale settings when editing message files and compiling with fglmkmsg: The current locale must match the locale used in the .msg files.

The .iem files used at runtime must match the current locale used by programs. This is automatic, as long as you put the correct files in the corresponding $FGLDIR/msg/$LANG directory.

Related concepts
Message files on page 1059
Message files centralize strings and larger texts identified by a number, that can be used in programs.

fglmkmsg on page 1976
The fglmkmsg tool compiles .msg message files into a binary version used by programs.

Using the charmap.alias file
The charmap.alias file can be used to map a system specific locale to a standard IANA locale.

The name of the character set defined within the LANG/LC_ALL environment variables can vary from system to system. For example, on a given platform, the ISO-8859-1 character set may be named "iso88591", while others platform will use "8859-1".

An example of locale configuration on HP/UX:

```
$ export LANG=en_US.iso88591
$ locale
LANG=en_US.iso88591
```
To communicate with other components like front-ends, or identify the encoding of XML files, Genero programs must use a normalized name for character sets. This normalized name must follow the IANA specifications [RFC2978].

In order to convert the operating system specific locale codeset name to an IANA name, the runtime system uses the charmap.alias mapping file, located in $FGLDIR/etc.

You can add your operating system specific locale, if not listed in the s file.

**Date, numeric and monetary formats**

This section describes how Genero BDL handles date, time, numeric and monetary formats.

Dates, numbers and monetary values must be displayed and entered in a format used in the country/region. These formats can be defined with the DBDATE and DBFORMAT environment variables.

Date and numeric format settings matter for data display and data input. For example, when displaying a DATE value to a form field, it will implicitly be formatted by the DBDATE setting. When the user enters a date in a form field bound to a DATE variable, the entered digits will be interpreted by the DBDATE format.

The default values of these environment variables depend on the type of platform where the program executes:

When using the FORMAT field attribute or the USING operator to format dates with abbreviated day and month names- by using ddd / mmm markers - the system uses English-language based texts for the conversion. This means, day (ddd) and month (mmm) abbreviations are not localized depending on the locale settings, they will always be in English.

- On desktop/server platforms, the default formats are set for the United States of America:
  - Dates are formatted as mm/dd/yyyy.
  - The decimal separator is a dot.
  - The currency symbol is the dollar sign ($).
- On mobile platforms, the default formats are set from the regional settings defined on the device.
  - Dates are formatted depend on the regional settings.
  - The decimal separator is defined depend on the regional settings.
  - The currency symbol is not defined. No currency symbol will display.

**Note:** While it is possible to define environment settings for date and numeric formats with FGLPROFILE entries, it is strongly recommended to leave the defaults, so as to get the expected formats if the user changes the regional settings on the mobile device.

**Related concepts**

- Formatting DATE values on page 284
- Date values must be formatted when converted to strings.

- Date-time values must be formatted when converted to strings.
- Formatting numeric values on page 281
- Numeric values must be formatted when converted to strings.
- DBDATE on page 232
Defines the default display and input format for DATE values.

**DBFORMAT** on page 233

Defines currency symbol, decimal and thousands separator for input and display of numeric values.

**Using the Ming Guo date format**

Genero BDL can be configured to use the The Ming Guo calendar.

The Ming Guo (or Minguo) calendar is still used in some Asian regions like Taiwan. This calendar is equivalent to the Gregorian calendar, except that the years are numbered with a different base. In the Ming Guo calendar, the first year (1) corresponds to the Gregorian year 1912, the year the Republic of China was founded.

Digit-based year Ming Guo date format can be enabled by adding the C1 modifier at the end of the value set for the DBDATE environment variable:

```
$ DBDATE="Y3MD/C1"
$ export DBDATE
```

With this DBDATE setting, dates will be displayed with a year following the Ming Guo calendar, and date input will also be interpreted based on that calendar. For example, if the user enters 90/3/24, it is equivalent to an input of 2002/3/24 when using the Gregorian calendar. Basically, the runtime system will subtract 1912 or add 1912 respectively when displaying or reading date values.

When using the C1 modifier, the possible values for the Yn symbol are Y4, Y3, Y2.

The **MDY()** operator is sensitive to the C1 modifier usage in DBDATE. For example, if DBDATE=Y3MD/C1, MDY(3,24,1) will build a date the corresponds in the Gregorian to MDY(3,24,1912).

The **USING** operator supports the c1 modifier as well. The c1 modifier must be specified at the end of the format. You can for example use the following format string: "yyyy-mm-ddc1".

The C2 modifier to use Era names is not supported.

Unlike Informix® 4gl, when using negative years, the minus sign is placed over the left-most zero of the year, to avoid miss-aligned dates.

For example, if DBDATE=Y3MD/C1:

```
MDY(3,2, 1) USING "yyy/mm/ddc1"
MDY(3,2,-1) USING "yyy/mm/ddc1"
```

Will align properly as follows:

```
0001/03/02
-001/03/02
```

**Note:** Front-ends may not support the Ming Guo calendar for widgets like **DATEEDIT**.

**Related concepts**

**Date, numeric and monetary formats** on page 424

This section describes how Genero BDL handles date, time, numeric and monetary formats.

**User's preferred language**

An application can get the user's preferred language and territory as configured on the front-end platform.

The user preferred language can, for example, be useful in selecting appropriate content based on language preferences, and in starting other programs by setting the expected application locale.

To get the user preferred language, perform a standard **feInfo** front call with the **userPreferredLang** option:

```
PRIVATE DEFINE fe_lang STRING
```
FUNCTION get_fe_lang()
  IF fe_lang IS NULL THEN
    CALL ui.Interface.frontCall( "standard", "feInfo", 
      ["userPreferredLang"], [fe_lang] )
  END IF
  RETURN fe_lang
END FUNCTION

For Genero Desktop Client and mobile front-ends, the front-end locale is defined by the operating system.
For Genero Browser Client, the front-end locale is defined in the web browser preferences.

The format of the returned value is:

```
language_territory
```

For example, when running the GDC front-end on a Linux® platform with LC_ALL defined as `en_US.utf8`, the front call will return:

```
en_US
```

**Related concepts**

**feInfo** on page 2500
Queries general front-end properties.

**Right-to-left languages support**
Genero supports right-to-left languages, such as Arabic and Hebrew.

**Right-to-left mode**

For specific front-end clients, Genero supports right-to-left languages with the reverse mode. With reverse mode, all forms are mirrored and the text direction changes to right-to-left, for display and input.

The reverse mode is enabled at runtime. The same form files are used to display in the default left-to-right and right-to-left mode.

**Note:** Right-to-left display is implicit on mobile devices. It is enabled depending on language settings on the device.

**Application locale**

Reverse mode is used with an application locale that defines a language written from right to left.

For example, for Arabic support on a Linux® platform, you can use the following LC_ALL value when using the ISO-8859-6 codeset:

```
$ export LC_ALL=ar_DZ.iso88596
```

**Reverse mode configuration**

To enable reverse mode, set the `reverse` style attribute for the `UserInterface` class to "yes" in your .4st file:

```
<StyleList>
  ...
  <Style name="UserInterface">
    <StyleAttribute name="reverse" value="yes" />
  </Style>
  ...
</StyleList>
```
Related reference
UserInterface style attributes on page 1116
UserInterface style presentation attributes define general options related to the application user interface.

Troubleshooting locale issues
This section describes common issues related to language locale definition.

Locale settings (LANG) corrupted on Microsoft™ platforms
On Microsoft™ Windows® XP / 2000 platforms, some system updates (Services Pack 2) or Office versions do set the LANG environment variable with a value for Microsoft™ applications (for example 1033). Such value is not recognized by Genero as a valid locale specification. Make sure that the LANG environment variable is properly set in the context of Genero applications.

Related concepts
What is my current character set? on page 412
Language and character set settings on page 412

A form is displayed with invalid characters
You may have different codesets on the client workstation and the application server. The typical mistake that can happen is the following: You have edited a form-file with the encoding CP1252; you compile this form-file on a UNIX-server (encoding ISO-8859-7). When displaying the form, invalid characters will appear. This is usually the case when you write your source file under a Windows® system (that uses Microsoft™ Code Page encodings), and use a Linux® server (that uses ISO codepages).

Keep in mind that all source files must be created/edited in the encoding of the server (where fglcomp and fglrun will be executed).

Related concepts
Language and character set settings on page 412
Compiling source files on page 1998
Describes how to build the runtime files from source files.

Checking the locale configuration on UNIX™ platforms
On UNIX™ systems, the locale command without parameters outputs information about the current locale environment.

Once the LANG environment variable is set, check that the locale environment is correct:

```
$ export LANG=en_US.ISO8859-1
$ locale
LANG=en_US.ISO8859-1
LC_CTYPE="en_US.ISO8859-1"
LC_NUMERIC="en_US.ISO8859-1"
LC_TIME="en_US.ISO8859-1"
LC_COLLATE="en_US.ISO8859-1"
LC_MONETARY="en_US.ISO8859-1"
LC_MESSAGES="en_US.ISO8859-1"
LC_PAPER="en_US.ISO8859-1"
LC_NAME="en_US.ISO8859-1"
LC_ADDRESS="en_US.ISO8859-1"
LC_TELEPHONE="en_US.ISO8859-1"
LC_MEASUREMENT="en_US.ISO8859-1"
LC_IDENTIFICATION="en_US.ISO8859-1"
LC_ALL=
```

If the locale environment is not correct, then it is recommended that you check the value of the following environment variables: LC_ALL, LC_CTYPE, LC_NUMERIC, LC_TIME, LC_COLLATE, etc.
The following examples show the effect of LC_ALL and LC_CTYPE on locale configuration. The LC_ALL variable overrides all other LC_..... environment variables.

```
$ export LANG=en_US.ISO8859-1
$ export LC_ALL=POSIX
$ export LC_CTYPE=fr_FR.ISO8859-15
$ locale
LANG=en_US.ISO8859-1
LC_CTYPE="POSIX"
LC_NUMERIC="POSIX"
LC_TIME="POSIX"
LC_COLLATE="POSIX"
LC_MONETARY="POSIX"
LC_MESSAGES="POSIX"
LC_PAPER="POSIX"
LC_ADDRESS="POSIX"
LC_TELEPHONE="POSIX"
LC_MEASUREMENT="POSIX"
LC_IDENTIFICATION="POSIX"
LC_ALL=POSIX
$ fglrun -i mbcs
LANG honored: yes
Charmap     : ANSI_X3.4-1968
Multibyte   : no
Stateless   : yes
```

The charset used is the ASCII charset. Clearing the LC_ALL environment variable produces the following output. Note the LC_CTYPE value:

```
$ unset LC_ALL
$ locale
LANG=en_US.ISO8859-1
LC_CTYPE="en_US.ISO8859-1"
LC_NUMERIC="en_US.ISO8859-1"
LC_TIME="en_US.ISO8859-1"
LC_COLLATE="en_US.ISO8859-1"
LC_MONETARY="en_US.ISO8859-1"
LC_MESSAGES="en_US.ISO8859-1"
LC_PAPER="en_US.ISO8859-1"
LC_NAME="en_US.ISO8859-1"
LC_ADDRESS="en_US.ISO8859-1"
LC_TELEPHONE="en_US.ISO8859-1"
LC_MEASUREMENT="en_US.ISO8859-1"
LC_IDENTIFICATION="en_US.ISO8859-1"
LC_ALL=
$ fglrun -i mbcs
Error: locale not supported by C library, check LANG.
$ locale charmap
ANSI_X3.4-1968
```

After clearing the LC_ALL value, the value of the variable LC_CTYPE is used. It appears that it is not correct. After clearing this value we get the following output:

```
$ unset LC_CTYPE
$ locale
LANG=en_US.ISO8859-1
LC_CTYPE="en_US.ISO8859-1"
LC_NUMERIC="en_US.ISO8859-1"
LC_TIME="en_US.ISO8859-1"
LC_COLLATE="en_US.ISO8859-1"
LC_MONETARY="en_US.ISO8859-1"
```
Related concepts

Operating system environment variables on page 228

Verifying if the locale is properly supported by the runtime system

You can check if the LANG/LC_ALL locale is supported properly by using the `-i mbcs` option of the compilers and runner programs:

```bash
$ fglcomp -i mbcs
Charmap          : UTF-8
Multibyte        : yes
Stateless        : yes
Length Semantics : CHAR
```

The lines printed with this option indicate if the locale can be supported by the operating system libraries. Here is a short description of each line:

Table 131: -i info line descriptions

<table>
<thead>
<tr>
<th>Verification Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Charmap</td>
<td>This is the normalized IANA name of the character set used by the runtime system to communicate with external components (front-end, I/O of XML files). The mapping from the system locale name to a normalized name is defined in FGLDIR/etc/charmap.alias.</td>
</tr>
<tr>
<td>Multibyte</td>
<td>This line indicates if the character set is multibyte.</td>
</tr>
<tr>
<td>Stateless</td>
<td>A few character sets are using an internal state that can change during the character flow. Only stateless character sets can be supported (the value must be 'yes').</td>
</tr>
</tbody>
</table>

How to retrieve the list of available locales on the system

On UNIX™ systems, the `locale` command with the parameter `'-a'` writes the names of available locales.

```bash
$ locale -a
... en_US en_US.iso885915 en_US.utf8 en_ZA en_ZA.utf8 en_ZW ...
```

---

```bash
LC_MESSAGES="en_US.ISO8859-1"
LC_PAPER="en_US.ISO8859-1"
LC_NAME="en_US.ISO8859-1"
LC_ADDRESS="en_US.ISO8859-1"
LC_TELEPHONE="en_US.ISO8859-1"
LC_MEASUREMENT="en_US.ISO8859-1"
LC_IDENTIFICATION="en_US.ISO8859-1"
LC_ALL=
$ locale charmap
ISO-8859-1
$ fglrun -i mbcs
LANG honored: yes
Charmap     : ISO-8859-1
Multibyte   : no
Stateless   : yes
```
How to retrieve the list of available codesets on the system

On UNIX™ systems, the `locale` command with the parameter `'-m'` writes the names of available codesets.

```
$ locale -m
...
ISO-8859-1
ISO-8859-10
ISO-8859-13
ISO-8859-14
ISO-8859-15
...
```

Localized strings

Localized strings provide a means of writing applications in which the text of strings can be customized on site.

This string localization feature is a simple way to define external resource files which the runtime system can search, in order to assign text to elements displayed by programs. It can be used to implement internationalization in your application, or to use site-specific text, for example, when business terms are specific to the territory where the application is used.

The localized string resource files (.42s) are loaded at runtime and shared by all `fglrun` processes. Localized strings are used to replace the original strings found in the p-code modules (.42m), in the compiled form (.42f), and in any XML resource files loaded in the abstract user interface tree (.4ad, .4st, .4tb, etc).

Related concepts

Form specification files on page 1132
Form specification files are the source files defining the layout and content of application forms.

The abstract user interface tree on page 1010
The abstract user interface tree is the XML representation of the application forms displayed to the end user.

Steps for application internationalization

Follow these steps to internationalize your application.

1. Identify the current character set used in your sources and make sure the application locale (LANG/LC_ALL) is set correctly.
2. In .4gl sources, add a `% prefix to the strings that must be localized (translated). For parameterized messages, replace concatenated strings by a SFMT() usage with %n placeholders for variable message parts.
3. In .per sources LAYOUT section, replace hard-coded form elements like text labels with static LABEL form items and define the TEXT attributes with a % prefix in the ATTRIBUTES section.
4. In XML resources, add `<LStr />` elements under the elements where text attributes must be localized.
5. Extract the strings from the .4gl sources with `fglcomp -m` and use `fglform -m` for .per sources.
6. Organize the generated .str source string files (identify duplicated strings and put them in a common file).
7. At this point, the string identifiers (on the left) are the same as the string texts (on the right). These string identifiers can be used as is, or can be changed to clear ASCII identifiers such as "customer.list.title".
Using simple identifiers allows you to distinguish strings depending on the context and use ASCII encoding for your sources. Keeping string identifiers with the original text requires no source changes (except adding the % prefix), but makes sources dependent to a locale: If you want to support multiple languages, you must use UTF-8 in sources and at runtime.

8. When using simple ASCII identifiers, replace original strings with the new string identifiers. Strings to be replaced can be located by their % prefix. You can, for example, use a script with an utility like the `sed` UNIX™ command to read the .str files and apply the changes automatically.

9. Recompile the .4gl and .per sources (when using simple ASCII strings identifiers, sources are expected to be full ASCII now).

10. Compile the .str files in the locale used by these files,
11. Setup FGLPROFILE fglrun.localization.* entries, to let fglrun find the string resource files.
12. Run your programs to check whether the application displays the text properly.
13. Copy the existing .str files, and translate the string text into another language (make sure the locale is correct).
14. Compile the new .str files, and copy the .42s files into another distribution directory, defined with the FGLRESOURCEPATH environment variable.
15. Run your programs again, to check that texts and labels of the other language are displayed.
16. Next changes to the .per and .4gl source files are done in the ASCII locale, and .str string files must be edited with their specific locale.

Related concepts
Application locale on page 405
The application locale defines the language and codeset for your application.

Creating source string files
A source string file contains localized string definitions for a given language (or localization context).

What is a source string file?
A source string file is basically a mapping table that defines an identifier for each string.
After compiling source string files, programs can load and use a given string by referencing its identifier (or key).
By convention, the source files of localized strings have the .str extension.

Syntax
Define a list of string identifiers, and the corresponding text, by using the following syntax:

```
"string-identifier" = "string-text"
```

For example:

```
"Cancel" = "Annuler"
```

Note: Localized string keys are case sensitive. Consider using lower case characters only to avoid mistakes.
As an alternative, you can define string identifiers as a dot-separated list of identifiers:

```
identifier. [.....] = "string-text"
```

For example:

```
common.button.cancel = "Annuler"
```

If needed, you can add comment lines with the # or -- markers, like in other Genero source files:

```
# a comment
-- another comment
```
Special characters

The \fglin\kstr compiler accepts the backslash "\" as the escape character, to define non-printable characters:

\l \n \r \t \\

Example

```
# A comment line
"Original text" = "Original text"
forms.customer.list = "Customer List"
special.characters.backslash = "\\"
special.characters.newline = "\n"
```

Related concepts

Extracting strings from sources on page 434

Localized strings can be easily extracted from .4gl and .per source files.

Localized strings in program sources

A localized string is specified in the source code of program modules or form specification files with the 
"string" notation, to identify a string that must be replaced at runtime by the corresponding text found in 
compiled string files. In programs, localized strings can be loaded dynamically with the LSTR() operator.

Syntax 1: Static localized string

```
%"sid"
```

1. *sid* is a character string literal that defines both the string identifier and the default text.

Syntax 2: Dynamic localized string

```
LSTR(eid)
```

1. *eid* is a character string expression used at runtime as the string identifier to load the text.

Static localized strings

A static localized string specification begins with a percent sign (%), followed by the identifier of the string which 
will be used to find the text to be loaded. Since the identifier is a string, you can use any type of characters, but it 
is recommended that you use a naming convention. For example, you can specify a path by using several names 
separated by a dot:

```
MAIN
  DISPLAY %"common.message.welcome"
END MAIN
```

The string after the percent sign defines both the localized string identifier and the default text to be used for 
 extraction, or the default text when no string resource files are provided at runtime.

You can use this notation in form specification files any place where a string literal can be used.

```
LAYOUT
  VBOX
    GROUP g1 (TEXT=%"group01")
...
It is not possible to specify a static localized string directly in the area of containers like GRID, TABLE, TREE or SCROLLGRID. You can use static label form items to define localized strings in layout labels:

```
LAYOUT
  GRID
  {
    [lab01  |f001               ]
    
  } END
END
ATTRIBUTES
LABEL lab01: TEXT=%"myform.label01";
EDIT f001 = FORMONLY.field01;
END
```

**Dynamic localized strings**

The language provides a special operator to load a localized string dynamically, using an expression as string identifier. The name of this operator is `LSTR()`.

The following code example builds a localized string identifier with an integer and loads the corresponding string with the `LSTR()` operator:

```
MAIN
  DEFINE n INTEGER
  LET n = 234
  DISPLAY LSTR("str"||n)  -- loads string 'str234'
END MAIN
```

**Related concepts**

- **Text literals** on page 289
  Text literals define a character string in an expression.

- **LABEL item type** on page 1175
  Defines a simple text area to display a read-only value.

- **LSTR()** on page 322
  The `LSTR()` operator returns a localized string.

**Localized strings in XML resource files**

In XML resource files, localized string specification must follow the XML syntax and therefore must be defined as an XML node.

**Syntax: Localized string in XML files**

```
<ParentNode attribute = "default" [...]>
  <LStr attribute = "sid" [...] />
</ParentNode>
```

1. `ParentNode` is the node type of the parent where the localized strings must be applied.
2. `attribute` is the attribute in the parent node that will get the localized string identified by `sid`.
3. `default` is the default text of an attribute, if not localized string is found for `sid`.
4. `sid` is a character string literal that defines both the string identifier and the default text.

**Description**

In .42m p-code modules, the localized strings are coded in a proprietary binary format. But, for XML files such as action defaults files (.4ad), the localized strings must be written with a specific node, following the XML standards. To support localized strings in XML files, any file loaded into the Abstract User Interface tree is parsed to search for
<LStr> nodes. The <LStr> nodes define the same attributes as in the parent node with localized string identifiers, for example:

```xml
<Label text="Hello!" >
  <LStr text="label01" />
</Label>
```

The runtime system automatically replaces corresponding attributes in the parent node (text="Hello!"), with the localized text for the string identifier (label01) found in the compiled string files. After interpretation, the <LStr> nodes are removed from the XML data.

To take effect, a localized attribute in the <LStr> node must have a corresponding attribute in the parent node.

**Extracting strings from sources**

Localized strings can be easily extracted from .4gl and .per source files.

Use the fglcomp and fglform compilers with the -m option to extract localized strings.

```bash
$ fglcomp -m mymodule.4gl
```

The compilers dumps all localized string to stdout. This output can be redirected to a file to generate the default source string file with all the localized strings used in the source file. Source string files can then be re-organized, to centralize common messages in a unique .str file, and can then be compiled by fglmkstr into .4st files to be used by the runtime system.

**Related concepts**

- Creating source string files on page 431
- A source string file contains localized string definitions for a given language (or localization context).
- fglcomp on page 1972
  - The fglcomp tool compiles .4gl source files into .42m p-code modules.
- fglform on page 1970
  - The fglform tool compiles form specification files into XML formatted files used by programs.

**Organizing string resources**

Good practice in use of localized strings.

**What application strings to localize?**

When modifying sources to add % prefixes to the strings that have to be localized, you need to consider which string is the subject of internationalization, and leave other strings without a % prefix.

For example, strings used to build an SQL statement at runtime obviously must not be localized:

```sql
LET sql = "SELECT * FROM customers ", where_part
```

Typical strings to be localized are application messages:

```sql
MESSAGE %"The customer name is mandatory!"
```

Furthermore, you may also need to localize application data. In this case, you can store localized string identifiers in the database, and use the LSTR() function at runtime to get the localized string from your string resource files:

```sql
SELECT order_warning INTO rec.order_warning
    FROM orders WHERE ... 
LET msg = LSTR(rec.order_warning) 
DISPLAY BY NAME msg
```
Messages with parameters

Applications often display messages with variable parts. The message text is usually built at runtime with comma concatenation expression, where the message is split into different string literals:

```plaintext
LET msg = "There are ", ord_count USING "<<<&", " orders not yet validated for ", rec.cust_name, "."
```

To simplify translation, consider reviewing the message construction by using the `SFMT()` operator, to set the variable parameters in your messages:

```plaintext
LET msg = SFMT("orders.message.valid_count", ord_count, rec.cust_name)
```

You can then easily define the corresponding localized strings with `%n` placeholders:

```
-- English string file:
orders.message.valid_count = "There are %1 orders not yet validated for %2."

-- French string file:
orders.message.valid_count = "%1 commandes ne sont pas encore validées pour %2."
```

Note that in `SFMT()` calls, the `%n` placeholders can be specified at different positions, depending on the language needs.

Development and runtime locale

The character set encoding (LANG/LC_ALL locale) used in sources and at runtime must match. For more details, see Application locale on page 405.

A good practice is to have sources in ASCII, and have string resources in the locale of your choice: The runtime locale can be a specific ISO8859-? encoding for each language, or UTF-8, to have a common encoding for all languages to be supported. However, you can also use UTF-8 in sources and at runtime, if you want to use original texts as string identifiers in your sources.

Note: The locale to be used at runtime will depend on the database locale used. You may need to support a set of string files using ISO8859-? and a set of files using UTF-8, if you need to deploy your application with ISO8859-? databases and UTF-8 databases.

String identifiers

A localized string must be identified with a unique name. By default, if you add a `%` prefix before existing strings and you extract the strings with `fglcomp -m` or `fglform -m`, you will get string identifiers with the original text:

```
"OK" = "OK"
"Cancel = "Cancel"
"Close" = "Close"
"There are %1 orders not yet validated for %2." = "There are %1 orders not yet validated for %2."
```

At this point, you can keep the original text for string identifiers, or re-define more abstract identifiers (without quotes, such as `common.button.text.ok`).

Using the original text as string identifier has the advantage of been fast. It also simplifies translation because the original text is directly visible for the translator. However, the character set encoding should be UTF-8.

Note: If you want to leave the original text for string identifiers, you must make sure that the locale used at compile time matches the runtime locale. If the languages to be supported do not fit in a single encoding like ISO8859-15, you will have to convert your sources to UTF-8 and use UTF-8 at runtime.
Using abstract identifiers allows to maintain the sources in pure ASCII. Additionally, you can give an indication of the usage context by using a clear identifier. It is recommended that you also group common messages in a single string resource file. Using abstract identifiers will simplify uniqueness checking.

**common.str:**

```plaintext
common.button.text.accept = "OK"
common.button.text.cancel = "Cancel"
common.button.text.close = "Close"
common.topmenu.text.accept = "Validate"
...
```

**orders001.str:**

```plaintext
orders.messages.valid_count = "There are %1 orders not yet validated for %2."
...
```

**Create directories for each language**

At runtime, the `.42s` string resource files to be loaded must be declared with the `fglrun.localization.*` FGLPROFILE entries.

In order to provide a set of string files for each language you want to support, organize the string files in directories dedicated to a given language:

```
/opt/app/resource/strings/fr_FR.iso8859-15  -- French strings in iso8859-15 code-set
/opt/app/resource/strings/jp_JP.utf8        -- Japanese strings in utf-8 code-set
```

**Related concepts**

- [Loading localized strings at runtime](#)
- [Compiling string resource files](#)

**Compiling string resource files**

The `.str` source string files must be compiled to `.42s` binary files, in order to be loaded by the runtime system.

To compile a source string file, use the `fglmkstr` compiler.

```
$ fglmkstr filename.str
```

The `fglmkstr` tool generates a `.42s` file with the `filename` prefix.

**Important:** When compiling a `.str` source string file, you must set the locale (character set) corresponding to the encoding used in the `.str` file.

**Related concepts**

- [fglmkstr](#)

The `fglmkstr` tool compiles `.str` localized string resource files.

- [Extracting strings from sources](#)
Localized strings can be easily extracted from .4gl and .per source files.

**Loading localized strings at runtime**
Understand the rules for using localized strings at runtime.

**Distributing compiled string files**
The compiled string files (.42s) must be distributed with the program files in a directory specified in the DBPATH/FGLRESOURCEPATH environment variable.

**Setting the correct locale**
The locale (LANG/LC_ALL) corresponding to the encoding used in the .42s files must be set before starting the application. If the locale is wrong, the strings will not be loaded properly.

**How does the runtime system load the strings?**
The .42s compiled string resource files are loaded in the following order of precedence:

1. The files defined in FGLPROFILE.
2. A file having the same name as the current program (myprog.42m loads myprog.42s).
3. A file with the name "default.42s".

Each .42s string resource file is searched in several directories, as described in the FGLRESOURCEPATH reference topic.

**String resource file sharing**
Like .42m program pcode files, the .42s string resource files are shared by all fglrun processes running on the computer: The string file is loaded into memory with the mmap operating system function.

**Defining a list of string files in FGLPROFILE**
Specify a list of compiled string files with entries in the FGLPROFILE configuration file with the fglrun.localization entries.

First, define the total number of files with:

```plaintext
fglr.run.localization.file.count = integer
```

For each file, define the file name (with the .42s extension), including an index number (start index must be 1):

```plaintext
fglr.run.localization.file.index.name = "filename.42s"
```

Warning switches can be specified in FGLPROFILE.

If the text of a string is not found at runtime, the runtime system can show a warning, for development purposes.

```plaintext
fglr.run.localization.warnKeyNotFound = boolean
```

By default, this warning switch is disabled.

**What happens if a 42s string file is not found?**
If the 42s string file was defined with fglrun.localization.* FGLPROFILE entries, it is considered as mandatory, and the runtime system will raise error -8006 if the file is not found. If the progname.42s and default.42s string files are not found, no error is raised, because these are fallback string resource files.
What happens if a string is not defined in a resource file?

If a localized string is not defined in one of the compiled string files, the runtime system uses the string identifier as default text.

What happens if a string is defined more that once?

When a localized string is defined in several compiled string files, the runtime system uses the first string found.

For example, if the string "hello" is defined in `program.42s` as "hello from program", and in `default.42s` as "hello from default", the runtime system will use the text "hello from program".

Organizing .42s resource files in distribution directories

A set of .42s files using the same language and codeset is typically copied in a distribution directory with a name identifying the locale.

For example:

```
/opt/app/resource/strings/fr_FR.iso8859-15  -- French strings in iso8859-15 code-set
/opt/app/resource/strings/jp_JP.utf8        -- Japanese strings in utf-8 code-set
```

At runtime, specify the string file search path in the `DBPATH/FGLRESOURCEPATH` environment variable by adding the name of current locale as sub-directory. For example, to find the correct string files in one of the locale-specific directories shown above, set the `FGLRESOURCEPATH` variable as follows (UNIX™ shell):

```
$ echo $LC_ALL
jp_JP.utf8
$ FGLRESOURCEPATH="$FGLRESOURCEPATH:/opt/app/resource/strings/$LC_ALL"
$ export FGLRESOURCEPATH
$ echo $FGLRESOURCEPATH
/opt/app/forms:/opt/app/resource/strings/jp_JP.utf8
```

Localized string files on mobile devices

On mobile devices, the language is determined by the operating system regional settings.

- On iOS devices (version 8.1), the language is determined by Settings >> General >> International >> Language
- On Android™ devices (version 4.4), the language is determined by Settings >> Language & Input >> Language

The selected language is identified by a locale code following the ISO 639 standard. Below are some language code examples; see the mobile OS documentation for information about available languages and their corresponding ISO 639-x codes.

- en - English (for all regions)
- en_US - English in the United States
- en_GB - English in the United Kingdom

On startup, the mobile app will search for localized string files (.42s) in the following directories:

3. `appdir/defaults`: the fallback directory where default string files are located.

In order to localize your application, you simply need to place your .42s localized string files in the appropriate language sub-directory.
Note: If the .42s file names do not match the main program name, define the list of localized strings files in the app's fglprofile file.

If you want to distinguish language categories (Simplified/Tradition Chinese), or if you want to use different texts for territories that share the same language (English in USA or Great Britain), create language sub-directories with the exact OS locale identifier:

- For English in the USA, use "en_US"
- For English in the United Kingdom, use "en_GB"
- For English in Canada, use "en_CA"
- etc...

```
appdir/en_US/mystrings.42s
appdir/en_GB/mystrings.42s
appdir/en_CA/mystrings.42s
```

If the language category or region can be ignored, create language sub-directories with names matching the language identifier only:

- For English, use "en"
- For French, use "fr"
- For German, use "de"
- etc...

```
appdir/en/mystrings.42s
appdir/fr/mystrings.42s
appdir/de/mystrings.42s
```

A default set of string files can be provided under appdir/defaults, in case the regional settings of the device do not match one of the locale directories you provide, otherwise the application will stop with error -8006:

```
appdir/defaults/mystrings.42s
```

For more details about the mobile app directory structures (appdir), see Directory structure for GMA apps on page 3315 and Directory structure for GMI apps on page 3330.

**Selecting the application language at runtime**

In order to implement a typical login dialog where the end user can choose the application language, it must be possible to reset the path to find localized strings at runtime.

This is possible with the `base.Application.reloadResources()` method. However, this method has a limited impact. For example, localized strings of already loaded .42m modules and .42f forms are left unchanged. Subsequent loaded forms and modules will get localized strings depending on the new lookup path. Therefore, this method must only be called for the initial form, when the program starts.

```
IMPORT os
MAIN
  DEFINE done BOOLEAN
  DEFINE rec RECORD
      user STRING,
      pswd STRING,
      lang CHAR(2)
  END RECORD,
  path STRING

  -- Login dialog with language selection
  LET rec.lang = "en" -- Can be "en", "fr", "de" ...
  WHILE NOT done
      LET path = os.Path.join(base.Application.getProgramDir(), rec.lang)
```
CALL base.Application.reloadResources(path)
OPEN FORM f FROM "main"
DISPLAY FORM f
INPUT BY NAME rec.* WITHOUT DEFAULTS
ON CHANGE lang
  EXIT INPUT -- restarts the input with the new locale settings
ON ACTION cancel
  EXIT PROGRAM
AFTER INPUT
  LET done = TRUE
END INPUT
END WHILE
-- Here starts the real application code
...
END MAIN

Locale and character set basics on page 409
This section is an introduction to locale and character set basics.

Predefined application strings
The runtime system may need to display text to the user.

For example, the runtime system library includes a report viewer, which displays a form. By default the text is in English, and you may need to localize the text in another language. So the strings of this component must be 'localizable', as in other application strings.

To customize the built-in strings, the runtime system uses the mechanism of localized strings.

All strings used by the runtime system are centralized in a unique file:

$FGLDIR/src/default.str

which is compiled into:

$FGLDIR/lib/default.42s

This file is always loaded by the runtime system.

To overwrite the defaults, you can redefine these strings in your own localized string files.

Best practices for localized strings
This section describes good practices to localize your application messages.

Program files and runtime language charset
Localization implies choosing a locale character set to use when executing a program.

The character set used at runtime must be the same as (or compatible with) the development character set: The compiled program files ( .42m, .42f ) are encoded in the character set used during compilation.

If the character set used in existing source files is different from the character set used at runtime for a different target language, consider using ASCII-7 only your source code, and put application messages in .str localized string files, using the appropriate character set for each target language.
To support multiple languages at runtime, use the UTF-8 character set to encode your `.str` (and `.42s`) localized string files. When using UTF-8 in your source code and at runtime, the string keys can contain UTF-8 characters and you can use the original text as string key.

For more details about character set usage, see Application locale on page 405.

**Defining the string key as identifier or as original text?**

With localized strings, you have the choice of using the original text as string key, or of using a more programmatic-type string identifier.

String key as original text (English):

"The transaction has been validated." = "La transaction a été validée."

String key as identifier:

`shipments.transaction.validated = "La transaction a été validée."`

**Pros and cons when using the original text as string key:**

1. It is the fastest solution to localizing your application; you just need to add a percent sign (%) before texts in your source code, extract texts with `fglcomp -m`, and translate string files.
2. It simplifies the translation process, since the original text is always available as the string key.
3. If the charset used during development is different from the charset used at runtime, make sure to use ASCII-7 only characters in the string key, otherwise your `.str` file will be dependent on the locale character set used in development.
4. Long texts can be used as string keys. For common messages that are often used in your sources, consider defining string constants in a dedicated module as described below.

**Pros and cons when using identifiers as string key:**

1. You can clearly distinguish messages depending on the context. For example, the test "Ok" may be the same in the English button label and transaction status, but may require different texts in other languages.
2. Distinct identifiers are easier to manage in the translation process, for example to store ids and texts in a database.
3. String identifiers can be used directly with the `%"ident"` notation in sources, and do not required you to define constants for common strings.
4. String identifiers require you to replace the original text in the source code by the string identifier preceded by the `%` sign. When using the original text as key, you just need to add the `%` sign in the source.

**Note:** There is no constraint to exclusively using one of these patterns, you are free to use both methods for the same application.

**Defining CONSTANT strings for common messages**

Instead of repeating the same long string key in many places, group all common localized strings in modules and define constants:

```
-- mystrings.4gl module
PUBLIC CONSTANT STR_CONF_DEL_REC = "%"Are you sure you want to delete this record?"
PUBLIC CONSTANT STR_TX_COMMITTED = "%"The transaction has been committed."
...
```

**Note:** When using the `IMPORT FGL` instruction, constant definitions are available with code completion.
Using parameterized strings

If a message contains a variable part, or must display a value that is only known at runtime, consider using the SFMT() operator to replace %n placeholders in your strings.

```plaintext
orders.item.validated = "The item %1 has been validated."
```

Since %n placeholders are replaced by position, it is easy to put the placeholder at the position required by the language grammar.

English strings file:

```plaintext
stock.items.count = "Stock %1 contains now %2 aditional items."
```

French strings file:

```plaintext
stock.items.count = "%2 elements ajoutés dans le stock %1."
```

When using the original text as string key, it is good practice to identify parameter placeholders with a different notation to the %n notation of SFMT(). For example, you can use P1, P2, etc:

```plaintext
"The item P1 has been validated." = "The item %1 has been validated."
```

Composed messages can be defined with %n and SFMT():

```plaintext
"P1 must be entered." = "%1 must be entered."
"Product code" = "Product code"
"Customer code" = "Customer code"
```

Then in the program code:

```plaintext
LET str = SFMT("P1 must be entered.", "%"Customer code")
```

To get the string "Customer Code must be entered."

Example

Here is an example using localized strings.

The source string file "common.str" (to be compiled with fglmkstr):

```plaintext
common.accept = "OK"
common.cancel = "Cancel"
common.yes = "Yes!"
common.no = "No!"
```

The source string file "customer.str" (to be compiled with fglmkstr):

```plaintext
customer.mainwindow.title = "Customers"
customer.listwindow.title = "Customer List"
customer.l_custnum = "Number:"
customer.l_custname = "Name:"
customer.c_custname = "The customer name"
customer.q_delete = "Do you want to delete this customer?"
```

The FGLPROFILE configuration file parameters:

```plaintext
fglr.run.localization.file.count = 1
fglr.run.localization.file.1.name = "common.42s"
```
Remark: The 'customer' string file does not have to be listed in FGLPROFILE since it is loaded as it has the same name as the program.

The form specification file "customer.per":

```
ACTION_DEFAULTS
  ACTION accept (TEXT=%"common.accept")
  ACTION cancel (TEXT=%"common.cancel")
END
LAYOUT (TEXT=%"customer.mainwindow.title")
GRID
  [lab1] [f01]
  [lab2] [f02]
END
END
ATTRIBUTES
  LABEL lab1: TEXT=%"customer.l_custnum";
  EDIT f01 = FORMONLY.custnum;
  LABEL lab2: TEXT=%"customer.l_custname";
  EDIT f02 = FORMONLY.custname, COMMENT=%"customer.c_custname";
END
```

The program "customer.4gl" using the strings file:

```
MAIN
  DEFINE rec RECORD
      custnum INTEGER,
      custname CHAR(20)
  END RECORD
  OPEN FORM f1 FROM "customer"
  DISPLAY FORM f1
  INPUT BY NAME rec.*
  ON ACTION delete
      MENU "%customer.mainwindow.title"
          ATTRIBUTES(STYLE="dialog", COMMENT=%"customer.q_delete")
          COMMAND "%common.yes"
          COMMAND "%common.no"
      END MENU
  END ACTION
END MAIN
```

**Related concepts**

  The .str source string files must be compiled to .42s binary files, in order to be loaded by the runtime system.

**Runtime stack**

The runtime stack is used to pass/return values to/from functions.

When passing arguments to a function or when returning values from a function, you are using the runtime stack. When you call a function, parameters are pushed on the stack; before the function code executes, parameters are popped from the stack in the local variables defined in the function. On the other hand, each parameter returned by a function is pushed on the stack and popped into variables specified in the RETURNING clause of the caller.
Elements are pushed on the stack in a given order, then popped from the stack in the reverse order. This is transparent to the programmer. However, if you want to implement a C extension, you must keep this in mind.

According to the data type, parameters are passed and returned by value or by reference. When an element is passed/returned by value, a complete copy of the value is passed. When an element is passed by reference, only the handle of the object is passed/returned. If the type allows it, elements passed by reference can be manipulated in the called function to modify the value.

**Table 132: Function parameter and returning rules by language element type**

<table>
<thead>
<tr>
<th>Mode</th>
<th>Data type or data structure</th>
</tr>
</thead>
<tbody>
<tr>
<td>By value</td>
<td>BOOLEAN, BIGINT, INTEGER, SMALLINT, TINYINT, FLOAT, SMALLFLOAT, DECIMAL, MONEY, CHAR, VARCHAR, DATE, DATETIME, INTERVAL, records and static arrays (cannot be returned).</td>
</tr>
<tr>
<td>By reference</td>
<td>Dynamic arrays, dictionaries, objects (from Java, built-in or extension classes), BYTE/TEXT, STRING (but cannot be modified)</td>
</tr>
</tbody>
</table>

- Passing simple typed values as parameter on page 444
- Passing a record as parameter on page 445
- Passing a static array as parameter on page 446
- Passing a dynamic array as parameter on page 446
- Passing a dictionary as parameter on page 447
- Passing objects as parameter on page 448
- Passing a TEXT/BYTE as parameter on page 448
- Returning simple typed values from functions on page 448
- Returning dynamic arrays from functions on page 449
- Returning dictionaries from functions on page 449
- Returning TEXT/BYTE values from functions on page 450
- Implicit data type conversion on the stack on page 450

**Passing simple typed values as parameter**

Simple data types such as INTEGER, DECIMAL, VARCHAR are passed by value in function parameters. When passing a function parameter by value, the runtime system pushes a copy of the data on the stack.

The STRING data type is an exception to this rule for simple types: elements of this type are passed by reference. In fact the runtime system passes a reference to the string value, so the actual string data is not copied on the stack as for other simple types. However, the value of the caller cannot be modified. If a STRING parameter gets a new value in a function, a new string reference is created. Passed STRING parameters improve performances compared to CHAR/VARCHAR, with the same semantics as VARCHAR().

When passing a simple typed value to a function, the local variable receiving the value can be changed without affecting the variable used by the caller:

```
MAIN
   DEFINE c CHAR(10), s STRING
   LET c = "abc"
   LET s = "def"
   CALL func(c, s)
   DISPLAY c -- Shows "abc"
   DISPLAY s -- Shows "def"
END MAIN

FUNCTION func(pc, ps)
   DEFINE pc CHAR(10), ps STRING
   DISPLAY c -- Shows "abc" (this is a copy of the string)
   DISPLAY s -- Shows "def" (this is the original string)
```
LET pc = "zz" -- Assigns new value to local variable
LET ps = "zz" -- Assigns new value to local variable
END FUNCTION

Selecting the correct data type assists you in the input, storage, and display of your data.

Type conversions on page 274
Explains data type conversion rules of the language.

Records on page 382
Records allow structured program variables definitions.

Flow control on page 340
Definition of language elements and instructions that control the flow of a program.

Passing a record as parameter
You can pass a RECORD structure as a function parameter with the dot star (.* ) notation. In this case, the record is expanded and each member of the structure is pushed on the stack. The receiving local variables in the function can then be defined individually or with the same record structure as the caller. The next example illustrates this:

MAIN
  DEFINE rec RECORD
    a INT,
    b VARCHAR(50)
  END RECORD
  CALL func_r(rec.*)
  CALL func_ab(rec.*)
END MAIN

-- Function defining a record like that in the caller
FUNCTION func_r(r)
  DEFINE r RECORD
    a INT,
    b VARCHAR(50)
  END RECORD
  ...
END FUNCTION

-- Function defining two individual variables
FUNCTION func_ab(a, b)
  DEFINE a INT, b VARCHAR(50)
  ...
END FUNCTION

Related concepts
Data types on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

Type conversions on page 274
Explains data type conversion rules of the language.

Records on page 382
Records allow structured program variables definitions.

Flow control on page 340
Definition of language elements and instructions that control the flow of a program.

**Passing a static array as parameter**

It is possible to pass a complete static array as a function parameter, but this is not recommended. When passing a static array to a function, the complete array is copied on the stack and every element is passed by value. The receiving local variables in the function must be defined with the same static array definition as the caller:

```plaintext
MAIN
   DEFINE arr ARRAY[5] OF INT
   CALL func(arr)
END MAIN

FUNCTION func(x)
   DEFINE x ARRAY[5] OF INT
   ...
END FUNCTION
```

Note: Dynamic arrays are passed by reference.

**Related concepts**

- **Data types** on page 253
  Selecting the correct data type assists you in the input, storage, and display of your data.

- **Type conversions** on page 274
  Explains data type conversion rules of the language.

- **Arrays** on page 386
  Arrays (static or dynamic) allow to handle an ordered collection of elements.

**Passing a dynamic array as parameter**

Passing a dynamic array as a function parameter is legal and efficient. When passed as parameter, the runtime system pushes a reference of the dynamic array on the stack, and the receiving local variables in the function can then manipulate the original data.

Returning a dynamic array from a function is also possible: The runtime system pushes the reference of the dynamic array on the stack.

```plaintext
MAIN
   DEFINE arr DYNAMIC ARRAY OF INT
   DISPLAY arr.getLength()
   LET arr = init(10)
   DISPLAY arr.getLength()
   CALL modify(arr)
   DISPLAY arr[50]
   DISPLAY arr[51]
   DISPLAY arr.getLength()
END MAIN

FUNCTION init(c)
   DEFINE c INT
   DEFINE x DYNAMIC ARRAY OF INT
   FOR i=1 TO c
      LET x[i] = i
   END FOR
   RETURN x
END FUNCTION

FUNCTION modify(x)
   DEFINE x DYNAMIC ARRAY OF INT
   LET x[50] = 222
```
LET x[51] = 333
END FUNCTION

Output of the program:

0
10
222
333
51

Related concepts
Data types on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

Passing a dictionary as parameter

Passing a dictionary as a function parameter is legal and efficient. When passed as parameter, the runtime system pushes a reference of the dictionary on the stack, and the receiving local variables in the function can then manipulate the original data.

Returning a dictionary from a function is also possible: The runtime system pushes the reference of the dictionary on the stack.

```
MAIN
    DEFINE dic DICTIONARY OF STRING
    DISPLAY dic.getLength()
    LET dic = init()
    DISPLAY dic.getLength()
    CALL modify(dic)
    DISPLAY dic["first"]
    DISPLAY dic["second"]
    DISPLAY dic.getLength()
END MAIN

FUNCTION init()
    DEFINE x DICTIONARY OF STRING
    LET x["first"] = "abc"
    LET x["second"] = "def"
    RETURN x
END FUNCTION

FUNCTION modify(x)
    DEFINE x DICTIONARY OF STRING
    LET x["first"] = "xyz"
    LET x["third"] = "ijk"
END FUNCTION
```

Output of the program:

0
2
xyz
def
3
Related concepts

Dictionary on page 393
A dictionary holds an unordered collection of elements accessed by a key.

Passing objects as parameter

Like other object oriented programming languages, objects of built-in classes or Java classes are passed by reference. It would not make much sense to pass an object by value, actually. The runtime pushes the reference of the object on the stack (i.e. the object handler is passed by value), and the reference is then popped to the receiving object variable in the function. The function can then be used to manipulate the original object.

```
MAIN
    DEFINE ch base.Channel
    LET ch = base.Channel.create()
    CALL open(ch)
    CALL ch.close()
END MAIN

FUNCTION open(x)
    DEFINE x base.Channel -- Channel object reference
    CALL x.openFile("filename","r")
END FUNCTION
```

The Java interface on page 2071
The Java interface allows you to import Java classes and instantiate Java objects in your programs.

Passing a TEXT/BYTE as parameter

BYTE or TEXT data types define large data object (LOB) handlers internally implemented as "locators". When you pass a BYTE or TEXT to a function, the locator is pushed on the stack and popped to the receiving BYTE or TEXT variable in the function. The actual LOB data is not copied, only the locator is passed by value.

Important: Since the information of the locator structure is copied (like the file name specified with a LOCATE IN FILE instruction). If you modify the locator storage information inside the function with a LOCATE instruction, the locator in the caller will become invalid. Therefore, only read and write the actual data of BYTE and TEXT parameters in functions, do not modify the storage.

Related concepts

LOCATE (for TEXT/BYTE) on page 373
The LOCATE statement specifies where to store data of TEXT and BYTE variables.

TEXT on page 271
The TEXT data type stores large text data.

BYTE on page 255
The BYTE data type stores any type of binary data, such as images or sounds.

Returning simple typed values from functions

Simple data types such as INTEGER, DECIMAL, VARCHAR are returned by value. When returning a simple typed value, the runtime system pushes a copy of the data on the stack. The STRING data type is an exception to this rule: elements of this type are return by mutable reference: the whole string value is not copied on the stack, only the reference to the string value is copied.

```
MAIN
    DEFINE x INTEGER
    LET x = int_add(10,20)
```
FUNCTION int_add(n1,n2)
    DEFINE n1, n2 INTEGER
    RETURN (n1+n2)
END FUNCTION

Related concepts
RETURN on page 343
The RETURN instruction gives the control of execution back to the caller, eventually by returning values on the stack.

Type conversions on page 274
Explains data type conversion rules of the language.

Arrays on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

Returning dynamic arrays from functions
When returned by a function, dynamic arrays are pushed on the stack by reference. Therefore you can create a dynamic array in a function and return it to the caller for usage:

MAIN
    DEFINE arr DYNAMIC ARRAY OF INTEGER
    LET arr = create_array(10)
    DISPLAY arr.getLength()
END MAIN

FUNCTION create_array(n)
    DEFINE n, i INTEGER
    DEFINE arr DYNAMIC ARRAY OF INTEGER
    FOR i=1 TO n
        LET arr[i] = i
    END FOR
    RETURN arr
END FUNCTION

Related concepts
RETURN on page 343

Arrays on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

Returning dictionaries from functions
When returned by a function, dictionaries are pushed on the stack by reference.

Therefore, you can create a dictionary in a function and return it to the caller for usage:

MAIN
    DEFINE dic DICTIONARY OF STRING
    LET dic = create_dictionary(10)
    DISPLAY dic["item3"]
    DISPLAY dic["item10"]
END MAIN

FUNCTION create_dictionary(n)
    DEFINE n, i INTEGER
    DEFINE dic DICTIONARY OF STRING
FOR i=1 TO n
    LET dic[SFMT("item%1",i)] = SFMT("This is item %1",i)
END FOR
RETURN dic
END FUNCTION

Related concepts
RETURN on page 343
The RETURN instruction gives the control of execution back to the caller, eventually by returning values on the stack.

Returning TEXT/BYTE values from functions

When returning a TEXT or BYTE value from a function, the locator is pushed in on the stack. Storage information of the TEXT/BYTE is defined in the locator structure, therefore you can define the storage of the large object variable in a function, initialize the object with a value, and return it.

MAIN
DEFINE t TEXT
LET t = init_text(t)
DISPLAY "t size = ", LENGTH(t)
END MAIN

FUNCTION init_text(t)
DEFINE t TEXT
LOCATE t IN MEMORY
LET t = "abc"
RETURN t
END FUNCTION

The above sample will produce following output:

    t size = 3

TEXT on page 271
The TEXT data type stores large text data.

BYTE on page 255
The BYTE data type stores any type of binary data, such as images or sounds.

Implicit data type conversion on the stack

When a value or a reference is popped from the stack, implicit data conversion takes place. This means, for example, that you can pass a string value to a function that defines the receiving variable as a numeric data type; no compilation error will occur, but you can get a runtime error if the string cannot be converted to a numeric. The same principle applies to values returned from functions, since the stack is also used in this case.

MAIN
DEFINE s STRING
LET s = "123"
CALL display_integer(s) -- Will be accepted
LET s = "abc"
CALL display_integer(s) -- Will fail with conversion error
END MAIN
FUNCTION display_integer(x)
  DEFINE x  INTEGER
  DISPLAY x
END FUNCTION

Exceptions
Describes exception (error) handling in the programs.
- Understanding exceptions on page 451
- Exception classes on page 451
- Exception actions on page 452
- WHENEVER instruction on page 452
- TRY - CATCH block on page 455
- Tracing exceptions on page 456
- Default exception handling on page 457
- Non-trappable errors on page 457
- Examples on page 457

Understanding exceptions
Exceptions are abnormal runtime events that can be trapped for control.

If an instruction executes abnormally, the runtime system throws exceptions that can be handled by the program.

Specific exception actions can be taken based on the class of the exception.

Runtime errors (exceptions) can be trapped by a WHENEVER exception handler or by a TRY/CATCH block. Note that some specific errors cannot be trapped.

A Genero exception is identified by its number and has a description. For a complete list of BDL errors, see Genero BDL errors on page 2998.

Exception handlers are typically used to detect database errors when executing SQL statement. For more details, see SQL execution diagnostics on page 529

Exception classes
Exception classes indirectly define the exception type.

The default action can be changed by specifying the exception class in the WHENEVER instruction.

Table 133: Exception classes

<table>
<thead>
<tr>
<th>Class</th>
<th>Error reason</th>
<th>Default Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR (or SQLERROR)</td>
<td>Language or SQL statement error.</td>
<td>STOP</td>
</tr>
<tr>
<td>ANY ERROR (or ANY SQLERROR)</td>
<td>Language, SQL statement and expression error.</td>
<td>CONTINUE (1)</td>
</tr>
<tr>
<td>NOT FOUND</td>
<td>SQL statements returning status NOTFOUND.</td>
<td>CONTINUE</td>
</tr>
<tr>
<td>WARNING</td>
<td>SQL statements setting SQLCA.SQLAWARN flags.</td>
<td>CONTINUE</td>
</tr>
</tbody>
</table>
For example, the following `WHENEVER` instruction defines the behavior for the `ANY ERROR` exception class:

```
WHENEVER ANY ERROR CONTINUE
```

**Related reference**

- [Genero BDL errors](#) on page 2998
- System error messages sorted by error number.

**Exception actions**

Exception actions define the type of action to be taken when an exception occurs.

There are five exception actions that can be executed if an exception is raised:

- **STOP**
  - The program is immediately terminated. A message is displayed to the standard error with the location of the related statement, the error number, and the details of the exception.

- **CONTINUE**
  - The program continues normally. The exception is ignored, but can be checked by testing the `STATUS` register, or the `SQLCA.SQLCODE` register for SQL errors.

- **CALL exception-function**
  - The function `exception-function` is called by the runtime system. The function can be defined in any module, and must have zero parameters and zero return values. The `STATUS` variable will be set to the corresponding error number.

- **GOTO exception-label**
  - The program execution continues at the label identified by `exception-label`, as if a `GOTO` instruction was issued after trapping the exception.

- **RAISE**
  - This statement instructs the runtime system that the exception must propagated to the calling function.
    
    **Important:** The `WHENEVER[ANY] ERROR RAISE` is not supported in a `REPORT` routine.

**Related reference**

- [Genero BDL errors](#) on page 2998
- System error messages sorted by error number.

**WHENEVER instruction**

Use the `WHENEVER` instruction to define how exceptions must be handled for the rest of the module.

**Syntax**

```
WHENEVER exception-class
   exception-action
```

where `exception-class` is one of:

- `[ANY] ERROR`
- `[ANY] SQLERROR`
- `NOT FOUND`
- `WARNING`
and **exception-action** is one of:

```
| CONTINUE
| STOP
| CALL [module.]function
| RAISE
| GOTO label |
```

1. **function** can be any function name defined in the program.
2. **module** is the name of a module imported with `IMPORT FGL`.
3. **label** must be a label defined in the current program block (main, function or report routine).

**Usage**

The **WHENEVER** instruction defines the exception handling by associating an **exception class** with an **exception action**.

**Important:** The scope of a **WHENEVER** instruction is similar to a C preprocessor macro. It is local to the module and defines the error handling for the rest of the module, unless a new **WHENEVER** instruction is encountered by the compiler, or a **TRY/CATCH** block is used.

If no **WHENEVER** instruction is used, the default is **WHENEVER ERROR STOP**. Stopping the program in case of error is the recommended default. However, this default does not catch expression errors like type conversion errors. Consider using the `fglrun.mapAnyErrorToError` FGLPROFILE entry, to catch conversion errors. For more details, see Default exception handling on page 457.

This code example shows a typical **WHENEVER** instruction usage:

```
WHENEVER ERROR CONTINUE
DROP TABLE mytable -- SQL error will be ignored
CREATE TABLE mytable ( k INT, c VARCHAR(20) )
WHENEVER ERROR STOP
IF SQLCA.SQLCODE != 0 THEN
   ERROR "Could not create the table..."
END IF
```

Exception classes ERROR and SQLERROR are synonyms: In the previous example it is also possible to use **WHENEVER SQLERROR instead of WHENEVER ERROR.**

Actions for classes ERROR, WARNING and NOT FOUND can be set independently:

```
WHENEVER ERROR STOP
WHENEVER WARNING CONTINUE
WHENEVER NOT FOUND GOTO not_found_handler
```

When using the **WHENEVER ... CALL function** instruction, the program flow will go to the specified function and return to the code block where the exception occurred:

```
MAIN
   DEFINE x INTEGER
   WHENEVER ANY ERROR CALL error_handler
   -- WHENEVER handler takes effect
   LET x = 1/0
   DISPLAY "Back in MAIN..."
END MAIN

FUNCTION error_handler()
   DISPLAY "error_handler: ", STATUS
END FUNCTION
```
Note: In a WHENEVER ... CALL instruction, you do not handle to specify parentheses after the function name.

A TRY/CATCH block takes precedence over the last WHENEVER instruction, see the following example:

```plaintext
MAIN
  DEFINE x INTEGER
  WHENEVER ANY ERROR CONTINUE
     -- WHENEVER handler takes effect
     LET x = 1/0
     DISPLAY "WHENEVER: ", STATUS
     -- WHENEVER handler is hidden by TRY/CATCH block
     TRY
       LET x = 1/0
       CATCH
         DISPLAY "CATCH: ", STATUS
       END TRY
     -- WHENEVER handler takes again effect
     CALL func()
  END MAIN

FUNCTION func()
  DEFINE x INTEGER
  LET x = 1/0
  DISPLAY "WHENEVER: ", STATUS
END FUNCTION
```

The RAISE option can be used to propagate exceptions to the caller, which typically traps the error in a TRY/CATCH block:

```plaintext
-- main.4gl
IMPORT FGL myutils
MAIN
  TRY
     -- Pass a NULL form name to get error -1110
     CALL myutils.open_form(NULL)
  CATCH
     DISPLAY "Error: ", status
  END TRY
END MAIN

-- myutils.4gl
FUNCTION open_form(fn)
  DEFINE fn STRING
  WHENEVER ERROR RAISE -- Propagate exceptions to caller
  OPEN FORM f1 FROM fn
END FUNCTION
```

Important: WHENEVER [ANY] ERROR RAISE is not supported in a REPORT routine.

Related concepts
The SQLCA diagnostic record on page 532
The SQLCA variable is a predefined record containing SQL statement execution information.

**STATUS** on page 517

STATUS is a predefined variable that contains the execution status of the last instruction.

### TRY - CATCH block

Use TRY / CATCH blocks to trap runtime exceptions in a delimited code block.

**Syntax:**

```
TRY
  instruction
 [...]
CATCH
  instruction
 [...]
END TRY
```

**Usage:**

Any language instruction in the TRY block will be executed until an exception is thrown. After an exception the program execution continues in the CATCH block. If no CATCH block is provided, the execution continues after END TRY.

If no exception is raised by the statements between the TRY and CATCH keywords, the instructions in the CATCH section are ignored and the program flow continues after END TRY.

This code example shows a TRY block executing an SQL statement:

```
TRY
  SELECT COUNT(*) INTO num_cust FROM customers WHERE ord_date <= max_date
CATCH
  ERROR "Error caught during SQL statement execution:", SQLCA.SQLCODE
END TRY
```

A TRY block can be compared with WHENEVER ANY ERROR GOTO. Here is the equivalent of the previous code example:

```
WHENEVER ANY ERROR GOTO catch_error
  SELECT COUNT(*) INTO num_cust FROM customers WHERE ord_date <= max_date
GOTO no_error
LABEL catch_error:
  ERROR "Error caught during SQL statement execution:", SQLCA.SQLCODE
LABEL no_error
```

The TRY statement can be nested in other TRY statements. In this example, the instruction in line #5 will be executed in case of SQL error:

```
TRY
  TRY
    SELECT COUNT(*) INTO num_cust FROM customers
  CATCH
    ERROR "Try block 2: ", SQLCA.SQLCODE
  END TRY
CATCH
  ERROR "Try block 1: ", SQLCA.SQLCODE
END TRY
```
The **WHENEVER ERROR RAISE** instruction can be used module-wide to define the behavior when an exception occurs in a function that is called from a **TRY / CATCH** block. If an exception occurs in a statement after the **WHENEVER ERROR RAISE** instruction, the program flow returns from the function and raises the exception as if it had occurred in the code of the caller. If the exception is thrown in the **MAIN** block, the program stops because the exception cannot be processed by a caller. In this example, the instruction in line #5 will be executed if an exception occurs in the **cust_report()** function:

```
MAIN
  TRY
    CALL cust_report()
  CATCH
    ERROR "An error occurred during report execution: ", STATUS
  END TRY
END MAIN

FUNCTION cust_report()
  WHENEVER ERROR RAISE
  START REPORT cust_rep ...
  ...
END FUNCTION
```

**Important**: It is not possible to set a debugger break point at **TRY, CATCH or END TRY**: The **TRY** statement is a pseudo statement, the compiler does not generate p-code for this statement.

**Related concepts**
SQL execution diagnostics on page 529
If an SQL statement execution fails, error description can be found in the **SQLCA.SQLCODE**, **SQLSTATE**, **STATUS** and **SQLERRMESSAGE** predefined registers.

The **SQLCA** diagnostic record on page 532
The **SQLCA** variable is a predefined record containing SQL statement execution information.

**Tracing exceptions**
Exception can be logged in a file when using the **STARTLOG()** function.

Exceptions are automatically logged in a file, if all the following conditions are true:

- The **STARTLOG** function has been previously called to specify the name of the exception logging file.
- The **exception action** is set to CALL, GOTO or STOP. Exceptions are not logged when the action is CONTINUE or RAISE.
- The **exception class** is an ERROR, ANY ERROR or WARNING. NOT FOUND exceptions cannot be logged.

In other words, errors will not be logged in the case of **WHENEVER [ANY] ERROR [ANY] WARNING [NOT FOUND]**, or when controlled by a **TRY/CATCH** block.

Each log entry contains:

- The system-time
- The location of the related instruction (source-file, line)
- The error-number
- The text of the error message, giving human-readable details for the exception

**Related concepts**
SQL error identification on page 533
Identify SQL exceptions in your programs with **SQLCA.SQLCODE**.

**Related reference**
Genero BDL errors on page 2998
System error messages sorted by error number.

**Default exception handling**

By default, WHENEVER ANY ERROR action is to CONTINUE the program flow.

You can force the runtime system to execute the action defined with WHENEVER ERROR exception class with the following FGLPROFILE entry:

```
fglrun.mapAnyErrorToError = true
```

When this entry is set to true, expression errors such as a division by zero will be trapped and execute the action defined by the last WHENEVER ERROR instruction, the default being STOP the program with error display.

```
-- FGLPROFILE env var is defined to file with:
--    fglrun.mapAnyErrorToError = true

MAIN
  DEFINE x INT
  WHENEVER ERROR CALL my_error_handler
  LET x = 1 / 0   -- error handler will be called here
  DISPLAY "It continues...."
END MAIN

FUNCTION my_error_handler()
  DISPLAY "Handler: ", STATUS
END FUNCTION
```

**Related reference**

Genero BDL errors on page 2998

System error messages sorted by error number.

**Non-trappable errors**

Some specific Genero runtime errors are not trappable.

If a non-trappable error occurs, neither WHENEVER instructions, nor TRY/CATCH blocks can trap the error: The runtime system will output the error message to the standard error stream, file an error log record if STARTLOG was previously called, display a pop-up window with the error message to the end user when using a GUI front-end, and the program is stopped.

Non-trappable errors are typically fatal errors that generally prevent further program execution. For example, the errors -1110, -1320, -1328 cannot be trapped.

**Examples**

WHENEVER and TRY/CATCH usage examples.

**Example 1: Defining a error handler function**

This code example defines a WHENEVER ERROR handler function called my_error_handler. After connecting to the database, a SELECT statements tries to fetch a row from a table that does not exist, and raises SQL error -217 when connected to Informix®:

```
MAIN
  WHENEVER ERROR CALL my_error_handler
  DATABASE stores
  SELECT dummy FROM systables WHERE tabid=1
END MAIN

FUNCTION my_error_handler()
  DISPLAY "Error: ", STATUS
  EXIT PROGRAM 1
```
Example 2: SQL error handling with WHENEVER

This code shows a typical SQL error handling block. It uses WHENEVER ERROR CONTINUE before executing SQL statements, tests the SQLCA.SQLCODE register for errors after each SQL instruction, and resets the default exception handler with WHENEVER ERROR STOP after the set of SQL commands to be controlled:

```plaintext
MAIN
DEFINE
tabname VARCHAR(50),
sqlstmt STRING,
rowcount INTEGER

# In the DATABASE statement, no error should occur...
DATABASE stores

# But next SELECT may fail, if the user enters an invalid table name.
WHENEVER ERROR CONTINUE
PROMPT "Enter a table name:" FOR tabname
LET sqlstmt = "SELECT COUNT(*) FROM " || tabname
PREPARE s FROM sqlstmt
IF sqlca.sqlcode THEN
    DISPLAY "SQL Error occurred:", sqlca.sqlcode
    EXIT PROGRAM 1
END IF
EXECUTE s INTO rowcount
IF sqlca.sqlcode THEN
    DISPLAY "SQL Error occurred:", sqlca.sqlcode
    EXIT PROGRAM 1
END IF
WHENEVER ERROR STOP

... (more instructions, stopping the program in case of error)
END MAIN
```

Program output in case of invalid table name:

```
SQL Error occurred: -217
```

Example 3: Typical TRY / CATCH block

This example uses a TRY/CATCH block to trap errors. In this case, we try to connect to an invalid database, which will raise an SQL error and make the program flow go to the line after the CATCH statement:

```plaintext
MAIN
TRY
    DATABASE invalid_database_name
    DISPLAY "Will not be displayed"
CATCH
    DISPLAY "Exception caught, SQL error: ", SQLCA.SQLCODE
END TRY
END MAIN
```
Program output (with Informix®):

```
Exception caught, SQL error:      -329
```

**Example 4: TRY / CATCH in conjunction with WHENEVER**

This code illustrates the fact that a TRY/CATCH block can be used together with a WHENEVER instruction: The program first executes a WHENEVER ANY ERROR to define an error handler named foo and later it uses a TRY/ CATCH block to trap expression errors.

In this example, we intentionally force a division by zero. After the TRY/CATCH block, we force another division by zero error, which will call the foo error handler:

``` Informix
MAIN
  DEFINE i INTEGER
  WHENEVER ANY ERROR CALL foo
  TRY
    DISPLAY "Next exception should be handled by the catch statement"
    LET i = i / 0
  CATCH
    DISPLAY "Exception caught, status: ", STATUS
  END TRY
  -- Previous error handler is restored after the TRY - CATCH block
  LET status = 0
  DISPLAY "Next exception should be handled by the foo function"
  LET i = i / 0
END MAIN

FUNCTION foo()
  DISPLAY "Function foo called, status: ", STATUS
END FUNCTION
```

Program output:

```
Next exception should be handled by the catch statement
Exception caught, status:      -1202
Next exception should be handled by the foo function
Function foo called, status:      -1202
```

**Example 5: WHENEVER RAISE exception propagation**

This example shows the usage of WHENEVER ... RAISE to propagate a potential exception to the caller. First the program defines the foo function as exception handler with WHENEVER ANY ERROR CALL foo, then it calls the do_exception function, which instructs the runtime system to propagate a potential error to the caller. As result, the division by zero in line #13 will be caught by the error handler defined in the MAIN block and call the foo function:

``` Informix
MAIN
  DEFINE i INTEGER
  WHENEVER ANY ERROR CALL foo
  DISPLAY "Next function call will generate an exception"
  DISPLAY do_exception(100, 0)
  WHENEVER ANY ERROR STOP -- reset default handler for rest of program
  ...
END MAIN

FUNCTION do_exception(a, b)
  DEFINE a, b INTEGER
  WHENEVER ANY ERROR RAISE
  RETURN a / b
END FUNCTION
```
FUNCTION foo()
    DISPLAY "Exception caught, status: ", STATUS
END FUNCTION

Program output:

Next function call will generate an exception
Exception caught, status: -1202

OOP support

Describes Object Oriented Programming basics in the language.

• Understanding classes and objects on page 460
• DEFINE ... package.class on page 460
• Distinguish class and object methods on page 460
• Working with objects on page 461
• What class packages exist? on page 463

Understanding classes and objects

The Genero language supports basic Object Oriented Programming (OOP) concepts.

Classes are grouped into packages which are: a) built-in and directly usable, and b) available as libraries which need to be imported with the IMPORT instruction.

It is not possible to define classes with the language.

Related concepts

Built-in packages on page 2244
These topics cover the built-in classes provided by the Genero Business Development Language.

Extension packages on page 2574
Several utility classes and functions are provided in additional packages to be included with the IMPORT instruction.

DEFINE ... package.class

Object reference variables allow to manipulate class instances.

Syntax:

DEFINE object package.class

1. object is the variable that references the object.
2. package is the name of the package the class comes from.
3. class is the name of the class.

For more details about variables referencing objects, see Working with objects on page 461.

Related concepts

DEFINE on page 367
A variable contains volatile information of a specific data type.

Distinguish class and object methods

Class methods can be invoked from the class, while object methods can only be invoked from the variable referencing the object.

Methods can be invoked like regular functions, by passing parameters and/or returning values, and can be used in expressions when they return a scalar value.
Class methods

Class methods are called by using the class identifier as prefix, with the period as separator. The class identifier includes the package name and class name.

```
package.classname.method( parameter [, ...] )
```

For example, to call the `refresh()` method of the `Interface` class, which is part of the `ui` package:

```
CALL ui.Interface.refresh()
```

Object methods

Object methods are called through the variable referencing the object. To use object methods, the object must exist. Call the object methods by using the object variable as a prefix, with a period as the separator.

```
object.method( parameter [, ...] )
```

For example, to call the `setFieldActive()` method of an object of the `Dialog` class, which is part of the `ui` package:

```
DEFINE d ui.Dialog
LET d = ui.Dialog.getCurrent()
CALL d.setFieldActive("cust_addr", FALSE)
```

Working with objects

This topic describes basic object usage in Genero BDL.

Instantiating objects

In order to instantiate an object in your program:

1. Define an object variable using the class identifier.
2. Instantiate the object; this is usually done by invoking a class method.

An object variable only contains a reference to the object. For example, when passed to a function, only the reference to the object is copied onto the stack.

In the following code example, the object referenced by the variable `n` is instantiated using the `create()` class method of the `DomDocument` class. The object referenced by the variable `b` is instantiated using the `getDocumentElement()` object method of the `DomDocument` class. This method returns the `DomNode` object that is the root node of the `DomDocument` object referenced by `n`:

```
DEFINE n om.DomDocument, b DomNode
LET n = om.DomDocument.create("Stock")
LET b = n.getDocumentElement()
```

Destroying objects

Objects created during program execution do not need to be explicitly destroyed. This is done automatically by the runtime system, based on a reference counter.

```
MAIN
  DEFINE d om.DomDocument
  LET d = om.DomDocument.create("Stock")  -- Reference counter = 1
END MAIN  -- d is removed, reference counter = 0 => object is destroyed.
```
When an object is referenced by several variables, an internal counter is incremented and decremented:

```
MAIN
  DEFINE d1, d2 om.DomDocument
  LET d1 = om.DomDocument.create("Stock")  -- Reference counter = 1
  LET d2 = d1                                -- Reference counter = 2
  LET d1 = NULL                              -- Reference counter = 1
  LET d2 = NULL                              -- Reference counter = 0, object is destroyed
END MAIN
```

### Using object references within functions

Object references can be passed to and returned from functions.

In this example, the function creates the object and returns its reference on the stack:

```
MAIN
  DEFINE x om.DomDocument
  LET x = createStockDomDocument()
END MAIN

FUNCTION createStockDomDocument()
  DEFINE d om.DomDocument
  LET d = om.DomDocument.create("Stock")  -- Reference counter = 1
  RETURN d
END FUNCTION  -- Reference counter is still 1 because d is on the stack
```

Another part of the program can get the result of that function and pass it as a parameter to another function:

```
MAIN
  DEFINE x om.DomDocument
  LET x = createStockDomDocument()
  CALL writeStockDomDocument( x )
END MAIN

FUNCTION createStockDomDocument()
  DEFINE d om.DomDocument
  LET d = om.DomDocument.create("Stock")
  RETURN d
END FUNCTION

FUNCTION writeStockDomDocument( d )
  DEFINE d om.DomDocument
  DEFINE r om.DomNode
  LET r = d.getDocumentElement()
  CALL r.writeXml("Stock.xml")
END FUNCTION
```

### Invoking class and object methods

Class methods must be invoked with the package and class name:

```
DEFINE d om.DomDocument
LET d = om.DomDocument.create("Stock")
```

Object methods are invoked with the variable referencing the object:

```
DEFINE ch base.Channel
LET ch = base.Channel.create()
```
CALL ch.openFile("myfile.txt","r")

If a method returns an object reference, it can be directly used to invoke another method of the returned object:

```
DEFINE s STRING
LET s = "abc"
LET s = s.substring(1, 10).toLowerCase()
```

### What class packages exist?

A set of utility packages including useful classes are part of the distribution. Built-in packages such as `ui`, `om` and `base`, are part of the runtime system and can be referenced directly.

Extension packages such as `util`, `os`, `com` and `xml` need to be loaded explicitly with the `IMPORT` instruction, at the beginning of program modules.

Recent versions of the language support Java classes. Note that using Java will create a Java Virtual Machine (JVM) that will be part of the runtime system process.

### XML support

Introduces to DOM and SAX standards and describes the XML utility classes built-in the language.

These classes are useful to perform basic XML processing and manipulate the abstract user interface tree.

Use the full-featured XML classes provided in the [web services extension](#) for other needs.

- [DOM and SAX standards](#)
- [DOM and SAX built-in classes](#)
- [Limitations of XML built-in classes](#)
- [Exception handling with XML classes](#)
- [Controlling the user interface with XML classes](#)

#### DOM and SAX standards

DOM and SAX are both programming interfaces that can work with XML.

The [DOM](#) (Document Object Model) is a programming interface specification being developed by the World Wide Web Consortium (W3C) that lets a programmer create and modify HTML pages and XML documents as full-fledged program objects. DOM is a full-fledged object-oriented, complex but complete API, providing methods to manipulate the full XML document as a whole. DOM is designed for small XML trees manipulation.

The [SAX](#) (Simple API for XML) is a programming interface for XML, simpler than DOM. SAX is event-driven, streamed-data based, and designed for large trees.

#### DOM and SAX built-in classes

The DOM and SAX APIs both contain a set of built-in classes.

The DOM API is composed of:
• The `om.DomDocument` class, that defines the interface to a DOM document. Instances of this class can be used to identify and manipulate an XML tree. `DomNode` object manipulation methods are provided by this class.
• The `om.DomNode` class, that defines the interface to an DOM node. Instances of this class can be used to identify and manipulate a branch of an XML tree. Child nodes and node attributes management methods are provided by this class.
• The `om.NodeList` class, to handle a list of `DomNode` objects.

The SAX API is composed of:
• The `om.SaxAttributes` class represents a set of element attributes. It is used with an `om.XmlReader` or an `om.XmlWriter` object.
• The `om.XmlReader` class, that is defined to read XML. The XML document processing is based on SAX events.
• The `om.XmlWriter` class, that is defined to write XML. The XML document processing is based on SAX events.
• The `om.SaxDocumentHandler` class, which provides an interface to implement a SAX driver using functions defined in a .4gl module loaded dynamically.

**Limitations of XML built-in classes**
The built-in XML classes are provided for convenience, to help you manipulate XML content easily without loading a complete external XML library such as Java XML classes or a C-based XML libraries.

The features of these built-in classes are limited to basic XML usage. For example, there is no DTD / XML Schema validation done; you can create the same attribute twice or set an invalid attribute value. You must take care to follow the definition of the XML document when using these classes.

For a complete XML support, use the full-featured XML classes provided in the web services extension.

**Exception handling with XML classes**
Errors can occur while using XML built-in classes.

For example, calling methods of a SAX handler in an invalid order raises the runtime error `-8004`.

By default, the program stops in case of exception. XML errors can be trapped with the `WHENEVER ERROR` or `TRY/CATCH` exception handlers of Genero. If an error occurs during a method call of an XML class, the runtime system sets the `STATUS` variable.

This code example shows the trapping of XML classes errors.

```
MAIN
  DEFINE w om.SaxDocumentHandler
  LET w = om.SaxDocumentHandler.createFileWriter("sample.xml")
  TRY
    CALL w.endDocument()
  CATCH
    DISPLAY "ERROR: ", STATUS
  END TRY
END
```

**Related concepts**
The `SaxDocumentHandler` class on page 2467
The `om.SaxDocumentHandler` class provides an interface to write an XML filter with events.

Exceptions on page 451
Describes exception (error) handling in the programs.

**Controlling the user interface with XML classes**
The runtime system represents the user interface of a program with a DOM tree. User interface elements can be manipulated with the DOM and SAX built-in classes.

However, you must pay attention when modifying the AUI tree directly through the use of these classes. Invalid node or attribute creation can lead to unpredictable results.

**Related concepts**
The abstract user interface tree on page 1010
The abstract user interface tree is the XML representation of the application forms displayed to the end user.

DOM and SAX built-in classes on page 463
The DOM and SAX APIs both contain a set of built-in classes.

**JSON support**
Genero BDL supports JSON data manipulation.

- JSON to BDL type conversion rules on page 471

**Related concepts**
Records on page 382
Records allow structured program variables definitions.

Arrays on page 386
Arrays (static or dynamic) allow to handle an ordered collection of elements.

**What is JSON?**
JSON (JavaScript Object Notation) is a well known lightweight data-interchange format for JavaScript.

A JSON string (or object) is a comma-separated list of name/value pairs, with a : colon separating the key and the value. The list of name/value pairs is enclosed in {} curly brackets.

The names are delimited by double-quotes.

The value can be a single numeric value, a double-quotes string, an array, or a sub-element.

Arrays are defined by a comma-separated list of values enclosed in [ ] square brackets.

Sub-elements are defined inside {} curly brackets and define name/value pairs.

For example:

```
{
    "cust_num":865234,
    "cust_name":"McCarlson",
    "order_ids":[234,3456,24656,34561],
    "address": {
        "street":"34, Sunset Bld",
        "city":"Los Angeles",
        "state":"CA"
    }
}
```
JSON utility classes

Genero BDL provides utility classes to manipulate JSON formatted data.

JSON classes

The following JSON utility classes are provided as an extension:

- The util.JSON class on page 2614 implements basic conversion methods.
- The util.JSONObject class on page 2621 implements detail JSON Object control.
- The util.JSONArray class on page 2631 implements detail JSON Array control.

BDL/JSON conversion basics

When the data structures and member names match, Genero BDL variables can be converted from/to JSON data with the util.JSON* utility classes.

Matching BDL and JSON data structures

In order to convert a BDL variable to/from a JSON string, the program RECORD or DYNAMIC ARRAY and the JSON data string must have the same structure.

JSON object elements and BDL RECORD member are associated by name, not by position. Elements in the JSON string and in the BDL variable can be at a different ordinal position.

JSON array elements and BDL DYNAMIC ARRAY elements are associated by position.

A JSON object can also be converted to a BDL DICTIONARY, when the JSON object is a list of named elements, using the same structure as the dictionary.

Example of BDL data structure:

```bdl
DEFINE rec RECORD
    pkey INT,
    name VARCHAR(50),
    arr DYNAMIC ARRAY OF STRING,
    dic DICTIONARY OF DECIMAL
END RECORD

LET rec.pkey = 999
LET rec.name = "Tim Birton"
LET rec.arr[1] = "item1"
LET rec.arr[2] = "item2"
LET rec.dic["abc"] = 14.45
LET rec.dic["def"] = 18.11
```

JSON equivalent:

```json
{
    "pkey": 999,
    "name": "Tim Birton",
    "arr": ["item1","item2"],
    "dic": {
        "def": 18.11,
        "abc": 14.45
    }
}
```
BDL to JSON conversion

BDL variables can be converted to JSON strings for example with the `util.JSON.stringify()` method.

The JSON elements get the same names of the record members, as defined in the program source. For more details about BDL to JSON names handling, see BDL names and JSON element names on page 467.

Program array members in the record are converted to JSON arrays delimited by square brackets (`[]`).

Special consideration needs to be taken regarding empty dynamic arrays records where all elements are null. The Genero JSON API provides options to control the production of JSON elements for empty records and array. For more details, see NULLs and empty structures on page 468.

For details about BDL to JSON data type conversion rules, see BDL to JSON type conversion rules on page 470.

JSON to BDL conversion

When conversion from JSON to BDL, elements in the JSON string that do not match an Genero BDL record member are ignored; no error is thrown if there is no corresponding Genero BDL member.

Genero BDL record members that have no matching JSON element are initialized to NULL.

The JSON value must match the data format of the destination member. If the value does not correspond to the type (for example, if the JSON value is a character string while the target record member is defined with a numeric type), the target member will be set to NULL.

JSON arrays delimited by square brackets are used to fill a program array of the destination record. The destination array should be a dynamic array. If the array is defined as static, the additional elements of the source JSON array will be discarded, while missing elements will be initialized to NULL.

The JSON source string must follow the JSON format specification. It can contain multilevel structured data. If the source string is not well formatted, the runtime system will throw error -8109.

For details about JSON to BDL data type conversion rules, see JSON to BDL type conversion rules on page 471.

BDL names and JSON element names

To identify elements, JSON standards use different format as Genero BDL variable names.

As in many other programming languages, Genero BDL variables are named with simple identifiers. These identifiers are case-insensitive, must start with a letter or underscore, and cannot contain special characters such as spaces.

By default, JSON/BDL element name matching is case-insensitive. For example, if the Genero BDL record member is defined as `CustNo`, and the JSON data string contains the "custno":999 name/value pair, the value will be assigned. However, since Genero BDL record member names are used as-is to write JSON data, it is strongly recommended to define the Genero BDL records with the exact names used in JSON data string. Since JSON is case-sensitive, make sure the names of the Genero BDL record members match exactly the names expected in the resulting JSON data string: `CustNo` will be different from `custNo`.

**Important:** JSON specifications allow you to define element names with characters that cannot be used in Genero BDL identifiers. For example, a JSON element name can be "customer.name" or "customer:name". To work around this issue, use the `json_name` attribute when defining the BDL variable.

If the JSON element name cannot be defined as a Genero BDL variable identifier, it is possible to define the BDL variable with the `json_name` attribute, to specify the exact name of the corresponding JSON element.

In the next example, the BDL variable `cust_name` will be mapped to the JSON element "Customer Name":

```sql
DEFINE cust_name INTEGER ATTRIBUTES(json_name="Customer Name")
```

**Note:** When converting JSON to BDL structures, elements in the JSON string that do not match an Genero BDL record member are ignored; no error is thrown if there is no corresponding Genero BDL member.

Related concepts

Definition attributes on page 372
Variables can be defined with meta-data information.

**NULLs and empty structures**

Unlike Genero BDL, JSON distinguishes NULL, empty and undefined elements.

**JSON notation for NULL, empty and undefined**

In JSON notation, a NULL element is defined with the `null` keyword. In the next example, the "name" element is null:

```
{ "key":345, "name":null }
```

Empty JSON objects are represented with an opening followed by a closing curly brace:

```
{ "key":345, "address":{} }
```

Empty JSON arrays are represented with an opening followed by a closing square brace:

```
{ "key":345, "list":[] }
```

Undefined elements do not appear in the JSON string representation. In the next example, the corresponding BDL record could have a "key" and "name" member. In the JSON notation, the "name" element is just omitted:

```
{ "key":345 }
```

**States of Genero BDL variables**

Genero BDL variables defined with a primitive type such as INTEGER can have a value or can be NULL, but they cannot be undefined as in JSON.

RECORD variables cannot be NULL. However, all elements of a RECORD can be NULL and thus the record can be considered as empty or null.

A DYNAMIC ARRAY containing zero elements can be considered as empty or null.

**Controlling JSON serialization from BDL**

By default, the `util.JSON.stringify()` method writes all elements of the BDL variable.

Sub-records and dynamic arrays are written to the JSON output:

```BDL
DEFINE rec RECORD
    field1 INTEGER,
    subarr DYNAMIC ARRAY OF INTEGER
END RECORD
INITIALIZE rec.* TO NULL
LET rec.field1 = 999
DISPLAY util.JSON.stringify(rec)
```

Produces following output:

```
{"field1":999,"subarr":[]}
```

If you want to omit all empty RECORD or DYNAMIC ARRAY elements in the JSON string, use the `util.JSON.stringifyOmitNulls()` method:

```BDL
IMPORT util
MAIN
DEFINE rec RECORD
```
field1 INTEGER,
subarr DYNAMIC ARRAY OF INTEGER
END RECORD
INITIALIZE rec.* TO NULL
LET rec.field1 = 999
DISPLAY util.JSON.stringifyOmitNulls(rec)
END MAIN

Produces following output (the subarr element is omitted because it is empty):

{"field1":999}

If you want to have a find-grained control on the JSON serialization of null values and empty records and dynamic arrays, use the util.JSON.stringify() method, in conjunction with the json_null attribute when defining the BDL variable. The json_null variable definition attribute can be set to "null" or "undefined".

Using the json_null="null" attribute

When defining a BDL variable with the json_null="null" attribute, the following BDL elements will be represented with the null keyword in the resulting JSON string:

1. Simple primitive variables that are NULL,
2. RECORD variables where all members are NULL,
3. Empty DYNAMIC ARRAY that contain zero elements.

In the next example, the sub-record and sub-array are written to the JSON output as nulls:

DEFINE rec RECORD
   field1 INTEGER ATTRIBUTES(json_null="null"),
   field2 CHAR(1) ATTRIBUTES(json_null="null"),
   subrec1 RECORD ATTRIBUTES(json_null="null")
      field11 INTEGER,
      field12 VARCHAR(30)
   END RECORD,
   subarr1 DYNAMIC ARRAY ATTRIBUTES(json_null="null") OF INTEGER
END RECORD
INITIALIZE rec.* TO NULL
DISPLAY util.JSON.stringify(rec)

Produces following output:

{"field1":null,"field2":null,"subrec1":null,"subarr1":null}

Using the json_null="undefined" attribute

When defining a BDL variable with the json_null="undefined" attribute, the following BDL elements will be omitted in the resulting JSON string:

1. Simple primitive variables that are NULL (in fact, json_null="undefined" is the default for primitives),
2. RECORD variables where all members are NULL,
3. Empty DYNAMIC ARRAY that contain zero elements.

In the next example, all elements of the record (except field1) are omitted in the resulting JSON output:

DEFINE rec RECORD
   field1 INTEGER ATTRIBUTES(json_null="undefined"),
   field2 CHAR(1) ATTRIBUTES(json_null="undefined"),
   subrec1 RECORD ATTRIBUTES(json_null="undefined")
      field11 INTEGER,
      field12 VARCHAR(30)
   END RECORD,
subarr1 DYNAMIC ARRAY ATTRIBUTES(json_null="undefined") OF INTEGER
END RECORD
INITIALIZE rec.* TO NULL
LET rec.field1 = 999
DISPLAY util.JSON.stringify(rec)

Produces following output:

{"field1":999}

**Exception of NULL dynamic array elements**

If elements of a dynamic array are NULL, the JSON serialization class will always produce a `null` keyword, even if you specify the `json_null="undefined"` attribute at the primitive type level.

This is mandatory because JSON requires null keyword for undefined array elements.

See the following example:

```plaintext
DEFINE rec RECORD
    subarr DYNAMIC ARRAY OF INTEGER ATTRIBUTES(json_null="undefined")
END RECORD
INITIALIZE rec.* TO NULL
LET rec.subarr[3] = 999
DISPLAY util.JSON.stringify(rec)
```

Produces this JSON output:

{"subarr":null,null,999]}

**BDL to JSON type conversion rules**

Specific type conversion rules apply when converting a BDL variable to JSON.

**Table 134: Genero BDL to JSON type conversion rules**

<table>
<thead>
<tr>
<th>Source Genero BDL type</th>
<th>JSON result string</th>
</tr>
</thead>
<tbody>
<tr>

</table>
|                        |     {
|                        |     "record-element-name" : json-value [, ...] }
| DYNAMIC ARRAY OF ...   | The JSON string will be a JSON array in the form: |
|                        |     [ json-value [, ...] ] |
| DICTIONARY OF ...      | The JSON string will be a JSON object in the form: |
|                        |     { "dictionary-key" : json-value [, ...] } |
| BOOLEAN                | Will be serialized with the JSON values true or false. |
**JSON to BDL type conversion rules**

Specific type conversion rules apply when parsing a JSON string to fill a BDL variable.

**Table 135: JSON to Genero BDL type conversion rules**

<table>
<thead>
<tr>
<th>JSON source string</th>
<th>Target Genero BDL type</th>
</tr>
</thead>
<tbody>
<tr>
<td>The JSON string must be a JSON object in the form:</td>
<td>RECORD ... END RECORD</td>
</tr>
<tr>
<td><code>{ &quot;record-element-name&quot; : json-value [, ...] }</code></td>
<td>DYNAMIC ARRAY OF ...</td>
</tr>
<tr>
<td>The JSON string must be a JSON array in the form:</td>
<td></td>
</tr>
<tr>
<td><code>[ json-value [, ...] ]</code></td>
<td></td>
</tr>
</tbody>
</table>

---

**Source Genero BDL type** | **JSON result string**
--- | ---
TINYINT, SMALLINT, INTEGER, BIGINT, SMALLFLOAT, FLOAT, DECIMAL, MONEY | Any numeric type will be serialized to this form: an optional minus sign (-), a sequence of digits (0–9), containing a optional decimal separator (.), followed by an optional exponent. The exponent has the form (e) followed by an optional minus sign and an sequence of digits. The representation of numeric values does not depend from the current locale. The decimal separator is always a dot (.) MONEY values will be represented like DECIMAL values: the currency symbol will be omitted.

DATE | The date value will be formatted as "YYYY-MM-DD" (with double quotes)

DATETIME | The date-time value will be formatted as "YYYY-MM-DD hh:mm:ss.fffff" (with double quotes), based on the date-time type definition. For example, a DATETIME HOUR TO MINUTE will produce "hh:mm" formatted values.

Note that the YYYY-MM-DD hh:mm:ss.fffff format is used to represent the local time. When exchanging date-time values in communications across different time zones, consider converting date-time values to Coordinated Universal Time (UTC), by using the `util.Datetime` methods.

INTERVAL | The interval value will be formatted as "YYYY-MM" or "DD hh:mm:ss.fffff" (with double quotes), depending on the interval type definition.

BYTE | Will be serialized to a Base64 encoded double quoted string. The Base64 encoding is described in [RFC4648].

TEXT, CHAR, VARCHAR, STRING | Character string data will be serialized as a double quoted string with backslash escaping.

List of characters requiring escaping:
- `\` backslash U+005C
- " quotation mark U+0022
- \b backspace U+0008
- \f form feed U+000C
- \n line feed U+000A
- \r carriage return U+000D
- \t tab U+0009

Other | Any other type will be serialized as a double quoted (" ) string.
### JSON source string

The JSON string must be a JSON object in the form:

```json
{ "dictionary-key" : json-value [ , ... ] }
```

The JSON value should be `null`, `true` or `false`. If the JSON value is a number or a string, the language conversion rules from number/string to BOOLEAN apply.

A JSON number. The JSON number can be assigned to any language numeric type. The limits of the target type cause potential overflows errors. On error the target variable will be initialized to NULL, the parser continues without an error.

The JSON value must be a string formatted as "YYYY-MM-DD".

A JSON string representing a datetime or a JSON number.

If the value is a JSON string, it must be formatted as "YYYY-MM-DD hh:mm:ss.fffff", or represent as an ISO 8601 formatted date-time, in UTC (with Z indicator) or with a timezone offset (+/-hh[hm]). For example: "2013-02-21T15:18:44.456Z", "2013-02-21T20:18:44.456+02:00".

If the value is a JSON number, it is interpreted as UNIX™ time (seconds since the Epoch 00:00:00 UTC, January 1, 1970).

Note that the YYYY-MM-DD hh:mm:ss.ffff format is used to represent the local time. When exchanging date-time values in communications across different time zones, consider converting date-time values to Coordinated Universal Time (UTC), by using the `util.Datetime` methods.

The JSON value must be a string formatted as "YYYY-MM" or "DD hh:mm:ss.fffff", depending on the interval class of the target variable.

The JSON string value must be encoded in Base64.

The Base64 encoding is described in [RFC4648].

A JSON string or number.

If the JSON value is a number, the resulting BDL string value uses the locale specific decimal point.

If the JSON value is a string: Any character in the Basic Multilingual Plane (U+0000 through U+FFFF) may be escaped: \u followed by exactly 4 hexadecimal digits ([0-9a-fA-F]). The hexadecimal digits encode the code point. Characters outside the Basic Multilingual Plane may be escaped by there UTF-16 surrogate pairs. For example, the representation of the G clef character (U+1D11E) is "\uD834\uDD1E".

### Target Genero BDL type

<table>
<thead>

For example, the representation of the G clef character (U+1D11E) is "\uD834\uDD1E". | |

### Globals

Global variables can be shared among all modules of a program.

- Understanding global blocks on page 473
- GLOBALS on page 473
- Rules for globals usage on page 473
- Database schema in globals on page 474
Understanding global blocks

Global symbols can be defined with the GLOBALS instruction

The GLOBALS instruction can be used to declare variables, constants and types for the whole program.

**Important**: Defining global elements shared by all modules of a program is an old programming concept. To increase code re-usability and readability, avoid global elements in your programs. Use modular concepts instead, by defining **PUBLIC** variables, constants and types in modules that will be imported into other modules with the **IMPORT FGL** instruction.

**Related concepts**

- **Importing modules** on page 496
- Use the **IMPORT ...** instruction to import BDL, C or Java external modules in the current module.

**GLOBALS**

The GLOBALS / END GLOBALS block and the GLOBALS instruction.

**Syntax 1: Global block declaration**

```
GLOBALS
declaration-statement

END GLOBALS
```

1. **declaration-statement** is a variable, constant or type declaration.

**Syntax 2: Importing definitions from a globals file**

```
GLOBALS "filename"
```

1. **filename** is the name of a file containing the definition of globals.
2. Use this syntax to include global declarations in the current module.

**Related concepts**

- **Variables** on page 366
  - Explains how to define program variables.
- **Constants** on page 379
  - The definition of constants allows to centralize common static values.
- **Types** on page 397
  - Types can be defined by the programmer to centralize the definition of complex/structured variables.

**Rules for globals usage**

Follow the rules described in this topic in order to use globals properly.

In order to extend the scope of variables, constants or user types to the whole program, define a module containing a GLOBALS ... END GLOBALS block and including this global module with the GLOBALS "filename" statement in other modules.

The **filename** should contain the .4gl suffix. However, the compiler uses the file name as it is. Therefore it can accept other file extensions such as GLOBALS "stock.glb".

The **filename** can be a relative or an absolute path. To specify a path, the slash (/) directory separator can be used for UNIX™ and Windows® platforms.
Note: When the filename specified by GLOBALS defines a relative file path, the globals file will be searched relatively to the current directory when executing fglcomp. As a general rule, execute fglcomp in the directory of the source file passed as argument.

If you modify the globals file, you must recompile all the modules that include the file.

If a local element has the same name as another variable that you declare in the GLOBALS statement, only the local variable is visible within its scope of reference.

You can declare several GLOBALS .. END GLOBALS blocks in the same module.

A GLOBALS file must not contain any executable statement.

Do not write a declaration statement outside a GLOBALS ... END GLOBALS block in a GLOBALS file.

You do not need to compile the source file containing the GLOBALS block. However, it is recommended to compile the globals file to detect errors.

You can declare several GLOBALS "filename" instructions in the same module.

Although you can include multiple GLOBALS ... END GLOBALS statements in the same application, do not declare the same identifier within more than one GLOBALS declaration. Even if several declarations of a global elements defined in multiple places are identical, declaring any global element more than once can result in compilation errors or unpredictable runtime behavior.

A GLOBALS block can hold GLOBALS "filename" instructions. In such case, the specified files will be included recursively.

Tip: Using global elements is not recommended, it is preferred to export module elements with the PUBLIC keyword, and include the module in other modules with the IMPORT FGL instruction.

Database schema in globals

Globals files can define the database schema to be used by the compiler to resolve DEFINE ... LIKE statements.

The schema specification must appear before the GLOBALS keyword starting the globals block.

The schema specification is propagated to the modules including the globals file defining the database schema. These modules can use DEFINE ... LIKE without an explicit SCHEMA instruction.

Furthermore, when using the DATABASE instruction instead of SCHEMA, if the module including the globals contains the MAIN block, the DATABASE specification of the globals file will be propagated and result in an implicit database connection at runtime.

Example

```
SCHEMA stores
GLOBALS
    DEFINE cust_rec LIKE customer.*
    ...
END GLOBALS
```

Related concepts

Database schema on page 476
Defines database table structures with column type information to be reused in program variable definitions.

Content of a globals file

A globals file contains a GLOBALS ... END GLOBALS block.

As a GLOBALS block can also be defined in regular modules, it is possible to include a source containing more than a GLOBALS block. When including such module, the sections before and after the GLOBALS block are ignored by the compiler. The source defining the global elements can be compiled individually.

For example, it is allowed to define a module A with a GLOBALS ... END GLOBALS block, followed by function definitions. This module can be compiled and functions will be taken into account. Module A can then be included in
module B with a \texttt{GLOBALS "filename"} instruction, and when compiling module B the function definitions of the included module A will be ignored. \texttt{IMPORT} instructions before the a \texttt{GLOBALS ... END GLOBALS} block will also be ignored in such case.

**Related concepts**

Functions on page 353  
Describes user defined functions.  
Importing modules on page 496  
Use the \texttt{IMPORT ... END GLOBALS} instruction to import BDL, C or Java external modules in the current module.

**Examples**

Globals usage examples.

**Example 1: Multiple GLOBALS file**

Module "labels.4gl": This module defines the text that is displayed on the screen

```4gl
GLOBALS
  CONSTANT g_lbl_val = "Index:"  
  CONSTANT g_lbl_idx = "Value:"  
END GLOBALS
```

Module "globals.4gl": Declares a global array and a constant containing its size

```4gl
GLOBALs "labels.4gl" -- this statement could be line 2 of main.4gl
GLOBALs
  DEFINE g_idx ARRAY[100] OF CHAR(10)  
  CONSTANT g_idxsize = 100
END GLOBALS
```

Module "database.4gl": This module is dedicated to database access

```4gl
GLOBALs "globals.4gl"
FUNCTION get_id()
  DEFINE li INTEGER
  FOR li = 1 TO g_idxsize -- this could be a FOREACH statement
    LET g_idx[li] = g_idxsize - li
  END FOR
END FUNCTION
```

Module "main.4gl": Fill in the global array and display the result

```4gl
GLOBALs "globals.4gl"
MAIN
  DISPLAY "Initializing constant values for this application..."
  DISPLAY "Filling the data from function get_id in module database.4gl..."
  CALL get_id()
  DISPLAY "Retrieving a few values from g_idx"
  CALL display_data()
END MAIN
FUNCTION display_data()
  DEFINE li INTEGER
  LET li = 1
  WHILE li <= 10 AND li <= g_idxsize
    DISPLAY g_lbl_idx CLIPPED || li || " " || g_lbl_val CLIPPED ||
    g_idx[li]
```
Database schema

Defines database table structures with column type information to be reused in program variable definitions.

- Understanding database schemas on page 476
- SCHEMA on page 477
- Structure of database schema files on page 478
- Database schema extractor options on page 478

Understanding database schemas

Database schemas hold the definition of the database tables and columns.

Purpose of database schema files

In program sources or form specification files, specify the database schema file with the SCHEMA instruction.

When the database schema is defined, it is possible to declare program variables and form fields by referencing the database table or column name.

The program variables and form fields will get the type of the database column, as defined in the schema file.

What contain database schema files?

The schema files contain the column data types (\*.sch file), data validation rules (\*.val file), and console/tty display attributes (\*.att file).

**Note:** The \*.val and \*.att files are supported for backward compatibility and are not recommended in new developments.

For more details about schema file content, see Structure of database schema files on page 478.

How to declare program variables from column definitions?

Program variables can be defined with the LIKE keyword, to get the data type defined in the schema files:

```
SCHEMA stores
MAIN
   DEFINE rec_cust RECORD LIKE customer.*
   DEFINE name LIKE customer.cust_name
   
END MAIN
```

Multiple database schemas can be used by specifying the schema prefix in the LIKE clause:

```
DEFINE rec_cust RECORD LIKE orders:customer.*
DEFINE rec_item RECORD LIKE stock:item.*
```

For more details, see the DEFINE on page 367 instruction.

Locating database schema files

The FGLDBPATH environment variable can be used to define a list of directories where the compiler can find database schema files.

For more details, see FGLDBPATH on page 239.
When are database column types used to define program variable?
The data types, display attributes, and validation rules are taken from the database schema files during compilation.

**Important:** Make sure that the schema files of the development database correspond to the production database, otherwise the elements defined in the compiled version of your modules and forms will not match the table structures of the production database.

**Optimized compilation with schema files**
With large projects, the database schema file can contain thousands of column definitions.

To improve compilation time, the fglcomp compiler will automatically produce a .42d index file from the .sch schema file, in the same directory as the .sch file.

When the .sch file changes, the .42d index file is re-generated.

The .42d file can be safely removed, to cleanup source directories.

**Extracting database schemas with fgldbsch**
The database schema files are generated with the fgldbsch tool from the system tables of an existing database.

**Note:** It is strongly recommended that you re-generate the schema files when upgrading to a new compiler version. Bug fixes and new data type support can require schema file changes. If the schema file holds data type codes that are unknown to the current version, the compilers will raise the error -6634.

The fgldbsch must connect to the database server, with a db user allowed to query the database system tables (for example, INFORMATION_SCHEMA in an Oracle® MySQL database).

**Note:** For some types of databases, the table owner is mandatory to extract schema information. If you do not specify the -ow option in the comment line, fgldbsch will take the -un user name as default. If you do not use the -un/-up options because you are using indirect database connection with FGLPROFILE settings to identify the database user, or if the database user is authenticated by the operating system, the fgldbsch tool will try to identify the current database user after connection and use this name as table owner to extract the schema.

For more details, see Database schema extractor options on page 486.

**Related concepts**
- **File extensions** on page 2997
  This page describes the file extensions used by the language.
- **Database connections** on page 600
  Explains how to manage database connections in a program.
- **Form specification files** on page 1132
  Form specification files are the source files defining the layout and content of application forms.

**SCHEMA**
Defines the database schema files to be used for compilation.

**Syntax 1: Database schema specification**

```
SCHEMA  dbname
```

1. `dbname` identifies the database schema file (.sch).

**Syntax 2: Database schema and default connection specification**

```
[DESCRIBE]  DATABASE  dbname
```

1. `dbname` identifies the database schema file (.sch).
Usage

The SCHEMA dbname instruction defines the database schema to be used for compilation, where dbname identifies the name of the database schema files (.sch).

The DESCRIBE DATABASE instruction defines the compilation database schema, and the default connection for the MAIN block when the program starts.

Tip: Instead of DESCRIBE DATABASE, use the SCHEMA instruction: The SCHEMA instruction defines only the compilation database schema and allows to use a database schema name different from the connection database name.

The dbname database name must be expressed explicitly; it cannot be a variable as in a DATABASE instruction inside a program block.

Use the SCHEMA instruction outside any program block, before a variable declaration with DEFINE LIKE instructions. SCHEMA must precede any program block in each module that includes a DEFINE ... LIKE declaration or INITIALIZE ... LIKE and VALIDATE...LIKE statements. It must also precede any DEFINE ... LIKE declaration of module variables.

Database schema information such as data types for DEFINE ... LIKE are taken from the schema files during compilation. Make sure that the database schema file of the development database corresponds to the production database; otherwise the program variables defined in the p-code modules will not match the table structures of the production database.

For backward compatibility with IBM® Informix®, dbname can be written with different syntaxes. You can specify an Informix server, or a more complex Informix source with a string like "//server/database". Such database schema specification is not recommended, as it prevents use of database type other than Informix:

```
database
    database @ server
    "string"
```

When using a simple identifier for the database name, the compiler converts the name to lowercase, before searching the schema file. However, if a double quoted string is used as database name, the name will be used as is to find the schema file.

With the SCHEMA instruction, the name of the database schema during development can be different from the name of the database source used at runtime.

Note: To handle uppercase characters in the database name you must quote the name: SCHEMA "myDatabase"

Example

```
SCHEMA dev_db -- Compilation database schema
DEFINE rec RECORD LIKE customer.*
MAIN
   DATABASE prod_db -- Runtime database specification
   SELECT * INTO rec.* FROM customer WHERE custno=1
END
```

Opens a new database connection in unique-session mode.

Structure of database schema files

A database schema is composed by three files (.sch, .val, .att)

- Column Definition File (.sch) on page 479
- Column Validation File (.val) on page 482
- Column Video Attributes File (.att) on page 485
**Column Definition File (.sch)**
The .sch database schema file contains the data types of database table columns.

**Description**
The data type of program variables or form fields used to hold data of a given database column must match the data type used in the database. The definition of these elements is simplified by centralizing the information in external .sch files, which contain column data types.

In forms, you can directly specify the table and column name in the field definition in the ATTRIBUTES section of forms.

In programs, you can define variables with the data type of a database column by using the LIKE keyword.

As column data types are extracted from the database system tables, you may get different results with different database servers. For example, Informix® provides the DATE data type to store simple dates in year, month, and day format (= DATE FGL type), while Oracle® stores dates as year to second (= DATETIME YEAR TO SECOND FGL type).

The table describes the fields you will find in a row of the .sch file:

**Table 136: Structure of the .sch file**

<table>
<thead>
<tr>
<th>Pos</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>

</tbody>
</table>
|                |                          | \[
|                |                          | length = (precision * 256) + scale |
| Unused         | 9                        | N/A                         |
| DATETIME       | 10                       | For DATETIME types, the length is determined using the formula: |
|                |                          | \[
|                |                          | length = (digits * 256) + (qual1 * 16) + qual2 |
|                |                          | where digits is the total number of digits used when displaying the datetime value. For example, a DATETIME YEAR TO MINUTE (YYYY-MM-DD hh:mm) uses 12 digits. |
|                |                          | The qual1 and qual2 elements identify datetime qualifiers using the following codes: |
|                |                          | • 0 = YEAR |
|                |                          | • 2 = MONTH |
|                |                          | • 4 = DAY |
|                |                          | • 6 = HOUR |
|                |                          | • 8 = MINUTE |
|                |                          | • 10 = SECOND |
|                |                          | • 11 = FRACTION(1) |
|                |                          | • 12 = FRACTION(2) |
|                |                          | • 13 = FRACTION(3) |
|                |                          | • 14 = FRACTION(4) |
|                |                          | • 15 = FRACTION(5) |
|                |                          | For example, a DATETIME YEAR TO MINUTE size length is computed as follows: |
|                |                          | \[
|                |                          | (12 * 256) + (0 * 16) + 8 = 3080 |
| BYTE           | 11                       | Length of descriptor       |
| TEXT           | 12                       | Length of descriptor       |
| VARCHAR        | 13                       | Maximum number of characters or bytes (see note) |
|                |                          | If the length is positive: |
|                |                          | \[
|                |                          | length = (min_space * 256) + max_size |
|                |                          | If length is negative: |
|                |                          | \[
<p>|                |                          | length + 65536 = (min_space * 256) + max_size |</p>

<tr>
<td>NVARCHAR2</td>
<td>202</td>
<td>Maximum number of characters</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In programs, will be converted to a VARCHAR type.</td>
</tr>
</tbody>
</table>

**Note:** Data type length (field #4) is a SMALLINT value encoding the length or composite length of the type. For character string types, the unit of the length used to define character program variables and form fields depends on the length semantics.
Informix® SERIAL types

When the database schema defines SERIAL, BIGSERIAL or SERIAL8 types, form fields referencing the serial column will get the NOENTRY attribute automatically, except if defined with the TYPE LIKE syntax.

Informix® DISTINCT types

Informix® IDS version 9.x and higher allow you to define DISTINCT types from a base type with the CREATE DISTINCT TYPE instruction. In the syscolumns table, Informix® identifies distinct types in the coltype column by adding the 0x0800 bit (2048) to the base type code. For example, a distinct type defined with the VARCHAR built-in type (code 13) will be identified with the code 2061 (13 + 2048). Informix® sets additional bits when the distinct type is based on the LVARCHAR or BOOLEAN opaque types. If the base type is an LVARCHAR, the type code used in coltype gets the 0x2000 bit set (8192) and when the base type is BOOLEAN, the type code gets the 0x4000 bit (16384).

When extracting a schema from an Informix® database defining columns with DISTINCT types, the schema extractor will keep the original type code of the distinct type in the .sch file for columns using distinct types based on built-in types (with the 0x0800 bit set). Regarding the exception of opaque types, BOOLEAN-based distinct types get the code 45 (+ 256 if NOT NULL), and LVARCHAR-based distinct types are mapped to the code 201 (+ 256 if NOT NULL) if the -cv option enables conversion from LVARCHAR to VARCHAR2.

The fglcomp and fglform compilers understand the distinct type code bit 0x0800, so you can define program variables with a DEFINE LIKE instruction based on a column that was created with a distinct Informix® type.

Example

```
customer^customer_num^258^4^1^  
customer^customer_name^256^50^2^  
customer^customer_address^0^100^3^  
order^order_num^258^4^1^  
order^order_custnum^258^4^2^  
order^order_date^263^4^3^  
order^order_total^261^1538^4^  
```

Column Validation File (.val)
The .val database schema file holds functional and display attributes of database table columns.

Description

The .val file holds default attributes and validation rules for database columns.

Important: The form field attribute definition in the .val file is supported for backward compatibility. Do not use this feature in new developments.
In form files, the attributes are taken from the .val file as defaults if the corresponding attribute is not explicitly specified in the field definition of the ATTRIBUTES section. The attributes in the .val file can be considered as a default configuration for a form field.

In programs, you can validate variable values in accordance with the INCLUDE attribute by using the VALIDATE instruction.

The .val file can be generated by fgl dbsch from the IBM® Informix® specific syscolval table, or can be edited by an external column attributes editor.

This table describes the structure of the .val file:

**Related concepts**

VALIDATE on page 377
The VALIDATE instructions checks a variable value based on database schema validation rules.

**Column Video Attributes File (.att)**
The .att database schema file contains the default video attributes of database table columns.

**Description:**
The .att file is generated by fgldbsch from the IBM® Informix® specific syscolatt table.

**Important:** The form field video attributes definition in the .att file is supported for backward compatibility. Do not use this feature in new developments.

This table describes the structure of the .att file:

**Table 140: Structure of the .att file**

*Form fields* on page 1138
*Form fields* are form elements designed for data input and/or data display.

*fgldbsch* on page 1978
The `fgldbsch` tool generates the database schema files from an existing database.

**Database schema extractor options**

The `fgldbsch` tool extracts the schema description for an existing database.

Schema information is extracted from the database catalog tables. `fgldbsch` on page 1978 detects the type of database server after connection and queries the appropriated system catalog tables.

The database system must be available and the database client environment must be set properly in order to connect to the database engine and generate the schema files.

Generate the database schema files in the directory where the source code resides or in one of the directories listed in the `FGLDBPATH` environment variable.

The **fgldbsch** tool generates the database schema files from an existing database.

**Passing database user login and password**

The database user name and password can be specified with the `-un username` and `-up password` options.

```
fgldbsch -db test1 -un scott -up fourjs
```

**Related concepts**

- **User name and password (username/password)** on page 609
- **fgldbsch** on page 1978

The **fgldbsch** tool generates the database schema files from an existing database.

**Data type conversion control**

The **fglcomp** and **fglform** compilers expect known language data types (FGL types) in the schema file. While most data types correspond to IBM® Informix® SQL data types, some databases (including Informix®) can use specific types that do not map to an FGL type. Therefore, data types in the schema file are generated from the system catalog tables based on some conversion rules.

Type conversion can be controlled with the `-cv` option. Each character position of the string passed by this option represents a line in the conversion table of the corresponding source database. Give a conversion code for each data type (for example: `-cv AABAAAB`).

When using X as conversion code, the columns using the corresponding data types will be ignored and not written to the `.sch` file. This is particularly useful in the case of auto-generated columns like SQL Server's `uniqueidentifier` data type, when using a `DEFAULT NEWID()` clause.

Run the tool with the `-ct` option to see all the data type conversion tables, or use the `-cx dbtype` option to display the conversion table for a given database type (`dbtype` must be ifx, ora, db2, msv, pgs, mys, ...).

```
fgldbsch -cx ifx
```

<table>
<thead>
<tr>
<th>Informix</th>
<th>Informix A</th>
<th>Informix B</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 BOOLEAN</td>
<td>BOOLEAN (t=45)</td>
<td>CHAR (1)</td>
</tr>
<tr>
<td>2 INT8</td>
<td>INT8</td>
<td>DECIMAL(19,0)</td>
</tr>
<tr>
<td>3 SERIAL8</td>
<td>SERIAL8</td>
<td>DECIMAL(19,0)</td>
</tr>
<tr>
<td>4 LVARCHAR(m)</td>
<td>VARCHAR2 (m)</td>
<td>VARCHAR2 (m)</td>
</tr>
<tr>
<td>5 BIGINT</td>
<td>BIGINT</td>
<td>DECIMAL (19,0)</td>
</tr>
<tr>
<td>6 BIGSERIAL</td>
<td>BIGSERIAL</td>
<td>DECIMAL (19,0)</td>
</tr>
</tbody>
</table>

(ns) = Not supported in 4gl.

```
fgldbsch -db test1 -cv BAAABB
```

In the above example, the `-cv` option instructs **fgldbsch** to use the types of the "Informix® A" column for all original column types except for BOOLEAN, BIGINT and BIGSERIAL, which must be converted to a VARCHAR2 (m) FGL type.

The IBM® Informix® LVARCHAR(m) type can be converted by default to a VARCHAR2 (m) pseudo type (code 201), which will be identified as a VARCHAR(m) by compilers.

In schema files, VARCHAR2 (m) (type code 201) is equivalent to VARCHAR (m) (type code 13), without the 255 bytes limitation of the original Informix® VARCHAR type.

Not all native data types can be converted to FGL types. For example, user-defined types or spatial types are not supported by the language. When a table column with such unsupported data type is found, **fgldbsch** stops and displays an error to bring the problem to your attention. Use the `-ie` option of **fgldbsch** to ignore the database
tables having columns with unsupported types. When this option is used, none of the table columns definition will be written to the schema file.

**Related concepts**
- **Data types** on page 253
  - Selecting the correct data type assists you in the input, storage, and display of your data.
- **fgldbsch** on page 1978
  - The fgldbsch tool generates the database schema files from an existing database.
- **Column Definition File (.sch)** on page 479
  - The .sch database schema file contains the data types of database table columns.

**Skip unsupported table definitions**

By default fgldbsch stops with an error, if a database table column is defined with an SQL data type that cannot be supported by Genero BDL.

Use the `-ie` option, to skip such tables from the schema extraction.

**Note:** When using the `-ie` option, the whole table definition is skipped when a column type is not supported. Otherwise, the .sch file would contain a subset of the column definitions of the table, and a `SELECT * INTO record-defined-like.* FROM tabname` would fail because the number of columns in the table and into the record definition would not match.

```
fgldbsch -db test1 -ie
```

**Related concepts**
- **fgldbsch** on page 1978
  - The fgldbsch tool generates the database schema files from an existing database.

**Specifying the table owner**

With some databases, the owner of tables is mandatory to extract a schema, otherwise you could get multiple definitions of the same table in the .sch schema file, if tables with the same name exist in different database user schemas.

To prevent such duplicates, specify the schema owner with the `-ow owner` option. If this option is not used, fgldbsch will use the database login name passed with the `-un username` option. This is usually the case with SQL Server and SAP ASE, where the owner of tables is "dbo".

```
fgldbsch -db test1 -un scott -up fourjs -ow dbo
```

**Related concepts**
- **Database connections** on page 600
  - Explains how to manage database connections in a program.
- **fgldbsch** on page 1978
  - The fgldbsch tool generates the database schema files from an existing database.

**Force extraction of system tables**

By default fgldbsch does not extract the definition of database system tables.

Use the `-st` option to extract schema information of system tables.

```
fgldbsch -db test1 -st
```

**Related concepts**
- **fgldbsch** on page 1978
The fgl dbsch tool generates the database schema files from an existing database.

**Specifying the output file name**

By default, the generated schema files get the name of the database source specified with the `-db` option.
The name of the schema file can be forced with the `-of filename` option.

Specify the output file name without the `.sch` extension.

**Note:** The file name specified with the `-of` option will also be used to generate the files containing column validation rules and column attributes (extracted from IBM® Informix® syscolval and syscolatt tables).

```bash
fgldbsch -db test1 -of myschema
```

**Related concepts**

- [Column Validation File (.val)](page 482) on page 482
  The `.val` database schema file holds functional and display attributes of database table columns.
- [Column Video Attributes File (.att)](page 485) on page 485
  The `.att` database schema file contains the default video attributes of database table columns.

**Extracting definition of a single table**

In some cases, you may just want to extract schema file of new created tables.
Use the `-tn tabname` option, to extract schema information of a specific table.

```bash
fgldbsch -db test1 -tn customers
```

**Related concepts**

- [fgldbsch](page 1978) on page 1978
  The `fgldbsch` tool generates the database schema files from an existing database.

**Controlling the character case**

By default, table and column names are converted to lower case letters to enforce compatibility with IBM® Informix®.
Force lower case, upper case or case-sensitive table and column names by using the `-cl`, `-cu` or `-cc` options.

```bash
fgldbsch -db test1 -cc
```

As a general rule, it is strongly recommended to keep table and column names in lowercase, in all areas (including the objects created in the database entity).

**Related concepts**

- [fgldbsch](page 1978) on page 1978
  The `fgldbsch` tool generates the database schema files from an existing database.

**Using the verbose mode**

By default, `fgldbsch` extracts the database schema silently without any output.
Use the `-v` option to get verbose output from `fgldbsch`:

```bash
fgldbsch -db test1 -v
```

**Important:** Do not base other tools or development procedures on the output format of the `fgldbsch -v` option:
The output can change in later versions.
**Related concepts**

*fgldbsch* on page 1978

The *fgldbsch* tool generates the database schema files from an existing database.

### IBM® Informix® synonym tables

When using IBM® Informix®, *fgldbsch* extracts synonyms by default. Only PUBLIC synonyms are extracted, to avoid duplicates in the .sch file, when the same name is used by several synonyms for different table owners.

To extract PRIVATE synonyms, use the -ow option to specify the owner of the tables and synonyms.

```
fgldbsch -db test1 -ow mike
```

**Related concepts**

*fgldbsch* on page 1978

The *fgldbsch* tool generates the database schema files from an existing database.

### IBM® Informix® shadow columns

Starting with IBM® Informix® IDS version 11.50.xC1, you can create shadow columns on tables by using DDL options such as ADD VERCOLS.

Shadow columns are visible in the system catalog tables and would be listed in the column descriptions of the .sch schema file. However, since shadow columns are not part of the SELECT * list, it is not expected to get these columns in the .sch schema file.

By default, the *fgldbsch* tool will not extract shadow columns from an IBM® Informix® database.

Use the -sc option to force the extraction of shadow columns:

```
fgldbsch -db test1 -sc
```

### Running schema extractor in old mode

The *fgldbsch* program can be executed in old mode by specifying the -om option as first parameter, followed by the database source. You can pass the -c and -r options after the database source:

```
fgldbsch -om test1 -c -r
```

**Important:** Use the *fgldbsch* -om mode for IBM® Informix® databases only.

The -c option is equivalent to -cv BBBBBBBBBB in the default mode: Columns defined with an SQL type that is not a native Genero type will be converted to an equivalent type (see -cv and -ct options for more details).

If the -r option is specified, the schema extractor will ignore columns defined with unsupported SQL types. Unsupported types have no equivalent FGL type to store and handle the value, such as BLOB or CLOB for example. Understand that unlike the -ie option, which skips the whole table definition, -r will exclude table columns with unsupported types, but the other columns defined with supported types will be written to the .sch file. Thus, a record declared with DEFINE RECORD rec LIKE table.* (from a partial schema definition of a table) cannot be used in a SELECT * INTO rec.* statement, because the number of columns in the database table is different from the record definition.

**Note:** When using the *fgldbsch* -om mode, *fgldbsch* will extract system catalog tables (informix.sys*) for IBM® Informix® databases.

**Related concepts**

*fgldbsch* on page 1978
The fgldbsch tool generates the database schema files from an existing database.

**Programs**

Explains program structure basics and global instructions/registers.

- Structure of a program on page 491
- Structure of a module on page 492
- The MAIN block / function on page 493
- Importing modules on page 496
- Predefined constants on page 502
- Configuration options on page 504
- Program registers on page 516

**Structure of a program**

The structure of a program consists of MAIN and FUNCTION blocks defined in several modules.

The program starts from the MAIN block. From the MAIN block, the code can invoke other blocks of instructions defined as callable routines with FUNCTION / END FUNCTION blocks. The language statements are executed by the runtime system in the order that they appear in the code:

```plaintext
MAIN
   CALL func1()
END MAIN

FUNCTION func1()
   DISPLAY "Hello from func1()!"
END FUNCTION
```

Some instructions can include other instructions. Such instructions are called *compound statements*. Every compound statement of the language supports the END statement keyword (where statement is the name of the compound statement), to mark the end of the compound statement construct within the source code module. Most compound statements also support the EXIT statement keywords, to transfer control of execution to the statement that follows the END statement keywords. By definition, every compound statement can contain at least one statement block, a group of one or more consecutive statements. In the syntax diagram of a compound statement, a statement block always includes this element:

```plaintext
MAIN
   INPUT BY NAME rec.*
   ...
   ON ACTION quit
      EXIT INPUT
   END INPUT
END MAIN
```

**Related concepts**

- Structure of a module on page 492
- Importing modules on page 496

A module defines a set of program elements such as functions, report routines, types, constants and variables.
Use the IMPORT ... instruction to import BDL, C or Java external modules in the current module.

Structure of a module

A module defines a set of program elements such as functions, report routines, types, constants and variables.

Syntax

The declaration order of elements defined in a program module is constrained. Define module elements in the following way:

```
[ compiler-options
  import-statement [...]  
  schema-statement
  globals-inclusion
  constant-definition [...] 
  type-definition [...]  
  variable-definition [...]  
]

[ MAIN-block ]

[ dialog-block
  function-block
  report-routine
  [...] ]
```

1. `compiler-options` are described in OPTIONS (Compilation) on page 505.
2. `import-statement` imports an external module, see Importing modules on page 496.
3. `schema-statement` defines a database schema for the compilation.
4. `globals-inclusion` includes a globals file.
5. `constant-definition` defines constants.
6. `type-definition` defines user types.
7. `variable-definition` defines variables.
8. `MAIN-block` declares the main block of the program.
9. `dialog-block` declares a declarative dialog.
10. `function-block` declares a function.
11. `report-routine` declares a report routine.

Usage

A module defines a set of program elements that can be used by other modules when defined as PUBLIC, or to be local to the current module when defined as PRIVATE. Program elements are user-defined types, variables, constants, functions, report routines, and declarative dialogs.

A module can import other modules with the IMPORT FGL instruction. A module can define functions, reports, module variables, constants and types, as well as declarative dialogs.

Program modules are written as .4gl source files and are compiled to .42m files. Compiled modules (.42m files) can be linked together to create a program. However, linking is supported for backward compatibility only. The preferred way is to define module dependencies with the IMPORT FGL instruction. For better code re-usability, module elements can be shared by each other by qualifying module variables, constants, types, and functions with PRIVATE or PUBLIC keywords. PUBLIC module elements can be referenced in other modules.

Example

```
OPTIONS SHORT CIRCUIT
IMPORT FGL cust_data
SCHEMA stores
```
PRIVATE CONSTANT c_title = "Customer data form"
PUBLIC TYPE t_cust RECORD LIKE customer.*
PRIVATE DEFINE cust_arr DYNAMIC ARRAY OF t_cust

MAIN
...
END MAIN

DIALOG cust_dlg()
  INPUT BY NAME cust_rec.*
  ...
  END INPUT
END DIALOG

FUNCTION cust_display()
...
END FUNCTION

FUNCTION cust_input()
...
END FUNCTION

REPORT cust_rep(row)
...
END REPORT

Related concepts
SCHEMA on page 477
Defines the database schema files to be used for compilation.

Reports on page 1924
Structure of a procedural DIALOG block on page 1490
Structure of a declarative DIALOG block on page 1553
A declarative DIALOG instruction is made of a single sub-dialog block, with an optional DEFINE clause to declare local variables.

Structure of a program on page 491
The structure of a program consists of MAIN and FUNCTION blocks defined in several modules.

The MAIN block / function
The MAIN block is the starting point of the program.

Syntax 1 (MAIN / END MAIN)

```
MAIN
  local-declaration
  ...[...]
  instruction
  ...[...]
END MAIN
```

1. `local-declaration` is a DEFINE, CONSTANT or TYPE instruction.
2. `instruction` is a language statement.

Syntax 2 (FUNCTION main())

```
FUNCTION main()
  local-declaration
```

1. *local-declaration* is a DEFINE, CONSTANT or TYPE instruction.
2. *instruction* is a language statement.

**Usage**

A Genero program starts in the **MAIN** block, to perform the instructions defined in this block.

**Important:** If a DATABASE instruction was specified (for the compilation DB schema) before the **MAIN / END MAIN** block, an implicit connection will occur in **MAIN**. For more details see the SCHEMA on page 477 instruction.

The **MAIN** block typically consists of:

1. The signal handling instructions **DEFER INTERRUPT** and **DEFER QUIT**.
2. The exception handling instruction **WHENEVER ERROR CALL**.
3. Global runtime configuration settings with the **OPTIONS** instruction.
4. A database connection with the **CONNECT TO** or **DATABASE** instruction.
5. In an interactive program, a call to function implementing the main dialog instruction controlling the main form.

The **MAIN / END MAIN** block must appear before any other **FUNCTION / END FUNCTION** block:

```
IMPORT FGL cust_module
MAIN
  DEFINE uname, upswd STRING
  DEFER INTERRUPT
  DEFER QUIT
  OPTIONS FIELD ORDER FORM, INPUT WRAP,
      SQL INTERRUPT ON, HELP FILE "myhelp"
  CALL get_login() RETURNING uname, upswd
  TRY
    CONNECT TO "stores" USER uname USING upswd
  CATCH
    IF SQLCA.SQLCODE < 0 THEN
      DISPLAY "Error: Could not connect to database."
      EXIT PROGRAM 1
    END IF
  END TRY
  CALL cust_module.customer_input()
END MAIN
```

**FUNCTION main()**

The **MAIN** block can also be defined as a regular function with **FUNCTION main() / END FUNCTION**.

In fact a **MAIN / END MAIN** block is equivalent to **FUNCTION main() / END FUNCTION** (returning no values), except that with a **MAIN** block, an implicit database connection is performed, if the DATABASE instruction is used before **MAIN / END MAIN**, to define the compilation database schema (the implicit database connection does not occur, when using the SCHEMA instruction).
The `FUNCTION main()` is very useful, when the main block must be defined after other functions, for example when using function references where functions must be declared before they are referenced:

```golang
TYPE t_func FUNCTION (p1 INT, p2 INT) RETURNS INT
FUNCTION add(p1 INT, p2 INT) RETURNS INT
    RETURN p1 + p2
END FUNCTION

FUNCTION sub(p1 INT, p2 INT) RETURNS INT
    RETURN p1 - p2
END FUNCTION

FUNCTION main()
    DEFINE op t_func
    LET op = FUNCTION add
    DISPLAY op( 5, 10 )
    LET op = FUNCTION sub
    DISPLAY op( 5, 10 )
END FUNCTION
```

**Defining MAIN in imported modules**

When using `IMPORT FGL` (that is, when not linking programs), a MAIN block or `main()` function can be defined in the imported modules.

This allows for example to write unit tests in the same source module.

File `math.4gl`:

```golang
MAIN
    DEFINE
        p1 INT = 6,
        p2 INT = 9,
        res INT
    DISPLAY "Unit testing add (", p1, " , ", p2, ")"
    LET res = add(p1, p2)
    IF res = 15 THEN
        DISPLAY " PASSED"
    ELSE
        DISPLAY " FAILED"
    END IF
END MAIN

PUBLIC FUNCTION add(p1 INT, p2 INT) RETURNS INT
    RETURN p1 + p2
END FUNCTION
```

File `main.4gl`:

```golang
IMPORT FGL math
MAIN
    DISPLAY math.add(5, 4)
END MAIN
```

Compiling and running both modules:

```
$ fglcomp math.4gl
$ fglrun math.42m
Unit testing add (          6 ,           9)
PASSED
```
Related concepts

Exceptions on page 451
Describes exception (error) handling in the programs.

Importing modules

Use the IMPORT ... instruction to import BDL, C or Java external modules in the current module.

The IMPORT {JAVA|FGL} instruction can be used to declare the usage of an external module. All (public) symbols of the external module can be referenced in the current module.

The IMPORT {JAVA|FGL} instruction must be the first instruction in the current module. If you specify this instruction after DEFINE, CONSTANT or GLOBALS, fglcomp will report a syntax error.

The IMPORT {JAVA|FGL} instruction can import a compiled Genero module, a Java class or a C extension library:

- IMPORT FGL modulename: Imports a Genero module implementing functions, reports, types and variables.
- IMPORT JAVA classname: Imports a Java class or class element.
- IMPORT libname: Imports a C extension implementing functions and variables.

Note: The name specified after the IMPORT FGL or IMPORT JAVA instruction is case-sensitive; program module (.4gl) or Java class must exactly match the file name. However, for backward compatibility, C extension library names are converted to lowercase by the compiler (therefore, we recommend you to use lowercase file names for C extensions). A character case mismatch will be detected on UNIX™ platforms, but not on Windows® where the file system is not case-sensitive. Regarding the usage of imported symbols in the rest of the code (not in the IMPORT instruction): C extensions and Genero symbols are case-insensitive, while Java symbols are case-sensitive.

fgllink on page 1975
The fgllink tool assembles p-code modules produced with fglcomp into a .42r program or a .42x library.

IMPORT C-Extension

The IMPORT instruction imports c extension module elements to be used by the current module.

Syntax

| IMPORT cextname |

1. cextname is an identifier defining the C extension module to be imported (without the file extension).
**Usage**

Using `IMPORT cextname` instructs the compiler and runtime system to use the `cextname` C extension for the current module.

**Important:** At runtime, all imported C extension modules are loaded when the program starts.

The name of the module specified after the `IMPORT` keyword is converted to lowercase by the compiler. Therefore it is recommended to use lowercase file names only.

The C extension must exist as a shared library (.DLL or .so) and be loadable (environment variables must be set properly). C extension modules used with the `IMPORT` instruction do not have to be linked to `fglrun`; the runtime system loads dependent C extension modules dynamically.

The `FGLLDPATH` environment variable specifies the directories to search for the C extension modules. You may also have to set up the system environment properly (such as `PATH` on Windows® and `LD_LIBRARY_PATH` on UNIX™) if the C extension library is dependent on other libraries.

By default, the runtime system tries to load a C extension module with the name `userextension`, if it exists. This simplifies the migration of existing C extensions; you just need to create a shared library named `userextension.so` (or `userextension.dll` on Windows®), and copy the file to one of the directories defined in `FGLLDPATH`.

**Related concepts**

- **Importing modules** on page 496
  - Use the `IMPORT ...` instruction to import BDL, C or Java external modules in the current module.

- **C-Extensions** on page 2109
  - With `C-Extensions`, you can bind your own C libraries in the runtime system, to call C function from the application code.

**IMPORT FGL module**

The `IMPORT FGL` instruction imports module symbols.

**Syntax**

```
IMPORT FGL modulename
```

1. `modulename` is an identifier defining the module to be imported (without the file extension).

**Usage**

With `IMPORT FGL modulename`, the symbols of the named .42m module can be referenced in the current module.

**Important:** At runtime, the imported modules are only loaded on demand, when the program flow reaches an instruction that uses an element of the imported module. For example, when calling a function or when assigning a (public) module variable of the imported module.

The name specified after the `IMPORT FGL` instruction is case-sensitive.

The imported module symbols that can be referenced are:

- Public functions
- Public constants
- Public types
- Public module variables

**Compilation with IMPORT FGL**

`IMPORT FGL` instructs the `fglcomp` compiler and `fglrun` runtime system to load/check the specified modules.
When using only IMPORT FGL to define module dependency, there is no longer a need to link programs or use libraries.

With IMPORT FGL, the compiler can check the number of parameters and returning values in functions calls, and the autocompletion in source code editors is improved as it can suggest all imported symbols.

**Auto-compilation of (local) imported modules**

It is recommended to compile imported modules before compiling the importing module.

The FGLLDPATH environment variable specifies the directories to search for the .42m modules used by IMPORT FGL.

When the imported module is located in the same directory as the compiled module, if the .42m file of the imported module does not exist, or is older than the corresponding source file, fglcomp will automatically compile the imported module.

To avoid implicit compilation of imported modules, use the --implicit=none option of fglcomp. If the .42m file exists but the .4gl source file cannot be found, fglcomp imports the .42m file as is.

**Important:** Auto-compilation of imported modules is only supported if the imported module is in the current directory. Modules located in other directories and found by FGLLDPATH must already be compiled.

**Avoid circular module references**

Circular references are not allowed. For example, when module A imports module B, which in turn imports module A, you cannot compile one of the modules because the .42m file of the imported module is needed.

In case of circular module reference, fglcomp will give error -8403, indicating that the imported module cannot be found:

Module "mod_a.4gl":

```4gl
IMPORT FGL module_b
FUNCTION func_a()
  CALL func_b()
END FUNCTION
```

Module "mod_b.4gl":

```4gl
IMPORT FGL module_a
FUNCTION func_b()
  CALL func_a()
END FUNCTION
```

**Identify used modules with fgrun --print-imports**

When migrating existing projects using traditional linking, after compiling all the .4gl sources, consider using the --print-imports option of fgrun, to print the IMPORT FGL suggestions for all the modules specified in the fgrun command line.

The --print-imports option will try to resolve all symbols as done during linking, but instead of producing a .42r program, it will list the IMPORT FGL instructions to be added in each module, and thus avoid linking:

```4gl
$ cat main.4gl
MAIN
  CALL func1()
END MAIN
$ cat mod1.4gl
FUNCTION func1()
  CALL func2()
END FUNCTION
```
FUNCTION func2()
    CALL func1()
END FUNCTION

$ fgldr --print-imports main.42m mod1.42m mod2.42m
    -- in main.4gl
IMPORT FGL mod1
    -- in mod1.4gl
IMPORT FGL mod2
    -- in mod2.4gl
# Cyclic import: IMPORT FGL mod1
#   caused by CALL func1

Scope of module symbols (PRIVATE/PUBLIC)

The PRIVATE/PUBLIC modifiers can be used to hide / publish symbols to other modules.

Note: Functions are by default public, for backward compatibility. Module variables, types and constants are by default private.

The following example declares a module variable that can be used by other modules, and a private function to be used only locally:

PUBLIC DEFINE custlist DYNAMIC ARRAY OF RECORD
    id INT,
    name VARCHAR(50),
    address VARCHAR(200)
END RECORD
...
PRIVATE FUNCTION myfunction()
...
END FUNCTION

Resolving symbol name conflicts with module prefix

If a symbol is defined twice with the same name in two different modules, the symbol must be qualified by the name of the module.

This feature overcomes the traditional 4GL limitation, requiring unique function names within a program.

In the following example, both imported modules define the same "init()" function, but this can be resolved, by adding the module name followed by a dot before the function names:

IMPORT FGL orders
IMPORT FGL customers
MAIN
    CALL orders.init()
    CALL customers.init()
...
END MAIN

If a symbol is defined twice with the same name in the current and the imported module, an unqualified symbol will reference the current module symbol.

The following example calls the "init()" function with and without a module qualifier. The second call will reference the local function:

IMPORT FGL orders
MAIN
CALL orders.init() -- orders module function
CALL init() -- local function
...
END MAIN
FUNCTION init()
...
END FUNCTION

Mixing IMPORT FGL and .42r linking

Traditional linking is still supported for backward compatibility. To ease migration from traditional linking to imported modules, you can mix IMPORT FGL usage with fgllink.

By default, even when IMPORT FGL is used, fgllink does not raise an error, if a referenced function is not found in the imported modules. This is mandatory to compile the 42m file to be linked later with the module defining the missing function.

Use the -W implicit or the --resolve-calls option to check for imported functions.

When the -W implicit option is used and at least one IMPORT FGL is defined in the module, fgllink will print warning -8406 for any referenced function that cannot be found in the imported modules.

Note: The -W implicit option is silently ignored, if no IMPORT FGL is used in the module.

To enable full symbol resolution by the compiler, use the --resolve-calls option. This option will force the compiler to check all function symbols referenced in a module, and raise error -8406, if a symbol is not found in the imported modules.

Note: The --resolve-calls option is typically used to compile programs that are only based on IMPORT FGL and no longer use the link phase.

For more details about the linker, see Linking programs on page 2004.

Example

Module "account.4gl":

PRIVATE DEFINE current_account VARCHAR(20)

PUBLIC FUNCTION set_account(id)
  DEFINE id VARCHAR(20)
  LET current_account = id
END FUNCTION

Module "myutils.4gl":

PRIVATE DEFINE initialized BOOLEAN

PUBLIC TYPE t_prog_info RECORD
  name STRING,
  version STRING,
  author STRING
END RECORD

PUBLIC FUNCTION init()
  LET initialized = TRUE
END FUNCTION

PUBLIC FUNCTION fini()
  LET initialized = FALSE
END FUNCTION

PUBLIC FUNCTION tokenize(s STRING,
    a DYNAMIC ARRAY OF STRING)
DEFINE tok base.StringTokenizer,
  x INTEGER
LET tok = base.StringTokenizer.create(s, "\t\n")
call a.clear()
LET x=0
WHILE tok.hasMoreTokens()
  LET x=x+1
  LET a[x] = tok.nextToken()
END WHILE
END FUNCTION

Module "program.4gl":

IMPORT FGL myutils
IMPORT FGL account
DEFINE filename STRING
DEFINE proginfo t_prog_info  -- Type is defined in myutils
MAIN
  DEFINE arr DYNAMIC ARRAY OF STRING
  LET proginfo.name = "program"
  LET proginfo.version = "0.99"
  LET proginfo.author = "scott"
  CALL myutils.init()  -- with module prefix
  CALL set_account("CFX4559")  -- without module prefix
  CALL tokenize("aaa bbb ccc",arr)
  DISPLAY arr[2]
END MAIN

Related concepts
Program execution on page 519

IMPORT JAVA classname
The IMPORT JAVA instruction imports Java module elements.

Syntax

```
IMPORT JAVA \ packagename . [ ... ] \ classname
```

1. `packagename` and `classname` define the Java class to be imported.

Usage

The IMPORT JAVA instruction can be used to import a Java class.

Important: At runtime, the imported Java classes are only loaded on demand, when the program flow reaches an instruction that uses the class. For example, when reaching the declaration of a variable defined to reference an object of a Java class.

The name specified after the IMPORT JAVA instruction is case-sensitive.

The CLASSPATH environment variable defines the directories for Java packages. See the Java documentation for more details.

Note: To mimic the Java import rules, the fglcomp compiler allows subsequent IMPORT JAVA instructions with the same class name. However, it is recommended that you avoid duplicating the same IMPORT JAVA instructions:

```
IMPORT JAVA java.util.regex.Matcher
...
IMPORT JAVA java.util.regex.Matcher
```
**Related concepts**

  Defines the search paths to load program modules.

- **The Java interface** on page 2071
  
  The Java interface allows you to import Java classes and instantiate Java objects in your programs.

**Predefined constants**

The language defines a set of global constants that can be used in the programs.

- **NULL** on page 502
- **TRUE** on page 503
- **FALSE** on page 503
- **NOTFOUND** on page 504

**NULL**

The NULL constant is provided as the "nil" value.

**Syntax**

```
NULL
```

**Usage**

When comparing variables to NULL, use the `IS NULL` operator, not the equal operator.

If an element of an expression is null, the expression is evaluated to NULL.

Variables are initialized to null or to zero, according to their data type.

Empty character string literals ("") are equivalent to NULL.

NULL cannot be used with the `=` equal comparison operation, you must use `IS NULL`.

**Example**

```
MAIN
    DEFINE s CHAR(5)
    LET s = NULL
    DISPLAY "s IS NULL evaluates to:"
    IF s IS NULL THEN
        DISPLAY "TRUE"
    ELSE
        DISPLAY "FALSE"
    END IF
END MAIN
```

**Related concepts**

- **Initialization values** on page 371
  
  Variables are initialized differently depending on the data type.

- **IS NULL** on page 302
  
  The `IS NULL` operator checks for NULL values.

- **Data types** on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

**TRUE**

TRUE is a predefined constant to be used in boolean expressions.

**Syntax**

```
TRUE
```

**Usage**

TRUE is a predefined constant that can be used as a boolean value in boolean expressions. The TRUE constant is equal to 1 (one).

TRUE and FALSE are typically used as return values of functions that give a binary result.

**Example**

```
MAIN
    DEFINE short BOOLEAN
    LET short = is_short("abcdef")
    IF short THEN
        DISPLAY "String is short."
    END IF
END MAIN

FUNCTION is_short(s)
    DEFINE s STRING
    IF s.getLength() < 10 THEN
        RETURN TRUE
    ELSE
        RETURN FALSE
    END IF
END FUNCTION
```

**Related concepts**

- **Boolean expressions** on page 294
  This section covers boolean expression evaluation rules.

- **BOOLEAN** on page 257
  The BOOLEAN data type stores a logical value, TRUE or FALSE.

**FALSE**

FALSE is a predefined constant to be used in boolean expressions.

**Syntax**

```
FALSE
```

**Usage**

FALSE is a predefined constant that can be used as a boolean value in boolean expressions. The FALSE constant is equal to 0 (zero).

TRUE and FALSE are typically used as return values of functions that give a binary result.

**Example**

```
MAIN
```
DEFINE odd BOOLEAN
LET odd = is_odd(125763)
IF odd THEN
    DISPLAY "Number is odd."
END IF
END MAIN

FUNCTION is_odd(value)
    DEFINE value INTEGER
    IF value MOD 2 = 1 THEN
        RETURN TRUE
    ELSE
        RETURN FALSE
    END IF
END IF
END FUNCTION

BOOLEAN on page 257
The BOOLEAN data type stores a logical value, TRUE or FALSE.

NOTFOUND
NOTFOUND is a predefined constant used to check if an SQL statement returns rows.

Syntax

NOTFOUND

Usage
The NOTFOUND constant is used to test the execution status of an SQL statement returning a result, to check whether rows have been found.

The NOTFOUND constant is equal to 100.

You typically compare SQLCA.SQLCODE to NOTFOUND, after a SELECT statement execution.

Example

MAIN
    DATABASE stores
    SELECT tabid FROM systables WHERE tabid = 1
    IF SQLCA.SQLCODE = NOTFOUND THEN
        DISPLAY "No row was found"
    END IF
END MAIN

Related concepts

If an SQL statement execution fails, error description can be found in the SQLCA.SQLCODE, SQLSTATE, STATUS and SQLERRMESSAGE predefined registers.

SELECT on page 645
Produces a result set from a query on database tables.

Configuration options
Compiler and runtime system can be controlled with several configuration settings.

- OPTIONS (Compilation) on page 505
OPTIONS (Compilation)
OPTIONS outside program blocks defines semantics of the language for the compiler.

Syntax

```
OPTIONS
  ↓ SHORT CIRCUIT
  ↓ ↓ ↓ ↓ ↓
```

Usage

The OPTIONS statement used before any MAIN, FUNCTION or REPORT program block defines language semantics options, that will take effect for the current module only. Unlike runtime options, compiler options cannot be changed during program execution.

The statement to define compiler options must be placed before the MAIN block in the main module, or before the first FUNCTION / REPORT block in other modules.

The OPTIONS compiler directive allows for the control of features Controlling semantics of AND / OR operators on page 505

Example

```
OPTIONS SHORT CIRCUIT
MAIN
  DISPLAY "Global Options example"
END MAIN
```

Related concepts
OPTIONS (Runtime) on page 506
The OPTIONS instruction inside program blocks controls program behavior at runtime.

Controlling semantics of AND / OR operators
The OPTIONS SHORT CIRCUIT defines the semantics of AND/OR operators.

When using OPTIONS SHORT CIRCUIT at the beginning of a module, the runtime system will optimize the evaluation of boolean expressions involving AND and OR operators, by using the short-circuit evaluation method (also called minimal evaluation method). This behavior is enabled for the whole module.

By default, the behavior of AND and OR operators is to evaluate all operands on the left and right side of the operator. In fact this is not required. If the left operand of the AND evaluates to FALSE, there is no need to evaluate the right operand, because the result of the AND operator will be false, anyway. Similarly, when the left operand of an OR expression evaluates to TRUE, there is no need to evaluate the right operand, since the result of the boolean expression will be true, anyway.

This method can improve performances and simplify programming. However, existing code may rely on the fact that all parts of a boolean expression are evaluated, especially when calling functions that do some processing. By using the short-circuit evaluation method, it is unsure that the function used in the right operand of AND/OR will be called, because it depends on the result of the left operand.

By using short-circuit evaluation, it is possible to reference a dynamic array in the same boolean expression, after checking that the index is in the current array element range:

```
IF x<=arr.getLength() AND arr[x].order_date > TODAY THEN
  ...
END IF
```
With the default AND semantics, in this code, the right operand is also evaluated. If the $x$ index is greater than the array length, new array elements will be automatically created in the expression on the right of the AND operator. To avoid this situation, you are forced to write the following code, when OPTIONS SHORT CIRCUIT is not used:

```plaintext
IF x<=arr.getLength() THEN
  IF arr[x].order_date > TODAY THEN
    ...
  END IF
END IF
```

**Related concepts**

- **Boolean expressions** on page 294
  This section covers boolean expression evaluation rules.

- **AND** on page 312
  The AND operator is the logical intersection operator.

- **OR** on page 312
  The OR operator is the logical union operator.

**OPTIONS (Runtime)**

The OPTIONS instruction inside program blocks controls program behavior at runtime.

**Syntax**

```plaintext
OPTIONS options-clause [, ...]
```

**Usage**

Use the OPTIONS instruction inside a function block to control the behavior of the runtime system for the rest of the program execution.

A program can execute successive OPTIONS statements at different places in the code.

The runtime OPTIONS statement allows for control of the following runtime features:

- Defining the position of reserved lines on page 506
- Defining default TTY attributes on page 507
- Defining field tabbing order method on page 509
- Defining the field input loop on page 509
- Application termination on page 511
- Front-end termination on page 511
- Defining the message file on page 512
- Defining control keys on page 512
- Setting default screen modes for sub-programs on page 514
- Enabling/disabling SQL interruption on page 514

**Defining the position of reserved lines**

The OPTIONS element LINE defines position of dedicated screen lines.

**Syntax**

```plaintext
OPTIONS
  MENU LINE line-value
  MESSAGE LINE line-value
  COMMENT LINE [OFF] line-value
  PROMPT LINE line-value
  ERROR LINE line-value
  FORM LINE line-value
```
Usage

The `OPTIONS` statement can define the positions of reserved lines for menus, forms and messages.

Reserved window lines are used in TUI mode. These options are not required in GUI mode. In GUI mode, these options have no effect, except when using the traditional mode, where program windows are rendered as in a dumb terminal.

- **COMMENT_LINE** specifies the position of the comments for fields. Field comments are defined with the `COMMENT` attribute in the form specification file. The default is `(LAST-1)` for the `SCREEN`, and `LAST` for all other windows. The field comment display can be disabled with `COMMENT LINE OFF`.
- **ERROR_LINE** specifies the position on the screen for the text of the `ERROR` statement. The text of the `ERROR` statement is always displayed independently to the current window. The default is the `LAST` line of the screen.
- **MESSAGE_LINE** specifies the position of the message line in the current window. This reserved line displays the text of the `MESSAGE` statement. The default is `FIRST+1` (line 2 in the current window). Note that the default message line position is the same as the `MENU` option comment line.
- **FORM_LINE** specifies the window line where forms are displayed. The default is `FIRST+2` (line 3 in the current window).
- **MENU_LINE** specifies the position of the menu line in the current window. This line displays the menu name and options, as defined by the `MENU` statement. The default is the `FIRST` line in the current window.
- **PROMPT_LINE** specifies the position of the prompt line where the text of `PROMPT` statements is displayed. The default value is the `FIRST` line in the current window.

You can specify any of the following positions for each reserved line:

**Table 141: Reserved line expressions**

<table>
<thead>
<tr>
<th>Expression</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIRST</td>
<td>The first line of the screen or window.</td>
</tr>
<tr>
<td>FIRST + integer</td>
<td>A relative line position from the first line.</td>
</tr>
<tr>
<td>integer</td>
<td>An absolute line position in the screen or window.</td>
</tr>
<tr>
<td>LAST - integer</td>
<td>A relative line position from the last line.</td>
</tr>
<tr>
<td>LAST</td>
<td>The last line of the screen or window.</td>
</tr>
</tbody>
</table>

Related concepts

[Genero user interface modes on page 1013](#)
User interface modes allow you to adapt the application form rendering to different types of displays.

**Defining default TTY attributes**

The `OPTIONS { INPUT DISPLAY } ATTRIBUTES` defines default TTY attributes for dialogs and display statements.

**Syntax**

```plaintext
OPTIONS {
  INPUT ATTRIBUTES {
    FORM WINDOW \attributes\
  }
  DISPLAY ATTRIBUTES {
    FORM WINDOW \attributes\
  }
}
```
Usage

OPTIONS INPUT ATTRIBUTES defines the default color and terminal effect attributes that will be used in subsequent dialog statement.

OPTIONS DISPLAY ATTRIBUTES defines the default attributes for display statements.

The display attributes are based on dumb terminal (i.e. TTY) possibilities, but will be rendered accordingly on GUI mode. Graphical front-ends can be configured to render TTY attributes in a specific way. Instead of TTY based attributes, consider using presentation styles in new developments.

Any display attribute defined by the OPTIONS statement remains in effect until the runtime system encounters a statement that redefines the same attribute. This can be another OPTIONS statement, or an ATTRIBUTE clause in one of the following statements:

- CONSTRUCT
- INPUT
- DISPLAY
- DIALOG
- INPUT ARRAY
- DISPLAY ARRAY
- OPEN WINDOW

The ATTRIBUTE clause in these statements only redefines the attributes temporarily. After the window closes or after the dialog statement terminates, the runtime system restores the attributes from the most recent OPTIONS statement.

The FORM keyword in INPUT ATTRIBUTE or DISPLAY ATTRIBUTE clauses instructs the runtime system to use the input or display attributes of the current form. Similarly, you can use the WINDOW keyword of the same clauses to instruct the program to use the input or display attributes of the current window. You cannot combine the FORM or WINDOW attributes with any other attributes.

This table shows the valid input and display attributes:

### Table 142: Input and display attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLACK, BLUE, CYAN, GREEN, MAGENTA, RED, WHITE, YELLOW</td>
<td>The TTY color of the displayed text.</td>
</tr>
<tr>
<td>BOLD, DIM, INVISIBLE, NORMAL</td>
<td>The TTY font attribute of the displayed text.</td>
</tr>
<tr>
<td>REVERSE, BLINK, UNDERLINE</td>
<td>The TTY video attribute of the displayed text.</td>
</tr>
</tbody>
</table>

## Defining the field input loop

The **OPTIONS INPUT NO WRAP** instructions defines field wrapping in dialogs.

### Syntax

```
OPTIONS INPUT NO WRAP
```

### Usage

By default, an interactive statement such as **CONSTRUCT** or **INPUT** terminates when the focus leaves the last field controlled by the dialog instruction.

The **OPTIONS INPUT WRAP** instruction can change this behavior, causing the cursor to move from the last field to the first, repeating the sequence of fields until the dialog is validated or canceled.

The **INPUT NO WRAP** option restores the default input loop behavior.

### Example

```
MAIN
   OPTIONS INPUT WRAP
   ...
END MAIN
```

**Editable record list (INPUT ARRAY)** on page 1425
The **INPUT ARRAY** instruction provides always-editable record list handling in an application form.

**Defining field tabbing order method** on page 509

### Defining field tabbing order method

### Syntax

```
OPTIONS FIELD ORDER ▼ CONSTRANED ▼ UNCONSTRAINED ▼ FORM ▼
```
Usage

Tabbing order is used in interactive instructions such as INPUT, INPUT ARRAY, or CONSTRUCT, where individual fields can get the focus.

The FIELD ORDER runtime option defines the default behavior when moving from field to field with the TAB and SHIFT-TAB keys in GUI mode, and with the Up / Down arrow keys in TUI mode.

**Note:** The OPTIONS FIELD ORDER defines the global field order mode. The field order mode can also be defined at the dialog level, with the FIELD ORDER dialog attribute.

By default, the tabbing order is defined by the list of fields used by the program instruction. This corresponds to FIELD ORDER CONSTRAINED option, which is the default.

When using FIELD ORDER UNCONSTRAINED in TUI mode, the Up and Down arrow keys will move the cursor to the field above or below the current field, respectively. When using the default FIELD ORDER CONSTRAINED option, the Up and Down arrow keys move the cursor to the previous or next field, respectively. If FIELD ORDER UNCONSTRAINED is used, the Dialog.fieldOrder FGLPROFILE entry is ignored.

The UNCONSTRAINED option can only be supported in TUI mode, with a simple form layout. It is not recommended to use this option in GUI mode.

The FIELD ORDER FORM option instructs interactive instructions to use the tabbing order defined by the TABINDEX attributes of the current form fields. With this option, tabbing order can be defined in the layout of the form, independently from the program instruction. This is the preferred way in GUI mode. When FIELD ORDER FORM is used, the Dialog.fieldOrder FGLPROFILE entry is ignored.

Example

Form "form1.per":

```
LAYOUT
GRID
{
   First name:  [f001]  Last name:  [f002]
   Address:     [f003]
}
END
END

ATTRIBUTES
EDIT f001 = FORMONLY.fname, TABINDEX = 2;
EDIT f002 = FORMONLY.lname, TABINDEX = 1;
EDIT f003 = FORMONLY.address, TABINDEX = 0;
END
```

Module "main.4gl":

```
MAIN
   DEFINE rec RECORD
      fname VARCHAR(20),
      lname VARCHAR(20),
      address VARCHAR(50)
   END RECORD

   OPTIONS INPUT WRAP

   OPEN FORM f1 FROM "form1"
   DISPLAY FORM f1

   OPTIONS FIELD ORDER CONSTRAINED
   INPUT BY NAME rec.*

   OPTIONS FIELD ORDER UNCONSTRAINED
```
Related concepts
Defining the tabbing order on page 1630
Control the order of tabbing through the fields with the TABINDEX attribute.

Application termination
The OPTIONS TERMINATE SIGNAL defines a callback function in case of SIGTERM signal.

Syntax
OPTIONS ON TERMINATE SIGNAL CALL function

Usage
The OPTIONS ON TERMINATE SIGNAL CALL function defines the function that must be called when the application receives the SIGTERM signal. With this option, you can control program termination. If this statement is not called, the program is stopped with an exit value of SIGTERM (15).

On Microsoft™ Windows® platforms, the function will be called in the following cases:

• The console window that the program was started from is closed.
• The current user session is terminated (i.e. the user logs off).
• The system is shut down.

Use the OPTIONS ON TERMINATE SIGNAL CALL function instruction with care, and do not execute complex code in the callback function. The code is expected to contain only simple and short cleanup operations; any interactive instruction must be avoided.

Front-end termination
The OPTIONS CLOSE APPLICATION instruction defines the callback function in case of front-end termination.

Syntax
OPTIONS ON CLOSE APPLICATION CALL function

Usage
The OPTIONS ON CLOSE APPLICATION CALL function can be used to execute specific code when the front-end stops. For example, when the front-end program is stopped, when the user workstation session is ended, or when the workstation is shut down.

Before stopping, the front-end sends an internal event that is trapped by the runtime system. When a callback function is specified with this program option command, the application code that was executing is canceled, and the callback function is executed before the program stops.

Use the OPTIONS ON CLOSE APPLICATION CALL function instruction with care, and do not execute complex code in the callback function. The code is expected to contain only simple and short cleanup operations; any interactive instruction must be avoided.

A front-end program crash or network failure is not detected and cannot be handled by this instruction.

Related concepts
GUI front-end connection on page 1017
This section explains runtime to front-end connection in its simplest form.

**Defining the message file**
The OPTIONS HELP FILE instruction defines the name of the message file.

**Syntax**

```
OPTIONS HELP FILE filename
```

**Usage**
The OPTIONS HELP FILE instruction specifies an expression that returns the file name of a help file. This file name can also include a path name. Messages in this file can be referenced by number in form-related statements, and are displayed at runtime when the user presses the Help key.

Message files are found in the directories as described in the FGLRESOURCEPATH reference topic.

**Related concepts**
Message files on page 1059

Message files centralize strings and larger texts identified by a number, that can be used in programs.

**Defining control keys**
The OPTIONS action KEY instruction defines physical keys for common dialog actions.

**Syntax**

```
OPTIONS
  INSERT KEY key-name
  DELETE KEY key-name
  NEXT KEY key-name
  PREVIOUS KEY key-name
  ACCEPT KEY key-name
  HELP KEY key-name
```

**Usage**

This OPTIONS clause can specify physical keys to support logical key functions in the interactive instructions.

The physical key definition options are only provided for backward compatibility with the TUI mode. Use the action defaults configuration to define accelerator keys for actions.

Description of the keys:

- The ACCEPT KEY specifies the key that validates a CONSTRUCT, INPUT, DIALOG, INPUT ARRAY, or DISPLAY ARRAY statement.
  - The default ACCEPT KEY is ESCAPE.
- The DELETE KEY specifies the key in INPUT ARRAY statements that deletes a screen record.
  - The default DELETE KEY is F2.
- The INSERT KEY specifies the key that opens a screen record for data entry in INPUT ARRAY.
  - The default INSERT KEY is F1.
- The NEXT KEY specifies the key that scrolls to the next page of a program array of records in an INPUT ARRAY or DISPLAY ARRAY statement.
  - The default NEXT KEY is F3.
- The PREVIOUS KEY specifies the key that scrolls to the previous page of program records in an INPUT ARRAY or DISPLAY ARRAY statement.
The default `PREVIOUS` key is F4.

- The `HELP` key specifies the key to display help messages.

  The default `HELP` key is `CONTROL-W`.

You can specify the following keywords for the physical key names:

**Table 143: Keywords for physical key names**

<table>
<thead>
<tr>
<th>Key Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESC or ESCAPE</td>
<td>The ESC key (not recommended, use ACCEPT instead).</td>
</tr>
<tr>
<td>INTERRUPT</td>
<td>The interruption key (on UNIX™, interruption signal).</td>
</tr>
<tr>
<td>TAB</td>
<td>The TAB key (not recommended).</td>
</tr>
<tr>
<td>CONTROL-char</td>

- Multiple dialogs (DIALOG - inside functions) on page 1481
  The procedural DIALOG instruction allows for the combination of record list, record input, and query criteria input in the same application form.
- Parallel dialogs (START DIALOG) on page 1600
  The START DIALOG and TERMINATE DIALOG instructions provide dialogs functionality executing concurrently in different application forms.
- Record input (INPUT) on page 1373
  The INPUT instruction provides single record input control in an application form.
- Editable record list (INPUT ARRAY) on page 1425
  The INPUT ARRAY instruction provides always-editable record list handling in an application form.
- Record list (DISPLAY ARRAY) on page 1394
  The DISPLAY ARRAY instruction provides record list navigation in an application form, with optional record modification actions.
- Configuring actions on page 1646
Action attributes related to decoration, keyboard shortcuts, and behavior can be defined with *action attributes*.

### Setting default screen modes for sub-programs

The `OPTIONS RUN IN` instruction defines the TTY mode to run sub-programs.

**Syntax**

```
OPTIONS RUN IN FORM|LINE_MODE
```

**Usage**

When using character terminals, the runtime system recognizes two screen display modes: line mode (`IN LINE MODE`) and formatted mode (`IN FORM MODE`). The `OPTIONS` and `RUN` statements can explicitly specify a screen mode. The `OPTIONS` statement can set separate defaults for these statements.

After `IN LINE MODE` is specified, the terminal is in the same state (in terms of `stty` options) as when the program began. This usually means that the terminal input is in cooked mode, with interruption enabled, and input not available until after a newline character has been typed.

The `IN FORM MODE` keywords specify raw mode, in which each character of input becomes available to the program as it is typed or read.

By default, a program operates in line mode, but so many statements take it into formatted mode (including `OPTIONS` statements that set keys, `DISPLAY`, `OPEN WINDOW`, `DISPLAY FORM`, and other screen interaction statements), that typical programs are actually in formatted mode most of the time.

When the `OPTIONS` statement specifies `RUN IN FORM MODE`, the program remains in formatted mode if it currently is in formatted mode, but it does not enter formatted mode if it is currently in line mode.

When the `OPTIONS` statement specifies `RUN IN LINE MODE`, the program remains in line mode if it is currently in line mode, and it switches to line mode if it is currently in formatted mode.

**Related concepts**

- **DISPLAY BY NAME** on page 1348
  The `DISPLAY BY NAME` instruction displays data to form fields explicitly *by name*.
- **OPEN WINDOW** on page 1034
  Creates and displays a new window.
- **DISPLAY FORM** on page 1044
  Displays and associates a form with the current window.

### Enabling/disabling SQL interruption

The `OPTIONS SQL INTERRUPT` instruction enables or disables SQL statement interruption.

**Syntax**

```
OPTIONS SQL INTERRUPT ON OFF
```

**Usage**

The `OPTIONS SQL INTERRUPT` instruction controls interruption event detection during the execution of long running SQL statements.

By default, SQL interruption is off.

Pay attention to the fact that not all database servers support SQL interruption.

Depending on the type of database server and client, SQL interruption handling may require additional overhead. Consider enabling SQL interruption only for SQL queries that can take a while to execute or can be blocked for a long time because of concurrent access (locks).
If an SQL statement is interrupted, SQLCA.SQLCODE is set to -213 and the runtime system raises an error. Use a TRY/CATCH block or WHENEVER ERROR CONTINUE to trap this SQL error.

Example

```plsql
MAIN
  DEFINE cnt INTEGER
  DEFER INTERRUPT -- Do not stop if interrupt signal is caught
  CONNECT TO "mydb"
  WHENEVER ERROR CONTINUE -- Continue in case of SQL interrupt error
  OPTIONS SQL INTERRUPT ON -- Enable SQL interruption
  SELECT COUNT(*) INTO cnt FROM stock -- Long running query
  OPTIONS SQL INTERRUPT OFF -- Disable SQL interruption
  WHENEVER ERROR STOP -- Reset default exception handler
  IF SQLCA.SQLCODE == -213 THEN
    DISPLAY "SQL Statement interrupted by user"
  END IF
END MAIN
```

Related concepts

Interrupt long running SQL queries, or interrupt queries waiting for locked data.

Runtime configuration in FGLPROFILE

The behavior of the runtime system can be controlled with FGLPROFILE configuration parameters.

- Responding to CTRL_LOGOFF_EVENT on page 515

Responding to CTRL_LOGOFF_EVENT

FGLPROFILE fglrun.ignoreLogoffEvent controls program behavior in case of logoff events on Windows™ platforms.

Syntax

```plaintext
fglr.run.ignoreLogoffEvent = true
```

Usage

On Windows™ platforms, when the user disconnects, the system sends a CTRL_LOGOFF_EVENT event to all console applications. When the runtime system receives this event, it stops immediately.

On a Windows™ Terminal Server, if an Administrator user closes his session, a CTRL_LOGOFF_EVENT is sent to all console applications started by ANY user connected to the machine (even if these applications were not started by the administrator).

To prevent the runtime system from stopping on a logoff event, you can use the fglrun.ignoreLogoffEvent entry in the FGLPROFILE configuration file. If this entry is set to true, the CTRL_LOGOFF_EVENT event is ignored by the runtime system.

As a result, when the administrator user disconnects on a Windows™ Terminal Server, programs started by remote users would not stop.

Related concepts

The FGLPROFILE file(s) on page 220
FGLPROFILE environment variable defines Genero BDL configuration files

**DEFER INTERRUPT / QUIT**
The DEFER instruction defines the program behavior when interruption or quit signals are received.

**Syntax**

```
DEFER { INTERRUPT | QUIT }
```

**Usage**
The DEFER instruction controls the behavior of the program when an interruption or quit signal has been received. DEFER INTERRUPT and DEFER QUIT instructions should only be used in the MAIN block, to be executed at the beginning of the program.

DEFER INTERRUPT indicates that the program must continue when it receives an interrupt signal. By default, the program stops when it receives an interrupt signal.

Once deferred, you cannot reset to the default behavior.

When an interrupt signal is caught by the runtime system and DEFER INTERRUPT is used, the INT_FLAG global variable is set to true by the runtime system.

Interrupt signals are raised on terminal consoles when the user presses a key like CTRL-C, depending on the stty configuration. When a program is displayed through a front end, no terminal console is used; therefore, users cannot send interrupt signals with the CTRL-C key. To send an interruption request from the front end, you must define an ‘interrupt’ action view.

DEFER QUIT indicates that the program must continue when it receives a quit signal. By default, the program stops when it receives a quit signal.

When a quit signal is caught by the runtime system and DEFER QUIT is used, the QUIT_FLAG global variable is set to true by the runtime system.

**Related concepts**

Allow the end user to cancel the execution of a procedure in the program.

**Program registers**
Predefined global registers can be used in programs to detect errors, signals and events.

- STATUS on page 517
- INT_FLAG on page 518
- QUIT_FLAG on page 519
**STATUS**

STATUS is a predefined variable that contains the execution status of the last instruction.

**Syntax**

```sql
STATUS
```

**Usage**

STATUS is a predefined variable that contains the execution status of the last program instruction. STATUS allows diagnostic information about procedural, interactive, and SQL instructions to be obtained.

The data type of STATUS is INTEGER.

**Note:** While STATUS can be modified by hand, it is not recommended except in specific situations as shown in the STATUS example.

STATUS is typically used with WHENEVER ERROR CONTINUE or WHENEVER ERROR CALL, or TRY/CATCH blocks, to identify the type of error that occurred.

STATUS will be set for expression evaluation errors only when WHENEVER ANY ERROR is used.

After an SQL statement execution, STATUS contains the value of SQLCA.SQLCODE.

STATUS is set to an error code when an instruction produces an error, or it is reset to zero when non-assignment instructions succeed. A typical mistake is to test STATUS after a DISPLAY STATUS instruction, written after an SQL statement:

```sql
WHENEVER ERROR CONTINUE
DELETE FROM _invalid_table_name_ where col = 1
WHENEVER ERROR STOP
DISPLAY "STATUS:", STATUS  -- this DISPLAY instruction reset STATUS to zero
IF STATUS<0 THEN        -- Will never be the case, since STATUS==0
   DISPLAY "SQL Error!"
   EXIT PROGRAM 1
END IF
```

**Tip:** Use SQLCA.SQLCODE for SQL error detection, and use STATUS for other language instructions.

**Example**

```sql
MAIN
   DISPLAY is_number(NULL)
   DISPLAY is_number("abc")
   DISPLAY is_number("-12.45")
END MAIN

FUNCTION is_number(s)
   DEFINE s STRING
   DEFINE f FLOAT, l_status INTEGER
   IF length(s)==0 THEN
      RETURN FALSE
   END IF
   WHENEVER ANY ERROR CONTINUE
   LET STATUS=0 # Needed, as STATUS won't be set if succeeds
   LET f = s
   LET l_status = STATUS
   WHENEVER ANY ERROR CONTINUE
   IF l_status == 0 THEN
      RETURN TRUE
   ELSE
      RETURN FALSE
   END IF
END FUNCTION
```
END IF
END FUNCTION

The SQLCA diagnostic record on page 532
The SQLCA variable is a predefined record containing SQL statement execution information.

WHENEVER instruction on page 452
Use the WHENEVER instruction to define how exceptions must be handled for the rest of the module.

INT_FLAG
INT_FLAG is a predefined variable set to TRUE when an interruption event is detected.

Syntax

```
INT_FLAG
```

Usage

INT_FLAG is set to TRUE by the runtime system when an interruption event is detected by the runtime system. The interruption event is raised when the user presses the interruption key, or when the graphical front-end sends an interruption event while the program is running in a procedure or SQL query.

INT_FLAG must be used with the DEFER INTERRUPT configuration instruction. If the DEFER INTERRUPT instruction is not specified, and interruption signal will stop the program execution.

When an interruption event occurs during a procedural instruction (FOR loop), the runtime system sets INT_FLAG to TRUE. It is up to the program to check the INT_FLAG variable.

When an interruption event occurs during an interactive instruction (INPUT, CONSTRUCT), the runtime system sets INT_FLAG to TRUE and exits from the interactive instruction. It is recommended that you test INT_FLAG after an interactive instruction to check whether the input has been canceled.

Once INT_FLAG is set to TRUE, it must be reset to FALSE in order to detect a new interruption event.

INT_FLAG will also be used by the runtime system as diagnostic flag for predefined action block execution such as ON INSERT in DISPLAY ARRAY.

Example

```
MAIN
  DEFER INTERRUPT
  LET INT_FLAG = FALSE
  INPUT BY NAME ...
    AFTER INPUT
      IF INT_FLAG THEN
        MESSAGE "The input is canceled."
      END IF
    ...
  END INPUT
  ...
END MAIN
```

Related concepts

DEFER INTERRUPT / QUIT on page 516
The DEFER instruction defines the program behavior when interruption or quit signals are received.

TRUE on page 503
TRUE is a predefined constant to be used in boolean expressions.

**QUIT_FLAG**
QUIT_FLAG is a predefined variable set to TRUE when a quit event is detected.

### Syntax

```
QUIT_FLAG
```

### Usage

QUIT_FLAG is set to TRUE when a quit event is detected by the runtime system. The quit event is raised when the user presses the quit signal key ([Ctrl]+[Backslash]), or when another process sends the quit signal to the runtime system.

QUIT_FLAG must be used with the DEFER QUIT configuration instruction. If the DEFER QUIT instruction is not specified, and quit signal will stop the program execution.

When the quit event arrives during a procedural instruction (FOR loop), the runtime system sets QUIT_FLAG to TRUE and continues the program execution. It is up to the program to check the QUIT_FLAG variable.

When the quit event arrives during an interactive instruction (INPUT, CONSTRUCT), the runtime system sets QUIT_FLAG to TRUE and continues with the execution of the interactive instruction.

Once QUIT_FLAG is set to TRUE, it must be reset to FALSE to detect a new quit event.

### Example

```
MAIN
  DEFINE n INTEGER
  DEFER QUIT
  LET QUIT_FLAG = FALSE
  FOR n = 1 TO 1000
    IF QUIT_FLAG THEN EXIT FOR END IF
    ...
  END FOR
END MAIN
```

### Program execution

This section describes program execution and language instructions related to program execution.

- Executing programs on page 520
- RUN on page 521
- EXIT PROGRAM on page 524
- BREAKPOINT on page 524
Executing programs

There are different ways to execute compiled programs, depending on the configuration and the development or production context.

Prerequisites before executing a program

Make sure that all required environment variables are properly defined, such as: FGLPROFILE on page 243, FGLGUI on page 240, FGLSERVER on page 245, FGLLDPATH on page 243, LC_ALL (or LANG) on page 228.

To display program forms in graphical mode, the GUI front-end must run on the computer defined by FGLSERVER, and all network security components (such as firewalls) must allow TCP connections on the port defined by this environment variable.

Verify the database client environment settings, and check that the database server is running and can be accessed, for example by using a database vendor specific tool to execute SQL commands.

Starting a program from the command line on the server

A program can be executed with the fglrun tool from the server command line:

```
fglrun myprogram
```

This method is typically used in development context. After compiling the programs and forms, for example with the make utility, execute the programs with fglrun.

Note: The file extension (.42m or .42r) can be omitted. If no file extension is specified, fglrun will try to load progname.42r, then progname.42m.

Executing sub-programs from a parent program with RUN

Sub-programs can be executed from the main program with the RUN instruction. There can be limitations, depending on the platform where the parent program executes.

Starting a program from the front-end

It is also possible to start programs on the application server from the platform where the front-end resides.

This is actually the typical way to start applications in a production environment.

- For a desktop front-end (GDC) application, define application shortcuts and use rlogin/ssh network protocols to start programs on the server or by using HTTP through a web server (GAS).
- For a web-browser application (GBC), configure the application server (GAS) to run applications from an URL.
- For a mobile device application (GMI/GMA), in a configuration where the programs run on a GAS application server, use the "runOnServer" front call, to start a program from the GAS.

Starting programs on a mobile device

After deploying program files on a mobile device, it can be executed as a local application, typically with a tap on the application icon.

- For a GMA (Android™) application, program files and GMA must be bundled together in an .apk Android™ package to be deployed. For more details, see Deploying mobile apps on Android devices on page 3315.
- For a GMI (iOS) application, program files and GMI must be bundled together in an .ipa package to be deployed. For more details, see Deploying mobile apps on iOS devices on page 3330.
- To start programs on an application server from a small embedded mobile application (starter), use the runOnServer front call. For more details, see Running mobile apps on an application server on page 3342.
Mobile app foreground and background modes

On mobile devices, apps can switch between the foreground and background mode.
The app state can be detected and managed in your Genero program code.
For more details, Background/foreground modes on page 3299.

Common app directories on mobile platforms

On mobile devices, you can use the following APIs to get common directories:

1. `base.Application.getProgramDir` on page 2270 returns the directory path where the main .42m is located. Consider this location read-only and safe (no other app can access it).
2. `os.Path.pwd` on page 2653 returns the path to the current working directory. When a mobile application is started, the GMA and the GMI set the working directory to the default application directory. Consider this location read-write and safe (no other app can access it).
3. The front call `standard.feInfo/dataDirectory` returns the front-end side temporary directory. Storage on this directory may be erased by the OS. On an embedded mobile application, as the runtime and the front-end run on the same system, the program can use this front call to retrieve a temporary directory and use the path to store temporary files. Consider this location read-write and unsafe. Applications executed remotely through a `runOnServer` front call, can use the `sandboxRunOnServer` directory under the directory returned by the `feInfo/dataDirectory` front call, to exchange files with the embedded application.

RUN

The RUN instruction executes the command passed as argument.

Syntax

```
RUN command
    \ IN \{FORM|LINE\} \ MODE \]
    \ RETURNING \variable \ WITHOUT \ WAITING \]
```

1. `command` is a string expression with the command to be executed.
2. `variable` is an integer variable receiving the execution status of the command.

Understanding the RUN command

The RUN instruction hands the argument command to the command interpreter. When not specifying the WITHOUT WAITING clause, the calling process waits for the called process to finish execution. Otherwise, the calling process waits the command termination.

Important: The RUN instruction has limited support on mobile platforms.

- The RUN instruction is not supported on mobile devices, because of operating system limitations.
- RUN command WITHOUT WAITING is not supported when programs run on an application server and display on a mobile device, because the Genero GUI protocol is not able to handle multiple connections at the same time.

Defining the command execution shell

In order to execute the command line, the RUN instruction uses the OS-specific shell defined in the environment of the current user. On UNIX™, this is defined by the SHELL environment variable. On Windows®, this is defined
by COMSPEC. On Windows®, the program defined by the COMSPEC variable must support the /c option as CMD.EXE.

**Waiting for the subprocess**

By default, the runtime system waits for the end of the execution of the command, suspending the execution of the current program. After executing the command, the display of the parent program is restored.

If you specify WITHOUT WAITING, the specified command line is executed as a background process, and generally does not affect the visual display. This clause can be used when the command takes some time to execute, and the parent program does not need the result to continue. It is also typically used in GUI mode to start another program. Do not use this clause in TUI mode when the sub-program displays forms, otherwise both programs would run simultaneously on the same terminal.

**Catching the execution status**

The RETURNING clause saves the termination status code of the command that RUN executes in a program variable of type SMALLINT. Examine the variable after execution to determine the next action to take. A status code of zero usually indicates that the command has terminated normally. A non-zero exit status indicates an error.

**Important:**

The execution status provided by the RETURNING clause is platform-dependent. On UNIX™ systems, the value is composed of two bytes having different meanings. On Windows® platforms, the execution status is usually zero for success, not zero if an error occurred.

On UNIX™ systems, the lower byte (x mod 256) of the return status defines the termination status of the RUN command. The higher byte (x / 256) of the return status defines the execution status of the program. On Windows® systems, the value of the return status defines the execution status of the program.

**IN LINE MODE and IN FORM MODE**

When using the TUI mode, programs operate by default in line mode, but as many statements take it into form mode (including OPTIONS statements that set keys, DISPLAY, OPEN WINDOW, DISPLAY FORM>, and other screen interaction statements), typical interactive TUI programs are actually in form mode most of the time.

According to the type of command to be executed, you may need to use the IN {LINE | FORM} MODE clause with the RUN instruction. It defines how the terminal or the graphical front-end behaves when running the child process.

Besides RUN, the OPTIONS, START REPORT and REPORT statements can explicitly specify a screen mode. If no screen mode is specified in the RUN command, the current value from the OPTIONS statement is used. This is, by default, IN LINE MODE. The default screen mode for PIPE specifications in reports is IN FORM MODE.

When the RUN statement specifies IN FORM MODE, the program remains in form mode if it is currently in form mode, but it does not enter form mode if it is currently in line mode. When the prevailing RUN option specifies IN LINE MODE, the program remains in line mode if it is currently in line mode, and it switches to line mode if it is currently in form mode. This also applies to the PIPE option.

Typically, if you need to run another interactive program, you must use the IN LINE MODE clause:

- In TUI mode, the terminal is in the same state (in terms if tty options) as when the program began. Usually the terminal input is in cooked mode, with interrupts enabled and input not becoming available until after a newline character is typed.
- In GUI mode, if the WITHOUT WAITING clause is used, the front-end is warned before the child process is started (this causes a first network round-trip). After the child is started, the front-end is warned that the command was executed (second network round-trip). If the RUN command must wait for child termination (i.e. no WITHOUT WAITING clause is used), no particular action is taken.

However, if you want to execute a subprocess running silently (batch program without output), you must use the IN FORM MODE clause:
• In TUI mode, the screen stays in *form mode* if it was in *form mode*, which saves a clear / redraw of the screen. The *FORM mode* specifies the terminal raw mode, in which each character of input becomes available to the program as it is typed or read.

• In GUI mode, no particular action is taken to warn the front-end (there is no need to warn the front-end for batch program execution).

To summarize, no matter if you are in TUI or GUI mode, run silent (batch) programs in FORM MODE, and if the program to run is interactive, or displays messages to the terminal, or if you don't known what it does, use the LINE MODE (which is the default).

A good practice is to encapsulate child program and system command execution in functions.

**Example**

```main
MAIN
    DEFINE result SMALLINT
    CALL runApplication("app2 -p xxx")
    CALL runBatch("ls -l", FALSE) RETURNING result
    CALL runBatch("ls -l > /tmp/files", TRUE) RETURNING result
END MAIN

FUNCTION runApplication(pname)
    DEFINE pname, cmd STRING
    LET cmd = "fglrun " || pname
    IF fgl_getenv("FGLGUI") == 0 THEN
        RUN cmd
    ELSE
        RUN cmd WITHOUT WAITING
    END IF
END FUNCTION

FUNCTION runBatch(cmd, silent)
    DEFINE cmd STRING
    DEFINE silent STRING
    DEFINE result SMALLINT
    IF silent THEN
        RUN cmd IN FORM MODE RETURNING result
    ELSE
        RUN cmd IN LINE MODE RETURNING result
    END IF
    IF fgl_getenv("OS") MATCHES "Win*" THEN
        RETURN result
    ELSE
        RETURN ( result / 256 )
    END IF
END FUNCTION
```

  The OPTIONS instruction inside program blocks controls program behavior at runtime.

- **DISPLAY TO** on page 1346
  The DISPLAY TO instruction displays data to form fields explicitly.

- **OPEN WINDOW** on page 1034
EXIT PROGRAM

The **EXIT PROGRAM** instruction terminates the execution of the program.

**Syntax**

```
EXIT PROGRAM [exit-code]
```

1. `exit-code` is a valid integer expression that can be read by the process which invoked the program.

**Usage**

Use the **EXIT PROGRAM** instruction to stop the execution of the current program instance.

`exit-code` must be zero by default for normal, successful program termination.

`exit-code` is converted into a positive integer between 0 and 255 (8 bits).

**Example**

```
MAIN
  DISPLAY "Emergency exit."
  EXIT PROGRAM -1
  DISPLAY "This will never be displayed."
END MAIN
```

**Related concepts**

**RUN** on page 521

The **RUN** instruction executes the command passed as argument.

**The MAIN block / function** on page 493

The **MAIN** block is the starting point of the program.

BREAKPOINT

The **BREAKPOINT** instruction sets a program breakpoint when running in debug mode.

**Syntax**

```
BREAKPOINT
```

**Usage**

Normally, to set a breakpoint when you debug a program, you must use the `break` command of the debugger. But in some situations, you might need to set the breakpoint in program sources. Therefore, the **BREAKPOINT** instruction has been added to the language.

When you start **fglr** in debug mode with the `-d` option, if the program flow encounters a **BREAKPOINT** instruction, the program execution stops and the debug prompt is displayed, to let you enter a debugger command. The **BREAKPOINT** instruction is ignored when not running in debug mode.

**Example**

```
MAIN
```
DEFINE i INTEGER
LET i=123
BREAKPOINT
DISPLAY i
END MAIN

Front calls
Front call functions execute on the platform where the front-end is installed.

- Understanding front calls on page 525
- ui.Interface.frontCall on page 526
- User-defined front calls on page 528

Related concepts
Built-in front calls on page 2485
This section contains the description of all built-in front calls.

User-defined front calls on page 2129
Front-ends can be extended with custom functions to access specific features.

Understanding front calls
Front calls execute a native function on the front-end platform.

In your Genero program, use the ui.Interface.frontCall() class method to invoke front-end functions. When calling a user function from programs, specify a module name and a function name. Input and output parameters can be passed/returned in order to transmit/receive values to/from the front-end. A typical example is an "open file" dialog window that allows you to select a file from the front-end workstation file system.

Important: Front calls can be specific to the platform or front-end technology and may not be supported. For example, it is not possible to execute a shell command (shellexec) with the Web Browser front-end.

A set of front-end functions is built-in by default in front-ends. However, it is possible to write your own functions in order to extend the front-end possibilities.

Tip: While you can use DDE/OLE APIs to manipulate Microsoft™ Office documents, there are freeware alternatives such as the Apache POI Java library which can be used with the Java Interface. For an example, see Java Interface: Example 2.

Related concepts
The abstract user interface tree on page 1010
The abstract user interface tree is the XML representation of the application forms displayed to the end user.

**ui.Interface.frontCall**

ui.Interface.frontCall performs a function call to the current front-end.

**Syntax**

```
ui.Interface.frontCall(
    moduleName STRING,
    functionName STRING,
    [ valueList ],
    [ variableList ]
)
```

1. `moduleName` defines the shared library or classpath where the function is implemented.
2. `functionName` defines the name of the function to be called.
3. `valueList` is a list of input parameters.
4. `variableList` is a list of output parameters.

**Important:** The variables are passed by reference to the `frontCall()` method.

**Usage**

The `ui.Interface.frontCall()` class method can be used to execute a procedure on the front-end workstation through the front-end software component. You can for example launch a front-end specific application like a browser or a text editor, or manage the clipboard content.

**Important:** When calling the `ui.Interface.frontCall()` method, the connection to the front-end is initiated, if it is not yet established. Consider avoiding front calls in batch programs and interactive programs using the `text mode`. This is also important to consider in `graphical mode`, if no interactive instruction was issued before the front call.

The method takes four parameters:

1. The module, identifying the shared library (`.so` or `.DLL`) or the Java class (GMA) implementing the front call function.
2. The function of the module to be executed.
3. The list of input parameters, using the square brace notation.
4. The list of output parameters, using the square brace notation.

Input and output parameters are provided as a variable list of parameters, by using the square brackets notation `([param1,param2,...])`:

- Input and output parameters can be of any simple type like `INTEGER`, a `RECORD` or a `DYNAMIC ARRAY`.
- An empty list of input or output parameters is specified with `[]`.
- Input parameters can be an expression such as `(10 * var)`.
- Output parameters must be variables only, to receive the returning values.
- Output parameters are optional. If the front call returns values, these values will be ignored by the runtime system, if no output parameters are provided to receive these values.

Simple front call example:

```
FUNCTION call()
    DEFINE info STRING
    CALL ui.Interface.frontCall( "standard", "feInfo", ["feName"], [info] )
END FUNCTION
```
Some front calls need a file path as parameter. File paths must follow the syntax of the front end workstation file system. You may need to escape backslash characters in such parameters. The following example shows how to pass a file path with a space in a directory name to a front-end running on a Microsoft™ Windows® workstation:

```plaintext
FUNCTION call()
    DEFINE path STRING, res INTEGER
    LET path = "\"c:\work dir\my report.doc\"
    -- This is: "c:\work dir\my report.doc"
    CALL ui.Interface.frontCall( "standard", "shellExec", [path], [res] )
END FUNCTION
```

When using RECORD and DYNAMIC ARRAY as front call input or output parameters, the runtime system will use JSON serialization, to pass and return such structured data to/from the front-end. This is important to know when implementing your own custom front calls. Note that one can use the json_null and json_name variable definition attributes to control JSON serialization:

```plaintext
DEFINE optrec RECORD
    mode INTEGER ATTRIBUTES(json_null="null"),
    filter STRING ATTRIBUTES(json_name="Data Filter")
END RECORD
DEFINE flags DYNAMIC ARRAY OF INTEGER ATTRIBUTES(json_null="undefined")
DEFINE result_list DYNAMIC ARRAY OF STRING
LET optrec.mode = 999
LET optrec.filter = "*A*"
LET flags[1] = 111
LET flags[3] = 333
CALL ui.Interface.frontCall( "m1", "fc1", [optrec, flags], [result_list] )
```

**Front call cost**

A front call is a remote procedure call requiring a full network round trip between the server app and the front end. Depending on the current network speed, this may result in delays in the millisecond to sub second range.

**Note:** In mobile application development or runOnServer mode, the execution time of a front can be much slower when running the app on the server, compared to embedded apps.

**Front call error handling**

Exception handling instructions can be used to check the execution status of a front call. Both WHENEVER ERROR directives or TRY/CATCH blocks can surround the front call to avoid program stopping in case of error, and to check the error number returned in the STATUS variable.

**Note:** There is no need to surround front calls with exception handlers such as TRY/CATCH, if the front call is always supposed to execute without error. For example, the feInfo front call will never produce an exception.

Example of front call error handling with a TRY/CATCH block:

```plaintext
FUNCTION takePhoto()
    DEFINE path STRING
    TRY -- This front call may fail if the front-end is not a mobile device:
        CALL ui.Interface.frontCall( "mobile", "takePhoto", [], [path] )
    CATCH
        MESSAGE "Cannot take photo: ", STATUS, " ", err_get(STATUS)
        LET path = NULL
    END TRY
    RETURN path
END FUNCTION
```

If the front call module name or the function name is invalid, the errors -6331 or -6332 will be raised, respectively.
If the front call execution fails for some reason, the error -6333 will be raised. The description of the problem can be found in the second part of the error message, returned by a call to the ERR_GET() function.

The error -6334 can be raised in case of input or output parameter mismatch. The control of the number of input and output parameters is in the hands of the front-end. Most of the standard front calls have optional returning parameters and will not raise error -6334, if the output parameter list is left empty. However, front-end specific extensions or user-defined front-end functions may return an invalid execution status in case of input or output parameter mismatch, raising error -6334. If the front-end sends a call execution status of zero (OK), and the number of returned values does not match the number of program variables, the runtime system will set unmatched program variables to NULL. As a general rule, it is recommended that the program provides the expected input and output parameters as specified in the documentation.

**Related concepts**

- *Front calls* on page 525
  
  Front call functions execute on the platform where the front-end is installed.

**User-defined front calls**

Extend the Genero language possibilities by implementing your own front-end functions.

For more details, see *User-defined front calls* on page 2129.

**SQL programming**

Covers topics about interacting with a database server using SQL.

- SQL basics on page 528
- SQL security on page 543
- SQL portability on page 545
- SQL performance on page 595

**SQL basics**

This section contains fundamental information to know about SQL programming with Genero BDL.

- Database and application locales on page 529
- SQL execution diagnostics on page 529
- The SQLCA diagnostic record on page 532
- SQL error identification on page 533
- Cursors and connections on page 536
**Database and application locales**

Choose the right locale for your database and application programs.

When designing a database and the application programs that connect to this database, it is important to consider what character set will be used in the database server, and the character set used by application programs.

Most database servers support character set conversion options, thus it is possible to have different configurations, for example:

1. Database uses ISO8859-1, application programs use ISO8859-1
2. Database uses UTF-8, application programs use ISO8859-1
3. Database uses UTF-8, application programs use UTF-8

**Important:** The locale definition of the database client software must match the application locale defined for Genero. For more details, see Database client settings on page 419.

Consider also the length semantics to be used (is CHAR(10) 10 bytes or 10 characters?).

For a detailed discussion about character sets and length semantics, see CHAR and VARCHAR types on page 555.

**Related concepts**

Application locale on page 405

The application locale defines the language and codeset for your application.

**SQL execution diagnostics**

If an SQL statement execution fails, error description can be found in the SQLCA.SQLCODE, SQLSTATE, STATUS and SQLERRMESSAGE predefined registers.

**Trapping SQL errors**

By default, SQL errors stop program execution and display the error message to the standard output. Most SQL statements executed by a program should not return an error and thus do not require error trapping. However, in some cases, a program must keep the control when an SQL error occurs. For example, when connecting to the database, the user might enter an invalid password that will raise a login denied error. The program must trap such SQL connection error in order to return to the login dialog and let the user enter a new login and password.

To trap potential SQL errors, surround the SQL statements to be checked either with a WHENEVER ERROR exception handler or with a TRY / CATCH block:

```sql
-- WHENEVER ERROR handler
WHENEVER ERROR CONTINUE
   INSERT INTO orders VALUES ( rec_ord. * )
IF SQLCA.SQLCODE = -75623 THEN
   ...
END IF
WHENEVER ERROR STOP -- restore the default

-- TRY / CATCH block
TRY
   INSERT INTO orders VALUES ( rec_ord. * )
CATCH
   IF SQLCA.SQLCODE = -75623 THEN
      ...
END IF
```
Using SQLCA.SQLCODE

SQL error codes are provided in the SQLCA.SQLCODE register. This register always contains an IBM® Informix® error code, even when connected to a database that is different from IBM® Informix®.

STATUS is the global error code register that can be set for any kind of error (even non-SQL). When an SQL error occurs, both SQLCA.SQLCODE and STATUS hold the SQL error code.

Use SQLCA.SQLCODE for SQL error management, and use STATUS to detect errors with other language instructions.

When connecting to a database that is different from IBM® Informix®, the database driver tries to convert the native SQL error to an IBM® Informix® error which will be copied into the SQLCA.SQLCODE and STATUS registers. If the native SQL error cannot be converted, SQLCA.SQLCODE and STATUS will be set to -6372 (a general SQL error). You can then check the native SQL error in SQLCA.SQLERRD[2]. The native SQL error code is always available in SQLCA.SQLERRD[2], even if it cannot be converted to an IBM® Informix® error.

Using SQLSTATE

SQLSTATE is a register that contains an error code following ISO standards. However, not all database servers support this standard. Preferably use SQLSTATE for SQL error checking, as long as the target databases support this feature.

Note: The SQLSTATE codes are defined by the ISO standards. However, not all database types support this standard.

Table 144: SQLSTATE error codes supported per database server type

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>Supports SQLSTATE errors</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW (UNIX™)</td>

</tr>
<tr>
<td>PostgreSQL</td>
<td>Yes, since version 7.4</td>
</tr>
<tr>
<td>SAP® ASE</td>
<td>Yes</td>
</tr>
<tr>
<td>SAP HANA®</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Centralize SQL error checking

SQL error identification sometimes requires complex code to check several RDBMS-specific error numbers. Therefore, it is strongly recommended that you centralize SQL error identification in a function. When needed, this allows you to write the RDBMS-specific code only once.

For maximum SQL portability, centralize SQL error checking in functions, to test either SQLCA.SQLCODE or SQLSTATE, depending on the database server type. Furthermore, consider defining error identifiers with constants:

```sql
CONSTANT SQLERR_INVALID_DATABASE = -1001,
       SQLERR_INVALID_USER = -1002,
...

FUNCTION do_connect()
```
DEFINE uname, upswd VARCHAR(100)
WHILE TRUE
    CALL login() RETURNING uname, upswd
    TRY
        CONNECT TO "stores" USER uname USING upswd
        CATCH
            CASE check_sql_error()
                WHEN SQLERR_INVALID_DATABASE
                    DISPLAY SQLERRMESSAGE
                    EXIT PROGRAM 1 -- Fatal error: Stop!
                WHEN SQLERR_INVALID_USER
                    ERROR "Invalid login, try again"
                    CONTINUE WHILE
            END CASE
        END TRY
    EXIT WHILE
END WHILE
END FUNCTION

SQL error messages

SQLERRMESSAGE is a register that contains the database-specific error message. These messages are different for every database type. Only use SQLERRMESSAGE to print or log SQL execution diagnostics.

SQL warnings

Some SQL instructions can produce SQL warnings. Unlike SQL errors, SQL warnings indicate a minor issue that can often be ignored. For example, when connecting to an IBM® Informix® database, a warning is returned to indicate that a database connection was opened. Another warning may also be returned if the database supports transactions. None of these facts are critical, but that information may help with program execution.

If an SQL warning is raised, SQLCA.SQLCODE/STATUS remain zero, and the program flow continues. To detect if an SQL warning has occurred, the SQLCA.SQLAWARN register must be checked. SQLCA.SQLAWARN is defined as a CHAR(7) variable. If SQLCA.SQLAWARN[1] contains the W letter, it means that the last SQL instruction returned a warning. The other character positions (SQLCA.SQLAWARN[2-8]) may contain W letters too, depending on the database server type and the type of SQL instruction that was executed.

If SQLCA.SQLAWARN is set, you can also check the SQLSTATE and SQLCA.SQLERRD[2] registers to get more details about the warning. The SQLERRMESSAGE register might also contain the warning description.

In this example, the program connects to a database and displays the content of the SQLCA.SQLAWARN register:

```
MAIN
    DATABASE stores
    DISPLAY "[", sqlca.sqlawarn, "]"
END MAIN
```

When connecting to an IBM® Informix® database with transactions, the program will display the following:

```
[WW W ]
```

By default, SQL warnings do not stop the program execution. To trap SQL warnings with an exception handler, use the WHENEVER WARNING instruction, as shown in this example:

```
MAIN
    DEFINE cust_name VARCHAR(50)
    DATABASE stores
    WHENEVER WARNING STOP
    SELECT cust_lname, cust_address INTO cust_name
        FROM customer WHERE cust_id = 101
    WHENEVER WARNING CONTINUE
```
The `SELECT` statement in the above example uses two columns in the select list, while only one INTO variable is provided. This is legal and does not raise an SQL error. However, `SQLCA.SQLAWARN` is set to indicate that the number of target variables does not match the select-list items.

See also `WHENEVER WARNING` exception.

**Display detailed debug information in case of internal driver error**

If an unexpected problem happens within the database driver, it will return the error `-6319` (indicating an internal error in the database driver). When this SQL error occurs, set the `FGLSQLDEBUG` environment variable to get more details about the internal error.

**Related concepts**

- SQL error identification on page 533
  - Identify SQL exceptions in your programs with `SQLCA.SQLCODE`.
- `STATUS` on page 517
  - `STATUS` is a predefined variable that contains the execution status of the last instruction.
- The SQLCA diagnostic record on page 532
  - The `SQLCA` variable is a predefined record containing SQL statement execution information.
- `SQLSTATE` on page 326
  - The `SQLSTATE` variable returns the code corresponding to the last SQL error.
- `SQLERRMESSAGE` on page 327
  - The `SQLERRMESSAGE` variable holds the error message corresponding to the last SQL error.
- `FGLSQLDEBUG` on page 245
  - Defines the debug level for tracing SQL instructions.
- TRY - CATCH block on page 455
  - Use TRY / CATCH blocks to trap runtime exceptions in a delimited code block.

**The SQLCA diagnostic record**

The `SQLCA` variable is a predefined record containing SQL statement execution information.

**The SQLCA record definition**

The `SQLCA` record is defined as follows:

```
DEFINE SQLCA RECORD
  SQLCODE INTEGER,
  SQLERRM VARCHAR(71),
  SQLERRP CHAR(7),
  SQLERRD ARRAY[6] OF INTEGER,
  SQLAWARN CHAR(7)
END RECORD
```

1. `SQLCODE` contains the SQL execution code (`0 = OK, 100 = not row found, <0 = error`).
2. `SQLERRM` contains the error message parameter.
3. `SQLERRP` is not used at this time.
4. `SQLERRD[1]` is not used at this time.
5. `SQLERRD[2]` contains the last SERIAL or the native SQL error code.
6. `SQLERRD[3]` contains the number of rows processed in the last statement (server dependent).
9. `SQLERRD[6]` contains the ROWID of the last row that was processed (server dependent).
10. `SQLAWARN` contains the ANSI warning represented by a W character at a given position in the string.
11. SQLWARN[1] is set to W when any of the other warning characters have been set to W. 
12. SQLWARN[2–7] have specific meanings, see database server documentation for more details.

Usage
The "SQLCA" acronym stands for the SQL Communication Area variable.
The SQLCA record can be used to get an SQL execution diagnostic. Error and warning information can be found in this structure.
The SQLCA record is filled after each SQL statement execution.
SQLCA is not designed to be modified by user code. It must be used as a read-only record.

Portability
SQLCA.SQLCODE will be set to a specific IBM® Informix® SQL error code, provided that the database driver can convert the native SQL error to an IBM® Informix® SQL error. In case of error, SQLCA.SQLERRD[2] will hold the native SQL error produced by the database server.
Other SQLCA record members are specific to IBM® Informix® databases. For example, after inserting a row in a table with a SERIAL column, SQLCA.SQLERRD[2] will contain the new generated serial number. After an SQL error occurred, SQLCA.SQLERRD[2] will contain the native SQL error. Furthermore, the SQLCA.SQLERRD[3] member may be set with the number of processed rows, as long as the database client supports this feature. Other SQLCA.SQLERRD[n] members must be considered as non portable.

Example

```main
WHENEVER ERROR CONTINUE
  DATABASE stores
    SELECT COUNT(*) FROM foo   -- Table should not exist!
    DISPLAY SQLCA.SQLCODE, SQLCA.SQLERRD[2]
END MAIN
```

SQL error identification
Identify SQL exceptions in your programs with SQLCA.SQLCODE.
Every database type has its own set of error numbers. Portable SQL code must take care of this when checking for SQL errors in programs.
The IBM® Informix® compatible error code is stored in the SQLCA.SQLCODE register. This aims at simplifying migration to another database type. Existing code based on Informix® error numbers does not need to be modified.
Database drivers map native SQL errors to Informix® SQL errors, as listed in the following table:

</tbody>
</table>

Sometimes the native error code of the database cannot be converted to an Informix® error code. In such case, the SQLCA.SQLCODE register will be set to -6372. To properly identify an SQL error, the native SQL error code is also provided in the SQLCA.SQLERRD[2] register.

Centralize SQL error identification in a function:

```sql
-- sqlerr.4gl module
```
PUBLIC CONSTANT SQLERRTYPE_FATAL = -1
PUBLIC CONSTANT SQLERRTYPE_LOCK  = -2
PUBLIC CONSTANT SQLERRTYPE_CONN  = -3
PUBLIC CONSTANT SQLERRTYPE_UNDEF = -999

FUNCTION lastSqlErrorType()
    CASE
        WHEN SQLCA.SQLCODE == -201
            OR SQLCA.SQLERRD[2] == ...
            RETURN SQLERRTYPE_FATAL
        WHEN SQLCA.SQLCODE == -263
            OR SQLCA.SQLCODE == -244
            OR SQLCA.SQLERRD[2] == ...
            RETURN SQLERRTYPE_LOCK
        OTHERWISE
            RETURN SQLERRTYPE_UNDEF
    END CASE
END FUNCTION

Then you can then easily use this function after every SQL statement:

IMPORT FGL sqlerr
MAIN
    DATABASE stores
    WHENEVER ERROR CONTINUE
    UPDATE customer SET cust_address = NULL
        WHEN cust_name IS NULL
        IF lastSqlErrorType() == SQLERRTYPE_LOCK THEN
            ...
        END IF
    ...
END MAIN

Cursors and connections
How to use database cursors across connections?

Several database connections can be opened simultaneously with the CONNECT TO instruction. Once connected, you can DECLARE cursors or PREPARE statements to be used in parallel within different connection contexts. This section describes how to use SQL cursors and SQL statements in a multiple-connection program.

When you DECLARE a cursor or when you PREPARE a statement, you actually create an SQL statement handle; the runtime system allocates resources for that statement handle before sending the SQL text to the database server via the database driver.

The SQL statement handle is created in the context of the current connection, and must be used in that context, until it is freed or recreated with another DECLARE or PREPARE statement. Using an SQL statement handle in a different connection context than the one for which it was created will produce a runtime error.

The SET CONNECTION instruction changes the connection context. Connections are identified by a name. The AS clause of the CONNECT TO instruction allows you to specify a connection name. If the AS clause is omitted, the connection gets a default name based on the data source name.
This small program example illustrates the use of two cursors with two different connections:

```sql
MAIN
    CONNECT TO "db1" AS "s1"
    CONNECT TO "db2" AS "s2"
    SET CONNECTION "s1"
    DECLARE c1 CURSOR FOR SELECT tab1.* FROM tab1
    SET CONNECTION "s2"
    DECLARE c2 CURSOR FOR SELECT tab1.* FROM tab1
    SET CONNECTION "s1"
    OPEN c1
    SET CONNECTION "s2"
    OPEN c2
    ...
END MAIN
```

The `DECLARE` and `PREPARE` instructions are a type of creator instruction; if an SQL statement handle is recreated in a connection other than the original connection for which it was created, old resources are freed and new resources are allocated in the current connection context.

This allows you to re-execute the same cursor code in different connection contexts, as in this example:

```sql
MAIN
    CONNECT TO "db1" AS "s1"
    CONNECT TO "db2" AS "s2"
    SET CONNECTION "s1"
    IF checkForOrders() > 0 ... THEN
    SET CONNECTION "s2"
    IF checkForOrders() > 0 ... THEN
    ...
END MAIN

FUNCTION checkForOrders(d)
    DEFINE d DATE, i INTEGER
    DECLARE c1 CURSOR FOR SELECT COUNT(*) FROM orders WHERE ord_date = d
    OPEN c1
    FETCH c1 INTO i
    CLOSE c1
    FREE c1
    RETURN i
END FUNCTION
```

If the SQL statement handle was created in a different connection, the resources used in the old connection context are freed automatically, and new statement handle resources are allocated in the current connection context.

**Related concepts**

  Prepares an SQL statement for execution.

**Concurrent data access**

Understanding concurrent data access and data consistency.

*Data concurrency* is the simultaneous access of the same data by many users. On the other hand, *data consistency* means that each user sees a consistent view of the database. Without adequate concurrency and consistency controls, data may be changed improperly, compromising data integrity. To write inter-operable applications, you must adapt the program logic to the behavior of the database server regarding concurrency and consistency management. This
issue requires good knowledge of multiuser application programming, transactions, locking mechanisms, isolation
levels and wait mode. If you are not familiar with these concepts, carefully read the documentation of each database
server which covers this subject.

Processes accessing the database can change transaction parameters such as the isolation level. Existing programs
might have to be adapted in order to work with this new behavior.

The following is the best configuration to get common behavior with all types of database engines:

• The database must support transactions; this is usually the case.
• Transactions must be as short as possible (under a second is fine, 3 or more seconds is a long transaction).
• The isolation level should be set to COMMITTED READ or CURSOR STABILITY. IBM® Informix® IDS 11 has
  introduced the LAST COMMITTED option for the COMMITTED READ isolation level, which makes IDS behave
  like other database server using row-versioning, returning the most recently committed version of the row, rather
  than wait for a lock to be released. This option can also be turned on implicitly with the USELASTCOMMitted
  configuration parameter, saving code changes.
• The wait mode for locks must be WAIT or WAIT n (timeout). Wait mode can be adapted to wait for the longest
  transaction.

Remarks: With this configuration, the locking granularity does not have to be at the row level. To improve
performance with IBM® Informix® databases, you can use the LOCK MODE PAGE locking level, which is the
default. However, if the application requires row-level locking, you must use LOCK MODE ROW clause, or define the
DEF_TABLES_LOCKMODE configuration parameter to ROW, in the onconfig file of the server.

Related concepts
Database transactions on page 631
Database transaction concepts and handling.

Database transactions
Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

The BDL instructions to define a transaction block are:

• BEGIN WORK
• COMMIT WORK
• ROLLBACK WORK

Additional BDL instructions related to transaction management is available, such as SET LOCK MODE ..., SET
ISOLATION ..., SAVEPOINT, etc. For a complete description, see Database transactions on page 631
When performing a transaction instruction, the database drivers execute the corresponding native SQL instruction (or database client API call) to begin, commit or rollback a transaction.

In this example a basic transaction block executes inside a TRY/CATCH block to rollback the transaction in case of SQL error:

```
MAIN
    CONNECT TO ...
    TRY
        BEGIN WORK
        UPDATE tab1 SET col1 = 'aaa' WHERE pkey = 123
        UPDATE tab2 SET col2 = 'bbb' WHERE pkey = 456
        ...
        COMMIT WORK
    CATCH
        ROLLBACK WORK
    END TRY
END MAIN
```

  Commit database changes by blocks of transaction speeds performance with some database servers.

- **TRY - CATCH block** on page 455
  Use TRY / CATCH blocks to trap runtime exceptions in a delimited code block.

**Using SQL interruption**

Interrupt long running SQL queries, or interrupt queries waiting for locked data.

If the database server supports SQL interruption, a program can interrupt a long running SQL statement.

SQL interruption is not enabled by default. Use the `OPTIONS SQL INTERRUPT ON` instruction to enable SQL interruption.

**Note:** The `OPTIONS SQL INTERRUPT ON` instruction must be used together with signal handling instructions `DEFER INTERRUPT` and `DEFER QUIT`, otherwise the program will stop immediately in case of an interruption event.

When the program receives an interruption event (either a SIGINT signal from the system, or an interrupt event from the front-end) and SQL interrupt is enabled with `OPTIONS SQL INTERRUPT ON`, the following happens:

- The running SQL statement is stopped,
- The `INT_FLAG` global variable is set to `TRUE`,
- The `SQLCA.SQLCODE` is set with error `-213`.

SQL interruption results in abnormal SQL statement execution and raises a runtime error. Therefore, the SQL statement that can be interrupted must be protected by a `WHENEVER ERROR` exception handler or TRY/CATCH block.

```
MAIN
    DEFINE n INTEGER
    DEFER INTERRUPT
```
When SQL interruption is supported by a database server type other than IBM® Informix®, the database drivers will return error -213 in case of interruption, to behave as in IBM® Informix®.

**Important:** Not all database servers support SQL interruption.

Use the \texttt{WHENEVER} instruction to define how exceptions must be handled for the rest of the module.

**Implicit database connection**

An implicit database connection is made with the \texttt{DATABASE} instruction used before \texttt{MAIN}; use \texttt{SCHEMA} to avoid the implicit connection.

The \texttt{DATABASE} statement can be used in two distinct ways, depending on the context of the statement within its source module:

- To specify a default database.
  
  Typically used in a \texttt{GLOBALS} module, to define variables with the \texttt{DEFINE ... LIKE}, but it is also used for the \texttt{INITIALIZE} and \texttt{VALIDATE} statements. Using the \texttt{DATABASE} statement in this way results in that database being opened automatically at run time.

- To specify a current database.

  In \texttt{MAIN} or in a \texttt{FUNCTION}, used to connect to a database. A variable can be used in this context (\texttt{DATABASE varname}).

A default database is almost always used, because many programs contain \texttt{DEFINE ... LIKE} statements. A problem occurs when the production database name differs from the development database name, because the default database specification will result in an automatic connection (just after \texttt{MAIN}):

```
DATABASE stock_dev -- Default database, used at compile time
DEFINE
  p_cust RECORD LIKE customer.*
MAIN -- Connection to default database occurs at MAIN
  DEFINE dbname CHAR(30)
  LET dbname = "stock1"
  DATABASE dbname -- Real database used in production
  ...
END MAIN
```

In order to avoid the implicit connection, you can use the \texttt{SCHEMA} instruction instead of \texttt{DATABASE}:

```
SCHEMA stock_dev -- Schema specification only
DEFINE
  p_cust RECORD LIKE customer.*
MAIN -- No default connection occurs...
  DEFINE dbname CHAR(30)
  LET dbname = "stock1"
  DATABASE dbname
END MAIN
```

This instruction will define the database schema for compilation only, and will not make an implicit connection at runtime.

**Related concepts**

- \texttt{SCHEMA} on page 477
  Defines the database schema files to be used for compilation.

- \texttt{DATABASE} on page 626
  Opens a new database connection in unique-session mode.

- \texttt{DEFINE} on page 367
  A variable contains volatile information of a specific data type.

- \texttt{INITIALIZE} on page 372
  The \texttt{INITIALIZE} instruction initializes program variables with NULL or default values.

- \texttt{VALIDATE} on page 377
  The \texttt{VALIDATE} instructions checks a variable value based on database schema validation rules.

- \texttt{Globals} on page 472
Global variables can be shared among all modules of a program.

**Debugging SQL statements**

Set the FGLSQLDEBUG environment variable to print SQL debug info.

SQL debug information is printed by the runtime system when the FGLSQLDEBUG environment variable is set to a value different from zero.

Possible values for the FGLSQLDEBUG environment variable are:

**Table 148: FGLSQLDEBUG values**

<table>
<thead>
<tr>
<th>FGLSQLDEBUG</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disable SQL debug log.</td>
</tr>
<tr>
<td>-1</td>
<td>Print global SQL debug message only when an SQL statement produces an error.</td>
</tr>
<tr>
<td>1,2,3,4,...</td>
<td>Print SQL debug message of the specified level, for each executed SQL statement.</td>
</tr>
</tbody>
</table>

The debug messages are sent to the standard error stream. If needed, you can redirect the standard error output into a file.

UNIX™ (shell) example:

```bash
FGLSQLDEBUG=3
export FGLSQLDEBUG
fglrun myprog 2>sqldbg.txt
```

When FGLSQLDEBUG is set with a positive value, the runtime system prints an SQL debug message for each SQL statement executed by the program.

SQL debug messages show detailed information about the SQL statement execution, for example:

```sql
SQL: DATABASE
  4gl source : c.4gl line=2
  loading driver : [/opt/fgl/dbdrivers/dbmdefault]
  db driver type : ifx
  sqlcode : 0
  curr driver : ident='dbmdefault'
  curr connection : ident='-_1' (dbspec=[test1])
  Execution time : 00:00:00.02689

SQL: DELETE FROM mytable WHERE pkey IS NULL
  4gl source : c.4gl line=4
  sqlcode : -206
  sqlstate : 42000
  sqlerrd2 : -111
  sql message : The specified table (mytable) is not in the database.
  sql msg param : mytable
  curr driver : ident='dbmdefault'
  curr connection : ident='-_1' (dbspec=[test1])
  Execution time : 00:00:00.00035
```

**Note:** The most important information is the SQL error code and the source code line where the SQL statement failed. For performance tuning, the execution time can be used to identify slow SQL statements.

If the SQL debug log generates too many messages, set FGLSQLDEBUG to -1, in order to produce an SQL debug message only for the SQL statements that produce an SQL error. Once the SQL statement producing the error is identified, you can find the source code line where the error occurred, to reproduce the problem. Before reproducing the error, set FGLSQLDEBUG to a high positive level, to get detailed debug information.

**MAIN**

```c
DATABASE stores
```
DELETE FROM mytable WHERE pkey IS NULL  -- SQL debug if FGLSQLDEBUG is set
CALL fgl_sqldebug(3)
DELETE FROM mytable WHERE pkey IS NULL  -- SQL debug is enabled
CALL fgl_sqldebug(0)
DELETE FROM mytable WHERE pkey IS NULL  -- SQL debug if FGLSQLDEBUG is set
END MAIN

Note: When FGLSQLDEBUG is set to a positive value, an SQL debug header is printed before executing the underlying database driver code. If the driver code crashes or raises an assertion, you can easily find the last SQL instruction that was executed by the program, and report to your support center. When FGLSQLDEBUG is set to -1, the SQL debug header is not printed before executing the database driver code, because the SQL execution status (SQLCA.SQLCODE) is not known before executing the statement. If the driver code crashes, no error message will be printed. If you experience database driver crashes, use FGLSQLDEBUG with a positive value in order to identify the problem.

The database utility library
The fgldbutl.4gl library provides several database-related utility functions.

You find this library in the FGLDIR/src directory.

The DB utility library implements helpers for the following areas:
- Database type identification
- Sequence number generation
- Nested transaction control

See the fgldbutl.4gl source file for more details.

SQL security
It is important to consider security aspects when programming with SQL.
- Database user authentication on page 543
- Avoiding SQL injection on page 544

Database user authentication
Understanding how users are authenticated to the database server.

When connecting to a database server, the user must be identified by the server. Once connected, the current user is authenticated and identified by the db server, and the database system can then apply specific privileges, audit user activity, and so on.

Database user authentication is typically achieved by specifying a login and password in the CONNECT TO instruction. However, most database servers support additional user authentication methods, such as OS user authentication, trusted connections, LDAP authentication, Single Sign-On authentication, and even specific pluggable authentication methods.

Follow these simple security patterns to avoid basic user authentication problems:
• Make sure that application files installed on your production server have the appropriate file system permissions set. For regular users it is recommended that they have read-only access to program and resource files. If any OS user can replace a program file with another program, it could harm your database or retrieve sensitive private data.
• Each physical end user must have a specific database account. If several end users connect as the same db application account, they cannot be distinguished in the security and auditing system.
• For normal application users, always use database accounts with the minimum database privileges required to achieve the daily work (GRANT/REVOKE). For example, regular users are not given permission to execute Data Definition Language statements (drop tables).
• Instead of asking a name and password in a login dialog when an application starts, some applications hard code the db user names and passwords in the program code, in scripts or configurations files such as FGLPROFILE. This is not a good practice and must be avoided. If a login dialog is not appropriate, you must set up another user authentication method supported by the database server, such as Single Sign-On.

Related concepts

Different database user authentication methods exist.
The FGLPROFILE file(s) on page 220
FGLPROFILE environment variable defines Genero BDL configuration files

Avoiding SQL injection
Prevent SQL injection attacks in your programs.

SQL injection is a well-known attack that started to appear with Web applications, where the end user enters SQL statement fragments in form fields that are normally designed to hold simple data. When the entered text is used to complete an SQL statement without further checking, there is a risk of SQL statements being injected by the user to intentionally harm the database.

To illustrate the problem, see the following code:

```main
DEFINE sql CHAR(200), cn CHAR(50), n INTEGER
OPEN FORM f FROM "custform"
DISPLAY FORM f
INPUT BY NAME cn
LET sql = "SELECT COUNT(*) FROM customers WHERE custname = ", cn, ",""
PREPARE stmt FROM sql
EXECUTE stmt INTO n
DISPLAY "Count = ", n
END MAIN
```

If the end user enters for example:

```
[xxx' ; delete from customers ]
```

The resulting SQL statement will contain an additional DELETE command that will drop all rows of the customers table:

```
SELECT COUNT(*) FROM customers WHERE custname = 'xxx' ; DELETE FROM customers
```

In some applications, you may also want to let the end user choose sort columns to be added in an ORDER BY clause. The recommendation is that code for such a feature controls the user input. For example, by providing a list of columns to choose from, instead of allowing free text input that will be added to the ORDER BY clause.

To avoid SQL injection attacks, do not build SQL instructions dynamically by concatenating user input that is not checked. Instead of basic concatenation, use static SQL statements with program variables (if dynamic SQL is not needed), use parameterized queries (with ? parameter placeholders), or use the CONSTRUCT instruction to implement a query by example form.
Simple static SQL example:

```
MAIN
  DEFINE cn CHAR(50), n INTEGER
  OPEN FORM f FROM "custform"
  DISPLAY FORM f
  INPUT BY NAME cn
  SELECT COUNT(*) INTO n FROM customers WHERE custname = cn
  DISPLAY "Count = ", n
END MAIN
```

Parameterized query example:

```
MAIN
  DEFINE sql CHAR(200), cn CHAR(50), n INTEGER
  OPEN FORM f FROM "custform"
  DISPLAY FORM f
  INPUT BY NAME cn
  LET sql = "SELECT COUNT(*) FROM customers WHERE custname = ?"
  PREPARE stmt FROM sql
  EXECUTE stmt USING cn INTO n
  DISPLAY "Count = ", n
END MAIN
```

CONSTRUCT example:

```
MAIN
  DEFINE sql CHAR(200), cond CHAR(50), n INTEGER
  OPEN FORM f FROM "custform"
  DISPLAY FORM f
  CONSTRUCT BY NAME cond ON custname
  LET sql = "SELECT COUNT(*) FROM customers WHERE ", cond
  PREPARE stmt FROM sql
  EXECUTE stmt INTO n
  DISPLAY "Count = ", n
END MAIN
```

SQL portability

Writing portable SQL is mandatory, to support different kind of database servers.

This section provides hints to solve SQL incompatibility problems in your programs.

In addition to this SQL portability guide, read carefully the database-specific guides which contain database specific information about SQL compatibility issues.

To easily detect SQL statements with specific syntax, you can use the `-W stdsql` option of fglcomp:

```
$ fglcomp -W stdsql orders.4gl
module.4gl:15: SQL Statement or language instruction with specific SQL syntax.
```

This compiler option can only detect non-portable SQL syntax in static SQL statements.

Database entities
The database entity concept across different database engines.

Most database servers can handle multiple database entities (you can create multiple 'databases'), but this is not possible with all engines:

Table 149: Multiple database entities by Database server type

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>Multiple Database support</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW</td>
<td>Yes, see details</td>
</tr>
<tr>
<td>IBM® Informix®</td>
<td>Yes, see details</td>
</tr>
<tr>
<td>IBM® Netezza®</td>

<td>SAP® ASE</td>
<td>Yes, see details</td>
</tr>
<tr>
<td>SAP HANA®</td>
<td>Yes, see details</td>
</tr>
<tr>
<td>SQLite</td>
<td>Yes, see details</td>
</tr>
</tbody>
</table>
When using a database server that does not support multiple database entities, you can emulate different databases with schema entities, but this requires you to check for the database user definition. Each database user must have privileges to access any schema, and to see any table of any schema without needing to set a schema prefix before table names in SQL statements.

Some database drivers allow to select a specific schema at connection with the following FGLPROFILE entry:

```
dbi.database.dbname.dbtype.schema = "schema-name"
```

Some databases also allow you to define a default schema for each database user. When the user connects to the database, the default schema is automatically selected.

**Related concepts**

The FGLPROFILE file(s) on page 220

FGLPROFILE environment variable defines Genero BDL configuration files

**Database users and security**

Properly identifying database users allows to use database security and audit features.

To get the benefit of the database server security features, you should identify each physical user as a database user.

Some applications use a single database user for different end users, to avoid user management and connection issues in the database. This is not good practice because all user-related features of the database are unusable. Furthermore, the single db user often has all database privileges and thus can lead in security issues.

According to the type of server, you must do this steps to create a database user:

1. Define the user as an operating system user.
2. Declare the user in the database server.
3. Grant database access privileges.

Each database server has its specific users management and data access privilege mechanisms. Check the vendor documentation for security features and make sure you can define the users, groups, and privileges in all database servers you want to use.

**Related concepts**

Database user authentication on page 623
Different database user authentication methods exist.

**Creating a database from programs**
Creating a database from within a program requires special consideration.

**Understanding database creation statements**
The Genero language syntax supports database creation statements such as:

```
CREATE DATABASE mydb WITH BUFFERED LOG
```

Such instruction performs an implicit connection to the database server (this means that no CONNECT TO or DATABASE is required before a CREATE DATABASE), which leads to a default connection.

**Creating a database in a database server**
When using a database server engine, the creation of a database entity is not a trivial operation. The process usually requires additional tasks such as data storage configuration, database user creation, data access policy, and so on. These tasks are typically left to the database administrator.

Database creation statements such as CREATE DATABASE, CREATE DBSPACE, and DROP DATABASE can be used in programs connected to an IBM® Informix® server, but these statements are not portable. Use database creation statements only for development or testing purpose.

**Creating a database on mobile devices (SQLite)**
Mobile applications usually create their database at first execution. Database creation on a mobile device is a much simpler operation than database creation on a database server. For example, with SQLite, creating a database only requires creating an empty file.

The SQLite database file must be created in the application sandbox, in a writable directory. This directory is specific to the type of mobile device, and can be found in programs with the `os.Path.pwd` on page 2653 method.

To build the full path to the database file, get the current working directory (`os.Path.pwd()` ) and add this path to the database file name. This defines the `source` specification in the database connection parameters, to build the string used for the CONNECT instruction.

**Note:** Backslashes (\) in the parameters of the connection string must be escaped, before using the connection string in a CONNECT TO or DATABASE instruction. In the next code example, when executing on a Windows® platform, the file path to the SQLite database file will contain backslashes, that need to be doubled. Note that a backslash in a string literal of the BDL source is also doubled: "\\" represents in fact a single backslash.

```r
IMPORT os
...
DEFINE dbfile, source, connstr VARCHAR(256)

FUNCTION init_connection_strings()
    LET dbfile = "contacts.dbs"
    LET source = os.Path.join(os.Path.pwd(), dbfile)
    LET connstr = SFMT("contacts+source='\\%l'", escape_backslashes(source) )
    IF NOT base.Application.isMobile() THEN
        -- Add db driver spec when in development mode
        LET connstr = connstr, ",driver='dbmsqt'"
    END IF
END FUNCTION

FUNCTION escape_backslashes(str)
    DEFINE str STRING
    DEFINE buf base.StringBuffer
    LET buf = base.StringBuffer.create()
    CALL buf.append(str)
```
CALL buf.replace("\\", "\\\\", 0)
RETURN buf.toString()
END FUNCTION

If not specified, the `source` connection parameter (i.e., the path to the database file) defaults to the database name specification in the `CONNECT` instruction. Thus, the `source='dbpath'` parameter is usually omitted, and `dbpath` is specified directly as the database name. In this case, however, the identifier of the database connection is the complete path to the SQLite database file. For more details about database connection parameters, see Database connections on page 600.

Before executing the `CONNECT` instruction, check if the database file already exists with `os.Path.exists(source)`. Create the database file and tables only if needed:

```sql
IMPORT os
...
CALL init_connection_strings()
IF os.Path.exists(source) THEN
    CONNECT TO connstr AS "c1"
ELSE
    CALL create_empty_file(source)
    CONNECT TO connstr AS "c1"
    CALL create_database_tables()
END IF
...
```

FUNCTION create_empty_file(fn)
DEFINE fn STRING
DEFINE ch base.Channel
LET ch = base.Channel.create()
CALL ch.openFile(fn,"w")
CALL ch.close()
END FUNCTION

Instead of creating an empty database file, it is also possible to prepare a template (pre-configured) SQLite database file on the development platform, deploy the template database with the other program files, and copy the template file from the program files directory (`base.Application.getProgramDir` on page 2270) into the working directory (`os.Path.pwd` on page 2653) on the first application execution (that is when the database file in the working directory does not yet exist):

```sql
IMPORT os
...
CALL init_connection_strings()
IF NOT prepare_database("template.dbs", source) THEN
    ERROR "Could not prepare database"
    EXIT PROGRAM 1
END IF
CONNECT TO connstr AS "c1"
...
```

FUNCTION prepare_database(template, target)
DEFINE template, target STRING
DEFINE tplpath STRING
IF os.Path.exists(target) THEN
    RETURN TRUE
END IF
LET tplpath = os.Path.join(base.Application.getProgramDir(), template)
IF NOT os.Path.exists(tplpath) THEN
    ERROR "Database template file not found"
    RETURN FALSE
END IF
RETURN os.Path.copy(tplpath, target)
Important: When creating an initial database file in the working directory from a template file deployed in the program files directory, different file names should be used for the template and actual database file, as folders pointed to by base.Application.getProgramDir on page 2270 and os.Path.pwd on page 2653 may be the same on some devices.

Handling nested transactions
You can manage nested transactions in different parts of a program.

A program can become very complex if it contains a lot of nested functions calls, doing SQL processing within transactions. You may want to centralize transaction control commands in wrapper functions. The fgldbutl.4gl library contains special functions to manage the beginning and the end of a transaction with an internal counter, in order to implement nested function calls inside a unique transaction.

```
MAIN
  IF a() <> 0 THEN
    ERROR "..."
  END IF
  IF b() <> 0 THEN
    ERROR "..."
  END IF
END MAIN

FUNCTION a()
  DEFINE s INTEGER
  LET s = db_start_transaction()
  UPDATE ...
  LET s = SQLCA.SQLCODE
  IF s = 0 THEN
    LET s = b()
  END IF
  LET s = db_finish_transaction((s==0))
  RETURN s
END FUNCTION

FUNCTION b()
  DEFINE s INTEGER
  LET s = db_start_transaction()
  UPDATE ...
  LET s = SQLCA.SQLCODE
  LET s = db_finish_transaction((s==0))
  RETURN s
END FUNCTION
```

In this example, you see in the MAIN block that both functions a() and b() can be called separately. However, the transaction SQL commands will be used only if needed: When function a() is called, it starts the transaction, then calls b(), which does not start the transaction since it was already started by a(). When function b() is called directly, it starts the transaction.

The function db_finish_transaction() is called with the expression (s==0), which is evaluated before the call. This allows you to write in one line the equivalent of the following IF statement:

```
IF s==0 THEN
  LET s = db_finish_transaction(1)
```

Transaction blocks across connections
Transaction blocks manage transactions when connected to several database servers.

In some cases, you need to copy data from a database to another. Database vendor export / import tools exist for this task and their use is preferred when large data transfer is needed. However, it is also possible to achieve this with a BDL program connected to both databases, reading data from the source database and inserting rows into the target database.

If the rows created in the target database need to be committed as a whole, you must open a transaction with the BEGIN WORK instruction, use SET CONNECTION to switch between the connections to read/write rows, and terminate the transaction with a COMMIT WORK.

In order to keep a transaction open when switching to another database connection, the connection must be initiated with the WITH CONCURRENT TRANSACTION clause. If this option is not used, databases servers might raise an error when changing the connection context. For example IBM® Informix® will return the SQL error -1801: Multiple-server transaction not supported.

The example opens two database connections, reads rows from a table of the first database, and uses a transaction to insert rows in a table of the second database:

```sql
MAIN
   DEFINE rec RECORD
       pk INTEGER,
       name VARCHAR(50)
   END RECORD

   CONNECT TO "test1+driver='dbmifix'" AS "s1"
       USER "ifxuser" USING "fourjs"
       WITH CONCURRENT TRANSACTION
   CREATE TEMP TABLE tt1 ( pk INT, name VARCHAR(50) )
   INSERT INTO tt1 VALUES ( 1, "Item 1" )
   INSERT INTO tt1 VALUES ( 2, "Item 2" )

   CONNECT TO "test1+driver='dbmmys'" AS "s2"
       USER "mysuser" USING "fourjs"
       WITH CONCURRENT TRANSACTION
   CREATE TEMP TABLE tt2 ( pk INT, name VARCHAR(50) )

   SET CONNECTION "s1"
   DECLARE c1 CURSOR FOR SELECT * FROM tt1

   SET CONNECTION "s2"
   BEGIN WORK

   SET CONNECTION "s1"
   FOREACH c1 INTO rec.*
       SET CONNECTION "s2"
       INSERT INTO tt2 VALUES ( rec.* )
   END FOREACH

   SET CONNECTION "s2"
```

Transaction savepoints

Using transaction savepoints with different database engines.

IBM® Informix® IDS 11.50 introduced transaction savepoints, following the ANSI SQL standards. While most recent database servers support savepoints, you must pay attention and avoid Informix® specific features. For example, Oracle® (11), SQL Server (2008 R2), SAP® ASE (15.5) do not support the RELEASE SAVEPOINT instruction. The UNIQUE clause of SAVEPOINT is only supported by IBM® Informix® and IBM® DB2® LUW.

Data definition statements

It is recommended to avoid use of DDL in programs.

When using Data Definition Statements like CREATE TABLE, ALTER TABLE, DROP TABLE, only a limited SQL syntax works on all database servers. Most databases support NOT NULL, CHECK, PRIMARY KEY, UNIQUE, FOREIGN KEY constraints, but the syntax for naming constraints is different.

The following statement works with most database servers and creates a table with equivalent properties in all cases:

```
CREATE TABLE customer  (
  cust_id INTEGER NOT NULL,`
Some engines like SQL Server have a different default behavior for NULL columns when you create a table. You may need to set up database properties to make sure that a column allows nulls if the NOT NULL constraint is not specified.

When you want to create tables in programs using non-standard clauses (for example to define storage options), you must use dynamic SQL and adapt the statement to the target database server.

**Related concepts**

Dynamic SQL management on page 654

Explains how to execute and manage SQL statements at runtime.

**Using portable data types**

Only a limited set of data types are really portable across several database engines.

The ANSI SQL specification defines standard data types, but for historical reasons most databases vendors have implemented native (non-standard) data types. You can usually use a synonym for ANSI types, but the database server will use the native types behind the scenes. For example, when you create a table with an INTEGER column in Oracle, the native NUMBER data type is used.

In your programs, avoid data types that do not have a native equivalent in the target database. This includes simple types like floating point numbers, as well as complex data types like INTERVAL. Numbers may cause rounding or overflow problems, because the values stored in the database have different limits. For the DECIMAL types, always use the same precision and scale for the program variables and the database columns.

To write portable applications, we strongly recommend using the following data types only:

- CHAR(n)
- VARCHAR(n)
- BIGINT
- INTEGER
- SMALLINT
- DECIMAL(p,s)
- DATE
- DATETIME HOUR TO MINUTE
- DATETIME HOUR TO SECOND
- DATETIME HOUR TO FRACTION(n)
- DATETIME YEAR TO MINUTE
- DATETIME YEAR TO SECOND
- DATETIME YEAR TO FRACTION(n)

Data types on page 253

Selecting the correct data type assists you in the input, storage, and display of your data.

Data manipulation statements

Make sure that SQL statement syntaxes are supported by all target database engines.

Several SQL syntaxes for the INSERT, UPDATE and DELETE statements are supported by the compiler. Some of the syntaxes are IBM® Informix® specific, but will be converted to standard SQL at compile time.

The following statements are standard SQL and work with all database servers:

(1) INSERT INTO table (column-list) VALUES (value-list)
(2) UPDATE table SET column = value, ... [WHERE condition]
(3) DELETE FROM table [WHERE condition]

The next statements are not standard SQL, but are converted by the compiler to standard SQL, working with all database servers:

(4) INSERT INTO table VALUES record.*
   -- where record is defined LIKE a table from db schema
(5) UPDATE table SET (column-list) = (value-list) [WHERE condition]
(6) UPDATE table SET {[table.1]*|(column-list)}
   = record.* ... [WHERE condition]
   -- where record is defined LIKE a table from db schema
(7) UPDATE table SET [table.1]* = (value-list) [WHERE condition]

For maximum SQL portability, INSERT statements should be reviewed to avoid the SERIAL column from the value list.

Note: You can easily search for non-portable SQL statements in your sources by compiling with the -W stdsql fglcomp option.

For example, the following statement:

```
INSERT INTO tab (col1, col2, ...) VALUES ( 0, p_value2, ... )
```

should be converted to:

```
INSERT INTO tab (col2, ...) VALUES ( p_value2, ... )
```

A static SQL INSERT statement using records defined from the schema file should also be reviewed:

```
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES ( rec.* ) -- will use the serial column
```
should be converted to:

```
INSERT INTO tab VALUES rec.* -- without parentheses, serial column is removed
```

**Note:** Using the `record.*` notation in static INSERT and UPDATE syntax may not be compatible with database-specific features, where some automatically-assigned columns must not be set or modified by the statement. For example, with Microsoft SQL Server temporal tables, timestamp columns are automatically assigned and must not be changed by INSERT or UPDATE statements. In such case, it is mandatory to explicitly list all modifiable columns and corresponding program variables.

**Related concepts**

**CHAR and VARCHAR types**
Using the CHAR and VARCHAR data types with different databases.

The CHAR and VARCHAR types are designed to store character strings, but all database servers do not have the same semantics for these types.

**Important:** The maximum size, supported characters sets and length semantics of CHAR and VARCHAR types can be very different from one database system to another. Consider using character types and sizes that are common across all the database systems you target.

The behavior of database servers may differ in the following areas related to CHAR/VARCHAR types.

**Byte or Character Length semantics?**

When defining a CHAR/VARCHAR database column or program variable, you must specify a size. When using a multibyte character set, the unit of this size matters: it can be specified in bytes or characters. In programs, the size unit of CHAR/VARCHAR variables depends on the length semantics defined by the `FGL_LENGTH_SEMANTICS` environment variable. In databases, the size unit of the CHAR/VARCHAR columns can be expressed in bytes or characters, depending on the database server and its configuration.
Related concepts

Length semantics settings on page 414

**SQL character type for Unicode/UTF-8**

This section explains database server specifics regarding Unicode / UTF-8 support with character string SQL types.

All database servers can store UNICODE data in character strings types, but there are some specifics you must be aware of. Genero BDL programs typically use the CHAR and VARCHAR types to store UTF-8 strings. But the corresponding SQL type may have a different name, depending on the database server type. Use the correct SQL type when creating your database tables. When the database uses a different UNICODE codeset as UTF-8 to store the character string data, the database client or the Genero database driver take care of the codeset conversion, as long as the runtime system and database client locale are properly defined.

**Table 154: Database server character types for Unicode / UTF-8 data**

This section describes the settings defining the locale for the database client.

**Empty strings and NULLs**

At the SQL level, most databases distinguish ' ' empty strings from NULL (with some exceptions like Oracle® DB). However, in programs, an empty string is the equivalent to NULL in program variables. As result, it is not possible to distinguish an empty string from a NULL when such values are fetched from the database. This limitation is only visible when fetching VARCHAR columns and expressions fetched into VARCHAR variables, because CHAR columns get filled with blanks if the database returns a CHAR column value that was filled with an empty string; CHAR columns get blanks up to the max size.

**Trailing blanks in CHAR/VARCHAR**

**Trailing blanks in CHAR/VARCHAR database columns**

With all kinds of databases servers, CHAR columns are always filled with blanks up to the size of the column (this is called blank padding).

With IBM® Informix®, trailing blanks are not significant in comparisons:

```
CHAR('abc ') = CHAR('abc')
```

With other database servers, trailing blanks are significant when comparing VARCHAR values:

```
VARCHAR('abc ') != VARCHAR('abc')
```

This is a major issue if you mix CHAR and VARCHAR columns and variables in your SQL statements, because the result of an SQL query can be different depending on whether you are using IBM® Informix® or another database server.

Furthermore, the semantics of the SQL LIKE operator regarding trailing blanks and CHAR/VARCHAR types can differ from database to database. For example, try the following expressions with your database, with a CHAR(5) column containing a row with the value 'abc':

```sql
create table t1 ( k int, c char(5), vc varchar(5) )
insert into t1 values ( 1, 'abc', 'abc' )
select * from t1 where c like 'ab_'
select * from t1 where vc like 'ab_'
select * from t1 where rtrim(c) like 'ab_'
select * from t1 where c like '%c'
select * from t1 where vc like '%c'
select * from t1 where rtrim(c) like '%c'
```
See discussion about MATCHES and LIKE operators in adaption guides for more details.

**CHAR blank padding versus VARCHAR**

In all database engines, `CHAR(N)` data is blank padded. This means that the database engine fills the column value with trailing blanks when needed.

Because of the IBM® Informix® SQL `VARCHAR()` limit of 255 bytes, there may be legacy code using the `CHAR` data type for larger sizes, such as `CHAR(400)` or `CHAR(2000)`.

The problem with large `CHAR()` columns is blank padding. For example, with `CHAR(500)`, if you store and pass the value "abc" in program variables, SQL parameters, and SQL statements, you pass abc + 497 blanks, because `CHAR` values are blank-padded.

On the other hand, `VARCHAR` types only store the actual value that was provided ('abc' in our case), and trailing blanks only if explicitly provided ('abc ').

In order to optimize your application, consider replacing large `CHAR()` columns by `VARCHAR()`. The `CHAR()` type can be used to store small, fixed-size, character string values (such as phone or credit card numbers).

Informix® IDS supports the `LVARCHAR()` type with a larger limit. Genero BDL supports this Informix® SQL type.

See also [Passing small CHAR parameters to functions](#) on page 404.

**Trailing blanks in CHAR/VARCHAR program variables**

In programs, `CHAR` variables are filled with blanks, even if the value used does not contain all spaces.

The following example:

```
DEFINE c CHAR(5)
LET c = "abc"
DISPLAY c || " ."
```

shows the value "abc ." (5 chars + dot).

`VARCHAR` variables are assigned with the exact value specified, with significant trailing blanks.

For example, this code:

```
DEFINE v VARCHAR(5)
LET v = "abc 
DISPLAY v || " ."
```

shows the value "abc ." (4 chars + dot).

Assigning an empty string to a `CHAR` or `VARCHAR` variable will set the variable to `NULL`:

```
DEFINE v VARCHAR(5)
LET v = 
IF v IS NULL THEN
    DISPLAY "is null" -- will be displayed
END IF
```

When comparing `CHAR` or `VARCHAR` variables in an expression, the trailing blanks are **not significant**:

```
DEFINE c CHAR(5)
DEFINE v1, v2 VARCHAR(5)
LET c = "abc"
LET v1 = "abc 
LET v2 = "abc 
IF c == v1 THEN
    DISPLAY "c==v1"
END IF
```
IF c == v2 THEN
    DISPLAY "c==v2"
END IF
IF v1 == v2 THEN
    DISPLAY "v1==v2"
END IF

All three messages are shown.

Additionally, when you assign a VARCHAR variable from a CHAR, the target variable gets the trailing blanks of the CHAR variable:

DEFINE pc CHAR(50)
DEFINE pv VARCHAR(50)
LET pc = "abc"
LET pv = pc
DISPLAY pv || "."

"abc <47 spaces>. " (50 chars + dot) is shown.

To avoid this, use the CLIPPED operator:

LET pv = pc CLIPPED

**Trailing blanks in SQL statement parameters**

When you insert a row containing a CHAR variable into a CHAR or VARCHAR column, the database interface removes the trailing blanks to avoid overflow problems, (insert CHAR(100) into CHAR(20) when value is "abc" must work).

In this example:

```sql
DEFINE c CHAR(5)
LET c = "abc"
CREATE TABLE t ( v1 CHAR(10), v2 VARCHAR(10) )
INSERT INTO tab VALUES ( c, c )
```

The value in column v1 and v2 would be "abc" (3 chars in both columns).

When you insert a row containing a VARCHAR variable into a VARCHAR column, the VARCHAR value in the database gets the trailing blanks as set in the variable. When the column is a CHAR(N), the database server fills the value with blanks so that the size of the string is N characters.

In this example:

```sql
DEFINE vc VARCHAR(5)
LET vc = "abc  " -- note 2 spaces at end of string
CREATE TABLE t ( v1 CHAR(10), v2 VARCHAR(10) )
INSERT INTO tab VALUES ( vc, vc )
```

The value in column v1 would be "abc " (10 chars ) and v2 would be "abc " (5 chars ).

**Related concepts**

**MATCHES and LIKE operators** on page 579
Use the standard LIKE operator instead of the MATCHES operator.

**CHAR(size)** on page 257
The CHAR data type is a fixed-length character string data type.

**VARCHAR(size)** on page 273
The VARCHAR data type is a variable-length character string data type, with a maximum size.

**CLIPPED** on page 321
The `CLIPPED` operator removes trailing blanks of a string expression.

**What should you do?**

Make sure that you have correctly defined the locale and length semantics for your character string data types.

When designing your database tables, consider using `CHAR(N)` for fixed-length string data (such as codes) and `VARCHAR(N)` for variable-length string data, such as names, address and comments.

Use `VARCHAR` variables for `VARCHAR` columns, and `CHAR` variables for `CHAR` columns to achieve portability across all kinds of database servers.

Avoid storing empty strings in `VARCHAR` columns, or make sure that your program is prepared to get nulls while the database stores empty strings.

Using byte or character length semantics depends mainly on the character set of your application. When using a single-byte character set, keep the default byte length semantics. When using a multibyte character set such as UTF-8, use character length semantics in both the database and the programs. The database column definition and the program variable definition must match, this can be simplified by using a database schema.

  The semantics of the `LENGTH()` SQL function differs according to the database engine.

**Scrollable cursors**

How scrollable cursors can be supported on different databases.

Scrollable cursors can be used to go forward and backward in an SQL query result set:

```sql
DEFINE cust_rec RECORD LIKE customer.*
DECLARE sc SCROLL CURSOR
  FOR SELECT * FROM customer
OPEN sc
FETCH NEXT sc INTO cust_rec.*
FETCH LAST sc INTO cust_rec.*
FETCH FIRST sc INTO cust_rec.*
CLOSE sc
```

This is a useful feature to implement record set navigation in applications. Scrollable cursors are typically implemented in the database server. But not all database servers support scrollable cursors.

When scrollable cursors are not supported by the target database server, the database driver will emulate it with temporary files.

The temporary files are create in a temporary directory, that can be defined with the `DBTEMP` environment variable. If `DBTEMP` is not defined, the default temporary directory dependents from the platform used.

It is recommended that you avoid scroll cursor usage if the target database does not support this feature:

With emulated scrollable cursors, when scrolling to the last row, all rows will be fetched into the temporary file. This can generate a lot of network traffic and can produce a large temporary file if the result-set contains a lot of rows. Additionally, programs are dependent on the file system resource allocated to the OS user (ulimit).

The following table lists the native scroll cursor availability for each supported database:

Optimistic locking

Implementing optimistic locking to handle access concurrently to the same database records.

This section describes how to implement optimistic locking in applications. Optimistic locking is a portable solution to control simultaneous modification of the same record by multiple users.

Traditional IBM® Informix® applications use a cursor declared with SELECT FOR UPDATE to set a lock on the row to be edited by the user. This is called pessimistic locking. The SELECT FOR UPDATE cursor is executed before the interactive part of the code, as described here:

1. When the end user chooses to modify a record, the program declares and opens a cursor with a SELECT FOR UPDATE. At this point, an SQL error might be raised if the record is already locked by another process. Otherwise, the lock is acquired and user can modify the record.
2. The user edits the current record in the input form.
3. The user validates the dialog.
4. The UPDATE SQL instruction is executed.
5. The transaction is committed or the SELECT FOR UPDATE cursor is closed. The lock is released.

If the IBM® Informix® database was created with transaction logging, you must either start a transaction or define the SELECT FOR UPDATE cursor WITH HOLD option.

Unfortunately, this is not a portable solution. The lock wait mode should preferably be WAIT for portability reasons. Pessimistic locking is based on a NOT WAIT mode to return control to the program if a record is already locked by another process. Therefore, following the portable concurrency model, the pessimistic locking mechanisms must be replaced by the optimistic locking technique.

Basically, instead of locking the row before the user starts to modify the record data, the optimistic locking technique makes a copy of the current values (i.e. before modification values (BVM)), allows the user to edit the record, and when it's time to write data into the database, checks if the BMVs still correspond to the current values in the database:
1. A SELECT is executed to fill the record variable used by the interactive instruction for modifications.
2. The record variable is copied into a backup record to keep Before Modification Values.
3. The user enters modifications in the input form; this updates the values in the modification record.
4. The user validates the dialog.
5. A transaction is started with BEGIN WORK.
6. Declare a cursor with a SELECT FOR UPDATE, to select the row to be updated.
7. Open the SELECT FOR UPDATE cursor and fetch the row into the temporary record.
8. If the SQL status is NOTFOUND, the row has been deleted by another process, and the transaction can stop with ROLLBACK WORK.
9. If the row was found, the program compares the temporary record values with the backup record values with the 
(recl.*==rec2.*) notation.
10. If these values have changed, the row has been modified by another process, and the transaction can stop with ROLLBACK WORK.
11. If the values in the database have not changed, the UPDATE statement is executed to apply the last changes of the user.
12. The transaction is committed with a COMMIT WORK.

To compare 2 records (with NULL checking), simply write:

```sql
IF new_record.* != bmv_record.* THEN
    LET values_have_changed = TRUE
END IF
```

The optimistic locking technique can be implemented with a unique SQL instruction: an UPDATE can compare the column values to the BMVs directly (UPDATE ... WHERE kcol = kvar AND coll = bmv.var1
AND ...). But, this is not possible when BMVs can be NULL. The database engine always evaluates conditional expressions such as "col=NULL" to FALSE. Therefore, you must use "col IS NULL" when the BMV is NULL.
This means dynamic SQL statement generation based on the DMV values. Additionally, to use the same number of SQL parameters (? markers), you would have to use "col=?" when the BMV is not null and "col IS NULL
and ? IS NULL" when the BMV is null. Unfortunately, the expression " ? IS [NOT] NULL " is not supported by all database servers (DB2® raises error SQL0418N).

If you are designing a new database application from scratch, you can also use the row versioning method. Each table of the database must have a column that identifies the current version of the row. The column can be a simple INTEGER (to hold a row version number) or it can be a timestamp (DATETIME YEAR TO FRACTION(5) for example). To guaranty that the version or timestamp column is updated each time the row is updated, it is recommended that you implement a trigger to increment the version or set the timestamp when an UPDATE statement is issued. If this is in place, you just need to check that the row version or timestamp has not changed since the user modifications started, instead of testing all field of the BMV record. If you are only using one specific database type, you may check if the server supports a versioning column natively. For example, IBM® Informix® IDS 11.50.xC1 introduced the ALTER TABLE ... ADD VERCOLS option to get a version + checksum column to a table, you can then query the table with the ifx_insert_checksum and ifx_row_version columns.

**Auto-incremented columns (serials)**
How to implement automatic record keys.

IBM® Informix® provides the SERIAL, BIGSERIAL or SERIAL8 data types which can be emulated with database drivers for most non-Informix® database engines by using native sequence generators (when "ifxemul.serial" FGLPROFILE setting is true). But, this requires additional configuration and maintenance tasks. If you plan to review the programming pattern of sequences, it is recommended that you use a portable implementation instead of
the serial emulation provided by the database drivers. This section describes different solutions to implement auto-incremented fields. The preferred implementation is the solution using SEQUENCES.

Solution 1: Use database specific serial generators

Principle
In accordance with the target database, you must use the appropriate native serial generation method. Get the database type with the fgl_db_driver_type() built-in function and use the appropriate SQL statements to insert rows with serial generation.

This solution uses the native auto-increment feature of the target database and is fast at execution time, but is not very convenient as it requires different code for each database type to be written. Solutions for auto-incremented columns are vendor-specific. It is of course not realistic to use this solution in a large application with hundreds of tables.

Implementation
1. Create the database objects required for serial generation in the target database (for example, create tables with SERIAL columns in IBM® Informix®, tables with IDENTITY columns in SQL Server, and SEQUENCE database objects in Oracle).
2. Adapt your programs to use the native sequence generators in accordance with the database type.

Example

```sql
DEFINE t1rec RECORD
   id    INTEGER,
   name  CHAR(50),
   cdate DATE
END RECORD

CASE fgl_db_driver_type()
WHEN "ifx"
   INSERT INTO t1 ( id, name, cdate )
   VALUES ( 0, t1rec.name, t1rec.cdate )
   LET t1rec.id = SQLCA.SQLERRD[2]
WHEN "ora"
   INSERT INTO t1 ( id, name, cdate )
   VALUES ( t1seq.nextval, t1rec.name, t1rec.cdate )
   SELECT t1seq.currval INTO t1rec.id FROM dual
WHEN "msv"
```
As you can see in this example, this solution requires database engine specific coding. Querying the last generated serial can be centralized in a function, but the insert statements would still need to be specific to the type of database.

**Related concepts**

fgl_db_driver_type() on page 2156
Returns the 3-letter identifier/code of the current database driver.

**Solution 2: Generate serial numbers from your own sequence table**

**Purpose**
The goal is to generate unique INTEGER or BIGINT numbers. These numbers will usually be used for primary keys.

**Prerequisites**

1. The database must use transactions. This is usually the case with non-Informix databases, but IBM® Informix® databases default to auto commit mode. Make sure your IBM® Informix® database allows transactions.
2. The sequence generation must be called inside a transaction (BEGIN WORK / COMMIT WORK).
3. The transaction isolation level must guarantee that a row UPDATED in a transaction cannot be read or written by other db sessions until the transaction has ended (typically, COMMITTED READ is ok, but some db servers require a higher isolation level)
4. The lock wait mode must be WAIT. This is usually the case in non-Informix databases, but Informix defaults to NOT WAIT. You must change the lock wait mode with "SET LOCK MODE TO WAIT" or "WAIT seconds" when using IBM® Informix®.
5. Other applications or stored procedures must implement the same technique when inserting records in tables with auto-incremented columns.

**Principle**

A dedicated table named "SEQREG" is used to register sequence numbers. The key is the name of the sequence. This name will usually be the table name the sequence is generated for. In short, this table contains a primary key that identifies the sequence and a column containing the last generated number.

The uniqueness is granted by the concurrency management of the database server. The first executed instruction is an UPDATE that sets an exclusive lock on the SEQREG record. When two processes try to get a sequence at the same time, one will wait for the other until its transaction is finished.

**Implementation**

The "fgldbut1.4gl" utility library implements a function called "db_get_sequence()" which generates a new sequence. You must create the SEQREG table as described in the fgldbut1.4gl source found in FGLDIR/src, and make sure that every user has the privileges to access and modify this table.

In order to guarantee the uniqueness of the generated number, the call to db_get_sequence() must be done inside a transaction block that includes the INSERT statement. Concurrent db sessions must wait for each other in case of conflict and the transaction isolation level must be high enough to make sure that the row of the sequence table will not be read or written by other db sessions until the transaction end.

**Example**

```sql
IMPORT FGL fgldbut1
DEFINE rec RECORD
    id INTEGER,
    name CHAR(100)
```
END RECORD

BEGIN WORK
LET rec.id = db_get_sequence("CUSTID")
INSERT INTO CUSTOMER (CUSTID, CUSTNAME) VALUES (rec.*)
COMMIT WORK

Solution 3: Use native SEQUENCE database objects

Principle

Most recent database engines support SEQUENCE database objects. If all database server types you want to use support sequences, it is recommended that you use this solution.

Implementation

1. Create a SEQUENCE object for each table that previously used a SERIAL column in the IBM® Informix® database.
2. In database creation scripts (CREATE TABLE), replace all SERIAL types by INTEGER (or BIGINT if you need large integers).
3. Adapt your programs to retrieve a new sequence before inserting a new row. Consider writing a function to retrieve a new sequence number, using dynamic SQL to pass the name of the sequence as parameter, and adapt to the target database specifics to retrieve a single row (see example below).

Example

MAIN
  DEFINE item_rec RECORD
    item_num BIGINT,
    item_name VARCHAR(40)
  END RECORD
DATABASE test1
CREATE TABLE item (    
  item_num BIGINT NOT NULL PRIMARY KEY,
  item_name VARCHAR(50)
)
CALL sequence_create("item")
LET item_rec.item_num = sequence_next("item")
DISPLAY "New sequence: ", item_rec.item_num
LET item_rec.item_name = "Item#" || item_rec.item_num
INSERT INTO item VALUES (item_rec.*)
DROP TABLE item
DROP SEQUENCE item_seq
END MAIN

PRIVATE FUNCTION is_sql_server() RETURNS BOOLEAN
  RETURN (fgl_db_driver_type()="esm"
          OR fgl_db_driver_type()="ftm"
          OR fgl_db_driver_type()="snc")
FUNCTION sequence_create(tabname STRING)
  DEFINE sql STRING
  IF is_sql_server() THEN
    LET sql = "CREATE SEQUENCE "||tabname||"_seq START WITH 1"
  ELSE
    LET sql = "CREATE SEQUENCE "||tabname||"_seq"
  END IF
  EXECUTE IMMEDIATE sql
END FUNCTION

FUNCTION sequence_next(tabname STRING) RETURNS BIGINT
  DEFINE sql STRING, newseq BIGINT
  CASE
    WHEN fgl_db_driver_type()=='pg'
      LET sql = "SELECT nextval('"||tabname||"_seq')"||
      unique_row_condition()
    WHEN is_sql_server()
      LET sql = "SELECT NEXT VALUE FOR "||tabname||"_seq"
    OTHERWISE
      LET sql = "SELECT "||tabname||"_seq.nextval "||
      unique_row_condition()
  END CASE
  PREPARE seq FROM sql
  IF SQLCA.SQLCODE!=0 THEN RETURN -1 END IF
  EXECUTE seq INTO newseq
  IF SQLCA.SQLCODE!=0 THEN RETURN -1 END IF
  RETURN newseq
END FUNCTION

FUNCTION unique_row_condition() RETURNS STRING
  CASE fgl_db_driver_type()
    WHEN "ifx" RETURN " FROM systables WHERE tabid=1"
    WHEN "db2" RETURN " FROM sysibm.systables WHERE name='SYSTABLES'"
    WHEN "pgs" RETURN " FROM pg_class WHERE relname='pg_class'"

IBM® Informix® SQL ANSI Mode
Understanding the impact of the SQL ANSI mode of IBM® Informix®.

IBM® Informix® allows you to create databases in ANSI mode, which is supposed to be closer to ANSI standard behavior. Other databases like ORACLE and DB2® are 'ANSI' by default.

If you are not using the ANSI mode with IBM® Informix®, we suggest you keep the database as is, because turning an IBM® Informix® database into ANSI mode can result in unexpected behavior of the programs.

Here are some ANSI mode issues extracted from the IBM® Informix® books:

- Some actions, like CREATE INDEX will generate a warning but will not be forbidden.
- Buffered logging is not allowed to enforce data recovery. (Buffered logging provides better performance)
- The table-naming scheme allows different users to create tables without having to worry about name conflicts.
• Owner specification is required in database object names (SELECT ... FROM "owner".table). You must quote the owner name to prevent automatic translation of the owner name into uppercase: SELECT ... FROM owner.table becomes SELECT .. FROM OWNER.table and thus, the table is not found in the database.
• Default privileges differ: When creating a table, the server grants privileges to the table owner and the DBA only. The same thing happens for the 'Execute' privilege when creating stored procedures.
• Default isolation level is REPEATABLE READ.
• An error is generated if any character field is filled with a value that is longer than the field width.
• DECIMAL (p) (floating point decimals) are automatically converted to DECIMAL (p, 0) (fixed point decimals).
• Closing a closed cursor generates an SQL error.

It will take more time to adapt the programs to the IBM® Informix® ANSI mode than using the database interface to simulate the native mode of IBM® Informix®.

**Positioned UPDATE/DELETE**

Using positioned updates/deletes with named database cursors.

The "WHERE CURRENT OF cursor-name" clause in UPDATE and DELETE statements is not supported by all database engines.

**Table 157: Database server support of WHERE CURRENT OF**

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>WHERE CURRENT OF support</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW</td>

<td>SAP® ASE</td>
<td>Yes, see details</td>
</tr>
<tr>
<td>SAP HANA®</td>
<td>No, see details</td>
</tr>
<tr>
<td>SQLite</td>
<td>No, see details</td>
</tr>
</tbody>
</table>

Some database drivers can emulate WHERE CURRENT OF mechanisms by using rowids, but this requires additional processing. You should review the code to disable this option.

The standard SQL solution is to use primary keys in all tables and write UPDATE / DELETE statements with a WHERE clause based on the primary key:

```sql
DEFINE rec RECORD
  id    INTEGER,
  name  CHAR(100)
END RECORD
BEGIN WORK
  UPDATE CUSTOMER SET CUSTNAME = rec.name
    WHERE CUSTID = rec.id
  ...
COMMIT WORK
```
**WITH HOLD and FOR UPDATE**

Hold cursors and not portable.

**IBM® Informix®** supports **WITH HOLD** cursors using the **FOR UPDATE** clause. Such cursors can remain open across transactions (when using **FOR UPDATE**, locks are released at the end of a transaction, but the **WITH HOLD** cursor is not closed). This kind of cursor is **IBM® Informix**-specific and not portable. The SQL standards recommend closing **FOR UPDATE** cursors and release locks at the end of a transaction. Most database servers close **FOR UPDATE** cursors when a **COMMIT WORK** or **ROLLBACK WORK** is done. All database servers release locks when a transaction ends.

**Table 158: Database server support of WITH HOLD FOR UPDATE**

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>WITH HOLD FOR UPDATE support</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW</td>
<td>No, see details</td>
</tr>
<tr>
<td>IBM® Informix®</td>
<td>Yes, native SQL feature</td>
</tr>
<tr>
<td>IBM® Netezza</td>
<td>No, see details</td>
</tr>
<tr>
<td>Microsoft™ SQL Server</td>
<td>No, see details</td>
</tr>
<tr>
<td>Oracle® MySQL</td>
<td>No, see details</td>
</tr>
<tr>
<td>Oracle® Database Server</td>
<td>No, see details</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>No, see details</td>
</tr>
<tr>
<td>SAP® ASE</td>
<td>No, see details</td>
</tr>
<tr>
<td>SAP HANA®</td>
<td>No, see details</td>
</tr>
<tr>
<td>SQLite</td>
<td>No, see details</td>
</tr>
</tbody>
</table>

It is mandatory to review code using **WITH HOLD** cursors with a **SELECT** statement having the **FOR UPDATE** clause.

The standard SQL solution is to declare a simple **FOR UPDATE** cursor outside the transaction and open the cursor inside the transaction:

```sql
DECLARE c1 CURSOR FOR SELECT ... FOR UPDATE
BEGIN WORK
   OPEN c1
   FETCH c1 INTO ...
   UPDATE ...
   COMMIT WORK
```

If you need to process a complete result set with many rows including updates of master and detail rows, first fetch the primary keys of all master rows into a program array, declare a cursor with the **SELECT FOR UPDATE**, then for all rows in the array, start a transaction and perform the **UPDATE WHERE CURRENT OF** for the current master record and the **UPDATE** for detail rows, then commit the transaction and continue with the next master record:

```sql
DEFINE x, mkeys DYNAMIC ARRAY OF INTEGER
DECLARE c1 CURSOR FOR SELECT key FROM master ... FOREACH c1 INTO x
   LET mkeys[mkeys.getLength()+1] = x
END FOREACH
DECLARE c2 CURSOR FOR SELECT * FROM master WHERE key=? FOR UPDATE
FOR x = 1 TO mkeys.getLength()
   BEGIN WORK
      OPEN c2 USING mkeys[x]
      FETCH c2 INTO mrec.*
      IF STATUS==NOTFOUND THEN
         ROLLBACK WORK
      END IF
      UPDATE master ... WHERE CURRENT OF c2
      COMMIT WORK
```

**WITH HOLD and FOR UPDATE**

Hold cursors and not portable.

**IBM® Informix®** supports **WITH HOLD** cursors using the **FOR UPDATE** clause. Such cursors can remain open across transactions (when using **FOR UPDATE**, locks are released at the end of a transaction, but the **WITH HOLD** cursor is not closed). This kind of cursor is **IBM® Informix**-specific and not portable. The SQL standards recommend closing **FOR UPDATE** cursors and release locks at the end of a transaction. Most database servers close **FOR UPDATE** cursors when a **COMMIT WORK** or **ROLLBACK WORK** is done. All database servers release locks when a transaction ends.

**Table 158: Database server support of WITH HOLD FOR UPDATE**

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>WITH HOLD FOR UPDATE support</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW</td>
<td>No, see details</td>
</tr>
<tr>
<td>IBM® Informix®</td>
<td>Yes, native SQL feature</td>
</tr>
<tr>
<td>IBM® Netezza</td>
<td>No, see details</td>
</tr>
<tr>
<td>Microsoft™ SQL Server</td>
<td>No, see details</td>
</tr>
<tr>

</tr>
<tr>
<td>SQLite</td>
<td>No, see details</td>
</tr>
</tbody>
</table>

It is mandatory to review code using **WITH HOLD** cursors with a **SELECT** statement having the **FOR UPDATE** clause.

The standard SQL solution is to declare a simple **FOR UPDATE** cursor outside the transaction and open the cursor inside the transaction:

```sql
DECLARE c1 CURSOR FOR SELECT ... FOR UPDATE
BEGIN WORK
   OPEN c1
   FETCH c1 INTO ...
   UPDATE ...
   COMMIT WORK
```

If you need to process a complete result set with many rows including updates of master and detail rows, first fetch the primary keys of all master rows into a program array, declare a cursor with the **SELECT FOR UPDATE**, then for all rows in the array, start a transaction and perform the **UPDATE WHERE CURRENT OF** for the current master record and the **UPDATE** for detail rows, then commit the transaction and continue with the next master record:

```sql
DEFINE x, mkeys DYNAMIC ARRAY OF INTEGER
DECLARE c1 CURSOR FOR SELECT key FROM master ... FOREACH c1 INTO x
   LET mkeys[mkeys.getLength()+1] = x
END FOREACH
DECLARE c2 CURSOR FOR SELECT * FROM master WHERE key=? FOR UPDATE
FOR x = 1 TO mkeys.getLength()
   BEGIN WORK
      OPEN c2 USING mkeys[x]
      FETCH c2 INTO mrec.*
      IF STATUS==NOTFOUND THEN
         ROLLBACK WORK
      END IF
      UPDATE master ... WHERE CURRENT OF c2
      COMMIT WORK
```
CONTINUE FOREACH
END IF
UPDATE master SET ... WHERE CURRENT OF c2
UPDATE detail SET ... WHERE master_key=mkeys[x]
COMMIT WORK
END FOR

Insert cursors
Using insert cursors with non-Informix databases.

Database cursors defined with "DECLARE cursor-name CURSOR FOR INSERT ..." are designed for IBM® Informix® databases, to optimize row insertion when a lot of data must be loaded in the table.

This is an IBM® Informix® specific feature. With non-Informix databases, insert cursors are emulated by executing the INSERT

```
DEFINE rec RECORD
  id    INTEGER,
  name  CHAR(100)
END RECORD,
  i INTEGER
DECLARE c1 CURSOR FOR INSERT INTO customer VALUES (?,?)
BEGIN WORK
  OPEN c1
  FOR i=1 TO 100
    LET rec.id = i
    LET rec.name = "name"||i
    PUT c1 FROM rec.*
  END FOR
  FLUSH c1
  CLOSE c1
COMMIT WORK
```

Insert cursors are an IBM® Informix® specific feature. The IBM® Informix® insert cursors buffers the provided rows and flushes blocks of rows into the database after a given number of rows, or when the program explicitly executes a FLUSH or CLOSE. In case of errors, for example when inserting a character string value for a numeric column, the SQL error is returned at "flush time" with Informix®.

With non-Informix databases, the rows are not buffered: insert cursors are emulated in db drivers by executing the INSERT statement on every PUT instruction. As result, this can lead to poor performances, and SQL errors can be returned earlier at PUT time.

Note that the LOAD instruction is based on an insert cursor. The same performance issue applies to the LOAD instruction when using a non-Informix database.

If you need to feed your database with a lot of data, coming for example from external sources, we recommend to use database vendor specific tools to load the data. This option is much more efficient than using a Genero program to load data.

**String literals in SQL statements**

Single quotes is the standard for delimiting string literals in SQL.

Some database servers like IBM® Informix® allow single and double quoted string literals in SQL statements, both are equivalent:

```sql
SELECT COUNT(*) FROM table
WHERE col1 = "abc"'def"ghi"
AND col1 = 'abc''def"ghi'
```

Most database servers do not support this specific feature.

**Table 160: Database servers support of double-quoted string literals**

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>Double quoted string literals</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW</td>
<td>No</td>
</tr>
<tr>
<td>IBM® Informix®</td>
<td>Yes</td>
</tr>
<tr>
<td>Microsoft™ SQL Server</td>
<td>Yes</td>
</tr>
<tr>
<td>Oracle® MySQL</td>
<td>No</td>
</tr>
<tr>
<td>Oracle Database Server</td>
<td>No</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>No</td>
</tr>
<tr>
<td>SAP® ASE</td>
<td>No</td>
</tr>
<tr>
<td>SAP HANA®</td>
<td>No</td>
</tr>
<tr>
<td>SQLite</td>
<td>Yes</td>
</tr>
</tbody>
</table>

The ANSI SQL standards define doubles quotes as database object names delimiters, while single quotes are dedicated to string literals:

```sql
CREATE TABLE "my table" ( "column 1" CHAR(10) )
SELECT COUNT(*) FROM "my table" WHERE "column 1" = 'abc'
```

If you want to write a single quote character inside a string literal, you must write 2 single quotes:

```sql
... WHERE comment = 'John''s house'
```

When writing static SQL in your programs, the double quoted string literals as converted to ANSI single quoted string literals by the fglcomp compiler. However, dynamic SQL statements are not parsed by the compiler and therefore need to use single quoted string literals.
We recommend that you always use single quotes for string literals and, if needed, double quotes for database object names.

**Related concepts**

  Describes static SQL statements supported in the language.
- **Dynamic SQL management** on page 654
  Explains how to execute and manage SQL statements at runtime.

**Date/time literals in SQL statements**

Good practices for date and time handling in SQL.

**Date and time strings in SQL Statements**

IBM® Informix® allows you to specify date and time values as a quoted character string in a specific format, depending upon DBDATE and GLS environment variables. For example, if DBDATE=DMY4, the following statement specifies a valid DATE represented by a string literal:

```
SELECT COUNT(*) FROM table WHERE date_col = '24/12/2005'
```

Other database servers do support date/time literals as quoted character strings, but the date/time format specification is quite different. The parameter to specify the date/time format can be a database parameter, an environment variable, or a session option.

In order to write portable SQL, use SQL parameters instead of string literals for date-time values:

```
DEFINE cnt INTEGER
DEFINE adate DATE
LET adate = MDY(12,24,2005)
SELECT COUNT(*) INTO cnt FROM table
  WHERE date_col = adate
```

Or, when using dynamic SQL:

```
DEFINE cnt INTEGER
DEFINE adate DATE
LET adate = MDY(12,24,2005)
PREPARE s1 FROM "SELECT COUNT(*) FROM table WHERE date_col = ?"
EXECUTE s1 USING adate INTO cnt
```

Similarly, when fetching rows from the database server into program variables, IBM® Informix® allows string literals (representing date values in DBDATE format) to be fetched into DATE variables:

```
DEFINE adate DATE
SELECT '24/12/2005' INTO adate FROM ...
```

With other database servers, consider casting the original date string to a real date value, to avoid any conversion issue at FETCH time.

As a general rule, always store and handle date values in DATE columns and variables, on both db server or program side.

**Date-time literals**

IBM® Informix® DATETIME and INTERVAL literals are not converted automatically by the SQL translator of the database driver:

```
SELECT COUNT(*) FROM order WHERE ord_when > DATETIME (1999-10-12) YEAR TO DAY
```
Check your code, to detect where you are using such expressions in the SQL statements, and use an SQL parameter instead.

**Informix-specific date/time keywords**
SQL statements using expressions such as `TODAY`, `CURRENT`, and `EXTEND` are specific to Informix SQL.

Database drivers try to translate date/time constant expressions to native SQL syntax, but this is only provided to simplify migration.

Date/time expression translation can be controlled with the following FGLPROFILE entries:

```sql
dbi.database.dsname.ifxemul.today = {true | false}
dbi.database.dsname.ifxemul.current = {true | false}
dbi.database.dsname.ifxemul.extend = {true | false}
```

**Important:** To ease migration to a new database type, Informix-specific expressions such as `TODAY`, `CURRENT` and `EXTEND` are converted to native date/time expressions. However, the date/time returned by the native SQL function may use a different timezone / daylight saving time convention.

Check your code, to detect where you are using `TODAY/CURRENT/EXTEND` expressions in the SQL statements, and consider using SQL parameters with program variables assigned with the `TODAY/CURRENT/EXTEND` instruction of Genero BDL.

**Date-time expressions with parameters**
Date-time arithmetic expressions using SQL parameters (USING variables) are not portable.

For example:

```sql
PREPARE s1 FROM "SELECT ... WHERE datecol < ? + 1"
```

Might generate an error with non-Informix databases.

**DATEs as a number of days**
IBM Informix can automatically convert integers to a DATE values, as a number of days since 12/31/1899 (1 = 01/01/1900). This is however not supported by other database engines.

Check your code, to detect where you are using integers with DATE columns.

**Related concepts**

- **DBDATE** on page 232
  Defines the default display and input format for DATE values.

**Naming database objects**

- **Name syntax**
  Database object naming conventions are different for each database engine.
  
The table below describes the naming conventions for database objects (tables, sequences, stored procedures):
Table 161: Database server naming conventions for database objects

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>Naming Syntax</th>
</tr>
</thead>

<td>SQLite</td>
<td><code>_database.]identifier</code></td>
</tr>
</tbody>
</table>

Case-sensitivity
Handling case-sensitivity with different database engines.

Most database engines have case-sensitive object identifiers. In most cases, when you do not specify identifiers in double quotes, the SQL parser automatically converts names to uppercase or lowercase, so that the identifiers match if the objects are also created without double quoted identifiers.

```sql
CREATE TABLE Customer ( cust_ID INTEGER )
```

In ORACLE, this statement would create a table named "CUSTOMER" with a "CUST_ID" column.

This table shows the behavior of each database engine regarding case sensitivity and double quoted identifiers:

Table 162: Database server support of case sensitivity and double-quoted identifiers

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>Un-quoted names</th>
<th>Double-quoted names</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW</td>

</tbody>
</table>
### SQL support

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>Un-quoted names</th>
<th>Double-quoted names</th>
</tr>
</thead>
<tbody>
<tr>
<td>SAP HANA®</td>
<td>Converts to uppercase</td>
<td>Case sensitive</td>
</tr>
<tr>
<td>SQLite</td>
<td>Not converted, kept as is</td>
<td>Case insensitive</td>
</tr>
</tbody>
</table>

1. If not ANSI database mode.
2. When case-sensitive charset/collation used.

Take care with database servers marked in red, because object identifiers are case sensitive and are not converted to uppercase or lowercase if not delimited by double-quotes. This means that, by error, you can create two tables with a similar name:

```sql
CREATE TABLE customer ( cust_id INTEGER )  -- first table
CREATE TABLE Customer ( cust_id INTEGER )  -- second table
```

It is recommended to design databases with lowercase table and column names.

**Size of identifiers**

Avoid using long database object names.

The maximum size of a table or column name depends on the database server type. Some database engines allow very large names (256c), while others support only short names (30c max). Therefore, using short names is required for writing portable SQL. Short names also simplify SQL programs.

We recommend that you use simple and short (<30c) database object names, without double quotes and without a schema/owner prefix:

```sql
CREATE TABLE customer ( cust_id INTEGER )
SELECT customer.cust_id FROM table
```

You may need to set the database schema after connection, so that the current database user can see the application tables without specifying the owner/schema prefix each time.

**Tip:** Even if all database engines do not required unique column names for all tables, we recommend that you define column names with a small table prefix (for example, CUST_ID in CUSTOMER table).

**LOAD and UNLOAD instructions**

The LOAD and UNLOAD instructions can produce different data formats depending on the database server type.

When executing the LOAD and UNLOAD instruction from a BDL program, SQL commands are not sent as is to the database server.

In fact, the Genero BDL runtime system implements the LOAD and UNLOAD instructions, using basic INSERT (for LOAD) or SELECT (for UNLOAD) SQL commands.

With this implementation, the LOAD and UNLOAD instruction can be supported with various database servers.

However, LOAD and UNLOAD require the description of the column types in order to work.

Since each database has its own set of SQL data types, you must pay attention to the BDL type that results from the native database column type.

Depending on the native data type, data formatting may be different from Informix®.

For example, when using Oracle DB, if the table contains a DATE column, the LOAD and UNLOAD instruction will use the date/time format YYYY-MM-DD hh:mm:ss. Since the native Oracle DATE type can be used to store both Informix® DATE or DATETIME YEAR TO SECOND values, and as LOAD / UNLOAD need to make date/time to string conversions when reading from or writing to unload files, it is not possible to select one of the Informix/BDL native date type formats.

**Note:** When using LOAD/UNLOAD, if the target database server provides the exact equivalent date types as the native Informix/BDL DATE, the date values will use the DBDATE format setting.
Table 163: Database server support of LOAD and UNLOAD

**Related concepts**

**SQL LOAD and UNLOAD** on page 683
Describes the instructions to export/import information from/to a database.

**Temporary tables**
Syntax for temporary table creation is not unique across all database engines.

Not all database servers support temporary tables. The engines supporting this feature often provide it with a specific table creation statement:
Table 164: Database server support of temporary tables

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>Native temp table creation syntax</th>
<th>Temp table support</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW</td>
<td>DECLARE GLOBAL TEMPORARY TABLE tablename ( column-defs ) DECLARE GLOBAL TEMPORARY TABLE tablename AS ( SELECT ... )</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>IBM® Informix®</td>

</tr>
<tr>
<td>Oracle® Database Server</td>
<td>CREATE GLOBAL TEMPORARY TABLE tablename ( column-defs ) CREATE GLOBAL TEMPORARY TABLE tablename AS SELECT ...</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>CREATE TEMP TABLE tablename ( column-defs ) SELECT select-list INTO TEMP tablename FROM ...</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>SAP® ASE</td>
<td>CREATE TABLE #tablename ( column-defs ) SELECT select-list INTO #tablename FROM ...</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>SAP HANA®</td>
<td>CREATE LOCAL TEMPORARY TABLE #tablename ( column-defs )</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>SQLite</td>
<td>CREATE TEMP TABLE tablename ( column-defs )</td>
<td>Emulated, see details</td>
</tr>
</tbody>
</table>

*Note:* DB2 Version 11.1 supports CREATE TEMP TABLE syntax for compatibility with Netezza.

*Note:* With ORACLE global temporary tables, only the data is local to the SQL session. The table is shared among all programs.

Some databases even have a different behavior when using temporary tables. For example, Oracle® 9i supports a kind of temporary table, but it must be created as a permanent table. The table is not specific to an SQL session: it is shared by all processes - only the data is local to a database session.
Important:

Simple Informix-style SQL statement creating temporary tables can be converted to a native SQL equivalent instruction. However, complex SQL statements such as SELECT ... INTO TEMP with subqueries may fail. In such case, create a view from the complex query and then create the temp table from the view. Or, disable Informix emulation and use the native SQL syntax to create the temporary table (EXECUTE IMMEDIATE "/* fglhint_no_ifxemul */ ...")

With Informix SQL, if the source table has a column defined as SERIAL or BIGSERIAL, a SELECT ... INTO TEMP will produce a new temp table with an auto-incremented serial column. With the SELECT ... INTO TEMP emulation for non-Informix databases, not using the native sequence generators (such as IDENTIFY columns in SQL Server), the resulting temporary table will get a simple INTEGER or BIGINT column, instead of an auto-incremented column.

Consider reviewing programs using temporary tables, and adapt the code to create temporary tables with native SQL syntax.

Outer joins

Use standard ISO outer join syntax instead of the old IBM® Informix® OUTER() syntax.

Old IBM® Informix® SQL outer joins specified with the OUTER keyword in the FROM part are not standard:

```sql
SELECT * FROM master, OUTER (detail) WHERE master.mid = detail.mid AND master.cdate IS NOT NULL
```

Table 165: Informix OUTER JOIN syntax by database brand

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>Informix OUTER join support</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>IBM® Informix®</td>
<td>Yes, native SQL feature</td>
</tr>
<tr>
<td>IBM® Netezza</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>Microsoft™ SQL Server</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>Oracle® MySQL</td>
<td>Emulated</td>

<td>Emulated, see details</td>
</tr>
<tr>
<td>PostgreSQL</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>SAP® ASE</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>SAP HANA®</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>SQLite</td>
<td>Emulated, see details</td>
</tr>
</tbody>
</table>

Most recent database servers now support the standard ANSI outer join specification:

```sql
SELECT * FROM master LEFT OUTER JOIN detail ON (master.mid = detail.mid) WHERE master.cdate IS NOT NULL
```

it is recommended that you use recent database servers and use ANSI outer joins only.

Substring expressions

Handle substrings expressions with different database engines.

Only IBM® Informix® supports substring specification with square brackets:

```sql
SELECT * FROM item WHERE item_code[1,4] = "XBFG"
```
This syntax is specific to Informix SQL. Other database server types provide a function that extracts substrings from a character string.

**Table 166: Substrings support by database server brand**

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>Substring function</th>
<th>col[x,y] support</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW</td>
<td>SUBSTR(expr,start,length)</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>IBM® Informix®</td>
<td>SUBSTR(expr,start,length)</td>
<td>Yes, native SQL feature</td>
</tr>
<tr>
<td>IBM® Netezza</td>
<td>SUBSTRING(expr,start,length)</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>Microsoft™ SQL Server</td>
<td>SUBSTRING(expr,start,length)</td>

</tr>
<tr>
<td>SAP® ASE</td>
<td>SUBSTRING(expr,start,length)</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>SAP HANA®</td>
<td>SUBSTRING(expr,start,length)</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>SQLite</td>
<td>SUBSTR(expr,start,length)</td>
<td>Emulated, see details</td>
</tr>
</tbody>
</table>

Informix® allows you to update some parts of a CHAR and VARCHAR column by using the substring specification (UPDATE tab SET col[1,2] = 'ab'). This is not possible with other databases.

Review the SQL statements using substring expressions and use the database specific substring function.

You can also create your own SUBSTRING() user function in all databases that do not support this function, to have a common way to extract substrings. In Microsoft™ SQL Server, when you create a user function, you must specify the owner as prefix when using the function. Therefore, it is recommended that you create a SUBSTRING() user function instead of SUBSTR().

**Using ROWID columns**

Automatic ROWID columns is not a common database feature.

Rowids are implicit primary keys generated by the database engine. Not all database servers support rowids:

**Table 167: Database server support of rowid**

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>Rowid keyword</th>
<th>Rowid type</th>
<th>ROWID support</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW</td>
<td>No</td>
<td>N/A</td>
<td>Yes, see details</td>
</tr>
</tbody>
</table>
Informix® fills the SQLCA.SQLERRD[6] register with the ROWID of the last updated row. This register is an INTEGER and cannot be filled with rowids having CHAR(*) type.

Search for ROWID and SQLCA.SQLERRD[6] in your code and review the code to remove the usage of rowids.

**Related concepts**

The SQLCA diagnostic record on page 532
The SQLCA variable is a predefined record containing SQL statement execution information.

**MATCHES and LIKE operators**

Use the standard LIKE operator instead of the MATCHES operator.

The MATCHES operator is specific to IBM® Informix® SQL, it allows to compare a character string column to a search pattern:

```
SELECT * FROM customer WHERE customer_name MATCHES "A*"
```

**Note:** The Genero language supports a MATCHES operator. Do not confuse the language MATCHES operator (used in BDL instructions such as IF custname MATCHES "S*"), with the SQL MATCHES operator (used in SQL statements). There is no problem in using the MATCHES operator of BDL.

The standard SQL operator for pattern search is LIKE:

```
SELECT * FROM customer WHERE customer_name LIKE "A%"
```

When using a non-Informix driver, the MATCHES expressions using a string constant are replaced by a LIKE expression.

**Important:** Only MATCHES expressions with a string constant can be converted to LIKE expressions, if the MATCHES uses a ? SQL parameter place holder, no translation is done.

**Table 168: SQL MATCHES operator support by database brand**

<table>
<thead>
<tr>
<th>Database Server Type</th>
<th>SQL MATCHES support</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® DB2® LUW</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>IBM® Informix®</td>
<td>Yes, native SQL feature</td>
</tr>
<tr>
<td>IBM® Netezza</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>Microsoft™ SQL Server</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>Oracle® MySQL</td>
<td>Emulated, see details</td>
</tr>
<tr>
<td>SQLite</td>
<td>Yes, see details</td>
</tr>
</tbody>
</table>
For maximum portability, replace SQL MATCHES expressions by LIKE expression. MATCHES uses * and ? as wildcards. The equivalent wildcards in the LIKE operator are % and _.

**Important:** MATCHES character ranges such as [a–z] cannot be converted for the LIKE operator.

Pay attention to blank padding semantics of the target database when using a program variable (or ? SQL parameter place holder) after the LIKE operator: If the program variable is defined as a CHAR(N), it is filled by the runtime system with trailing blanks, in order to have a size of N. For example, when a CHAR(10) variable is assigned with "ABC%", it contains actually "ABC %" (with 6 additional blanks). If this variable is used in a LIKE expression in an SQL statement, the database server will search for column values matching "ABC"+ some characters + 6 blanks. To avoid automatic blanks, use a VARCHAR(N) data type instead of CHAR(N) to hold LIKE patterns.

Pay also attention to database specific semantics of the LIKE operation, especially when using CHAR(N) data types. For example, with Oracle® DB, the expression custname LIKE '%h', if custname is defined as CHAR(30), Oracle® will only find the rows when the custname values end with a 'h' at the last character position (30), values such as 'Smith' will not be found. Similarly, when doing custname LIKE 'ab%', rows where the column type is CHAR(N>3), with values such as 'abc' will not match in Oracle®, IBM® DB2® and PostgreSQL, because of the significant trailing blanks.

PostgreSQL provides the SIMILAR TO operator, allowing [start-end] character range specification as in MATCHES.

As a general advice, use the VARCHAR type for variable string data, and leave CHAR usage for fixed-length character string data such as codes.

**Related concepts**

MATCHES on page 304

The MATCHES operator returns TRUE if a string matches a given mask.

**GROUP BY clause**

Some databases allow you to specify a column index in the GROUP BY clause:

```sql
SELECT a, b, sum(c) FROM table GROUP BY 1,2
```

This is not possible with all database servers:

**Table 169: Database server support of GROUP BY column index**
Search for GROUP BY in your SQL statements and use explicit column names.

**The LENGTH() function in SQL**

The semantics of the LENGTH() SQL function differs according to the database engine.

The SQL LENGTH() function must be used with care: Each database server has different semantics for this function, regarding length and trailing blanks handling.

*Note:* The language provides a LENGTH built-in function which is part of the runtime system. Do not confuse this with the SQL LENGTH() function, used in SQL statements. The LENGTH() function of the language returns zero when the string expression is NULL.

**Table 170: SQL LENGTH() support by database brand**

</tbody>
</table>
Search for LENGTH() usage in your SQL statements and review the code of the database-specific function.

**stored procedures**
Executing stored procedures with different database engine types.

Stored procedures execution needs to be addressed specifically depending on the database type. There are different ways to execute a stored procedure. This section describes how to execute stored procedures on the supported database engines.

**Tip:** In order to write reusable code, it is recommended that you encapsulate each stored procedure execution in a FUNCTION performing database-specific SQL based on a global database type variable. The program function would just take the input parameters and return the output parameters of the stored procedure, hiding database-specific execution steps from the caller.

**Specifying input and output parameters**
Input and output parameters can be specified in SQL statement execution to pass and return values to/from stored procedures, depending on the database type:

```
EXECUTE stmt USING param1 IN, param2 INOUT, param3 INOUT
```

**related concepts**

EXECUTE (SQL statement) on page 656
This instruction runs an SQL statement previously prepared.

**stored procedures returning a result set**
With some database servers it is possible to execute stored procedures that produce a result set, and fetch the rows as normal SELECT statements, by using DECLARE, OPEN, FETCH. Some databases can return multiple result sets and cursor handles declared in a stored procedure as output parameters, but Genero supports only unique and anonymous result sets. See the examples.

- Stored procedure call with SAP HANA on page 593

**stored procedure call with IBM® Informix®**
IBM® Informix® stored procedures are written in the SPL, C or Java programming languages, also known as User Defined Routines.

To create a stored procedure in an IBM® Informix® database, use the CREATE FUNCTION statement. See reference documentation for more details.

**stored functions returning values**
To return values from an IBM® Informix® SPL routine, execute the routine and fetch the output values, as you would for a regular SELECT statement producing a result set.

**Note:** Informix® distinguishes between stored functions from stored procedures. Only stored functions (with a RETURNING clause) can return values. Stored procedures do not return values.

To execute an Informix® stored function from a BDL program, use the EXECUTE FUNCTION SQL instruction:

```
PREPARE stmt FROM "execute function proc1(?)"
```
In order to retrieve returning values into program variables, use an **INTO** clause in the **EXECUTE** instruction.

This example shows how to call a stored function:

```sql
MAIN
DEFINE n INTEGER
DEFINE d DECIMAL(6,2)
DEFINE c VARCHAR(200)
DATABASE test1
EXECUTE IMMEDIATE "create function proc1( p1 integer )"
   " returning decimal(6,2), varchar(200);"
   " define p2 decimal(6,2);"
   " define p3 varchar(200);"
   " let p2 = p1 + 0.23;"
   " let p3 = 'Value = ' || p1;"
   " return p2, p3;"
   " end function;"
PREPARE stmt FROM "execute function proc1(?)"
LET n = 111
EXECUTE stmt USING n INTO d, c
DISPLAY d
DISPLAY c
END MAIN
```

**Stored functions defined with output parameters**

Starting with IDS 10.00, IBM® Informix® introduced the concept of output parameters for stored functions.

To retrieve the output parameters, you must execute the routine in a **SELECT** statement defining **Statement Local Variables**. These variables will be listed in the select clause to be fetched as regular column values. See Informix® documentation for more details.

In order to retrieve returning values into program variables, use an **INTO** clause in the **EXECUTE** instruction.

This example shows how to call a stored function with output parameters:

```sql
MAIN
DEFINE pi, pr INTEGER
DATABASE test1
EXECUTE IMMEDIATE "create function proc2(i INT, OUT r INT)"
   " returning int;"
   " let r=i+10;"
   " return r;"
   " end function"
PREPARE s FROM "select r from systables where tabid=1 and proc2(?,'?#int)==1"
LET pi = 33
EXECUTE s USING pi INTO pr
DISPLAY "Output value: ", pr
EXECUTE IMMEDIATE "drop function proc2"
END MAIN
```

**Stored functions returning a result set**

To retrieve the rows of a result set produced by an IBM® Informix® stored function, you must create a cursor, as you would for a regular **SELECT** statement.

This example shows how to execute a stored function producing a result set:

```sql
MAIN
DEFINE m, p_pk INT, p_name VARCHAR(10)
DATABASE test1
CREATE TABLE t1 ( pk INT, name VARCHAR(10) )
INSERT INTO t1 VALUES (1, 'aaaa')
```
STORED procedure call with Oracle DB

Oracle supports stored procedures and stored functions as a group of PL/SQL statements that you can call by name.

To create a stored procedure in an Oracle database, use the `CREATE PROCEDURE` statement. See reference documentation for more details.

Stored procedures with output parameters

Oracle® stored procedures or stored functions must be called with the input and output parameters specification in the `USING` clause of the `EXECUTE`, `OPEN` or `FOREACH` instruction. As in normal dynamic SQL, parameters must correspond by position, and the `IN/OUT/INOUT` options must match the parameter definition of the stored procedure.

To execute the stored procedure, you must include the procedure in an anonymous PL/SQL block with `BEGIN` and `END` keywords:

```
PREPARE stmt FROM "begin proc1(?,?,?); end;"
```

Remark: Oracle® stored procedures do not specify the size of number and character parameters. The size of output values (especially character strings) are defined by the calling context (i.e. the data type of the variable used when calling the procedure). When you pass a `CHAR(10)` to the procedure, the returning value will be filled with blanks to reach a size of 10 bytes.

Note that for technical reasons, the Oracle® driver uses dynamic binding with `OCIBindDynamic()`. The Oracle® Call Interface does not support stored procedures parameters with the `CHAR` data type when using dynamic binding. You must use `VARCHAR2` instead of `CHAR` to define character string parameters for stored procedures.

Here is a complete example creating and calling a stored procedure with output parameters:

```
MAIN
    DEFINE n INTEGER
    DEFINE d DECIMAL(6,2)
    DEFINE c VARCHAR(200)
    DATABASE test1
    EXECUTE IMMEDIATE
        "create procedure procl("
        "            p1 in int,"
        "            p2 in out number,"
        "            p3 in out varchar2"
        "        )"
    "    is begin"
    "        p2:= p1 + 0.23;"
    "        p3:= 'Value = ' || to_char(p1);"
```
Stored functions with a return value

To execute the stored function returning a value, you must include the function in an anonymous PL/SQL block with BEGIN and END keywords, and use an assignment expression to specify the place holder for the returning value:

```
PREPARE stmt FROM "begin ?:= func1(??,?,?); end;"
```

Stored procedures with result set

Oracle supports result set generation from stored procedures with the concept of cursor variables (REF CURSOR).

Note that Genero does not support cursor references produced by Oracle stored procedures or functions.

**Stored procedure call with IBM® DB2®**

IBM® DB2® supports stored procedures as a saved collection of SQL statements, which can accept and return user-supplied parameters.

IBM® DB2® stored procedures can also produce one or more result sets.

To create a stored procedure in an IBM® DB2® database, use the **CREATE PROCEDURE** statement. See reference documentation for more details.

Stored procedures with output parameters

IBM® DB2® stored procedures must be called with the input and output parameters specification in the USING clause of the EXECUTE, OPEN or FOREACH instruction. As in normal dynamic SQL, parameters must correspond by position and the IN/OUT/INOUT options must match the parameter definition of the stored procedure.

To execute the stored procedure, you must use the CALL SQL instruction:

```
PREPARE stmt FROM "call proc1(?,?,?)"
```

Here is a complete example creating and calling a stored procedure with output parameters:

```
MAIN
DEFINE n INTEGER
DEFINE d DECIMAL(6,2)
DEFINE c VARCHAR(200)
DATABASE test1
EXECUTE IMMEDIATE
  "create procedure proc1(" | "end"
  " in pl int," | "end"
  " out p2 decimal(6,2)," | "end"
  " inout p3 varchar(20)"
  ")" | "end"
  " language sql begin"
  " set p2 = pl + 0.23;"
  " set p3 = 'Value = ' || char(p1);"
  "end"
PREPARE stmt FROM "call proc1(??,?,?)"
LET n = 111
EXECUTE stmt USING n IN, d OUT, c INOUT
DISPLAY d
DISPLAY c
END MAIN
```
Stored procedures with result set

With IBM® DB2®, you can execute stored procedures returning a result set. To do so, you must declare a cursor and fetch the rows:

```sql
MAIN
    DEFINE i, n INTEGER
    DEFINE d DECIMAL(6,2)
    DEFINE c VARCHAR(200)
    DATABASE test1
    CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
    INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
    INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbb' )
    INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
    EXECUTE IMMEDIATE "create procedure proc2( in key integer )" ||
        " result sets 1"
        || " language sql"
        || "  begin"
        || "  declare c1 cursor with return for"
        || "    select * from tab1 where c1 > key;"
        || "  open c1;"
        || "  end"
    DECLARE curs CURSOR FROM "call proc2(?)"
    LET i = 1
    FOREACH curs USING i INTO n, d, c
    DISPLAY n, d, c
END FOREACH
END MAIN
```

Stored procedures with output parameters and result set

It is possible to execute IBM® DB2® stored procedures with output parameters and a result set.

The output parameter values are available after the OPEN cursor instruction:

```sql
OPEN curs USING n IN, d OUT, c INOUT
FETCH curs INTO rec.*
```

**Stored procedure call with Microsoft™ SQL Server**

SQL Server supports stored procedures, as a saved collection of Transact-SQL statements that can take and return user-supplied parameters.

SQL Server stored procedures can also produce one or more result sets.

To create a stored procedure in an SQL Server database, use the CREATE PROCEDURE statement. See reference documentation for more details.

**Stored procedures with output parameters**

SQL Server stored procedures must be called with the input and output parameters specification in the USING clause of the EXECUTE, OPEN or FOREACH instruction. As in normal dynamic SQL, parameters must correspond by position and the IN/OUT/INOUT options must match the parameter definition of the stored procedure.

To execute the stored procedure, you must use an ODBC call escape sequence:

```sql
PREPARE stmt FROM "( call proc1(?,?,?) )"
```

Here is a complete example creating and calling a stored procedure with output parameters:
DATABASE test1
EXECUTE IMMEDIATE
   "create procedure procl"
   "   @v1 integer,"
   "   @v2 decimal(6,2) output,"
   "   @v3 varchar(20) output"
   " as begin"
   "   set @v2 = @v1 + 0.23"
   "   set @v3 = 'Value = ' || cast(@v1 as varchar)"
   "end"
PREPARE stmt FROM "( call procl(?,?,?) )"
LET n = 111
EXECUTE stmt USING n IN, d OUT, c OUT
DISPLAY d
DISPLAY c
END MAIN

Stored procedures with result set

With SQL Server, you can execute stored procedures returning a result set. To do so, you must declare a cursor and fetch the rows.

The next example uses a stored procedure with a simple SELECT statement. If the stored procedure contains additional Transact-SQL statements such as SET or IF (which is the case in complex stored procedures), SQL Server generates multiple result sets. By default the Genero SQL Server driver uses "server cursors" to support multiple active SQL statements. But SQL Server stored procedures generating multiple result sets cannot be used with server cursors: The server cursor is silently converted to a "default result set" cursor by the ODBC driver. Since Default result set cursors do not support multiple active statements, you cannot use another SQL statement while processing the results of such stored procedure. You must CLOSE the cursor created for the stored procedure before continuing with other SQL statements.

MAIN
   DEFINE i, n INTEGER
   DEFINE d DECIMAL(6,2)
   DEFINE c VARCHAR(200)
   DATABASE test1
   CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
   INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
   INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbb' )
   INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
   EXECUTE IMMEDIATE "create procedure proc2 @key integer"
   " as select * from tab1 where c1 > @key"
   DECLARE curs CURSOR FROM "( call proc2(?) )"
   LET i = 1
   FOREACH curs USING i INTO n, d, c
     DISPLAY n, d, c
   END FOREACH
END MAIN

It is possible to fetch large objects (text/image) from stored procedure generating a result set. However, if the stored procedure executes other statements as the SELECT (like SET/IF commands), the SQL Server ODBC driver will convert the server cursor to a regular default result set cursor, requiring the LOB columns to appear at the end of the select list. Thus, in most cases (stored procedures typically use SET/IF statements), you will have to move the LOB columns and the end of the column list.

Stored procedures returning a cursor as output parameter

SQL Server supports "cursor output parameters": A stored procedure can declare/open a cursor and return a reference of the cursor to the caller.
SQL Server stored procedures returning a cursor as output parameter are not supported. There are two reasons for this: The language does not have a data type to store a server cursor reference, and the underlying ODBC driver does not support this anyway.

Stored procedures with return code

SQL Server stored procedures can return integer values. To get the return value of a stored procedure, you must use an assignment expression in the ODBC call escape sequence:

```
PREPARE stmt FROM "(? = call proc3(?,?,?))"
```

Then the statement can be executed with the EXECUTE instruction, by specifying the output parameter receiving the returned value as first element in the USING list, with the OUT modifier:

```
MAIN
  DEFINE p1, p2, r INTEGER
  CONNECT TO ...
  WHENEVER ERROR CONTINUE
  EXECUTE IMMEDIATE "DROP PROCEDURE p_mul"
  WHENEVER ERROR STOP
  EXECUTE IMMEDIATE "CREATE PROCEDURE p_mul ( @p1 INT, @p2 INT )
  AS BEGIN
  DECLARE @r INT
  SET @r = @p1 * @p2;
  RETURN @r;
  END"
  LET p1 = 15
  LET p2 = 3
  PREPARE s1 FROM "(? = call p_mul(?,?))"
  EXECUTE s1 USING r OUT, p1 IN, p2 IN
  DISPLAY "r = ", r
END MAIN
```

Stored procedures with output parameters, return code and result set

With SQL Server you can call stored procedures with a return code, output parameters and producing a result set.

Return codes and output parameters are the last items returned to the application by SQL Server; they are not returned until the last row of the result set has been fetched, after the SQLMoreResults() ODBC function is called. If output parameters are used, the SQL Server driver executes a SQLMoreResults() call when closing the cursor instead of SQLCloseCursor(), to get the return code and output parameter values from SQL Server.

```
MAIN
  DEFINE r, i, n INTEGER
  DEFINE d DECIMAL(6,2)
  DEFINE c VARCHAR(200)
  DATABASE test1
  CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
  INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
  INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbbbb' )
  INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
  EXECUTE IMMEDIATE "create procedure proc3 @key integer output"
  | " as begin"
  | "  set @key = @key - 1"
  | "  select * from tab1 where c1 > @key"
  | "  return (@key * 3)"
  | " end"
  DECLARE curs CURSOR FROM "(? = call proc3(?))"
  LET i = 1
  OPEN curs USING r INOUT, i INOUT
  DISPLAY r, i
  FETCH curs INTO n, d, c
  FETCH curs INTO n, d, c
```

The return code and output parameter variables must be defined as **INOUT** in the **OPEN** instruction.

**Stored procedure call with PostgreSQL**

PostgreSQL implements stored functions that can return values. If the function returns more that one value, you must specify the returning values as function parameters with the **OUT** keyword. If the function returns a unique value, you can use the **RETURNS** clause.

To create a stored procedure in a PostgreSQL database, use the **CREATE FUNCTION** statement. See reference documentation for more details.

**Note:** Pay attention to the function signature; PostgreSQL allows function overloading. For example, `func(int)` and `func(char)` are two different functions. To drop a function, you must specify the parameter type to identify the function signature properly.

**Stored functions with output parameters**

To execute a stored function with PostgreSQL, you must use `SELECT * FROM function`, as shown in this line:

```sql
PREPARE stmt FROM "select * from proc1(?)"
```

In order to retrieve returning values into program variables, you must use an **INTO** clause in the **EXECUTE** instruction.

The following example shows how to call a stored function with PostgreSQL:

```sql
MAIN
DEFINE n INTEGER
DEFINE d DECIMAL(6,2)
DEFINE c VARCHAR(200)
DATABASE test1
EXECUTE IMMEDIATE "create function proc1(" || "          p1 integer," || "          out p2 numeric(6,2)," || "          out p3 varchar(200)"
   || "          )"
   || " as $$
   || "  begin"
   || "    p2:= p1 + 0.23;"
   || "    p3:= 'Value = ' || cast(p1 as text);"
   || "  end;"
   || " $$ language plpgsql"
PREPARE stmt FROM "select * from proc1(?)"
LET n = 111
EXECUTE stmt USING n INTO d, c
DISPLAY d
DISPLAY c
END MAIN
```

**Stored functions with result set**

With PostgreSQL, you can execute stored procedures returning a result set. To do so, you must declare a cursor and fetch the rows:

```sql
MAIN
DEFINE i, n INTEGER
DEFINE d DECIMAL(6,2)
```
**SQL support**

```
DEFINE c VARCHAR(200)
DATABASE test1
CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbbbb' )
INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
EXECUTE IMMEDIATE "create function proc2(integer)"
  " returns setof tab1"
  " as $$"
  " select * from tab1 where c1 > $1;"
  " $$ language sql"
DECLARE curs CURSOR FROM "select * from proc2(?)"
LET i = 1
FOREACH curs USING i INTO n, d, c
  DISPLAY n, d, c
END FOREACH
END MAIN
```

**Stored functions with output parameters and result set**

With PostgreSQL you cannot return output parameters and a result set from the same stored procedure; both use the same technique to return values to the client, in the context of result columns to be fetched.

**Stored procedure call with Oracle MySQL / MariaDB**

Oracle® MySQL and MariaDB implement stored procedures and stored functions as a collection of SQL statements that can take and return user-supplied parameters. Functions are very similar to procedures, except that they return a scalar value and can be used in SQL expressions.

To create a stored procedure in a Oracle® MySQL or MariaDB database, use the `CREATE PROCEDURE` statement. See reference documentation for more details.

**Stored procedures with output parameters**

Since Oracle® MySQL C API (version 5.0) does not support an output parameter specification, the `IN/OUT/INOUT` technique cannot be used.

In order to return values from a MySQL stored procedure or stored function, you must use SQL variables. There are three steps to execute the procedure or function:

1. With the `SET` SQL statement, create and assign an SQL variables for each parameter.
2. `CALL` the stored procedure or stored function with the created SQL variables.
3. Perform a `SELECT` statement to return the SQL variables to the application.

In order to retrieve returning values into program variables, you must use an `INTO` clause in the `EXECUTE` instruction.

The following example shows how to call a stored procedure with output parameters:

MySQL version 5.0 does not allow you to prepare the `CREATE PROCEDURE` statement; you may need to execute this statement from the mysql command line tool.

MySQL version 5.0 cannot execute "SELECT @variable" with server-side cursors. Since the MySQL driver uses server-side cursors to support multiple active result sets, it is not possible to execute the `SELECT` statement to return output parameter values.

MySQL version >=5.0 evaluates "@variable" user variables assigned with a string as large text (CLOB) expressions. That type of values must normally be fetched into `TEXT` variable. To workaround this behavior, you can use the `substring(@var,1,255)` function to return a `VARCHAR()` expression from MySQL and fetch into a `VARCHAR()` variable.

```
MAIN
  DEFINE n INTEGER
  DEFINE d DECIMAL(6,2)
  DEFINE c VARCHAR(200)
```
DATABASE test1
EXECUTE IMMEDIATE
"create procedure proc1(
   p1 integer,
   out p2 numeric(6,2),
   out p3 varchar(200)
)"
"no sql begin"
  set p2 = p1 + 0.23;
  set p3 = concat( 'Value = ', p1 );"
"end;"

LET n = 111
EXECUTE IMMEDIATE "set @p1 = ", n
EXECUTE IMMEDIATE "set @p2 = NULL"
EXECUTE IMMEDIATE "set @p3 = NULL"
EXECUTE IMMEDIATE "call proc1(@p1, @p2, @p3)"
PREPARE stmt FROM "select @p2, substring(@p3,1,200)"
EXECUTE stmt INTO d, c
DISPLAY d
DISPLAY c
END MAIN

Stored functions returning values

The following example shows how to retrieve the return value of a stored function with Oracle® MySQL:

MySQL version 5.0 does not allow you to prepare the CREATE FUNCTION statement; you may need to execute this statement from the mysql command line tool.

MAIN
DEFINE n INTEGER
DEFINE c VARCHAR(200)
DATABASE test1
EXECUTE IMMEDIATE "create function func1(p1 integer)"
"no sql begin"
  return concat( 'Value = ', p1 );"
"end;"
PREPARE stmt FROM "select func1(?)"
LET n = 111
EXECUTE stmt USING n INTO c
DISPLAY c
END MAIN

Stored procedures with result set

Note that Oracle® MySQL version 5.0 stored procedures and stored functions cannot return a result set.

Stored procedure call with SAP ASE

SAP® ASE supports stored procedures, which can take and return user-supplied parameters.

SAP® ASE stored procedures can also produce one or more result sets.

To create a stored procedure in a SAP® ASE database, use the CREATE PROCEDURE statement. See reference documentation for more details.

Stored procedures with output parameters

SAP® ASE stored procedures must be called with the input and output parameters specification in the USING clause of the EXECUTE, OPEN or FOREACH instruction. As in normal dynamic SQL, parameters must correspond by position and the IN/OUT/INOUT options must match the parameter definition of the stored procedure.
To execute the stored procedure, you must use a specific syntax to have the database driver identify the statement as an RPC call. The syntax of an RPC call must be:

```
!rpc procedure-name ( [ @param-name [, ...] ] )
```

The parameter names must be specified, with the same names as the arguments of the stored procedure, because the ODI driver must bind stored procedure parameters by name.

Example:

```
PREPARE stmt FROM "!rpc update_account ( @custid, @old, @new )"
```

Here is a complete example creating and calling a stored procedure with output parameters:

```sql
MAIN
DEFINE n INTEGER
DEFINE d DECIMAL(6,2)
DEFINE c VARCHAR(200)
DATABASE test1
EXECUTE IMMEDIATE
   "create procedure proc1"
   "   @v1 integer,"
   "   @v2 decimal(6,2) output,"
   "   @v3 varchar(20) output"
   " as begin"
   "   set @v2 = @v1 + 0.23"
   "   set @v3 = 'Value = ' || cast(@v1 as varchar)"
   "end"
PREPARE stmt FROM "!rpc proc1( @v1, @v2, @v3 )"
LET n = 111
EXECUTE stmt USING n IN, d OUT, c OUT
DISPLAY d
DISPLAY c
END MAIN
```

Stored procedures with result set

With SAP ASE, you can execute stored procedures returning a result set. To do so, you must declare a cursor and fetch the rows.

When the stored procedure generates multiple active statements, you cannot use another SQL statement while processing the results of such stored procedure. You must close the cursor created for the stored procedure before continuing with other SQL statements.

```sql
MAIN
DEFINE i, n INTEGER
DEFINE d DECIMAL(6,2)
DEFINE c VARCHAR(200)
DATABASE test1
CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbb' )
INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
EXECUTE IMMEDIATE "create procedure proc2 @key integer"
    " as select * from tab1 where c1 > @key"
DECLARE curs CURSOR FROM "!rpc proc2( @key )"
LET i = 1
FOREACH curs USING i INTO n, d, c
    DISPLAY n, d, c
END FOREACH
END MAIN
```
Stored procedures with output parameters, return code and result set

With SAP® ASE stored procedures, you call stored procedures with a return code, output parameters and producing a result set.

Return codes and output parameters are the last items returned to the application by SAP® ASE; they are not returned until the last row of the result set has been fetched.

```sql
MAIN
    DEFINE r, i, n INTEGER
    DEFINE d DECIMAL(6,2)
    DEFINE c VARCHAR(200)
    DATABASE test1
    CREATE TABLE tab1 ( c1 INTEGER, c2 DECIMAL(6,2), c3 VARCHAR(200) )
    INSERT INTO tab1 VALUES ( 1, 123.45, 'aaaaaa' )
    INSERT INTO tab1 VALUES ( 2, 123.66, 'bbbbbbbb' )
    INSERT INTO tab1 VALUES ( 3, 444.77, 'cccccc' )
    EXECUTE IMMEDIATE "create procedure proc3 @key integer output"
        "  as begin"
        "     set @key = @key - 1"
        "     select * from tab1 where c1 > @key"
        "     return (@key * 3)"
        "  end"
    DECLARE curs CURSOR FROM "!rpc proc3( @key ) }"
    LET i = 1
    OPEN curs USING r OUT, i OUT
    DISPLAY r, i
    FETCH curs INTO n, d, c
    FETCH curs INTO n, d, c
    FETCH curs INTO n, d, c
    DISPLAY r, i
    CLOSE curs
    DISPLAY r, i -- Now the returned values are available
END MAIN
```

**Stored procedure call with SAP HANA®**

SAP HANA® supports stored procedures as a saved collection of SQL statements, which can accept and return user-supplied parameters.

SAP HANA® stored procedures can also produce one result set that can be accessed through a result view.

To create a stored procedure in SAP HANA® database, use the CREATE PROCEDURE statement. See reference documentation for more details.

**Stored procedures with output parameters**

SAP HANA® stored procedures must be called with the input and output parameters specification in the USING clause of the EXECUTE, OPEN or FOREACH instruction. As in normal dynamic SQL, parameters must correspond by position and the IN/OUT/INOUT options must match the parameter definition of the stored procedure.

To execute the stored procedure, you must use the CALL SQL instruction:

```sql
PREPARE stmt FROM "call procl(?,?,?)"
```

Here is a complete example creating and calling a stored procedure with output parameters:

```sql
MAIN
    DEFINE n INTEGER
    DEFINE d DECIMAL(6,2)
    DEFINE c VARCHAR(200)
    DATABASE test1
    EXECUTE IMMEDIATE "create procedure procl("
With SAP HANA®, you can execute stored procedures returning a result set. To do so, you must:

1. Define a user type with \texttt{CREATE TYPE}, with the same structure as the result set.
2. DECLARE a cursor to fetch the rows from the result view associated to the stored procedure (the name of the result view is defined by the \texttt{WITH RESULT VIEW} clause in \texttt{CREATE PROCEDURE}.
3. The \texttt{SELECT} statement used by the cursor must specify named input parameters with the \texttt{PLACEHOLDER} keyword, and since parameter names must be enclosed in double quotes, you need to disable the Informix emulation with the \texttt{fglhint_no_ifxemul} special hint.

\textbf{Note:} Pay attention to \texttt{VARCHAR} / \texttt{NVARCHAR} translation done by the driver, to support non-ASCII character sets (the type must be created with \texttt{NVARCHAR} since the SQL translator does makes the conversion only for \texttt{CREATE TABLE}).

\textbf{Important:} It is no possible to execute SAP HANA® stored procedures with output parameters and a result set.
SQL performance

Execution time can be drastically improved, when using SQL instructions in the right way.

- Performance with dynamic SQL on page 595
- Performance with transactions on page 596
- Avoiding long transactions on page 597
- Declaring prepared statements on page 597
- Saving SQL resources on page 597
- Optimizing scrollable cursors on page 598

Performance with dynamic SQL

Comparing static SQL statements and dynamic SQL statements used in a loop.

Although SQL statements can be directly specified in the program source as a part of the language as static SQL, it is sometimes more efficient to use dynamic SQL instead, when you are executing SQL statements repeatedly.

Dynamic SQL allows you to prepare the SQL statements once and execute N times, improving performance.

Note however that implementing prepared statements with dynamic SQL has a cost in terms of database resources and code readability. When a simple static SQL statement is executed, database client and server resources are allocated for the statement and are reused for the next Static SQL statement. With dynamic SQL, you define a statement handle and allocate database resources that last until you free the handle. Regarding code readability, static SQL statements can be written directly in the source code (as another language statement), while Dynamic SQL uses several instructions and takes the SQL text as a string expression. Additionally, static SQL statements are parsed at compile time so you can detect syntax errors in the SQL text before executing the programs.

Therefore, dynamic SQL should only be used if the SQL statement is created at runtime (with a where part generated by a construct for example) or if the execution time is too long with static SQL (assuming that it’s only a statement preparation issue).

To perform static SQL statement execution, the database interface must use the basic API functions provided by the database client. These are usually equivalent to the prepare and execute instructions. So when you write a static SQL statement in your program, it is actually converted to a prepare + execute behind the scene.

For example, the following code:

```
FOR n=1 TO 100
  INSERT INTO tab VALUES ( n, c )
END FOR
```

is actually equivalent to:

```
FOR n=1 TO 100
  PREPARE s FROM "INSERT INTO tab VALUES ( ?, ? )"
  EXECUTE s USING n, c
END FOR
```

To improve the performance of the preceding code, use a prepare instruction before the loop and put an execute instruction inside the loop:

```
PREPARE s FROM "INSERT INTO tab VALUES ( ?, ? )"
FOR n=1 TO 100
  EXECUTE s USING n, c
END FOR
```

Describes static SQL statements supported in the language.

**Query by example (CONSTRUCT)** on page 1461

The CONSTRUCT instruction implements database query criteria input in an application form.

**Performance with transactions**

Commit database changes by blocks of transaction speeds performance with some database servers.

To mimic the IBM® Informix® auto-commit behavior with an ANSI compliant RDBMS like Oracle® or DB2®, the database driver must perform an implicit commit after each statement execution, if the SQL statement is not inside a transaction block. This generates unnecessary database operations and can slow down big loops. To avoid this implicit commit, you can control the transaction with **BEGIN WORK**/**COMMIT WORK** around the code containing a lot of SQL statement execution.

This technique is especially recommended with SQLite, because the SQLite database library performs a lot of operations during a commit.

For example, the following loop will generate 2000 basic SQL operations (1000 inserts plus 1000 commits):

```sql
PREPARE s FROM "INSERT INTO tab VALUES ( ?, ? )"
FOR n=1 TO 100
   EXECUTE s USING n, c  -- Generates implicit COMMIT
END FOR
```

You can improve performance if you put a transaction block around the loop:

```sql
PREPARE s FROM "INSERT INTO tab VALUES ( ?, ? )"
BEGIN WORK
FOR n=1 TO 100
   EXECUTE s USING n, c  -- In transaction -> no implicit COMMIT
END FOR
COMMIT WORK
```

With this code, only 1001 basic SQL operations will be executed (1000 inserts plus 1 commit).

However, you must take care when generating large transactions because all modifications are registered in transaction logs. This can result in a lack of database server resources ("transaction too long" errors, for example) when the number of operations is very big. If the SQL operation does not require a unique transaction for database consistency reasons, you can split the operation into several transactions, as in this example:

```sql
PREPARE s FROM "INSERT INTO tab VALUES ( ?, ? )"
BEGIN WORK
FOR n=1 TO 100
   IF n MOD 10 == 0 THEN
      COMMIT WORK
      BEGIN WORK
   END IF
   EXECUTE s USING n, c  -- In transaction -> no implicit COMMIT
END FOR
COMMIT WORK
```

Note that the **LOAD** instruction automatically starts a transaction, if not yet initiated. Therefore there is no need to enclose the **LOAD** statement within a **BEGIN WORK**/**COMMIT WORK**, except if other SQL statements are part of the transaction and need to be processed as a single atomic database change.

**Related concepts**

**Database transactions** on page 631
Database transaction concepts and handling.

**Avoiding long transactions**
Long transactions consume resources and decrease concurrent data access.

Old applications based on IBM® Informix® database without transaction logging might perform long running SQL modifications.

With recent database engines, using huge transactions can lead to errors because of transaction log buffer overflow. For example, if a table holds many rows, a "DELETE FROM table" might produce a "snapshot too old" error in Oracle, if the rollback segments are too small.

Therefore, you must avoid long transactions when connected to a database using transactions:

- keep transactions as short as possible.
- access the least amount of data possible while in a transaction.
- split a long transaction into many short transactions. Use a loop to handle each block.
- to delete all rows from a table use the "TRUNCATE TABLE" instruction instead of "DELETE FROM" (Not for all vendors).
- In the end, increase the size of the transaction log to avoid filling it up.

- Database transactions on page 631
  Database transaction concepts and handling.
- Performance with transactions on page 596
  Commit database changes by blocks of transaction speeds performance with some database servers.

**Declaring prepared statements**
Optimize prepared cursor statements by using the FROM clause of DECLARE CURSOR.

Line 2 of this example shows a cursor declared with a prepared statement:

```
PREPARE s FROM "SELECT * FROM table WHERE ", condition
DECLARE c CURSOR FOR s
```

While this has no performance impact with IBM® Informix® database drivers, it can become a bottleneck when using non-IBM Informix® databases:

Statement preparation consumes a lot of memory and processor resources. Declaring a cursor with a prepared statement is a native IBM® Informix® feature, which consumes only one real statement preparation. Non-IBM Informix® databases do not support this feature, so the statement is prepared twice (once for the PREPARE, and once for the DECLARE). When used in a big loop, this code can cause performance problems.

To optimize the code, use the FROM clause in the DECLARE statement:

```
DECLARE c CURSOR FROM "SELECT * FROM table WHERE " || condition
```

By using this solution only one statement preparation will be done by the database server.

**Note:** This performance problem does not occur with DECLARE statements using static SQL.

**Related concepts**
- DECLARE (result set cursor) on page 663
  Associates a database cursor with an SQL statement producing a result set.

**Saving SQL resources**
SQL cursors and prepared statement consume resources that should be freed when useless.

To write efficient SQL in your programs, you can use dynamic SQL. However, when using dynamic SQL, you allocate an SQL statement handle on the client and server side, consuming resources. According to the database type,
this can be a few bytes or a significant amount of memory. When executing several static SQL statements, the same statement handle is reused and thus less memory is needed.

The language allows you to use either static SQL or dynamic SQL, so it’s in your hands to choose memory or performance. However, in some cases the same code will be used by different kinds of programs, needing either low resource usage or good performance. In many OLTP applications you can actually distinguish two type of programs:

- Programs where memory usage is not a problem but good performance is needed (typically, batch programs executed as a unique instance during the night).
- Programs where performance is less important but memory usage must be limited (typically, interactive programs executed as multiple instances for each application user).

To reuse the same code for interactive programs and batch programs, you can do this:

1. Define a local module variable as an indicator for the prepared statement.
2. Write a function returning the type of program (for example, 'interactive' or 'batch' mode).
3. Then, in a reusable function using SQL statements, prepare and free the statement based on the indicators, as shown in the next example.

```sql
PRIVATE DEFINE up_prepared BOOLEAN

FUNCTION getUserPermissions( username )
    DEFINE username VARCHAR(20)
    DEFINE cre, upd, del CHAR(1)

    IF NOT up_prepared THEN
        PREPARE up_stmt FROM "SELECT can_create, can_update, cab_delete"
            || " FROM user_perms WHERE name = ?"
        LET up_prepared = TRUE
    END IF

    EXECUTE up_stmt USING username INTO cre, upd, del

    IF isInteractive() THEN
        FREE up_stmt
        LET up_prepared = FALSE
    END IF

    RETURN cre, upd, del
END FUNCTION
```

The first time this function is called, the `up_prepared` value will be `FALSE`, so the statement will be prepared. The next time the function is called, the statement will be re-prepared only if `up_prepared` is `TRUE`. The statement is executed and values are fetched into the variables returned. If the program is interactive, the statement is freed and set the `up_prepared` module variable back to `FALSE`, forcing statement preparation in the next call of this function.

**Optimizing scrollable cursors**

A programming pattern to get fresh data from scrollable cursors.

Generally, when using scrollable cursors, the database server or the database client software (i.e. the application) will make a static copy of the result set produced by the `SELECT` statement. For example, when using an IBM® Informix® database engine, each scrollable cursor will create a temporary table to hold the result set. Thus, if the `SELECT` statement returns all columns of the table(s) in the `FROM` clause, the database software will make a copy of all these values. This practice has two disadvantages: A lot of resources are consumed, and the data is static.
A good programming pattern to save resources and always get fresh data from the database server is to declare two cursors based on the primary key usage, if the underlying database table has a primary key (or unique index constraint): The first cursor must be a scrollable cursor that executes the `SELECT` statement, but returns only the primary keys. The `SELECT` statement of this first cursor is typically assembled at runtime with the where-part produced by a `CONSTRUCT` interactive instruction, to give a subset of the rows stored in the database. The second cursor (actually, a `PREPARE/EXECUTE` statement handle) performs a single-row `SELECT` statement listing all columns to be fetched for a given record, based on the primary key value of the current row in the scrollable cursor list. The second statement must use a `?` question mark place holder to execute the single-row `SELECT` with the current primary key as SQL parameter.

If the primary key `SELECT` statement needs to be ordered, check that the database engine allows that columns used in the `ORDER BY` clause do not need to appear in the `SELECT` list. For example, this was the case with IBM® Informix® servers prior to version 9.4. If needed, the `SELECT` list can be completed with the columns used in `ORDER BY`, you can then just list the variable that holds the primary key in the `INTO` clause of `FETCH`.

Note also that the primary key result set is static. That is, if new rows are inserted in the database or if rows referenced by the scroll cursor are deleted after the scroll cursor was opened, the result set will be outdated. In this case, you can refresh the primary key result set by re-executing the scroll cursor with `CLOSE/OPEN` commands.

This code example illustrates this programming pattern:

```sql
MAIN
    DEFINE wp VARCHAR(500)
    DATABASE test1
    -- OPEN FORM / DISPLAY FORM with c_id and c_name fields
    ...
    -- CONSTRUCT generates wp string...
    ...
    LET wp = "c_name LIKE 'J%'"
    DECLARE clist SCROLL CURSOR FROM "SELECT c_id FROM customer WHERE " || wp
    PREPARE crec FROM "SELECT * FROM customer WHERE c_id = ?"
    OPEN clist
    MENU "Test"
        COMMAND "First" CALL disp_cust("F")
        COMMAND "Next" CALL disp_cust("N")
        COMMAND "Previous" CALL disp_cust("P")
        COMMAND "Last" CALL disp_cust("L")
        COMMAND "Refresh" CLOSE clist OPEN clist
        COMMAND "Quit" EXIT MENU
    END MENU
    FREE crec
    FREE clist
END MAIN

FUNCTION disp_cust(m)
    DEFINE m CHAR(1)
    DEFINE rec RECORD
        c_id INTEGER,
        c_name VARCHAR(50)
    END RECORD
    CASE m
        WHEN "F" FETCH FIRST clist INTO rec.c_id
        WHEN "N" FETCH NEXT clist INTO rec.c_id
        WHEN "P" FETCH PREVIOUS clist INTO rec.c_id
        WHEN "L" FETCH LAST clist INTO rec.c_id
    END CASE
    INITIALIZE rec.* TO NULL
    IF SQLCA.SQLCODE == NOTFOUND THEN
        ERROR "You reached to top or bottom of the result set."
    ELSE
        EXECUTE crec USING rec.c_id INTO rec.*
    END IF
```
IF SQLCA.SQLCODE == NOTFOUND THEN
  ERROR "Row was not found in the database, refresh the result set."
END IF
END IF
DISPLAY BY NAME rec.*
END FUNCTION

Understanding database connections

This is an introduction to database connections.

A database connection is a session of work, opened by the program to communicate with a specific database server, in order to execute SQL statements as a specific user.

Before working with database connections, make sure you have properly installed and configured all software, using the correct database client software/environment, and BDL database driver. It is very important to understand database client settings, regarding user authentication as well as database client character set configuration.

Note that on some platforms like on mobile devices, Genero BDL includes the SQLite lightweight database library, which is the default. Therefore, when executing programs on these platforms, there is no need to install a database client software and configure the database driver for the runtime system.

A database connection is initiated with the DATABASE instruction, or with the CONNECT TO instruction: The CONNECT TO instruction allows to specify database user credentials with the USER/USING clauses.

Multiple database connections can be established in a Genero BDL program.
The database user can be identified explicitly for each connection. Usually, the user is identified by a login and a password, or by using the authentication mechanism of the operating system (or even from a tier security system).

**Note:** Database connection instructions cannot be prepared and executed as dynamic SQL statements.

There are two kinds of connection modes: **unique-session** and **multi-session** mode. When using the `DATABASE` and `CLOSE DATABASE` instructions, the program is in unique-session mode. When using the `CONNECT TO`, `SET CONNECTION` and `DISCONNECT` instructions, the program is in multi-session mode.

**Important:** It is not possible to mix unique-session and multi-session modes.

Once connected to a database server, the program uses the current session to execute SQL statements in that context.

**Related concepts**

  This section describes the settings defining the locale for the database client.
- [Database driver specification (driver)](#) on page 606

**Opening a database connection**

A database connection identifies the SQL database server and the database entity the program connects to, in order to execute SQL statements.

To connect to a database server, the database driver needs to be loaded, and the SQL data source must be provided. Additionally, user authentication with username / password may also be needed. All these parameters define connection information.

There are different ways to give connection information, and it is possible to mix the different methods to specify connection parameters. However, if provided, the database user name and password have to be specified together with the same method.

A database connection is performed in programs with the `DATABASE` or `CONNECT TO` instruction:

```
CONNECT TO dbspec [USER username USING password]
```

or

```
DATABASE dbspec
```

Prefer the `CONNECT TO` instruction, as it allows to specify a user name and password.
For portability reasons, it is not recommended that you use database vendor specific syntax (such as 'dbname@dbserver') in the DATABASE or CONNECT TO instructions: Connections must be identified in programs by a single name, while connection parameters are provided in external files.

Indirect database specification uses entries in the FGLPROFILE configuration file: When a DATABASE or CONNECT TO instruction is executed with the parameter \texttt{dbspec}, the runtime system first looks into FGLPROFILE for entries starting with \texttt{dbi.database.dbspec}, and uses these connection parameters if found. Otherwise, the runtime system will do direct database specification, by using the \texttt{dbspec} string to connect to the server.

**Important:** When using FGLPROFILE entries for database connection parameters, keep in mind that entries must be written in lowercase.

Use a string variable with the DATABASE or CONNECT TO statement, in order to specify the database source at runtime. This solution gives you the best flexibility.

The string variable can be set from your own configuration file, from a program argument or from an environment variable.

**Example**

```plaintext
MAIN
    DEFINE db, us, pwd CHAR(50)
    LET db = fgl_getenv("MYDBSOURCE")
    LET us = arg_val(2)
    LET pwd = arg_val(3)
    CONNECT TO db USER us USING pwd
    ...
END MAIN
```

- Genero BDL applies direct database source specification when no FGLPROFILE entry corresponds to the database name used in programs.
- Indirect database specification method on page 613
- Genero BDL allows to define database connection parameters in FGLPROFILE, that can be referenced by a single identifier in programs.
- Unique session mode connection instructions on page 626
- Opening and closing a database for a unique session.
- Multi-session mode connection instructions on page 628
- Opening and closing a database for a unique session.

**Database client environment**

To connect to a database server, Genero BDL programs use vendor's database client software.

The database client software is usually included in the database server software, so you do not need to install it when your programs are executed on the same machine as the database server.

However, you must install the database client software in three-tier configurations, when applications and database servers run on different systems.

This section describes basic configuration elements of the database client environment for some well-known database servers.

**Microsoft® SQL Server**
1. Make sure that ODBC data source is defined on database client and database server systems, with the correct ODBC driver. Note that Genero FGL provides different types of SQL Server drivers:
   - On Microsoft® Windows® platforms:
     - Use an SNC (dbmsnc*) driver either with the Microsoft ODBC driver for SQL Server, or with the Microsoft SQL Native Client driver:
       - For Microsoft ODBC 17 (MSODBCSQL17.DLL), use dbmsnc_17.
       - For Microsoft ODBC 13 (MSODBCSQL13.DLL), use dbmsnc_13.
       - For Microsoft SQL Native Client 11 (SQLNCLI11.DLL), use dbmsnc_11.
       - For Microsoft SQL Native Client 10 (SQLNCLI10.DLL), use dbmsnc_10.

     **Important:** Configure your ODBC data source to use the appropriate Microsoft SQL Server driver.
   - On Linux® platforms:
     - With the SNC (dbmsnc*) driver, use the Microsoft ODBC for SQL Server on Linux® client (msdn.microsoft.com):
       - For Microsoft ODBC 17 (libmsodbcsql-17.so), use dbmsnc_17.
       - For Microsoft ODBC 13 (libmsodbcsql-13.so), use dbmsnc_13.

     Minimum Microsoft ODBC for SQL Server on Linux® version: 13.0.
   - With the FTM (dbmftm*) driver, use the FreeTDS ODBC client (www.freetds.org).
     Minimum FreeTDS version: 1.00.
   - With the ESM (dbmesm*) driver, use the Easysoft ODBC driver for SQL Server (www.easysoft.com).
     Minimum Easysoft version 1.5; Version 1.9 is strongly recommended.

2. On Windows® platforms, the PATH environment variable must define the access path to database client programs (ODBC32.DLL). On UNIX platforms, check database client software documentation for environment settings (LD_LIBRARY_PATH, ldconfig).
3. On Windows®, check the SQL Server Client configuration with the Client Network Utility tool. Verify that the ANSI to OEM conversion corresponds to the execution of applications in a CONSOLE environment.

4. Make sure the database client locale is properly defined. On UNIX platforms, check that the client character set parameter of the ODBC data source corresponds the locale used by the application (LANG/LC_ALL).

5. On Windows®, you can make a connection test with the Microsoft™ Query Analyzer tool. On UNIX, see client software documentation for available SQL command tools (isql command line tool for example).

**Related tasks**

Prepare the runtime environment - connecting to the database on page 770

**SQLite**

1. The SQLite database driver includes the SQLite library, except on systems where that library is commonly available, like Linux® distributions, Mac OS X and mobile devices.

2. Database locale: The SQLite library uses UTF-8. If the current application character set (LANG/LC_ALL) is not UTF-8, like plain ASCII or UTF-8, the SQLite database driver will make appropriate character set conversions.

3. You can make a connection test with the sqlite3 command line tool.

**Related tasks**

Prepare the runtime environment - connecting to the database on page 923

**SAP ASE**

1. The SYBASE environment variable must define the SAP® ASE software installation path.

2. The PATH environment variable must define the access path to database client programs.

3. On UNIX™, LD_LIBRARY_PATH (or equivalent) must hold the path to the client libraries libsybct.so and libsybcs.so. On Windows®, the path to the DLLs must be defined in PATH.

4. Check the SAP® ASE Client configuration, especially server name definition in connection's directory source, see DSQUERY environment variable.

5. Make sure the database client locale is properly defined.

6. You can make a connection test with the SAP ASE isql command line tool.

**Related tasks**

Prepare the runtime environment - connecting to the database on page 948

**SAP HANA**

1. The PATH environment variable must define the access path to SAP HANA® database client programs.

2. On UNIX™, LD_LIBRARY_PATH (or equivalent) must hold the path to the client libraries libodbcHDB.so. On Windows®, the path to the DLL must be defined in PATH.

3. Check the SAP HANA ODBC parameters, especially the SERVERNODE and DATABASENAME parameters.

4. There is no need to define any database client locale for the SAP HANA client: The Genero ODI driver will do the appropriate codeset conversions based on LANG/LC_ALL settings.

5. You can make a connection test with the SAP HANA hdbsql command line tool:

```bash
hdbsql -n fermi:39013 -d test1 -u hdbuser -p fourjs
```

**Related tasks**

Prepare the runtime environment - connecting to the database on page 979

**Connection parameters**

This section describes the different parameters which need to be specified in order to connect to a database.

The parameters can be provided with different methods (in the connection string or in FGLPROFILE settings). Some of these parameters are optional.

For example, if the database user is authenticated by the operating system, username/password parameters are not needed.
Database source specification (source)

In database connection parameters, the source parameter identifies the data source name.

If the source parameter is defined with an empty value (""'), the database interface connects to the default database server, which is usually the local server.

If the source entry is not present in FGLPROFILE, direct database specification method takes place.

Direct database specification method on page 612
Genero BDL applies direct database source specification when no FGLPROFILE entry corresponds to the database name used in programs.

Database driver specification (driver)

In database connection parameters, the driver parameter identifies the type of database driver to be used.

The driver must correspond to the database client software.

Important: Pay attention to the binary architecture of the database client software: Genero runtime system and database client binaries must match. For example, a 32 bit Oracle® client can not be used with a Genero 64 bit runtime system.

We distinguish two types of database driver names:

- Generic driver names ("dbmora", "dbmsnc"), and aliases ("oracle", "sqlserver")
- Version-stamped driver names ("dbmora_12", "dbmsnc_10", "dbmsnc_11")

A driver name "dbmxxx" identifies a generic driver name for the database server identified by the code xxx.

For example, in FGLPROFILE, to define the database driver for the Oracle® OCI client (code "ora"), use the name "dbmora":

```
dbi.database.stores.driver = "dbmora"
```

**Note:** For convenience, it is also possible to specify a long name (alias) such as "oracle" or "sqlserver", as defined in the database driver table below.

The generic driver names (like dbmora) require the latest database client software available on the platform. This can change from one Genero BDL release to another, when supporting a new database client version. Use the version-stamped driver name (like dbmora_12), to point to a specific database client version, for example when the most recent database client software is not available on the platform.

Check for library dependency on your system, to identify the database client library required by the driver with the generic name. The driver definition table below lists the driver names for each supported database client types and versions. For example, on Linux® platform, use the ldd command:

```
$ ldd $FGLDIR/dbdrivers/dbmmys.so
...  
libmysqlclient.so.21 => ...
...
```

Drivers with generic names are compatible with the latest database client version available on the platform. Depending on the platform, the same generic driver name can refer to different database client software versions. For example, on an old platform where only MySQL 5.7 client is available, dbmmys will identify the dbmmys_5_7 driver. On a more recent platform where MySQL 8.0 is available, dbmmys will identify the dbmmys_8_0 driver.

To limit the number of drivers, if the database client software allows it, the drivers are built with the oldest database client version that is compatible with the latest available database client versions. For example, the dbmdb2_10 driver is linked to libdb2.so.1, which is supported by the IBM DB2 V10 and V11 client software.

Note that a given driver (combined with the corresponding database client software) can connect to a database server of an older version, if the database vendor client/server protocol supports the combination. For example, you can use an Oracle® client version 12c to connect to an 11g server. The ODI driver will then adapt SQL translations and emulations to the target database server.

A default driver can be specified with the dbi.default.driver FGLPROFILE entry. This driver will be used for all database connections that do not specify the driver explicitly:

```
dbi.default.driver = "dbmora"
```

If this entry is not defined, and if no driver parameter is specified for the data source, the driver name defaults to dbmdefault. This default driver is a copy of the database driver that was chosen during installation.

**Related concepts**

**Default database driver**

The `dbi.default.driver` FGLPROFILE entry defines a default database driver to be loaded, if the driver is not specified by the connection parameters.

```
dbi.default.driver = "driver-name"
```

The driver name must be specified without the .so or .DLL extension.

If this configuration entry is not defined, the driver name defaults to `dbmdefault`.

**Related concepts**

**User name and password (username/password)**

In database connection parameters, the `username` and `password` parameters define the default database user, when the program uses the `DATABASE` instruction or the `CONNECT TO` instruction without the `USER/USING` clause.

The `username` and `password` FGLPROFILE entries are not encrypted. These parameters are provided to simplify migration and are not recommended in production. It is better to use CONNECT TO with a USER / USING clause to avoid any security hole, setup OS user authentication, or use the connection callback method. Example of database servers supporting OS user authentication are: IBM® Informix®, Oracle®, and SQL Server.

**Important:** Do not write clear user passwords in your sources! It is recommended that `username` and `password` parameters are set from variables.
For backward compatibility reasons, when using the IBM® Informix® driver, the username / password specification is ignored by the DATABASE instruction, only the CONNECT TO instruction takes external (or callback) login parameters into account.

### Connection parameters in database specification

Connection parameters can be provided in the database specification string passed to the DATABASE and CONNECT TO instructions.

#### Using connection parameters at runtime

In the database name specification of CONNECT TO or DATABASE instructions, a + plus sign starts the list of connection specification parameters.

The connection specification parameters override the dbi.database connection parameters defined in FGLPROFILE.

In this example, driver, source and resource parameters are specified in the database specification string of the CONNECT TO instruction:

```plaintext
MAIN
   DEFINE db, un, up STRING
   LET db = "stores+driver='dbmora',source='orcl',resource='myconfig'"
   LET un = ...
   LET up = ...
   CONNECT TO db USER un USING up
   ...
END MAIN
```

**Important:**
- Do not hard code connection parameters in programs to be installed on a production site. Instead, build the connection string at runtime, or consider using the indirect database specification method.
- Do not specify the username and password parameters in connection specification parameters. Instead, provide the SQL user credentials with the USER/USING clause of CONNECT TO.
- Consider backslash interpretation in connection strings, as described below in [Connection parameter parsing](#) on page 611.

#### Syntax for connection parameters

Each parameter is defined with a name followed by an equal sign and a value enclosed in single quotes. Connection parameters must be separated by a comma:

```
dbname+parameter='value'[, ...]
```

In this syntax, *parameter* can be one of the following:
Table 173: Connection parameters in the database specification string

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resource</td>
<td>Specifies which 'dbi.database' entries have to be read from the FGLPROFILE configuration file. When this property is set, the database interface reads dbi.database.name.* entries, where name is the value specified for the resource parameter.</td>
</tr>
<tr>
<td>driver</td>
<td>Defines the database driver library to be loaded (filename without extension).</td>
</tr>
<tr>
<td>source</td>
<td>Specifies the data source of the database.</td>
</tr>
<tr>
<td>username</td>
<td>Defines the name of the database user. <strong>Important:</strong> Consider using CONNECT TO with USER/USING clause instead!</td>
</tr>
<tr>
<td>password</td>
<td>Defines the password of the database user. <strong>Important:</strong> Do not write clear user passwords in your sources! This parameter should be set from a variable value.</td>
</tr>
</tbody>
</table>

Passing a plus sign in a connection parameter

With some databases, the source connection parameter can take different forms, that may contain a + sign. When specified directly as default source in the database connection specification, this + sign will be interpreted as the starting character for connection specification parameters, and produce error -6373: Invalid database connection string.

To workaround the + sign interpretation, put the source parameter explicitly in the connection specification.

For example, with SQL Server, you can specify ODBC connection string parameters with the ?options syntax:

```
CONNECT TO "mydsn?APP=myappid;" USER un USING up
```

In the above example, the connection specification passed to the CONNECT TO instruction defines implicitly the "source" connection parameter. This string contains the ODBC data source name (mydsn), and, after the ? question mark, the ODBC connection string parameter APP=myappid; defining the SQL client application identifier.

When using a plus sign in the ODBC connection string parameters, it will produce the error -6373. This can happen for example when using authentication credentials, as with the CRED parameter in the next example:

```
CONNECT TO "mydsn?APP=myappid;CRED=ZXB+2A" USER un USING up
```

To solve this issue, use an explicit "source" parameter in the connection specification of CONNECT TO:

```
CONNECT TO "mydbc+source='mydsn?APP=myappid;CRED=ZXB+2A'" USER un USING up
```

The plus sign in the "CRED" ODBC parameter value will be considered as part of the "source" parameter value.

Connection parameter parsing

The parameters and values after the + sign are parsed, and backslashes are interpreted as in a string literal.

For example, \n becomes a new line character in the final value used in the database driver.

To pass a backslash to the driver (for example when specifying a Windows® path), it must be doubled in the string value.
Furthermore, a backslash in a string literal of the source code must be quadrupled.

Consider implementing a utility function to double backslashes in a string:

```sql
FUNCTION escape_backslashes(str)
  DEFINE str STRING
  DEFINE buf base.StringBuffer
  LET buf = base.StringBuffer.create()
  CALL buf.append(str)
  CALL buf.replace("\\","\\\\",0)
  RETURN buf.toString()
END FUNCTION
```

**Related concepts**

**Direct database specification method**

Genero BDL applies direct database source specification when no FGLPROFILE entry corresponds to the database name used in programs.

*Direct database specification method* takes place when the database name used in a `DATABASE` or `CONNECT TO` instruction is not defined in FGLPROFILE with a `'dbi.database.dbname.source'` entry. In this case, the database specification used in the connection instruction is used as the data source.

This method is well known for IBM® Informix® databases, for example to specify the IBM® Informix® server:

```sql
MAIN
  DATABASE stores@orion
  ...
END MAIN
```

In the next example, the database server is PostgreSQL. The string used in the connection instruction defines the PostgreSQL database (stock), the host (localhost), and the TCP service (5432) the postmaster is listening to. As PostgreSQL syntax is not allowed in the language, a CHAR variable must be used:

```sql
MAIN
  DEFINE db CHAR(50)
  LET db = "stock@localhost:5432"
  DATABASE db
  ...
END MAIN
```

This method ties the compiler programs to a given database server configuration. Prefer indirect database specification method instead of direct database specification.

**Related concepts**

- [Indirect database specification method](#) on page 613
- Genero BDL allows to define database connection parameters in FGLPROFILE, that can be referenced by a single identifier in programs.
- [The FGLPROFILE file(s)](#) on page 220
FGLPROFILE environment variable defines Genero BDL configuration files

**Indirect database specification method**

Genero BDL allows to define database connection parameters in FGLPROFILE, that can be referenced by a single identifier in programs.

*Indirect database specification method* takes place when the database name used in the DATABASE or CONNECT TO instruction corresponds to a 'dbi.database.dbname.source' entry defined in the FGLPROFILE configuration file. In this case, the *dbname* database specification is used as a key to read the connection information from the configuration file.

In FGLPROFILE, the entries starting with 'dbi.database' group information defining connection parameters for indirect database specification:

```plaintext
dbi.database.dbname.source   = "value"
dbi.database.dbname.driver   = "value"
dbi.database.dbname.username = "value"
dbi.database.dbname.password = "value"
-- Warning: Password is not encrypted, do not use in production!
```

Keep in mind that FGLPROFILE entry names are converted to lower case when loaded by the runtime system. In order to avoid any mistakes, it is recommended to write FGLPROFILE entry names and program database names in lower case.

In the next example, the program specifies a data source with the name *stores*, and FGLPROFILE defines the *source* and *driver* parameters for the *stores* data source:

Program:

```plaintext
MAIN
  DATABASE stores
  ...
END MAIN
```

FGLPROFILE:

```plaintext
dbi.database.stores.source   = "stock@localhost:5432"
dbi.database.stores.driver   = "dbmpgs"
```

The indirect database specification technique is a flexible technique to define the database source: The database name in programs is a kind of alias for the real data source, which is defined in an external configuration file (i.e. FGLPROFILE), where entries can be easily changed on production sites without needing program recompilation.

IBM® Informix® emulation parameters in FGLPROFILE

Emulation of Informix® specific SQL features can be controlled with FGLPROFILE entries.

**What are Informix® SQL emulation settings used for?**

To simplify the migration process to other database servers such as IBM® Informix®, the database drivers can emulate some IBM® Informix-specific features like SERIAL columns and temporary tables; the drivers can also do some SQL syntax translation.

Avoid using IBM® Informix® emulations; write portable SQL code instead. IBM® Informix® emulations are only provided to help you in the migration process. Disabling IBM® Informix® emulations improves performance, because SQL statements do not have to be parsed to search for IBM® Informix-specific syntax.

Emulations can be controlled with FGLPROFILE parameters. You can disable all possible switches one-by-one, in order to test your programs for SQL compatibility.

**dbi.database.dsnname.ifxemul**

This is a global switch to enable or disable IBM® Informix® emulations.

Values can be true or false. Default is true.

```
dbi.database.stores.ifxemul = false
```

**dbi.database.dsnname.ifxemul.datatype.type**

The 'ifxemul.datatype' switches define whether the specified data type must be converted to a native type (for example, when creating a table with the CREATE TABLE statement).

Where `type` can be one of `char`, `varchar`, `datetime`, `decimal`, `money`, `float`, `real`, `integer`, `smallint`, `serial`, `text`, `byte`, `bigint`, `bigserial`, `int8`, `serial8`, `boolean`.

Default is true for all types.

```
dbi.database.stores.ifxemul.datatype.serial = false
```

**dbi.database.dsnname.ifxemul.datatype.serial.emulation**

This parameter can be used to control the SERIAL generation technique used by the driver to generate auto-incremented values.

The value can be one of the following:

- `native` uses the database's native sequence generator directly in the table definitions (depends on the db type).
- `native2` uses a secondary native sequence generator directly in the table definitions (depends on the db type).
- `regtable` uses the SERIALREG table with triggers. It is slower than the `native` emulation.
- `trigseq"`, uses database sequence generator with triggers (not supported by all drivers).

Default is "native".

```
dbi.database.stores.ifxemul.datatype.serial.emulation = "native"
```

SERIAL emulations depend on the type of database server used. See SQL database guides on page 689 for more details.
**dbi.database.dsnname.ifxemul.temptables**

This switch can be used to control temporary table emulation. Defaults is true.

```
  dbi.database.stores.ifxemul.temptables = false
```

**dbi.database.dsnname.ifxemul.temptables.emulation**

This parameter can be used to specify what technique must be used to emulate temporary tables in the database server. Possible values are "default" and "global".

```
  dbi.database.stores.ifxemul.temptables.emulation = "global"
```

See SQL database guides on page 689 for more details.

**dbi.database.dsnname.ifxemul.dblquotes**

This switch can be used to define whether double quoted strings must be converted to single quoted strings. Default is true.

```
  dbi.database.stores.ifxemul.dblquotes = false
```

If this emulation is enabled, all double quoted strings are converted, including database object names.

**dbi.database.dsnname.ifxemul.outers**

This switch can be used to control IBM® Informix® OUTER translation to native SQL outer join syntax. Default is true.

```
  dbi.database.stores.ifxemul.outers = false
```

**Note:** Consider using standard ISO outer joins in your SQL statements (LEFT OUTER).

**dbi.database.dsnname.ifxemul.today**

This switch can be used to convert the TODAY keyword to a native expression returning the current date. Default is true.

```
  dbi.database.stores.ifxemul.today = false
```

**dbi.database.dsnname.ifxemul.current**

This switch can be used to convert the CURRENT X TO Y expressions to a native expression returning the current time. Default is true.

```
  dbi.database.stores.ifxemul.current = false
```

**dbi.database.dsnname.ifxemul.selectunique**

This switch can be used to convert the SELECT UNIQUE to SELECT DISTINCT.
Default is true.

```
dbi.database.stores.ifxemul.selectunique = false
```

**Note:** Consider replacing all `UNIQUE` keywords by `DISTINCT`.

**dbi.database.dsname.ifxemul.colsubs**

This switch can be used to control column substrings expressions (col[x,y]) to native substring expressions.

Default is true.

```
dbi.database.stores.ifxemul.colsubs = false
```

**Note:** Consider using substring SQL functions instead of [x,y] expressions in SQL.

**dbi.database.dsname.ifxemul.matches**

This switch can be used to define whether `MATCHES` expressions must be converted to `LIKE` expressions.

Default is true.

```
dbi.database.stores.ifxemul.matches = false
```

**Note:** Consider using `LIKE` expressions instead of `MATCHES` in SQL.

**dbi.database.dsname.ifxemul.length**

This switch can be used to define whether `LENGTH()` function names have to be converted to the native equivalent.

Default is true.

```
dbi.database.stores.ifxemul.length = true
```

**dbi.database.dsname.ifxemul.rowid**

This switch can be used to define whether `ROWID` keywords have to be converted to native equivalent (for example, `OID` in PostgreSQL).

Default is true.

```
dbi.database.stores.ifxemul.rowid = false
```

**Note:** Consider using primary keys instead of ROWIDs.

**dbi.database.dsname.ifxemul.listupdate**

This switch can be used to convert the `UPDATE` statements using non-ANSI syntax.

Default is true.

```
dbi.database.stores.ifxemul.listupdate = false
```

**dbi.database.dsname.ifxemul.extend**

This switch can be used to convert simple `EXTEND()` expressions to native date/time expressions.

Default is true.

```
dbi.database.stores.ifxemul.extend = true
```

Database type specific parameters in FGLPROFILE

Specific connection parameters can be configured with FGLPROFILE entries.

The FGLPROFILE entries for database-server specific configuration all following the same syntax scheme:

```
  dbi.database.dsname.dbtype.param[.subparam] = "value"
```

Where `dbtype` identifies the database vendor type, such as ifx, ora, db2.

- IBM DB2 specific FGLPROFILE parameters on page 617

- SAP ASE specific FGLPROFILE parameters on page 622
- SAP HANA specific FGLPROFILE parameters on page 622

**IBM® DB2® specific FGLPROFILE parameters**

`dbi.database.dsname.db2.schema`

Name of the database schema to be selected after connection is established.

```
  dbi.database.stores.db2.schema = "store2"
```

Set this parameter to a specific schema in order to share the same table with all users.

`dbi.database.dsname.db2.prepare.deferred`

True/False boolean to enable/disable deferred prepare.

```
  dbi.database.stores.db2.prepare.deferred = true
```

Set this parameter to true if you do not need to get SQL errors during PREPARE statements: SQL statements will be sent to the server when executing the statement (OPEN or EXECUTE). The default is false (SQL statements are sent to the server when doing the PREPARE).

Default is `false`.

**Oracle DB specific FGLPROFILE parameters**

`dbi.database.dsname.ora.schema`

Name of the database schema to be selected after connection is established.

```
  dbi.database.stores.ora.schema = "store2"
```

Set this parameter to a specific schema in order to share the same table with all users.

For more details, see Database users on page 847.
**dbi.database.dsname.ora.prefetch.rows**

Maximum number of rows to prefetch.

```
.dbi.database.stores.ora.prefetch.rows = 50
```

Use this parameter to increase performance by defining the maximum number of rows to be fetched into the db client buffer. However, the bigger this parameter is, the more memory that is used by each program. This parameter applies to all cursors in the program.

The default is 10 rows.

**dbi.database.dsname.ora.prefetch.memory**

Maximum buffer size for prefetching (in bytes).

```
.dbi.database.stores.ora.prefetch.memory = 4096
```

This parameter is equivalent to `prefetch.rows`, but here you can specify the memory size instead of the number of rows. Like `prefetch.rows`, this parameter applies to all cursors in the program.

The default is 0, which means that memory size is not included in computing the number of rows to prefetch.

**dbi.database.dsname.ora.sid.command**

SQL command (SELECT) to generate a unique session id (used for temp table names).

```
.dbi.database.stores.ora.sid.command = "SELECT TO_CHAR(SID)||'_'||TO_CHAR(SERIAL#)
FROM V$SESSION WHERE AUDSID=USERENV('SESSIONID')"
```

By default, the driver uses "SELECT USERENV('SESSIONID') FROM DUAL". This is the standard session identifier in Oracle®, but it can become a very large number and cannot be reset.

This parameter gives you the freedom to provide your own way to generate a session id.

The SELECT statement must return a single row with one single column.

Value can be an integer or an identifier.

**dbi.database.dsname.ora.date.ifxfetch**

Controls the way an Oracle® DATE is fetched into program variables, especially CHAR/VARCHAR targets.

```
.dbi.database.stores.ora.date.ifxfetch = true
```

By default, since Oracle® DATE type is equivalent to DATETIME YEAR TO SECOND, values are fetched into CHAR/VARCHAR with time information and are formatted with the style YYYY-MM-DD hh:mm:ss. If you need to get the IBM® Informix® behavior, to fetch DATES only with the YMD part following the DBDATE environment variable, set this parameter to true. However, this parameter is useless when fetching Oracle® DATES into DATE or DATETIME variables, which is the recommended way to hold date and time values in programs.

Default is false (with time information, using normalized format).

**dbi.database.dsname.ora.temptables.schema.source**

Defines the source of the schema name used for temporary table emulation.

Possible values are:

- "login": The user name specified in the connection parameters.
• "command" : The value returned by a SELECT statement specified in the 
  ora.temptables.schema.command parameter.

  
  dbi.database.stores.ora.temptables.schema.source = "login"

By default, when using the default temporary table emulation, the driver uses no schema at all. When using global temporary table emulation, the driver uses the TEMPTABS schema by default.

When specifying a "command" source for the schema, you can provide your own SELECT statement to produce the schema name to be used when creating a table.

  
  dbi.database.dsn.ora.temptables.schema.command

SQL command (SELECT) to get the schema name to be used for temporary table emulation.

  dbi.database.stores.ora.temptables.schema.source = "command"
  dbi.database.stores.ora.temptables.schema.command = "SELECT
  SYS_CONTEXT('USERENV','SESSION_USER') FROM DUAL"

This configuration parameter is only taken into account if the ora.temptables.schema.source parameter is defined as "command".

The SELECT statement must return a single row with one single column.

Value must be a character string.

  
  dbi.database.dsn.ora.temptables.tablespace

Defines the tablespace to be used for temporary table emulation.

  
  dbi.database.stores.ora.temptables.tablespace = "mytemptabs"

By default, when using the default temporary table emulation, the driver uses the TEMPTABS tablespace. When using global temporary table emulation, the driver uses no tablespace by default.

For more details, see Temporary tables on page 872.

Oracle® MySQL specific FGLPROFILE parameters

  
  dbi.database.dsn.mys.config

Defines an explicit configuration to read MySQL options from.

  
  dbi.database.stores.mys.config = "/opt/myapp/etc/my.cnf"

This parameter will be passed to the MySQL API function mysql_options((MYSQL*), MYSQL_READ_DEFAULT_FILE, filename ).

It can be used to bypass reading the default MySQL configuration files, to define database client settings in the [client] group, such as the client character set with the default-character-set option.

Note:

On Microsoft™ Windows® platforms, the configuration file must be in DOS format.
MariaDB specific FGLPROFILE parameters

dbi.database.dsname.mdb.config
Defines an explicit configuration to read MariaDB options from.

```bash
dbi.database.stores.mdb.config = "/opt/myapp/etc/my.cnf"
```

This parameter will be passed to the MariaDB API function mysql_options((MYSQL*), MYSQL_READ_DEFAULT_FILE, filename).

It can be used to bypass reading the default MariaDB configuration files, to define database client settings in the [client] group, such as the client character set with the default-character-set option.

**Note:**
On Microsoft™ Windows® platforms, the configuration file must be in DOS format.

PostgreSQL specific FGLPROFILE parameters

dbi.database.dsname.pgs.prefetch.rows
Maximum number of rows to be pre-fetched.

```bash
dbi.database.stores.pgs.prefetch.rows = 50
```

Use this parameter to increase performance by defining the maximum number of rows to be fetched into the db client buffer. However, the bigger this parameter is, the more memory is used by each program. This parameter applies to all cursors in the program.

The default is 10 rows, which is a good compromise for regular interactive OTLP applications.

When using server-side cursors (DECLARE CURSOR), this parameter will define the number of rows fetched with the PostgreSQL FETCH cursor FORWARD nbrows command. This parameter has no effect on static SELECT statements, nor on SELECT statements executed with PREPARE + EXECUTE INTO.

SQL Server (MS ODBC) specific FGLPROFILE parameters

dbi.database.dsname.snc.logintime
Connection timeout (in seconds).

```bash
dbi.database.stores.snc.logintime = 5
```

Set this parameter to raise an SQL error if the connection can not be established after the given number of seconds. The default is 5 seconds.

**dbi.database.dsname.snc.prefetch.rows**
Maximum number of rows to be pre-fetched.

```bash
dbi.database.stores.snc.prefetch.rows = 50
```

Use this parameter to increase performance by defining the maximum number of rows to be fetched into the db client buffer. However, the bigger this parameter is, the more memory is used by each program.

The default is 10 rows.

**dbi.database.dsname.snc.widechar**
Control single-char / wide-char mode usage for character string data.
**Note:** Only set the `snc.widechar` parameter to `false`, if you use char/varchar/text columns in the database, and the application locale is a multi-byte character set (such as BIG5).

```plaintext
dbi.database.stores.snc.widechar = false
```

By default, the SNC driver will select the expected char mode, depending on the current application locale (LANG/LC_ALL):

- In wide char mode, the SNC driver uses SQLWCHAR ODBC API functions, by converting the character data from the current locale to UCS/2, it will add the N prefix before string literals, and will bind SQL parameters with `SQL_C_WCHAR` and `SQL_WCHAR/SQL_WVARCHAR` types.
- In single char mode, the SNC driver will pass the character strings without conversion to "ASCII" ODBC API functions, it will leave the string literals (without adding the N prefix) and bind character string parameters with `SQL_C_CHAR` and `SQL_CHAR/SQL_VARCHAR` SQL types.

For more details, see also [SQL Server Adaptation Guide: CHARACTER data types](#).

### SQL Server (FreeTDS driver) specific FGLPROFILE parameters

**`dbi.database.dsnname.ftm.logintime`**

Connection timeout (in seconds).

```plaintext
dbi.database.stores.ftm.logintime = 5
```

Set this parameter to raise an SQL error if the connection can not be established after the given number of seconds. The default is 5 seconds.

**`dbi.database.dsnname.ftm.prefetch.rows`**

Maximum number of rows to be pre-fetched.

```plaintext
dbi.database.stores.ftm.prefetch.rows = 50
```

Use this parameter to increase performance by defining the maximum number of rows to be fetched into the db client buffer. However, the bigger this parameter is, the more memory is used by each program. The default is 10 rows.

### SQL Server (Easysoft driver) specific FGLPROFILE parameters

**`dbi.database.dsnname.esm.logintime`**

Connection timeout (in seconds).

```plaintext
dbi.database.stores.esm.logintime = 5
```

Set this parameter to raise an SQL error if the connection can not be established after the given number of seconds. The default is 5 seconds.

**`dbi.database.dsnname.esm.prefetch.rows`**

Maximum number of rows to be pre-fetched.

```plaintext
dbi.database.stores.esm.prefetch.rows = 50
```

Use this parameter to increase performance by defining the maximum number of rows to be fetched into the db client buffer. However, the bigger this parameter is, the more memory is used by each program.
The default is 10 rows.

**SAP ASE specific FGLPROFILE parameters**

`dbi.database.dsnname.ase.logintime`

Connection timeout (in seconds).

```
dbi.database.stores.ase.logintime = 10
```

Set this parameter to raise an SQL error if the connection can not be established after the given number of seconds. The default is 5 seconds.

`dbi.database.dsnname.ase.prefetch.rows`

Maximum number of rows to be pre-fetched.

```
dbi.database.stores.ase.prefetch.rows = 50
```

Use this parameter to increase performance by defining the maximum number of rows to be fetched into the db client buffer. However, the bigger this parameter is, the more memory is used by each program. The default is 10 rows.

**SAP HANA® specific FGLPROFILE parameters**

`dbi.database.dsnname.hdb.schema`

Name of the database schema to be selected after connection is established.

```
dbi.database.stores.hdb.schema = "store2"
```

Set this parameter to a specific schema in order to share the same table with all users.

**SQL connection identifier**

Database client programs can be identified by name with some database server types.

**Purpose of SQL connection identifiers**

When connecting to databases such as PostgreSQL or SQL Server, it is possible to define a name for the database client program.

This allows for the association of a name with a database client connection in the database server, to be used in logging and trace utilities.

For example, if you don't define the application identifier for SQL Server client programs, all connections will get the name "ODBC".

**SQL application identifier with SQL Server**

The SQL Server client application identifier can be defined by using the `APP=name` ODBC connection string parameter. The ODBC application identifier will be available in the SQL Server session with `sp_who` and `APP_NAME()` SQL functions. This name will also be visible in the "ApplicationName" column of SQL Profiler trace logs.

To pass ODBC connection string parameters to SQL Server, use the `?options` notation in the "source" connection parameter.
With an FGLPROFILE entry:

```
  dbi.database.mydb.source = "mydatasource?APP=myappid;"
```

At runtime with connection parameters in database specification:

```
  CONNECT TO "mydb+source='mydatasource?APP=myappid;'" USER un USING up
```

**Note:** ODBC connection string parameters must be terminated by a ; semi-colon.

**SQL application identifier with PostgreSQL**

The PostgreSQL client application identifier can be defined with the `application_name` PostgreSQL URL connection string parameter.

To pass URL connection string parameters to PostgreSQL, use the `?options` notation in the "source" connection parameter:

With an FGLPROFILE entry:

```
  dbi.database.mydb.source = "mydatabase?application_name=myappid"
```

At runtime with connection parameters in database specification:

```
  CONNECT TO "mydb+source='mydatabase?application_name=myappid'" USER un USING up
```

**Note:** PostgreSQL URL connection string parameters must be separated by a & ampersand.

**Related concepts**

- [Database source specification (source)](#) on page 606
- [Connection parameters in database specification](#) on page 610

Connection parameters can be provided in the database specification string passed to the DATABASE and CONNECT TO instructions.

**Database user authentication**

Different database user authentication methods exist.

Connecting to a database server is not just specifying a database name: the current user must be identified by the database server. Database users must be declared in the database server and must be authenticated.

The typical user authentication is done by passing a login name and password at connection time. Some database servers support external authentication methods, that do not require login/password information (for example when db users are based on operating system users), as well as delegated user authentication via credential tokens (for example, when using an LDAP distinguished name). See database vendor specific documentation for more details.

Additional user authentication solutions are provided to simplify migration from IBM® Informix® databases, but are not recommended in production for security reasons.

See also SQL adaptation guides for database vendor specific notes regarding user authentication.

**Specifying a user name and password with CONNECT**

In order to specify a user name and password, use the CONNECT instruction with the USER/USING clause:

```
MAIN
  DEFINE uname, upswd STRING
  CALL login_dialog() RETURNING uname, upswd
  CONNECT TO "stock" USER uname USING upswd
...
END MAIN
```
This is the recommended way to connect to a database server.

With some database types, it is possible to use an external user authentication service, such as Kerberos, SSL/TLS, LDAP-based directory services. To connect as an external user, configure database client settings to authenticate the external user and perform the CONNECT TO instruction without specifying a login/password:

```
CONNECT TO "stock"
```

For more details, see for example database user handling in the Oracle SQL Adaptation Guide.

**Specifying a user name and password with DATABASE**

The `DATABASE` instruction does not support the `USER/USING` clause as `CONNECT TO` does. If you don't use an automatic user authentication method of the database server, you must provide a user name and password in some way.

The best way to identify database users is to replace every `DATABASE` instruction by a `CONNECT TO` with `USER/USING` clause. However, it is also possible to provide the user name and password with the user authentication callback function, by defining a global FGLPROFILE entry.

In a development environment, a default login and password can be specified with the `dbi.database.dbname.username` and `dbi.database.dbname.password` FGLPROFILE entries. This solution must not be used in a production environment because the password is not encrypted. For backward compatibility reasons, when using the IBM® Informix® driver, these FGLPROFILE entries are ignored by the `DATABASE` instruction, only the `CONNECT TO` instruction takes external (or callback) login parameters into account.

Login parameters can also be provided in the connection string used in the database name specification in `DATABASE` instruction.

**Related concepts**

- `DATABASE` on page 626
  - Opens a new database connection in unique-session mode.
- Indirect database specification method on page 613
  - Genero BDL allows to define database connection parameters in FGLPROFILE, that can be referenced by a single identifier in programs.
- User authentication callback function on page 624

**User authentication callback function**

When using the `DATABASE` connection instruction, the database user name and password can be provided at runtime by a callback function. The callback function must be defined with the `dbi.default.userauth.callback` FGLPROFILE entry:

```

```

This callback method is provided when a lot of programs use the `DATABASE` instruction, and database user credentials are mandatory. If possible, use the `CONNECT TO` instruction with the `USER/USING` clause instead of `DATABASE`.

**Note:** With the IBM® Informix® driver, the callback method is also called, but the user name and password are ignored by the `DATABASE` instruction: Only `CONNECT TO` will take the login parameters into account for IBM® Informix®.

The callback function must have the following signature:

```
CALL function-name(dbspec STRING)
    RETURNS ( STRING, -- username
                  STRING -- password
    )
```
If you do not specify the module name, the callback function must be linked to the 42r program. By using the "module-name.function-name" syntax in the FGLPROFILE entry, the runtime system will automatically load the module. In both cases, the module must be located in a directory where the runtime system can find it, defined by the FGLLDPATH environment variable.

In the callback function body, the value of dbspec can be used to identify the database source, read user name and encrypted password from FGLPROFILE entries with the fgl_getResource() function, then decrypt password with the algorithm of your choice and return user name and decrypted password.

**User authentication callback function for DATABASE:**

```plaintext
FUNCTION getUserAuth(dbspec)
DEFINE dbspec STRING
DEFINE un, ep STRING
LET un = fgl_getResource("dbi.database."||dbspec||".username")
LET ep = fgl_getResource("dbi.database."||dbspec||".password.encrypted")
RETURN un, decrypt_user_password(dbspec, un, ep)
END FUNCTION
```

**Related concepts**

- **DATABASE** on page 626
  Opens a new database connection in unique-session mode.

- **CONNECT TO** on page 628
  Opens a new database session in multi-session mode.

- **FGLLDPATH** on page 243
  Defines the search paths to load program modules.

**Order of precedence for database user specification**

Database user login can be specified with different methods, as show in this table. Precedence order if defined from top to bottom:

**Table 174: Database user login methods**

<table>
<thead>
<tr>
<th>Connection Instruction</th>
<th>FGLPROFILE</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONNECT TO &quot;dbname&quot; USER &quot;user&quot; USING &quot;pswd&quot;</td>
<td>N/A (ignored)</td>
<td>The user information in the USER/USING clause of the CONNECT TO instruction or in the connection string of the DATABASE instruction are used to identify the actual user. These are used to identify the actual user. Connection string can also be used with CONNECT TO.</td>
</tr>
<tr>
<td>or</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DEFINE db VARCHAR(200)</td>
<td></td>
<td></td>

<tr>
<td>DATABASE db</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Unique session mode connection instructions

Opening and closing a database for a unique session.

In unique-session mode, the `DATABASE` instruction initiates a connection the database server and creates the current session. The database connection is terminated with the `CLOSE DATABASE` instruction, or when another `DATABASE` instruction is executed, or when the program ends.

- **DATABASE** on page 626
- **CLOSE DATABASE** on page 627

#### DATABASE

Opens a new database connection in unique-session mode.

**Syntax**

```
DATABASE { dbname [@dbserver] | variable | string } [EXCLUSIVE]
```

1. `dbname` identifies the database name.
2. `dbserver` identifies the IBM® Informix® database server (INFORMIXSERVER).
3. `variable` can be any character string defined variable containing the database specification.
4. `string` can be a string literal containing the database specification.

#### Usage

The `DATABASE` instruction opens a connection to the database server, like `CONNECT TO`, but without user and password specification.

```
MAIN
  DATABASE stores
  ...
END MAIN
```

It is possible to use a program variable containing the database specification.

```
MAIN
  DEFINE dbname VARCHAR(100)
```
If a current connection exists, it is automatically closed before connecting to the new database.

The connection is closed with the \texttt{CLOSE DATABASE} instruction, or when the program ends.

The \texttt{DATABASE} instruction raises an exception if the connection can not be established, for example, if you specify a database that the runtime system cannot locate, or cannot open, or for which the user of your program does not have access privileges.

The \texttt{EXCLUSIVE} keyword can be used to open an IBM\textsuperscript{®} Informix\textsuperscript{®} database in exclusive mode to prevent access by anyone but the current user. This keyword is IBM\textsuperscript{®} Informix\textsuperscript{®} specific and is not recommended when writing a portable SQL application.

The \texttt{CONNECT TO} instructions allow better control over database connections; it is recommended that you use these instructions instead of \texttt{DATABASE} and \texttt{CLOSE DATABASE}.

When used outside a program block, the \texttt{DATABASE} instruction defines the database schema for compilation. See \texttt{SCHEMA} on page 477 for more details.

**Related concepts**

- \texttt{CLOSE DATABASE} on page 627
  Closes the current database connection created by a \texttt{DATABASE} instruction.

- \texttt{CONNECT TO} on page 628
  Opens a new database session in multi-session mode.

- \texttt{Opening a database connection} on page 601
  A database connection identifies the SQL database server and the database entity the program connects to, in order to execute SQL statements.

- \texttt{Exceptions} on page 451
  Describes exception (error) handling in the programs.

**CLOSE DATABASE**

Closes the current database connection created by a \texttt{DATABASE} instruction.

**Syntax**

```
CLOSE DATABASE
```

**Usage**

The \texttt{CLOSE DATABASE} instruction closes the current database connection opened by a \texttt{DATABASE} instruction.

The current connection is automatically closed when the program ends.

**Example**

```
MAIN
  DATABASE stores1
  CLOSE DATABASE
  DATABASE stores2
  CLOSE DATABASE
END MAIN
```

**Related concepts**

- \texttt{DATABASE} on page 626
Opens a new database connection in unique-session mode.

**Multi-session mode connection instructions**

Opening and closing a database for a unique session.

In multi-session mode, open a database session with the `CONNECT TO` instruction. Other connections can be created with subsequent `CONNECT TO` instructions. To switch to a specific session, use the `SET CONNECTION` instruction; this suspends other opened connections. Disconnect from a specific or from all sessions with the `DISCONNECT` instruction. The end of the program disconnects all sessions automatically.

- `CONNECT TO` on page 628
- `SET CONNECTION` on page 629
- `DISCONNECT` on page 630

**CONNECT TO**

Opens a new database session in multi-session mode.

**Syntax**

```
CONNECT TO { dbname | DEFAULT } [ AS session ]
[ USER login USING auth ]
[ WITH CONCURRENT TRANSACTION ]
```

1. `dbname` is the database specification.
2. `session` identifies the database session. By default, it is `dbname`.
3. `login` is the name of the database user.
4. `auth` is a string to authenticate the database user, like a password.

**Usage**

The `CONNECT TO` instruction opens a database connection. If the instruction successfully connects to the database environment, the connection becomes the current database session for the program.

The session name is case-sensitive.

A program can connect to several database environments at the same time (using different database drivers), and it can establish multiple connections to the same database environment, provided each connection has a unique connection name.

The connection is closed with the `DISCONNECT` instruction, or when the program ends.

When the `USER login USING auth` clause is specified, the database user is identified by `login` and `auth`, ignoring all other user settings defined in `FGLPROFILE` or as connection string parameters.

The `auth` parameter can be a simple password for internal database users, but for some types of database engines, it can be used to specify an external authentication token, such as a distinguished name (DN). For more details, see the SQL adaptation guide for your database type.

The `WITH CONCURRENT TRANSACTION` clause allows a program to open several transactions concurrently in different database sessions: The transaction can be started with the `BEGIN WORK` statement in a given connection context, then the program can switch to another connection with `SET CONNECTION`, and when done, switch back to the first connection to issue a `COMMIT WORK` or `ROLLBACK WORK`. This is supported for IBM® Informix® database servers. The option is ignored with other database server types, but it can be used in the `CONNECT` statement for consistency with Informix.

A `CONNECT TO` statement cannot be executed with dynamic SQL (`PREPARE + EXECUTE`).

With IBM® Informix® database servers, when using the `CONNECT TO DEFAULT`, you connect to the default IBM® Informix® database server, identified by the `INFORMIXSERVER` environment variable, without any database selection.
When using IBM® Informix® databases on UNIX™, the only restriction on establishing multiple connections to the same database environment is that an program can establish only one connection to each local server that uses the shared-memory connection mechanism. To find out whether a local server uses the shared-memory connection mechanism or the local-loopback connection mechanism, examine the $INFORMIXDIR/etc/sqlhosts file.

Example

```
MAIN
  DEFINE uname, upswd VARCHAR(50)
  CONNECT TO "stores1" -- Session name is "stores1"
  CONNECT TO "stores1" AS "SA" -- Session name is "SA"
  CALL login_dialog() RETURNING uname, upswd
  CONNECT TO "stores2" AS "SB" USER uname USING upswd
END MAIN
```

**SET CONNECTION**

Selects the current session when in multi-session mode.

**Syntax**

```
SET CONNECTION {
  session | DEFAULT |
  CURRENT DORMANT |
```

1. *session* is a string expression identifying the name of the database session to be set as current.

**Usage**

The **SET CONNECTION** instruction makes a given connection current.

The session name is case-sensitive.

When using the **DEFAULT** keyword, it identifies the default database server connection established with a CONNECT TO DEFAULT or a DATABASE instruction. This clause is specific to IBM® Informix® databases.

To make the current connection dormant, use CURRENT DORMANT keyword. This clause is specific to IBM® Informix® databases.

A **SET CONNECTION** statement cannot be executed with dynamic SQL (PREPARE + EXECUTE).
Example

```
MAIN
    DEFINE c1, c2, c3 INT
    CONNECT TO "stores1"
    CONNECT TO "stores2" AS "SA"
    CONNECT TO "stores3" AS "SB"
    SET CONNECTION "stores1"    -- Select first session
    SELECT COUNT(*) INTO c1 FROM customers
    SET CONNECTION "SA"         -- Select second session
    SELECT COUNT(*) INTO c2 FROM customers
    SET CONNECTION "SB"         -- Select third session
    SELECT COUNT(*) INTO c3 FROM customers
    SET CONNECTION "stores1"    -- Select first session again
END MAIN
```

**CONNECT TO** on page 628
Opens a new database session in multi-session mode.

**Database transactions** on page 631
Database transaction concepts and handling.

**Dynamic SQL management** on page 654
Explains how to execute and manage SQL statements at runtime.

**DISCONNECT**
Terminates database sessions when in multi-session mode.

Syntax

```
DISCONNECT { ALL | CURRENT | session }
```

1. `session` is a string expression identifying the name of the database session to be terminated.

Usage

The `DISCONNECT` instruction closes a given database connection.

The session name is case-sensitive.

When using the `DEFAULT` keyword, it identifies the default database server connection established with a `CONNECT TO DEFAULT` or a `DATABASE` instruction. This clause is specific to IBM® Informix® databases.

Use the `ALL` keyword to terminate all opened connections. From that point, you must establish a new connection to execute SQL statements.

Use the `CURRENT` keyword to terminate the current connection only. From that point, in order to execute SQL statements, you must select another connection with `SET CONNECTION`, or establish a new connection with `CONNECT TO`.

A `DISCONNECT` statement cannot be executed with dynamic SQL (i.e. `PREPARE` + `EXECUTE`).

If a `DISCONNECT` statement is used while a database transaction is active, the transaction is automatically rolled back.

Example

```
MAIN
    CONNECT TO "stores1"    -- Will be identified by "stores1"
    CONNECT TO "stores1" AS "SA"
    CONNECT TO "stores2" AS "SB" USER "scott" USING "tiger"
    DISCONNECT "stores1"
```
DISCONNECT "SB"
SET CONNECTION "SA"
END MAIN

Miscellaneous SQL statements
These are particular SQL statements supported in the static SQL syntax.

- **SET EXPLAIN** on page 631
- **UPDATE STATISTICS** on page 631

**SET EXPLAIN**
Turns on/off SQL report of the optimizer plan.

**Syntax:**

```
SET EXPLAIN { ON | OFF }
```

**Usage:**

**Important:** This SQL instruction is specific to IBM® Informix® databases.

**UPDATE STATISTICS**
Updates the statistics for all or for the specified table in the database.

**Syntax:**

```
UPDATE STATISTICS [ FOR TABLE table-specification ]
```

**Usage:**

**Important:** This SQL instruction is specific to IBM® Informix® databases.

- **SET LOCK MODE** on page 637
Understanding database transactions

This is an introduction to database transactions.

A database transaction delimits a set of database operations (SQL statements), that are processed as a whole.

Database operations included inside a transaction are validated or canceled as a unique operation.

**Figure 22: Database transaction**

The database server is in charge of data concurrency and data consistency. Data concurrency allows for the simultaneous access of the same data by many users, while data consistency gives each user a consistent view of the database.

Without adequate concurrency and consistency control, data can be changed improperly, compromising integrity of your database. If you want to write applications that can work with different kinds of database servers, you must adapt the program logic to the behavior of the database servers, regarding concurrency and consistency management. This requires good knowledge of multiuser database application programming, transactions, locking mechanisms, isolation levels, and wait mode. If you are not familiar with these concepts, carefully read the documentation of each database server that covers this subject.

Usually, database servers set exclusive locks on rows that are modified or deleted inside a transaction. These locks are held until the end of the transaction to control concurrent access to that data. Some database servers implement row versioning (before modifying a row, the server makes a copy of the original row). This technique allows readers to see a consistent copy of the rows that are updated during a transaction not yet committed. When the isolation level is high (REPEATABLE READ) or when using a `SELECT FOR UPDATE` statement, the database server sets shared locks on fetched rows, to prevent other users from changing the rows fetched by the reader. These locks are held until the end of the transaction. Some database servers allow read locks to be held regardless of the transactions (WITH HOLD cursor option), but this is not a standard.

Programs accessing the database can change transaction parameters such as the isolation level or lock wait mode. To write portable applications, you must use a configuration that produces the same behavior on every database engine.

The recommended programming pattern regarding transactions is the following:

- The database must support transactions; this is usually the case.
- Transactions must be as short as possible (a few seconds).
- The isolation level must be at least COMMITTED READ.
- The wait mode for locks must be WAIT or WAIT n (lock timeout).

To write portable SQL applications, programmers use the **BEGIN WORK, COMMIT WORK** and **ROLLBACK WORK** instructions described in this section to delimit transaction blocks and define concurrency parameters with **SET**
ISOLATION and SET LOCK MODE. These instructions are part of the language syntax. At runtime, the database driver generates the appropriate SQL commands to be used with the target database server. This allows you to use the same source code for different kinds of database servers.

If you initiate a transaction with a BEGIN WORK statement, you must issue a COMMIT WORK at the end of the transaction. If one of the SQL statement fails in the transaction, you typically issue a ROLLBACK WORK to force the database server to cancel any modifications that the transaction made to the database. If you do not issue a BEGIN WORK statement to start a transaction, each statement executes within its own transaction. These single-statement transactions do not require either a BEGIN WORK statement or a COMMIT WORK statement.

Recent database engines support transaction savepoints, which allows you to set markers in the current transaction, in order to rollback to a specific point without canceling the complete transaction. The transaction savepoint instructions SAVEPOINT, ROLLBACK TO SAVEPOINT and RELEASE SAVEPOINT are part of the language syntax and can be directly used in the code.

Some database servers do not support a Data Definition Language (DDL) statements (like CREATE TABLE) inside transactions, and some automatically commit the transaction when such a statement is executed. Therefore, it is strongly recommended that you avoid DDL statements inside transactions.

A transaction that processes many rows can exceed the limits that your operating system or the database server configuration imposes on the maximum number of simultaneous locks. Include a limited number of SQL operations in a transaction blocks.

When a program is using several database connections, and if transactions are not terminated before switching to another connection (SET CONNECTION), it is mandatory to use the WITH CONCURRENT TRANSACTION option in the CONNECT instruction.

**Related concepts**

  - Explains how to manage database connections in a program.
- Concurrent data access on page 537
  - Understanding concurrent data access and data consistency.
- CONNECT TO on page 628
  - Opens a new database session in multi-session mode.

**BEGIN WORK**

Starts a database transaction in the current connection.

**Syntax**

BEGIN WORK

**Usage**

Use the BEGIN WORK instruction to indicate where the database transaction starts in your program. Each row that an UPDATE, DELETE, or INSERT statement affects during a transaction is locked and remains locked throughout the transaction.

BEGIN WORK is part of the language syntax, the underlying database driver executes the native SQL statement corresponding to this SQL instruction.

In order the

**Example**

The next code example starts a transaction block, inserts a row and updates the row, then commits the transaction. To other users, the INSERT and UPDATE instruction will be seen as an single atomic database modification:
BEGIN WORK
    INSERT INTO items VALUES ( ... )
    UPDATE items SET ...
    COMMIT WORK
END MAIN

Related concepts

**COMMIT WORK** on page 635
Validates and terminates a database transaction in the current connection.

**ROLLBACK WORK** on page 635
Cancels and terminates a database transaction in the current connection.

**Database transactions** on page 631
Database transaction concepts and handling.

**SAVEPOINT**
Defines or resets the position of a rollback point in the current transaction.

**Syntax**

```
SAVEPOINT spVname [UNIQUE]
```

1. `spname` is the savepoint identifier.

**Usage**
The **SAVEPOINT** instruction declares a new rollback label at the current position in the lexical order within the current transaction. After defining a savepoint, you can rollback to the specified point in the transaction by using the **ROLLBACK WORK TO SAVEPOINT** instruction.

If the same savepoint name was used in a prior **SAVEPOINT** instruction, the previous savepoint is destroyed and the name is reused to flag the new rollback position. The optional `UNIQUE` keyword specifies that you do not want to reuse the same savepoint name in a subsequent **SAVEPOINT** instruction. Reusing the same name after a **SAVEPOINT** `spname UNIQUE` will raise an SQL error.

**Example**

In this example, a first savepoint is defined before the **INSERT** statement, then reset before the **UPDATE** statement. The **ROLLBACK TO SAVEPOINT** instruction will cancel the **UPDATE** statement only:

```
MAIN
    DATABASE stock
    BEGIN WORK
    DELETE FROM items
    SAVEPOINT sp1
    INSERT INTO items VALUES ( ... )
    SAVEPOINT sp1 -- releases previous savepoint named sp1
    UPDATE items SET ...
    ROLLBACK WORK TO SAVEPOINT sp1
    COMMIT WORK
END MAIN
```

Related concepts

**RELEASE SAVEPOINT** on page 636
Destroys the specified savepoint in the current transaction.

**ROLLBACK WORK** on page 635
Cancels and terminates a database transaction in the current connection.

**Database transactions** on page 631
Database transaction concepts and handling.

**COMMIT WORK**
Validates and terminates a database transaction in the current connection.

**Syntax**

```
COMMIT WORK
```

**Usage**

Use the **COMMIT WORK** instruction to commit all modifications made to the database from the beginning of a transaction. The database server takes the required steps to make sure that all modifications that the transaction makes are completed correctly and saved to disk.

**COMMIT WORK** is part of the language syntax, the underlying database driver executes the native SQL statement corresponding to this SQL instruction.

The **COMMIT WORK** statement releases all exclusive locks that have been set during the transaction. With some databases, shared locks are not released if the **FOR UPDATE** cursor is declared with **WITH HOLD** option. However, the **COMMIT WORK** statement closes all cursors not declared with the **WITH HOLD** option.

**Related concepts**

- [BEGIN WORK](#) on page 633
  Starts a database transaction in the current connection.
- [Database transactions](#) on page 631
  Database transaction concepts and handling.

**ROLLBACK WORK**
Cancels and terminates a database transaction in the current connection.

**Syntax**

```
ROLLBACK WORK [TO SAVEPOINT |spname|]
```

- `spname` is the savepoint identifier.

**Usage**

Use **ROLLBACK WORK** to cancel the current transaction and invalidate all changes since the beginning of the transaction. After the execution of this instruction, the database is restored to the state that it was in before the transaction began. All row and table locks that the canceled transaction holds are released. If you issue this statement when no transaction is pending, an error occurs.

**ROLLBACK WORK** is part of the language syntax, the underlying database driver executes the native SQL statement corresponding to this SQL instruction.

When specifying a savepoint with the **TO SAVEPOINT** clause, all SQL statements executed since the specified savepoint will be canceled. The transaction is not canceled, however, and you can continue to execute other SQL statements.

**Example**

This example checks for a potential SQL error after the **DELETE** statement and cancels the complete transaction with a **ROLLBACK** instruction:

```
MAIN
    DATABASE stock
```
WHENEVER ERROR CONTINUE
BEGIN WORK
INSERT INTO orders_hist VALUES ( ... )
DELETE FROM orders WHERE ...
IF SQLCA.SQLCODE < 0 THEN
   ROLLBACK WORK
ELSE
   COMMIT WORK
END IF
END MAIN

Related concepts
BEGIN WORK on page 633
Starts a database transaction in the current connection.

SAVEPOINT on page 634
Defines or resets the position of a rollback point in the current transaction.

Database transactions on page 631
Database transaction concepts and handling.

RELEASE SAVEPOINT
Destroys the specified savepoint in the current transaction.

Syntax

RELEASE SAVEPOINT spname

• spname is the savepoint identifier.

Usage

Use the RELEASE SAVEPOINT instruction to delete a savepoint defined by the SAVEPOINT instruction. See database documentation for more details about the behavior of this SQL statement. Note for example that IBM® Informix® IDS will also release any savepoint that has been declared between the specified savepoint and the RELEASE SAVEPOINT instruction.

Example

In the next example, the RELEASE SAVEPOINT instruction cancels the UPDATE and INSERT statements and destroys the sp1 and sp2 savepoints. Only the DELETE statement will take effect at the end of the transaction:

MAIN
   DATABASE stock
   BEGIN WORK
   DELETE FROM items
   SAVEPOINT sp1
   INSERT INTO items VALUES ( ... )
   SAVEPOINT sp2
   UPDATE items SET ... 
   RELEASE SAVEPOINT sp1
   ROLLBACK WORK TO SAVEPOINT
   COMMIT WORK
END MAIN

Related concepts
SAVEPOINT on page 634
Defines or resets the position of a rollback point in the current transaction.

ROLLBACK WORK on page 635
Cancels and terminates a database transaction in the current connection.

**Database transactions** on page 631

Database transaction concepts and handling.

### SET ISOLATION

Defines the transaction isolation level for the current connection.

**Syntax**

```
SET ISOLATION TO
   ↓ DIRTY READ
   ↓ COMMITTED READ [LAST COMMITTED] [RETAIN UPDATE LOCKS]
   ↓ CURSOR STABILITY
   ↓ REPEATABLE READ }
```

**Usage**

The **SET ISOLATION** instruction sets the transaction isolation level for the current connection. See database concepts in your database server documentation for more details about isolation levels and concurrency management.

When possible, the underlying database driver sets the corresponding transaction isolation level. If the isolation level cannot be set, the runtime system generates an exception.

When using the **DIRTY READ** isolation level, the database server might return a phantom row, which is an uncommitted row that was inserted or modified within a transaction that has subsequently rolled back. No other isolation level allows access to a phantom row.

On most database servers, the default isolation level is **COMMITTED READ**, which is appropriate to portable database programming.

The **LAST COMMITTED** and **RETAIN UPDATE LOCKS** options have been added to the language syntax for conformance with IBM® Informix® IDS 11. The **LAST COMMITTED** option can be turned on implicitly with a server configuration parameter, saving unnecessary code changes.

**Example**

```
MAIN
   DATABASE stock
   SET ISOLATION TO COMMITTED READ
   ...
END MAIN
```

**Related concepts**

Database transaction concepts and handling.

**SQL execution diagnostics** on page 529

If an SQL statement execution fails, error description can be found in the **SQLCA.SQLCODE**, **SQLSTATE**, **STATUS** and **SQLERRMESSAGE** predefined registers.

### SET LOCK MODE

Defines the behavior of the program that tries to access a locked row or table.

**Syntax**

```
SET LOCK MODE TO ↓ NOT WAIT ↓ WAIT↓ seconds ↓ }
```
Usage

The `SET LOCK MODE` instruction defines the timeout for lock acquisition for the current connection.

When possible, the underlying database driver sets the corresponding connection parameter to define the timeout for lock acquisition. But some database servers may not support setting the lock timeout parameter. In this case, the runtime system generates an exception.

When using the `NOT WAIT` clause, the timeout is set to zero. If the resource is locked, the database server ends the operation immediately and raises an exception with the SQL error.

`seconds` defines the number of seconds to wait for lock acquisition. If the resource is locked, the database server ends the operation after the elapsed time and raises an exception with the SQL error.

When using the `WAIT` clause without a number of seconds, the database server waits for lock acquisition for an infinite time.

With most database servers, the default is to wait for locks to be released.

Make sure that the database server and corresponding database driver both support a lock acquisition timeout option, otherwise the program will raise an exception.

Example

```
MAIN
  DATABASE stock
  SET LOCK MODE TO WAIT 20
  ...
END MAIN
```

Understanding static SQL statements

This is an introduction to static SQL statements.

Static SQL statements are SQL instructions that are a part of the Genero BDL language syntax. Static SQL statements can be used directly in the source code as a normal procedural instruction. The static SQL statements are parsed and validated at compile time. At runtime, these SQL statements are automatically prepared and executed by the runtime system.

Program variables can be used inside static SQL statements. Variables are detected by the compiler and handled as SQL parameters at runtime.

The following example defines two variables that are directly used in an INSERT statement:

```
MAIN
    DEFINE iref INTEGER, name CHAR(10)
    DATABASE stock
    LET iref = 65345
    LET name = "Kartopia"
    INSERT INTO item (item_ref, item_name) VALUES (iref, name)
    SELECT item_name INTO name FROM item WHERE item_ref = iref
END MAIN
```

As it is integrated in the language syntax, static SQL statement usage clarifies the source code, but the SQL text is hard-coded and cannot be modified at runtime as is possible with `PREPARE / EXECUTE instructions` of dynamic SQL.

Limited SQL syntax is part of the language, only common SQL statements such as `INSERT, UPDATE, DELETE, SELECT` are supported.

The compiler supports also `SQL ... END SQL` blocks to write free SQL text in your programs. The SQL syntax in SQL blocks is not limited to the static SQL syntax.

**Related concepts**

- Variables on page 366
  Explains how to define program variables.
- Database connections on page 600
  Explains how to manage database connections in a program.

Using program variables in static SQL

Static SQL syntax supports the usage of program variables as SQL parameters.

Using program variables directly in static SQL statements gives a better understanding of the source code and requires less lines as when using SQL parameters in dynamic SQL statements.

```
MAIN
    DEFINE c_num INTEGER
    DEFINE c_name CHAR(10)
    DATABASE stock
    SELECT cust_name INTO c_name FROM customer WHERE cust_num = c_num
END MAIN
```
If a database column name conflicts with a program variable, you can use the @ sign as the column prefix. The compiler will treat the identifier following the @ as a table column:

```sql
MAIN
  DEFINE cust_name CHAR(10)
  DEFINE cnt INTEGER
  DATABASE stock
  SELECT COUNT(*) INTO cnt FROM customer WHERE @cust_name = cust_name
END MAIN
```

The @ sign will not figure in the resulting SQL statement stored in the .42m compiled module.

**Related concepts**

- **Variables** on page 366
  Explains how to define program variables.

- **Dynamic SQL management** on page 654
  Explains how to execute and manage SQL statements at runtime.

**Table and column names in static SQL**

How are SQL object names and keywords converted in static SQL?

In static SQL statements, table and column names will be converted to lowercase by the fglcomp compiler. The SQL keywords are always converted to uppercase.

For example:

```sql
UPDATE CUSTOMER set CUST_name = 'undef' WHERE cust_name is null
```

Will be converted to:

```sql
UPDATE customer SET cust_name = 'undef' WHERE cust_name IS NULL
```

While SQL keywords are not case sensitive for database servers, table names and column names can be case-sensitive.

You can dump the static SQL statement texts with the -S option of fglcomp.

**Related concepts**

- **SQL basics** on page 528
  This section contains fundamental information to know about SQL programming with Genero BDL.

  fglcomp on page 1972
  The fglcomp tool compiles .4gl source files into .42m p-code modules.

**SQL texts generated by the compiler**

The Genero BDL compiler provides an option to extract static SQL statements from .4gl sources.

The fglcomp compiler parses the static SQL statements and modifies them before writing the resulting SQL text to the .42m module.

You can extract all static SQL statements from the source by using the -S option of fglcomp:

**Example**

```sql
MAIN
  DEFINE c_name CHAR(10)
  DEFINE cnt INTEGER
  DATABASE stock
  SELECT COUNT(*) INTO cnt FROM customer WHERE customer.cust_name = c_name
```
Related concepts

fglcomp on page 1972

The fglcomp tool compiles .4gl source files into .42m p-code modules.

## INSERT

Creates a new row in a database table.

### Syntax 1:

This is the most standard syntax, working with all type of database engines.

```sql
INSERT INTO table-specification ( column, ... ) VALUES ( variable, sql-expression, ... )
```

### Syntax 2:

The fglcomp compiler will automatically generate a standard INSERT statement with the complete list of members of the record. The generated SQL will depend on the definition of the record.

```sql
INSERT INTO table-specification VALUES ( record.* )
```

### Syntax 3:

This syntax requires a database schema specification with the SCHEMA instruction, and the corresponding database schema file.

```sql
INSERT INTO table-specification VALUES record.*
```

where **table-specification** is:

```sql
[dbname[@dbserver]:][owner.]table
```

1. **dbname** identifies the database name.
2. **dbserver** identifies the database server (INFORMIXSERVER).
3. **owner** identifies the owner of the table, with optional double quotes.
4. **table** is the name of the database table.
5. **column** is a name of a table column.
6. **variable** is a program variable, a record member or an array member used as a parameter buffer to provide values.
7. **sql-expression** is an expression supported by the database server, this can be a literal or NULL for example.
8. **select-statement** is a static SELECT statement with or without parameters as variables.
9. **record** is the name of a record (followed by dot star in this syntax).

### Usage

The INSERT SQL statement can be used to create a row in a specified database table.

The **dbname**, **dbserver** and **owner** prefix of the table name should be avoided for maximum SQL portability.
When using the VALUES clause, the statement inserts a row in the table with the values specified in variables, as literals, or with NULL. If a record is available, you can specify all record members with the star notation (record.*).

The third syntax can be used to avoid serial column usage in the value list. The record member corresponding to a column defined as SERIAL, SERIAL8 or BIGSERIAL in the schema file will be removed by the compiler. This is useful when using databases like Microsoft™ SQL Server, where IDENTITY columns must be omitted in INSERT statements.

When using a select-statement, the statement inserts all rows returned in the result set of the SELECT statement. The columns returned by the result set must match the column number and data types of the target table. For SQL portability, it is not recommended that you use this syntax.

**Example**

```plaintext
MAIN
  DEFINE myrec RECORD
      key INTEGER,
      name CHAR(10),
      cdate DATE,
      comment VARCHAR(50)
  END RECORD
DATABASE stock
LET myrec.key = 123
LET myrec.name = "Katos"
LET myrec.cdate = TODAY
LET myrec.comment = "xxxxxx"
INSERT INTO items VALUES ( 123, 'Practal', NULL, myrec.comment )
INSERT INTO items VALUES ( myrec.* )
INSERT INTO items VALUES myrec.* -- without serial (if one is used)
INSERT INTO items SELECT * FROM histitems WHERE name = myrec.name
END MAIN
```

**Related concepts**

  Records allow structured program variables definitions.

- **Variables** on page 366
  Explains how to define program variables.

- **PREPARE (SQL statement)** on page 655
  Prepares an SQL statement for execution.

**UPDATE**

Modifies rows of a database table.

**Syntax 1:**

This is the most standard syntax, working with all type of database engines.

```plaintext
UPDATE table-specification
SET
  column = [ variable | sql-expression | [,...] ]
  | sql-condition |
```
Syntax 2:
This syntax is not standard, but will be converted by the compiler to a portable UPDATE syntax.

```sql
UPDATE table-specification
SET (column [, ...])
    = (variable | sql-expression [, ...])
    sql-condition
```

Syntax 3:
This syntax is not portable, and is not converted by the compiler.

```sql
UPDATE table-specification
SET [table.*]
    = (variable | sql-expression [, ...])
    sql-condition
```

Syntax 4:
This syntax requires a database schema specification with SCHEMA instruction, and the corresponding database schema file.

```sql
UPDATE table-specification
SET [table.*] (column [, ...])
    = record.*
    sql-condition
```

where `table-specification` is:

```
[dbname[@dbserver]:][owner.]table
```

And `sql-condition` is:

```sql
WHERE condition CURRENT OF cursor
```

1. `dbname` identifies the database name.
2. `dbserver` identifies the database server (INFORMIXSERVER).
3. `owner` identifies the owner of the table, with optional double quotes.
4. `table` is the name of the database table.
5. `column` is a name of a table column.
6. `variable` is a program variable, a record member or an array member used as a parameter buffer to provide values.
7. `sql-expression` is an expression supported by the database server, this can be a literal or NULL for example.
8. `record` is the name of a record (followed by dot star in this syntax).
9. `condition` is an SQL expression to select the rows to be updated.
10. `cursor` is the identifier of a database cursor.

Usage
The UPDATE SQL statement can be used to modify one or more rows in the specified database table.

It is recommended to avoid using the `dbname`, `dbserver` and `owner` prefix of the table name to ensure maximum SQL portability.

The third syntax is not standard and will not work with all database types. It is not recommended.

The fourth syntax can be used if the database schema file has been generated with the correct data types. This is especially important when using SERIAL columns or equivalent auto-incremented columns. The `fglcomp` compiler...
will automatically extend the SQL text with the columns identified by the record variable. The columns defined in the database schema file as SERIAL (code 262) will be omitted in the generated column list.

column with a subscript expression (column[a,b]) is not recommended because most database servers do not support this notation.

For more details about the WHERE CURRENT OF clause, see Positioned updates/deletes on page 672.

Example

```plaintext
MAIN
  DEFINE myrec RECORD
    key INTEGER,
    name CHAR(10),
    cdate DATE,
    comment VARCHAR(50)
  END RECORD
DATABASE stock
LET myrec.key     = 123
LET myrec.name    = "Katos"
LET myrec.cdate   = TODAY
LET myrec.comment = "xxxxxx"
UPDATE items SET
  name    = myrec.name,
  cdate   = myrec.cdate,
  comment = myrec.comment
WHERE key = myrec.key
END MAIN
```

This is an introduction to SQL insert cursors.

PREPARE (SQL statement) on page 655
Prepares an SQL statement for execution.

DELETE

Removes rows from a database table.

Syntax

```
DELETE FROM table-specification
     | WHERE | condition | CURRENT OF cursor |
```

where table-specification is:

```
[dbname[@dbserver]:][owner.]table
```

1. `dbname` identifies the database name.
2. `dbserver` identifies the database server (INFORMIXSERVER).
3. `owner` identifies the owner of the table, with optional double quotes.
4. `table` is the name of the database table.
5. condition is an SQL expression to select the rows to be deleted.
6. cursor is the identifier of a database cursor.

Usage

The DELETE SQL statement can be used to delete one or more rows from the specified database table.

It is recommended to avoid using the dbname, dbserver and owner prefix of the table name to ensure maximum SQL portability.

If you do not specify the WHERE clause, all rows in the table will be deleted. No warning will be generated by the compiler.

For more details about the WHERE CURRENT OF clause, see Positioned updates/deletes on page 672.

Example

```sql
MAIN
    DATABASE stock
    DELETE FROM items WHERE name LIKE 'A%'
END MAIN
```

This is an introduction to SQL insert cursors.

Positioned updates/deletes on page 672
Describes row modification based on a FOR UPDATE cursor.

PREPARE (SQL statement) on page 655
Prepares an SQL statement for execution.

SELECT

Produces a result set from a query on database tables.

Syntax

```
select-statement | UNION [ALL] select-statement
| [.....]
```

where select-statement is:

```
SELECT |subset-clause| |duplicates-option| |*| |select-list| |
| INTO variable |,...,|
| FROM table-list |,...,|
| WHERE condition |
| |GROUP BY column-list |HAVING condition |
| |ORDER BY column |ASC|ASC| |
```

where subset-clause is:

```
| SKIP |integer|variable|
| |FIRST|MIDDLE|LIMIT| |
```

where duplicates-option is:

```
| ALL
| DISTINCT
| UNIQUE
| |
```
where `select-list` is:

```
[ table-specification.* ]
[ table-specification.] [ column ]
[ literal ]
[ [ AS1 column-alias ] ]
[ .... ]
```

where `table-list` is:

```
tag-name
OUTER tag-name
OUTER ( table-name [ , ... ] )
[ .... ]
```

where `tag-name` is:

```
table-specification [ AS1 table-alias]
```

where `table-specification` is:

```
[dbname[@dbserver] ] [ owner.] table
```

where `column-list` is:

```
column-name [ , ... ]`
```

where `column-name` is:

```
[ table. ] column
```

1. `dbname` identifies the database name.
2. `dbserver` identifies the database server (INFORMIXSERVER).
3. `owner` identifies the owner of the table, with optional double quotes.
4. `table` is the name of the database table.
5. `table-alias` defines a new name to reference the `table` in the rest of the statement.
6. `integer` is an integer constant.
7. `variable` is a program variable.
8. `column` is a name of a table column.
9. `column-alias` defines a new name to reference the `column` in the rest of the statement.
10. `condition` is an SQL expression to select the rows to be deleted.

**Usage**

It is recommended to avoid using the `dbname`, `dbserver` and `owner` prefix of the table name to ensure maximum SQL portability.

If the `SELECT` statement returns only one row of data, you can write it directly as a procedural instruction. However, you must use the into clause to provide the list of variables where column values will be fetched. The into clause provides the list of fetch buffers. This clause is not part of the SQL language sent to the database server; it is extracted from the statement by the compiler.

```main
DEFINE myrec RECORD
key INTEGER,
name CHAR(10),
cdate DATE,
```
If the SELECT statement returns more than one row of data, you must declare a database cursor to process the result set.

The SELECT statement can include the INTO clause, but it is strongly recommended that you use that clause in the FETCH instruction only.

The SELECT INTO TEMP statement creates temporary tables. Such a statement does not return a result set.

### Related concepts
- **Result set processing** on page 661
  - Shows how to fetch rows from a database query.
- **Records** on page 382
  - Records allow structured program variables definitions.

### SQL ... END SQL
Perform an SQL that is not part of the static SQL syntax.

**Syntax**

```sql
SQL
  sql-statement
END SQL
```

where `sql-statement` is:

```sql
  sql-keyword
  identifier
  INTO $host-variable [, ...]
  $host-variable
  (+ sql-directive )
  --- sql-directive
  ---# fgl-comment
```
1. *sql-keyword* is any keyword of the SQL language.
2. *identifier* is a regular SQL identifier such as a table or column name.
3. *host-variable* is a program variable defined in the current scope.
4. *sql-directive* is a special comment to be kept in the SQL statement.
5. *fgl-comment* defines a comment that will be interpreted as a regular syntax element.

**Usage**

SQL blocks provide a convenient way to execute specific SQL statements that are not supported in the language as static SQL statements.

SQL blocks start with the `SQL` keyword and end with the `END SQL` keywords. The content of the SQL block is parsed by the `fglcomp` compiler to extract host variables, but the SQL statement syntax is not checked. This is actually the main purpose of SQL blocks, compared to regular static SQL statements; with SQL blocks, you can use any recent SQL statement introduced by the latest version of your database server. Note, however, that you can achieve the same result using dynamic SQL instructions.

Only one SQL statement can be included in an SQL block. Using the `;` semicolon statement separator is forbidden. Program variables can be used inside the SQL statement. However, unlike static SQL statements, each host variable must be identified with a `$` dollar prefix. The list of fetch targets must be preceded by the `INTO` keyword, as in static `SELECT` statements. Complete records can be used in SQL blocks by using the dot star notation (`$record.*`), you can also use the `THROUGH` or `THRU` keywords), as well as array elements.

SQL blocks can also be used to declare a cursor with the `DECLARE mycursor CURSOR FOR SQL ... END SQL` syntax.

SQL directives can be used inside SQL blocks as special comments with the `{+}` or `--+` syntax. The SQL directives will be kept in the SQL text that will be executed by the database server. You typically write optimizer hints with the SQL directives syntax.

The `--#` specific comment is supported for backward compatibility. The SQL text following this marker will be parsed as regular SQL text, but will be ignored by other compilers. It is not recommended to use this feature.

You can check the resulting SQL statement after parsing by using the `-S` option of `fglcomp`.

**Example**

```plaintext
MAIN
    DEFINE myrec RECORD
        key INTEGER,
        name CHAR(10)
    END RECORD
DATABASE stock
LET myrec.key = 123
SQL
    SELECT (+EXPLAIN) items.* INTO $myrec.*
        FROM items WHERE key=$myrec.key
END SQL
END MAIN
```

**Related concepts**

Result set processing on page 661
Shows how to fetch rows from a database query.

Records on page 382
Records allow structured program variables definitions.

**CREATE SEQUENCE**

Creates a new sequence object in the database.

**Syntax:**

```
CREATE SEQUENCE [ IF NOT EXISTS ] sequence-name
[ INCREMENT BY integer ]
[ START WITH integer ]
[ NOMAXVALUE ]
[ MAXVALUE integer ]
[ NOMINVALUE ]
[ MINVALUE integer ]
[ CYCLE ]
[ NOCYCLE ]
[ CACHE integer ]
[ NOCACHE ]
[ ORDER ]
[ NOORDER ]
```

**Related concepts**

- **ALTER SEQUENCE** on page 649
  Modifies the definition of an existing sequence in the database.

- **DROP SEQUENCE** on page 650
  Drops a sequence object from the database.

**ALTER SEQUENCE**

Modifies the definition of an existing sequence in the database.

**Syntax:**

```
ALTER SEQUENCE sequence-name
[ INCREMENT BY integer ]
[ RESTART WITH integer ]
[ NOMAXVALUE ]
[ MAXVALUE integer ]
[ NOMINVALUE ]
[ MINVALUE integer ]
[ CYCLE ]
[ NOCYCLE ]
[ CACHE integer ]
[ NOCACHE ]
[ ORDER ]
[ NOORDER ]
```

**Related concepts**

- **CREATE SEQUENCE** on page 649
  Creates a new sequence object in the database.

- **DROP SEQUENCE** on page 650
Drops a sequence object from the database.

**DROP SEQUENCE**

Drops a sequence object from the database.

**Syntax:**

```
DROP SEQUENCE [ IF EXISTS ] sequence-name
```

**Related concepts**

- **CREATE SEQUENCE** on page 649
  Creates a new sequence object in the database.
- **ALTER SEQUENCE** on page 649
  Modifies the definition of an existing sequence in the database.

**CREATE TABLE**

Creates a new table object in the database.

**Syntax:**

```
CREATE [ TEMP ] TABLE [ IF NOT EXISTS ] table-specification
{
  column-name data-type
  [ DEFAULT default-value ] [ NOT NULL ]
  [ PRIMARY KEY | contraint-name ]
  [ UNIQUE | contraint-name ]
  [ CHECK ( sql-condition ) | contraint-name ]
  REFERENCES table-name
  ( column-name [ ,... ] )
  [ ON DELETE CASCADE ]
  [ constraint-name ]
  [ PRIMARY KEY ( column-name [ ,... ] ) | constraint-name ]
  [ UNIQUE ( column-name [ ,... ] ) | constraint-name ]
  [ FOREIGN KEYS ( column-name [ ,... ] ) ]
  REFERENCES table-name
  ( column-name [ ,... ] )
  [ ON DELETE CASCADE ]
  [ constraint-name ]
  [ ,... ]
  [ WITH NO LOG ]
  [ IN tablespace-name ]
  [ EXTENT SIZE integer ]
  [ NEXT SIZE integer ]
  [ LOCK MODE | PAGE | ROW ]
}
```

**Related concepts**

- **ALTER TABLE** on page 651
  Modifies the definition of an existing table in the database.
- **DROP TABLE** on page 652
Drops a table object from the database.

**ALTER TABLE**

Modifies the definition of an existing table in the database.

**Syntax:**

```
ALTER TABLE table-specification

( DROP ( column-name [, ...] )
  ADD ( column-name data-type
        | DEFAULT default-value | NOT NULL |
        | PRIMARY KEY constraint-name |
        | UNIQUE constraint-name |
        | CHECK ( sql-condition ) constraint-name |
        REFERENCES table-name
        | ( column-name [, ...] ) |
        | ON DELETE CASCADE |
        | constraint-name |
        | BEFORE column-name |
    )

  MODIFY ( column-name data-type
            | DEFAULT default-value | NOT NULL |
            | PRIMARY KEY constraint-name |
            | UNIQUE constraint-name |
            | CHECK ( sql-condition ) constraint-name |
            REFERENCES table-name
            | ( column-name [, ...] ) |
            | ON DELETE CASCADE |
            | constraint-name |
    )

  DROP CONSTRAINT constraint-name

  ADD CONSTRAINT
  | PRIMARY KEY ( column-name [, ...] ) constraint-name |
  | UNIQUE ( column-name [, ...] ) constraint-name |
  | CHECK ( sql-condition ) constraint-name |
  | FOREIGN KEY ( column-name [, ...] ) |
  REFERENCES table-name
  | ( column-name [, ...] ) |
  | ON DELETE CASCADE |
  | constraint-name |

  LOCK MODE ( PAGE | ROW )

  MODIFY NEXT SIZE integer
  )
```

**Related concepts**

CREATE TABLE on page 650
Creates a new table object in the database.

DROP TABLE on page 652
Drops a table object from the database.

**DROP TABLE**
Drops a table object from the database.

**Syntax:**
```
DROP TABLE \[ IF EXISTS \] table-specification
```

**Related concepts**
- **ALTER TABLE** on page 651
  Modifies the definition of an existing table in the database.
- **CREATE TABLE** on page 650
  Creates a new table object in the database.

**CREATE INDEX**
Creates a new index object in the database.

**Syntax:**
```
CREATE \[ UNIQUE \| CLUSTER \| UNIQUE CLUSTER \| INDEX \[ IF NOT EXISTS \] \] index-name
  ON table-specification
  ( column-name \[ ASCENCDING \| DESCENDING \] \[ , ... \])
```

**Related concepts**
- **ALTER INDEX** on page 652
  Modifies the definition of an existing index in the database.
- **DROP INDEX** on page 652
  Drops an index object from the database.

**ALTER INDEX**
Modifies the definition of an existing index in the database.

**Syntax:**
```
ALTER INDEX index-name TO \[ NOT \] CLUSTER
```

**Related concepts**
- **CREATE INDEX** on page 652
  Creates a new index object in the database.
- **DROP INDEX** on page 652
  Drops an index object from the database.

**DROP INDEX**
Drops an index object from the database.

**Syntax:**
```
DROP INDEX \[ IF EXISTS \] index-name
```
**CREATE VIEW**

Creates a new view object in the database.

**Syntax:**

```
CREATE VIEW IF NOT EXISTS view-name
    ( column-alias-name [, ... ] ) AS
    sub-query
    WITH CHECK OPTION
```

where `sub-query` is a limited syntax of the `SELECT` statement.

**Related concepts**

- **DROP VIEW** on page 653
  - Drops a view object from the database.

**DROP VIEW**

Drops a view object from the database.

**Syntax:**

```
DROP VIEW IF EXISTS view-name
```

**Related concepts**

- **CREATE VIEW** on page 653
  - Creates a new view object in the database.

**CREATE SYNONYM**

Creates a new synonym object in the database.

**Syntax:**

```
CREATE SYNONYM IF NOT EXISTS synonym-name
    FOR table-specification
```

**Related concepts**

- **DROP SYNONYM** on page 653
  - Drops a synonym object from the database.

**DROP SYNONYM**

Drops a synonym object from the database.

**Syntax:**

```
DROP SYNONYM IF EXISTS synonym-name
```

**Related concepts**

- **CREATE SYNONYM** on page 653
Dynamic SQL management

Explains how to execute and manage SQL statements at runtime.

- Understanding dynamic SQL on page 654
- PREPARE (SQL statement) on page 655

- fglhint_* SQL comments on page 660

Understanding dynamic SQL

This is an introduction to dynamic SQL programming.

Basic SQL instructions are part of the language syntax as static SQL statements, but only a limited number of SQL instructions are supported this way. Dynamic SQL management allows you to execute any kind of SQL statement, hard coded or created at runtime, with or without SQL parameters, returning or not returning a result set.

In order to execute an SQL statement dynamically, you must first PREPARE the SQL statement to initialize a statement handle, then EXECUTE the prepared statement one or more times:

![Dynamic SQL management diagram]

Figure 23: Dynamic SQL management diagram

When you no longer need the prepared statement, you can FREE the statement handle to release allocated resources:

RENAME

Renames an object in the database.

Syntax:

RENAME ↓ TABLE ↓ COLUMN ↓ INDEX ↓ SEQUENCE ↓

old-name TO new-name

CREATESYN

Creates a new synonym object in the database.
Figure 24: FREE statement diagram

When using insert cursors or SQL statements that produce a result set (like `SELECT`), you must declare a cursor with a prepared statement handle.

Prepared SQL statements can contain SQL parameters by using `?` placeholders in the SQL text. In this case, the `EXECUTE` or `OPEN` instruction supplies input values in the `USING` clause.

**Note:** To increase performance efficiency of SQL executed in a loop, use `PREPARE` outside the loop, together with `EXECUTE` inside the loop, to eliminate overhead caused by redundant parsing and optimizing.

The `EXECUTE IMMEDIATE` instruction prepares and executes an SQL statement in a single instruction. SQL parameters and result sets cannot be used with `EXECUTE IMMEDIATE`.

The `base.SQLHandle` built-in class is a 3GL API to execute SQL statements dynamically and perform SQL introspection (to get result set column types).

**PREPARE (SQL statement)**

Prepares an SQL statement for execution.

**Syntax**

```sql
PREPARE sid FROM sqltext
```

1. `sid` is an identifier to handle the prepared SQL statement.
2. `sqltext` is a string expression containing the SQL statement to be prepared.

**Usage**

The `PREPARE` instruction allocates resources for an SQL statement handle, in the context of the current database connection. The SQL text is sent to the database server for parsing, validation and to generate the execution plan.

Prepared SQL statements can be executed with the `EXECUTE` instruction, or, when the SQL statement generates a result set, the prepared statement can be used to declare cursors with the `DECLARE` instruction.

A statement identifier (`sid`) can represent only one SQL statement at a time. You can execute a new `PREPARE` instruction with an existing statement identifier if you wish to assign the text of a different SQL statement to the statement identifier. The scope of reference of the `sid` statement identifier is local to the module where it is declared. That is, the identifier of a statement that was prepared in one module cannot be referenced from another module.

The SQL statement can have parameter placeholders, identified by the question mark (`?`) character. You cannot directly reference a variable in the text of a prepared SQL statement. You cannot use question mark (`?`) placeholders for SQL identifiers such as a table name or a column name; you must specify these identifiers in the statement text when you prepare it.

Resources allocated by `PREPARE` can be released later by the `FREE` instruction.

The number of prepared statements in a single program is limited by the database server and the available memory. Make sure that you free the resources when you no longer need the prepared statement.

Some database servers support multiple SQL statement preparation in a unique `PREPARE` instruction, but most database servers deny multiple statements. It is recommended that you only prepare one SQL statement at a time.

**Example**

```sql
FUNCTION deleteOrder(n)
    DEFINE n INTEGER
    PREPARE s1 FROM "DELETE FROM order WHERE key=?"
    EXECUTE s1 USING n
    FREE s1
END FUNCTION
```

See `EXECUTE` for more code examples.

**Related concepts**

- Variables on page 366
  Explains how to define program variables.

- FREE (SQL statement) on page 658
  Releases the resources allocated to a prepared statement.

- Multi-session mode connection instructions on page 628
  Opening and closing a database for a unique session.

**EXECUTE (SQL statement)**

This instruction runs an SQL statement previously prepared.

**Syntax**

```sql
EXECUTE sid
    USING pvar [IN|OUT|INOUT] [, ...] 
    INTO fvar [, ...] 
```

1. `sid` is an identifier to handle the prepared SQL statement.
2. `pvar` is a variable containing an input value for an SQL parameter.
3. `fvar` is a variable used as fetch buffer.
Usage

The EXECUTE instruction performs the execution of a prepared SQL statement. Once prepared, an SQL statement can be executed as often as needed.

If the SQL statement has (?) parameter placeholders, you must specify the USING clause to provide a list of variables as parameter buffers. Parameter values are assigned by position.

If the SQL statement returns a result set with one row, you can specify the INTO clause to provide a list of variables to receive the result set column values. Fetched values are assigned by position. If the SQL statement returns a result set with more than one row, the instruction raises an exception.

The IN, OUT or INOUT options can only be used for simple variables, you cannot specify those options for a complete record with the record.* notation.

The IN, OUT or INOUT options can be used to call stored procedures having input / output parameters. Use the IN, OUT or INOUT options to indicate if a parameter is respectively for input, output or both.

You cannot execute a prepared SQL statement based on database tables if the table structure has changed (ALTER TABLE) since the PREPARE instruction; you must re-prepare the SQL statement.

Example

```main
DEFINE var1 CHAR(20)
DEFINE var2 INTEGER

DATABASE stores

PREPARE s1 FROM "UPDATE tab SET col=? WHERE key=?"
LET var1 = "aaaa"
LET var2 = 345
EXECUTE s1 USING var1, var2

PREPARE s2 FROM "SELECT col FROM tab WHERE key=?"
LET var2 = 564
EXECUTE s2 USING var2 INTO var1

PREPARE s3 FROM "CALL myproc(?,?)"
LET var1 = 'abc'
EXECUTE s3 USING var1 IN, var2 OUT

END MAIN
```

Releases the resources allocated to a prepared statement.

Exceptions on page 451
Describes exception (error) handling in the programs.

Stored procedures on page 582
Executing stored procedures with different database engine types.

**FREE (SQL statement)**
Releases the resources allocated to a prepared statement.

**Syntax**

```
FREE sid
```

1. *sid* is the identifier of the prepared SQL statement.

**Usage**
The `FREE` instruction takes the name of a statement as parameter.
All resources allocated to the SQL statement handle are released.
After resources are released, the statement identifier cannot be referenced by a cursor, or by the `EXECUTE` statement, until you prepare the statement again.
Free the statement if it is not needed anymore, this saves resources on the database client and database server side.

**Example**

```plaintext
FUNCTION update_customer_name( key, name )
    DEFINE key INTEGER
    DEFINE name CHAR(10)
    PREPARE s1 FROM "UPDATE customer SET name=? WHERE customer_num=?"
    EXECUTE s1 USING name, key
    FREE s1
END FUNCTION
```

  Executing stored procedures with different database engine types.

**EXECUTE IMMEDIATE**
Performs a simple SQL execution without SQL parameters or result set.

**Syntax**

```
EXECUTE IMMEDIATE sqltext
```

1. *sqltext* is a string expression containing the SQL statement to be executed.

**Usage**
The `EXECUTE IMMEDIATE` instruction passes an SQL statement to the database server for execution in the current database connection.
The SQL statement used by `EXECUTE IMMEDIATE` must be a single statement without SQL parameters and must not produce a result set.

This instruction is equivalent to `PREPARE`, `EXECUTE` and `FREE` in one step.

**Example**

```
MAIN
  DATABASE stores
  EXECUTE IMMEDIATE "UPDATE tab SET col='aaa' WHERE key=345"
END MAIN
```

**The base.SQLHandle built-in class**

Handle SQL queries with a 3GL API.

Genero BDL provides a 3GL API to execute SQL queries and introspect result set column information with the `base.SqlHandle` built-in class.

The class implements typical SQL statement execution methods existing in well-known APIs, such as:

- `prepare("sql-text")`
- `setParameter()`
- `execute()`
- `open(),openScrollCursor()`
- `fetch(),fetchFirst(),fetchLast(),...`

The class also implements introspection methods for the result set columns:

- `getResultCount()`
- `getResultType(index)`
- `getResultName(index)`
- `getResultValue(index)`

This class is provided to allow generic code implementation for specific needs. Consider using traditional static and dynamic SQL instruction for regular code implementing your business rules; the 3GL code based on the SqlHandle class is not as readable as static or dynamic SQL.

**Related concepts**

- [The SqlHandle class](#) on page 2292
  The `base.SqlHandle` class is a built-in class providing an API to execute parameterized SQL statements, with or without result sets.
- [Static SQL statements](#) on page 638
Describes static SQL statements supported in the language.

**fglhint_* SQL comments**

Using special SQL comment hints to control statement execution.

**Syntax**

```c
/*
 * * fglhint_insert
 * * fglhint_update
 * * fglhint_delete
 * * fglhint_select
 * * fglhint_other
 * *
 * [ fglhint_no_ifxemul ]
 */
```

The `fglhint_*` indicators help the database driver to identify the SQL statement and control Informix® emulation:

1. **fglhint_insert**: Regular INSERT (preparable, without result set).
2. **fglhint_update**: Regular UPDATE (preparable, without result set).
3. **fglhint_delete**: Regular DELETE (preparable, without result set).
4. **fglhint_select**: Regular SELECT (preparable, with result set).
5. **fglhint_other**: Any other non-preparable SQL statement (maybe with result set).
6. **fglhint_no_ifxemul**: Disable Informix® emulation (like the FGLPROFILE entry, but for this statement only).

**Usage**

When preparing an SQL statement, the ODI database drivers must identify the type of SQL statement, in order to set database client API options to perform the statement properly.

For example, when executing an SELECT statement that returns a result set, ODBC options for a server-side cursor must be set with Microsoft® SQL Server clients. If a server-side cursor is not used only one active cursor is used in a Genero program.

Or, for example, when executing an SELECT statement that creates temporary tables with SQL Server, it must be done with a direct ODBC execution (using ODBC SQLExecDirect instead of SQLPrepare/SQLExecute), otherwise the temporary table is created in the scope of the sp_prepare() stored procedure, and is dropped immediately after returning from the sp_prepare() call.

Specified inside /* */ C-style comments, the `fglhint_*` keywords can be used as SQL statement recognition directives:

- When the SQL statement looks like a regular INSERT statement, but uses an OUTPUT INSERTED.* clause, add the `/* fglhint_select */` SQL comment, to indicate that it must be treated as a regular, preparable SELECT statement returning a result set.
- When the SQL statement looks like a regular SELECT statement, but has an INTO newtable clause to create a new table, add the `/* fglhint_insert */` SQL comment, to indicate that it must be treated as a regular, preparable INSERT statement.
- When the SQL statement looks like a regular SELECT statement, but has an INTO #newtemptable clause to create a new temporary table, add the `/* fglhint_other */` SQL comment, to indicate that it must be treated as a non-preparable INSERT statement (to be executed directly).

**Note**: /* */ C-style comments are only allowed in dynamic SQL statements, the BDL language does not allow such comments in static SQL statements, which is based on the Informix-SQL syntax.
For example, this statement performs an INSERT with an OUTPUT clause, that will produce a result set. Use the fglhint_select hint, to indicate that the statement must be executed as a regular SELECT:

```
DECLARE c1 CURSOR
    FROM /* fglhint_select */ INSERT INTO table1 OUTPUT INSERTED.* SELECT * FROM customers"
```

This statement performs a SELECT INTO newtable, that will be executed as an INSERT (without a result set), because we use the fglhint_insert hint:

```
EXECUTE IMMEDIATE /* fglhint_insert */ SELECT * INTO newtable FROM customers WHERE cust_valid='Y'
```

In order to perform a SELECT INTO #temptable, the statement must be executed directly without using the sp_prepare/sp_execute procedures of SQL Server (otherwise the temp table will only exist in the context of the stored procedures). Therefore, we use the fglhint_other hint to force a direct SQL execution:

```
EXECUTE IMMEDIATE /* fglhint_other */ SELECT * INTO #tmptab SELECT * FROM customers"
DECLARE c2 CURSOR FROM "SELECT * FROM #tmptab ...
```

Furthermore, Informix® SQL emulation can be disabled by using the fglhint_no_ifxemul hint:

```
PREPARE s1 FROM "/* fglhint_no_ifxemul */ SELECT * FROM [dbo].[mytable]
```

**Note:** When using the fglhint_no_ifxemul hint, Informix® emulation will only be disabled for this SQL statement. Other SQL statements executed by your program can use the Informix® emulations.

SQL statement type identification and Informix® emulation hints can be combined:

```
PREPARE s1 FROM "/* fglhint_no_ifxemul fglhint_select */ INSERT INTO [dbo].[mytable] OUTPUT ...
```

**Related concepts**

**Result set processing**

Shows how to fetch rows from a database query.

- **Understanding database result sets** on page 661
- **DECLARE (result set cursor)** on page 663
- **OPEN (result set cursor)** on page 666
- **FETCH (result set cursor)** on page 667
- **CLOSE (result set cursor)** on page 669
- **FREE (result set cursor)** on page 670
- **FOREACH (result set cursor)** on page 670

**Understanding database result sets**

This is an introduction to database result sets.

A *database result set* is a group of rows produced by an SQL statement such as `SELECT`. The result set is maintained by the database server. In a program, you handle a result set with a *database cursor*. 
First you must declare the database cursor with the `DECLARE` instruction. This instruction sends the SQL statement to the database server for parsing, validation and to generate the execution plan.

![Diagram of FQL Program and Database](image)

**Figure 25: Database result set**

The result set is produced after execution of the SQL statement, when the database cursor is associated with the result set by the `OPEN` instruction. At this point, no data rows are transmitted to the program. You must use the `FETCH` instruction to retrieve data rows from the database server.

![Diagram of FETCH instruction](image)

**Figure 26: FETCH instruction**

When finished with the result set processing, you must `CLOSE` the cursor to release the resources allocated for the result set on the database server. The cursor can be reopened if needed. If the SQL statement is no longer needed, you can free the resources allocated to statement execution with the `FREE` instruction.
The scope of reference of a database cursor is local to a module, so a cursor that was declared in one source file cannot be referenced in a statement in another file.

The language supports sequential cursors and scrollable cursors. Sequential cursors, which are unidirectional, are used to retrieve rows for a REPORT, for example. Scrollable cursors allow you to move backwards or to an absolute or relative position in the result set. Specify whether a cursor is scrollable with the SCROLL option of the DECLARE instruction.

For better code readability, use a FOREACH / END FOREACH loop, to perform the equivalent of an OPEN + FETCH (in WHILE loop) + CLOSE.

**Related concepts**

Reports on page 1924

**DECLARE (result set cursor)**

Associates a database cursor with an SQL statement producing a result set.

**Syntax 1: Cursor declared with a static SQL statement.**

```sql
DECLARE cid [SCROLL] CURSOR [WITH HOLD] FOR select-statement
```

1. `cid` is the identifier of the database cursor.
2. `select-statement` is a SELECT statement defined in static SQL.

**Syntax 2: Cursor declared with a prepared statement.**

```sql
DECLARE cid [SCROLL] CURSOR [WITH HOLD] FOR sid
```

1. `cid` is the identifier of the database cursor.
2. `sid` is the identifier of a prepared SQL statement.

**Syntax 3: Cursor declared with a string expression.**

```sql
DECLARE cid [SCROLL] CURSOR [WITH HOLD] FROM expr
```

1. `cid` is the identifier of the database cursor.
2. `expr` is any expression that evaluates to a string.

Syntax 4: Cursor declared with an SQL Block.

```
DECLARE cid [SCROLL] CURSOR [WITH HOLD] FOR SQL sql-statement END SQL
```

1. `cid` is the identifier of the database cursor.
2. `sql-statement` is a statement defined in an SQL block.

**Usage**

The `DECLARE` instruction allocates resources for an SQL statement handle, in the context of the current connection. The SQL text is sent to the database server for parsing, validation and to generate the execution plan.

After declaring the cursor, you can use the `OPEN` instruction to execute the SQL statement and produce the result set. Rows can be fetched with the `FETCH` instruction or in a `FOREACH` loop.

`DECLARE` must precede any other statement that refers to the cursor during program execution.

The scope of reference of the `cid` cursor identifier is local to the module where it is declared.

Resources allocated by the `DECLARE` `cursor-name` can be released later by the `FREE` `cursor-name` instruction.

The static `select-statement` used in the `DECLARE` can contain program variables, or ? (question mark) parameter placeholders, that can be bound to program variables with the `USING` clause of the `OPEN` instruction.

**Important:** When using program variables in a static SQL statement of a `DECLARE CURSOR` instruction, make sure that these variables are available when executing the `OPEN` or `FOREACH` instruction. Otherwise, the behavior is unexpected and can make the runtime system crash. Do not mix ? SQL parameter placeholders with program variables: This would lead to a runtime error at `OPEN` or `FOREACH` time, because the number of SQL parameters will not match the number of variable provided in the `USING` clause. The `fglcomp -S` option extracts the static SQL statements showing ? placeholders instead of programs variables. This can help to check the actual number of SQL parameters in a static SQL statement.

The maximum number of declared cursors in a single program is limited by the database server and the available memory. Make sure that you free the resources when you no longer need the declared cursor.

When declaring a cursor with a static `select-statement`, the statement can include an `INTO` clause. However, to be consistent with prepared statements you better omit the `INTO` clause in the SQL text and use the `INTO` clause of the `FETCH` statement to retrieve the values from the result set.

You can add the `FOR UPDATE` clause in the `SELECT` statement to declare an update cursor. You can use the update cursor to modify (update or delete) the current row.

You should use the `WITH HOLD` option with care, because this feature is specific to IBM® Informix® servers. Other database servers do not behave as Informix® does with this type of cursor. For example, if the `SELECT` is not declared `FOR UPDATE`, most database servers keep cursors open after the end of a transaction, but IBM® DB2® automatically closes all cursors when the transaction is rolled back.

**Forward only cursors**

If you use only the `DECLARE CURSOR` keywords, you create a sequential cursor, which can fetch only the next row in sequence from the result set. The sequential cursor can read through the result set only once each time it is opened.

If you are using a sequential cursor for a select cursor, on each execution of the `FETCH` statement, the database server returns the contents of the current row and locates the next row in the result set.

Cursors can be declare with a static `SELECT` statement:

```
MAIN
  DATABASE stores
  DECLARE c1 CURSOR FOR SELECT * FROM customer
```
Cursors can also be declared with a SELECT statement defined in a character string:

```sql
MAIN
    DEFINE key INTEGER
    DEFINE cust RECORD
        num INTEGER,
        name CHAR(50)
    END RECORD
DATABASE stores
PREPARE s1
    FROM "SELECT customer_num, cust_name FROM customer WHERE customer_num>?
DECLARE c1 CURSOR FOR s1
LET key=101
FOREACH c1 USING key INTO cust.*
    DISPLAY cust.*
END FOREACH
END MAIN
```

**Scrollable cursors**

Use the `DECLARE SCROLL CURSOR` keywords to create a *scrollable cursor*, which can fetch rows of the result set in any sequence. Until the cursor is closed, the database server retains the result set of the cursor in a static data set (for example, in a temporary table like Informix®). You can fetch the first, last, or any intermediate rows of the result set as well as fetch rows repeatedly without having to close and reopen the cursor. On a multiuser system, the rows in the tables from which the result set rows were derived might change after the cursor is opened and a copy of the row is made in the static data set. If you use a scroll cursor within a transaction, you can prevent copied rows from changing, either by setting the isolation level to `REPEATABLE READ` or by locking the entire table in share mode during the transaction. Scrollable cursors cannot be declared `FOR UPDATE`.

With most database servers, scrollable cursors take quite a few resources to hold a static copy of the result set. Therefore you should consider optimizing scrollable cursor usage by fetching only the primary keys of rows, and execute a secondary `SELECT` statement to fetch other fields for each row that must be displayed.

The `DECLARE [SCROLL] CURSOR FROM` syntax allows you to declare a cursor directly with a string expression, so that you do not have to use the `PREPARE` instruction. This simplifies the source code and speeds up the execution time for non-Informix® databases, because the SQL statement is not parsed twice.

```sql
MAIN
    DEFINE key INTEGER
    DEFINE cust RECORD
        num INTEGER,
        name CHAR(50)
    END RECORD
DATABASE stores
DECLARE c1 SCROLL CURSOR
    FROM "SELECT customer_num, cust_name FROM customer WHERE customer_num>?
LET key=101
FOREACH c1 USING key INTO cust.*
    DISPLAY cust.*
END FOREACH
END MAIN
```

**Hold cursors**

Use the `WITH HOLD` option with Informix® databases to create a *hold cursor*. A hold cursor allows uninterrupted access to a set of rows across multiple transactions. Ordinarily, all cursors close at the end of a transaction. A hold
cursor does not close; it remains open after a transaction ends. A hold cursor can be either a sequential cursor or a scrollable cursor. Hold cursors are only supported by Informix® database engines.

You can use the ? question mark place holders with prepared or static SQL statements, and provide the parameters at execution time with the USING clause of the OPEN or FOREACH instructions.

```
MAIN
  DEFINE key INTEGER
  DEFINE cust RECORD
    num INTEGER,
    name CHAR(50)
  END RECORD
DATABASE stores
DECLARE c1 CURSOR WITH HOLD
  FOR SELECT customer_num, cust_name FROM customer WHERE customer_num > ?
LET key=101
FOREACH c1 USING key INTO cust.*
  BEGIN WORK
    UPDATE cust2 SET name=cust.cust_name WHERE num=cust.num
  COMMIT WORK
END FOREACH
END MAIN
```

**Related concepts**

**CLOSE (result set cursor)** on page 669
Closes a database cursor and frees resources allocated on the database server for the result set.

**FREE (result set cursor)** on page 670
Releases SQL cursor resources allocated by the DECLARE instruction.

**OPEN (result set cursor)**
Executes the SQL statement with result set associated with the specified database cursor

**Syntax**

```
OPEN cid
  USING pvar |IN|OUT|INOUT| [, ... ] |
  WITH REOPTIMIZATION |
```

1. `cid` is the identifier of the database cursor.
2. `pvar` is a variable containing an input value for an SQL parameter.

**Usage:**
The OPEN instruction executes the SQL statement of a declared cursor. The result set is produced on the server side and rows can be fetched.

The USING clause is required to provide the SQL parameters as program variables, if the cursor was declared with a prepared statement that includes (?) question mark placeholders.

A subsequent OPEN statement closes the cursor and then reopens it. When the database server reopens the cursor, it creates a new result set, based on the current values of the variables in the USING clause. If the variables have changed since the previous OPEN statement, reopening the cursor can generate an entirely different result set.

The IN, OUT or INOUT options can be used to call stored procedures having input / output parameters and generating a result set. Use the IN, OUT or INOUT options to indicate if a parameter is respectively for input, output or both.

Sometimes, query execution plans need to be re-optimized when SQL parameter values change. Use the WITH REOPTIMIZATION clause to indicate that the query execution plan has to be re-optimized on the database server (this operation is normally done during the DECLARE instruction). If this option is not supported by the database server, it is ignored.
In an IBM® Informix® database that is ANSI-compliant, you receive an error code if you try to open a cursor that is already open. **Informix® only!**

A cursor is closed with the `CLOSE` instruction, or when the parent connection is terminated (typically, when the program ends). By using the `CLOSE` instruction explicitly, you release resources allocated for the result set in the db client library and on the database server.

The database server evaluates the values that are named in the `USING` clause of the `OPEN` statement only when it opens the cursor. While the cursor is open, subsequent changes to program variables in the `OPEN` clause do not change the result set of the cursor; you must re-open the cursor to re-execute the statement.

If you release cursor resources with a `FREE` instruction, you cannot use the cursor unless you declare the cursor again.

The `IN`, `OUT` or `INOUT` options can only be used for simple variables, you cannot specify those options for a complete record with the record.* notation.

**Example**

```sql
MAIN
    DEFINE k INTEGER
    DEFINE n VARCHAR(50)
    DATABASE stores
    DECLARE c1 CURSOR FROM "SELECT cust_name FROM customer WHERE cust_id > ?"
    LET k = 102
    OPEN c1 USING k
    FETCH c1 INTO n
    LET k = 103
    OPEN c1 USING k
    FETCH c1 INTO n
END MAIN
```

**Related concepts**

- **DECLARE (result set cursor)** on page 663
  Associates a database cursor with an SQL statement producing a result set.

- **FETCH (result set cursor)** on page 667
  Moves a cursor to a new row in the corresponding result set and retrieves the row values into fetch buffers.

- **CLOSE (result set cursor)** on page 669
  Closes a database cursor and frees resources allocated on the database server for the result set.

- **FREE (result set cursor)** on page 670
  Releases SQL cursor resources allocated by the `DECLARE` instruction.

- **FOREACH (result set cursor)** on page 670
  Processes a series of data rows returned from a database cursor.

- **Database transactions** on page 631
  Database transaction concepts and handling.

**FETCH (result set cursor)**

Moves a cursor to a new row in the corresponding result set and retrieves the row values into fetch buffers.

**Syntax**

```sql
FETCH [ direction ] cid
    INTO fvar [, ... ]
```

where `direction` is one of:

```sql
NEXT
PREVIOUS
PRIOR
```
1. cid is the identifier of the database cursor.
2. fvar is a variable used as fetch buffer.
3. direction options different from NEXT can only be used with scrollable cursors.
4. position is an positive integer expression.
5. offset is a positive or negative integer expression.

Usage

The FETCH instruction retrieves a row from a result set of an opened cursor. The cursor must be opened before using the FETCH instruction.

The INTO clause can be used to provide the fetch buffers that receive the result set column values.

A sequential cursor can fetch only the next row in sequence from the result set.

The NEXT clause (the default) retrieves the next row in the result set. If the row pointer was on the last row before executing the instruction, the SQL code is set to 100 (NOTFOUND), and the row pointer remains on the last row. (if you issue a FETCH PREVIOUS at this time, you get the next-to-last row).

The PREVIOUS clause retrieves the previous row in the result set. If the row pointer was on the first row before executing the instruction, the SQL code is set to 100 (NOTFOUND), and the row pointer remains on the first row. (if you issue a FETCH NEXT at this time, you get the second row).

The CURRENT clause retrieves the current row in the result set.

The FIRST clause retrieves the first row in the result set.

The LAST clause retrieves the last row in the result set.

The ABSOLUTE clause retrieves the row at position in the result set. If the position is not correct, the SQL code is set to 100 (NOTFOUND). Absolute row positions are numbered from 1.

The RELATIVE clause moves offset rows in the result set and returns the row at the current position. The offset can be a negative value. If the offset is not correct, the SQL code is set to 100 (NOTFOUND). If offset is zero, the current row is fetched.

Fetching rows can have specific behavior when the cursor was declared FOR UPDATE to perform a positioned update or delete.

Example

```main
DEFINE cust_rec RECORD
   cnum INTEGER,
   cname CHAR(20)
END RECORD
DATABASE stores
DECLARE c1 SCROLL CURSOR FOR SELECT customer_num, cust_name FROM customer
OPEN c1
FETCH c1 INTO cust_rec.*
FETCH LAST c1 INTO cust_rec.*
FETCH PREVIOUS c1 INTO cust_rec.*
FETCH FIRST c1 INTO cust_rec.*
FETCH LAST c1 -- INTO clause is optional
FETCH FIRST c1 -- INTO clause is optional
```
Related concepts

**FETCH (result set cursor)** on page 667
Moves a cursor to a new row in the corresponding result set and retrieves the row values into fetch buffers.

**CLOSE (result set cursor)** on page 669
Closes a database cursor and frees resources allocated on the database server for the result set.

**FREE (result set cursor)** on page 670
Releases SQL cursor resources allocated by the `DECLARE` instruction.

**FOREACH (result set cursor)** on page 670
Processes a series of data rows returned from a database cursor.

**SQL execution diagnostics** on page 529
If an SQL statement execution fails, error description can be found in the `SQLCA.SQLCODE`, `SQLSTATE`, `STATUS` and `SQLERRMESSAGE` predefined registers.

**Positioned updates/deletes** on page 672
Describes row modification based on a FOR UPDATE cursor.

**Database transactions** on page 631
Database transaction concepts and handling.

**NOTFOUND** on page 504
`NOTFOUND` is a predefined constant used to check if an SQL statement returns rows.

---

## CLOSE (result set cursor)

Closes a database cursor and frees resources allocated on the database server for the result set.

**Syntax**

```
CLOSE cid
```

1. `cid` is the identifier of the database cursor.

**Usage**

The `CLOSE` instruction releases the resources allocated for the result set on the database server.

After using the `CLOSE` instruction, you must reopen the cursor with `OPEN` before retrieving values with `FETCH`.

It is recommended that you close the cursor when the result set is no longer used, this saves resources on the database client and database server side.

**Example**

```
MAIN
   DATABASE stores
   DECLARE c1 CURSOR FOR SELECT * FROM customer
   OPEN c1
   CLOSE c1
   OPEN c1
   CLOSE c1
END MAIN
```

**Related concepts**

**FETCH (result set cursor)** on page 667
Moves a cursor to a new row in the corresponding result set and retrieves the row values into fetch buffers.

**FREE (result set cursor)** on page 670
Releases SQL cursor resources allocated by the DECLARE instruction.

**FREE (result set cursor)**
Releases SQL cursor resources allocated by the DECLARE instruction.

**Syntax**

```sql
FREE cid
```

1. `cid` is the identifier of the database cursor.

**Usage**
The FREE instruction takes the name of a cursor as parameter.
All resources allocated to the database cursor are released.
If not done, the cursor is automatically closed when doing a FREE.
When cursor resources are released with FREE, the cursor must be declared again before usage.
Free the cursor when the result set is no longer used by the program; this saves resources on the database client and database server side.

**Example**

```sql
MAIN
  DEFINE i, j INTEGER
  DATABASE stores
  FOR i=1 TO 10
    DECLARE c1 CURSOR FOR SELECT * FROM customer
    FOR j=1 TO 10
      OPEN c1
      FETCH c1
      CLOSE c1
    END FOR
    FREE c1
  END FOR
END MAIN
```

**Related concepts**
- **CLOSE (result set cursor)** on page 669
  Closes a database cursor and frees resources allocated on the database server for the result set.
- **DECLARE (result set cursor)** on page 663
  Associates a database cursor with an SQL statement producing a result set.

**FOREACH (result set cursor)**
Processes a series of data rows returned from a database cursor.

**Syntax**

```sql
FOREACH cid
  ↓ USING pvar [IN|OUT|INOUT] [,....] ↓
  ↓ WITH REOPTIMIZATION ↓
  ↓ INTO fvar [,....] ↓
  ↓ statement
  ↓ CONTINUE FOREACH
  ↓ EXIT FOREACH
```

```sql
```
1. *cid* is the identifier of the database cursor.
2. *pvar* is a variable containing an input value for an SQL parameter.
3. *fvar* is a variable used as fetch buffer.

**Usage**

Use the FOREACH instruction to retrieve and process database rows that were selected by a query. This instruction is equivalent to using the OPEN, FETCH and CLOSE cursor instructions:

1. Open the specified cursor
2. Fetch the rows selected
3. Close the cursor (after the last row has been fetched)

You must declare the cursor (by using the DECLARE instruction) before the FOREACH instruction can retrieve the rows. A compile-time error occurs unless the cursor was declared prior to this point in the source module. You can reference a sequential cursor, a scroll cursor, a hold cursor, or an update cursor, but FOREACH only processes rows in sequential order.

The FOREACH statement performs successive fetches until all rows specified by the SELECT statement are retrieved. Then the cursor is automatically closed. It is also closed if a WHENEVER NOT FOUND exception handler within the FOREACH loop detects a NOTFOUND condition.

After a FOREACH loop, STATUS and SQLCA.SQLCODE will not be set to NOTFOUND/100 if no rows are returned by the query: If no error occurred, these registers will hold the value zero.

The USING clause is required to provide the SQL parameter buffers, if the cursor was declared with a prepared statement that includes (?) question mark placeholders.

The IN, OUT or INOUT options can be used to call stored procedures having input / output parameters and generating a result set. Use the IN, OUT, or INOUT options to indicate if a parameter is respectively for input, output, or both.

The INTO clause can be used to provide the fetch buffers that receive the row values.

Use the WITH REOPTIMIZATION clause to indicate that the query execution plan has to be re-optimized.

The CONTINUE FOREACH instruction interrupts processing of the current row and starts processing the next row. The runtime system fetches the next row and resumes processing at the first statement in the block.

The EXIT FOREACH instruction interrupts processing and ignores the remaining rows of the result set.

The IN, OUT, or INOUT options can only be used for simple variables; you cannot specify those options for a complete record with the record.* notation.

**Example**

```main
MAIN
  DEFINE clist ARRAY[200] OF RECORD
cnum INTEGER,
cname CHAR(50)
END RECORD
DEFINE i INTEGER
DATABASE stores
DECLARE c1 CURSOR FOR SELECT customer_num, cust_name FROM customer
LET i=0
FOREACH c1 INTO clist[i+1].*
  LET i=i+1
  DISPLAY clist[i].*
END FOREACH
DISPLAY "Number of rows found: ", i
END MAIN
```

If an SQL statement execution fails, error description can be found in the SQLCA, SQLCODE, SQLSTATE, STATUS and SQLERRMESSAGe predefined registers.

Positioned updates/deletes

Describes row modification based on a FOR UPDATE cursor.

- Understanding positioned update or delete on page 672
- DECLARE (SELECT ... FOR UPDATE) on page 674
- UPDATE ... WHERE CURRENT OF on page 674
- DELETE ... WHERE CURRENT OF on page 675
- Examples on page 676

Understanding positioned update or delete

This is an introduction to SQL positioned UPDATE/DELETE.

When declaring a database cursor with a SELECT statement using a unique table and ending with the FOR UPDATE keywords, you can modify the current row pointed by the FOR UPDATE cursor with UPDATE ... WHERE CURRENT OF, or the current row with DELETE ... WHERE CURRENT OF statements. Such an operation is called positioned update or positioned delete.

Do not confuse positioned update with the use of SELECT FOR UPDATE statements that are not associated with a database cursor. Executing SELECT FOR UPDATE statements is supported by the language, but you cannot perform positioned updates since there is no cursor identifier associated with the result set.

Note: Some database servers do not support hold cursors (WITH HOLD) declared with a SELECT statement including the FOR UPDATE keywords. The SQL standards require for update cursors to be automatically closed at the end of a transaction. Therefore, it is strongly recommended that you use positioned updates in a transaction block.

To perform a positioned update or delete, perform a DECLARE instruction with a SELECT FOR UPDATE statement.

![Figure 28: SELECT FOR UPDATE statement](image)

Then, start a transaction, OPEN the cursor and FETCH a row.
Then, **UPDATE** or **DELETE** the current row with the **WHERE CURRENT OF** clause, before ending the transaction.

**Figure 30: Delete the row**

**Related concepts**

- **Result set processing** on page 661
  Shows how to fetch rows from a database query.

- **Database transactions** on page 631
  Database transaction concepts and handling.

- **Example 1: Positioned UPDATE statement** on page 676
DECLARE (SELECT ... FOR UPDATE)

Associate a database cursor with a SELECT statement to perform positioned updates and deletes

**Syntax**

```sql
DECLARE cid \[SCROLL\] CURSOR \[WITH HOLD\]
   FOR \select-statement \[ sid \]
```

1. `cid` is the identifier of the database cursor.
2. `select-statement` is a SELECT statement defined in static SQL, with the FOR UPDATE keywords.
3. `sid` is the identifier of a prepared SELECT statement including the FOR UPDATE keywords.

**Usage**

DECLARE ... FOR UPDATE will define a cursor that can be used to do positioned updates and deletes with the WHERE CURRENT OF clause.

DECLARE must precede any other statement that refers to the cursor during program execution.

To perform positioned updates, the `select-statement` must include the FOR UPDATE keywords.

The scope of reference of the `cid` cursor identifier is local to the module where it is declared. Therefore, you must execute the DECLARE, UPDATE or DELETE instructions in the same module.

The static `select-statement` used in the DECLARE can contain ? (question mark) parameter placeholders, that can be bound to program variables with the USING clause of the OPEN instruction.

Use the WITH HOLD option carefully, because this feature is specific to IBM® Informix® servers. Other database servers do not behave as Informix® does with such cursors. For example, if the SELECT is not declared FOR UPDATE, most database servers keep cursors open after the end of a transaction, but IBM® DB2® automatically closes all cursors when the transaction is rolled back.

**Related concepts**

- [Result set processing](#) on page 661
  Shows how to fetch rows from a database query.
- [Database transactions](#) on page 631
  Database transaction concepts and handling.
- [SELECT](#) on page 645
  Produces a result set from a query on database tables.
- [Dynamic SQL management](#) on page 654
  Explains how to execute and manage SQL statements at runtime.
- [UPDATE ... WHERE CURRENT OF](#) on page 674
  Updates the current row in a result set of a database cursor declared for update.
- [DELETE ... WHERE CURRENT OF](#) on page 675
  Deletes the current row in a result set of a database cursor declared for update.

**UPDATE ... WHERE CURRENT OF**

Updates the current row in a result set of a database cursor declared for update.

**Syntax**

```sql
UPDATE table-specification
SET
   column = \variable \sql-expression \[,...]
WHERE CURRENT OF cid
```
1. `table-specification` identifies the target table (see UPDATE for more details).
2. `column` is a name of a table column.
3. `variable` is a program variable, a record member or an array member used as a parameter buffer to provide values.
4. `sql-expression` is an expression supported by the database server, this can be a literal or NULL for example.
5. `cid` is the identifier of the database cursor declared for update.

**Usage**

Use `UPDATE ... WHERE CURRENT OF` to modify the values of the row currently pointed by the associated FOR UPDATE cursor.

The `UPDATE` statement does not advance the cursor to the next row, so the current row position remains unchanged.

The scope of reference of the `cid` cursor identifier is local to the module where it is declared. Therefore, you must execute the DECLARE, UPDATE or DELETE instructions in the same module.

There must be a current row in the result set. Make sure that the SQL status returned by the last FETCH is equal to zero.

If the DECLARE statement that created the cursor specified one or more columns in the FOR UPDATE clause, you are restricted to updating only those columns in a subsequent `UPDATE ... WHERE CURRENT OF` statement.

**Related concepts**

DECLARE (SELECT ... FOR UPDATE) on page 674
Associate a database cursor with a SELECT statement to perform positioned updates and deletes

FETCH (result set cursor) on page 667
Moves a cursor to a new row in the corresponding result set and retrieves the row values into fetch buffers.

Database transactions on page 631
Database transaction concepts and handling.

DELETE ... WHERE CURRENT OF on page 675
Deletes the current row in a result set of a database cursor declared for update.

Example 1: Positioned UPDATE statement on page 676

**DELETE ... WHERE CURRENT OF**

Deletes the current row in a result set of a database cursor declared for update.

**Syntax**

```
DELETE FROM table-specification
WHERE CURRENT OF cid
```

1. `table-specification` identifies the target table
2. `cid` is the identifier of the database cursor declared for update.

**Usage**

Use `DELETE ... WHERE CURRENT OF` to remove the row currently pointed by the associated FOR UPDATE cursor.

After the deletion, no current row exists; you cannot use the cursor to delete or update a row until you reposition the cursor with a FETCH statement.

The scope of reference of the `cid` cursor identifier is local to the module where it is declared. Therefore, you must execute the DECLARE, UPDATE or DELETE instructions in the same module.

There must be a current row in the result set. Make sure that the SQL status returned by the last FETCH is equal to zero.

UPDATE ... WHERE CURRENT OF on page 674
Updates the current row in a result set of a database cursor declared for update.

Examples

WHERE CURRENT OF usage examples.

Example 1: Positioned UPDATE statement

```sql
MAIN
  DEFINE pname CHAR(30)
  DATABASE stock
  DECLARE uc CURSOR FOR
    SELECT name FROM item WHERE key=123 FOR UPDATE
  BEGIN WORK
    OPEN uc
    FETCH uc INTO pname
    IF sqlca.sqlcode=0 THEN
      LET pname = "Dummy"
      UPDATE item SET name=pname WHERE CURRENT OF uc
    END IF
    COMMIT WORK
    FREE uc
  END MAIN
```

SQL insert cursors

Explains how to insert a log of rows into a table efficiently.

- Understanding SQL insert cursors on page 676
- DECLARE (insert cursor) on page 679
- OPEN (insert cursor) on page 680
- PUT (insert cursor) on page 680
- FLUSH (insert cursor) on page 681
- CLOSE (insert cursor) on page 681
- FREE (insert cursor) on page 682
- Examples on page 682

Understanding SQL insert cursors

This is an introduction to SQL insert cursors.

An insert cursor is a database cursor declared with a restricted form of the INSERT statement, designed to perform buffered row insertion in database tables.

The insert cursor simply inserts rows of data; it cannot be used to fetch data. When an insert cursor is opened, a buffer is created in memory to hold a block of rows. The buffer receives rows of data as the program executes PUT statements. The rows are written to disk only when the buffer is full. You can use the CLOSE, FLUSH, or COMMIT
WORK statement to flush the buffer when it is less than full. You must close an insert cursor to insert any buffered rows into the database before the program ends. You can lose data if you do not close the cursor properly.

When the database server supports buffered inserts, an insert cursor increases processing efficiency (compared with embedding the INSERT statement directly). This process reduces communication between the program and the database server and also increases the speed of the insertions.

Before using the insert cursor, you must declare it with the DECLARE instruction using an INSERT statement.

**Figure 31: Declaring a cursor**

Once declared, you can open the insert cursor with the OPEN instruction. This instruction prepares the insert buffer. When the insert cursor is opened, you can add rows to the insert buffer with the PUT statement.

**Figure 32: OPEN and PUT statements**

Rows are automatically added to the database table when the insert buffer is full. To force row insertion in the table, you can use the FLUSH instruction.
Finally, when all rows are added, you can `CLOSE` the cursor and if you no longer need it, you can deallocate resources with the `FREE` instruction.

By default, insert cursors must be opened inside a transaction block, with `BEGIN WORK` and `COMMIT WORK`, and they are automatically closed at the end of the transaction. If needed, you can declare insert cursors with the `WITH HOLD` clause, to allow uninterrupted row insertion across multiple transactions.

**Related concepts**

Database transactions on page 631
Database transaction concepts and handling.

**DECLARE (insert cursor)**

The `DECLARE` with an `INSERT` instruction defines an insert cursor.

**Syntax**

```
DECLARE cid CURSOR [WITH HOLD] FOR { insert-statement | sid }
```

1. `cid` is the identifier of the insert cursor.
2. `insert-statement` is an `INSERT` statement defined in static SQL.
3. `sid` is the identifier of a prepared `INSERT` statement.

**Usage**

Use the `DECLARE` instruction with an `INSERT` instruction to define a new insert cursor in the current database session.

The `INSERT` statement is parsed, validated and the execution plan is created.

`DECLARE` must precede any other statement that refers to the cursor during program execution.

The scope of reference of the `cid` cursor identifier is local to the module where it is declared.

The static `insert-statement` statement can include a list of variables in the `VALUES` clause. These variables are automatically read by the `PUT` statement; you do not have to provide the list of variables in that statement. As an alternative, use the `?` (question mark) SQL parameter placeholder in the `VALUE` clause to bind program variables provided in the `FROM` clause of the `PUT` instruction.

When declaring a cursor with a prepared `sid` statement, the statement can include `?` (question mark) placeholders for SQL parameters. In this case you must provide a list of variables in the `FROM` clause of the `PUT` statement.

Use the `WITH HOLD` option to declare cursors that have uninterrupted inserts across multiple transactions.

Resources allocated by the `DECLARE` can be released later by the `FREE` instruction.

The number of declared cursors in a single program is limited by the database server and the available memory. Make sure that you free the resources when you no longer need the declared insert cursor.

The identifier of a cursor that was declared in one module cannot be referenced from another module.

**Related concepts**

- **FREE (result set cursor)** on page 670
  Releases SQL cursor resources allocated by the `DECLARE` instruction.
- **OPEN (insert cursor)** on page 680
  Initializes an insert cursor.
- **Variables** on page 366
  Explains how to define program variables.
- **Dynamic SQL management** on page 654
  Explains how to execute and manage SQL statements at runtime.
- **INSERT** on page 641
OPEN (insert cursor)

Initializes an insert cursor.

Syntax

```
OPEN cid
```

1. `cid` is the identifier of the insert cursor.

Usage

The `OPEN` statement initializes the insert cursor if the specified cursor was declared with an `INSERT` statement. Once the insert cursor is opened, you can add rows with the `PUT` statement.

When used with an insert cursor, the `OPEN` instruction cannot include a `USING` clause.

A subsequent `OPEN` statement closes the cursor and then reopens it.

If the insert cursor was not declared with `WITH HOLD` option, the `OPEN` instruction generates an SQL error if there is no current transaction started.

If you release cursor resources with a `FREE` instruction, you cannot use the cursor unless you declare the cursor again.

Related concepts
FREE (result set cursor) on page 670
Releases SQL cursor resources allocated by the `DECLARE` instruction.

DECLARE (insert cursor) on page 679
The `DECLARE` with an `INSERT` instruction defines an insert cursor.

Variables on page 366
Explains how to define program variables.

Database transactions on page 631
Database transaction concepts and handling.

PUT (insert cursor)

Adds a new row to the insert cursor buffer.

Syntax

```
PUT cid FROM pvar [, ...]
```

1. `cid` is the identifier of the insert cursor.
2. `pvar` is a variable containing an input value for the new row.

Usage

The `PUT` instruction adds a row to the insert cursor buffer.

If the insert cursor was not declared with `WITH HOLD` option, the `PUT` instruction generates an SQL error if there is no current transaction started.

If the insert buffer has no room for the new row when the statement executes, the buffered rows are written to the database in a block, and the buffer is emptied. As a result, some `PUT` statement executions cause rows to be written to the database, and some do not.
Related concepts
OPEN (insert cursor) on page 680
Initializes an insert cursor.
FLUSH (insert cursor) on page 681
Flushes the buffer of an insert cursor.
Variables on page 366
Explains how to define program variables.
Database transactions on page 631
Database transaction concepts and handling.

FLUSH (insert cursor)
Flushes the buffer of an insert cursor.

Syntax

```sql
FLUSH cid
```

1. `cid` is the identifier of the insert cursor.

Usage

When flushing an insert cursor, all buffered rows are inserted into the target database table and the insert buffer is cleared.

The insert buffer may be automatically flushed by the runtime system if there no room when a new row is added with the `PUT` instruction.

Related concepts
PUT (insert cursor) on page 680
Adds a new row to the insert cursor buffer.
OPEN (insert cursor) on page 680
Initializes an insert cursor.
Database transactions on page 631
Database transaction concepts and handling.

CLOSE (insert cursor)
Flushes and closes an insert cursor.

Syntax

```sql
CLOSE cid
```

1. `cid` is the identifier of the insert cursor.

Usage

If rows are present in the insert buffer, they are inserted into the target table.

Closing the insert cursor releases the resources allocated for the insert buffer on the database server.

After using the `CLOSE` instruction, you must reopen the cursor with `OPEN` before adding new rows with `PUT/FLUSH`.

Related concepts
FLUSH (insert cursor) on page 681
Flushes the buffer of an insert cursor.

**PUT (insert cursor) on page 680**  
Adds a new row to the insert cursor buffer.

**OPEN (insert cursor) on page 680**  
Initializes an insert cursor.

**Database transactions on page 631**  
Database transaction concepts and handling.

### FREE (insert cursor)
Releases resources allocated for an insert cursor.

**Syntax**

```
FREE cid
```

1. *cid* is the identifier of the insert cursor.

**Usage**

After executing the `FREE` statement, all resources allocated to the insert cursor are released.

It is recommended that the cursor be explicitly closed before it is freed.

If you release cursor resources with this instruction, you cannot use the cursor unless you declare the cursor again.

**Related concepts**

**CLOSE (insert cursor) on page 681**  
Flushes and closes an insert cursor.

**DECLARE (insert cursor) on page 679**  
The `DECLARE` with an `INSERT` instruction defines an insert cursor.

**Examples**

Insert cursor usage examples.

**Example 1: Insert Cursor declared with a Static INSERT**

```
MAIN
  DEFINE i INTEGER
  DEFINE rec RECORD
    key INTEGER,
    name CHAR(30)
  END RECORD
DATABASE stock
DECLARE ic CURSOR FOR
  INSERT INTO item VALUES (rec.*)
BEGIN WORK
  OPEN ic
  FOR i=1 TO 100
    LET rec.key = i
    LET rec.name = "Item #" || i
    PUT ic
    IF i MOD 50 = 0 THEN
      FLUSH ic
    END IF
  END FOR
  CLOSE ic
COMMIT WORK
FREE ic
```
Example 2: Insert Cursor declared with an SQL text

```sql
MAIN
  DEFINE i INTEGER
  DEFINE rec RECORD
    key INTEGER,
    name CHAR(30)
  END RECORD
  DATABASE stock
  DECLARE ic CURSOR FROM "INSERT INTO item VALUES (?,?)"
  BEGIN WORK
  OPEN ic
  FOR i=1 TO 100
    LET rec.key = i
    LET rec.name = "Item #" || i
    PUT ic FROM rec.*
    IF i MOD 50 = 0 THEN
      FLUSH ic
    END IF
  END FOR
  CLOSE ic
  COMMIT WORK
  FREE ic
END MAIN
```

Example 3: Insert Cursor declared with 'hold' option

```sql
MAIN
  DEFINE name CHAR(30)
  DATABASE stock
  DECLARE ic CURSOR WITH HOLD FOR
  INSERT INTO item VALUES (1,name)
  OPEN ic
  LET name = "Item 1"
  PUT ic
  BEGIN WORK
  UPDATE refs SET name="xyz" WHERE key=123
  COMMIT WORK
  PUT ic
  PUT ic
  FLUSH ic
  CLOSE ic
  FREE ic
END MAIN
```

**SQL LOAD and UNLOAD**

Describes the instructions to export/import information from/to a database.

- **LOAD** on page 684
- **UNLOAD** on page 687
LOAD

Inserts data from a file into an existing database table.

Syntax

```
LOAD FROM filename [ DELIMITER delimiter]
  { INSERT INTO table-specification [ ( column [, ...]) ]
    insert-string
  }
```

where `table-specification` is:

```
[dbname[@dbserver]:][owner.etable
```

1. `filename` is a string expression containing the name of the file the data is read from.
2. `delimiter` is the character used as the value delimiter.
3. The `INSERT` clause is a pseudo `INSERT` statement (without the `VALUES` clause), where you can specify the list of columns in parentheses.
4. `dbname` identifies the database name.
5. `dbserver` identifies the database server (INFORMIXSERVER).
6. `owner` identifies the owner of the table, with optional double quotes.
7. `table` is the name of the database table.
8. `column` is a name of a table column.
9. `insert-string` is a string expression containing the pseudo-`INSERT` statement.

Usage

The `LOAD` instruction reads serialized data from an input file and inserts new rows in a database table specified in the `INSERT` clause. A file created by the `UNLOAD` statement can be used as input for the `LOAD` statement if its values are compatible with the schema of `table`.

The `LOAD` statement must include a pseudo-`INSERT` statement (either directly or as text in a variable) to specify where to store the data. `LOAD` appends the new rows to the specified table, synonym, or view, but does not overwrite existing data. It cannot add a row that has the same key as an existing row.

Avoid use of the the `dbname`, `dbserver` and `owner` prefix of the table name for maximum SQL portability.

The number and the order of columns in the `INSERT` statement must match the values of the input file.

The `LOAD` instruction cannot be prepared with a `PREPARE` statement. However, `LOAD` can take a string literal as parameter, that allows to build the `INSERT` statement at runtime.

The variable or string following the `LOAD` FROM keywords must specify the name of a file of ASCII characters (or characters that are valid for the current locale) that holds the data values that are to be inserted.

Each set of data values in `filename` that represents a new row is called an input record. Each input record must contain the same number of delimited data values. If the `INSERT` clause has no list of columns, the sequence of values in each input record must match the columns of `table` in number and order. Each value must have the literal format of the column data type, or of a compatible data type.

If `LOAD` is executed within a transaction block (BEGIN WORK / COMMIT WORK), the rows inserted by the `LOAD` instruction are part of the transaction. With some database servers the insert rows remain locked until the COMMIT WORK or ROLLBACK WORK statement terminates the transaction. Consider locking the whole table to

If the database does not support transactions, a failing `LOAD` statement cannot remove any rows that were loaded before the failure occurred. You must manually remove the already loaded records from either the load file or from the receiving table, repair the erroneous records, and rerun `LOAD`.

If the database supports transactions, you can do the following actions:

- Run LOAD as a singleton transaction, so that any error causes the entire LOAD statement to be automatically rolled back.
- Run LOAD within an explicit BEGIN WORK / COMMIT WORK transaction block, so that a data error merely stops the LOAD statement in place with the transaction still open.

**Note:** When the LOAD instruction is not surrounded by BEGIN WORK and COMMIT WORK or ROLLBACK WORK instructions, terminating the transaction when LOAD is finished will automatically close cursors not defined WITH HOLD option. To keep cursors open, either use the WITH HOLD option in DECLARE CURSOR, or surround the DECLARE, OPEN and LOAD instruction with an explicit BEGIN WORK / COMMIT WORK.

A single character delimiter instructs LOAD to read data in the default format. When using "CSV" as delimiter specification, the LOAD instruction will read the data in CSV format. If the DELIMITER clause is not specified, the delimiter is defined by the DBDELMITER environment variable. If the DBDELMITER environment variable is not set, the default is a | pipe. The field delimiter can be a blank character. It cannot be backslash or any hexadecimal digit (0-9, A-F, a-f). If the delimiter specified in the LOAD command is NULL, the runtime system will use the default delimiter or DBDELMITER if the variable is defined.

At this time, data type description of the input file fields is implicit; in order to create the SQL parameter buffers to hold the field values for inserts, the LOAD instruction uses the current database connection to get the column data types of the target table. Those data types depend on the type of database server. For example, IBM® Informix® DATE columns do not store the same data as the Oracle® DATE data type. Therefore, be careful when using the LOAD/UNLOAD instructions; if the application connects to different kinds of database servers, it can result data conversion errors.

Pay attention to numeric (DECIMAL, MONEY) and date/time values (DATE, DATETIME): These must match the current format settings (DBFORMAT, DBDATE). As a general programming pattern, use simple INSERT statements to load default and configuration data into your database, in order to be independent from the numeric and date format settings.

### Default LOAD format

The next table describes the recommended representation for data values in the input file used by the LOAD instruction. Values must be serialized with a character string following the SQL data type of the receiving column of the table.

<table>
<thead>
<tr>
<th>Data type</th>
<th>Input Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR, VARCHAR, TEXT</td>
<td>Values can have more characters than the declared maximum length of the column, but any extra characters are ignored. A backslash () is required before any literal backslash or any literal delimeter character, and before any NEWLINE character anywhere in character value. Blank values can be represented as one or more blank characters between delimiters, but leading blanks must not precede other CHAR, VARCHAR, or TEXT values.</td>
</tr>
<tr>
<td>DATE</td>
<td>In the default locale, values must be in month/day/year format unless another format is specified by DBDATE environment variable. The day and month must be a 2-digit number, and the year must be a 4-digit number.</td>
</tr>
<tr>
<td>DATETIME</td>
<td>DATETIME values must be in the format: year-month-day hour:minute:second.fraction or a contiguous subset, without the DATETIME keyword or qualifiers. Time units outside the declared column precision can be omitted. The year must be a four-digit number; all other time units (except fraction) require two digits.</td>
</tr>
<tr>
<td>Data type</td>
<td>Input Format</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------</td>
</tr>
</tbody>
</table>
| INTERVAL | INTERVAL values must be formatted:  
  year-month  
  or  
  day hour:minute:second.fraction  
  or a contiguous subset thereof, without the INTERVAL keyword or qualifiers. Time units outside the declared column precision can be omitted. All time units (except year and fraction) require two digits. |
| DECIMAL, MONEY | Values must use the decimal separator defined by DBFORMAT/DBMONEY. For MONEY, values can include currency symbols, but these are not required. |
| BYTE | Values must be ASCII-hexadecimals; no leading or trailing blanks. |
| SERIAL, BIGSERIAL, SERIAL8 | Values can be represented as 0 to tell the database server to supply a new serial value. You can specify a literal integer greater than zero, but if the column has a unique index, an error results if this number duplicates an existing value. |

The NEWLINE character must terminate each input record in *filename*. Specify only values that the language can convert to the data type of the database column. For database columns of character data types, inserted values are truncated from the right if they exceed the declared length of the column.

NULL values of any data type must be represented by consecutive delimiters in the input file; you cannot include anything between the delimiter symbols.

The LOAD statement expects incoming data in the format specified by environment variables like DBFORMAT, DBMONEY, DBDATE, GL_DATE, and GL_DATETIME. The precedence of these format specifications is consistent with forms and reports. If there is an inconsistency, an error is reported and the LOAD is canceled.

The backslash symbol (\) serves as an escape character in the input file to indicate that the next character in a data value is a literal. The LOAD statement scans for backslash escaped elements to read special characters in the following contexts:
- The backslash character appears anywhere in the value.
- The delimiter character appears anywhere in the value.
- The NEWLINE character appears anywhere in a value.

**CSV LOAD format**

The CSV (comma separated values) format is similar to the default format when using a simple comma delimiter, with the following differences:
- Input values might be surrounded with " double quotes.
- If an input value contains a comma or a NEWLINE, it is not escaped be the value must be quoted in the file.
- Double-quote characters in input values are doubled and will be converted to a unique " character; the value must be quoted.
- Backslash characters are not escaped in the input file and are read as; the value must be quoted.
- Leading and trailing blanks are kept (no truncation).
- No ending delimiter is expected at the end of the input record.

**Example**

```sql
MAIN  
  DATABASE stores  
  BEGIN WORK  
  DELETE FROM items  
  LOAD FROM "items01.unl" INSERT INTO items
```
LOAD FROM "items02.unl" INSERT INTO items
   COMMIT WORK
END MAIN

Related concepts

UNLOAD on page 687
Copies data from the database tables into a file.

UNLOAD
Copies data from the database tables into a file.

Syntax

UNLOAD TO filename [ DELIMITER delimiter]
   select-statement
   select-string

1. filename is a string expression containing the name of the file the data is written to.
2. delimiter is the character used as the value delimiter.
3. select-statement is static SELECT statement.
4. select-string is string expression containing the SELECT statement.

Usage

The UNLOAD instruction serializes into a file the SQL data produced by a SELECT statement.

The UNLOAD command cannot be used in a PREPARE statement. However, the UNLOAD command accepts a string literal in place of a static SELECT statement:

UNLOAD TO file-name
   select-string

The filename after the TO keyword identifies an output file in which to store the rows retrieved from the database by the SELECT statement. In the default (U.S. English) locale, this file contains only ASCII characters. (In other locales, output from UNLOAD can contain characters from the codeset of the locale.)

The UNLOAD statement must include a SELECT statement (directly, or in a variable) to specify what rows to copy into filename. UNLOAD does not delete the copied data.

A single character delimiter instruct UNLOAD to write data in the default format. When using "CSV" as delimiter specification, the UNLOAD instruction will write the data in CSV format. If the DELIMITER clause is not specified, the delimiter is defined by the DBDELIMITER environment variable. If the DBDELIMITER environment variable is not set, the default is a | pipe. The field delimiter can be a blank character. It cannot be backslash or any hexadecimal digit (0-9, A-F, a-f). If the delimiter specified in the UNLOAD command is NULL, the runtime system will use the default delimiter or DBDELIMITER if the variable is defined.

When using a select-string, do not attempt to substitute question marks (?) in place of host variables to make the SELECT statement dynamic, because this usage has binding problems.

At this time, data type description of the output file fields is implicit; in order to create the fetch buffers to hold the column values, the UNLOAD instruction uses the current database connection to get the column data types of the generated result set. Those data types depend on the type of database server. For example, IBM® Informix® INTEGER columns are integers of 4 bytes, while the Oracle INTEGER data type is actually a NUMBER(10, 0) type. Therefore, be aware when using this instruction that if your application connects to different kinds of database servers, you may get data conversion errors.
Default UNLOAD format

A set of values in the output representing a row from the database is called an output record. A NEWLINE character (ASCII 10) terminates each output record.

The UNLOAD statement represents each value in the output file as a character string based on the current locale, depending on the data type of the database column:

Table 176: Default UNLOAD format

<table>
<thead>
<tr>
<th>Data type</th>
<th>Output Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR, VARCHAR, TEXT</td>
<td>Trailing blanks are dropped from CHAR and TEXT (but not from VARCHAR) values. A \ character is inserted before any literal \ character or delimiter character and before a NEWLINE character in a character value.</td>
</tr>
<tr>
<td>DECIMAL, FLOAT, INTEGER,</td>
<td>Values are written as literals with no leading blanks. MONEY values are represented with no leading currency symbol. Zero values are represented as 0 for INTEGER or SMALLINT columns, and as 0.00 for FLOAT, SMALLFLOAT, DECIMAL, and MONEY columns.</td>
</tr>
<tr>
<td>MONEY, SMALLFLOAT, SMALLINT</td>
<td>DATE Values are written in the format month/day/year unless some other format is specified by the DBDATE environment variable.</td>
</tr>
<tr>
<td>DATETIME</td>
<td>DATETIME values are formatted year-month-day hour:minute:second.fraction or a contiguous subset, without DATETIME keyword or qualifiers. Time units outside the declared precision of the database column are omitted.</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>INTERVAL values are formatted year-month or day hour:minute:second.fraction or a contiguous subset, without INTERVAL keyword or qualifiers. Time units outside the declared precision of the database column are omitted.</td>
</tr>
<tr>
<td>BYTE</td>
<td>BYTE Values are written in ASCII hexadecimal form, without any added blank or NEWLINE characters. The logical record length of an output file that contains BYTE values can be very long, and thus might be very difficult to print or to edit.</td>
</tr>
</tbody>
</table>

NULL values of any data type are represented by consecutive delimiters in the output file, without any characters between the delimiter symbols.

The backslash symbol (\) serves as an escape character in the output file to indicate that the next character in a data value is a literal. The UNLOAD statement automatically inserts a preceding backslash to prevent literal characters from being interpreted as special characters in the following contexts:

- The backslash character appears anywhere in the value.
- The delimiter character appears anywhere in the value.
- The NEWLINE character appears anywhere in a value.

CSV UNLOAD format

The CSV (comma separated values) format is similar to the standard format when using a simple comma delimiter, with the following differences:

- A comma character generates a quoted output value, and the comma is written as is (not escaped).
• A “double-quote character generate quoted output value and the quote in the value is doubled.
• NEWLINE characters generate a quoted output value, and the NEWLINE is written as is (not escaped).
• Backslash characters are written as is in the output value (i.e. not escaped).
• Leading and trailing blanks are not truncated in the output value.
• No ending delimiter is written at the end of the output record.

Example

```plaintext
MAIN
    DEFINE var INTEGER
    DATABASE stores
    LET var = 123
    UNLOAD TO "items.unl"
        SELECT * FROM items WHERE item_num > var
    END MAIN
```

SQL database guides

This section includes the SQL guides for various supported database servers.

The SQL guides provide you with information about installation and configuration requirements, as well as details on what is and is not supported when using database-specific SQL.

Note: The SQL adaptation guides focus specific features of the target database. Read first the General SQL programming topics, which cover good practices in database programming with Genero BDL.

• IBM Informix Dynamic Server on page 689
• IBM DB2 Linux-Unix-Windows on page 701
• IBM Netezza on page 741
• Microsoft SQL Server on page 769
• Oracle MySQL / MariaDB on page 811
• Oracle Database on page 839
• PostgreSQL on page 887
• SQLite on page 922
• SAP ASE on page 945
• SAP HANA on page 978

IBM® Informix® Dynamic Server

For supported versions, see Supported IBM Informix server and CSDK versions on page 690

Purpose of the Informix® SQL guide

This section contains information to configure your Genero runtime system to work with an Informix® database engine, and describes the IBM® Informix® SQL features that are not supported (or partially supported) by Genero BDL.
Understand that Genero BDL was designed to work with IBM® Informix® databases, so most of the IBM® Informix® SQL features are supported. However, new features implemented in recent server versions need modifications in the Genero BDL compilers and runtime system to be supported.

Some topics show an enhancement reference note with a number, identifying the request id as filed in our internal "TODO" database. If the SQL feature is mission critical for your application, contact the support center and mention the enhancement identifier.

**Installation (Runtime Configuration)**

ODI adaptation guide Installation topics.

**Supported IBM® Informix® server and CSDK versions**

**Supported versions**

Genero BDL is certified with all IBM® Informix® servers from version 5.x to the last available version, including the Standard Engine, On-Line and IDS server families, as long as the IBM® Informix® Client SDK is compatible with the server.

Genero BDL is certified with IBM® Informix® CSDK version 3.70 or higher.

**Install IBM® Informix® and create a database - database configuration/design tasks**

1. Install the IBM® Informix® database software (IDS for example) on your database server.
2. Install the IBM® Informix® Software Development Kit (SDK) on your application server.
   With some IBM® Informix® distributions (IDS 11), this package is included in the server bundle. It is recommended that you check the IBM® web site for SDK upgrades or patches. Genero BDL is certified with IBM® Informix® SDK version 3.70 or higher.
3. Setup the IDS server (onconfig file, etc)
   a) Starting with IDS version 11, the TEMPTAB_NOLOG is set to 1 by default.
      Consider setting the TEMPTAB_NOLOG parameter to 0, if you want to log temporary table changes. This can affect the behavior of programs expecting that a ROLLBACK WORK cancels changes done on a temporary table.
   b) Starting with IDS version 11, by default the precision of SQL statement timing is the second (USEOSTIME is 0). For example, CURRENT HOUR TO FRACTION(3) returns a fraction part of zero.
      If sub-second precision is required, set the USEOSTIME configuration parameter to 1.
4. Define a database user dedicated to your application: the application administrator.
   This user will manage the database schema of the application (all tables will be owned by this user). With IBM® Informix®, database users reference Operating System users, and must be part of the IBM® Informix® group. See IBM® Informix® documentation.
5. Connect to the server as IBM® Informix® user (for example with the dbaccess tool) and give all requested database administrator privileges to the application administrator.

   GRANT CONNECT TO appadmin;
   GRANT RESOURCE TO appadmin;
   GRANT DBA TO appadmin;

6. Define the database locale before creating the database.
   According to the language(s) supported in your application, consider using UTF-8 locale by setting the Informix® environment variables defining the locale for the database server and data: CLIENT_LOCALE, DB_LOCALE, SERVER_LOCALE.
7. Connect as application administrator and create an IBM® Informix® database entity, for example with the following SQL statement:

   CREATE DATABASE dbname WITH BUFFERED LOG;
8. Create the application tables.
Prepare the runtime environment - connecting to the database

1. In order to connect to IBM® Informix®, you must have a database driver "dbmifx" in FGLDIR/dbdrivers.
2. Make sure the IBM® Informix® client environment variables are properly set.
   Check for example INFORMIXDIR (the path to the installation directory), INFORMIXSERVER (the name of the server defined in the sqlhosts list), etc. For more details, see the IBM® Informix® documentation.
3. In order to connect to an IBM® Informix® server, you must define a line in the $INFORMIXDIR/etc/sqlhosts file, referencing the server name specified in the INFORMIXSERVER environment variable. On Windows® platforms, the sqlhost entries are defined in the registry database. See IBM® Informix® documentation.
4. Verify the environment variable defining the search path for IBM® Informix® SDK database client shared libraries.

Table 177: Shared library environment setting for IBM® Informix® SDK version

<table>
<thead>
<tr>
<th>IBM® Informix® SDK version</th>
<th>Shared library environment setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>All versions</td>
<td><strong>UNIX</strong>: Add $INFORMIXDIR/lib, $INFORMIXDIR/lib/esql, $INFORMIXDIR/lib/tools and $INFORMIXDIR/lib/cli to LD_LIBRARY_PATH (or its equivalent). <strong>Windows</strong>: Add $INFORMIXDIR%\bin to PATH.</td>
</tr>
</tbody>
</table>

5. Check the database client locale settings (CLIENT_LOCALE, DB_LOCALE, etc).
   The database client locale must match the locale used by the runtime system (LC_ALL, LANG).
6. To verify if the IBM® Informix® client environment is correct, you can start the SQL command interpreter:

   ```bash
   $ dbaccess - -
   > CONNECT TO "dbname" USER "appadmin";
   ENTER PASSWORD: password
   ``

7. Set up the fglprofile entries for database connections.
   **Important**: Make sure that you are using the ODI driver corresponding to the database client and server version.

**Fully supported IBM® Informix® SQL features**

Fully supported IBM® Informix® SQL features.

**What are the supported IBM® Informix® SQL features?**

Genero BDL was first designed for IBM® Informix® databases. The answer to this question is: Every SQL feature that is not listed in the other sections of this chapter.

The following list gives an idea of the IBM® Informix® SQL elements you can use with Genero BDL:

- Database connection control instructions (DATABASE, CONNECT). See Connections, with DB user authentication.
- Transaction control instructions and concurrency settings (BEGIN WORK, SET ISOLATION). See Transactions.
- Basic, portable data types (INT, BIGINT, DECIMAL, CHAR, VARCHAR, DATE, DATETIME, TEXT, BYTE, etc). See data types.
- SERIAL, BIGSERIAL with last generated serial in SQLCA.SQLERRD[2] after INSERT.
- Common Data Definition Language statements (CREATE TABLE, DROP TABLE, etc). See Static SQL.
- Common Data Manipulation Language statements (SELECT, INSERT, UPDATE, DELETE, etc). See Static SQL.
- Cursors declared with SELECT … FOR UPDATE, with or without the WITH HOLD option.
- Result set handling with cursors (DECLARE / OPEN / FETCH / CLOSE / FREE). See Result Sets.
- Positioned UPDATEs and DELETEs (UPDATE/DELETE WHERE CURRENT OF). See Positioned Updates.
• Cursors to insert rows (DECLARE / OPEN / PUT / FLUSH). See Insert Cursors.
• Stored procedure calls. See SQL Programming.
• SQL statement interruption. See Using SQL interruption on page 539.
• SQL execution status and error messages (SQLCA, SQLSTATE). See Connections.
• Global Language Support with single and multibyte character sets for CHAR/ VARCHAR data storage. See Localization.
• LOAD and UNLOAD utility statements. See I/O SQL instructions.
• Database schema extraction to define program variables LIKE database columns. See Database Schema.

**Partially supported IBM® Informix® SQL features**

Partially supported IBM® Informix® SQL features.

**The BIGSERIAL / SERIAL8 data types**

IBM® Informix® database supports the BIGSERIAL and SERIAL8 data types for auto-generated 64 bit integer sequences.

The BIGINT data type can be used to store data from BIGSERIAL SERIAL8 values.

Note that SQLCA.SQLERRD[2] is defined as an INTEGER and therefore cannot be used to get the last generated serial. To retrieve the last generated BIGSERIAL or SERIAL8, you must use the `dbinfo()` SQL function as in the following code example:

```sql
MAIN
    DEFINE new_val BIGINT
    INSERT INTO mytable VALUES ( 0, 'aaaa' )
    SELECT dbinfo('bigserial') INTO new_val
    FROM systables WHERE tabid=1
    DISPLAY new_val
END MAIN
```

**Related concepts**

The SQLCA diagnostic record on page 532
The SQLCA variable is a predefined record containing SQL statement execution information.

**SERIAL data types** on page 861

**The NCHAR / NVARCHAR data types**

IBM® Informix® supports the standard NCHAR and NVARCHAR data types. These types are equivalent to CHAR and VARCHAR (the same character set is used), except that the collation order is locale specific with NCHAR/ NVARCHAR types.

With Genero BDL, you can handle character strings of NCHAR/NVARCHAR database columns by using program variables defined with the CHAR/VARCHAR types. Since the character set is identical for NCHAR/NVARCHAR and CHAR/VARCHAR, not specific consideration needs to be given for the "N" character types.

When extracting a database schema with `fgldbsch`, NCHAR/NVARCHAR types will be identified in the `.sch` file by the native Informix® type codes 15 and 16. When compiling `.4gl` or `.per` sources referencing NCHAR/ NVARCHAR columns in the schema file, the compilers will automatically use the CHAR and VARCHAR Genero BDL types for the type codes 15 and 16.

However, Genero BDL is missing full support of NCHAR and NVARCHAR types as it is not possible to declare program variables directly with the NCHAR / NVARCHAR keywords. Furthermore, sorting features of Genero should follow the same collation order as the IBM® Informix® database when using "N" character types.

*Enhancement reference: 20004*

**Related concepts**

Data types on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

The LVARCHAR data type

IBM® Informix® supports the LVARCHAR type as a "large" VARCHAR type. The LVARCHAR type was introduced to bypass the 255 bytes size limitation of the standard VARCHAR type. Starting with IDS version 9.4, the LVARCHAR size limit is 32739 bytes. In older versions the limit was 2048 bytes.

Genero BDL does not support the LVARCHAR type natively, but it has the VARCHAR type which can hold up to 65535 bytes. IBM® Informix® LVARCHAR values can be inserted or fetched by using the BDL VARCHAR type.

Static SQL statements such as CREATE TABLE can include the LVARCHAR column type.

When extracting a schema with fgldbsch, LVARCHAR(N) columns will by default be converted to VARCHAR2(N) in the schema file. VARCHAR2 is a Genero BDL-only pseudo type identified with the type code 201 that allows for VARCHAR variables with a size that can be greater than 255 bytes to be defined.

Enhancement reference: 3464

Related concepts

Data types on page 253
Selecting the correct data type assists you in the input, storage, and display of your data.

DISTINCT data types

IBM® Informix® supports DISTINCT data types as User Defined Types based on a source data type, but with different casts and functions than those on the source data type.

Genero BDL partially supports the IBM® Informix® DISTINCT data types:

The fgldbsch schema extractor can extract columns defined with a distinct type and write the distinct type code in the .sch schema file. For more details, see the list of distinct types in the Column Definition File (.sch) on page 479

However, there are some restrictions you must be aware of:

• It is not possible to define BDL variables explicitly with the name of a distinct type. Variables must be defined indirectly with the schema by using the DEFINE LIKE statement.
• The static SQL syntax does not support OPAQUE-related syntax elements:
  • The DDL statements CREATE DISTINCT TYPE, DROP TYPE, CREATE CAST, and DROP CAST are not allowed,
  • In CREATE TABLE / ALTER TABLE DDL statements, the data type must be a built-in type.
  • The :: cast operator is not supported.

Enhancement reference: 20003

Stored Procedures

With IBM® Informix® database servers, you can write stored procedures with the SPL (Stored Procedure Language) or with an external language in C or JAVA.

If you plan to support different types of database servers, you must be aware that each DB vendor has defined its own stored procedure language. In such cases, you may consider writing most of your business logic in BDL, and implementing only some stored procedures in the database, mainly to get better performance or to use database features that only exist with stored procedures.

Genero BDL partially supports SP creation, but has full support of SP invocation:

• The Genero BDL static SQL syntax does not include CREATE FUNCTION and CREATE PROCEDURE with a body block. However, you can create stored procedures with a body block by using dynamic SQL (EXECUTE IMMEDIATE), or with CREATE PROCEDURE and the FROM filename clause, which is supported by Genero BDL static SQL.
• The EXECUTE FUNCTION or EXECUTE PROCEDURE instruction is not allowed in the static SQL syntax. To invoke a stored procedure with Informix®, you must use the PREPARE instruction, followed by EXECUTE or OPEN. The PREPARE instruction must initiate the EXECUTE FUNCTION/PROCEDURE instruction.
For more details about stored procedure invocation, see SQL Programming.

**Related concepts**
- Stored procedure call with IBM Informix on page 582
- Static SQL statements on page 638
  Describes static SQL statements supported in the language.
- Dynamic SQL management on page 654
  Explains how to execute and manage SQL statements at runtime.
- PREPARE (SQL statement) on page 655
  Prepares an SQL statement for execution.

**Database Triggers**
Triggers can be created for IBM® Informix® database tables with the CREATE TRIGGER instruction.

If you plan to support different types of database servers, you must be aware that each DB vendor has defined its own trigger creation syntax and stored procedure language. In such cases, you may consider writing most of your business logic in BDL, and implementing only some triggers in the database, mainly to get better performance or use database features that only exist with stored procedures.

Genero BDL partially supports trigger creation:
- The Genero BDL static SQL syntax does not include the CREATE TRIGGER and DROP TRIGGER instructions. However, you can create database triggers by using dynamic SQL (EXECUTE IMMEDIATE).

**Related concepts**
- Static SQL statements on page 638
  Describes static SQL statements supported in the language.
- EXECUTE IMMEDIATE on page 658
  Performs a simple SQL execution without SQL parameters or result set.

**Optimizer directives**
IBM® Informix® SQL allows you to specify query optimization directives to force the query optimizer to use a different path than the implicit plan. With IBM® Informix®, optimizer directives are specified with the following SQL comment markers followed by a plus sign:

```sql
/*+ optimizer-directives */
{+ optimizer-directives }
--- optimizer-directives
```

Genero BDL partially supports optimizer directives:
- The static SQL syntax does not allow the C-style optimizer syntax.
- The curly-brace and dash-dash optimizer directive syntaxes cannot be used in static SQL statements, because these correspond to the 4GL language comments.
- However, you can execute queries with optimization directives with Dynamic SQL.

**Tip:** Optimization directives are not portable. If you plan to use different types of database servers, it is recommended that you avoid the usage of query plan hints.

**Related concepts**
- Static SQL statements on page 638
  Describes static SQL statements supported in the language.

**XML publishing support**
IBM® Informix® IDS 11.10 introduced a set of XML built-in functions when the `idsxmlvp` virtual processor is turned on. Built-in XML functions are of two types: those returning `LVARCHAR` values, and those returning `CLOB` values.
For example, \texttt{genxml()} returns an \texttt{LVARCHAR(32739)}, while \texttt{genxmlclob()} returns a \texttt{CLOB}. XML data is typically stored in \texttt{LVARCHAR} or \texttt{CLOB} columns.

Genero BDL partially supports XML functions:

- Because Genero BDL does not support \texttt{BLOB/CLOB} types, functions returning \texttt{CLOB} values cannot be used. You can however use the XML functions returning \texttt{LVARCHAR} values, and fetch the result into a \texttt{VARCHAR} variable of the appropriate size.
- Some of the XML functions such as \texttt{genxml()} take \texttt{ROW()} values as parameters. Because literal unnamed \texttt{ROW()} expressions are like regular function calls, you can use XML functions in static SQL statements.

Example:

```sql
FUNCTION get_cust_data(id)
  DEFINE id INT, v VARCHAR(5000)
  SELECT genxml(ROW(cust_name, cust_address), "custdata") INTO v
  FROM customers WHERE cust_id = id
  RETURN v
END FUNCTION
```

- **Static SQL statements** on page 638
  Describes static SQL statements supported in the language.

DataBlade\textsuperscript{®} modules

IBM\textsuperscript{®} Informix\textsuperscript{®} IDS provides several database extensions implemented with the DataBlade\textsuperscript{®} Application Programming Interface, such as MQ Messaging, Large OBjects management, Text Search DataBlades, Spatial DataBlade\textsuperscript{®} Module, etc.

Genero BDL partially supports DataBlade\textsuperscript{®} modules:

- DataBlade\textsuperscript{®} extensions are based on User Defined Functions and User Defined Types. It is not possible to define program variables with specific User Defined Types. For example, you cannot define a program variable with the \texttt{ST_Point} type implemented by the Spatial DataBlade\textsuperscript{®} module.
- The static SQL grammar does not support DataBlade\textsuperscript{®} specific syntax. For example, it is not possible to create a Basic Text Search index with the \texttt{USING bts} clause of the CREATE INDEX statement.

However, as long as the syntax of the DataBlade\textsuperscript{®} functions follows basic SQL expressions, it can be used in static SQL statements. For example, this query uses the \texttt{bts_contains()} function of the Basic Text Search extension:

```
SELECT id FROM products WHERE bts_contains( brands, 'standard' )
```

You can also use Dynamic SQL to perform queries with a syntax that is not allowed in the static SQL grammar.

Related concepts

- **Static SQL statements** on page 638
  Describes static SQL statements supported in the language.

Specific CREATE INDEX clauses

In addition to the standard index-key specification using a column list, the CREATE INDEX statement supported by IBM\textsuperscript{®} Informix\textsuperscript{®} SQL allows specific clauses, for example to define storage options.

Genero BDL partially supports the CREATE INDEX statement; the following are not supported in static SQL grammar:

- The IF NOT EXISTS clause.
- Functional index specification is not allowed in the index-key list.
- Storage options such as \texttt{IN dbspace}, \texttt{EXTEND SIZE}, \texttt{NEXT SIZE}.
- The index mode clauses such as \texttt{FILTERING WITH/WITHOUT ERROR}.
- The \texttt{USING} clause.
• The HASH ON clause.
• The FILLFACTOR clause.

You can use Dynamic SQL to execute CREATE INDEX statements with clauses that are not allowed in the static SQL grammar.

**Related concepts**

Static SQL statements on page 638
Describes static SQL statements supported in the language.

**Other SQL instructions**

Genero BDL static SQL syntax implements common Data Manipulation Statements such as SELECT, INSERT, UPDATE and DELETE. Data Definition Language statements such as CREATE TABLE, CREATE INDEX, CREATE SEQUENCE and their corresponding ALTER and DROP statements are also part of the static SQL grammar. These are supported with a syntax limited to the standard SQL clauses. For example, Genero BDL might not support the most recent CREATE TABLE storage options supported by IBM® Informix® SQL.

Since the first days of the 4GL language the SQL language has been extended, and it has become so large that it's impossible to embed all the existing new statements without introducing grammar conflicts with the 4GL language. In addition, each DB vendor has improved the standard SQL language with proprietary SQL statements that are not portable; it would not be a good idea to use these specific instructions if you plan to make your application run with different types of database engines.

However, the Genero BDL static SQL is constantly being improved with standard SQL syntax that works with most types of database servers. For example, Genero BDL supports the ANSI outer join syntax, constraints definition in DDL statements, sequence instructions, BIGINT and BOOLEAN data types, and there is more to come.

If a statement is unsupported in static SQL, that does not mean that you cannot execute it. If you want to execute an SQL instruction that is not part of the static SQL grammar, you can use Dynamic SQL as follows:

• Use PREPARE + EXECUTE for statements that do not generated a result set
• Use (PREPARE/) DECLARE + OPEN for statements returning a result set
• Use EXECUTE IMMEDIATE if no SQL parameters are required and no result set is generated

Dynamic SQL instructions take a string as the input, so there is no limitation regarding the SQL text you can execute. However, only one statement can be executed at a time. Preferably, write your SQL statements directly in static SQL when possible, because it makes the code more readable and the syntax is checked at compiled time.

For more details about statements supported in the static SQL syntax, see Static SQL.

Below is a list of the IBM® Informix® SQL statements that are not allowed in the static SQL syntax (last updated from IDS 11.50 SQL instructions). The IBM® Informix® SQL Syntax manual includes ESQL/C specific statements such as ALLOCATE DESCRIPTOR, which are not part of the basic SQL statements supported by the engines. ESQL/C specific statements are not listed here:

```
ALTER ACCESS_METHOD
ALTER FRAGMENT
ALTER FUNCTION
ALTER PROCEDURE
ALTER ROUTINE
ALTER SECURITY LABEL COMPONENT
CREATE ACCESS_METHOD
CREATE AGGREGATE
CREATE CAST
CREATE DISTINCT TYPE
CREATE EXTERNAL TABLE Statement
CREATE FUNCTION (with body)
CREATE OPAQUE TYPE
CREATE OPCLASS
CREATE PROCEDURE (with body)
CREATE ROLE
CREATE ROUTINE FROM
```
Unsupported IBM® Informix® SQL features

Unsupported IBM® Informix® SQL features.

CLOB and BLOB data types

In addition to the TEXT and BYTE data types (known as Simple Large Objects), IBM® Informix® servers support the CLOB and BLOB types to store large objects. CLOB/BLOB are known as Smart Large Objects. The main difference is that Smart Large Objects support random access to the data - seek, read and write through the LOB as if it was an OS file.
Genero BDL does not support the CLOB and BLOB types:

- It is not possible to define BDL variables with the CLOB or BLOB types, so you cannot manipulate CLOB/BLOB objects within programs.
- Defining a TEXT / BYTE variable to hold CLOB / BLOB column data is not supported; you will get error -609 (Illegal attempt to use a Text/Byte host variable).
- The static SQL syntax for DDL statements like CREATE TABLE does not allow the CLOB / BLOB keywords for column types.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a CLOB or BLOB column.

You can, however:

- Create a table with CLOB/BLOB columns by using Dynamic SQL.
- Use the Smart Large Object functions FILETOBLOB(), FILETOCLOB(), LOCOPY(), LOTOFILE() in static SQL statements.

*Enhancement reference: 476*

**Related concepts**

- Static SQL statements on page 638
  Describes static SQL statements supported in the language.

**The LIST data type**

In IBM® Informix® databases, the LIST type is a collection type that can store ordered elements of a specific base type. Unlike the MULTISET type, the elements of a LIST have ordinal positions. Elements can be duplicated.

Genero BDL does not support the IBM® Informix® LIST data type:

- It is not possible to define BDL variables with the LIST type.
- The static SQL syntax does not support collection-related syntax elements:
  - DDL statements like CREATE TABLE cannot use the LIST keyword for column types,
  - The collection-derived notation TABLE() is not allowed,
  - The INSERT AT position instruction is not supported,
  - The LIST { } literal syntax is not allowed.
  - The value IN identifier syntax is not allowed.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a LIST column.

*Related concepts*

- Static SQL statements on page 638
  Describes static SQL statements supported in the language.

**The MULTISET data type**

The MULTISET IBM® Informix® data type is a collection type that can store non-ordered elements of a specific base type. Unlike the LIST type, the elements of a MULTISET have no ordinal positions. Elements can be duplicated.

Genero BDL does not support the IBM® Informix® MULTISET data type:

- It is not possible to define BDL variables with the MULTISET type.
- The static SQL syntax does not support collection-related syntax elements:
  - DDL statements like CREATE TABLE cannot use the MULTISET keyword for column types,
  - The collection-derived notation TABLE() is not allowed,
  - The MULTISET { } literal syntax is not allowed.
  - The value IN identifier syntax is not allowed.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a MULTISET column.
The SET data type

The SET IBM® Informix® data type is a collection type that stores non-ordered unique elements of a specific base type. Unlike the LIST type, the elements of a LIST have no ordinal positions. Elements cannot be duplicated.

Genero BDL does not support the IBM® Informix® SET data type:

- It is not possible to define BDL variables with the SET type.
- The static SQL syntax does not support collection-related syntax elements:
  - DDL statements like CREATE TABLE cannot use the SET keyword for column types,
  - The collection-derived notation TABLE() is not allowed,
  - The SET { } literal syntax is not allowed.
  - The value IN identifier syntax is not allowed.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a SET column.

The ROW data types

IBM® Informix® supports the named and unnamed ROW data types. A ROW type is a complex type that combines several table columns. You create a ROW type with the CREATE ROW TYPE instruction, and then you can reuse the type definition for a table column.

Genero BDL does not support the IBM® Informix® ROW data types:

- It is not possible to define BDL variables with a named ROW type. The equivalent would be a RECORD variable, but data is not mapped directly from a structured ROW column, you must list individual fields of the ROW column.
- The static SQL syntax does not support ROW-related syntax elements:
  - The DDL statements CREATE ROW TYPE, DROP ROW TYPE, CREATE CAST and DROP CAST are not allowed,
  - In CREATE TABLE / ALTER TABLE DDL statements, the data type must be a built-in type.
  - The :: cast operator is not supported when specifying a ROW() literal. However, the CAST() expressions are allowed.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a column defined with a ROW type.

However:

- Static SQL allows multilevel single-dot notation, so you can, for example, identify a ROW field as employee.address.city.
- Dynamic SQL can be used to insert or update rows with ROW type columns.
- Individual ROW column fields can be fetched to BDL program variables, as long as the basic types match.

Enhancement reference: 19159
Explains how to execute and manage SQL statements at runtime.

**OPAQUE data types**

Opaque User Defined Types can be implemented in IBM® Informix® with the CREATE OPAQUE TYPE statement. The storage structure of an OPAQUE type is unknown to the database server, data can only be accessed through user-defined routines.

Genero BDL does not support the IBM® Informix® OPAQUE data types:

- It is not possible to define BDL variables with an opaque type.
- The static SQL syntax does not support OPAQUE-related syntax elements:
  - The DDL statements CREATE OPAQUE TYPE, DROP TYPE, CREATE CAST and DROP CAST are not allowed,
  - In CREATE TABLE / ALTER TABLE DDL statements, the data type must be a built-in type.
  - The :: cast operator is not supported. However, the CAST( ) expressions are allowed.
- The fgldbsch schema extractor will report an invalid data type if you try to get the schema for a table with a column defined with a OPAQUE type.

**Related concepts**

*Static SQL statements* on page 638
Describes static SQL statements supported in the language.

**The :: cast operator**

IBM® Informix® SQL implements the :: cast operator and the CAST() expressions to do an explicit cast of a value:

```sql
CREATE TABLE tab ( v INTEGER )
INSERT INTO tab VALUES ( 123456::INTEGER )
SELECT 'abcdef'::CHAR(20)||'.' FROM tab
SELECT CAST('abcdef' AS CHAR(20))||'.' FROM tab
```

Genero BDL does not support the :: cast operator in the static SQL grammar. However, the CAST() expressions are allowed. If you need to use the :: cast operator, you must use Dynamic SQL to perform such queries.

*Enhancement reference: 19190*

**Related concepts**

*Static SQL statements* on page 638
Describes static SQL statements supported in the language.

**Table inheritance**

IBM® Informix® SQL allows you to define a table hierarchy through named row types. Table inheritance allows a table to inherit the properties of the supertable in the meaning of constraints, storage options, triggers. You must first create the types with CREATE ROW TYPE, then you can create the tables with the UNDER keyword to define the hierarchy relationship.

```sql
CREATE ROW TYPE person_t ( name VARCHAR(50) NOT NULL, address VARCHAR(200), birthdate DATE )
CREATE ROW TYPE employee_t ( salary INTEGER, manager VARCHAR(50) )
CREATE TABLE person OF TYPE person_t
CREATE TABLE employee OF TYPE employee_t UNDER person
```

A table hierarchy allows you to do SQL queries whose row scope is the supertable and its subtables. For example, after inserting one row in the person table and another one in the employee table, if you UPDATE the name column without a WHERE clause, it will update all rows from both tables. To limit the set of rows affected by the statement to rows of the supertable, you must use the ONLY keyword:

```sql
UPDATE ONLY(person) SET birthdate = NULL
```
SELECT * FROM ONLY(person)

Genero BDL static SQL grammar does not include the syntax elements related to table hierarchy management. You can however use Dynamic SQL to perform such queries.

Enhancement reference: 19200

Static SQL statements on page 638
Describes static SQL statements supported in the language.

IBM® DB2® Linux-Unix-Windows

Supported versions
Genero BDL supports the following IBM® DB2® LUW versions:

- IBM DB2 LUW 10.x
- IBM DB2 LUW 11.x

Installation (Runtime Configuration)
IBM® DB2® related installation topics.

Install IBM® DB2® and create a database - database configuration/design tasks

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. Install the IBM® DB2® LUW on your database server.
2. Create a DB2® database entity: **dbname**

   To create the database entity in DB2, use the `db2` command interpreter in a DB2 operating system user session (`db2inst`).

   **Note:** Consider creating your database with the correct database locale (codeset and territory)

   For example:

   ```
   $ db2
   ...
   db2 => CREATE DATABASE dbname
       AUTOMATIC STORAGE YES
       USING CODESET UTF-8 TERRITORY EN_US
   DB20000I  The CREATE DATABASE command completed successfully.
   ```

3. Connect to the new created database with the DB2 administrator user.

   Open a database connection as in the following example:

   ```
   db2 => connect to dbname
   ```

   **Database Connection Information**
   Database server = DB2/LINUX 10.1.0
   SQL authorization ID = DB2INST
   Local database alias = dbname

4. Declare a database user dedicated to your application: the application administrator. This user will manage the database schema of the application (all tables will be owned by it).

   Create the user as follows:

   ```
   db2 => GRANT CONNECT ON DATABASE TO USER appadmin
   DB20000I  The SQL command completed successfully.
   ```

5. Give all requested database administrator privileges to the application administrator.
Grant the privileges to create tables to the new created user as follows:

```
db2 => GRANT CREATETAB ON DATABASE TO USER appadmin
DB20000I  The SQL command completed successfully.
```

Or, provide full database administrator privileges to the new created user:

```
db2 => GRANT DBADM ON DATABASE TO USER appadmin
DB20000I  The SQL command completed successfully.
```

6. If you plan to use temporary table emulation, you must setup the database for DB2® global temporary tables (create a user temporary tablespace and grant privileges to all users).

   See Temporary tables on page 726.

7. Connect as the application administrator:

   Open a new database connection:

   ```
db2 => connect to dbname user appadmin using password
```

   Database Connection Information

   Database server       = DB2/LINUX 10.1.0
   SQL authorization ID   = DB2INST
   Local database alias   = dbname

8. Create the application tables with CREATE TABLE statements.

   Convert Informix® data types to DB2® data types. See issue Data Type Conversion Table for more details.

9. If you plan to use SERIAL column emulation, you must prepare the database.

   See SERIAL data types on page 716.

Prepare the runtime environment - connecting to the database

1. In order to connect to IBM® DB2®, you must have the database driver "dbmdb2" in FGLDIR/dbdrivers.

2. If you want to connect to a remote DB2® server, the "IBM® DB2® Client Application Enabler" must be installed and configured on the computer running the BDL applications.

   You must declare the data source set up as follows:

   a) Login as root.

   1. Create a user dedicated to the DB2® client instance environment, for example, "db2cli1".

   2. Create a client instance environment with the db2icrt tool as in following example:

      ```
      # db2dir /instance/db2icrt -a server -s client instance-user
      ```

   b) Login as the instance user (the environment is set automatically, verify DB2DIR).

   1. Catalog the remote server node:

      ```
      # db2 "catalog tcpip node db2node remote hostname server tcp-service"
      ```

   2. Catalog the remote database:

      ```
      # db2 "catalog database datasource at node db2node authentication server"
      ```

   3. Test the connection to the remote database:

      ```
      # db2 "connect to datasource user dbuser using password"
      ```

      (where dbuser is a database user declared on the remote database server)
See IBM® DB2® documentation for more details.

3. **Important:** If you have a non-English environment, you may need to set the PATCH2=15 configuration parameter in the DB2CLI.INI file to ensure that DECIMAL values will be properly inserted or fetched:

```
[datasource]
PATCH2=15
```

For more details, see the DB2® README.TXT file in the SQLLIB directory.

4. Make sure that the DB2® client environment variables are properly set.

Check variables such as DB2DIR (the path to the installation directory), DB2INSTANCE (the name of the DB2® instance), INSTHOME (the path to the home directory of the instance owner). On UNIX™, you will find environment settings in the file $INSTHOME/sqlib/db2profile. See IBM® DB2® documentation for more details.

5. Check the database client locale settings (DB2CODEPAGE, etc).

The database client locale must match the locale used by the runtime system (LC_ALL, LANG).

6. Verify the environment variable defining the search path for DB2 CLI database client shared libraries (libdb2.so on UNIX™, DB2CLI.DLL on Windows®).

<table>
<thead>
<tr>
<th>Table 178: Shared library environment setting for DB2® version</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB2® version</strong></td>
</tr>
<tr>
<td>DB2® 10.x and higher</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

7. To verify if the DB2® client environment is correct, you can, for example, start the db2 command interpreter and connect to the server:

```
$ db2
db2 => CONNECT TO dbname USER username USING password
```

8. Setup the fglprofile entries for **database connections**.

a) Define the IBM® DB2® database driver:

```
dbi.database.dbname.driver = "dbmdb2"
```

b) The "source" parameter defines the name of the IBM® DB2® database name.

```
dbi.database.dbname.source = "test1"
```

c) Define the database schema selection if needed:

Use the following entry to define the database schema to be used by the application. The database interface will automatically perform a SET SCHEMA name instruction to switch to a specific schema:

```
dbi.database.dbname.db2.schema = 'name'
```

Here dbname identifies the database name used in the BDL program (DATABASE dbname) and name is the schema name to be used in the SET SCHEMA instruction. If this entry is not defined, no "SET SCHEMA" instruction is executed and the current schema defaults to the user's name.
Database concepts
IBM® DB2® related database concept topics.

Database concepts
As with Informix®, an IBM® DB2® database server can handle more than one database entity. Informix® servers have an ID (INFORMIXSERVER) and databases are identified by name. IBM® DB2® instances are identified by the DB2INSTANCE environment variable and databases have to be cataloged as data sources (see IBM® DB2® documentation for more details).

Data storage concepts
When converting from Informix® to IBM® DB2® the aim is to try to preserve as much of the data storage information as possible in the process. The most important storage decisions made for Informix® database objects (like initial sizes and physical placement) can be applied to the IBM® DB2® database.

Storage concepts are quite similar in Informix® and in IBM® DB2®, but the names are different.

These tables compare Informix® storage concepts to IBM® DB2® storage concepts:

Table 179: Physical units of storage (Informix® vs. DB2®)

<table>
<thead>
<tr>
<th>Informix®</th>
<th>IBM® DB2®</th>
</tr>
</thead>
<tbody>
<tr>
<td>The largest unit of physical disk space is a &quot;chunk&quot;, which can be allocated either as a cooked file (I/O is controlled by the OS) or as raw device (=UNIX® partition, I/O is controlled by the database engine). A &quot;dbspace&quot; uses at least one &quot;chunk&quot; for storage. You must add &quot;chunks&quot; to &quot;dbspaces&quot; in order to increase the size of the logical unit of storage.</td>
<td>One or more &quot;containers&quot; are created for each &quot;tablespace&quot; to physically store the data of all logical structures. Like Informix® &quot;chunks&quot;, &quot;containers&quot; can be an OS file or a raw device. You can add &quot;containers&quot; to a &quot;tablespace&quot; in order to increase the size of the logical unit of storage or you can define EXTEND options.</td>
</tr>
<tr>
<td>A &quot;page&quot; is the smallest physical unit of disk storage that the engine uses to read from and write to databases. A &quot;chunk&quot; contains a certain number of &quot;pages&quot;. The size of a &quot;page&quot; must be equal to the operating system's block size.</td>
<td>At the finest level of granularity, IBM® DB2® stores data in &quot;data blocks&quot; with size corresponding to a multiple of the operating system's block size. You set the &quot;data block&quot; size when creating the database.</td>
</tr>
<tr>
<td>An &quot;extent&quot; consists of a collection of contiguous &quot;pages&quot; that the engine uses to allocate both initial and subsequent storage space for database tables. When creating a table, you can specify the first extent size and the size of future extents with the EXTENT SIZE and NEXT EXTENT options. For a single table, &quot;extents&quot; can be located in different &quot;chunks&quot; of the same &quot;dbspace&quot;.</td>
<td>An &quot;extent&quot; is a specific number of contiguous &quot;data blocks&quot;, obtained in a single allocation. When creating a table, you can specify the first extent size and the size of future extents with the STORAGE() option. For a single table, &quot;extents&quot; can be located in different &quot;data files&quot; of the same &quot;tablespace&quot;.</td>
</tr>
</tbody>
</table>

Table 180: Logical units of storage (Informix® vs. DB2®)

<table>
<thead>
<tr>
<th>Informix®</th>
<th>IBM® DB2®</th>
</tr>
</thead>
<tbody>
<tr>
<td>A &quot;table&quot; is a logical unit of storage that contains rows of data values.</td>
<td>Same concept as Informix®.</td>
</tr>
</tbody>
</table>
Informix® | IBM® DB2®
---|---
A "database" is a logical unit of storage that contains table and index data. Each database also contains a system catalog that tracks information about database elements like tables, indexes, stored procedures, integrity constraints and user privileges.

Database tables are created in a specific "dbspace", which defines a logical place to store data.

If no dbspace is given when creating the table, Informix® defaults to the current database dbspace.

Same concept as Informix®.

An IBM® DB2® instance can manage several databases.

Database tables are created in a specific "tablespace", which defines a logical place to store data. The main difference with Informix® "dbspaces", is that IBM® DB2® tablespaces belong to a "database", while Informix® "dbspaces" are external to a database.

Table 181: Other storage concepts (Informix® vs. DB2®)

<table>
<thead>
<tr>
<th>Informix®</th>
<th>IBM® DB2®</th>
</tr>
</thead>
<tbody>
<tr>
<td>When initializing an Informix® engine, a &quot;root dbspace&quot; is created to store information about all databases, including storage information (chunks used, other dbspaces, etc.).</td>
<td>Each IBM® DB2® database uses a set of &quot;control files&quot; to store internal information. These files are located in a dedicated directory: &quot;.../$DB2INSTANCE/NODEnnnn&quot;</td>
</tr>
<tr>
<td>The &quot;physical log&quot; is a set of continuous disk pages where the engine stores &quot;before-images&quot; of data that has been modified during processing. The &quot;logical log&quot; is a set of &quot;logical-log files&quot; used to record logical operations during on-line processing. All transaction information is stored in the logical log files if a database has been created with transaction log. Informix® combines &quot;physical log&quot; and &quot;logical log&quot; information when doing fast recovery. Saved &quot;logical logs&quot; can be used to restore a database from tape.</td>
<td>DB2® uses &quot;database log files&quot; to record SQL transactions.</td>
</tr>
</tbody>
</table>

Concurrency management

Data consistency and concurrency concepts

- **Data Consistency** applies to situations when readers want to access data currently being modified by writers.
- **Concurrent Data Access** applies to situations when several writers are accessing the same data for modification.
- **Locking Granularity** defines the amount of data concerned when a lock is set (for example, row, page, table).

Informix®

Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with **UPDATE**, **INSERT** or **DELETE**, an **exclusive lock** is set on the touched rows. The lock remains active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set **shared locks**, depending on **isolation level**. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification, or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the **lock wait mode**.

Control:

- Lock wait mode: **SET LOCK MODE TO** ...
- Isolation level: **SET ISOLATION TO** ...
- Locking granularity: **CREATE TABLE** ... **LOCK MODE {PAGE|ROW}**
- Explicit exclusive lock: **SELECT** ... **FOR UPDATE**
Defaults:
- The default isolation level is **READ COMMITTED**.
- The default lock wait mode is **NOT WAIT**.
- The default locking granularity is **PAGE**.

**IBM® DB2®**

As in Informix®, IBM® DB2® uses locks to manage data consistency and concurrency. The database manager sets *exclusive locks* on the modified rows and *shared locks* when data is read, based on the *isolation level*. The locks are held until the end of the transaction. When several processes want to modify the same data, the latest processes must wait until the first finishes its transaction. Readers do not have to wait for writers: Row versioning is supported, to allow data to be committed before the modification in progress. The *lock granularity* is at the row or table level. For more details, see DB2's Administration Guide, "Application Consideration".

Control:
- Lock wait mode: Always **WAIT**. Only the *Lock Timeout* can be changed, but this is a global database parameter.
- Isolation level: Can be set through an API function call or with a database client configuration parameter.
- Locking granularity: **Row level** or **Table level**.
- Explicit locking: **SELECT ... FOR UPDATE**

Defaults:
- The default isolation level is **Cursor Stability** (readers cannot see uncommitted data, no shared lock is set when reading data).

**Solution**

The *SET ISOLATION TO ...* Informix® syntax is replaced by an ODBC API call setting the `SQL_ATTR_TXN_ISOLATION` connection attribute. The next table shows the isolation level mappings applied by the database driver:

**Table 182: Isolation level mappings done by the IBM® DB2® LUW database driver**

<table>
<thead>
<tr>
<th>SET ISOLATION instruction in program</th>
<th>ODBC SQL_ATTR_TXN_ISOLATION connection attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET ISOLATION TO DIRTY READ</td>
<td>SQL_TXN_READ_UNCOMMITTED</td>
</tr>
<tr>
<td>SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]</td>
<td>SQL_TXN_READ_COMMITTED</td>
</tr>
<tr>
<td>SET ISOLATION TO CURSOR STABILITY</td>
<td>SQL_TXN_REPEATABLE_READ</td>
</tr>
<tr>
<td>SET ISOLATION TO REPEATABLE READ</td>
<td>SQL_TXN_SERIALIZABLE</td>
</tr>
</tbody>
</table>

For portability, it is recommended that you work with Informix® in the read committed isolation level, to make processes wait for each other (lock mode wait) and to create tables with the "lock mode row" option.

See Informix® and IBM® DB2® documentation for more details about data consistency, concurrency and locking mechanisms.

  - Implementing optimistic locking to handle access concurrently to the same database records.
- **WITH HOLD and FOR UPDATE** on page 568
Transactions handling

Informix®

With the Informix® native mode (non ANSI):

• Transactions blocks start with BEGIN WORK and terminate with COMMIT WORK or ROLLBACK WORK.
• Statements executed outside a transaction are automatically committed.
• DDL statements can be executed (and canceled) in transactions.

```
UPDATE tab1 SET ...   -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...                   -- end of TX block
COMMIT WORK
```

Informix® version 11.50 introduces savepoints:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT name
RELEASE SAVEPOINT name
```

IBM® DB2®

Transactions in IBM® DB2®:

• Beginning of transactions are implicit; two transactions are delimited by COMMIT or ROLLBACK.
• DDL statements can be executed (and canceled) in transactions.

Savepoints in IBM® DB2®:

• Savepoints must be declared with the ON ROLLBACK RETAIN CURSORS clause.
• Rollback must always specify the savepoint name.

Solution

The Informix® behavior is simulated with an autocommit mode in the IBM® DB2® interface. A switch to the explicit commit mode is done when a BEGIN WORK is performed by the BDL program. Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with IBM® DB2®.

Note: If you want to use savepoints, always specify the savepoint name in ROLLBACK TO SAVEPOINT.

See also SELECT FOR UPDATE

Related concepts
Database transactions on page 538
Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

Database users

Informix®

Until version 11.70.xC2, Informix® database users must be created at the operating system level and must be members of the ’informix’ group.

Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as in most other db servers.
Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.

**IBM® DB2®**

With DB2, users must be defined as operating system users with a specific DB2® environment.

The database administrator must grant the CONNECT authority to these users.

- *Database authorities* involve actions on a database as a whole. When a database is created, some authorities are automatically granted to anyone who accesses the database. For example, CONNECT, CREATETAB, BINDADD and IMPLICIT_SCHEMA authorities are granted to all users.

- *Database privileges* involve actions on specific objects within the database. When a database is created, some privileges are automatically granted to anyone who accesses the database. For example, SELECT privilege is granted on catalog views and EXECUTE and BIND privilege on each successfully bound utility is granted to all users.

Together, privileges and authorities act to control access to an instance and its database objects. Users can access only those objects for which they have the appropriate authorization, that is, the required privilege or authority.

**Solution**

Set up the IBM® DB2® environment for each user as described in the documentation.

**Related concepts**

- Database users and security on page 547
- Properly identifying database users allows to use database security and audit features.

**Setting privileges**

**Informix®**

Informix® users must have at least the CONNECT privilege to access the database:

```sql
GRANT CONNECT TO username
```

Application administration users need the RESOURCE privilege to create tables:

```sql
GRANT RESOURCE TO username
```

Since version 7.20, Informix® supports database roles:

```sql
GRANT rolename TO username
```

**IBM® DB2®**

IBM® DB2® supports the concept of *roles* to grant or revoke permissions to a group of users.

IBM® DB2® users must have at least the CONNECT authority to access the database:

```sql
GRANT CONNECT ON DATABASE TO (PUBLIC | user | group)
```

See IBM® DB2® documentation for more details.

**Solution**

Informix® and IBM® DB2® user privileges management are quite similar.

</tbody>
</table>

Notes:
1. For more details about serial emulation, see SERIAL data types on page 716.
**BOOLEAN data type**

**Informix®**

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values.

Genero BDL implements the BOOLEAN data type in a different way: A BOOLEAN variable stores integer values 1 or 0 (for TRUE or FALSE). This type is designed to hold the result of a boolean expression.

**IBM® DB2®**

IBM® DB2® does not provide a BOOLEAN SQL type.

**Solution**

The DB2® database interface converts BOOLEAN type to CHAR(1) columns and stores '1' or '0' values in the column.

The BOOLEAN type translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemul.datatype.boolean = {true | false}
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

*Using portable data types* on page 553

Only a limited set of data types are really portable across several database engines.

**CHAR and VARCHAR data types**

**Informix®**

Informix® supports the following character data types:

**Table 184: Informix® character data types**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>SBCS and MBCS character data (max is 32767 bytes)</td>
</tr>
<tr>
<td>VARCHAR (n, m)</td>
<td>SBCS and MBCS character data (max is 255 bytes)</td>
</tr>
<tr>
<td>NCHAR (n)</td>
<td>Same as CHAR, with specific collation order</td>
</tr>
<tr>
<td>NVARCHAR (n, m)</td>
<td>Same as VARCHAR, with specific collation order</td>
</tr>
<tr>
<td>LVARCHAR (n)</td>
<td>max size varies depending on the IDS version</td>
</tr>
</tbody>
</table>

With Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is in how they use sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order.

The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable.

The character set used by applications is defined by the CLIENT_LOCALE environment variable.

Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR (N) is expressed in bytes, not characters as in some other databases)

**IBM® DB2®**

IBM® DB2® supports following data types to store character data:
Table 185: IBM® DB2® character data types

<table>
<thead>
<tr>
<th>IBM® DB2® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>SBCS character data using the database character set, where (n) is specified in bytes (max is 255 bytes)</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>SBCS character data using the database character set, where (n) is specified in bytes (max is 32672 bytes)</td>
</tr>
<tr>
<td>GRAPHIC (n)</td>
<td>UNICODE/UCS-2 character data, where (n) is specified in characters (max is 127 characters)</td>
</tr>
<tr>
<td>VARGRAPHIC (n)</td>
<td>UNICODE/UCS-2 character data, where (n) is specified in characters (max is 16336 characters)</td>
</tr>
</tbody>
</table>

Like Informix®, IBM® DB2® uses Byte Length Semantics to define the length of CHAR/VARCHAR columns. However, GRAPHIC and VARGRAPHIC lengths are specified in characters (i.e. max number of double-byte characters).

The character set used by DB2® to store CHAR and VARCHAR data is defined in the database locale section when creating a new database. If your application uses UTF-8, consider creating the DB2® database with the UTF-8 codeset.

DB2® can automatically convert from/to the client and server characters sets. In the client applications, you define the character set with the DB2CODEPAGE profile variable.

**Solution**

Informix® CHAR \(N\) types must be mapped to DB2® CHAR \(N\) types, and Informix® VARCHAR \(N\) or LVARCHAR \(N\) columns must be mapped to DB2® VARCHAR \(N\).

**Important:**

- DB2® does not support NCHAR/NVARCHAR types. If your programs create tables with these types, you must review your code. The DB2® driver does not automatically convert the NCHAR/NVARCHAR Informix® types to GRAPHIC/VARGRAPHIC, because the meaning of the length is different.
- Check that your database schema does not use CHAR or VARCHAR types with a length exceeding the DB2® limits. Especially, the Informix® CHAR type has a very long size limit compared to DB2® CHAR.

When using a multibyte character set (such as UTF-8), if the DB2® database was created with the appropriate codeset (UTF-8), you can use the CHAR/VARCHAR columns, and use byte length semantics in programs. If the database code set is non multibyte, you must use the GRAPHIC and VARGRAPHIC data types to store multibyte character data, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a DB2® database, the fglgschc schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR\(10\) (characters) column a in DB2® database using the UTF-8 character set, the .sch file will get a size of 10, that will be interpreted by FGL_LENGTH_SEMANTICS as either a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

See also the section about Localization.

The CHAR/VARCHAR type translation can be controlled with the following FGLPROFILE entries:

```
  dbi.database.dname.ifxemul.datatype.char = { true | false }
  dbi.database.dname.ifxemul.datatype.varchar = { true | false }
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.
Related concepts
CHAR and VARCHAR types on page 555
Using the CHAR and VARCHAR data types with different databases.

NUMERIC data types

Informix®
Informix® supports several data types to store numbers:

Table 186: Informix® numeric data types

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>16 bit signed integer</td>
</tr>
<tr>
<td>INTEGER</td>
<td>32 bit signed integer</td>
</tr>
<tr>
<td>BIGINT</td>
<td>64 bit signed integer</td>
</tr>
<tr>
<td>INT8</td>
<td>64 bit signed integer (replaced by BIGINT)</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>Equivalent to DECIMAL(16)</td>
</tr>
<tr>
<td>DECIMAL(p)</td>
<td>Floating-point decimal number (max precision is 32)</td>
</tr>
<tr>
<td>DECIMAL(p, s)</td>
<td>Fixed-point decimal number (max precision is 32)</td>
</tr>
<tr>
<td>MONEY</td>
<td>Equivalent to DECIMAL(16,2)</td>
</tr>
<tr>
<td>MONEY(p)</td>
<td>Equivalent to DECIMAL(p, 2) (max precision is 32)</td>
</tr>
<tr>
<td>MONEY(p, s)</td>
<td>Equivalent to DECIMAL(p, s) (max precision is 32)</td>
</tr>
<tr>
<td>REAL / SMALLFLOAT</td>
<td>32-bit floating point decimal (C float)</td>
</tr>
<tr>
<td>DOUBLE PRECISION / FLOA[(n)]</td>
<td>64-bit floating point decimal (C double)</td>
</tr>
</tbody>
</table>

IBM® DB2®

IBM® DB2® supports the following numeric data types:

Note: DB2® V 9.1 introduces the DECFLOAT(16) and DECFLOAT(34) floating point decimal types to store large decimals. The next table lists the Informix® types and DB2® equivalents.

Table 187: IBM® DB2® numeric data types

<table>
<thead>
<tr>
<th>IBM® DB2® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>16 bit signed integer</td>
</tr>
<tr>
<td>INTEGER</td>
<td>32 bit signed integer</td>
</tr>
<tr>
<td>BIGINT</td>
<td>64 bit signed integer</td>
</tr>
<tr>
<td>DECFLOAT(16)</td>
<td>16 bit signed floating point decimal</td>
</tr>
<tr>
<td>DECFLOAT(34)</td>
<td>32 bit signed floating point decimal</td>
</tr>
<tr>
<td>DECIMAL(p, s)</td>
<td>Fixed point decimal</td>
</tr>
<tr>
<td>REAL</td>
<td>32-bit floating point decimal (C float)</td>
</tr>
<tr>
<td>FLOA[(n)] (DOUBLE)</td>
<td>64-bit floating point decimal (C double)</td>
</tr>
</tbody>
</table>
Solution

Use the following conversion rules to map Informix numeric types to DB2 numeric types:

Table 188: Informix® numeric data types and DB2® equivalents

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>IBM® DB2® equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>INTEGER</td>
<td>INTEGER</td>
</tr>
<tr>
<td>INT8 / BIGINT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>DECIMAL(p&lt;=16)</td>
<td>DECIMAL(p=16)</td>
</tr>
<tr>
<td>DECIMAL(p&gt;16)</td>
<td>DECIMAL(p&gt;16)</td>
</tr>
<tr>
<td>DECIMAL(p&lt;=31,s)</td>
<td>DECIMAL(p=s)</td>
</tr>
<tr>
<td>DECIMAL(32,s)</td>
<td>No equivalent</td>
</tr>
<tr>
<td>MONEY</td>
<td>DECIMAL(16,2)</td>
</tr>
<tr>
<td>MONEY(p)</td>
<td>DECIMAL(p,2)</td>
</tr>
<tr>
<td>MONEY(p,s)</td>
<td>DECIMAL(p,s)</td>
</tr>
<tr>
<td>SMALLFLOAT</td>
<td>REAL</td>
</tr>
<tr>
<td>FLOAT[(n)]</td>
<td>FLOAT[(n)] (DOUBLE)</td>
</tr>
</tbody>
</table>

SQL scripts to create databases must be converted manually. Tables created from BDL programs do not have to be converted; the database interface detects the MONEY data type and uses the DECIMAL type for DB2®.

Important: The maximum precision for DB2® decimals is 31 digits, while Informix® supports 32 digits.

The DECIMAL (p) data type is converted to DECIMAL(p=16) (for DECIMAL(p<=16)) or DECIMAL(p>16) (for DECIMAL(p>16)) to store floating point decimals. If you create tables with DECIMAL columns, you will lose the original DECIMAL precision when extracting the schema with fgldbsch, because IBM® DB2® supports only two precision specifications (16 or 34). Note also the DECIMAL(32) will be extracted as DECIMAL(32), since the Genero DECIMAL type has a maximum precision of 32 digits.

The numeric types translation can be controlled with the following FGLPROFILE entries:

```sql
$dbi.database.dsnname.ifxemul.datatype.smallint = [true | false]
$dbi.database.dsnname.ifxemul.datatype.integer = [true | false]
$dbi.database.dsnname.ifxemul.datatype.bigint = [true | false]
$dbi.database.dsnname.ifxemul.datatype.int8 = [true | false]
$dbi.database.dsnname.ifxemul.datatype.decimal = [true | false]
$dbi.database.dsnname.ifxemul.datatype.money = [true | false]
$dbi.database.dsnname.ifxemul.datatype.float = [true | false]
$dbi.database.dsnname.ifxemul.datatype.smallfloat = [true | false]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

DATE and DATETIME data types

Informix®

Informix® provides two data types to store date and time information:
• DATE = for year, month and day storage.
• DATETIME = for year to fraction (1-5) storage.

The DATE type is stored as an INTEGER with the number of days since 1899/12/31.

The DATETIME type can be defined with various time units, by specifying a start and end qualifier. For example, you can define a datetime to store an hour-to-second time value with DATETIME HOUR TO SECOND.

The values of Informix® DATETIME can be represented with a character string literal, or as DATETIME() literals:

<table>
<thead>
<tr>
<th>Character string literal</th>
<th>Conversion</th>
</tr>
</thead>
<tbody>
<tr>
<td>'2017-12-24 15:45:12.345'</td>
<td>DATETIME YEAR TO FRACTION(3)</td>
</tr>
<tr>
<td>'15:45'</td>
<td>DATETIME HOUR TO MINUTE</td>
</tr>
<tr>
<td>DATETIME(2017-12-24 12:45)</td>
<td>YEAR TO MINUTE</td>
</tr>
<tr>
<td>DATETIME(12:45:56.333)</td>
<td>HOUR TO FRACTION(3)</td>
</tr>
</tbody>
</table>

Informix® is able to convert quoted strings to DATE/DATETIME data, if the string contains matching environment parameters. The string to date conversion rules for DATE is defined by the DBDATE environment variable. The string to datetime format for DATETIME is defined by the GL_DATETIME environment variable.

**Note:** Within Genero programs, the string representation for DATETIME values is always ISO (YYYY-MM-DD hh:mm:ss.ffffff)

Informix® supports date arithmetic on DATE and DATETIME values. The result of an arithmetic expression involving dates/times is an INTEGER number of days when only DATE values are used, and an INTERVAL value if a DATETIME is used in the expression.

Informix® automatically converts an INTEGER to a DATE when the integer is used to set a value of a date column.

**IBM® DB2®**

IBM® DB2® provides the following data type to store date and time data:

**Table 189: IBM® DB2® date/time data types**

<table>
<thead>
<tr>
<th>IBM® DB2® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>for year, month, day storage</td>
</tr>
<tr>
<td>TIME</td>
<td>for hour, minutes, seconds storage</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>for year, month, day, hour, minutes, seconds, fraction(12) storage</td>
</tr>
</tbody>
</table>

Like Informix®, IBM® DB2® can convert quoted strings to dates, times or timestamps. Only one format is possible: 'yyyy-mm-dd' for dates, 'hh:mm:ss' for times and 'yyyy-mm-dd hh:mm:ss:f' for timestamps.

In IBM® DB2®, the result of a date/time arithmetic expression involving DATE values is a number of days with a decimal part representing the fraction of the day (0.5 = 12H00, 2.00694444 = (2 + (10/1440)) = 2 days and 10 minutes)). The result of a date/time arithmetic expression involving TIME or TIMESTAMP values is a number of seconds with a decimal part representing the fraction of seconds.

**Solution**

Use the following conversion rules to map Informix® date/time types to IBM® DB2® date/time types:

**Table 190: Informix® data types and IBM® DB2® equivalents**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>IBM® DB2® data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME HOUR TO SECOND</td>
<td>TIME</td>
</tr>
<tr>
<td>DATETIME q1 TO q2 (different from above)</td>
<td>TIMESTAMP</td>
</tr>
</tbody>
</table>
The DATE and DATETIME types translation can be controlled with the following FGLPROFILE entries:

\[
\begin{align*}
\text{dbi.database.dsnname.ifxemul.datatype.date} & = \{ \text{true}, \text{false} \} \\
\text{dbi.database.dsnname.ifxemul.datatype.datetime} & = \{ \text{true}, \text{false} \}
\end{align*}
\]

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

DB2® has the same DATE data type as Informix® DATE columns.

DB2® TIME data type can be used to store Informix® DATETIME HOUR TO SECOND values. The database interface makes the conversion automatically.

Informix® DATETIME values with any precision from YEAR to FRACTION(5) can be stored in DB2® TIMESTAMP columns. The database interface makes the conversion automatically. Missing date or time parts default to 1900-01-01 00:00:00.0. For example, when using a DATETIME HOUR TO MINUTE with the value of "11:45", the DB2® TIMESTAMP value will be "1900-01-01 11:45:00.0".

Important:

- Using integers as a number of days in an expression with dates is not supported by IBM® DB2®. Check your code to detect where you are using integers with DATE columns.
- Literal DATETIME and INTERVAL expressions (i.e. DATETIME (1999-10-12) YEAR TO DAY) are not converted.
- It is strongly recommended that you use BDL variables in dynamic SQL statements instead of quoted strings representing DATE values. For example:

\[
\text{LET stmt = "SELECT ... FROM customer WHERE creat_date > ', adate,'"}
\]

is not portable, use a question mark place holder instead and OPEN the cursor USING adate:

\[
\text{LET stmt = "SELECT ... FROM customer WHERE creat_date > ?"}
\]

- DATE arithmetic expressions using SQL parameters (USING variables) are not fully supported. The next example generates an error at PREPARE time:

\[
\text{SELECT ... WHERE datecol < ? +1}
\]

- SQL Statements using expressions with TODAY / CURRENT / EXTEND must be reviewed and adapted to the native syntax.

**Date/time SQL functions**

**Table 191: Informix® and IBM® DB2® date/time SQL functions**

<table>
<thead>
<tr>
<th>Informix®</th>
<th>IBM® DB2®</th>
</tr>
</thead>
<tbody>
<tr>
<td>today</td>
<td>current date</td>
</tr>
<tr>
<td>current hour to second</td>
<td>current time</td>
</tr>
<tr>
<td>current year to fraction(5)</td>
<td>current timestamp</td>
</tr>
</tbody>
</table>

**Related concepts**

- [Date/time literals in SQL statements](#) on page 571
- Good practices for date and time handling in SQL.

**INTERVAL data type**

Informix® provides the INTERVAL data type to store a value that represents a span of time.
INTERVAL types are divided into two classes:

- *year-month* intervals. For example: `INTERVAL YEAR(5) TO MONTH`
- *day-time* intervals. For example: `INTERVAL DAY(9) TO SECOND`

INTERVAL columns can be defined with various time units, by specifying a start and end qualifier. For example, you can define an interval to store a number of hours and minutes with `INTERVAL HOUR(n) TO MINUTE`, where \( n \) defines the maximum number of digits for the hour unit.

The values of Informix® INTERVAL can be represented with a character string literal, or as INTERVAL() literals:

- `'9834 15:45:12.345'` — an INTERVAL DAY(6) TO FRACTION(3)
- `'7623-11'` — an INTERVAL YEAR(9) TO MONTH
- `INTERVAL(18734:45) HOUR(5) TO MINUTE`
- `INTERVAL(-7634-11) YEAR(5) TO MONTH`

**IBM® DB2®**

IBM® DB2® does not provide a data type corresponding the Informix® INTERVAL data type.

**Solution**

The INTERVAL data type and values are converted CHAR(50) column with IBM® DB2®.

INTERVAL values can be stored and retrieved from the database. However, since IBM® DB2® does not support a native interval type, arithmetics cannot be performed on the database side in SQL statements.

The INTERVAL types translation can be controlled with the following FGLPROFILE entry:

```
  dbi.database.dsname.ifxemul.datatype.interval = \true \false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

**SERIAL data types**

**Informix®**

Informix® supports the SERIAL, BIGSERIAL data types to produce automatic integer sequences:

- SERIAL can produce 32 bit integers (INTEGER)
- BIGSERIAL can produced 64 bit integers (BIGINT)
- SERIAL8 is a synonym for BIGSERIAL

Steps to use serials with Informix®:

1. Create the table with a column using SERIAL, or BIGSERIAL.
2. To generate a new serial, no value or a zero value is specified in the INSERT statement:

   ```
   INSERT INTO tab1 ( c ) VALUES ( 'aa'
   INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa'
   ```

3. After INSERT, the new value of a SERIAL column is provided in SQLCA.SQLERRD[2], while the new value of a BIGSERIAL value must be fetched with a SELECT `dbinfo('bigserial')` query.
Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```sql
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

IBM® DB2®

IBM® DB2® supports IDENTITY columns:

```sql
CREATE TABLE tab ( k INTEGER GENERATED ALWAYS AS IDENTITY, name VARCHAR(50) )
```

To get the last generated IDENTITY value after an INSERT, DB2® provides the IDENTITY_VAL_LOCAL() function.

IBM® DB2® supports SEQUENCES:

```sql
CREATE SEQUENCE sq1 START WITH 100
```

To create a new sequence number, you must use the NEXTVAL FOR operator:

```sql
INSERT INTO table VALUES ( NEXTVAL FOR sq1, ... )
```

To get the last generated sequence number, you must use the PREVVAL FOR operator:

```sql
SELECT PREVVAL FOR sq1 ...
```

Solution

**Note:** For best SQL portability when using different type of databases, consider using sequences as described in Solution 3: Use native SEQUENCE database objects on page 565.

To emulate Informix® serials with IBM® DB2®, you can use IDENTITY columns (1), or insert triggers using sequences (2). The first solution is faster, but does not allow explicit serial value specification in insert statements; the second solution is slower but allows explicit serial value specification.

**Important:** The trigger-based solution is provided to simplify the conversion from Informix, but is slower as the solution using identity columns. We strongly recommend that you use native IDENTITY columns instead to get best performances.

The method used to emulate SERIAL types is defined by the `ifxemul.datatype.serial.emulation` FGLPROFILE parameter:

```sql
dbi.database.dbname.ifxemul.datatype.serial.emulation = {"native","trigseq"}
```

- native: uses IDENTITY columns.
- trigseq: uses insert triggers with sequences.

The default emulation technique is "native".

The serial types emulation can be enabled or disabled with the following FGLPROFILE entries:

```sql
dbi.database.dbname.ifxemul.datatype.serial = {true,false}
dbi.database.dbname.ifxemul.datatype.serial8 = {true,false}
```
Using the native serial emulation

In database creation scripts, all SERIAL\((n)\) data types must be converted by hand to:

\[ \text{INTEGER GENERATED ALWAYS AS IDENTITY}\left(\text{START WITH } n, \text{INCREMENT BY } 1\right) \]

while the SERIAL8 and BIGSERIAL\((n)\) types must be converted to:

\[ \text{BIGINT GENERATED ALWAYS AS IDENTITY}\left(\text{START WITH } n, \text{INCREMENT BY } 1\right) \]

Tables created from the BDL programs can use the SERIAL data type: When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the SERIAL\((n)\) data type to an IDENTITY specification.

In BDL, the new generated SERIAL value is available from the SQLCA.SQLERRD\[2\] variable. The database interface performs a call to the IDENTITY_VAL_LOCAL() function. However, SQLCA.SQLERRD\[2\] is defined as an INTEGER, it cannot hold values from BIGINT identity columns. If you are using BIGINT IDENTITY columns, you must use the IDENTITY_VAL_LOCAL() function.

Since IBM® DB2® does not allow you to specify the value of IDENTITY columns, it is mandatory to convert all INSERT statements to remove the SERIAL column from the list. For example, the following statement:

\[ \text{INSERT INTO tab (col1, col2) VALUES (0, p_value)} \]

must be converted to:

\[ \text{INSERT INTO tab (col2) VALUES (p_value)} \]

Static SQL INSERT using records defined from the schema file must also be reviewed:

\begin{verbatim}
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES (rec.*) -- will use the serial column
\end{verbatim}

must be converted to:

\begin{verbatim}
INSERT INTO tab VALUES rec.* -- without parentheses, serial column is removed
\end{verbatim}

Using the trigseq serial emulation

In database creation scripts, all SERIAL\((n)\) data types must be converted to INTEGER data types, SERIAL8/ BIGSERIAL must be converted to BIGINT, and you must create a sequence and a trigger for each table using a SERIAL.

To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native SQL commands to create the sequence and the trigger.

Tables created from the BDL programs can use the SERIAL data type: When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the SERIAL\((n)\) data type to INTEGER and creates the sequence and the insert trigger.

Note:

IBM® DB2® performs NOT NULL data controls before the execution of triggers. If the serial column must be NOT NULL (for example, because it is part of the primary key), you cannot specify a NULL value for that column in INSERT statements.
For example, the following statement:

```
INSERT INTO tab VALUES (NULL,p_value)
```

must be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

**Important:**

- IBM® DB2® triggers are not automatically dropped when the corresponding table is dropped. They become **inoperative** instead. Database administrators must take care of this behavior when managing schemas.
- With IBM® DB2®, INSERT statements using NULL for the SERIAL column will produce a new serial value:

```
INSERT INTO tab ( col_serial, col_data ) VALUES ( NULL, 'data' )
```

This behavior is mandatory in order to support INSERT statements which do not use the serial column:

```
INSERT INTO tab (col_data) VALUES ('data')
```

Check if your application uses tables with a SERIAL column that can contain a NULL value.
- With DB2®, trigger creation is not allowed on temporary tables. Therefore, the "trigseq" method cannot work with temporary tables using serials.

**Related concepts**

- [Auto-incremented columns (serials)](page 562)
- How to implement automatic record keys.

**ROWID columns**

**Informix®**

When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only).

The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

**Note:** Informix® ROWID usage was a common practice in the early days of Informix® 4GL programming. Today it is recommended to define all your database tables with a PRIMARY KEY to uniquely identify rows.

With Informix®, the SQLCA.SQLERRD[6] register contains the ROWID of the last modified row.

**IBM® DB2®**

IBM® DB2® ROWID columns were introduced in version 9.7. Unlike Informix® integer row ids, DB2® row ids are based on VARCHAR(16) FOR BIT DATA (128 bit integer) that are usually represented as a 32 char hexadecimal representation of the value. The IBM® DB2® ROWID is actually an alternative syntax for RID_BIT(), and a qualified reference to ROWID like `tablename.ROWID` is equivalent to `RID_BIT(tablename)`.

For example:

```
x'070000000000000000000065CE770000'
```

In DB2® SQL, to find a row with a rowid, you must specify the rowid value as an hexadecimal value:

```
SELECT * FROM customer WHERE ROWID = x'070000000000000000000065CE770000'
```

or convert the ROWID to an hexadecimal representation and then you can compare to a simple string:

```
SELECT * FROM customer WHERE HEX(ROWID) = '070000000000000000000065CE770000'
```
Solution

If the BDL application uses ROWIDs, it is recommended that the program logic is reviewed in order to use the real primary keys instead (usually serials, which can be supported). All references to SQLCA.SQLERRD[6] must be removed because this variable will not hold the ROWID of the last modified row.

The DB2® database driver will convert the ROWID keyword to HEX(ROWID), so it can be used as a VARCHAR(32) with the hexadecimal representation of the BIT DATA. You need however to replace all INTEGER variable definitions by VARCHAR(32) or CHAR(32).

To emulate Informix® integer ROWIDs, you can also use the DB2® GENERATE_UNIQUE built-in function, or the IDENTITY attribute of the INTEGER or BIGINT data types.

The ROWID keyword translation can be controlled with the following FGLPROFILE entry:

```plaintext
/dbi.database.dsnname.ifxemul.rowid = \[ true | false \]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Using ROWID columns on page 578
Automatic ROWID columns is not a common database feature.

TEXT and BYTE (LOB) types

Informix®

Informix® provides the TEXT, BYTE, CLOB and BLOB data types to store very large texts or binary data.

Legacy Informix® 4GL applications typically use the TEXT and BYTE types.

Genero BDL does not support the Informix® CLOB and BLOB types.

IBM® DB2®

IBM® DB2® supports the LONG VARCHAR/CLOB and BLOB/VARGRAPHIC/DBCLOB types for large objects storage

Solution

The DB2® database interface can convert BDL TEXT data to DB2® CLOB and BYTE data to DB2® BLOB.

Note that DB2® CLOB and BLOB columns are created with a size of 500K, while Genero TEXT/BYTE program variables have a limit of 2 gigabytes. Make sure that the large object data does not exceed this limit.

The TEXT and BYTE types translation can be controlled with the following FGLPROFILE entries:

```plaintext
/dbi.database.dsnname.ifxemul.text = \[ true | false \]
/dbi.database.dsnname.ifxemul.byte = \[ true | false \]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

Table constraints

Informix®

Informix® supports primary key, unique, foreign key, default and check constraints.
The constraint naming syntax is different in Informix® and most other databases: Informix expects the "CONSTRAINT" keyword after the constraint specification:

```sql
CREATE TABLE emp (
    ...
    emp_code CHAR(10) UNIQUE CONSTRAINT pk_emp,
    ...
)
```

While other databases it before:

```sql
CREATE TABLE emp (
    ...
    emp_code CHAR(10) CONSTRAINT pk_emp UNIQUE,
    ...
)
```

**IBM® DB2®**

IBM® DB2® supports primary key, unique, foreign key, default and check constraints.

**Constraint naming**

The constraint naming clause must be placed **before** the constraint specification.

**Primary keys**

Like Informix®, DB2® creates an index to enforce PRIMARY KEY constraints (some RDBMS do not create indexes for constraints). Using CREATE UNIQUE INDEX to define unique constraints is obsolete (use primary keys or a secondary key instead).

**Note:** DB2® primary key constraints do not allow NULLs; make sure your tables do not contain NULLs in the primary key columns.

**Unique constraints**

Like Informix®, DB2® creates an index to enforce UNIQUE constraints (some RDBMS do not create indexes for constraints).

**Note:** DB2® unique constraints do not allow NULLs; make sure your tables do not contain NULLs in the unique columns.

**Foreign keys**

Both Informix® and DB2® support the **ON DELETE CASCADE** option.

**Check constraints**

The check condition may be any valid expression that can be evaluated to **TRUE** or **FALSE**, including functions and literals. You must verify that the expression is not Informix-specific.

**Null constraints**

Informix® and DB2® support **NOT NULL** constraints, but Informix® does not allow you to give a name to **NOT NULL** constraints.

**Solution**

The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for DB2®.
Related concepts

Data definition statements on page 552

It is recommended to avoid use of DDL in programs.

Name resolution of SQL objects

Informix®

Informix® uses the following form to identify an SQL object:

```
database[@servername]:[{owner|"owner"}.]identifier
```

The ANSI convention is to use double quotes for identifier delimiters (For example: "customer"."cust_name").

Informix® database object names are not case-sensitive in non-ANSI databases. When using double-quoted identifiers, Informix® becomes case sensitive.

With non-ANSI Informix® databases, you do not have to give a schema name before the tables when executing an SQL statement:

```
SELECT ... FROM customer WHERE ...
```

In Informix® ANSI compliant databases:

- The table name must include "owner", unless the connected user is the owner of the database object.
- The database server shifts the owner name to uppercase letters before the statement executes, unless the owner name is enclosed in double quotes.

IBM® DB2®

IBM® DB2® database object names are case-sensitive. When a name is used without double quotes, it is automatically converted to uppercase letters. When using double quotes, the names are not converted:

```
CREATE TABLE tab1 ( Key INT, Col1 CHAR(20) )
-- Table name is "TAB1", column names are "KEY" and "COL1"
CREATE TABLE "Tab1" ( "Key" INT, "Col1" CHAR(20) )
-- Table name is "Tab1", column names are "Key" and "Col1"
```

In an IBM® DB2® database, tables always belong to a database schema. When executing a SQL statement, a schema name must be used as the high-order part of a two-part object name, unless the current schema corresponds to the table's schema.

The default (implicit) schema is the current user's name but it can be changed with the `SET SCHEMA` instruction.

Example: The table "TAB1" belongs to the schema "SCH1". User "MARK" (implicit schema is "MARK") wants to access "TAB1" in a SELECT statement:

```
SELECT ... FROM TAB1 WHERE ...
-- Error "MARK"."TAB1" is an undefined name. SQLSTATE=42704
SELECT ... FROM SCH1.TAB1 WHERE ...
-- OK.
SET SCHEMA SCH1
-- Changes the current schema to SCH1.
SELECT ... FROM TAB1 WHERE ...
-- OK.
```

Note: When executing the `SET SCHEMA` instruction, the database interface does not use double quotes around the schema name (= name is converted to uppercase letters). Make sure that the schema name is created with uppercase letters in the database.
DB2 provides *aliases*, but they cannot be used to make a database object name public because aliases belong to schemas also.

**Solution**

Case sensitivity in object names:

Avoid the usage of double quotes around the database object names. All names will be converted to uppercase letters.

The DB2 schema concept:

After a connection, the database interface can automatically execute a SET SCHEMA *name* instruction if the following FGLPROFILE entry is defined:

```
dbi.database.dbname.db2.schema= "name"
```

Here *dbname* identifies the database name used in the BDL program (DATABASE *dbname*) and *name* is the schema name to be used in the SET SCHEMA instruction. If this entry is not defined, no SET SCHEMA instruction is executed and the current schema defaults to the user's name.

Examples:

```
dbi.database.stores.db2.schema= "STORES1"
dbi.database.accnts.db2.schema= "ACCSCH"
```

**Note:** DB2 does not check the schema name when the SET SCHEMA instruction is executed. Setting a wrong schema name results in "undefined name" errors when performing subsequent SQL instructions like SELECT, UPDATE, INSERT.

In accordance with this automatic schema selection, you must create a DB2 schema for your application:

1. Connect as a user with the DBADM authority.
2. Create an administrator user dedicated to your application. For example, "STORESADM". Make sure this user has the IMPLICIT_SCHEMA privilege (this is the default in DB2).
3. Connect as the application administrator "STORESADM" to create all database objects (tables, indexes,...). In our example, a "STORESADM" schema will be created implicitly and all database objects will belong to this schema.

As a second option you can create a specific schema with the following SQL command:

```
CREATE SCHEMA "name" AUTHORIZATION "appadmin"
```

See the IBM DB2 manuals for more details about schemas.

**Data manipulation**

IBM DB2 related data manipulation topics.

**Reserved words**

**Informix**

With Informix, it is possible to create database objects with reserved words.

For example:

```
CREATE TABLE table ( char CHAR(10) );
```

Indeed this is not good practice, but Informix SQL allows this to be backward compatible when introducing a new keyword in the SQL syntax.

Most other database systems do not allow reserved words as database identifiers. If your legacy code is using SQL reserved words of the target database SQL syntax, an error will be thrown at CREATE TABLE execution.
**IBM® DB2®**

Even if IBM® DB2® allows SQL reserved keywords as SQL object names, verify this with your existing database schema and make sure that you do not use DB2® SQL words. An example of a common word which is part of DB2® SQL grammar is 'alias'.

**Solution**

See IBM® DB2® documentation for reserved keywords.

**Outer joins**

**Informix® OUTER() syntax**

In Informix® SQL, outer joins can be defined in the FROM clause with the OUTER keyword:

```
SELECT ... FROM a, OUTER (b)
   WHERE a.key = b.akey

SELECT ... FROM a, OUTER(b,OUTER(c))
   WHERE a.key = b.akey
   AND b.key1 = c.bkey1 AND b.key2 = c.bkey2
```

Informix® also supports the ANSI OUTER join syntax, which is the recommended way to specify outer joins with recent SQL database engines:

```
SELECT ... FROM cust LEFT OUTER JOIN order
   ON cust.key = order.custno
   WHERE ...
```

**IBM® DB2®**

IBM® DB2® supports the ANSI outer join syntax:

```
SELECT ... FROM cust LEFT OUTER JOIN order
   LEFT OUTER JOIN item
   ON order.key = item.ordno
   ON cust.key = order.custno
   WHERE order.cdate > current date
```

**Solution**

The Genero database drivers can convert Informix Informix® OUTER specifications to ANSI outer joins.

**Note:** For better SQL portability, use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The outer join translation can be controlled with the following FGLPROFILE entry:

```
dbi.database_dsname.ifxemulouters = \ true \ false \false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Prerequisites:**

1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.

   Example which does not work:

   ```
   ... FROM OUTER(tab2), tab1
   ```
2. The outer join in the WHERE clause must use the table name as prefix:

```sql
... WHERE tab1.col1 = tab2.col2
```

- **Restrictions:**
  1. Statements composed by 2 or more SELECT instructions are not supported:

```sql
SELECT ... UNION SELECT ...
```

or:

```sql
SELECT ... WHERE col IN (SELECT...)
```

2. Additional conditions on outer table columns cannot be detected and therefore are not supported:

```sql
... FROM tab1, OUTER(tab2)
    WHERE tab1.col1 = tab2.col2
    AND tab2.colx > 10
```

- **Notes:**
  1. Table aliases are detected in OUTER expressions.

    OUTER example with table alias:

    ```sql
    ... OUTER(tab alias1) ...
    ```

  2. In the outer join, `outertab.col` can be placed on both right or left sides of the equal sign:

    ```sql
    ... WHERE outertab.col1 = maintab.col2
    ```

  3. Table names detection is not case-sensitive:

    ```sql
    SELECT ... FROM tab1, TAB2
    WHERE tab1.col1 = tab2.col2
    ```

  4. **Temporary tables** are supported in OUTER specifications:

    ```sql
    CREATE TEMP TABLE tt1 ( ... )
    SELECT ... FROM tab1, OUTER(tt1) ...
    ```

**Related concepts**

- **Outer joins** on page 577
- Use standard ISO outer join syntax instead of the old IBM® Informix® OUTER() syntax.

**Transactions handling**

- **Informix®**

  With the Informix® native mode (non ANSI):
  
  - Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
  - Statements executed outside a transaction are automatically committed.
  - DDL statements can be executed (and canceled) in transactions.

```sql
UPDATE tab1 SET ...   -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK           -- end of TX block
```
Informix® version 11.50 introduces savepoints:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name]
RELEASE SAVEPOINT name
```

**IBM® DB2®**

Transactions in IBM® DB2®:

- Beginning of transactions are implicit; two transactions are delimited by COMMIT or ROLLBACK.
- DDL statements can be executed (and canceled) in transactions.

Savepoints in IBM® DB2®:

- Savepoints must be declared with the ON ROLLBACK RETAIN CURSORS clause.
- Rollback must always specify the savepoint name.

**Solution**

The Informix® behavior is simulated with an autocommit mode in the IBM® DB2® interface. A switch to the explicit commit mode is done when a BEGIN WORK is performed by the BDL program. Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with IBM® DB2®.

**Note:** If you want to use savepoints, always specify the savepoint name in ROLLBACK TO SAVEPOINT.

See also SELECT FOR UPDATE

**Related concepts**

[Database transactions](#) on page 538

Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Temporary tables**

**Informix®**

Informix® temporary tables are created with the CREATE TEMP TABLE DDL instruction or with SELECT ... INTO TEMP statement:

```
CREATE TEMP TABLE tt1 ( pkey INT, name VARCHAR(50) )
CREATE TEMP TABLE tt2 ( pkey INT, name VARCHAR(50) ) WITH NO LOG
SELECT * FROM tab1 WHERE pkey > 100 INTO TEMP tt2
```

Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the DROP TABLE command. There is no name conflict when several users create temporary tables with the same name.

BDL REPORTs can create a temporary table when the rows are not sorted externally (by the source SQL statement).

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

When creating temporary tables in Informix®, the WITH NO LOG clause can be used to avoid the overhead of recording DML operations in transaction logs.

**IBM® DB2®**

IBM® DB2® supports the DECLARE GLOBAL TEMPORARY TABLE instruction.

DB2® global temporary tables are quite similar to Informix® temporary tables with some exceptions:

- A user temporary table space must exist for the database.
- Users must have 'USE' privilege on a 'user temporary table space'.
• For usage, the temporary table name must be prefixed by 'SESSION'.
• No constraints or indexes can be created on temporary tables.

Note: IBM® DB2® version 11.x supports the CREATE TEMP TABLE syntax for compatibility with Netezza. However, IBM recommends to use the DECLARE GLOBAL TEMPORARY TABLE syntax, to create a temporary table.

For more details, see the DB2® documentation.

Solution

In accordance with some prerequisites, temporary tables creation in BDL programs can be supported by the database interface.

The general FGLPROFILE entry to control temporary table emulation is:

```
dbi.database.dsname.ifxemul.temptables = 1 true 1 false 1
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

How does it work?

• Informix-specific statements involving temporary table creation are automatically converted to IBM® DB2® DECLARE GLOBAL TEMPORARY TABLE statements.
• Once the temporary table has been created, all other SQL statements performed in the current SQL session are parsed to add the SESSION prefix to the table name automatically.

Prerequisites

• Fulfill the DB2® prerequisites to create global temporary tables, at minimum you must create a user temporary table space and grant the usage to database users:

```
CREATE USER TEMPORARY TABLESPACE tempspace01 MANAGED BY AUTOMATIC STORAGE
GRANT USE OF TABLESPACE tempspace01 TO PUBLIC
```

See DB2® documentation for more details.

Limitations

• Tokens matching the original table names are converted to unique names in all SQL statements. Make sure you are not using a temp table name for other database objects, like columns. The following example illustrates this limitation:

```
CREATE TEMP TABLE tmp1 ( col1 INTEGER, col2 CHAR(20) )
SELECT tmp1 FROM table_x WHERE ...
```

• Only the 'native' serial emulation mode is supported with temporary tables. See the issue about SERIALs for more details.

Related concepts

Temporary tables on page 575
Syntax for temporary table creation is not unique across all database engines.

Substrings in SQL

Informix®

Informix® SQL statements can use subscripts on columns defined with the character data type:

```
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
```
Important:  With other database servers as Informix®, when the subscript notation is used to modify column values in UPDATE statement, or as ORDER BY element, you will get and SQL error:

```
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...  
SELECT ... FROM tab1 ORDER BY col1[1,3] 
```

**IBM® DB2®**

IBM® DB2® provides different functions (SUBSTR, SUSTR2, SUBSTRING), to extract a substring from a string expression:

```
SELECT .... FROM tab1 WHERE SUBSTR(col1,2,2) = 'RO' 
SELECT SUBSTR('Some text',6,3) ... 
SELECT SUBSTRING(col1,3,CODEUNITS32) ... 
```

**Solution**

Replace all Informix® col[x,y] right-value expressions by SUBSTRING(col,x,y-x+1,CODEUNITS32).

Write UPDATE and ORDER BY clauses using col[x,y] expressions.

The translation of col[x,y] expressions can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsnname.ifxemul.colsubs = [true | false ]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Substring expressions on page 577
Handle substrings expressions with different database engines.

**String delimiters**

**Informix®**

The ANSI SQL string delimiter character is the single quote (‘string’), while double quotes are used to delimit database object names:

```
SELECT ... WHERE "tabname"."colname" = 'a string value' 
```

In Informix® databases created in native mode (non-ANSI), you can use double quotes as string delimiters:

```
SELECT ... WHERE tabname.colname = 'a string value' 
```

This is important, since many BDL programs use that character to delimit the strings in SQL commands.

**Note:** This problem concerns only double quotes within SQL statements. Double quotes used in pure BDL string expressions are not subject to SQL compatibility problems.

**IBM® DB2®**

IBM® DB2® follows the ANSI SQL specification, using single quotes for string delimiters and double quotes for database object names.
Solution

When using Static SQL statements, the fglcomp compiler converts string literals using double quotes to string literals with single quotes:

```bash
$ cat s.4gl
MAIN
  DEFINE n INT
  SELECT COUNT(*) INTO n FROM tab1 WHERE col1 = "abc"
END MAIN

$ fglcomp -S s.4gl
s.4gl^3^SELECT COUNT(*) FROM tab1 WHERE col1 = 'abc'
```

However, SQL statements created dynamically are not modified by the Genero compiler.

The Genero database interface can automatically replace all double quotes by single quotes in SQL statements. This applies to static and dynamic SQL statements.

The translation of double quoted expression to single quoted expressions can be controlled with the following FGLPROFILE entry:

```bash
dbi.database.dbname.ifxemul.dblquotes = [ true | false ]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

However, database object names must not be delimited by double quotes, because the database interface cannot determine the difference between a database object name and a quoted string! For example, if the program executes the SQL statement:

```sql
... WHERE "tabname"."colname" = "a string value"
```

replacing all double quotes by single quotes would produce:

```sql
... WHERE 'tabname'.'colname' = 'a string value'
```

This would produce an error since 'tabname'.'colname' is not allowed by ORACLE.

Escaped string delimiters can be used inside strings like the following:

```bash
'This is a single quote: ''
'This is a single quote: \
"This is a double quote: ""
"This is a double quote: \\
```

Although double quotes are replaced automatically in SQL statements, it is recommended that you use only single quotes to enforce portability.

Related concepts

String literals in SQL statements on page 570
Single quotes is the standard for delimiting string literals in SQL.

Single row SELECT

Informix®

With Informix®, you must use the system table with a condition on the table id:

```sql
SELECT user FROM systables WHERE tabid=1
```
IBM® DB2®

To retrieve a single row with IBM® DB2®, use the following syntax:

```sql
SELECT user FROM SYSIBM.SYSTABLES WHERE NAME='SYSTABLE'
```

**Solution**

Check the BDL sources for "FROM systables WHERE tabid=1" and use dynamic SQL to resolve this problem.

Consider writing a FUNCTION which produces the FROM and WHERE part, depending on the target database type.

**MATCHES and LIKE**

**Informix®**

Informix® supports MATCHES and LIKE operators in SQL statements.

MATCHES expects * and ? wild-card characters, while LIKE uses the % and _ wild-cards as equivalents.

```sql
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x' )
```

MATCHES accepts also brackets notation, to specify a set of matching characters at a given position:

```sql
( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )
```

**IBM® DB2®**

IBM® DB2® does not provide an equivalent of the Informix® MATCHES operator.

The LIKE operator is supported.

**Important:** With IBM® DB2®, columns defined as CHAR(N) are blank padded, and trailing blanks are significant in the LIKE expressions. As result, with a CHAR(5) value such as 'abc ' (with 2 trailing blanks), the expression (colname LIKE 'ab_') will not match. To workaround this behavior, you can do (RTRIM(colname) LIKE 'pattern'). However, consider adding the condition AND (colname LIKE 'pattern') to force the DB server to optimize the query of the column is indexed. The CONSTRUCT instruction uses this technique when the entered criteria does not end with a * star wildcard.

**Solution**

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.

The MATCHES to LIKE expression translation is controlled by the following FGLPROFILE entry:

```sql
dbi.database.dbname.ifxemul.matches = { true | false }
```

**Important:** Only [NOT] MATCHES followed by a search pattern provided as a string literal can be converted by ODI drivers. A [NOT] MATCHES followed by a ? question mark parameter place holder is not translated!

For maximum portability, consider replacing the MATCHES expressions with LIKE expressions in all SQL statements.

Avoid using CHAR(N) types for variable length character data (such as name, address).

**Related concepts**

MATCHES and LIKE operators on page 579
Use the standard LIKE operator instead of the MATCHES operator.

**SELECT * (asterisk)**

**Informix®**

Informix® allows you to use the star character in the select list along with other expressions:

```
SELECT col1, * FROM tab1 ...
```

**IBM® DB2®**

IBM® DB2® does not support the asterisk notation after another expression in the **SELECT** list.

Use the table name as a prefix to the star:

```
SELECT col1, tab1.* FROM tab1 ...
```

**Solution**

Always use the table name with stars.

**The LENGTH() function**

**Informix®**

Informix® provides the `LENGTH()` function to count the number of bytes of a character string expression:

```
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```

Informix® `LENGTH()` does not count the trailing blanks for CHAR or VARCHAR expressions, while Oracle counts the trailing blanks.

Informix® `LENGTH()` returns 0 when the given string is empty. That means, `LENGTH('')=0`.

**IBM® DB2®**

IBM® DB2® supports the `LENGTH()` function, but there are some differences with Informix® `LENGTH()`.

The IBM® DB2® `LENGTH()` function counts trailing blanks. When using a CHAR column, values are blank padded, and the function returns the size of the CHAR column. When using a VARCHAR column, trailing blanks are significant, and the function returns the number of characters, including trailing blanks.

**Solution**

Check if the trailing blanks are significant when using the `LENGTH()` SQL function in your application.

To count the number of characters by ignoring the trailing blanks, you must use the `RTRIM()` function:

```
SELECT LENGTH(RTRIM(col1)) FROM table
```

The translation of `LENGTH()` expressions can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemul.length = ↓ true ↓ false ↓
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

The `LENGTH()` function in SQL on page 581
The semantics of the LENGTH() SQL function differs according to the database engine.

**BDL programming**
IBM® DB2® related programming topics.

**INSERT cursors**

**Informix®**
Informix® provides *insert cursors* to optimize row creation in a database. An insert cursor is declared as a cursor, and rows as added with the PUT instruction. The rows are buffered and sent to the database server when executing a FLUSH instruction, or when the cursor is closed with CLOSE. When using transactions in Informix®, the OPEN, PUT and FLUSH instructions must be executed within a transaction block.

```sql
DECLARE c1 CURSOR FOR INSERT INTO tab1 ...
BEGIN WORK
OPEN c1
WHILE ...
  PUT c1 USING var-list
END WHILE
CLOSE c1
COMMIT WORK
```

**IBM® DB2®**
IBM® DB2® does not support insert cursors.

**Solution**
Insert cursors are emulated by the database interface, using basic INSERT SQL instructions. The performances might be not as good as with Informix®, but the feature is fully supported.

**Related concepts**
Insert cursors on page 569
Using insert cursors with non-Informix databases.

**Cursors WITH HOLD**

**Informix®**
Informix® closes opened cursors automatically when a transaction ends, unless the WITH HOLD option is used in the DECLARE instruction:

```sql
DECLARE c1 CURSOR WITH HOLD FOR SELECT ...
OPEN c1
BEGIN WORK
FETCH c1 ...
COMMIT WORK
FETCH c1 ...
CLOSE c1
```

**IBM® DB2®**
IBM® DB2® can keep cursors open across transactions, when the transaction is terminated with COMMIT.

When a transaction is canceled with a ROLLBACK, DB2® automatically closes all cursors.

**Solution**
Check that your source code does not use WITH HOLD cursors after transactions canceled with ROLLBACK.
Related concepts

**WITH HOLD and FOR UPDATE** on page 568
Hold cursors and not portable.

### SELECT ... FOR UPDATE

**Informix®**

Legacy BDL programs typically use a cursor with `SELECT FOR UPDATE` to implement pessimistic locking and avoid several users editing the same rows:

```sql
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

The row must be fetched in order to set the lock.

If the cursor is local to a transaction, the lock is released when the transaction ends. If the cursor is declared **WITH HOLD**, the lock is released when the cursor is closed.

**Informix®** provides the `SET LOCK MODE` instruction to define the lock wait timeout:

```sql
SET LOCK MODE TO {WAIT | NOT WAIT | WAIT seconds}
```

The default mode is **NOT WAIT**.

**IBM® DB2®**

IBM® DB2® locks are released when closing the cursor or when the transaction ends.

IBM® DB2®'s locking granularity is at the row level.

IBM® DB2® has no equivalent for `SET LOCK MODE TO NOT WAIT`: The system lock timeout parameter can be changed, but this is a database parameter, global to all SQL processes.

**Solution**

The database interface is based on an emulation of an Informix® engine using transaction logging. Therefore, opening a `SELECT ... FOR UPDATE` cursor declared outside a transaction will raise an SQL error -255 (not in transaction).

When used, you must review pessimistic locking implementation, because it is based on the **NOT WAIT** mode, which is not supported by IBM® DB2®.

**Related concepts**

**WITH HOLD and FOR UPDATE** on page 568
Hold cursors and not portable.

**SQL parameters limitation**

The IBM® DB2® SQL parser does not allow some uses of the '?' SQL parameter marker.

The following SQL expressions are not supported:

```sql
? IS [NOT] NULL
? operator ?
function( ? ?)
```

SQL instructions containing these expressions raise an error during the statement preparation.
Solution
Check that your BDL programs do not use these types of conditional expressions.
If you really need to test a BDL variable during the execution of a SQL statement, you must use the CAST() function for DB2® only:

```sql
... WHERE CAST( ? AS INTEGER ) IS NULL
```
See the DB2® documentation for more details.

**LOAD and UNLOAD**

**Informix®**
Informix® provides two SQL instructions to export / import data from / into a database table:
The UNLOAD instruction copies rows from a database table into a text file:

```sql
UNLOAD TO "filename.unl" SELECT * FROM tab1 WHERE ..
```
The LOAD instructions insert rows from a text file into a database table:

```sql
LOAD FROM "filename.unl" INSERT INTO tab1
```

**IBM® DB2®**
IBM® DB2® does not provide LOAD and UNLOAD instructions.

Solution
LOAD and UNLOAD instruction are implemented in the Genero BDL runtime system with basic INSERT (for LOAD) or SELECT (for UNLOAD) SQL commands. The LOAD and UNLOAD instruction can be supported with various database servers.
However, LOAD and UNLOAD require the description of the column types in order to work, that can lead to some differences in the data formatting.

Note: If no transaction is started, the LOAD instruction will automatically execute a BEGIN WORK and COMMIT WORK when finished, or ROLLBACK WORK if a row insertion failed while loading. Terminating a transaction will automatically close cursors not defined WITH HOLD option. To workaround this situation, see more details in the LOAD on page 684 reference topic.

The LOAD and UNLOAD BDL instructions are supported with IBM® DB2®.

**Related concepts**
**LOAD and UNLOAD instructions** on page 574
The LOAD and UNLOAD instructions can produce different data formats depending on the database server type.

**SQL Interruption**

**Informix®**
With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

**IBM® DB2®**
IBM® DB2® supports SQL Interruption: The db client must issue an SQLCancel() ODBC call to interrupt a query.
Solution
The IBM® DB2® database driver supports SQL interruption and converts the native SQL error code -952 to the Informix® error code -213.

Related concepts
Using SQL interruption on page 539
Interrupt long running SQL queries, or interrupt queries waiting for locked data.

Scrollable cursors

Informix®
Informix® SQL and Genero BDL support scrollable cursors when you specify the SCROLL clause in the DECLARE cursor instruction:

```
DECLARE c1 SCROLL CURSOR FOR SELECT ...
```

IBM® DB2®
IBM® DB2® supports native scrollable cursors with the CLI SQL_CURSOR_STATIC statement attribute.

Solution
The IBM® DB2® database driver uses the native scrollable cursors by setting the CLI statement attribute SQL_ATTR_CURSOR_TYPE to SQL_CURSOR_STATIC.

Related concepts
Scrollable cursors on page 560
How scrollable cursors can be supported on different databases.

Connecting to DB2® OS/400®

Note: Some of the following actions can be taken via the OS/400® Operations Navigator.

DB2® Architecture on OS/400®
On OS/400® machines, the DB2 Universal Database™ is integrated to the operating system. Therefore, some concepts change. For example, the physical organization of the database is quite different from UNIX™ or Windows™ platforms.

Table 192: Common terms for the physical organization of the database with DB2® OS/400®

<table>
<thead>
<tr>
<th>SQL Terms</th>
<th>DB2® OS/400® Terms</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>Physical file</td>
</tr>
<tr>
<td>Row</td>
<td>Record</td>
</tr>
<tr>
<td>Column</td>
<td>Field</td>
</tr>
<tr>
<td>Index</td>
<td>Keyed logical file, access path</td>
</tr>
<tr>
<td>View</td>
<td>Non keyed logical file</td>
</tr>
<tr>
<td>Schema</td>
<td>Library, Collection, Schema (OS/400® V5R1 only)</td>
</tr>
<tr>
<td>Log</td>
<td>Journal</td>
</tr>
<tr>
<td>Isolation Level</td>
<td>Commitment control level</td>
</tr>
</tbody>
</table>

A Collection is a library containing a Journal, Journal Receivers, Views on the database catalogs.
Login to the AS/400® server

First, login to the AS/400® machine with a 5250 display emulation. All the commands are executed in the 5250 display emulation (or telnet connection).

Collection (Schema) Creation

A collection or library in DB2® for OS/400® is equivalent to a schema in DB2® for UNIX™.

1. Launch "Interactive SQL"
   strSqlqL comfmit (*none)
2. Create a Collection
   CREATE COLLECTION
   Press F4
   Enter field values:
   LIBRARY: name of the collection (Schema)
   ASP: 1
   WITH DATA DICTIONARY: Y
   Press ENTER
   Press F3 to quit ( choose Option 1 (save and exit) ).

Note: Avoid giving the first letter of the name of the schema the letter “Q”; libraries beginning with “Q” are system libraries.

This procedure creates:
- A library for your new database,
- A catalog with a data dictionary,
- A journal (QSQJRN),
- A journal receiver (QSQJRN0001).

Source Physical File Creation

Each table in the database is stored in a Physical file. They can be created in the control center with SQL scripts (CREATE TABLE), or with OS/400® commands.

The table creation script file must be copied in the library in the form: library/sourcefile.member

Creation of a physical file:

Type:
CrtSRCPF
Enter field values:
FILE = name of the table (10 characters max).
LIBRARY = name of the library in which the table is created (schema).
RECORD LENGTH = length of the script creation file (in bytes)
MEMBER = *FILE

Execution of the SQL creation script:
Type
RUNSQLSTM
Press F10 for additional parameters
Enter field values:
SOURCE FILE = name of the source file of the script creation file
LIBRARY = name of the library (schema)
SOURCE MEMBER = name of the member of the script creation file
NAMING FIELD = *SQL (SQL Naming convention library.table)
COMMITMENT CONTROL = *NONE
IBM® SQL FLAGGING FIELD = *FLAG

If errors occur, you can use WRKSPLF to display error information saved in the spool file. Use option 5 in the Opt Field on the line of the script file you tried to execute.

**Trigger Creation**

With DB2® on OS/400®, triggers need to be external programs written in a high level language such as C, COBOL, RPG, or PL/I.

To create a trigger, use the following steps:

1. **Create an OS/400® Source file for the trigger programs**

   Create a physical file on your AS/400® for the trigger programs. Each trigger program will be stored in a separate member within this source file.

   Type:
   
   CRTSRCFILE FILE(library/file)
   
   where:

   • *library* is the name of the library you created for your new database
   • *file* is name you want to call the trigger source physical file

   The file name can be up to ten characters long. It is recommended that you give it a name with ten (or less) characters.

2. **Create a member for each trigger program**

   Create a source file member for each trigger program. After the creation of trigger programs (in the next step), the programs will be forwarded to these members.

   Type:
   
   ADDPFM

   Enter field values:

   FILE = name of the source file you just created
   LIBRARY = name of the library you created for your database
   MEMBER = name you want to give the trigger source member

   Repeat this operation for each trigger.

3. **Create trigger programs in an OS/400® supported high level language**

   The OS/400-compatible languages include: ILE C/400®, ILE COBOL, ILE RPG, COBOL, PL/I, and RPG.

   It is recommended that the script creation file for the trigger be send via FTP to library/sourcefile.member where sourcefile and member are the values specified in the previous step.

4. **Compile the trigger programs**

   Once the trigger programs are in AS/400® members, you can compile them. Use whichever compiler is appropriate for the language you used to create the trigger program.

5. **Bind the trigger programs**
After you compile the trigger programs, "bind" each compiled program file. Binding will establish a relationship between the program and any tables or views the program specifies.

**Type:**

**CRTPGM PGM** *(library/program) ACTGRP(*CALLER)*

**where:**

*library* is the name of the library you created for your new database

*program* is the name of the compiled trigger program

Repeat this operation for each trigger.

**6. Add the trigger programs to physical files**

The final step for migrating triggers is to add each program to a physical file. This will tie the trigger program to the table that calls it.

**Type:**

**ADDPFTRG**

Enter field values:

PHYSICAL FILE = name of the table you want to attach the trigger to

PHYSICAL FILE LIBRARY = name of the database library

TRIGGER TIME = either *BEFORE or *AFTER.

TRIGGER EVENT = *INSERT, *DELETE, or *UPDATE.

PROGRAM = name of the compiled program file

PROGRAM LIBRARY = name of the database library.

REPLACE TRIGGER = *YES.

ALLOW REPEATED CHANGES = *YES.

**Note:** The trigger program must be in the same library as the database.

The trigger program is now tied to the table specified in the *Physical File* field and will be called each time the database action you specified occurs. The trigger program may be called from interactive SQL, another AS/400® program, or an ODBC insert, delete, update, or procedure call.

**Permission Definition**

On OS/400®, database security is managed at the operating system level, not at the database level. When you set up permissions for the database, you determine the degree of access (read, add, delete, etc.) individual users, groups, and authorization lists may have. This operation can easily be done via Operation Navigator.

The privileges must include the following system authorities:

- *USE to the Create Physical File (CRTPF) command.
- *EXECUTE and *ADD to the library into which the table is created.
- *OBJOPR and *OBJMGT to the journal.
- *CHANGE to the data dictionary if the library into which the table is created is an SQL collection with a data dictionary.

To define a foreign key, the privileges must include the following on the parent table:

- The REFERENCES privilege or object management authority for the table.
- The REFERENCES privilege on each column of the specified parent key.
- Ownership of the table.

The REFERENCES privilege on a table consists of:
• Being the owner of the table.
• Having the REFERENCES privilege to the table.
• Having the system authorities of either *OBJREF or *OBJMGT to the table.

The REFERENCES privilege on a column consists of:
• Being the owner of the table.
• Having the REFERENCES privilege to the column.
• Having the system authority of *OBJREF to the column or the system authority of *OBJMGT to the table.

To EXECUTE a user-defined function, the privilege consists of:
• Being owner of the user-defined function.
• Having EXECUTE privilege to the user-defined function.
• Having the system authorities of *OBJOPR and *EXECUTE to the user-defined function.

Relational DB Directory Entry Creation

The relational database directory is equivalent to the database directory of the DB2® client. This is necessary to access the database with DRDA® clients (Distributed Relational Database Architecture™) like DB2® client.

Use the WRKRDBDIRE tool to add the entry in the database directory:
• Type
  WRKRDBDIRE
• Type Option 1 (add)
• Enter field values:
  ADDRESS = *LOCAL
  TYPE = *IP

Start the DDM server on the OS/400® which listens on the DRDA® 446 port:
• Type STRTCPSVR *DDM

Start the database server:
• Type STRHOSTSVR
• Enter field values:
  SERVER TYPE = *DATABASE
  REQUIRED PROTOCOL: *ANY

The DDM/DRDA server that listens on TCP/IP port 446 handles requests from a DRDA® client (examples are DB2 Connect™ or another AS/400®).

The database server is not needed for DRDA® clients, but it is needed for Client Access.

If a TCP/IP connection is desired, then your AS/400® server cannot have a release prior to V4R2 installed.

To manually configure the connection via the DB2® command line, you will need to enter catalog commands:

```
> db2 catalog tcpip node <node-name> remote <as400-address> server 446
> db2 catalog db <db-name-alias> at node <node-name> authentication dcs
> db2 catalog dcs db <db-name-alias> as <local-RDB-name-of-AS400>
```

If you catalogue the DB2® for iSeries® server incorrectly, you may get an SQL5048N error message. SQL7008N is another common error in that the DB2® for iSeries® tables being accessed on the server are not being journaled. To correct the SQL7008N error, you need to start journaling your tables or change the isolation level to No Commit.

The proper CCSID value (normally 37 for US English customers) is needed for any tables on the iSeries® accessed via DB2 Connect™. You can view the CCSID value with the DSPFD CL command or Operations Navigator. CCSID values can be changed with the ALTER TABLE statement or CHGPF CL command. Furthermore, to successfully
connect, you may need to change one of the following: the CCSID of the job, the CCSID of the user profile used, or the system CCSID value (QCCSID) if it's the default 65535.

**DB2® Client Configuration on Windows™**

To configure a DB2® client on Windows™ platforms, use the Client Configuration Assistant. This tool is available only under Microsoft™ Windows™. Under UNIX™, you have to use the command line as described in the previous chapter.

1. **Source:**
   - Select “Manually configure a connection to a database”.
2. **Protocol:**
   - Select “TCP/IP”.
   - Check “The database physically resides on a host or AS/400® System”.
3. **TCP/IP:**
   - Host Name: AS/400® system name.
   - Port Number: Port where DDM/DRDA server is listening (default: 446).
4. **Database:**
   - Database name: name defined in the relational database directory entries (with WRKRDBDIRE).
5. **ODBC:**
   - You can register the database as an ODBC data source. Not needed for DRDA® connection used by ODI.
6. **Node Options:**
   - Optional, but needed to access the database via the control center.
   - System name: AS/400® system name.
   - Instance name: not used for a connection to AS/400 (because only one instance is running on an AS/400®).
   - Operating System: OS/400®.
7. **Security Options:**
   - Optional.
8. **Host or AS/400 Options:**
   - Optional.

**Differences Between DB2® UNIX™ & DB2® OS/400®**

Some of the differences between DB2® for UNIX™/Windows™ and DB2® for OS/400® are:

- There is only one database on a system; you can not create two instances on the same database server. The database is a single system-wide database. The database name used for the connect statement is the name of the system. Schemas (Collections) can be used to manage different logical databases on the same OS/400® machine.
- There is no TABLESPACE concept on DB2® for iSeries®. All the storage is controlled by the database manager and operating system.
- The identity column is not supported (for serial emulation).
- The SET SCHEMA SQL command is not supported.
- NUMERIC data type is defined as zoned decimal on DB2® for iSeries® and packed decimal on other platforms.
- The FLOAT data type does not use the same storage. For portability across platforms, do not use FLOAT(n).
- Not all features of the CREATE FUNCTION statement are supported on each platform (see documentation).
- iSeries® prior to V5R1 requires the statement to be processed by a special schema processor. iSeries® as of V5R1 would require this only if the statement includes other DDL statements.
- OS/400® supports “SET DEFAULT” clause ON DELETE.
- OS/400® supports DROP statement with CASCADE behavior.
- Syntaxes of CREATE, ALTER and RENAME TABLE are different on the two systems.
Naming Conventions

The naming convention defines how database tables are identified.

DB2® OS/400® can use two kinds of naming conventions:

- The *SQL naming convention.
  The table has to be qualified with the name of the collection (schema) which must be the same name as the user connected to the database. All tables have to be in the same database.

- The *SYS naming convention.
  If a table is unqualified, it will be searched for in the *CURLIB collection. You can change the library list with the ADDLIB command. You may create a small CL program attached to the profile that will change the library list on sign on. You can also globally change the user portion of the library list using the QUSRLIBL system variable, but this would affect all users on the system.

IBM® Netezza®

Support versions

Genero BDL supports the following IBM Netezza versions:

- IBM Netezza 6.x
- IBM Netezza 7.x

Installation (Runtime Configuration)

IBM® Netezza® related installation topics.

Install IBM® Netezza® and create a database - database configuration/design tasks

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. An IBM® Netezza® appliance (the server) must be available.
2. Install the IBM® Netezza® client software with the IBM® Netezza® ODBC driver on the application server.
3. Create an IBM® Netezza® database with the nzsql utility.
   You must connect to the "system" database:
   
   $ nzsql -h hostname system username password

4. Create your database with the following SQL command:

   CREATE DATABASE mydatabase

   **Note:** The default character set for CHAR/VARCHAR types will be latin9. Unicode/UTF-8 character string data must be stored in NCHAR/NVARCHAR columns.

5. Create a database user dedicated to the administration of the new database and grant privileges:

   CREATE USER myadmin WITH PASSWORD 'password' ...
   GRANT ALL PRIVILEGES on mydatabase TO myadmin;
   GRANT ALL ADMIN TO myadmin;

6. Create the application tables.
   Convert Informix® data types to Netezza® data types. See Data type conversion table: Informix to Netezza on page 746 for more details.

7. If you plan to use the SERIAL emulation, you must prepare the database.
   See SERIAL data types on page 754 for more details.

Prepare the runtime environment - connecting to the database

1. In order to connect to IBM® Netezza®, you must have the "dbmntz" driver in FGLDIR/dbdrivers.
2. The IBM® Netezza® client software with ODBC driver is required to connect to a server. Check if the ODBC client library (libnzodbc.*) is installed on the machine where the BDL programs run.

3. Make sure that the IBM® Netezza® client environment variables are properly set. Check for example NZ_DIR (the path to the installation directory), NZ_ODBC_INI_PATH (the path to the ODBC data source file), etc. See IBM® Netezza® documentation for more details.

4. Verify the environment variable defining the search path for Netezza database client shared libraries (libnzodbc.so on UNIX™, ODBC32.DLL on Windows™).

<table>
<thead>
<tr>
<th>IBM® Netezza® version</th>
<th>Shared library environment setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>IBM® Netezza® 6 and higher</td>
<td>UNIX™: Add $NZ_DIR/lib (for 32 bit) or $NZ_DIR/lib64 (for 64 bit) to LD_LIBRARY_PATH (or its equivalent). Windows™: Add %NZ_DIR%\bin to PATH.</td>
</tr>
</tbody>
</table>

5. Check the database client locale settings.

   With IBM® Netezza®, there is no configuration setting to defined database client: When using CHAR/VARCHAR columns, the application character set (LC_ALL, LANG) and the database character set defined by CREATE DATABASE must match. When using NCHAR/NVARCHAR columns, the application character set must be UTF-8.

6. You can test the client environment by trying to connect to the server with the SQL command line tool:

   $ nzsql -h hostname system username password

7. Set up the fglprofile entries for database connections.
   a) Define the Netezza database driver:

   ```
   dbi.database.dbname.driver = "dbmntz"
   ```
   b) The "source" parameter defines the name of the ODBC source.

   ```
   dbi.database.dbname.source = "test1"
   ```

**Database concepts**

IBM® Netezza® related database concepts topics.

**Database concepts**

Like Informix® servers, Netezza® can handle multiple database entities. Tables created by a user can be accessed without the owner prefix by other users as long as they have access privileges to these tables.

**Solution**

Create a Netezza® database for each Informix® database.

**Concurrence management**

**Data consistency and concurrency concepts**

- *Data Consistency* applies to situations when readers want to access data currently being modified by writers.
- *Concurrent Data Access* applies to situations when several writers are accessing the same data for modification.
- *Locking Granularity* defines the amount of data concerned when a lock is set (for example, row, page, table).
Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with **UPDATE**, **INSERT** or **DELETE**, an exclusive lock is set on the touched rows. The lock remains active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set shared locks, depending on isolation level. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification, or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the lock wait mode.

Control:
- Lock wait mode: `SET LOCK MODE TO ...`
- Isolation level: `SET ISOLATION TO ...`
- Locking granularity: `CREATE TABLE ... LOCK MODE {PAGE|ROW}`
- Explicit exclusive lock: `SELECT ... FOR UPDATE`

Defaults:
- The default isolation level is `READ COMMITTED`.
- The default lock wait mode is `NOT WAIT`.
- The default locking granularity is `PAGE`.

Netezza® servers are designed for Data Warehouse applications, not for OLTP applications: Concurrent data access is not the best thing that a Netezza® server can do. There are a bunch of limitations that you must be aware of. You must not expect to be able to migrate an existing OLTP application running against Informix® or Oracle® to a Netezza® database server. The purpose of a Netezza-based application is mostly to do queries, with few insert or updates. Typically a Netezza® database is fed with data by using tools such as nzload, not by Genero BDL programs.

Some limitations of Netezza®:
- An application can only execute one cursor (or statement handle) at a time.
- Singular data modification statements (**INSERT**, **UPDATE**, **DELETE**) are much slower than with traditional OLTP database servers. Netezza® is, however, very good when it comes to loading a huge amount of data with special tools like the nzload utility.
- **SELECT ... FOR UPDATE** is not supported. Regular SELECT statement never lock rows.
- Locks can only be set for an entire table with `LOCK TABLE`.
- A maximum of 31 concurrent **INSERT** processes are allowed (Netezza® V6), and there must be only **INSERT** statements in a transaction block.
- **UPDATE/DELETE** statements lock the entire table, but don't prevent **SELECT** statements. Other processes doing **UPDATE/DELETE** statements will wait until the first session has committed.
- Netezza® (V6) understands the **SET TRANSACTION ISOLATION** statement, but currently implements only the **SERIALIZABLE** level.
- There is no way to define the **LOCK WAIT** mode. With Netezza®, processes always wait for locks to be released.

Solution

Understand that the main difference with Informix® is that Netezza® is not good at concurrent data modification. Note also that readers do not have to wait for writers in Netezza®.

It is recommended that Genero applications mainly do queries against a Netezza® server. You must review your program logic that modifies data, keeping in mind that only one process can modify a table at the time. Note however, that if you write short transactions, this is not visible to the end users, except that an **INSERT / UPDATE / DELETE** of a single row takes more time than with another database server.

The **SET ISOLATION TO ...** Informix® syntax is replaced by **SET TRANSACTION ISOLATION LEVEL ...** in Netezza®. However, only the **REPEATABLE READ** level is supported with Netezza®.
The table shows the isolation level mappings done by the Netezza® database driver:

### Table 194: Isolation level mappings done by the Netezza® database driver

<table>
<thead>
<tr>
<th>SET ISOLATION instruction in program</th>
<th>Native SQL command</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET ISOLATION TO DIRTY READ</td>
<td>Not supported (SQL Error)</td>
</tr>
<tr>
<td>SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]</td>
<td>Not supported (SQL Error)</td>
</tr>
<tr>
<td>SET ISOLATION TO CURSOR STABILITY</td>
<td>Not supported (SQL Error)</td>
</tr>
<tr>
<td>SET ISOLATION TO REPEATABLE READ</td>
<td>SET TRANSACTION ISOLATION LEVEL SERIALIZABLE</td>
</tr>
</tbody>
</table>

**Important**: Since Netezza® does not support the lock wait mode, you must check that your programs do not include a SET LOCK MODE instruction. This instruction will fail with error -6370 if it is executed when connected to Netezza®.

See the Informix® and Netezza® documentation for more details about data consistency, concurrency and locking mechanisms.

**Related concepts**

- **Concurrent data access** on page 537

- **Optimistic locking** on page 561
  Implementing optimistic locking to handle access concurrently to the same database records.

- **WITH HOLD and FOR UPDATE** on page 568
  Hold cursors and not portable.

**Transactions handling**

**Informix®**

With the Informix® native mode (non ANSI):

- Transactions blocks start with BEGIN WORK and terminate with COMMIT WORK or ROLLBACK WORK.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```sql
UPDATE tab1 SET ...  -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK           -- end of TX block
```

Informix® version 11.50 introduces savepoints:

```sql
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name] 
RELEASE SAVEPOINT name
```

**Netezza®**

- Transactions are started with BEGIN WORK.
- Transactions are validated with COMMIT WORK.
- Transactions are canceled with ROLLBACK WORK.
Statements executed outside of a transaction are automatically committed.
• DDL statements can be executed (and canceled) in transactions.
• If an SQL error occurs in a transaction, the whole transaction is aborted.
• A transaction must only contain INSERTs if you want concurrent processes to insert rows at the same time (UPDATES/DELETEs lock the whole table).
• Only the SERIALIZABLE isolation level is implemented by Netezza®.

Netezza® cancels the entire transaction if an SQL error occurs in one of the statements executed inside the transaction. The following code example illustrates this difference:

```sql
CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
WHENEVER ERROR CONTINUE
BEGIN WORK
INSERT INTO tab1 ( 1, 'abc' )
SELECT FROM unexisting WHERE key = 123   -- unexisting table = sql error
COMMIT WORK
```

With Informix®, the above code will leave the table with one row inside, since the first INSERT statement succeeded. With Netezza®, the table will remain empty after executing this piece of code, because the server will rollback the whole transaction.

**Solution**

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with Netezza®, Informix® transaction handling commands are automatically converted to Netezza® instructions to start, validate or cancel transactions. However, since Netezza® is not designed for OLTP applications, you must review any code doing complex data modifications. See the concurrency topic for more details.

You must review the SQL statements inside BEGIN WORK / COMMIT WORK instruction and check if these can raise an SQL error. To get the same behavior in case of error when connected to a different database than Netezza®, you must issue a ROLLBACK to cancel all the SQL statements that succeeded in the transaction, for example with a TRY/CATCH block.

```sql
TRY
    BEGIN WORK
    ...
    COMMIT WORK
CATCH
    ROLLBACK WORK
END TRY
```

**Related concepts**

Database transactions on page 538
Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Database users**

**Informix®**

Until version 11.70.xC2, Informix® database users must be created at the operating system level and must be members of the 'informix' group.

Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as in most other db servers.

Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.
Netezza®

Netezza® users must be registered in the database with the CREATE USER command, for example:

```
CREATE USER name WITH PASSWORD 'pswd' IN GROUP ...
```

See the Netezza® documentation for more details about user creation and database access/security.

Solution

Depending on the application logic (is it a multiuser application?), you have to create one or several Netezza® users.

Notes:

1. For more details about serial emulation, see SERIAL data types on page 754.

**BOOLEAN data type**

**Informix®**

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values.

Genero BDL implements the BOOLEAN data type in a different way: A BOOLEAN variable stores integer values 1 or 0 (for TRUE or FALSE). This type is designed to hold the result of a boolean expression.

**Netezza®**

Netezza® supports the BOOLEAN data type and stores 't' or 'f' values for TRUE and FALSE representation.

**Note:** It is not possible to insert the integer values 1 or 0 into Netezza BOOLEAN columns: Values must be true, false, 't', 'f', '1' or '0'.

**Solution**

The Netezza® database interface converts the BOOLEAN integer values to a CHAR(1) values '1' or '0'.

- For more details about serial emulation, see SERIAL data types on page 754.
- BOOLEAN data type
  - Informix® supports the BOOLEAN data type, which can store 't' or 'f' values.
  - Genero BDL implements the BOOLEAN data type in a different way: A BOOLEAN variable stores integer values 1 or 0 (for TRUE or FALSE). This type is designed to hold the result of a boolean expression.
  - Netezza® supports the BOOLEAN data type and stores 't' or 'f' values for TRUE and FALSE representation.
  - Note: It is not possible to insert the integer values 1 or 0 into Netezza BOOLEAN columns: Values must be true, false, 't', 'f', '1' or '0'.
  - Solution
    - The Netezza® database interface converts the BOOLEAN integer values to a CHAR(1) values '1' or '0'.
The **BOOLEAN** type translation can be controlled with the following FGLPROFILE entry:

```plaintext
dbi.database.dsname.ifxemul.datatype.boolean = true | false
```

For more details see [IBM Informix emulation parameters in FGLPROFILE](#) on page 614.

**Related concepts**

**Using portable data types** on page 553

Only a limited set of data types are really portable across several database engines.

**CHAR and VARCHAR data types**

**Informix**

Informix® supports the following character data types:

**Table 196: Informix® character data types**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>SBCS and MBCS character data (max is 32767 bytes)</td>
</tr>
<tr>
<td>VARCHAR (n, m)</td>
<td>SBCS and MBCS character data (max is 255 bytes)</td>
</tr>
<tr>
<td>NCHAR (n)</td>
<td>Same as CHAR, with specific collation order</td>
</tr>
<tr>
<td>NVARCHAR (n, m)</td>
<td>Same as VARCHAR, with specific collation order</td>
</tr>
<tr>
<td>LVARCHAR (n)</td>
<td>Max size varies depending on the IDS version</td>
</tr>
</tbody>
</table>

With Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is in how they use sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order.

The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable.

The character set used by applications is defined by the CLIENT_LOCALE environment variable.

Informix® uses Byte Length Semantics (the size N that you specify in VAR[CHAR] (N) is expressed in bytes, not characters as in some other databases)

**Netezza**

Netezza® supports following data types to store character data:

**Table 197: Netezza® character data types**

<table>
<thead>
<tr>
<th>Netezza® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>SBCS character data using the database character set, where n is specified in bytes (max is 64000 bytes)</td>
</tr>
<tr>
<td>VARCHAR (n)</td>
<td>SBCS character data using the database character set, where n is specified in bytes (max is 64000 bytes)</td>
</tr>
<tr>
<td>NCHAR (n)</td>
<td>Unicode/UTF-8 character data, where n is specified in characters (max is 16000 characters)</td>
</tr>
<tr>
<td>NVARCHAR (n)</td>
<td>Unicode/UTF-8 character data, where n is specified in characters (max is 16000 characters)</td>
</tr>
</tbody>
</table>
Netezza® stores single-byte character data in CHAR/VARCHAR columns, and stores UNICODE (UTF-8 encoded) character strings in NCHAR/NVARCHAR columns. You cannot store UTF-8 strings in CHAR/VARCHAR columns.

NCHAR/NVARCHAR data is always stored in UTF-8. The database character defines the encoding for CHAR and VARCHAR columns and is defined when creating the database with the CREATE DATABASE command; the default is latin9. Note that, at the time of writing these lines, Netezza® V6 does not yet support a different database character set than latin9.

No automatic character set conversion is done by the Netezza® software. When using CHAR/VARCHAR columns, the client application character set (LC_ALL, LANG) and the database character set defined by CREATE DATABASE must match. When using NCHAR/NVARCHAR columns, the client application character set must be UTF-8.

Solution

If your application uses a single-byte character set (i.e. latin9), you can create tables with the CHAR and VARCHAR types. However, if you want to store UNICODE (UTF-8) strings, you must use the NCHAR/NVARCHAR types instead when creating tables. In program sources you can use CHAR/VARCHAR; these types can hold single and multibyte character sets, based on the C POSIX locale.

**Important:** Netezza® (V6 while writing these lines) supports only the latin9 database character set for CHAR/VARCHAR types. Since character set conversion is not supported, you can only implement either latin9 or UTF-8 based applications.

When using a multibyte character set (such as UTF-8), define database columns as NCHAR and NVARCHAR, with the size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a Netezza® database, the fgldb sch schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters) ) column a in Netezza® database using the UTF-8 character set, the .sch file will get a size of 10, that will be interpreted by FGL_LENGTH_SEMANTICS as a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

See also the section about Localization.

The CHAR/VARCHAR type translation can be controlled with the following FGLPROFILE entries:

```
  dbi.databasedsnname.ifxemul.datatype.char = { true | false }
  dbi.databasedsnname.ifxemul.datatype.varchar = { true | false }
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

<td>Integer with precision (1\leq p\leq38)</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>Integer, same as NUMERIC(18,0)</td>
</tr>
<tr>
<td>FLOAT(p) with 1 (\leq) (p) (\leq) 6</td>
<td>16 bit approx floating point (C float)</td>
</tr>
<tr>
<td>FLOAT(p) with 7 (\leq) (p) (\leq) 15</td>
<td>32 bit approx floating point (C double)</td>
</tr>
<tr>
<td>REAL</td>
<td>Same as FLOAT(6)</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>Same as FLOAT(15)</td>
</tr>
</tbody>
</table>

**Solution**

Use the following conversion rules to map Informix numeric types to Netezza® numeric types:

**Table 200: Informix® numeric data types and Netezza® equivalents**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Netezza® equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>INTEGER</td>
<td>INTEGER</td>
</tr>
<tr>
<td>INT8 / BIGINT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>DECIMAL(p,s)</td>
<td>DECIMAL(p,s)</td>
</tr>
</tbody>
</table>
Important:

There is no Netezza® equivalent for the Informix® DECIMAL (p) floating point decimal (i.e. without a scale). If your application uses such data types, you must review the database schema in order to use Netezza® compatible types.

To workaround the Netezza® limitation, the NTZ database drivers converts DECIMAL (p) types to a DECIMAL( 2*p, p ), to store all possible numbers that an Informix® DECIMAL(p) can store. However, the original Informix® precision cannot exceed 19, since the Netezza® maximum DECIMAL precision is 38 (2*19). If the original precision is bigger than 19, a CREATE TABLE statement executed from a Genero program will fail with an SQL error.

The numeric types translation can be controlled with the following FGLPROFILE entries:

```plaintext
dbi.database.dsnname.ifxemul.datatype.smallint = {true | false}
dbi.database.dsnname.ifxemul.datatype.integer = {true | false}
dbi.database.dsnname.ifxemul.datatype.bigint = {true | false}
dbi.database.dsnname.ifxemul.datatype.int8 = {true | false}
dbi.database.dsnname.ifxemul.datatype.decimal = {true | false}
dbi.database.dsnname.ifxemul.datatype.money = {true | false}
dbi.database.dsnname.ifxemul.datatype.float = {true | false}
dbi.database.dsnname.ifxemul.datatype.smallfloat = {true | false}
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

**DATE and DATETIME data types**

**Informix®**

Informix® provides two data types to store date and time information:

- DATE = for year, month and day storage.
- DATETIME = for year to fraction (1-5) storage.

The DATE type is stored as an INTEGER with the number of days since 1899/12/31.

The DATETIME type can be defined with various time units, by specifying a start and end qualifier. For example, you can define a datetime to store an hour-to-second time value with DATETIME HOUR TO SECOND.

The values of Informix® DATETIME can be represented with a character string literal, or as DATETIME() literals:

```
'2017-12-24 15:45:12.345' -- a DATETIME YEAR TO FRACTION(3)
'15:45' -- a DATETIME HOUR TO MINUTE
DATETIME(2017-12-24 12:45) YEAR TO MINUTE
DATETIME(12:45:56.333) HOUR TO FRACTION(3)
```
Informix® is able to convert quoted strings to DATE / DATETIME data, if the string contains matching environment parameters. The string to date conversion rules for DATE is defined by the DBDATE environment variable. The string to datetime format for DATETIME is defined by the GL_DATETIME environment variable.

Note: Within Genero programs, the string representation for DATETIME values is always ISO (YYYY-MM-DD hh:mm:ss.fffff)

Informix® supports date arithmetic on DATE and DATETIME values. The result of an arithmetic expression involving dates/times is an INTEGER number of days when only DATE values are used, and an INTERVAL value if a DATETIME is used in the expression.

Informix® automatically converts an INTEGER to a DATE when the integer is used to set a value of a date column.

Netezza®

Netezza® supports the following data types to store date/time values:

**Table 201: Netezza® date/time data types**

<table>
<thead>
<tr>
<th>Netezza® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>for year, month, day storage</td>
</tr>
<tr>
<td>TIME</td>
<td>for hour, minute, second, fraction with (6 decimal positions)</td>
</tr>
<tr>
<td>TIME WITH TIME ZONE / TIMETZ</td>
<td>same as TIME, with time zone information</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>for year, month, day, hour, minute, second, fraction (with 6 decimal positions)</td>
</tr>
</tbody>
</table>

Like Informix®, Netezza® can convert quoted strings to date time data. Netezza® accepts different date formats, including ISO date time strings, and you can specify the cast operator (::date, ::time, ::timestamp) after the string literal.

With Netezza®, the result of an arithmetic expression involving DATE values is an INTEGER representing a number of days.

Complex DATETIME expressions (involving INTERVAL values for example) are Informix® specific and have no equivalent in Netezza®.

**Solution**

Use the following conversion rules to map Informix date/time types to Netezza® date/time types:

**Table 202: Informix® data types and Netezza® equivalents**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Netezza® data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME HOUR TO SECOND</td>
<td>TIME</td>
</tr>
<tr>
<td>DATETIME YEAR TO FRACTION(p)</td>
<td>TIMESTAMP</td>
</tr>
</tbody>
</table>

The DATE and DATETIME types translation can be controlled with the following FGLPROFILE entries:

```plaintext
dbi.database.dsnname.ifxemul.datatype.date = {true | false}
dbi.database.dsnname.ifxemul.datatype.datetime = {true | false}
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Netezza® and Informix® DATE data type are equivalent and store year, month, day values.
Netezza® TIME data type can be used to store Informix® DATETIME HOUR TO SECOND values. The database interface makes the conversion automatically.

Informix® DATETIME values with any precision from YEAR to FRACTION (5) can be stored in Netezza® TIMESTAMP columns. The database interface makes the conversion automatically. Missing date or time parts default to 1900-01-01 00:00:00.0. For example, when using a DATETIME HOUR TO MINUTE with the value of "11:45", the Netezza® TIMESTAMP value will be "1900-01-01 11:45:00.0".

**Note:** Informix® supports implicit DATE/DATETIME conversions, for example you can use a DATE variable when the target column is a DATETIME. This is not possible with Netezza®: The type of the SQL parameter must match the type of the column in the database table. Make sure that you are using the same type for the SQL parameter and the target column, DATE/DATETIME implicit conversion is not supported by Netezza®.

**Related concepts**

Date/time literals in SQL statements on page 571
Good practices for date and time handling in SQL.

**INTERVAL data type**

**Informix®**

Informix® provides the INTERVAL data type to store a value that represents a span of time.

INTERVAL types are divided into two classes:

- *year-month* intervals. For example: INTERVAL YEAR(5) TO MONTH
- *day-time* intervals. For example: INTERVAL DAY(9) TO SECOND

INTERVAL columns can be defined with various time units, by specifying a start and end qualifier. For example, you can define an interval to store a number of hours and minutes with INTERVAL HOUR(n) TO MINUTE, where \( n \) defines the maximum number of digits for the hours unit.

The values of Informix® INTERVAL can be represented with a character string literal, or as INTERVAL() literals:

```
'-9834 15:45:12.345' -- an INTERVAL DAY(6) TO FRACTION(3)
'7623-11'   -- an INTERVAL YEAR(9) TO MONTH
INTERVAL(18734:45) HOUR(5) TO MINUTE
INTERVAL(-7634-11) YEAR(5) TO MONTH
```

**Netezza®**

Netezza® implements the INTERVAL data type in a different way than Informix® does:

- Netezza® allows you to specify interval qualifiers (YEAR, MONTH, DAY, ...) but internally it always uses the same base type, storing values of any combination of units. Thus, there is no way to distinguish year-month intervals and day-time intervals with Netezza®.
- The precision of Netezza® intervals includes fraction of seconds with up to 6 significant digits. However, it is not possible to specify the scale of a Netezza® interval as with the Informix® FRACTION (p) qualifier.
- With Netezza®, interval literals must be include the units, as "-923 days 11 hours 22 minutes", while Informix® interval literals have the form INTERVAL(999-99...) start-qualifier TO end-qualifier.
- Netezza® normalizes all INTERVAL values to units of seconds, and considers a month to be thirty days for the purpose of interval comparisons. This approximation can lead to inaccuracies.

**Solution**

The Informix® INTERVAL types of the *day-time* class can be mapped to the native Netezza® INTERVAL type, for day to second time interval storage.

Since Netezza® does not clearly distinguish *year-month* interval class, such types are converted to CHAR (50) by the Netezza® driver.
**Important:** Netezza® (V6 at the time of writing) has several bugs regarding the INTERVAL type; we do not recommend using this type until Netezza® has fixed these problems.

The INTERVAL types translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsnname.ifxemul.datatype.interval = \true \false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

**Using portable data types** on page 553

Only a limited set of data types are really portable across several database engines.

**SERIAL data types**

**Informix®**

Informix® supports the SERIAL, BIGSERIAL data types to produce automatic integer sequences:

- SERIAL can produce 32 bit integers (INTEGER)
- BIGSERIAL can produced 64 bit integers (BIGINT)
- SERIAL8 is a synonym for BIGSERIAL

Steps to use serials with Informix®:

1. Create the table with a column using SERIAL, or BIGSERIAL.
2. To generate a new serial, no value or a zero value is specified in the INSERT statement:
   ```
   INSERT INTO tab1 ( c ) VALUES ( 'aa' )
   INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
   ```
3. After INSERT, the new value of a SERIAL column is provided in SQLCA.SQLERRD[2], while the new value of a BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```
CREATE TABLE tab ( k SERIAL ); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

**Netezza®**

Netezza® does not have a SERIAL data type.

Netezza® Version 6 supports sequences, but not triggers.

**Solution**

The lack of trigger support in Netezza® makes it impossible to emulate Informix® SERIALs.

**Note:** For best SQL portability when using different type of databases, consider using sequences as described in Solution 3: Use native SEQUENCE database objects on page 565.

If you are using Informix® SERIAL or BIGSERIAL columns, you must review the application logic and database schema to replace these columns with INTEGER/BIGINT columns, and generate the new keys from a SEQUENCE, as described in the SQL Programming page.
Related concepts

Auto-incremented columns (serials) on page 562
How to implement automatic record keys.

ROWID columns

Informix®

When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only).

The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

Note: Informix® ROWID usage was a common practice in the early days of Informix® 4GL programming. Today it is recommended to define all your database tables with a PRIMARY KEY to uniquely identify rows.

With Informix®, the SQLCA.SQLERRD[6] register contains the ROWID of the last modified row.

Netezza®

Netezza® implements ROWIDs like Informix®, except that the rowids are stored in a 64 bit integer.

Solution

If the BDL application uses ROWIDs, it is recommended that the program logic is reviewed in order to use the real primary keys instead (usually serials, which can be supported). All references to SQLCA.SQLERRD[6] must be removed because this variable will not hold the ROWID of the last modified row.

ROWIDs can be used with Netezza® as with Informix®, as long as you fetch rowid values into a BIGINT variable. However, the SQLCA.SQLERRD[6] register cannot be supported, because Netezza® rowids are 64 bit integers (BIGINT) while SQLCA.SQLERRD[6] is a 32 bit integer (INTEGER).

The ROWID keyword translation can be controlled with the following FGLPROFILE entry:

```
 dbi.database.dsnname.ifxemul.rowid = true down false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts

Using ROWID columns on page 578
Automatic ROWID columns is not a common database feature.

Indexes

Like most database servers, Informix® supports index creation on table columns. Indexes can be used to make the server find rows rapidly:

```
 CREATE INDEX cust_ix1 ON customer (cust_name)
```

Netezza® does not support index creation on tables. There is no need for indexes in a Netezza® database because performance is achieved by distributing data rows over several disks. Netezza® tracks min/max values of each column per disk extent to ignore extents which do not contain the values the query is looking for. See Netezza® documentation for more details.

Solution

You must remove all CREATE INDEX instructions from your programs and SQL scripts that create database tables.
TEXT and BYTE (LOB) types

Informix®
Informix® provides the TEXT, BYTE, CLOB and BLOB data types to store very large texts or binary data. Legacy Informix® 4GL applications typically use the TEXT and BYTE types.
Genero BDL does not support the Informix® CLOB and BLOB types.

Netezza®
Netezza® does not support large objects in the database.

Solution
If your application need to store large objects with TEXT and BYTE data types, you cannot use a Netezza® server.

Related concepts
Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

Table constraints

Informix®
Informix® supports primary key, unique, foreign key, default and check constraints.
The constraint naming syntax is different in Informix® and most other databases: Informix expects the "CONSTRAINT" keyword after the constraint specification:

```
CREATE TABLE emp (
    ...
    emp_code CHAR(10) UNIQUE CONSTRAINT pk_emp,
    ...
)
```

While other databases it before:

```
CREATE TABLE emp (
    ...
    emp_code CHAR(10) CONSTRAINT pk_emp UNIQUE,
    ...
)
```

Netezza®
Netezza® supports primary key, unique, foreign key, default and check constraints in a limited manner.

Important: Netezza® allows you to create tables with the UNIQUE and PRIMARY KEY and FOREIGN KEY syntax, but the constraints are not enforced.

Constraint naming syntax
The constraint naming clause must be placed before the constraint specification.

Solution
The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint-naming clauses for Netezza®.
Since Netezza® does not enforce constraints, you must test for unique values and foreign key references at the program level.

**Related concepts**

Data definition statements on page 552

It is recommended to avoid use of DDL in programs.

**Name resolution of SQL objects**

**Informix®**

Informix® uses the following form to identify an SQL object:

```
database[@dbname]:[{owner|"owner"}].identifier
```

The ANSI convention is to use double quotes for identifier delimiters (For example: "customer"."cust_name").

Informix® database object names are not case-sensitive in non-ANSI databases. When using double-quoted identifiers, Informix® becomes case sensitive.

With non-ANSI Informix® databases, you do not have to give a schema name before the tables when executing an SQL statement:

```
SELECT ... FROM customer WHERE ...
```

In Informix® ANSI compliant databases:

- The table name must include "owner", unless the connected user is the owner of the database object.
- The database server shifts the owner name to uppercase letters before the statement executes, unless the owner name is enclosed in double quotes.

**Netezza®**

With Netezza®, an object name takes the following form:

```
[database.[schema].]identifier
```

**Solution**

As a general rule, to write portable SQL, it is recommended that you only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

**Data manipulation**

IBM® Netezza® related data manipulation topics.

**Reserved words**

**Informix®**

With Informix®, it is possible to create database objects with reserved words.

For example:

```
CREATE TABLE table ( char CHAR(10) );
```

Indeed this is not good practice, but Informix® SQL allows this to be backward compatible when introducing a new keyword in the SQL syntax.

Most other database systems do not allow reserved words as database identifiers. If your legacy code is using SQL reserved words of the target database SQL syntax, an error will be thrown at CREATE TABLE execution.
Netezza®
In Netezza®, SQL object names like table and column names cannot be SQL reserved keywords.

Solution
Table or column names which are Netezza® reserved keywords must be renamed.
See the Netezza® SQL Reference guide for a list of reserved keywords.

Outer joins

Informix® OUTER() syntax
In Informix® SQL, outer joins can be defined in the FROM clause with the OUTER keyword:

```
SELECT ... FROM a, OUTER (b)
  WHERE a.key = b.akey

SELECT ... FROM a, OUTER (b, OUTER (c))
  WHERE a.key = b.akey
  AND b.key1 = c.bkey1 AND b.key2 = c.bkey2
```

Informix® also supports the ANSI OUTER join syntax, which is the recommended way to specify outer joins with recent SQL database engines:

```
SELECT ... FROM cust LEFT OUTER JOIN order
  ON cust.key = order.custno
  WHERE ...
```

Netezza®
Netezza® supports the ANSI outer join syntax:

```
SELECT ...
FROM cust LEFT OUTER JOIN order
  LEFT OUTER JOIN item
  ON order.key = item.ordno
  ON cust.key = order.custno
WHERE order.cdate > current date
```

Solution
The Genero database drivers can convert Informix Informix® OUTER specifications to ANSI outer joins.

Note: For better SQL portability, use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The outer join translation can be controlled with the following FGLPROFILE entry:

```
  dbi.database.dsnname.ifxemulouters = \ttrue \tfalse
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

• Prerequisites:
  1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.

Example which does not work:

```
  ... FROM OUTER(tab2), tab1
```
2. The outer join in the WHERE clause must use the table name as prefix:

```
... WHERE tab1.col1 = tab2.col2
```

- **Restrictions:**
  1. Statements composed by 2 or more SELECT instructions are not supported:

```
SELECT ... UNION SELECT ...
```

or:

```
SELECT ... WHERE col IN (SELECT...)
```

2. Additional conditions on outer table columns cannot be detected and therefore are not supported:

```
... FROM tab1, OUTER(tab2)
WHERE tab1.col1 = tab2.col2
AND tab2.colx > 10
```

- **Notes:**
  1. Table aliases are detected in OUTER expressions.

```
OUTER example with table alias:

... OUTER(tab alias1) ...
```

  2. In the outer join, `outertab.col` can be placed on both right or left sides of the equal sign:

```
... WHERE outertab.col1 = maintab.col2
```

  3. Table names detection is not case-sensitive:

```
SELECT ... FROM tab1, TAB2
WHERE tab1.col1 = tab2.col2
```

  4. **Temporary tables** are supported in OUTER specifications:

```
CREATE TEMP TABLE tt1 ( ... )
SELECT ... FROM tab1, OUTER(tt1) ... 
```

**Related concepts**

- Outer joins on page 577

Use standard ISO outer join syntax instead of the old IBM® Informix® OUTER() syntax.

**Transactions handling**

**Informix®**

With the Informix® native mode (non ANSI):

- Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```
UPDATE tab1 SET ...   -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK           -- end of TX block
```
Informix® version 11.50 introduces savepoints:

```sql
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name] 
RELEASE SAVEPOINT name
```

**Netezza®**

- Transactions are started with `BEGIN WORK`.
- Transactions are validated with `COMMIT WORK`.
- Transactions are canceled with `ROLLBACK WORK`.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.
- If an SQL error occurs in a transaction, the whole transaction is aborted.
- A transaction must only contain INSERTs if you want concurrent processes to insert rows at the same time (UPDATEs/DELETEs lock the whole table).
- Only the `SERIALIZABLE` isolation level is implemented by Netezza®.

Netezza® cancels the entire transaction if an SQL error occurs in one of the statements executed inside the transaction. The following code example illustrates this difference:

```sql
CREATE TABLE tab1 ( k INT PRIMARY KEY, c CHAR(10) )
WHENEVER ERROR CONTINUE
BEGIN WORK
INSERT INTO tab1 ( 1, 'abc' )
SELECT FROM unexisting WHERE key = 123   -- unexisting table = sql error
COMMIT WORK
```

With Informix®, the above code will leave the table with one row inside, since the first INSERT statement succeeded. With Netezza®, the table will remain empty after executing this piece of code, because the server will rollback the whole transaction.

**Solution**

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with Netezza®: Informix® transaction handling commands are automatically converted to Netezza® instructions to start, validate or cancel transactions. However, since Netezza® is not designed for OLTP applications, you must review any code doing complex data modifications. See the concurrency topic for more details.

You must review the SQL statements inside `BEGIN WORK / COMMIT WORK` instruction and check if these can raise an SQL error. To get the same behavior in case of error when connected to a different database than Netezza®, you must issue a `ROLLBACK` to cancel all the SQL statements that succeeded in the transaction, for example with a `TRY/CATCH` block.

```sql
TRY
    BEGIN WORK
    ...
    COMMIT WORK
CATCH
    ROLLBACK WORK
END TRY
```

**Related concepts**

Database transactions on page 538
Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Temporary tables**

**Informix®**

Informix® temporary tables are created with the `CREATE TEMP TABLE` DDL instruction or with `SELECT ... INTO TEMP` statement:

```sql
CREATE TEMP TABLE tt1 ( pkey INT, name VARCHAR(50) )
CREATE TEMP TABLE tt2 ( pkey INT, name VARCHAR(50) ) WITH NO LOG
SELECT * FROM tab1 WHERE pkey > 100 INTO TEMP tt2
```

Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the `DROP TABLE` command. There is no name conflict when several users create temporary tables with the same name.

BDL REPORTs can create a temporary table when the rows are not sorted externally (by the source SQL statement).

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

When creating temporary tables in Informix®, the `WITH NO LOG` clause can be used to avoid the overhead of recording DML operations in transaction logs.

**Netezza®**

Netezza® support temporary tables as Informix®, with a little syntax difference in the `SELECT INTO TEMP` instruction:

```sql
SELECT * INTO TEMP temptab FROM source
```

**Solution**

Temporary tables are well supported with native Netezza® temp tables.

The general `FGLPROFILE` entry to control temporary table emulation is:

```conf
dbi.database.dsname.ifxemul.temptables = true | false
```

For more details see IBM Informix emulation parameters in `FGLPROFILE` on page 614.

**Related concepts**

Temporary tables on page 575

Syntax for temporary table creation is not unique across all database engines.

**Substrings in SQL**

**Informix®**

Informix® SQL statements can use subscripts on columns defined with the character data type:

```sql
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R' -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

**Important:** With other database servers as Informix®, when the subscript notation is used to modify column values in `UPDATE` statement, or as `ORDER BY` element, you will get SQL error:

```sql
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
```
SELECT ... FROM tab1 ORDER BY col1[1,3]

**Netezza**

Netezza® provides the `SUBSTRING( ... from ... to ... )` function, to extract a substring from a string expression:

```sql
SELECT .... FROM tab1 WHERE SUBSTRING(col1 from 2 for 2) = 'RO'
SELECT SUBSTRING('Some text' from 6 for 3) ... -- Gives 'tex'
```

**Solution**

Replace all Informix® `col[x,y]` right-value expressions by `SUBSTRING( col from x for (y-x+1) )`.
Rewrite `UPDATE` and `ORDER BY` clauses using `col[x,y]` expressions.

The translation of `col[x,y]` expressions can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsnname.ifxemul.colsubs = | true | false 
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Substring expressions on page 577
Handle substrings expressions with different database engines.

**The LENGTH() function**

**Informix**

Informix® provides the `LENGTH()` function to count the number of bytes of a character string expression:

```sql
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```

Informix® `LENGTH()` does not count the trailing blanks for CHAR or VARCHAR expressions, while Oracle counts the trailing blanks.

Informix® `LENGTH()` returns 0 when the given string is empty. That means, `LENGTH('')=0`.

**Netezza**

Netezza® supports `LENGTH()` and `CHARACTER_LENGTH()` functions, but these count the number of characters (not bytes), and trailing blanks are significant.

The Netezza `LENGTH()` function ignores trailing blanks.
Netezza returns NULL if the `LENGTH()` parameter is NULL.

**Solution**

Review the program logic and make sure you do not pass NULL values to the `LENGTH()` SQL function.

The translation of `LENGTH()` expressions can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsnname.ifxemul.length = | true | false 
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

The `LENGTH()` function in SQL on page 581
The semantics of the LENGTH() SQL function differs according to the database engine.

**Name resolution of SQL objects**

**Informix®**

Informix® uses the following form to identify an SQL object:

```
database[@dbservername]:[[{owner}|"owner"].]identifier
```

The ANSI convention is to use double quotes for identifier delimiters (For example: "customer"."cust_name").

Informix® database object names are not case-sensitive in non-ANSI databases. When using double-quoted identifiers, Informix® becomes case sensitive.

With non-ANSI Informix® databases, you do not have to give a schema name before the tables when executing an SQL statement:

```
SELECT ... FROM customer WHERE ...
```

In Informix® ANSI compliant databases:

- The table name must include "owner", unless the connected user is the owner of the database object.
- The database server shifts the owner name to uppercase letters before the statement executes, unless the owner name is enclosed in double quotes.

**Netezza®**

With Netezza®, an object name takes the following form:

```
[database.[schema].]identifier
```

**Solution**

As a general rule, to write portable SQL, it is recommended that you only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

**String delimiters**

**Informix®**

The ANSI SQL string delimiter character is the single quote (‘string’), while double quotes are used to delimit database object names:

```
SELECT ... WHERE "tabname"."colname" = 'a string value'
```

In Informix® databases created in native mode (non-ANSI), you can use double quotes as string delimiters:

```
SELECT ... WHERE tabname.colname = 'a string value'
```

This is important, since many BDL programs use that character to delimit the strings in SQL commands.

**Note:** This problem concerns only double quotes within SQL statements. Double quotes used in pure BDL string expressions are not subject to SQL compatibility problems.

**Netezza®**

Netezza® follows the ANSI SQL specification, using single quotes for string delimiters and double quotes for database object names.
Solution

When using Static SQL statements, the fglcomp compiler converts string literals using double quotes to string literals with single quotes:

```
$ cat s.4gl
MAIN
  DEFINE n INT
  SELECT COUNT(*) INTO n FROM tab1 WHERE col1 = "abc"
END MAIN

$ fglcomp -S s.4gl
s.4gl^3^SELECT COUNT(*) FROM tab1 WHERE col1 = 'abc'
```

However, SQL statements created dynamically are not modified by the Genero compiler.

The Genero database interface can automatically replace all double quotes by single quotes in SQL statements. This applies to static and dynamic SQL statements.

The translation of double quoted expression to single quoted expressions can be controlled with the following FGLPROFILE entry:

```
dbi.database.dbname.ifxemul.dblquotes = [ true | false ]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

However, database object names must not be delimited by double quotes, because the database interface cannot determine the difference between a database object name and a quoted string! For example, if the program executes the SQL statement:

```
... WHERE "tabname"."colname" = "a string value"
```

replacing all double quotes by single quotes would produce:

```
... WHERE 'tabname'.'colname' = 'a string value'
```

This would produce an error since 'tabname'.colname' is not allowed by ORACLE.

Escaped string delimiters can be used inside strings like the following:

```
'This is a single quote: ''
'This is a single quote: \\
"This is a double quote: ""
"This is a double quote: ""
```

Although double quotes are replaced automatically in SQL statements, it is recommended that you use only single quotes to enforce portability.

Related concepts

String literals in SQL statements on page 570
Single quotes is the standard for delimiting string literals in SQL.

MATCHES and LIKE

Informix

Informix® supports MATCHES and LIKE operators in SQL statements.

MATCHES expects * and ? wild-card characters, while LIKE uses the % and _ wild-cards as equivalents.

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
```
MATCHES accepts also brackets notation, to specify a set of matching characters at a given position:

( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )

**Netezza**

Netezza® does not provide an equivalent of the Informix® MATCHES operator.

The LIKE operator is supported.

The Netezza® ~ operator expects regular expressions as follows: ( col ~ 'a.*' )

**Important:** With Netezza®, columns defined as CHAR(N) are blank padded, and trailing blanks are significant in the LIKE expressions. As result, with a CHAR(5) value such as 'abc ' (with 2 trailing blanks), the expression (colname LIKE 'ab_') will not match. To workaround this behavior, you can do (RTRIM(colname) LIKE 'pattern'). However, consider adding the condition AND (colname LIKE 'pattern%') to force the DB server to optimize the query of the column is indexed. The CONSTRUCT instruction uses this technique when the entered criteria does not end with a * star wildcard.

**Solution**

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.

The MATCHES to LIKE expression translation is controlled by the following FGLPROFILE entry:

```sql
dbi.database.dbname.ifxemul.matches = [ true | false ]
```

**Important:** Only [NOT] MATCHES followed by a search pattern provided as a string literal can be converted by ODI drivers. A [NOT] MATCHES followed by a ? question mark parameter place holder is not translated!

For maximum portability, consider replacing the MATCHES expressions with LIKE expressions in all SQL statements.

Avoid using CHAR(N) types for variable length character data (such as name, address).

**Related concepts**

MATCHES and LIKE operators on page 579

Use the standard LIKE operator instead of the MATCHES operator.

**BDL programming**

IBM® Netezza® related programming topics.

**UPDATE limitations in Netezza**

Netezza® has some limitations regarding the UPDATE statement:

- Like DELETE, an UPDATE statement locks the entire table.
- It is not possible to UPDATE distribution columns:
  - Netezza® database tables get distributed across all of the nodes using the distribution column. You can specify the distribution column(s) when you create the table. See Netezza® documentation for more details.
  - If you try to update a distribution column, you get error 46 "Attempt to UPDATE a distribution column".

**Solution**

Review the program logic if the UPDATE statements in your programs use distribution columns, and keep in mind that an UPDATE will lock the entire table.
**INSERT cursors**

**Informix**
Informix® provides *insert cursors* to optimize row creation in a database. An insert cursor is declared as a cursor, and rows as added with the **PUT** instruction. The rows are buffered and sent to the database server when executing a **FLUSH** instruction, or when the cursor is closed with **CLOSE**. When using transactions in Informix®, the **OPEN**, **PUT** and **FLUSH** instructions must be executed within a transaction block.

```
DECLARE c1 CURSOR FOR INSERT INTO tab1 ...
BEGIN WORK
OPEN c1
WHILE ...
  PUT c1 USING var-list
END WHILE
CLOSE c1
COMMIT WORK
```

**Netezza**
Netezza® does not support insert cursors.

**Solution**
Insert cursors are emulated by the database interface, using basic **INSERT** SQL instructions. The performances might be not as good as with Informix®, but the feature is fully supported.

**Related concepts**
- [Insert cursors](#) on page 569
- Using insert cursors with non-Informix databases.

**Cursors WITH HOLD**

**Informix**
Informix® closes opened cursors automatically when a transaction ends, unless the **WITH HOLD** option is used in the **DECLARE** instruction:

```
DECLARE c1 CURSOR WITH HOLD FOR SELECT ...
OPEN c1
BEGIN WORK
FETCH c1 ...
COMMIT WORK
FETCH c1 ...
CLOSE c1
```

**Netezza**
With Netezza®, cursors can be kept open when a transaction ends.

However, cursors declared with a **SELECT FOR UPDATE** are not supported with Netezza®.

**Solution**
Since **WITH HOLD** cursors are usually declared with **SELECT FOR UPDATE** and because Netezza® does not support **SELECT FOR UPDATE**, you must review the program logic if you are using cursors declared **WITH HOLD**.

**Related concepts**
- [WITH HOLD and FOR UPDATE](#) on page 568
Hold cursors and not portable.

**SELECT ... FOR UPDATE**

**Informix®**

Legacy BDL programs typically use a cursor with `SELECT FOR UPDATE` to implement pessimistic locking and avoid several users editing the same rows:

```sql
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

The row must be fetched in order to set the lock.

If the cursor is local to a transaction, the lock is released when the transaction ends. If the cursor is declared `WITH HOLD`, the lock is released when the cursor is closed.

**Informix®** provides the `SET LOCK MODE` instruction to define the lock wait timeout:

```sql
SET LOCK MODE TO { WAIT | NOT WAIT | WAIT seconds }
```

The default mode is `NOT WAIT`.

**Netezza®**

With Netezza®, locks are released when closing the cursor or when the transaction ends.

Netezza® does not support `SELECT FOR UPDATE` statements: Netezza® systems are designed for data warehouse applications, not for OLTP applications. In a DW context, concurrent data access is not required or a priority.

**Solution**

Review the program logic when using `SELECT FOR UPDATE` statements.

**Related concepts**

`WITH HOLD and FOR UPDATE` on page 568

Hold cursors and not portable.

**UPDATE/DELETE ... WHERE CURRENT OF**

**Informix®**

Informix® allows positioned UPDATEs and DELETEs with the "WHERE CURRENT OF cursor" clause, if the cursor has been DECLARED with a `SELECT ... FOR UPDATE` statement.

**Netezza®**

Netezza® servers do no support `SELECT FOR UPDATE`, and does not set locks.

Positioned UPDATE/DELETE with the WHERE CURRENT OF cursor clause cannot be supported with Netezza®.

**Solution**

Review the program logic and rewrite all positioned UPDATE/DELETE with a WHERE condition based on primary keys or rowids.
Related concepts
Positioned UPDATE/DELETE on page 567
Using positioned updates/deletes with named database cursors.

LOAD and UNLOAD

Informix®
Informix® provides two SQL instructions to export / import data from / into a database table:
The UNLOAD instruction copies rows from a database table into a text file:

```
UNLOAD TO "filename.unl" SELECT * FROM tab1 WHERE ..
```

The LOAD instructions insert rows from a text file into a database table:

```
LOAD FROM "filename.unl" INSERT INTO tab1
```

Netezza®
Netezza® does not support LOAD and UNLOAD instructions.
Netezza® provides tools like the nzload utility.

Solution
LOAD and UNLOAD instruction are implemented in the Genero BDL runtime system with basic INSERT (for LOAD) or SELECT (for UNLOAD) SQL commands. The LOAD and UNLOAD instruction can be supported with various database servers.

However, LOAD and UNLOAD require the description of the column types in order to work, that can lead to some differences in the data formatting.

Note: If no transaction is started, the LOAD instruction will automatically execute a BEGIN WORK and COMMIT WORK when finished, or ROLLBACK WORK if a row insertion failed while loading. Terminating a transaction will automatically close cursors not defined WITH HOLD option. To workaround this situation, see more details in the LOAD on page 684 reference topic.

The LOAD and UNLOAD BDL instructions are supported with Netezza®.

Related concepts
LOAD and UNLOAD instructions on page 574
The LOAD and UNLOAD instructions can produce different data formats depending on the database server type.

SQL Interruption

Informix®
With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

Netezza®
Netezza® supports SQL Interruption: The db client must issue an SQLCancel() ODBC call to interrupt a query.

Important: When the statement is interrupted, Netezza® issues an automatic ROLLBACK and returns a "Transaction rolled back by user", SQL error number 46.

Solution
The Netezza® database driver supports SQL interruption and converts the native SQL error 46 to the Informix® error code -213.
**Related concepts**

Using SQL interruption on page 539
Interrupt long running SQL queries, or interrupt queries waiting for locked data.

**Scrollable cursors**

**Informix®**

Informix® SQL and Genero BDL support scrollable cursors when you specify the SCROLL clause in the DECLARE cursor instruction:

```sql
DECLARE c1 SCROLL CURSOR FOR SELECT ...  
```

**Netezza®**

Netezza® does not support scrollable cursors.

**Solution**

The Netezza® database driver emulates scrollable cursors by fetching rows in a temporary file.

**Related concepts**

Scrollable cursors on page 560
How scrollable cursors can be supported on different databases.

**Microsoft™ SQL Server**

**Supported versions**

Genero BDL supports the following Microsoft SQL Server versions:

- Microsoft SQL Server 2008 (v10)
- Microsoft SQL Server 2012 (v11)
- Microsoft SQL Server 2014 (v12)
- Microsoft SQL Server 2016 (v13)
- Microsoft SQL Server 2017 (v14)

Genero BDL supports the following Microsoft Azure SQL Database versions:

- Microsoft Azure SQL Database v12

**Installation (Runtime Configuration)**

Microsoft™ SQL Server related installation topics.

Install Microsoft™ SQL Server and create a database - database configuration/design tasks

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. Install the Microsoft™ SQL Server on your computer.

   **Important:** Make sure that you select the correct collation when installing SQL Server: The default collation will apply to the tempdb database and will also be used for temporary tables, instead of inheriting the collation of the current database. If the default server collation does not match the collation of the current database, you will experience character set conflicts between permanent tables and temporary tables (SQL Server error message 468).

2. Create a SQL Server database entity with the SQL Server Management Studio.

   In the database properties:
   a) Choose the right code page / collation to get a case-sensitive database; this cannot be changed later.
Remember collation defines the character set for CHAR/VARCHAR columns, while NCHAR/NVARCHAR columns are always storing UNICODE (UCS-2) characters. Informix® collation order is a codeset base for CHAR/VARCHAR/TEXT columns. If you want to get the same sort order with SQL Server, you will need to use a binary collation such as Latin1_General_BIN.

b) Make sure the "ANSI NULL Default" option is true if you want to have the same default NULL constraint as in Informix® (a column created without a NULL constraint will allow null values, users must specify NOT NULL to deny nulls).

c) Make sure the "Quoted Identifiers Enabled" option is false to use database object names without quotes as in Informix®.

3. Create and declare a database user dedicated to your application: the application administrator.

4. If you plan to use SERIAL emulation based on triggers using a registration table, create the SERIALREG table and create the serial triggers for all tables using a SERIAL. See SERIAL data types on page 788.

5. Create the application tables.

Convert Informix® data types to SQL Server data types. See Data type conversion table: Informix to SQL Server on page 779. In order to make application tables visible to all users, make sure that the tables are created with the 'dbo' owner.

Prepare the runtime environment - connecting to the database

1. Genero BDL provides several database drivers based on different ODBC clients. This list describes each of them:

   • On Microsoft® Windows® platforms:
     - Use an SNC (dbmsnc*) driver either with the Microsoft ODBC driver for SQL Server, or with the Microsoft SQL Native Client driver:
       - For Microsoft ODBC 17 (MSODBCSQL17.DLL), use dbmsnc_17.
       - For Microsoft ODBC 13 (MSODBCSQL13.DLL), use dbmsnc_13.
       - For Microsoft SQL Native Client 11 (SQLNCLI11.DLL), use dbmsnc_11.
       - For Microsoft SQL Native Client 10 (SQLNCLI10.DLL), use dbmsnc_10.
       

       Important: Configure your ODBC data source to use the appropriate Microsoft SQL Server driver.

   • On Linux® platforms:
     - With the SNC (dbmsnc*) driver, use the Microsoft ODBC for SQL Server on Linux® client (msdn.microsoft.com):
       - For Microsoft ODBC 17 (libmsodbcsql-17.so), use dbmsnc_17.
       - For Microsoft ODBC 13 (libmsodbcsql-13.so), use dbmsnc_13.

       Minimum Microsoft ODBC for SQL Server on Linux® version: 13.0.

     - With the FTM (dbmftm*) driver, use the FreeTDS ODBC client (www.freetds.org).

       Minimum FreeTDS version: 1.00.

     - With the ESM (dbmesm*) driver, use the Easysoft ODBC driver for SQL Server (www.easysoft.com).

       Minimum Easysoft version 1.5; Version 1.9 is strongly recommended.

2. Check that the Genero distribution package has installed the SQL Server database driver you need. A "dbmsnc", "dbmftm", or "dbmesm" driver must exist in FGLDIR/dbdrivers.

3. An ODBC data source must be configured to allow the BDL program to establish connections to SQL Server. Make sure you select the correct ODBC driver (see step 1).

   Important: When using the FTM (FreeTDS) or ESM (EasySoft) database driver, you have to define the ODBCINI and ODBCINST environment variable to point to the odbc.ini and odbcinst.ini files.

4. Install and configure the database client software:
a) When using the SNC database driver on Windows®, you must have the "Microsoft ODBC for SQL Server" or "Microsoft SQL Native Client" software installed on the computer running Genero applications (see msdn.microsoft.com).

On Windows® platforms, as the SNC ODI driver uses ODBC32.DLL, there is no need to set the PATH environment variable to a specific database client library path.

On Windows®, the MS ODBC database client locale is defined by the Windows® regional settings of the application server and must match the BDL application locale (defined by LANG or LC_ALL). Character set conversion (current code set <=> Wide-Char) is done by the SNC ODI driver following the LANG environment variable. If the LANG environment variable is not defined, the application character set defaults to the ANSI code page (ACP).

On Linux® platforms, the dbmsnc_nn drivers are directly linked to the corresponding libmsodbcsql-<nn>.so ODBC driver library. There is no need to install the unixODBC software. The SNC drivers will be able to connect to SQL Server, as long as the dynamic linker can find the Microsoft ODBC driver library. The libmsodbcsql-<nn>.so shared library is a symbolic link located in /usr/lib64, which points to the real ODBC 13 shared library.

On Linux, the MS ODBC database client locale is always UTF-16: The dbmsnc ODI driver makes the required character set conversions between the BDL application locale (defined by LANG or LC_ALL) and UTF-16, for the Microsoft ODBC driver for SQL Server. Therefore, no ODBC configuration is required. You just need to set the application locale appropriately.

Unix ODBCINI sample for MS ODBC driver for SQL Server:

```
[snc_msvtest1_dirac_utf8]
Driver = /usr/lib64/libmsodbcsql-13.so
Description = SQL Server ODBC 13 / DIRAC SQL Server 2017 / v14
#Server = [protocol:]server[,port]
Server = tcp:dirac,1433
Database = msvtest1
### Always Encrypted (Column Encryption)
# ColumnEncryption = Enabled
### Transport encryption with SSL/TLS
# Encrypt = Yes/No
# TrustServerCertificate = xxx
# Trusted_Connection=yes
```

b) When using the FTM database driver, the FreeTDS driver must be installed (see www.freetds.org). There is no need to install unixODBC: The FTM driver is directly linked to libtdsodbc.so.0.

Make sure the FreeTDS environment variables are properly set. Check for example FREETDS (the path to the configuration file). See FreeTDS documentation for more details.

With the FTM driver, there is no need to install a driver manager like unixODBC: The FTM database driver is linked directly with the libtdsodbc.so shared library. Verify the environment variable (LD_LIBRARY_PATH or equivalent) specifies the search path for that database client shared library.

You must create the odbc.ini and odbcinst.ini files to defined the data source.

Define the client character set for FreeTDS (client charset parameter in freetds.conf or ClientCharset parameter in odbc.ini). You may need to link FreeTDS with the libiconv library to support character set conversions.

Important: You must set the TDS protocol version depending on the SQL Server version (2008, etc), by setting the tds_version parameter in freetds.conf or TDS_Version in odbc.ini. For example, for SQL Server version 2008, 2012 and 2014, use TDS_Version=7.3.

Unix ODBCINI sample for FreeTDS driver:

```
[ftm_msvtest1_ida_utf8_2017]
Description = SQL Server 2017
```
c) When using the ESM database driver, the EasySoft ODBC driver for SQL Server must be installed (see www.easysoft.com). There is no need to install unixODBC. The ESM driver is directly linked to \texttt{libessqlsrv.so}.

Make sure the EasySoft environment variables are properly set. Check for example \texttt{EASYSOFT_ROOT} (the path to the installation directory). See FreeTDS documentation for more details.

With the ESM driver, there is no need to install a driver manager like unixODBC. The ESM database driver is linked directly with the \texttt{libessqlsrv.so} shared library. Verify the environment variable (\texttt{LD_LIBRARY_PATH} or equivalent) specifies the search path for that database client shared library.

You must create the \texttt{odbc.ini} and \texttt{odbcinst.ini} files to define the data source.

Define the client character set for EasySoft with the \texttt{Client_CSet} parameter in \texttt{odbc.ini}. The client character set is an iconv name and must match the locale of your Genero application.

\textbf{Note:} To support all UNICODE characters when using UTF-8 with \texttt{NCHAR/NVARCHAR} columns, you need to define \texttt{Client_CSet=UTF-8} and \texttt{Server_UCSet=UTF-16LE}.

When using \texttt{CHAR/VARCHAR} types in the database and when the database collation is different from the client locale, you must also set the \texttt{Server_CSet} parameter to an iconv name corresponding to the database collation. For example, if \texttt{Client_CSet=BIG5} and the db collation is \texttt{Chinese_Taiwan_Stroke_BIN}, you must set \texttt{Server_CSet=BIG5HKSCS}, otherwise invalid data will be returned from the server.

You must also set the following DSN parameters:

\begin{itemize}
  \item \texttt{AnsiNPW=Yes}
  \item \texttt{Mars_Connection=No}
  \item \texttt{QuotedId=No}
\end{itemize}

\textbf{UNIX® ODBCINI sample for EasySoft ODBC for SQL Server driver:}

```ini
[esm_msvtest1_ida_utf8_2017]
Driver=Easysoft ODBC-SQL Server
Description=Easysoft SQL Server ODBC driver
Server=ida
Port=1683
Database=msvtest1
Mars_Connection=No
Logging=No
LogFile=/tmp/odbc.log
#QuotedId=No
AnsiNPW=Yes
Language=
Version?=No
ClientLB=No
Failover_Partner=
VarMaxAsLong=No
DisguiseWide=No
DisguiseLong=No
Trusted_Connection=No
Trusted_Domain=
IPv6=No
```
5. On Windows® platforms, BDL programs are executed in a CONSOLE environment, not a GUI environment. CONSOLE and GUI environments may use different code pages on your system. Start the "SQL Server Configuration Manager" to setup your client environment and make sure no wrong character conversion occurs. See Microsoft™ SQL Server documentation for more details.

6. Set up the fgprofile entries for database connections.
   a) Define the SQL Server database driver according to the database client used:

   ```
   dbi.database.dbname.driver = [ "dbmsnc" | "dbmesm" | "dbmftm" ]
   ```
   b) The "source" parameter defines the name of the ODBC source.

   ```
   dbi.database.dbname.source = "test1"
   ```
   c) With the SNC driver, set the snc.widechar fgprofile parameter to false, if database columns are defined with the CHAR/VARCHAR/TEXT SQL types, and your application is using a non-UTF-8, multi-byte encoding (typically with BIG5). When using ISO8859-? or UTF-8, do not set this parameter: The expected char mode will be used, depending on the current application locale. See CHAR and VARCHAR data types on page 780 for more details.

   ```
   dbi.database.dbname.snc.widechar = false
   ```
   d) If required, define the serial emulation method to "trigseq", when the INSERT statements use all columns of the table, including the serial column. For more details, see SERIAL data types on page 788.

   ```
   dbi.database.dbname.ifxemul.datatype.serial.emulation = "trigseq"
   ```
   e) If needed, define the login timeout with the following FGLPROFILE entry:

   ```
   dbi.database.stores.driver-code.logintime = 5
   ```
   f) If needed, define the number of rows to be fetched at once on the application side, for each single FETCH instruction:

   ```
   dbi.database.stores.driver-code.prefetch.rows = 50
   ```

   **Note:** The default is 10 rows. This is usually sufficient for regular interactive applications. Increase this parameter only in case of batch programs processing large result sets. The bigger this parameter is, the more memory is used by each program.

g) If needed, add ODBC connection string parameters with the `?options` notation, in the `source` parameter of the connection. You can for example define the SQL client application identifier for SQL Server.

   ```
   dbi.database.dbname.source = "test1?APP=myappid;"
   ```

   **Note:** The `source` parameter can also be defined at runtime in the database specification of CONNECT TO instruction.

**Database concepts**

Microsoft™ SQL Server related database concepts topics.

**Database concepts**

As in Informix®, an SQL SERVER engine can manage multiple database entities. When creating a database object like a table, Microsoft™ SQL SERVER allows you to use the same object name in different databases.
Data storage concepts

When converting from Informix® to Microsoft™ SQL Server the aim is to try to preserve as much of the data storage information as possible in the process. The most important storage decisions made for Informix® database objects (like initial sizes and physical placement) can be applied to the SQL Server database.

Storage concepts are quite similar in Informix® and in Microsoft™ SQL Server, but the names are different.

These table compares Informix® storage concepts to Microsoft™ SQL SERVER storage concepts:

**Table 203: Physical units of storage**

<table>
<thead>
<tr>
<th>Informix®</th>
<th>Microsoft™ SQL SERVER</th>
</tr>
</thead>
<tbody>
<tr>
<td>The largest unit of physical disk space is a &quot;chunk&quot;, which can be allocated either as a cooked file (I/O is controlled by the OS) or as raw device (= UNIX™ partition, I/O is controlled by the database engine). A &quot;dbspace&quot; uses at least one &quot;chunk&quot; for storage. You must add &quot;chunks&quot; to &quot;dbspaces&quot; in order to increase the size of the logical unit of storage. A &quot;page&quot; is the smallest physical unit of disk storage that the engine uses to read from and write to databases. A &quot;chunk&quot; contains a certain number of &quot;pages&quot;. The size of a &quot;page&quot; must be equal to the operating system's block size. An &quot;extent&quot; consists of a collection of continuous &quot;pages&quot; that the engine uses to allocate both initial and subsequent storage space for database tables. When creating a table, you can specify the first extent size and the size of future extents with the EXTENT SIZE and NEXT EXTENT options. For a single table, &quot;extents&quot; can be located in different &quot;chunks&quot; of the same &quot;dbspace&quot;.</td>
<td>SQL Server uses &quot;filegroups&quot;, based on Windows NT™ operating system files and therefore define the physical location of data. As in Informix®, SQL Server stores data in &quot;pages&quot; with a size fixed at 2Kb in V6.5 and 8Kb in V7 and later. An &quot;extent&quot; is a specific number of 8 contiguous pages, obtained in a single allocation. Extents are allocated in the filegroup used by the database.</td>
</tr>
</tbody>
</table>

**Table 204: Logical units of storage**

<table>
<thead>
<tr>
<th>Informix®</th>
<th>Microsoft™ SQL SERVER</th>
</tr>
</thead>
<tbody>
<tr>
<td>A &quot;table&quot; is a logical unit of storage that contains rows of data values. A &quot;database&quot; is a logical unit of storage that contains table and index data. Each database also contains a system catalog that tracks information about database elements like tables, indexes, stored procedures, integrity constraints and user privileges. Database tables are created in a specific &quot;dbspace&quot;, which defines a logical place to store data. If no dbspace is given when creating the table, Informix® defaults to the current database dbspace.</td>
<td>Same concept as Informix®. Same concept as Informix®. When creating a &quot;database&quot;, you must specify which &quot;database devices&quot; (V6.5) or &quot;filegroup&quot; (V7) has to be used for physical storage. Database tables are created in a database based on &quot;database devices&quot; (V6.5) or a &quot;filegroup&quot; (V7), which defines the physical storage.</td>
</tr>
</tbody>
</table>
Informix® | Microsoft™ SQL SERVER
--- | ---
The total disk space allocated for a table is the "tblspace", which includes "pages" allocated for data, indexes, blobs, tracking page usage within table extents. | No equivalent.

Table 205: Other concepts relating to storage

<table>
<thead>
<tr>
<th>Informix®</th>
<th>Microsoft™ SQL SERVER</th>
</tr>
</thead>
<tbody>
<tr>
<td>When initializing an Informix® engine, a &quot;root dbspace&quot; is created to store information about all databases, including storage information (chunks used, other dbspaces, etc.).</td>
<td>SQL Server uses the &quot;master&quot; database to hold system stored procedures, system messages, SQL Server logins, current activity information, configuration parameters of other databases.</td>
</tr>
<tr>
<td>The &quot;physical log&quot; is a set of continuous disk pages where the engine stores &quot;before-images&quot; of data that has been modified during processing.</td>
<td>Each database has its own &quot;transaction log&quot; that records all changes to the database. The &quot;transaction log&quot; is based on a &quot;database device&quot; (V6.5) or &quot;filegroup&quot; (V7) which is specified when creating the database.</td>
</tr>
<tr>
<td>The &quot;logical log&quot; is a set of &quot;logical-log files&quot; used to record logical operations during on-line processing. All transaction information is stored in the logical log files if a database has been created with transaction log.</td>
<td>SQL Server checks the &quot;transaction logs&quot; for automatic recovery.</td>
</tr>
<tr>
<td>Informix® combines &quot;physical log&quot; and &quot;logical log&quot; information when doing fast recovery. Saved &quot;logical logs&quot; can be used to restore a database from tape.</td>
<td></td>
</tr>
</tbody>
</table>

Concurrent management

Data consistency and concurrency concepts

- **Data Consistency** applies to situations when readers want to access data currently being modified by writers.
- **Concurrent Data Access** applies to situations when several writers are accessing the same data for modification.
- **Locking Granularity** defines the amount of data concerned when a lock is set (for example, row, page, table).

**Informix®**

Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with UPDATE, INSERT or DELETE, an **exclusive lock** is set on the touched rows. The lock remains active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set **shared locks**, depending on **isolation level**. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification, or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the **lock wait mode**.

Control:

- **Lock wait mode**: SET LOCK MODE TO ...
- **Isolation level**: SET ISOLATION TO ...
- **Locking granularity**: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- **Explicit exclusive lock**: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is **READ COMMITTED**.
- The default lock wait mode is **NOT WAIT**.
- The default locking granularity is **PAGE**.
Microsoft™ SQL Server

As in Informix®, SQL Server uses locks to manage data consistency and concurrency. The database manager sets exclusive locks on the modified rows and shared locks or update locks when data is read, based on the isolation level. The locks are held until the end of the transaction. When multiple processes want to access the same data, the latest processes must wait until the first finishes its transaction or the lock timeout occurs. The locking strategy of SQL Server is row locking with possible promotion to page or table locking. SQL Server dynamically determines the appropriate level at which to place locks for each Transact-SQL statement.

SQL Server supports snapshot isolation level, to force using a copy of the row when it is changed by a transaction. To turn this feature on, you must set the database property ALLOW_SNAPSHOT_ISOLATION ON. Setting the READ_COMMITTED_SNAPSHOT ON option allows access to versioned rows under the default READ COMMITTED isolation level (otherwise, snapshot isolation must be specified by every SQL Session).

Control:

- Lock wait mode: SET LOCK_TIMEOUT milliseconds (returns error 1222 on time out).
- Isolation level: SET TRANSACTION ISOLATION LEVEL ...
- Locking granularity: Row, Page, or Table level (Automatic - See Dynamic Locking).
- Explicit locking: SELECT ... FROM ... WITH (UPDLOCK) (See Locking Hints)

Defaults:

- The default isolation level is READ COMMITTED (readers cannot see uncommitted data).
- The default LOCK_TIMEOUT is -1 (indicates no timeout period, wait forever).

Solution

The SET ISOLATION TO ... in programs is converted to SET TRANSACTION ISOLATION LEVEL ... for SQL Server. The table shows the isolation level mappings applied by the database driver:

<table>
<thead>
<tr>
<th>SET ISOLATION instruction in program</th>
<th>Native SQL command</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET ISOLATION TO DIRTY READ</td>
<td>SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED</td>
</tr>
<tr>
<td>SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]</td>
<td>SET TRANSACTION ISOLATION LEVEL READ COMMITTED</td>
</tr>
<tr>
<td>SET ISOLATION TO CURSOR STABILITY</td>
<td>SET TRANSACTION ISOLATION LEVEL REPEATABLE READ</td>
</tr>
<tr>
<td>SET ISOLATION TO REPEATABLE READ</td>
<td>SET TRANSACTION ISOLATION LEVEL SERIALizable</td>
</tr>
</tbody>
</table>

For portability, it is recommended that you work with Informix® in the read committed isolation level, to make processes wait for each other (lock mode wait) and to create tables with the "lock mode row" option.

When using SET LOCK MODE ... in the programs, it will be converted to a SET LOCK_TIMEOUT instruction for SQL Server:

<table>
<thead>
<tr>
<th>SET LOCK MODE instruction in program</th>
<th>Native SQL command</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET LOCK MODE TO WAIT</td>
<td>SET LOCK_TIMEOUT -1 (wait forever)</td>
</tr>
<tr>
<td>SET LOCK MODE TO WAIT seconds</td>
<td>SET LOCK_TIMEOUT (seconds*1000) (wait N milliseconds)</td>
</tr>
<tr>
<td>SET LOCK MODE instruction in program</td>
<td>Native SQL command</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>SET LOCK MODE TO NOT WAIT</td>
<td>SET LOCK_TIMEOUT 0 (do not wait)</td>
</tr>
</tbody>
</table>

See Informix® and SQL Server documentation for more details about data consistency, concurrency and locking mechanisms.

**Related concepts**

- **Concurrent data access** on page 537
  Understanding concurrent data access and data consistency.

- **Optimistic locking** on page 561
  Implementing optimistic locking to handle access concurrently to the same database records.

- **WITH HOLD and FOR UPDATE** on page 568
  Hold cursors and not portable.

**Transactions handling**

**Informix®**

With the Informix® native mode (non ANSI):

- Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```sql
UPDATE tab1 SET ...   -- auto-committed
BEGIN WORK            -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK           -- end of TX block
```

Informix® version 11.50 introduces savepoints:

- `SAVEPOINT name [UNIQUE]`
- `ROLLBACK WORK TO SAVEPOINT name`
- `RELEASE SAVEPOINT name`

**Microsoft™ SQL Server**

Microsoft™ SQL Server supports named and nested transactions:

- Transactions are started with `BEGIN TRANSACTION [name]`.
- Transactions are validated with `COMMIT TRANSACTION [name]`.
- Transactions are canceled with `ROLLBACK TRANSACTION [name]`.
- Savepoints can be placed with `SAVE TRANSACTION name`.
- Transactions can be rolled back to a savepoint with `ROLLBACK TRANSACTION TO name`.
- Savepoints can not be released.
- Statements executed outside of a transaction are automatically committed (autocommit mode). This behavior can be changed with "SET IMPLICIT_TRANSACTION ON".
- DDL statements are not supported in transactions blocks.

**Solution**

Informix® transaction handling commands are automatically converted to Microsoft™ SQL Server instructions to start, validate or cancel transactions.
Regarding the transaction control instructions, the BDL applications do not have to be modified to work with Microsoft™ SQL Server.

**Important:** If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

**Related concepts**
- **Database transactions** on page 538
  Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Database users**

**Informix®**

Until version 11.70.xC2, Informix® database users must be created at the operating system level and must be members of the 'informix' group.

Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as in most other db servers.

Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.

**Microsoft™ SQL Server**

Before a user can access an SQL Server database, the system administrator (SA) must add the user's login to the SQL Server Login list and add a user name for that database. The user name is a name that is assigned to a login ID for the purpose of allowing that user to access a specified database. Database users are members of a user group; the default group is 'public'.

Microsoft™ SQL Server offers two authentication modes:

1. The **SQL Server authentication mode**, which requires a login name and a password
2. The **Windows™ authentication mode**, which uses the security mechanisms within Windows™ when validating login connections. With this mode, user do not have to enter a login ID and password - their login information is taken directly from the network connection.

**Solution**

Both SQL Server and Windows™ authentication methods can be used to allow BDL program users to connect to Microsoft™ SQL Server and access a specific database.

If you don't specify the USER/USING clause in the CONNECT TO instruction, operating system authentication takes place.

See SQL Server documentation for more details on database logins and users.

**Related concepts**
- **Database users and security** on page 547
  Properly identifying database users allows to use database security and audit features.

**Setting privileges**

**Informix®**

Informix® users must have at least the CONNECT privilege to access the database:

```
GRANT CONNECT TO username
```
Application administration users need the RESOURCE privilege to create tables:

```
GRANT RESOURCE TO username
```

Since version 7.20, Informix® supports database roles:

```
GRANT rolename TO username
```

**Microsoft™ SQL Server**

Microsoft™ SQL Server supports *user groups*, to grant or revoke permissions to more than one user at the same time. See SQL Server documentation for more details.

**Solution**

Informix® and Microsoft™ SQL Server user privileges management are quite similar.

**Data dictionary**

<td>VARCHAR(MAX)</td>
</tr>
<tr>
<td>BYTE</td>
<td>VARBINARY(MAX)</td>
</tr>
</tbody>
</table>

### Notes:

1. For more details about serial emulation, see SERIAL data types on page 788.

### BOOLEAN data type

**Informix®**

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values.

Genero BDL implements the BOOLEAN data type in a different way: A BOOLEAN variable stores integer values 1 or 0 (for TRUE or FALSE). This type is designed to hold the result of a boolean expression.

**Microsoft™ SQL Server**

Microsoft™ SQL Server supports the BIT data type to store boolean values.

### Solution

The SQL Server database interfaces converts BOOLEAN type to BIT columns and stores 1 or 0 values in the column. The BOOLEAN type translation can be controlled with the following FGLPROFILE entry:

```
   dbi.database.dsname.ifxemul.datatype.boolean = \{ true \ false \}
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

### Related concepts

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

### CHAR and VARCHAR data types

**Informix®**

Informix® supports the following character data types:

#### Table 209: Informix® character data types

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR(n)</td>
<td>SBCS and MBCS character data (max is 32767 bytes)</td>
</tr>
<tr>
<td>VARCHAR(n, m)</td>
<td>SBCS and MBCS character data (max is 255 bytes)</td>
</tr>
<tr>
<td>Informix® data type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>NCHAR ((n))</td>
<td>Same as CHAR, with specific collation order</td>
</tr>
<tr>
<td>NVARCHAR ((n, m))</td>
<td>Same as VARCHAR, with specific collation order</td>
</tr>
<tr>
<td>LVARCHAR ((n))</td>
<td>Max size varies depending on the IDS version</td>
</tr>
</tbody>
</table>

With Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is in how they use sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order.

The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable.

The character set used by applications is defined by the CLIENT_LOCALE environment variable.

Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR \((N)\) is expressed in bytes, not characters as in some other databases)

**Microsoft™ SQL Server**

Microsoft™ SQL Server supports following data types to store character data:

**Table 210: Microsoft™ SQL Server character data types**

<table>
<thead>
<tr>
<th>Microsoft™ SQL Server data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR ((n))</td>
<td>SBCS or MBCS character data using the database character set, where (n) is specified in bytes (max is 8000 bytes)</td>
</tr>
<tr>
<td>VARCHAR ((n))</td>
<td>SBCS or MBCS character data using the database character set, where (n) is specified in bytes (max is 8000 bytes)</td>
</tr>
<tr>
<td>VARCHAR ((MAX))</td>
<td>SBCS or MBCS character data using the database character set, to store large text data (max is (2^{31}-1) bytes)</td>
</tr>
<tr>
<td>NCHAR ((n))</td>
<td>Unicode/UCS-2 character data, where (n) is specified in characters (max is 4000 characters)</td>
</tr>
<tr>
<td>NVARCHAR ((n))</td>
<td>Unicode/UCS-2 character data, where (n) is specified in characters (max is 4000 characters)</td>
</tr>
<tr>
<td>NVARCHAR ((MAX))</td>
<td>Unicode/UCS-2 character data, to store large text data (max is (2^{31}-1) bytes)</td>
</tr>
</tbody>
</table>

**Note:** To store large text data (LOBs), Microsoft™ SQL Server (2005) provides the VARCHAR \((MAX)\)/NVARCHAR \((MAX)\) type as a replacement for the old TEXT/TEXT types. See TEXT and BYTE (LOB) types on page 795 for more details.

The use of NCHAR, NVARCHAR character types is the same as CHAR, VARCHAR respectively, except:

- The encoding is UCS-2 (an UTF-16 subset).
- The length \(N\) in N[VAR]CHAR \((N)\) defines a number of characters, not bytes.
- Since each character occupies 2 bytes, twice the space is needed to store the same strings as with CHAR/VARCHAR.
- The maximum size of NCHAR \((N)\) and NVARCHAR \((N)\) column is 4000 characters, compared to 8000 chars for CHAR/VARCHAR using a single-byte character set.
- Unicode string literals are specified with a leading N. For example: N’###’
- The LIKE statement behaves differently with CHAR and NCHAR columns when using the N prefix before the search pattern.

Note that SQL Server uses Byte Length Semantics to define the size of CHAR/VARCHAR columns, while NCHAR and NVARCHAR sizes are expressed in character units.
SQL Server defines the character encoding for `CHAR` and `VARCHAR` columns with the database collation. The database collation can be specified when creating a new database. Character strings are always stored in the UCS-2 encoding for `NCHAR/NVARCHAR` columns.

Automatic charset conversion is supported by SQL Server between the client application and the server. The client charset is defined by the Windows® operating system, in the language settings for non-Unicode applications.

**Solution**

Depending on the character set used by your application, you must either use `CHAR/VARCHAR` or `NCHAR/NVARCHAR` columns with SQL Server. If the charset is single-byte, you can use `CHAR/VARCHAR` columns. If the charset set is multibyte or Unicode (i.e. UTF-8), you must use `NCHAR/NVARCHAR` columns in SQL Server.

See also the section about Localization.

Make sure that the regional language settings for non-Unicode applications corresponds to the locale used by Genero programs.

Check that your database tables does not use `CHAR` or `VARCHAR` types with a length exceeding the SQL Server limit.

When using a multibyte character set (such as UTF-8), define database columns as `NCHAR` and `NVARCHAR`, with the size in character units, and use character length semantics in BDL programs with `FGL_LENGTH_SEMANTICS=CHAR`.

When extracting a database schema from a SQL Server database, the `fgldbsch` schema extractor uses the size of the column in characters, not the octet length. If you have created a `NCHAR(10)` column in an SQL Server database, the `.sch` file will get a size of 10, that will be interpreted by `FGL_LENGTH_SEMANTICS` as a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

The `CHAR/VARCHAR` type translation can be controlled with the following FGLPROFILE entries:

```
  dbi.database.dsname.ifxemul.datatype.char = [true | false]
  dbi.database.dsname.ifxemul.datatype.varchar = [true | false]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Using the SNC driver**

The SNC driver can work in `char` or in `wide-char` mode:

The `char` mode must be used with applications defining database columns with `CHAR/VARCHAR/TEXT` types. It is not mandatory (i.e. the `wide-char` mode could be used), but it appears that SQL Server performs better, when `char` bindings are used for `CHAR/VARCHAR/TEXT` columns. In `char` mode, the SNC driver binds SQL parameters (SQLBindParameter) with the `SQL_CHAR/SQL_VARCHAR` ODBC SQL types. When defining `CHAR(N)/VARCHAR(N)` columns in SQL Server, you specify N as a number of bytes. Therefore, it is recommended that you use byte length semantics in Genero programs, with `FGL_LENGTH_SEMANTICS=BYTE` (this is the default).

The `wide-char` mode must be used for applications defining database columns with `NCHAR/NVARCHAR/NTEXT` types. These SQL types are used to store UNICODE data. In such case, the runtime system must use a UTF-8 locale, with character length semantics (`FGL_LENGTH_SEMANTICS=CHAR`). In `wide-char` mode, the SNC driver binds SQL parameters (SQLBindParameter) with the `SQL_WCHAR/SQL_WVARCHAR` ODBC SQL types. Furthermore, all string literals of an SQL statement are automatically changed to get the N prefix. Thus, you don't need to add the N prefix by hand in all of your programs. This solution makes your Genero code portable to other databases. When defining `NCHAR(N)/NVARCHAR(N)` columns in SQL Server, you specify N as a number of characters. Therefore, it is recommended you use char length semantics in Genero programs, with `FGL_LENGTH_SEMANTICS=CHAR`.

By default, the SNC database driver selects the expected character mode, depending on the current application locale, assuming that the database column types fit to the application locale:
• If the application locale defines a single-byte encoding (such as ISO8859-1), we assume that the database columns are defined with CHAR/VARCHAR/TEXT types to store single-byte characters, and the SNC driver will use SQL_[VAR]CHAR.
• If the application locale defines a multibyte encoding (such as UTF-8 or BIG5), we assume that the database columns are defined with NCHAR/NVARCHAR/NTEXT types to store UNICODE characters, and the SNC driver will use SQL_W[VAR]CHAR.

The char / wide-char modes can be controlled with the following FGLPROFILE entry:

```
   dbi.database.dbname.snc.widechar= { true | false }
```

**Note:** Set the `dbi.database.dbname.snc.widechar` to `false`, only if you are using a multibyte encoding such as BIG5, with CHAR/VARCHAR/TEXT column types in the database.

### Using the ESM driver

When using the ESM (Easysoft) database driver, SQL Statements are prepared with SQLPrepare(), by using the current character set. Easysoft makes the necessary charset conversions from the client charset to UCS-2 or UTF-16 for the server. ODBC SQL parameters with character string data are bound (SQLBindParameter) with the C type SQL_C_CHAR and with the SQL type SQL_W[VAR]CHAR (=UNICODE) or with SQL_[VAR]CHAR, based on the current locale. The SQL_W[VAR]CHAR type is used if the current locale uses a multibyte encoding. When using a single-byte encoding, parameters are bound with the SQL_[VAR]CHAR type. String literals get the N prefix only if the current locale defines a multibyte encoding. String literals are not touched, if the locale uses a single-byte character set. As a result, the necessary character set conversion is controlled by Easysoft and is optimized for SQL Server when using a single-byte character set.

**Important:** Define the correct client character set in Easysoft configuration files. In the odbc.ini data source definition, the Easysoft client character set is specified with the "Client_CSet" parameter, and the server character set is defined by "Server_CSet" or "Server_UCSet" parameters. For example, to cover all UNICODE characters, define:

```
Client_CSet   = UTF-8
Server_UCSet  = UTF-16LE
```

### Using the FTM driver

With the FTM (FreeTDS) database driver, SQL Statements are prepared with SQLPrepare(), by using the current character set. FreeTDS makes the necessary charset conversions from the client charset to UCS-2 before sending the SQL text to the server. ODBC SQL parameters with character string data are bound (SQLBindParameter) with the C type SQL_C_CHAR and with the SQL type SQL_W[VAR]CHAR (=UNICODE) or with SQL_[VAR]CHAR, based on the current locale. The SQL_W[VAR]CHAR type is used if the current locale uses a multibyte encoding. When using a single-byte encoding, parameters are bound with the SQL_[VAR]CHAR type. String literals get the N prefix only if the current locale defines a multibyte encoding. String literals are not touched, if the locale uses a single-byte character set. As a result, the necessary character set conversion is controlled by FreeTDS and is optimized for SQL Server when using a single-byte character set.

**Important:** Define the correct client character set in FreeTDS configuration files. The FreeTDS client character set is defined with "ClientCharset" parameter in odbc.ini.

**CHAR and VARCHAR types** on page 555

Using the CHAR and VARCHAR data types with different databases.

### NUMERIC data types

**Informix®**

Informix® supports several data types to store numbers:
Table 211: Informix® numeric data types

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>16 bit signed integer</td>
</tr>
<tr>
<td>INTEGER</td>
<td>32 bit signed integer</td>
</tr>
<tr>
<td>BIGINT</td>
<td>64 bit signed integer</td>
</tr>
<tr>
<td>INT8</td>
<td>64 bit signed integer (replaced by BIGINT)</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>Equivalent to DECIMAL(16)</td>
</tr>
<tr>
<td>DECIMAL(p)</td>
<td>Floating-point decimal number (max precision is 32)</td>
</tr>
<tr>
<td>DECIMAL(p, s)</td>
<td>Fixed-point decimal number (max precision is 32)</td>
</tr>
<tr>
<td>MONEY</td>
<td>Equivalent to DECIMAL(16, 2)</td>
</tr>
<tr>
<td>MONEY(p)</td>
<td>Equivalent to DECIMAL(p, 2) (max precision is 32)</td>
</tr>
<tr>
<td>MONEY(p, s)</td>
<td>Equivalent to DECIMAL(p, s) (max precision is 32)</td>
</tr>
<tr>
<td>REAL / SMALLFLOAT</td>
<td>32-bit floating point decimal (C float)</td>
</tr>
<tr>
<td>DOUBLE PRECISION / FLOAT[(n)]</td>
<td>64-bit floating point decimal (C double)</td>
</tr>
</tbody>
</table>

Microsoft™ SQL Server

Microsoft™ SQL Server supports the following numeric data types:

Table 212: Microsoft™ SQL Server numeric data types

<table>
<thead>
<tr>
<th>Microsoft™ SQL Server data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>16 bit signed integer</td>
</tr>
<tr>
<td>INTEGER</td>
<td>32 bit signed integer</td>
</tr>
<tr>
<td>BIGINT</td>
<td>64 bit signed integer</td>
</tr>
<tr>
<td>DECIMAL(p, s)</td>
<td>Fixed point decimal.</td>
</tr>
<tr>
<td>SMALLMONEY</td>
<td>32-bit floating point decimal with currency</td>
</tr>
<tr>
<td>MONEY</td>
<td>64-bit floating point decimal with currency</td>
</tr>
<tr>
<td>REAL</td>
<td>32-bit floating point decimal (C float)</td>
</tr>
<tr>
<td>FLOAT[(n)] (DOUBLE)</td>
<td>64-bit floating point decimal (C double)</td>
</tr>
</tbody>
</table>

Notes about SQL Server DECIMAL type:

- Without any decimal storage specification, the precision defaults to 18 and the scale defaults to zero:
  - DECIMAL in SQL Server = DECIMAL(18, 0) in Genero BDL.
  - DECIMAL(p) in SQL Server = DECIMAL(p, 0) in Genero BDL.
- The maximum precision is 38.

Notes about the SQL Server MONEY and SMALLMONEY types:

- SQL Server provides the MONEY and SMALLMONEY data types, but the currency symbol handling is quite different. Therefore, it is recommended to implement Informix® MONEY columns as DECIMAL columns in SQL Server.
Solution

Use the following conversion rules to map Informix® numeric types to SQL Server numeric types:

**Table 213: Informix® data types and Microsoft™ SQL Server equivalents**

<table>
<thead>
<tr>
<th>Informix®</th>
<th>Microsoft™ SQL SERVER</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>INTEGER</td>
<td>INT / INTEGER</td>
</tr>
<tr>
<td>BIGINT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>INT8</td>
<td>BIGINT</td>
</tr>
<tr>
<td>DECIMAL(p,s)</td>
<td>DECIMAL(p,s)</td>
</tr>
<tr>
<td>DECIMAL(p&lt;=19)</td>
<td>DECIMAL(2*p,p)</td>
</tr>
<tr>
<td>DECIMAL(p&gt;19)</td>
<td>N/A</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>DECIMAL(32,16)</td>
</tr>
<tr>
<td>MONEY(p,s)</td>
<td>DECIMAL(p,s)</td>
</tr>
<tr>
<td>MONEY(p)</td>
<td>DECIMAL(p,2)</td>
</tr>
<tr>
<td>MONEY</td>
<td>DECIMAL(16,2)</td>
</tr>
<tr>
<td>REAL / SMALLFLOAT</td>
<td>REAL</td>
</tr>
<tr>
<td>FLOAT[(n)] / DOUBLE PRECISION</td>
<td>FLOAT(n) (Where n must be from 1 to 15)</td>
</tr>
</tbody>
</table>

When creating tables from BDL programs, the database interface automatically converts Informix® numeric data types to corresponding Microsoft™ SQL Server data types. In database creation scripts, apply the conversion rules as described in the above table.

**Important:** There is no SQL Server equivalent for the Informix® DECIMAL(p) floating point decimal (i.e. without a scale). If your application is using such data types, you must review the database schema in order to use SQL Server compatible types. To workaround the SQL Server limitation, the SQL Server database drivers convert DECIMAL(p) types to a DECIMAL( 2*p, p ) , to store all possible numbers an Informix® DECIMAL(p) can store. However, the original Informix® precision cannot exceed 19, since SQL Server maximum DECIMAL precision is 38 (2*19). If the original precision is bigger than 19, a CREATE TABLE statement executed from a Genero program will fail with an SQL Server error 2750.

The numeric types translation can be controlled with the following FGLPROFILE entries:

```
  dbi.database.dsname.ifxemul.datatype.smallint = [ true | false ]
  dbi.database.dsname.ifxemul.datatype.integer = [ true | false ]
  dbi.database.dsname.ifxemul.datatype.bigint = [ true | false ]
  dbi.database.dsname.ifxemul.datatype.int8 = [ true | false ]
  dbi.database.dsname.ifxemul.datatype.decimal = [ true | false ]
  dbi.database.dsname.ifxemul.datatype.money = [ true | false ]
  dbi.database.dsname.ifxemul.datatype.float = [ true | false ]
  dbi.database.dsname.ifxemul.datatype.smallfloat = [ true | false ]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

**DATE and DATETIME data types**

**Informix®**

Informix® provides two data types to store date and time information:

- **DATE** = for year, month and day storage.
- **DATETIME** = for year to fraction (1-5) storage.

The **DATE** type is stored as an **INTEGER** with the number of days since 1899/12/31.

The **DATETIME** type can be defined with various time units, by specifying a start and end qualifier. For example, you can define a datetime to store an hour-to-second time value with **DATETIME HOUR TO SECOND**.

The values of Informix® **DATETIME** can be represented with a character string literal, or as **DATETIME ()** literals:

- `'2017-12-24 15:45:12.345'` -- a **DATETIME YEAR TO FRACTION(3)**
- `'15:45'` -- a **DATETIME HOUR TO MINUTE**
- **DATETIME(2017-12-24 12:45)** **YEAR TO MINUTE**
- **DATETIME(12:45:56.333)** **HOUR TO FRACTION(3)**

Informix® is able to convert quoted strings to **DATE / DATETIME** data, if the string contains matching environment parameters. The string to date conversion rules for **DATE** is defined by the DBDATE environment variable. The string to datetime format for **DATETIME** is defined by the GL_DATETIME environment variable.

**Note:** Within Genero programs, the string representation for **DATETIME** values is always ISO (**YYYY-MM-DD hh:mm:ss.fffffff**) 

Informix® supports date arithmetic on **DATE** and **DATETIME** values. The result of an arithmetic expression involving dates/times is an **INTEGER** number of days when only **DATE** values are used, and an **INTERVAL** value if a **DATETIME** is used in the expression.

Informix® automatically converts an **INTEGER** to a **DATE** when the integer is used to set a value of a date column.

**Microsoft™ SQL Server**

Microsoft™ SQL Server (2008+) provides the following data type to store date and time data:

**Table 214: Microsoft™ SQL Server date/time data types**

<table>
<thead>
<tr>
<th>Microsoft™ SQL Server data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DATE</strong></td>
<td>for year, month, day storage</td>
</tr>
<tr>
<td><strong>DATETIME</strong></td>
<td>for year, month, day, hour, min, second, fraction(3) storage (from January 1, 1753 through December 31, 9999). Values are rounded to increments of .000, .003, or .007 seconds</td>
</tr>
<tr>
<td><strong>SMALLDATETIME</strong></td>
<td>for year, month, day, hour, minutes storage (from January 1, 1900, through June 6, 2079). Values with 29.998 seconds or lower are rounded down to the nearest minute; values with 29.999 seconds or higher are rounded up to the nearest minute</td>
</tr>
<tr>
<td><strong>TIME (n)</strong></td>
<td>for hour, minute, second and fraction(7) storage. Where n defines the precision of fractional seconds</td>
</tr>
<tr>
<td><strong>DATETIME2 (n)</strong></td>
<td>for year, month, day, hour, minute, second and fraction(7) storage. Where n defines the precision of fractional seconds</td>
</tr>
<tr>
<td><strong>DATETIMEOFFSET (n)</strong></td>
<td>for year, month, day, hour, minute, second, fraction(7) and time zone information storage. Where n defines the precision of fractional seconds</td>
</tr>
</tbody>
</table>
Like Informix®, Microsoft™ SQL Server can convert quoted strings to DATETIME data. The CONVERT() SQL function allows you to convert strings to dates.

Microsoft™ SQL Server does not allow direct arithmetic operations on datetimes; the date handling SQL functions must be used instead (DATEADD and DATEDIFF).

SQL Server provides equivalent functions for Informix® YEAR (), MONTH () and DAY (). Take care with the DAY () function on SQL Server because it begins from January 1, 1900 while Informix® begins from December 31, 1899.

**Table 215: Select first day example (Informix® vs. Microsoft™ SQL Server)**

<table>
<thead>
<tr>
<th>Informix®</th>
<th>Microsoft™ SQL SERVER</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT day(0), month(0), year(0) FROM systables WHERE tabid=1;</td>
<td>SELECT day(0), month(0), year(0)</td>
</tr>
<tr>
<td>31 12 1899</td>
<td>1 1 1900</td>
</tr>
</tbody>
</table>

The SQL Server equivalent for Informix® WEEKDAY () is the DATEPART(dw, date-value) function.

The weekday date part depends on the value set by SET DATEFIRST n, which sets the first day of the week (1=Monday ... 7=Sunday (default)).

**Solution**

Use the following conversion rules to map Informix® date/time types to Microsoft™ SQL Server date/time types:

**Table 216: Informix® data types and Microsoft™ SQL Server equivalents**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Microsoft™ SQL Server data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME HOUR TO SECOND</td>
<td>TIME(0)</td>
</tr>
<tr>
<td>DATETIME HOUR TO FRACTION(n)</td>
<td>TIME(n)</td>
</tr>
<tr>
<td>DATETIME YEAR TO SECOND</td>
<td>DATETIME2(0)</td>
</tr>
<tr>
<td>DATETIME q1 TO q2 (different from above)</td>
<td>DATETIME2(n)</td>
</tr>
</tbody>
</table>

The DATE and DATETIME types translation can be controlled with the following FGLPROFILE entries:

```
    dbi.database.dsnname.ifxemul.datatype.date = \\true \\false \\
    dbi.database.dsnname.ifxemul.datatype.datetime = \\true \\false \\
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

For heterogeneous DATETIME types like DATETIME HOUR TO MINUTE, the database interface fills missing date or time parts to 1900-01-01 00:00:00.0. For example, when using a DATETIME HOUR TO MINUTE with the value of "11:45", the SQL Server datetime value will be "1900-01-01 11:45:00.0".

**Important:**

- When fetching a TIME or DATETIME2 with a precision that is greater than 5 (the DATETIME precision limit), the database interface will allocate a buffer of VARCHAR(16) for the TIME and VARCHAR(27) for the DATETIME2 column. As a result, you can fetch such data into a CHAR or VARCHAR variable.
- Review the program logic if you are using the Informix® WEEKDAY () function because SQL Server uses a different basis for the days numbers ( Monday = 1 ).
- Use the SQL Server's GETDATE () function to get the system current date.
Related concepts
Date/time literals in SQL statements on page 571
Good practices for date and time handling in SQL.

INTERVAL data type

Informix®
Informix® provides the INTERVAL data type to store a value that represents a span of time.

INTERVAL types are divided into two classes:

- **year-month** intervals. For example: `INTERVAL YEAR(5) TO MONTH`
- **day-time** intervals. For example: `INTERVAL DAY(9) TO SECOND`

INTERVAL columns can be defined with various time units, by specifying a start and end qualifier. For example, you can define an interval to store a number of hours and minutes with `INTERVAL HOUR(n) TO MINUTE`, where \( n \) defines the maximum number of digits for the hours unit.

The values of Informix® INTERVAL can be represented with a character string literal, or as `INTERVAL()` literals:

- `'9834 15:45:12.345'` -- an `INTERVAL DAY(6) TO FRACTION(3)`
- `'7623-11'` -- an `INTERVAL YEAR(9) TO MONTH`
- `INTERVAL(18734:45) HOUR(5) TO MINUTE`
- `INTERVAL(-7634-11) YEAR(5) TO MONTH`

Microsoft™ SQL Server
Microsoft™ SQL Server does not provide a data type corresponding to the Informix® INTERVAL data type.

Solution
The INTERVAL data type and values are converted to a `CHAR(50)` column with IBM® DB2®.

INTERVAL values can be stored and retrieved from the database. However, since IBM® DB2® does not support a native interval type, arithmetics cannot be performed on the database side in SQL statements.

The INTERVAL types translation can be controlled with the following FGLPROFILE entry:

```
    dbi.database.dsnname.ifxemul.datatype.interval = \{true \| false \}
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Related concepts
Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

SERIAL data types

Informix®
Informix® supports the SERIAL, BIGSERIAL data types to produce automatic integer sequences:

- **SERIAL** can produce 32 bit integers (INTEGER)
- **BIGSERIAL** can produce 64 bit integers (BIGINT)
- **SERIAL8** is a synonym for **BIGSERIAL**

Steps to use serials with Informix®:

1. Create the table with a column using SERIAL, or BIGSERIAL.
2. To generate a new serial, no value or a zero value is specified in the \texttt{INSERT} statement:

\begin{verbatim}
INSERT INTO tab1 ( c ) VALUES ( 'aa' )
INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
\end{verbatim}

3. After \texttt{INSERT}, the new value of a \texttt{SERIAL} column is provided in SQLCA.SQLERRD[2], while the new value of a \texttt{BIGSERIAL} value must be fetched with a \texttt{SELECT dbinfo('bigserial')} query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future \texttt{INSERT} statements that are using a zero value:

\begin{verbatim}
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
\end{verbatim}

\textbf{Microsoft™ SQL Server}

Microsoft™ SQL Server \texttt{IDENTITY} columns:

- When creating a table, the \texttt{IDENTITY} keyword must be specified after the column data type:

\begin{verbatim}
CREATE TABLE tab1 ( k INTEGER IDENTITY, c NVARCHAR(10) )
\end{verbatim}

- You can specify a start value and an increment with "identity(start, incr)":

\begin{verbatim}
CREATE TABLE tab1 ( k INTEGER IDENTITY(100,2), ...)
\end{verbatim}

- A new number is automatically created when inserting a new row:

\begin{verbatim}
INSERT INTO tab1 ( c ) VALUES ( 'aaa' )
\end{verbatim}

- To get the last generated number, Microsoft™ SQL SERVER provides the \texttt{SCOPE_IDENTITY()} function.

The \texttt{@@IDENTITY} global T-SQL variable is not recommended, as it is scope-less.

- To put a specific value into an \texttt{IDENTITY} column, the \texttt{SET} command must be used:

\begin{verbatim}
SET IDENTITY_INSERT tab1 ON
INSERT INTO tab1 ( k, c ) VALUES ( 100, 'aaa' )
SET IDENTITY_INSERT tab1 OFF
\end{verbatim}

Informix® \texttt{SERIAL}s and SQL Server \texttt{IDENTITY} columns are quite similar; the main difference is that SQL Server does not allow you to use the zero value for the identity column when inserting a new row.

Starting with version 2012, Microsoft™ SQL Server supports sequences:

\begin{verbatim}
-- To create a sequence object:
CREATE SEQUENCE myseq START WITH 100 INCREMENT BY 1;

-- To get a new sequence value:
SELECT NEXT VALUE FOR myseq;

-- To find the current sequence value (last generated)
SELECT convert(bigint, current_value) FROM sys.sequences WHERE name = 'myseq';

-- To reset the sequence with a new start number:
ALTER SEQUENCE myseq START WITH 100;
\end{verbatim}
Solution

Note: For best SQL portability when using different type of databases, consider using sequences as described in Solution 3: Use native SEQUENCE database objects on page 565.

To emulate Informix® serials with SQL Server, you can use three different solutions:

1. Native SQL Server IDENTITY columns.
2. Insert triggers based on sequences (requires SQL Server 2012 and +).
3. Insert triggers based on the SERIALREG table (for SQL Server prior to 2012).

The method used to emulate SERIAL types is defined by the ifxemul.datatype.serial.emulation FGLPROFILE parameter:

```
  dbi.database.dbname.ifxemul.datatype.serial.emulation
  = {"native","trigseq","regtable"}
```

1. native: uses IDENTITY columns.
2. trigseq: uses insert triggers with sequences (CREATE SEQUENCE).
3. regtable: uses insert triggers with the SERIALREG table.

The default emulation technique is "native".

The serial types emulation can be enabled or disabled with the following FGLPROFILE entries:

```
  dbi.database.dbname.ifxemul.datatype.serial = {true,false}
  dbi.database.dbname.ifxemul.datatype.serial8 = {true,false}
  dbi.database.dbname.ifxemul.datatype.bigserial = {true,false}
```

The native IDENTITY-based solution is faster, but does not allow explicit serial value specification in insert statements; the other solutions are slower but allow explicit serial value specification in INSERT statements.

Important: The trigger-based solutions are provided to simplify the conversion from Informix, but are slower as the solution uses IDENTITY columns. To get best performances, we strongly recommend that you use native IDENTITY columns instead of triggers.

1. Using the native serial emulation

Make sure that the following FGLPROFILE entry is not defined, in order to use the default "native" emulation:

```
  dbi.database.dbname.ifxemul.datatype.serial.emulation ...
```

In database creation scripts, all SERIAL[(n)] data types must be converted by hand to INTEGER IDENTITY[(n,1)] data types, while BIGSERIAL[(n)] data types must be converted by hand to BIGINT IDENTITY[(n,1)] data types.

Tables created from the BDL programs can use the SERIAL data type. When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the "SERIAL[(n)]" data type to "INTEGER IDENTITY[(n,1)]".

In BDL, the new generated SERIAL value is available from the SQLCA.SQLERRD[2] variable. This is supported by the database interface which performs a "SELECT SCOPE_IDENTITY()". However, SQLCA.SQLERRD[2] is defined as an INTEGER, it cannot hold values from BIGINT identity columns. If you are using BIGINT IDENTITY columns, you must retrieve the last generated serial with the SCOPE_IDENTITY() SQL function.

By default (see SET IDENTITY_INSERT), SQL Server does not allow you to specify the IDENTITY column in INSERT statements; You must convert all INSERT statements to remove the identity column from the list.

For example, the following statement:

```
  INSERT INTO tab (col1,col2) VALUES (0, p_value)
```
must be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file (DEFINE rec LIKE tab.*) must also be reviewed:

```
INSERT INTO tab VALUES (rec.*) -- will use the serial column
```

must be converted to:

```
INSERT INTO tab VALUES rec.* -- without parentheses, serial column is removed
```

Since 2.10.06, SELECT * FROM table INTO TEMP with original table having an IDENTITY column is supported: The database driver converts the Informix® SELECT INTO TEMP to the following sequence of statements:

```
SELECT selection-items INTO #table FROM ... WHERE 1=2
SET IDENTITY_ INSERT #table ON
INSERT INTO #table (column-list) SELECT original select clauses
SET IDENTITY_ INSERT #table OFF
```

See also temporary tables.

2. Using the trigseq serial emulation (SQL Server 2012 and +)

In order to use the serial emulation based on triggers and sequences, make sure that all database users creating tables in program have permissions to create/drop sequences and triggers.

Define the FGLPROFILE entry to enable "trigseq" serial emulation:

```
dbi.database.dbname.ifxemul.datatype.serial.emulation = "trigseq"
```

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types, BIGSERIAL must be converted to BIGINT and you must create one trigger for each table. To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command using a sequence.

Tables created from the BDL programs can use the SERIAL data type. When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the "SERIAL[(n)]" data type to "INTEGER" and creates the insert triggers. When using BIGSERIAL[(n)], the column is converted to a BIGINT.

Important:

- SQL Server does not allow you to create triggers on temporary tables. Therefore, you cannot create temp tables with a SERIAL column when using this solution.
- SELECT ... INTO TEMP statements using a table created with a SERIAL column do not automatically create the SERIAL triggers in the temporary table. The type of the column in the new table is INTEGER. Similarly, a BIGSERIAL column becomes BIGINT.
- When a table is dropped, all associated triggers are also dropped.
- INSERT statements using NULL for the SERIAL column will produce a new serial value, instead of using NULL:
  ```
  INSERT INTO tab (col1, col2) VALUES (NULL, 'data')
  ```
  This behavior is mandatory in order to support INSERT statements which do not use the serial column:
  ```
  INSERT INTO tab (col2) VALUES ('data')
  ```
Check if your application uses tables with a SERIAL column that can contain a NULL value.

3. Using the `regtable` serial emulation (SQL Server versions prior to 2012)

**Note:** This solution is supported for SQL Server versions prior to 2012, if your server is a SQL Server 2012 or +, consider using the "trigseq" emulation instead.

In order to use the serial emulation based on triggers and the SERIALREG table, make sure that all database users creating tables in program have permissions to create/drop triggers.

Then, prepare the database and create the SERIALREG table as follows:

```sql
CREATE TABLE serialreg (
    tablename VARCHAR(50) NOT NULL,
    lastserial BIGINT NOT NULL,
    PRIMARY KEY ( tablename )
)
```

The SERIALREG table and columns have to be created with lower case names, since the SQL SERVER database is created with case sensitive names, because triggers are using this table in lower case.

Define the FGLPROFILE entry to enable "regtable" serial emulation:

```text
dbi.database.dbname.ifxemul.datatype.serial.emulation = "regtable"
```

In database creation scripts, all SERIAL[(n)] data types must be converted to INTEGER data types, BIGSERIAL must be converted to BIGINT and you must create one trigger for each table. To know how to write those triggers, you can create a small Genero program that creates a table with a SERIAL column. Set the FGLSQLDEBUG environment variable and run the program. The debug output will show you the native trigger creation command using the SERIALREG table.

Tables created from the BDL programs can use the SERIAL data type. When a BDL program executes a CREATE [TEMP] TABLE with a SERIAL column, the database interface automatically converts the "SERIAL[(n)]" data type to "INTEGER" and creates the insert triggers. When using BIGSERIAL[(n)], the column is converted to a BIGINT.

**Important:**

- The serial production is based on the SERIALREG table which registers the last generated number for each table. If you delete rows of this table, sequences will restart at 1 and you will get unexpected data.
- SQL Server does not allow you to create triggers on temporary tables. Therefore, you cannot create temp tables with a SERIAL column when using this solution.
- SELECT ... INTO TEMP statements using a table created with a SERIAL column do not automatically create the SERIAL triggers in the temporary table. The type of the column in the new table is INTEGER. Similarly, a BIGSERIAL column becomes BIGINT.
- When a table is dropped, all associated triggers are also dropped.
- INSERT statements using NULL for the SERIAL column will produce a new serial value, instead of using NULL:

```sql
INSERT INTO tab (col1,col2) VALUES ( NULL,'data')
```

This behavior is mandatory in order to support INSERT statements which do not use the serial column:

```sql
INSERT INTO tab (col2) VALUES ('data')
```

Check if your application uses tables with a SERIAL column that can contain a NULL value.

How to implement automatic record keys.
The SQLCA diagnostic record on page 532
The `SQLCA` variable is a predefined record containing SQL statement execution information.

List of FGLPROFILE entries on page 223
This is a summary of supported FGLPROFILE entries.

**SQL Server UNIQUEIDENTIFIER data type**

SQL Server supports a special type named `UNIQUEIDENTIFIER`, which can be used to store "Globally Unique Identifiers" (GUIDs). `UNIQUEIDENTIFIER` values can be generated with the NEWID() function. When creating a table, you typically define a `UNIQUEIDENTIFIER` column with a DEFAULT clause where the value is produced from a NEWID() call:

```
CREATE TABLE mytab ( k INT, id UNIQUEIDENTIFIER DEFAULT NEWID(), c VARCHAR(10) )
```

The `UNIQUEIDENTIFIER` type is based on the BINARY(16) SQL Server type. The Genero language does not have an equivalent type for BINARY(16). However, BINARY values can be represented as hexadecimal strings in CHAR or VARCHAR variables.

A `UNIQUEIDENTIFIER` value is usually represented as a GUID identifier, with the following hexadecimal format:

```
XXXXXXXX-XXXX-XXXX-XXXX-XXXXXXXXXXXX
```

where X can be 0-9, A-F.

You typically fetch `UNIQUEIDENTIFIER` data into a CHAR(36) Genero variable. The resulting value will be expressed in hexadecimal string using the format. You can then reuse that value in an SQL statement, but you have to convert the CHAR(36) hexadecimal string value back to a `UNIQUEIDENTIFIER` value with the CONVERT() SQL Server function, as shown in this example:

```
DEFINE pi CHAR(36)
CREATE TABLE mytab ( k INT, i UNIQUEIDENTIFIER DEFAULT NEWID(), c VARCHAR(10) )
INSERT INTO mytab ( k, c ) VALUES ( 1, 'aaa' )
SELECT i INTO pi FROM mytab WHERE k = 1
UPDATE mytab SET c = 'xxx' WHERE i = CONVERT(UNIQUEIDENTIFIER, pi)
```

When extracting a database schema, `UNIQUEIDENTIFIER` columns can be clearly distinguished from BINARY(N) columns. The `fgldbsch` tool will produce a CHAR(36) type code in the .sch file for `UNIQUEIDENTIFIER` columns.

You can also exclude the `UNIQUEIDENTIFIER` columns from the table definition in the schema file, by using the `x` character at the appropriate position of the string passed with the `-cv` data type conversion option of `fgldbsch`.

**SQL Server ROWVERSION data type**

SQL Server provides a special type named `ROWVERSION`, to stamp row modifications. The `ROWVERSION` data type replaces the old `TIMESTAMP` column definition. When you define a column with the `ROWVERSION`, SQL Server will automatically increment the version column when the row is modified. `ROWVERSION` is just an incrementing number, it does not preserve date or time information. It can be used to control concurrent access to the same rows.

The `ROWVERSION` type is based on the BINARY(8) SQL Server type. The Genero language does not have an equivalent type for BINARY(8). Therefore, you must fetch `ROWVERSION` data into a CHAR(16) variable. The resulting value will be expressed in hexadecimal. You can then reuse that value in an UPDATE statement to check that the row was not modified by another process, but you have to convert the CHAR(16) hexadecimal value back to a BINARY(8) value with the CONVERT() SQL Server function, as shown in this example:

```
DEFINE pv CHAR(16)
CREATE TABLE mytab ( k INT, v ROWVERSION, c VARCHAR(10) )
INSERT INTO mytab VALUES ( 1, NULL, 'aaa' )
SELECT v INTO pv FROM mytab WHERE k = 1
```
UPDATE mytab SET c = 'xxx' WHERE k = 1 AND v = CONVERT(BINARY(8), pv, 2)

Since ROWVERSION is a synonym for BINARY(8), ROWVERSION columns cannot be clearly identified in ODBC. Therefore, the following conversion rule applies when fetching data from the server:

- If the column is defined as BINARY(N), with N<=128, the data will be fetched as a CHAR(N*2), as an hexadecimal string.
- If the column is defined as BINARY(N), with N>128, the data will be fetched as a BYTE, as a regular binary value.

When extracting a database schema, ROWVERSION columns are identified as TIMESTAMP columns and can be clearly distinguished from BINARY(N) columns. The fgl dbsch tool will produce a CHAR(16) type code in the .sch file for ROWVERSION or TIMESTAMP columns.

**ROWID columns**

**Informix®**

When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only).

The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

**Note:** Informix® ROWID usage was a common practice in the early days of Informix® 4GL programming. Today it is recommended to define all your database tables with a PRIMARY KEY to uniquely identify rows.

With Informix®, the SQLCA.SQLERRD[6] register contains the ROWID of the last modified row.

**Microsoft™ SQL Server**

Microsoft™ SQL Server does not support ROWIDs.

**Solution**

If the BDL application uses ROWIDs, it is recommended that the program logic is reviewed in order to use the real primary keys instead (usually serials, which can be supported). All references to SQLCA.SQLERRD[6] must be removed because this variable will not hold the ROWID of the last modified row.

If your existing Informix® application depends on using ROWID values, you can use the IDENTITY property of the DECIMAL, INT, NUMERIC, SMALLINT, BIGINT, or TINYINT data types, to simulate this functionality.

The ROWID keyword translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsnname.ifxemul.rowid = [ true | false ]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

- Using ROWID columns on page 578
- Automatic ROWID columns is not a common database feature.

**Case sensitivity**

In Informix®, database object names like table and column names are not case sensitive:

CREATE TABLE Customer ( Custno INTEGER, ... )
SELECT CustNo FROM cuSTomer ...

In Microsoft™ SQL Server, database object names and character data are case-insensitive by default:

CREATE TABLE Customer ( Custno INTEGER, CustName CHAR(20) )
INSERT INTO CUSTOMER VALUES ( 1, 'TECHNOSOFT' )
SELECT CustNo FROM customer WHERE custname = 'techNOSoft'

The installation program of SQL Server allows you to customize the **sort order**. The sort order specifies the rules used by SQL Server to collate, compare, and present character data. **It also specifies whether SQL Server is case-sensitive.**

Genero compilers convert table and column names to lower case. For example, when writing following static SQL statement:

```
SELECT COUNT(*) FROM customer WHERE custname LIKE 'S%'
```

The SQL text stored in the pcode module will be:

```
SELECT COUNT(*) FROM customer WHERE custname LIKE 'S%'
```

**Solution**

Select the case-sensitive sort order when installing SQL Server to make queries case-sensitive.

Define the database tables and columns in lower case only, because Genero compilers convert them to lower case.

**TEXT and BYTE (LOB) types**

**Informix®**

Informix® provides the TEXT, BYTE, CLOB and BLOB data types to store very large texts or binary data.

Legacy Informix® 4GL applications typically use the TEXT and BYTE types.

Genero BDL does not support the Informix® CLOB and BLOB types.

**Microsoft™ SQL Server**

Microsoft™ SQL Server provides the VARCHAR (MAX), NVARCHAR (MAX) and VARBINARY (MAX) data types to store large object data.

The SQL Server TEXT, NTEXT and IMAGE data types still exist, but are considered as obsolete and will be removed in a future version.

In SQL Server, the VARCHAR (MAX), NVARCHAR (MAX) and VARBINARY (MAX) types have a limit of 2 gigabytes (2^31 -1 actually).

**Solution**

In Genero programs connecting to SQL Server, the TEXT and BYTE data types of DDL statements such as CREATE TABLE are respectively converted to VARCHAR (MAX) and VARBINARY (MAX) types.

SQL Server database drivers make the appropriate bindings to use TEXT and BYTE Genero types as SQL parameters and fetch buffers, and can be used for SQL SERVER text, image or VARCHAR (MAX), NVARCHAR (MAX) and VARBINARY (MAX) columns.

Genero TEXT/BYTE program variables and the SQL Server large object types have the same a limit of 2 gigabytes.

**Note:** When using a stored procedure that has SET/IF statements and produces a result set with LOBs, the LOB columns must appear at the end of the SELECT list. If LOB columns are followed by other columns with regular types, the fetching rows will fail. Using SET NOCOUNT ON in the stored procedure does not help, because the cursor type is changed from a server cursor to a default result set cursor.

The TEXT and BYTE types translation can be controlled with the following FGLPROFILE entries:

```
dbi.database.dsname.ifxemul.text = \[true \| false\]
dbi.database.dsname.ifxemul.byte = \[true \| false\]
```
For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

**Using portable data types** on page 553

Only a limited set of data types are really portable across several database engines.

**Table constraints**

**Informix**

Informix® supports primary key, unique, foreign key, default and check constraints.

The constraint naming syntax is different in Informix® and most other databases: Informix expects the "CONSTRAINT" keyword **after** the constraint specification:

```sql
CREATE TABLE emp (  
  ...  
  emp_code CHAR(10) UNIQUE CONSTRAINT pk_emp,  
  ...  
)
```

While other databases it **before**:

```sql
CREATE TABLE emp (  
  ...  
  emp_code CHAR(10) CONSTRAINT pk_emp UNIQUE,  
  ...  
)
```

**Microsoft™ SQL Server**

Microsoft™ SQL Server supports primary key, unique, foreign key, default and check constraints.

**Constraint naming**

The constraint naming clause must be placed **before** the constraint specification.

**Important:** SQL Server does not produce an error when using the Informix® syntax of constraint naming.

**The NULL / NOT NULL constraint**

**Note:** Microsoft™ SQL Server creates columns as NOT NULL by default, when no NULL constraint is specified (colname datatype (NULL | NOT NULL)). A special option is provided to invert this behavior: ANSI_NULL_DFLT_ON. This option can be enabled with the SET command, or in the database options of SQL Server Management Studio.

**Solutions**

**Constraint naming syntax**

The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for Microsoft™ SQL Server.

**The NULL / NOT NULL constraint**

Before using a database, you must check the "ANSI NULL Default" option in the database properties if you want to have the same default NULL constraint as in Informix® databases.

**Related concepts**

**Data definition statements** on page 552
It is recommended to avoid use of DDL in programs.

**Name resolution of SQL objects**

**Informix®**

Informix® uses the following form to identify an SQL object:

```
database[@dbservername][:][{owner|"owner"}.]identifier
```

The ANSI convention is to use double quotes for identifier delimiters (For example: "customer"."cust_name").

Informix® database object names are not case-sensitive in non-ANSI databases. When using double-quoted identifiers, Informix® becomes case sensitive.

With non-ANSI Informix® databases, you do not have to give a schema name before the tables when executing an SQL statement:

```
SELECT ... FROM customer WHERE ...
```

In Informix® ANSI compliant databases:

- The table name must include "owner", unless the connected user is the owner of the database object.
- The database server shifts the owner name to uppercase letters before the statement executes, unless the owner name is enclosed in double quotes.

**Microsoft™ SQL Server**

With Microsoft™ SQL Server, an object name takes the following form:

```
[[database.]owner.]identifier
```

Object names are limited to 128 characters in SQL Server and cannot start with one of the following characters: @ (local variable) # (temp object).

To support double quotes as string delimiters in SQL Server, you can switch OFF the database option "Use quoted identifiers" in the database properties panel. But quoted table and column names are not supported when this option is OFF.

**Solution**

As a general rule, to write portable SQL, it is recommended that you only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

Check for single or double quoted table or column names in your source and remove them.

**Data manipulation**

Microsoft™ SQL Server related data manipulation topics.

**Reserved words**

**Informix®**

With Informix®, it is possible to create database objects with reserved words.

For example:

```
CREATE TABLE table ( char CHAR(10) );
```

Indeed this is not good practice, but Informix® SQL allows this to be backward compatible when introducing a new keyword in the SQL syntax.
Most other database systems do not allow reserved words as database identifiers. If your legacy code is using SQL reserved words of the target database SQL syntax, an error will be thrown at `CREATE TABLE` execution.

**Microsoft™ SQL Server**

Microsoft™ Transact-SQL does not allow you to use reserved words as database object names (tables, columns, constraint, indexes, triggers, stored procedures, ...).

An example of a common word which is part of SQL Server grammar is 'go' (see the 'Reserved keywords' section in the SQL Server Documentation).

**Solution**

Database objects having a name which is a Transact-SQL reserved word must be renamed.

All BDL application sources must be verified. To check if a given keyword is used in a source, you can use UNIX™ 'grep' or 'awk' tools. Most modifications can be automatically done with UNIX™ tools like 'sed' or 'awk'.

You can use `SET QUOTED_IDENTIFIER ON` with double-quotes to enforce the use of keywords in the database objects naming, but it is not recommended.

**Outer joins**

**Informix® OUTER() syntax**

In Informix® SQL, outer joins can be defined in the `FROM` clause with the OUTER keyword:

```
SELECT ... FROM a, OUTER (b)
  WHERE a.key = b.akey

SELECT ... FROM a, OUTER(b, OUTER(c))
  WHERE a.key = b.akey
  AND b.key1 = c.bkey1 AND b.key2 = c.bkey2
```

Informix® also supports the ANSI OUTER join syntax, which is the recommended way to specify outer joins with recent SQL database engines:

```
SELECT ... FROM cust LEFT OUTER JOIN order
  ON cust.key = order.custno
  WHERE ...
```

**Microsoft™ SQL Server**

Microsoft™ SQL Server supports the ANSI outer join syntax:

```
SELECT ...
  FROM cust LEFT OUTER JOIN order
    LEFT OUTER JOIN item
    ON order.key = item.ordno
    ON cust.key = order.custno
  WHERE order.cdate > current date
```

**Note:**

The legacy syntax to define outers in SQL Server uses the `*=` notation:

```
SELECT ... FROM a, b WHERE a.key *= b.key
```

**Solution**

The Genero database drivers can convert Informix® OUTER specifications to ANSI outer joins.
Note: For better SQL portability, use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The outer join translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsnname.ifxemul.outers = ↓ true ↓ false ↓
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

- **Prerequisites:**
  1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.
     
     Example which does not work:
     
     ```
     ... FROM OUTER(tab2), tab1
     ```
  2. The outer join in the WHERE clause must use the table name as prefix:
     
     ```
     ... WHERE tab1.col1 = tab2.col2
     ```

- **Restrictions:**
  1. Statements composed by 2 or more SELECT instructions are not supported:
     
     ```
     SELECT ... UNION SELECT ...
     ```
     or:
     
     ```
     SELECT ... WHERE col IN (SELECT...)
     ```
  2. Additional conditions on outer table columns cannot be detected and therefore are not supported:
     
     ```
     ... FROM tab1, OUTER(tab2)
     WHERE tab1.col1 = tab2.col2
     AND tab2.colx > 10
     ```

- **Notes:**
  1. Table aliases are detected in OUTER expressions.

```
OUTER example with table alias:
```

```
... OUTER(tab1 alias1) ...
```

  2. In the outer join, `outertab.col` can be placed on both right or left sides of the equal sign:

```
... WHERE outertab.col = maintab.col2
```

  3. Table names detection is not case-sensitive:

```
SELECT ... FROM tab1, TAB2
WHERE tab1.col1 = tab2.col2
```

  4. Temporary tables are supported in OUTER specifications:

```
CREATE TEMP TABLE tt1 ( ... )
SELECT ... FROM tab1, OUTER(tt1) ...
```

**Related concepts**

*Outer joins* on page 577
Use standard ISO outer join syntax instead of the old IBM® Informix® OUTER() syntax.

Transactions handling

Informix®

With the Informix® native mode (non ANSI):

- Transactions blocks start with **BEGIN WORK** and terminate with **COMMIT WORK** or **ROLLBACK WORK**.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```sql
UPDATE tab1 SET ...    -- auto-committed
BEGIN WORK             -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...
COMMIT WORK            -- end of TX block
```

Informix® version 11.50 introduces savepoints:

```sql
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT name
RELEASE SAVEPOINT name
```

Microsoft™ SQL Server

Microsoft™ SQL Server supports named and nested transactions:

- Transactions are started with **BEGIN TRANSACTION [name]**.
- Transactions are validated with **COMMIT TRANSACTION [name]**.
- Transactions are canceled with **ROLLBACK TRANSACTION [name]**.
- Savepoints can be placed with **SAVE TRANSACTION name**.
- Transactions can be rolled back to a savepoint with **ROLLBACK TRANSACTION TO name**.
- Savepoints can not be released.
- Statements executed outside of a transaction are automatically committed (autocommit mode). This behavior can be changed with "**SET IMPLICIT_TRANSACTION ON**".
- DDL statements are not supported in transactions blocks.

Solution

Informix® transaction handling commands are automatically converted to Microsoft™ SQL Server instructions to start, validate or cancel transactions.

Regarding the transaction control instructions, the BDL applications do not have to be modified to work with Microsoft™ SQL Server.

**Important:** If you want to use savepoints, do not use the **UNIQUE** keyword in the savepoint declaration, always specify the savepoint name in **ROLLBACK TO SAVEPOINT**, and do not drop savepoints with **RELEASE SAVEPOINT**.

Related concepts

Database transactions on page 538
Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Temporary tables**

**Informix®**

Informix® temporary tables are created with the `CREATE TEMP TABLE` DDL instruction or with `SELECT ... INTO TEMP` statement:

```
CREATE TEMP TABLE tt1 ( pkey INT, name VARCHAR(50) )
CREATE TEMP TABLE tt2 ( pkey INT, name VARCHAR(50) ) WITH NO LOG
SELECT * FROM tab1 WHERE pkey > 100 INTO TEMP tt2
```

Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the `DROP TABLE` command. There is no name conflict when several users create temporary tables with the same name.

BDL REPORTs can create a temporary table when the rows are not sorted externally (by the source SQL statement).

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.

When creating temporary tables in Informix®, the `WITH NO LOG` clause can be used to avoid the overhead of recording DML operations in transaction logs.

**Microsoft™ SQL Server**

Microsoft™ SQL Server provides local (SQL session wide) or global (database wide) temporary tables by using the '#' or '##' characters as table name prefix:

```
CREATE TABLE #temp1 ( kcol INTEGER, .... )
```

The `INTO` clause can be used within a `SELECT` statement to create and fill a temporary table in one step:

```
SELECT * INTO #temp2 FROM customers WHERE ...
```

**Important:** SQL Server temporary tables are created by default with the collation of the tempdb database, instead of inheriting the collation of the current database you are connected to.

**Solution**

In BDL, Informix® temporary tables instructions are converted to generate native SQL Server temporary tables.

The general FGLPROFILE entry to control temporary table emulation is:

```
 dbi.database.dsnname.ifxemul.temptables = [true | false] 
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Note:** Microsoft™ SQL Server does not support scroll cursors based on a temporary table.

**Important:** In order to use the same collation in your temp tables as in your permanent tables, install SQL Server with the same collation as your database. See Installation for more details.

**Related concepts**

Temporary tables on page 575
Syntax for temporary table creation is not unique across all database engines.

**Substrings in SQL**

**Informix**

Informix® SQL statements can use subscripts on columns defined with the character data type:

```sql
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R' -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

**Important:** With other database servers as Informix®, when the subscript notation is used to modify column values in UPDATE statement, or as ORDER BY element, you will get and SQL error:

```sql
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

**Microsoft™ SQL Server**

Microsoft™ SQL Server provides the SUBSTR() function, to extract a substring from a string expression:

```sql
SELECT .... FROM tab1 WHERE SUBSTRING(col1,2,2) = 'RO'
SELECT SUBSTRING('Some text',6,3) FROM tab1 -- Gives 'tex'
```

**Solution**

Replace all Informix® col[x,y] right-value expressions with SUBSTRING(col,x,y-x+1).

Rewrite UPDATE and ORDER BY clauses using col[x,y] expressions.

The translation of col[x,y] expressions can be controlled with the following FGLPROFILE entry:

```sql
dbi.database.dsname.ifxemul.colsubs = true \ false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

**Substring expressions** on page 577

Handle substrings expressions with different database engines.

**String delimiters**

**Informix**

The ANSI SQL string delimiter character is the single quote ("string"), while double quotes are used to delimit database object names:

```sql
SELECT ... WHERE tabname."colname" = 'a string value'
```

In Informix® databases created in native mode (non-ANSI), you can use double quotes as string delimiters:

```sql
SELECT ... WHERE tabname.colname = 'a string value'
```

This is important, since many BDL programs use that character to delimit the strings in SQL commands.

**Note:** This problem concerns only double quotes within SQL statements. Double quotes used in pure BDL string expressions are not subject to SQL compatibility problems.
**Microsoft™ SQL Server**

Microsoft™ SQL Server follows the ANSI SQL specification, using single quotes for string delimiters and double quotes for database object names.

**Important:**

With SQL Server, all UNICODE strings must be prefaced with an `N` character:

```sql
UPDATE cust SET cust_name = N'###' WHERE cust_id=123
```

Without the `N` prefix, SQL Server will convert the characters from the current system locale to the database locale. With the `N` prefix, the server can recognize a UNICODE string and use it as is to insert into `NCHAR` or `NVARCHAR` columns.

**Solution**

When using Static SQL statements, the `fglcomp` compiler converts string literals using double quotes to string literals with single quotes:

```bash
$ cat s.4gl
MAIN
  DEFINE n INT
  SELECT COUNT(*) INTO n FROM tab1 WHERE col1 = "abc"
END MAIN

$ fglcomp -S s.4gl
s.4gl`3^SELECT COUNT(*) FROM tab1 WHERE col1 = 'abc'
```

However, SQL statements created dynamically are not modified by the Genero compiler.

The Genero database interface can automatically replace all double quotes by single quotes in SQL statements. This applies to static and dynamic SQL statements.

The translation of double quoted expression to single quoted expressions can be controlled with the following `FGLPROFILE` entry:

```
dbi.database.dbname.ifxemul.dblquotes = [true | false]
```

For more details see IBM Informix emulation parameters in `FGLPROFILE` on page 614.

However, database object names must not be delimited by double quotes, because the database interface cannot determine the difference between a database object name and a quoted string! For example, if the program executes the SQL statement:

```sql
... WHERE "tabname"."colname" = "a string value"
```

replacing all double quotes by single quotes would produce:

```sql
... WHERE 'tabname'.'colname' = 'a string value'
```

This would produce an error since 'tabname'.colname' is not allowed by ORACLE.

Escaped string delimiters can be used inside strings like the following:

```
'This is a single quote: '''
'This is a single quote: \''
"This is a double quote: '''
"This is a double quote: \"
```

Although double quotes are replaced automatically in SQL statements, it is recommended that you use only single quotes to enforce portability.
**National character strings**

When using the SNC database driver, all string literals of an SQL statement are automatically changed to get the N prefix. Thus, you don't need to add the N prefix by hand in all of your programs. This solution makes by the way your Genero code portable to other databases.

With the SNC database driver, character string data is converted from the current Genero BDL locale to Wide Char (Unicode UCS-2), before it is used in an ODBC call such as SQLPrepareW or SQLBindParameter(SQL_C_WCHAR). When fetching character data, the SNC database driver converts from Wide Char to the current Genero BDL locale. The current Genero BDL locale is defined by LANG, and if LANG is not defined, the default is the ANSI Code Page of the Windows™ operating system. See CHARACTER data types for more details.

When using the FTM (FreeTDS) or the ESM (Easysoft) database driver on UNIX™, string literals get the N prefix if the current locale is a multibyte encoding like BIG5, EUC-JP or UTF-8. If the current locale is a single-byte encoding like ISO-8859-1, no prefix will be added to the string literals.

**Related concepts**

String literals in SQL statements on page 570

Single quotes is the standard for delimiting string literals in SQL.

**Single row SELECT**

**Informix**

With Informix®, you must use the system table with a condition on the table id:

```
SELECT user FROM systables WHERE tabid=1
```

**Microsoft™ SQL Server**

With SQL Server, omit the FROM clause to generate one row only:

```
SELECT user
```

**Solution**

Check the BDL sources for "FROM systables WHERE tabid=1" and use dynamic SQL to resolve this problem.

Consider writing a FUNCTION which produces the FROM and WHERE part, depending on the target database type.

**MATCHES and LIKE**

**Informix**

Informix® supports MATCHES and LIKE operators in SQL statements.

MATCHES expects * and ? wild-card characters, while LIKE uses the % and _ wild-cards as equivalents.

```
( col MATCHES 'Smi*' AND col NOT MATCHES 'R?x' )
( col LIKE 'Smi%' AND col NOT LIKE 'R_x' )
```

MATCHES accepts also brackets notation, to specify a set of matching characters at a given position:

```
( col MATCHES '[Pp]aris' )
( col MATCHES '[0-9][a-z]*' )
```
**Microsoft™ SQL Server**

Microsoft™ SQL Server does not provide an equivalent of the Informix® MATCHES operator.

The LIKE operator is supported.

**Important:**

The LIKE operator of SQL Server does not evaluate to true with CHAR/NCHAR columns, if the LIKE pattern is provided as a UNICODE string literal (with the N prefix), and the search pattern matches the value in the column (without an ending % wildcard for example).

See the following test:

```sql
CREATE TABLE mytable ( k INT, nc NCHAR(20) )
INSERT INTO mytable VALUES ( 1, N'abc' )
SELECT * FROM mytable WHERE nc = 'abc' -- one row is returned
SELECT * FROM mytable WHERE nc = N'abc' -- one row is returned
SELECT * FROM mytable WHERE nc LIKE 'abc' -- one row is returned
SELECT * FROM mytable WHERE nc LIKE N'abc' -- no rows are found
SELECT * FROM mytable WHERE nc LIKE N'abc%' -- one row is returned
```

This can be an issue because the SQL Server driver will by default automatically add a N prefix before all string literals in SQL statements.

See Microsoft™ SQL Server documentation for more details about the LIKE semantics regarding blank padding and see also CHARACTER data types for the N prefix usage and single-char or wide-char mode usage.

**Solution**

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.

The MATCHES to LIKE expression translation is controlled by the following FGLPROFILE entry:

```sql
dbi.database.dbname.ifxemul.matches = \[true \| false \]
```

**Important:** Only [NOT] MATCHES followed by a search pattern provided as a string literal can be converted by ODI drivers. A [NOT] MATCHES followed by a ? question mark parameter place holder is not translated!

For maximum portability, consider replacing the MATCHES expressions with LIKE expressions in all SQL statements.

Avoid using CHAR(N) types for variable length character data (such as name, address).

**LIKE with UNICODE string literals on CHAR/NCHAR columns**

Pay attention to UNICODE string prefixes N'...' in the LIKE expressions when used with CHAR/NCHAR columns; You might want to always add a % wildcard at the end of the LIKE expression, or use the equal operator when doing a query with exact values.

**Related concepts**

MATCHES and LIKE operators on page 579

Use the standard LIKE operator instead of the MATCHES operator.

**The LENGTH() function**

**Informix®**

Informix® provides the LENGTH () function to count the number of bytes of a character string expression:

```sql
SELECT LENGTH("aaa"), LENGTH(col1) FROM table
```
Informix<sup>®</sup> LENGTH() does not count the trailing blanks for CHAR or VARCHAR expressions, while Oracle counts the trailing blanks.

Informix<sup>®</sup> LENGTH() returns 0 when the given string is empty. That means, \( \text{LENGTH('')} = 0 \).

**Microsoft™ SQL Server**

Microsoft™ SQL Server supports the LEN() function, but there are some differences with Informix<sup>®</sup> LENGTH().

**Note:** Do not confuse LEN() with DATALEN(), which returns the data size used for storage (number of bytes).

Like Informix<sup>®</sup>, Microsoft™ SQL Server ignores trailing blanks when computing the length of a string.

When passing NULL as parameter, the SQL Server LEN() function returns NULL.

**Solution**

The database driver is able to replace LENGTH() by the LEN() function name.

The translation of LENGTH() expressions can be controlled with the following FGLPROFILE entry:

```
  dbi.database.dsname.ifxemul.length = \[true \ | \ false \]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

The LENGTH() function in SQL on page 581

The semantics of the LENGTH() SQL function differs according to the database engine.

**String concatenation operator**

**Informix®**

The Informix® concatenation operator is the double pipe ( || ):

```
SELECT firstname || ' ' || lastname FROM employee
```

**Microsoft™ SQL Server**

The Microsoft™ SQL Server concatenation operator is the plus sign:

```
SELECT firstname + ' ' + lastname FROM employee
```

**Solution**

The database interface detects double-pipe operators in SQL statements and converts them to a plus sign automatically.

**BDL programming**

Microsoft™ SQL Server related programming topics.

**SQL errors on PREPARE**

**Informix®**

With Informix®, a PREPARE instruction returns an SQL error in case of problem:

```
TRY
  PREPARE stmt FROM "SELECT * FROM WHERE pk=1" -- table is missing!
CATCH
  DISPLAY "SQL ERROR:", SQLCA.SQLCODE
```
Microsoft™ SQL Server

The Genero database drivers for Microsoft™ SQL Server are based on ODBC drivers (SQL Native Client, MS ODBC SQL, FreeTDS or Easysoft drivers). These ODBC drivers use system stored procedures to prepare and execute SQL statements (you can check this with the SQL Server Profiler).

With SQL server, PREPARE or DECLARE instructions do not return an SQL error, because the statement preparation is deferred to the execution, improving overall performances.

When preparing an SQL statement with the BDL PREPARE or DECLARE instruction, no SQL error will be returned if the SQL statement is invalid. However, an SQL error will occur after the OPEN / FOREACH / EXECUTE instructions.

Solution

Make sure your BDL programs do not test the STATUS or SQLCA.SQLCODE variable just after PREPARE instructions.

Change the program logic in order to handle the SQL errors when opening the cursors (OPEN) or when executing SQL statements (EXECUTE).

INSERT cursors

Informix®

Informix® provides insert cursors to optimize row creation in a database. An insert cursor is declared as a cursor, and rows as added with the PUT instruction. The rows are buffered and sent to the database server when executing a FLUSH instruction, or when the cursor is closed with CLOSE. When using transactions in Informix®, the OPEN, PUT and FLUSH instructions must be executed within a transaction block.

```sql
DECLARE c1 CURSOR FOR INSERT INTO tab1 ... 
BEGIN WORK
OPEN c1
WHILE ...
  PUT c1 USING var-list
END WHILE
CLOSE c1
COMMIT WORK
```

Microsoft™ SQL Server

Microsoft™ SQL Server does not support insert cursors.

Solution

Insert cursors are emulated by the database interface, using basic INSERT SQL instructions.

The performances might be not as good as with Informix®, but the feature is fully supported.

Related concepts

Insert cursors on page 569
Using insert cursors with non-Informix databases.

**Cursors WITH HOLD**

**Informix®**

Informix® closes opened cursors automatically when a transaction ends, unless the `WITH HOLD` option is used in the `DECLARE` instruction:

```sql
DECLARE c1 CURSOR WITH HOLD FOR SELECT ... 
OPEN c1
BEGIN WORK
FETCH c1 ...
COMMIT WORK
FETCH c1 ...
CLOSE c1
```

**Microsoft™ SQL Server**

Microsoft™ SQL Server does not close cursors when a transaction ends.

This behavior is controlled with the `SET CURSOR_CLOSE_ON_COMMIT ON/OFF` instruction.

**Solution**

Even if Microsoft™ SQL Server supports cursors across transactions, for consistency with other ODI drivers, BDL cursors that are not declared `WITH HOLD` are automatically closed, when a `COMMIT WORK` or `ROLLBACK WORK` is performed.

**Related concepts**

`WITH HOLD and FOR UPDATE` on page 568

Hold cursors and not portable.

**SELECT ... FOR UPDATE**

**Informix®**

Legacy BDL programs typically use a cursor with `SELECT FOR UPDATE` to implement pessimistic locking and avoid several users editing the same rows:

```sql
DECLARE cc CURSOR FOR 
SELECT ... FROM tab WHERE ... FOR UPDATE 
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

The row must be fetched in order to set the lock.

If the cursor is local to a transaction, the lock is released when the transaction ends. If the cursor is declared `WITH HOLD`, the lock is released when the cursor is closed.

Informix® provides the `SET LOCK MODE` instruction to define the lock wait timeout:

```sql
SET LOCK MODE TO { 
WAIT | NOT WAIT | WAIT seconds } 
```

The default mode is `NOT WAIT`. 
Microsoft™ SQL Server

Microsoft™ SQL Server allows individual and exclusive row locking by using server cursors with *Scroll Locks* option, combined with SQL hints such as UPDLOCK in the FROM clause::

```
SELECT ... FROM tab1 WITH (UPDLOCK) WHERE ...
```

**Note:** In Transact-SQL, the FOR UPDATE [OF col-list] clause is not part of the SELECT syntax; it is part of T-SQL DECLARE CURSOR syntax.

Individual locks are acquired when fetching the rows.

When the cursor is opened outside a transaction (BDL WITH HOLD cursor option), locks are released when the cursor is closed.

When the cursor is opened inside a transaction, locks are released when the transaction ends.

SQL Server's locking granularity is at the row level, page level or table level (the level is automatically selected by the engine for optimization).

**Solution**

When executing a SELECT ... FOR UPDATE in the program, the SQL Server database drivers remove the FOR UPDATE clause from the SQL text and set the ODBC cursor attribute SQL_ATTR_CONCURRENCY to SQL_CONCUR_LOCK. This enables *Scroll Locks* concurrency in the server cursor.

The *Scroll Locks* option implements pessimistic concurrency control, in which the application attempts to lock the underlying database rows at the time they are read into the cursor result set.

SQL Server Transact-SQL hints such as UPDLOCK can be used to fine-tune the locking semantics that will be used by SQL Server.

When using server cursors with *Scroll Locks* option, an update lock is placed on the row when it is read into the cursor. If the cursor is opened within a transaction, the transaction update lock is held until the transaction is either committed or rolled back; the cursor lock is dropped when the next row is fetched.

If the cursor has been opened outside a transaction, the lock is dropped when the next row is fetched.

Therefore, it is recommended that a cursor is opened in a transaction whenever the user wants full pessimistic concurrency control.

An update lock prevents any other task from acquiring an update or exclusive lock, which prevents any other task from updating the row.

An update lock, however, does not block a shared lock, so it does not prevent other tasks from reading the row unless the second task is also requesting a read with an update lock.

SELECT FOR UPDATE statements are well supported in BDL as long as they are used inside a transaction. Avoid cursors declared WITH HOLD.

**Note:** The database interface is based on an emulation of an Informix® engine using transaction logging. Therefore, opening a SELECT ... FOR UPDATE cursor declared outside a transaction will raise an SQL error -255 (not in transaction).

The SELECT FOR UPDATE statement cannot contain an ORDER BY clause if you want to perform positioned updates/deletes with WHERE CURRENT OF.

Cursors declared with SELECT ... FOR UPDATE using the WITH HOLD clause cannot be supported with SQL Server.

Review the program logic if you use pessimistic locking, because it is based on the NOT WAIT mode which is not supported by SQL Server.

**Related concepts**

WITH HOLD and FOR UPDATE on page 568
Hold cursors and not portable.

**LOAD and UNLOAD**

**Informix®**

Informix® provides two SQL instructions to export / import data from / into a database table:

The **UNLOAD** instruction copies rows from a database table into a text file:

```sql
UNLOAD TO "filename.unl" SELECT * FROM tab1 WHERE ..
```

The **LOAD** instructions insert rows from a text file into a database table:

```sql
LOAD FROM "filename.unl" INSERT INTO tab1
```

**Microsoft™ SQL Server**

Microsoft™ SQL Server has **LOAD** and **UNLOAD** instructions, but those commands are related to database backup and recovery. Do not confuse with Informix® commands.

**Solution**

**LOAD** and **UNLOAD** instruction are implemented in the Genero BDL runtime system with basic **INSERT** (for **LOAD**) or **SELECT** (for **UNLOAD**) SQL commands. The **LOAD** and **UNLOAD** instruction can be supported with various database servers.

However, **LOAD** and **UNLOAD** require the description of the column types in order to work, that can lead to some differences in the data formatting.

**Note:** If no transaction is started, the **LOAD** instruction will automatically execute a **BEGIN WORK** and **COMMIT WORK** when finished, or **ROLLBACK WORK** if a row insertion failed while loading. Terminating a transaction will automatically close cursors not defined **WITH HOLD** option. To workaround this situation, see more details in the **LOAD** on page 684 reference topic.

The **LOAD** and **UNLOAD** BDL instructions are supported with Microsoft™ SQL Server with some limitations:

- The **LOAD** instruction does not work with tables using emulated **SERIAL** columns because the generated **INSERT** statement holds the **SERIAL** column which is actually a **IDENTITY** column in SQL Server. See the limitations of **INSERT** statements when using **SERIAL** types.

- Starting with Microsoft™ SQL Server 2008, Informix® **DATETIME** data is stored in SQL Server **DATETIME2(n<=5)** or **TIME(n<=5)** columns, depending on the precision of the original **DATETIME** type:
  - With **DATETIME2(n<=5)** columns, the result of **LOAD** and **UNLOAD** is equivalent to Informix® **DATETIME YEAR TO SECOND** or **DATETIME YEAR TO FRACTION(n)** columns. The data format will be "YYYY-MM-DD hh:mm:ss[.fff...]", where **fff...** depends on the precision (n) of the **DATETIME2(n)** column.
  - With **TIME(n)** columns, the result of **LOAD** and **UNLOAD** is equivalent to Informix® **DATETIME HOUR TO SECOND** or **DATETIME HOUR TO FRACTION(n)** columns. The data format will be "hh:mm:ss[.fff...]", where **fff...** depends on the precision (n) of the **TIME(n)** column.

- When using an Informix® database, simple dates are unloaded with the **DBDATE** format (ex: "23/12/1998"). Therefore, unloading from an Informix® database for loading into a Microsoft™ SQL SERVER database is not supported.

**Related concepts**

**LOAD and UNLOAD instructions** on page 574
The LOAD and UNLOAD instructions can produce different data formats depending on the database server type.

**SQL Interruption**

**Informix®**

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

**Microsoft™ SQL Server**

Microsoft™ SQL Server supports SQL Interruption: The db client must issue an SQLCancel() ODBC call to interrupt a query.

**Solution**

The SQL Server database drivers support SQL interruption and return the Informix® error code -213, when the statement is interrupted.

**Related concepts**

[Using SQL interruption](#) on page 539

Interrupt long running SQL queries, or interrupt queries waiting for locked data.

**Scrollable cursors**

**Informix®**

Informix® SQL and Genero BDL support scrollable cursors when you specify the SCROLL clause in the DECLARE cursor instruction:

```
DECLARE c1 SCROLL CURSOR FOR SELECT ...
```

**Microsoft™ SQL Server**

Microsoft™ SQL Server supports native scrollable cursors with the ODBC SQL_SCROLLABLE statement attribute.

**Solution**

All the SQL Server database drivers use the native SQL Server scrollable cursors, by setting the ODBC statement attribute SQL_ATTR_CURSOR_SCROLLABLE to SQL_SCROLLABLE.

**Related concepts**

Scrollable cursors on page 560

How scrollable cursors can be supported on different databases.

**Oracle® MySQL / MariaDB**

**Supported versions**

Genero BDL supports the following Oracle® MySQL versions:

- Oracle® MySQL 5.5 and 5.6 with dbmmys_5_5
- Oracle® MySQL 5.7 with dbmmys_5_7
- Oracle® MySQL 8.0 with dbmmys_8_0

Genero BDL supports the following MariaDB versions:

- MariaDB 10.0 and 10.1 with dbmmdb_5_5 (same driver as MySQL 5.5/5.6!)
- MariaDB 10.2+ with dbmmdb_10_2
**Installation (Runtime Configuration)**

**Oracle® MySQL related installation topics.**

**Install Oracle® MySQL/MariaDB and create a database - database configuration/design tasks**

If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. Install the Oracle® MySQL Server (or MariaDB) on your computer.
2. Configure the server with the appropriate storage engine.
   
   In order to have transaction support by default, you must use a storage engine that supports transactional tables, such as INNODB. In recent versions of MySQL, this is the default storage engine.
3. Consider setting the `sql_mode` configuration parameter to get the appropriate behavior of the MySQL server:
   
   a) When the STRICT_TRANS_TABLES mode is used, you will get a -1406 `error` (data too long) when inserting a character string that is too large for the target column.
      
      If you don’t use the STRICT_TRANS_TABLES mode, you get a -1265 `warning` (data truncated) when the value is too large.
   
   b) Blank padding of fetched CHAR data can be controlled with the `PAD_CHAR_TO_FULL_LENGTH`.
      
      You can use this parameter to get CHAR values padded with blanks to their full length, but the result of the `SQL LENGTH()` function will be different since trailing blanks are significant for that function in MySQL.
4. The `mysqld` process must be started to listen to database client connections. See MySQL documentation for more details about starting the database server process.
5. Create a database user dedicated to your application, the application administrator.

   Connect as the MySQL root user, create the application administrator user and grant all privileges to this user:

   ```sql
   $ mysql -u root -p
   ...
   mysql> create user 'mysuser'@'localhost' identified by 'password';
   mysql> grant all privileges on *.* to 'mysuser'@'localhost';
   ```

6. Connect as the application administrator and create a MySQL database with the `CREATE DATABASE` statement, and specify the character set to be used for this database:

   ```sql
   $ mysql -u mysuser -p
   ...
   mysql> create database mydatabase
       default character set utf8mb4
collate utf8mb4_unicode_ci;
   ```

7. Create the application tables.

   Convert Informix® data types to MySQL data types. See [Data type conversion table: Informix to MySQL](#) on page 817 for more details.

**Prepare the runtime environment - connecting to the database**

1. Check that the required ODI database driver is available in `FGLDIR/dbdrivers`.
   
   - For Oracle® MySQL 5.5 and 5.6, you must have the MySQL database driver "dbmmys_5_5".
   - For Oracle® MySQL 5.7, you must have the MySQL database driver "dbmmys_5_7".
   - For Oracle® MySQL 8.0, you must have the MySQL database driver "dbmmys" ("dbmmys_8_0").
   - For MariaDB 10.0/10.1, you must have the MySQL database driver "dbmmys_5_5".
   - For MariaDB 10.2+, you must have the MariaDB database driver "dbmmdb" ("dbmmdb_10_2").
2. Check that the MySQL/MariaDB database client software is available on the system.
   
   - For MySQL, check that the `libmysqlclient.*` library is installed on the system. The shared library version of the MySQL client library must match the `libmysqlclient` library version linked to the `dbmmys.so` ODI driver.
   - For MariaDB 10.0 and 10.1, check that the `libmysqlclient.so.18` library is installed on the system: This is the shared library linked to the `dbmmys_5_5.so` ODI driver.
• For MariaDB 10.2 and +, check that the libmariadb.* library is installed on the system. The shared library version of the MariaDB client library must match the libmariadb library version linked to the dbmmdb.so ODI driver.

3. Make sure that the MySQL/MariaDB client environment variables are properly set.
   Check for example MYSQL_HOME (the path to the installation directory), DATADIR (the path to the data files directory), etc. See MySQL documentation for more details about client environment variables to be set.

4. Check the MySQL/MariaDB client configuration options in the my.cnf file on your MySQL client environment.
   The driver will read the options defined in the [client] configuration group of the my.cnf file defined for the client application. Note that you can specify a particular configuration file with the following FGLPROFILE parameter:

   ```
   dbi.database.dbname.mys.config = "/opt/var/myapp/my.cnf"
   ```
   or, for MariaDB:

   ```
   dbi.database.dbname.mdb.config = "/opt/var/myapp/my.cnf"
   ```

5. Check the database client locale settings (default-character-set option in the my.cnf configuration file).
   The database client locale must match the locale used by the runtime system (LC_ALL, LANG). For example, in order to define (4-bytes) UTF-8 as MySQL client character set:

   ```
   [client]
   default-character-set="utf8mb4"
   ```

6. Verify the environment variable defining the search path for the database client shared library (libmysqlclient.so on UNIX™, LIBMYSQL.dll on Windows®).

   Table 217: Shared library environment setting for MySQL

<table>
<thead>
<tr>
<th>MySQL version</th>
<th>Shared library environment setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>MySQL 5.5 and higher and MariaDB 10.x</td>
<td>UNIX™: Add $MYSQL_HOME/lib to LD_LIBRARY_PATH (or its equivalent). Windows®: Add %MYSQL_HOME%\bin to PATH.</td>
</tr>
</tbody>
</table>

7. To verify if the MySQL/MariaDB client environment is correct, start the SQL command interpreter:

   ```
   $ mysql dbname -u appadmin -p
   ```

8. Set up the fglprofile entries for database connections.
   a) Define the MySQL/MariaDB database driver:
      For MySQL:

      ```
      dbi.database.dbname.driver = "dbmmys"
      ```
      For MariaDB:

      ```
      dbi.database.dbname.driver = "dbmmdb"
      ```
   b) The "source" parameter defines the name of the MySQL/MariaDB database.

      ```
      dbi.database.dbname.source = "test1"
      ```
**Database concepts**

Oracle® MySQL related database concepts topics.

**Database concepts**

Like Informix® servers, Oracle® MySQL can handle multiple database entities. Tables created by a user can be accessed without the owner prefix by other users as long as they have access privileges to these tables.

**Solution**

Create a MySQL database for each Informix® database.

**Data storage concepts**

When converting from Informix® to Oracle® MySQL the aim is to try to preserve as much of the data storage information as possible in the process. The most important storage decisions made for Informix® database objects (like initial sizes and physical placement) can be applied to the MySQL database.

Storage concepts are quite similar in Informix® and in MySQL, but the names are different.

**Concurrency management**

**Data consistency and concurrency concepts**

- *Data Consistency* applies to situations when readers want to access data currently being modified by writers.
- *Concurrent Data Access* applies to situations when several writers are accessing the same data for modification.
- *Locking Granularity* defines the amount of data concerned when a lock is set (for example, row, page, table).

**Informix®**

Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with UPDATE, INSERT or DELETE, an exclusive lock is set on the touched rows. The lock remains active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set shared locks, depending on isolation level. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification, or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the lock wait mode.

Control:

- Lock wait mode: SET LOCK MODE TO ...
- Isolation level: SET ISOLATION TO ...
- Locking granularity: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is READ COMMITTED.
- The default lock wait mode is NOT WAIT.
- The default locking granularity is PAGE.

**Oracle® MySQL**

When data is modified, exclusive locks are set and held until the end of the transaction. For data consistency, MySQL uses a locking mechanism. Readers must wait for writers as in Informix®.

Control:

- No lock wait mode control is provided.
- Isolation level: SET TRANSACTION ISOLATION LEVEL ...
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:
• The default isolation level is Read Committed.
• The default locking granularity is per table (per page when using BDB tables).

Solution
The `SET ISOLATION TO ...` Informix® syntax is replaced by `SET SESSION TRANSACTION ISOLATION LEVEL ...` in MySQL. The table shows the isolation level mappings applied by the MySQL database driver:

**Table 218: Isolation level mapping by the MySQL database driver**

<table>
<thead>
<tr>
<th>SET ISOLATION instruction in program</th>
<th>Native SQL command</th>
</tr>
</thead>
<tbody>
<tr>
<td>SET ISOLATION TO DIRTY READ</td>
<td>SET SESSION TRANSACTION ISOLATION LEVEL READ UNCOMMITTED</td>
</tr>
<tr>
<td>SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]</td>
<td>SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED</td>
</tr>
<tr>
<td>SET ISOLATION TO CURSOR STABILITY</td>
<td>SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED</td>
</tr>
<tr>
<td>SET ISOLATION TO REPEATABLE READ</td>
<td>SET SESSION TRANSACTION ISOLATION LEVEL REPEATABLE READ</td>
</tr>
</tbody>
</table>

For portability, it is recommended that you work with Informix® in the read committed isolation level, make processes wait for each other (lock mode wait), and create tables with the "lock mode row" option.

See Informix® and MySQL documentation for more details about data consistency, concurrency and locking mechanisms.

**Related concepts**

Concurrent data access on page 537
Understanding concurrent data access and data consistency.

Optimistic locking on page 561
Implementing optimistic locking to handle access concurrently to the same database records.

WITH HOLD and FOR UPDATE on page 568
Hold cursors and not portable.

Transactions handling

**Informix®**

With the Informix® native mode (non ANSI):

• Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
• Statements executed outside a transaction are automatically committed.
• DDL statements can be executed (and canceled) in transactions.

```
UPDATE tab1 SET ... -- auto-committed
BEGIN WORK          -- start of TX block
UPDATE tab1 SET ...
UPDATE tab2 SET ...
...                  -- end of TX block
COMMIT WORK
```

Informix® version 11.50 introduces savepoints:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT [name]
```
**Oracle® MySQL and MariaDB**

- Transactions are started with `START TRANSACTION`.
- Transactions are validated with `COMMIT [WORK]`.
- Transactions are canceled with `ROLLBACK [WORK]`.
- Savepoints can be placed with `SAVEPOINT name`.
- Transactions can be rolled back to a savepoint with `ROLLBACK [WORK] TO [SAVEPOINT] name`.
- Savepoints can be released with `RELEASE SAVEPOINT name`.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

**Solution**

Informix® transaction handling commands are automatically converted to MySQL instructions to start, validate or cancel transactions.

MySQL does not support transactions by default. You must set the server system parameter `table_type=InnoDB`.

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with MySQL, as long as you have a transaction manager installed with MySQL.

If you want to use savepoints, do not use the `UNIQUE` keyword in the savepoint declaration, always specify the savepoint name in `ROLLBACK TO SAVEPOINT`, and do not drop savepoints with `RELEASE SAVEPOINT`.

**Related concepts**

- **Database transactions** on page 538
- **Database users**
- **Informix®**
- **Oracle® MySQL and MariaDB**

MySQL users must be registered in the database:

```
$ mysql --host orion -u root -p
mysql> create user 'mysuser'@'localhost' identified by 'password';
mysql> grant all privileges on *.* to 'mysuser'@'localhost';
```

**Solution**

The solution depends on the application logic, for example, if it is a multi-user application, you have to create one or more MySQL users.

**Related concepts**

</thead>
<tbody>
<tr>
<td>TEXT</td>
<td>MEDIUMTEXT / LONGTEXT (max is 2Gb)</td>
</tr>
<tr>
<td>BYTE</td>
<td>MEDIUMBLOB / LONGBLOB (max is 2Gb)</td>
</tr>
</tbody>
</table>

**Notes:**

1. The CHAR types with a size > 255 are converted TEXT types. For more details, see CHAR and VARCHAR data types on page 818.
2. For more details about serial emulation, see SERIAL data type on page 825.
3. Only with MySQL >= 5.6.4 and MariaDB >= 5.3.0, for older versions DATETIME cannot use a fractional part.
4. The DECIMAL (32, 16) type is not supported by MySQL and MariaDB and will produce an SQL error.

### Related tasks

Install Oracle MySQL/MariaDB and create a database - database configuration/design tasks on page 812

### BOOLEAN data type

**Informix®**

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values.

Genero BDL implements the BOOLEAN data type in a different way: A BOOLEAN variable stores integer values 1 or 0 (for TRUE or FALSE). This type is designed to hold the result of a boolean expression.

**Oracle® MySQL and MariaDB**

MySQL supports the BOOLEAN data type and stores 1 or 0 integer values for TRUE and FALSE.

### Solution

The MySQL and MariaDB database interfaces support the BOOLEAN data type and stores 1 or 0 values in the column.

The BOOLEAN type translation can be controlled with the following FGLPROFILE entry:

```plaintext
dbi.database.dsname.ifxemul.datatype.boolean = true false
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

### Related concepts

Using portable data types on page 553

Only a limited set of data types are really portable across several database engines.

### CHAR and VARCHAR data types

**Informix®**

Informix® supports the following character data types:

#### Table 220: Informix® character data types

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>SBCS and MBCS character data (max is 32767 bytes)</td>
</tr>
<tr>

<td>SBCS and MBCS character data (max is 255 bytes)</td>
</tr>
<tr>
<td>NCHAR (n)</td>
<td>Same as CHAR, with specific collation order</td>
</tr>
<tr>
<td>NVARCHAR (n, m)</td>
<td>Same as VARCHAR, with specific collation order</td>
</tr>
</tbody>
</table>
Informix® data type | Description
--- | ---
LVARCHAR\((n)\) | max size varies depending on the IDS version

With Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is in how they use sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order.

The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable.

The character set used by applications is defined by the CLIENT_LOCALE environment variable.

Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR\((N)\) is expressed in bytes, not characters as in some other databases)

**Oracle® MySQL and MariaDB**

MySQL and MariaDB support the following data types to store character data:

**Table 221: MySQL character data types**

<table>
<thead>
<tr>
<th>MySQL data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR((n))</td>
<td>SBCS or MBCS character data using the database character set, where (n) is specified in characters (max is 255 characters)</td>
</tr>
<tr>
<td>VARCHAR((n))</td>
<td>SBCS or MBCS character data using the database character set, where (n) is specified in characters (max is 65535 characters)</td>
</tr>
<tr>
<td>NCHAR((n))</td>
<td>SBCS or MBCS character data using the national character set, where (n) is specified in characters (max is 255 characters)</td>
</tr>
<tr>
<td>NVARCHAR((n))</td>
<td>SBCS or MBCS character data using the national character set, where (n) is specified in characters (max is 65535 characters)</td>
</tr>
<tr>
<td>TEXT</td>
<td>The Large Object type to store SBCS or MBCS character data using the database character set</td>
</tr>
</tbody>
</table>

MySQL uses character length semantics to define the size of CHAR/VARCHAR columns, while Informix® and Genero use Byte Length Semantics.

MySQL can support multiple character sets, you can run the SHOW CHARACTER_SET statement to list supported encoding. There are different configuration levels to define the character set used by MySQL to store data. The server character set defines the default for database character sets if not specified in the CREATE DATABASE command. You can even define a specific character set at the table and column level, but this is not recommended with Genero applications. The database character set is used to store CHAR and VARCHAR columns. The NCHAR and NATIONAL VARCHAR types use a predefined character set which can be different from the database character set. In MySQL the national character set is UTF-8.

MySQL can automatically convert from/to the client and server characters sets. In the client applications, you define the character set with the SET NAMES instruction.

Note that by default, when fetching CHAR columns from MySQL, trailing blanks are trimmed. This does not matter as long as you fetch CHAR columns into CHAR variables, but this non-standard behavior will impact CHAR fetch into VARCHAR, or other SQL areas such as string concatenation for example. You can control the behavior of CHAR trailing blanks trimming with the PAD_CHAR_TO_FULL_LENGTH sql-mode parameter. But when this mode is used, the result of the SQL LENGTH\(()\) function will be different since trailing blanks are significant for that function in MySQL.
Solution

Informix® CHAR (N) types must be mapped to MySQL CHAR (N) types. Informix® VARCHAR (N) or LVARCHAR (N) types must be mapped to MySQL VARCHAR (N).

You can store single-byte or multibyte character strings in MySQL CHAR, VARCHAR and TEXT columns.

MySQL uses character length semantics: When you define a CHAR(20) and the database character set is multibyte, the column can hold more bytes/characters than the Informix® CHAR(20) type, when using byte length semantics. When using a multibyte character set (such as UTF-8), define database columns with the size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR.

When extracting a database schema from a MySQL database, the `fgldbsch` schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters) ) column in a MySQL database using the UTF8 character set, the .sch file will get a size of 10, which will be interpreted depending on FGL_LENGTH_SEMANTICS as a number of bytes or characters.

Do not forget to properly define the database client character set, which must correspond to the runtime system character set.

Review your database schema when using CHAR columns with a size exceeding the MySQL limits: If you need to store CHAR character strings larger as the MySQL CHAR limit, you can use the MySQL TEXT type. However, as of MySQL version 5.0.3 (supporting large VARCHAR sizes), as long as you use short sizes for CHAR (<100c), the character types can be used as is in MySQL.

The CHAR (N>255) types are converted by the SQL Translator to a MySQL TEXT type, because MySQL CHAR type has a limit of 255 characters. When designing a database, consider using CHAR only for short character string data storage (<50c), and use VARCHAR for larger character string data storage (name, address, comments).

**Note:** For each TEXT column fetched from MySQL, the MySQL database driver needs to allocate a temporary string buffer of 65535 bytes. The memory used by this temporary buffer is freed when freeing the cursor.

When using VARCHAR types, the SQL Translator leaves the type definition as is, even for N > 255, assuming that the target MySQL server version is at least 5.0.3 (supporting VARCHAR (N) up to 65535 characters).

See also the section about Localization.

The CHAR/VARCHAR type translation can be controlled with the following FGLPROFILE entries:

```
  dbi.database.dbname.ifxemul.datatype.char = { true | false }
  dbi.database.dbname.ifxemul.datatype.varchar = { true | false }
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

CHAR and VARCHAR types on page 555

Using the CHAR and VARCHAR data types with different databases.

**NUMERIC data types**

**Informix®**

Informix® supports several data types to store numbers:

**Table 222: Informix® numeric data types**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>16 bit signed integer</td>
</tr>
<tr>
<td>INTEGER</td>
<td>32 bit signed integer</td>
</tr>
<tr>
<td>BIGINT</td>
<td>64 bit signed integer</td>
</tr>
<tr>
<td>Informix® data type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>INT8</td>
<td>64 bit signed integer (replaced by BIGINT)</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>Equivalent to DECIMAL(16)</td>
</tr>
<tr>
<td>DECIMAL(p)</td>
<td>Floating-point decimal number (max precision is 32)</td>
</tr>
<tr>
<td>DECIMAL(p, s)</td>
<td>Fixed-point decimal number (max precision is 32)</td>
</tr>
<tr>
<td>MONEY</td>
<td>Equivalent to DECIMAL(16,2)</td>
</tr>
<tr>
<td>MONEY(p)</td>
<td>Equivalent to DECIMAL(p, 2) (max precision is 32)</td>
</tr>
<tr>
<td>MONEY(p, s)</td>
<td>Equivalent to DECIMAL(p, s) (max precision is 32)</td>
</tr>
<tr>
<td>REAL / SMALLFLOAT</td>
<td>32-bit floating point decimal (C float)</td>
</tr>
<tr>
<td>DOUBLE PRECISION / FLOA[T[M,D]]</td>
<td>64-bit floating point decimal (C double)</td>
</tr>
</tbody>
</table>

**Oracle® MySQL and MariaDB**

MySQL and MariaDB support the following data types to store numbers:

**Table 223: MySQL numeric data types**

<table>
<thead>
<tr>
<th>MySQL data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>16 bit signed integer</td>
</tr>
<tr>
<td>INTEGER</td>
<td>32 bit signed integer</td>
</tr>
<tr>
<td>BIGINT</td>
<td>64 bit signed integer</td>
</tr>
<tr>
<td>DECIMAL(p, s)</td>
<td>Fixed point decimal. Maximum precision depends on MySQL Version, see documentation</td>
</tr>
<tr>
<td>DECIMAL(p)</td>
<td>Stores whole numeric numbers up to p digits</td>
</tr>
<tr>
<td>FLOAT[M,D]</td>
<td>32 bit floating point number</td>
</tr>
<tr>
<td>DOUBLE[M,D]</td>
<td>64 bit floating point number</td>
</tr>
</tbody>
</table>

**Note:** Before MySQL 5.0.3, the maximum range of DECIMAL values is the same as for DOUBLE. Since MySQL 5.0.3, DECIMAL can store real precision numbers as in Informix®. However, the maximum number of digits depends on the version of MySQL, see documentation for more details. We strongly recommend that you make tests (INSERT + SELECT) to check whether large decimals are properly inserted and fetched back.

**Solution**

Use the following conversion rules to map Informix numeric types to MySQL numeric types:

**Table 224: Informix® numeric data types and MySQL equivalents**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>MySQL equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMALLINT</td>
<td>SMALLINT</td>
</tr>
<tr>
<td>INTEGER</td>
<td>INTEGER</td>
</tr>
<tr>
<td>INT8 / BIGINT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>DECIMAL(p&lt;=16)</td>
<td>DECFLOAT(16)</td>
</tr>
<tr>
<td>DECIMAL(p&gt;16)</td>
<td>DECFLOAT(34)</td>
</tr>
</tbody>
</table>
### Informix® data type | MySQL equivalent
---|---
DECIMAL(p<=31,s) | DECIMAL(p,s)
DECIMAL(32,s) | No equivalent
MONEY | DECIMAL(16,2)
MONEY(p) | DECIMAL(p,2)
MONEY(p,s) | DECIMAL(p,s)
SMALLFLOAT | REAL
FLOAT[(n)] | FLOAT[(n)] (DOUBLE)

The numeric types translation can be controlled with the following FGLPROFILE entries:

```
  dbi.database.dsname.ifxemul.datatype.smallint = {true | false}
  dbi.database.dsname.ifxemul.datatype.integer = {true | false}
  dbi.database.dsname.ifxemul.datatype.bigint = {true | false}
  dbi.database.dsname.ifxemul.datatype.int8 = {true | false}
  dbi.database.dsname.ifxemul.datatype.decimal = {true | false}
  dbi.database.dsname.ifxemul.datatype.money = {true | false}
  dbi.database.dsname.ifxemul.datatype.float = {true | false}
  dbi.database.dsname.ifxemul.datatype.smallfloat = {true | false}
```

For more details see [IBM Informix emulation parameters in FGLPROFILE](#) on page 614.

**Related concepts**

- [Using portable data types](#) on page 553

Only a limited set of data types are really portable across several database engines.

### DATE and DATETIME data types

**Informix®**

Informix® provides two data types to store date and time information:

- **DATE** = for year, month and day storage.
- **DATETIME** = for year to fraction (1-5) storage.

The **DATE** type is stored as an **INTEGER** with the number of days since 1899/12/31.

The **DATETIME** type can be defined with various time units, by specifying a start and end qualifier. For example, you can define a datetime to store an hour-to-second time value with **DATETIME HOUR TO SECOND**.

The values of Informix® **DATETIME** can be represented with a character string literal, or as **DATETIME()** literals:

- `'2017-12-24 15:45:12.345'` -- a **DATETIME YEAR TO FRACTION(3)**
- `'15:45'` -- a **DATETIME HOUR TO MINUTE**
- **DATETIME(2017-12-24 12:45)** **YEAR TO MINUTE**
- **DATETIME(12:45:56.333)** **HOUR TO FRACTION(3)**

Informix® is able to convert quoted strings to **DATE** / **DATETIME** data, if the string contains matching environment parameters. The string to date conversion rules for **DATE** is defined by the DBDATE environment variable. The string to datetime format for **DATETIME** is defined by the GL_DATETIME environment variable.

**Note:** Within Genero programs, the string representation for **DATETIME** values is always ISO (**YYYY-MM-DD hh:mm:ss.fffffff**)  

Informix® supports date arithmetic on **DATE** and **DATETIME** values. The result of an arithmetic expression involving dates/times is an **INTEGER** number of days when only **DATE** values are used, and an **INTERVAL** value if a **DATETIME** is used in the expression.
Informix® automatically converts an INTEGER to a DATE when the integer is used to set a value of a date column.

**Oracle® MySQL and MariaDB**

MySQL and MariaDB provide the following data type to store date and time data:

**Table 225: MySQL date/time data types**

<table>
<thead>
<tr>
<th>MySQL data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>for year, month, day storage</td>
</tr>
<tr>
<td>TIME((n))</td>
<td>for hour, minute, second and fraction of second storage</td>
</tr>
<tr>
<td>DATETIME((n))</td>
<td>for year, month, day, hour, minute, second and fraction of second storage</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>Like DATETIME, but is automatically updated when row is touched</td>
</tr>
</tbody>
</table>

Like Informix®, MySQL can convert quoted strings to datetime data based on the ISO datetime format (YYYY-MM-DD hh:mm:ss).

In MySQL, the result of an arithmetic expression involving DATE values is an INTEGER representing a number of days.

**Solution**

Use the following conversion rules to map Informix® date/time types to MySQL date/time types:

**Table 226: Informix® data types and MySQL equivalents**

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>MySQL data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>DATE</td>
</tr>
<tr>
<td>DATETIME HOUR TO MINUTE</td>
<td>TIME</td>
</tr>
<tr>
<td>DATETIME HOUR TO SECOND</td>
<td>TIME</td>
</tr>
<tr>
<td>DATETIME HOUR TO FRACTION((n))</td>
<td>TIME((n))</td>
</tr>
<tr>
<td>DATETIME YEAR TO MINUTE</td>
<td>DATETIME</td>
</tr>
<tr>
<td>DATETIME YEAR TO SECOND</td>
<td>DATETIME</td>
</tr>
<tr>
<td>DATETIME YEAR TO FRACTION((n))</td>
<td>DATETIME((n))</td>
</tr>
<tr>
<td>DATETIME q1 TO q2 (others than above)</td>
<td>DATETIME((p))</td>
</tr>
</tbody>
</table>

The DATE and DATETIME types translation can be controlled with the following FGLPROFILE entries:

```
  dbi.database.dsname.ifxemul.datatype.date = ↓ true ↓ false ↓
  dbi.database.dsname.ifxemul.datatype.datetime = ↓ true ↓ false ↓
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

MySQL and Informix® DATE data types both store year, month, day values.

The SQL Translator of the MySQL driver makes the following conversions automatically for the DATETIME types:

- DATETIME HOUR TO MINUTE is converted to MySQL TIME (seconds set to 00).
- DATETIME HOUR TO SECOND is converted to MySQL TIME.
- DATETIME HOUR TO FRACTION\((n)\) is converted to MySQL TIME\((n)\).
- DATETIME YEAR TO MINUTE is converted to MySQL DATETIME (seconds set to 00).
- DATETIME YEAR TO SECOND is converted to MySQL DATETIME.
• DATETIME YEAR TO FRACTION \(n\) is converted to MySQL DATETIME \(n\).

Other DATETIME types will be mapped to MySQL DATETIME \((n)\) columns. Missing date or time parts default to 1900-01-01 00:00:00.

**Important:** MySQL version older than 5.6.4 and MariaDB versions older than 5.3.0 do not support fractional part of DATETIME. If you try to store a DATETIME \(q1\) TO FRACTION \((p)\) with such an old server version, the fractional part is lost.

**Related concepts**

Date/time literals in SQL statements on page 571
Good practices for date and time handling in SQL.

**INTERVAL data type**

**Informix**

Informix® provides the INTERVAL data type to store a value that represents a span of time.

INTERVAL types are divided into two classes:

• *year-month* intervals. For example: INTERVAL YEAR(5) TO MONTH
• *day-time* intervals. For example: INTERVAL DAY(9) TO SECOND

INTERVAL columns can be defined with various time units, by specifying a start and end qualifier. For example, you can define an interval to store a number of hours and minutes with INTERVAL HOUR\(n\) TO MINUTE, where \(n\) defines the maximum number of digits for the hours unit.

The values of Informix® INTERVAL can be represented with a character string literal, or as INTERVAL() literals:

```
'-9834 15:45:12.345'  -- an INTERVAL DAY(6) TO FRACTION(3)
'7623-11'   -- an INTERVAL YEAR(9) TO MONTH
INTERVAL(18734:45) HOUR(5) TO MINUTE
INTERVAL(-7634-11) YEAR(5) TO MONTH
```

**Oracle® MySQL and MariaDB**

MySQL and Mariadb support an INTERVAL data type.

However, this native type is totally different from the Informix® INTERVAL type.

For example, you specify INTERVAL literals as follows:

```
25 years 2 months 23 days
```

**Solution**

The INTERVAL data type and values are converted CHAR(50) column with MySQL.

INTERVAL values can be stored and retrieved from the database. However, interval arithmetics cannot be performed on the database side in SQL statements.

The INTERVAL types translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemul.datatype.interval = \| true \| false \|
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

**SERIAL data type**

**Informix®**

Informix® supports the SERIAL, BIGSERIAL data types to produce automatic integer sequences:

- SERIAL can produce 32 bit integers (INTEGER)
- BIGSERIAL can produced 64 bit integers (BIGINT)
- SERIAL8 is a synonym for BIGSERIAL

Steps to use serials with Informix®:

1. Create the table with a column using SERIAL, or BIGSERIAL.
2. To generate a new serial, no value or a zero value is specified in the INSERT statement:

   ```sql
   INSERT INTO tab1 ( c ) VALUES ( 'aa' )
   INSERT INTO tab1 ( k, c ) VALUES ( 0, 'aa' )
   ```

3. After INSERT, the new value of a SERIAL column is provided in SQLCA.SQLERRD[2], while the new value of a BIGSERIAL value must be fetched with a SELECT dbinfo('bigserial') query.

Informix® allows you to insert rows with a value different from zero for a serial column. Using an explicit value will automatically increment the internal serial counter, to avoid conflicts with future INSERT statements that are using a zero value:

```sql
CREATE TABLE tab ( k SERIAL); -- internal counter = 0
INSERT INTO tab VALUES ( 0 ); -- internal counter = 1
INSERT INTO tab VALUES ( 10 ); -- internal counter = 10
INSERT INTO tab VALUES ( 0 ); -- internal counter = 11
DELETE FROM tab; -- internal counter = 11
INSERT INTO tab VALUES ( 0 ); -- internal counter = 12
```

**Oracle® MySQL and MariaDB**

MySQL supports the AUTO_INCREMENT column definition option as well as the SERIAL keyword:

- In CREATE TABLE, you specify a auto-incremented column with the AUTO_INCREMENT attribute
- Auto-incremented columns have the same behavior as Informix® SERIAL columns
- A start value can be defined with ALTER TABLE tabname AUTO_INCREMENT = value
- The column must be the primary key, or the first column of an index.
- When using the InnoDB engine, with MySQL 5.7 and earlier, auto-incremented columns might reuse unused sequences after a server restart. For example, if you insert rows that generate the numbers 101, 102 and 103, then you delete rows 102 and 103; When the server is restarted, next generated number will be 101 + 1 = 102. Starting with MySQL 8.0, the last auto-incremented value is written to the disk and persists across server restarts.
- SERIAL is a synonym for BIGINT UNSIGNED NOT NULL AUTO_INCREMENT UNIQUE.

**Solution**

**Note:** For best SQL portability when using different type of databases, consider using sequences as described in Solution 3: Use native SEQUENCE database objects on page 565.

The Informix® SERIAL data type is emulated with MySQL AUTO_INCREMENT option.

The serial types emulation can be enabled or disabled with the following FGLPROFILE entries:

```sql
dbi.database.dbname.ifxemul.datatype.serial = [true|false]
dbi.database.dbname.ifxemul.datatype.serial8 = [true|false]
dbi.database.dbname.ifxemul.datatype.bigserial = [true|false]
```
After an insert, SQLCA.SQLERRD[2] holds the last generated serial value. However, SQLCA.SQLERRD[2] is defined as an INTEGER, it cannot hold values from BIGINT auto incremented columns. If you are using BIGINT auto incremented columns, you must use the LAST_INSERT_ID() SQL function.

**AUTO_INCREMENT** columns must be primary keys. This is handled automatically when you create a table in a BDL program.

Like Informix®, MySQL allows you to specify a zero for auto-incremented columns. However, for SQL portability, it is recommended to review INSERT statements to remove the SERIAL column from the list.

For example, the following statement:

```
INSERT INTO tab (col1,col2) VALUES ( 0, p_value)
```

can be converted to:

```
INSERT INTO tab (col2) VALUES (p_value)
```

Static SQL INSERT using records defined from the schema file must also be reviewed:

```
DEFINE rec LIKE tab.*
INSERT INTO tab VALUES ( rec.* ) -- will use the serial column
```

can be converted to:

```
INSERT INTO tab VALUES rec.* -- without parentheses, serial column is removed
```

**Related concepts**

- Auto-incremented columns (serials) on page 562
- How to implement automatic record keys.

**ROWID columns**

**Informix®**

When creating a table, Informix® automatically adds a ROWID integer column (applies to non-fragmented tables only).

The ROWID column is auto-filled with a unique number and can be used like a primary key to access a given row.

**Note:** Informix® ROWID usage was a common practice in the early days of Informix® 4GL programming. Today it is recommended to define all your database tables with a PRIMARY KEY to uniquely identify rows.

With Informix®, the SQLCA.SQLERRD[6] register contains the ROWID of the last modified row.

**Oracle® MySQL and MariaDB**

MySQL and MariaDB do not support ROWIDs.

**Solution**

If the BDL application uses ROWIDs, it is recommended that the program logic is reviewed in order to use the real primary keys instead (usually serials, which can be supported). All references to SQLCA.SQLERRD[6] must be removed because this variable will not hold the ROWID of the last modified row.

The ROWID keyword translation can be controlled with the following FGLPROFILE entry:

```
dbi.database.dsname.ifxemul.rowid = ↓ true ↓ false ↓
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.
Related concepts
Using ROWID columns on page 578
Automatic ROWID columns is not a common database feature.

TEXT and BYTE (LOB) types

Informix®
Informix® provides the TEXT, BYTE, CLOB and BLOB data types to store very large texts or binary data.
Legacy Informix® 4GL applications typically use the TEXT and BYTE types.
Genero BDL does not support the Informix® CLOB and BLOB types.

Oracle® MySQL and MariaDB
MySQL provides the following types to store large objects in the database:

Table 227: MySQL and MariaDB LOB data types

<table>
<thead>
<tr>
<th>MySQL data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYTEXT</td>
<td>To store text data with a length &lt; $2^8$ bytes</td>
</tr>
<tr>
<td>TEXT</td>
<td>To store text data with a length &lt; $2^{16}$ bytes</td>
</tr>
<tr>
<td>MEDIUMTEXT</td>
<td>To store text data with a length &lt; $2^{24}$ bytes</td>
</tr>
<tr>
<td>LONGTEXT</td>
<td>To store text data with a length &lt; $2^{32}$ bytes</td>
</tr>
<tr>
<td>TINYBLOB</td>
<td>To store binary data with a length &lt; $2^8$ bytes</td>
</tr>
<tr>
<td>BLOB</td>
<td>To store binary data with a length &lt; $2^{16}$ bytes</td>
</tr>
<tr>
<td>MEDUMBLOB</td>
<td>To store binary data with a length &lt; $2^{24}$ bytes</td>
</tr>
<tr>
<td>LONGBLOB</td>
<td>To store binary data with a length &lt; $2^{32}$ bytes</td>
</tr>
</tbody>
</table>

Solution
The MySQL and MariaDB database interface can convert BDL TEXT data to LONGTEXT and BYTE data to LONGBLOB.
The TEXT and BYTE types translation can be controlled with the following FGLPROFILE entries:

```
  dbi.database.dsnname.ifxemul.text = \t{true \tfalse}
  dbi.database.dsnname.ifxemul.byte = \t{true \tfalse}
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.
Genero TEXT/BYTE program variables have a limit of 2 gigabytes, make sure that the large object data does not exceed this limit.

Note: Because MySQL/MariaDB CHAR and VARCHAR cannot exceed 255 bytes, we recommend that you use the MySQL TEXT type to store CHAR/VARCHAR values with a size larger than 255 bytes. When fetching TEXT columns from a MySQL database, these will be treated as CHAR/VARCHAR types by the MySQL database driver. See CHAR/VARCHAR types for more details.

Related concepts
Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

**Table constraints**

**Informix®**
Informix® supports primary key, unique, foreign key, default and check constraints.

The constraint naming syntax is different in Informix® and most other databases: Informix expects the "CONSTRAINT" keyword after the constraint specification:

```sql
CREATE TABLE emp (
    ...
    emp_code CHAR(10) UNIQUE CONSTRAINT pk_emp,
    ...
)
```

While other databases it before:

```sql
CREATE TABLE emp (
    ...
    emp_code CHAR(10) CONSTRAINT pk_emp UNIQUE,
    ...
)
```

**Oracle® MySQL and MariaDB**
MySQL and MariaDB support primary key, unique, foreign key and default constraints.

**Important:** MySQL and MariaDB do not support CHECK constraints. In fact, the syntax is allowed but the constraint is ignored.

**Constraint naming syntax**
The constraint naming clause must be placed **before** the constraint specification.

**Primary keys**
MySQL creates an index to enforce PRIMARY KEY constraints (some RDBMS do not create indexes for constraints). Using CREATE UNIQUE INDEX to define unique constraints is obsolete (use primary keys or a secondary key instead).

In MySQL, the name of a PRIMARY KEY is PRIMARY.

**Unique constraints**
Like Informix®, MySQL creates an index to enforce UNIQUE constraints (some RDBMS do not create indexes for constraints).

When using a unique constraint, Informix® allows only one row with a NULL value, while MySQL allows several rows with NULL! Using CREATE UNIQUE INDEX is obsolete.

**Foreign keys**
Both Informix® and MySQL support the ON DELETE CASCADE option. In MySQL, foreign key constraints are checked immediately, so NO ACTION and RESTRICT are the same.

**Check constraints**
Check constraints are not yet supported in MySQL.
**Solution**

**Constraint naming syntax**

The database interface does not convert constraint naming expressions when creating tables from BDL programs. Review the database creation scripts to adapt the constraint naming clauses for MySQL.

If your application tables use CHECK constraints, you need to implement these constraints with triggers.

**Related concepts**

- [Data definition statements](#) on page 552
- It is recommended to avoid use of DDL in programs.

**Name resolution of SQL objects**

**Informix®**

Informix® uses the following form to identify an SQL object:

```
database[@dbservername]:][{owner|"owner"].]identifier
```

The ANSI convention is to use double quotes for identifier delimiters (For example: 
"customer"."cust_name").

Informix® database object names are not case-sensitive in non-ANSI databases. When using double-quoted identifiers, Informix® becomes case sensitive.

With non-ANSI Informix® databases, you do not have to give a schema name before the tables when executing an SQL statement:

```
SELECT ... FROM customer WHERE ...
```

In Informix® ANSI compliant databases:

- The table name must include "owner", unless the connected user is the owner of the database object.
- The database server shifts the owner name to uppercase letters before the statement executes, unless the owner name is enclosed in double quotes.

**Oracle® MySQL and MariaDB**

With MySQL and MariaDB, an object name takes the following form:

```
[database.]identifier
```

**Solution**

As a general rule, to write portable SQL, it is recommended that you only use simple database object names without any database, server or owner qualifier and without quoted identifiers.

**Data manipulation**

Oracle® MySQL related data manipulation topics.

**Reserved words**

**Informix®**

With Informix®, it is possible to create database objects with reserved words.

For example:

```
CREATE TABLE table ( char CHAR(10) );
```
Indeed this is not good practice, but Informix® SQL allows this to be backward compatible when introducing a new keyword in the SQL syntax.

Most other database systems do not allow reserved words as database identifiers. If your legacy code is using SQL reserved words of the target database SQL syntax, an error will be thrown at `CREATE TABLE` execution.

**Oracle® MySQL and MariaDB**

SQL object names like table and column names cannot be SQL reserved words in MySQL.

**Solution**

Table or column names which are MySQL reserved words must be renamed.

**Outer joins**

**Informix® OUTER() syntax**

In Informix® SQL, outer joins can be defined in the FROM clause with the OUTER keyword:

```sql
SELECT ... FROM a, OUTER (b)
    WHERE a.key = b.akey

SELECT ... FROM a, OUTER(b, OUTER(c))
    WHERE a.key = b.akey
    AND b.key1 = c.bkey1 AND b.key2 = c.bkey2
```

Informix® also supports the ANSI OUTER join syntax, which is the recommended way to specify outer joins with recent SQL database engines:

```sql
SELECT ... FROM cust LEFT OUTER JOIN order
    ON cust.key = order.custno
```

**Oracle® MySQL and MariaDB**

MySQL and MariaDB support the ANSI outer join syntax:

```sql
SELECT ... FROM cust LEFT OUTER JOIN order
    LEFT OUTER JOIN item
    ON order.key = item.ordno
    ON cust.key = order.custno
    WHERE order.cdate > current date
```

**Solution**

The Genero database drivers can convert Informix Informix® OUTER specifications to ANSI outer joins.

**Note:** For better SQL portability, use the ANSI outer join syntax instead of the old Informix® OUTER syntax.

The outer join translation can be controlled with the following FGLPROFILE entry:

```ini
dbi.database.dsnname.ifxemulouters = true
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

- **Prerequisites:**
  1. In the FROM clause, the main table must be the first item and the outer tables must be listed from left to right in the order of outer levels.
Example which does not work:

```sql
... FROM OUTER(tab2), tab1
```

2. The outer join in the WHERE clause must use the table name as prefix:

```sql
... WHERE tab1.col1 = tab2.col2
```

### Restrictions:

1. Statements composed by 2 or more SELECT instructions are not supported:

```sql
SELECT ... UNION SELECT ...
```

or:

```sql
SELECT ... WHERE col IN (SELECT...)
```

2. Additional conditions on outer table columns cannot be detected and therefore are not supported:

```sql
... FROM tab1, OUTER(tab2)
WHERE tab1.col1 = tab2.col2
AND tab2.colx > 10
```

### Notes:

1. Table aliases are detected in OUTER expressions.

   OUTER example with table alias:

   ```sql
   ... OUTER(tab1 alias1) ...
   ```

2. In the outer join, `outertab.col` can be placed on both right or left sides of the equal sign:

   ```sql
   ... WHERE outertab.col1 = maintab.col2
   ```

3. Table names detection is not case-sensitive:

   ```sql
   SELECT ... FROM tab1, TAB2
   WHERE tab1.col1 = tab2.col2
   ```

4. Temporary tables are supported in OUTER specifications:

   ```sql
   CREATE TEMP TABLE tt1 ( ... )
   SELECT ... FROM tab1, OUTER(tt1) ...
   ```

**Related concepts**

**Outer joins** on page 577
Use standard ISO outer join syntax instead of the old IBM® Informix® `OUTER()` syntax.

**Transactions handling**

**Informix®**

With the Informix® native mode (non ANSI):

- Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
- Statements executed outside a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

```sql
UPDATE tab1 SET ... -- auto-committed
BEGIN WORK                 -- start of TX block
```
Informix® version 11.50 introduces savepoints:

```
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT _name_
RELEASE SAVEPOINT name
```

**Oracle® MySQL and MariaDB**

- Transactions are started with `START TRANSACTION`.
- Transactions are validated with `COMMIT [WORK]`.
- Transactions are canceled with `ROLLBACK [WORK]`.
- Savepoints can be placed with `SAVEPOINT name`.
- Transactions can be rolled back to a savepoint with `ROLLBACK [WORK] TO [SAVEPOINT] name`.
- Savepoints can be released with `RELEASE SAVEPOINT name`.
- Statements executed outside of a transaction are automatically committed.
- DDL statements can be executed (and canceled) in transactions.

**Solution**

Informix® transaction handling commands are automatically converted to MySQL instructions to start, validate or cancel transactions.

MySQL does not support transactions by default. You must set the server system parameter `table_type=InnoDB`.

Regarding the transaction control instructions, the BDL applications do not have to be modified in order to work with MySQL, as long as you have a transaction manager installed with MySQL.

If you want to use savepoints, do not use the `UNIQUE` keyword in the savepoint declaration, always specify the savepoint name in `ROLLBACK TO SAVEPOINT`, and do not drop savepoints with `RELEASE SAVEPOINT`.

**Related concepts**

- [Database transactions](#) on page 538
  Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Temporary tables**

**Informix®**

Informix® temporary tables are created with the `CREATE TEMP TABLE DDL` instruction or with `SELECT ... INTO TEMP` statement:

```
CREATE TEMP TABLE tt1 ( pkey INT, name VARCHAR(50) )
CREATE TEMP TABLE tt2 ( pkey INT, name VARCHAR(50) ) WITH NO LOG
SELECT * FROM tab1 WHERE pkey > 100 INTO TEMP tt2
```

Temporary tables are automatically dropped when the SQL session ends, but they can also be dropped with the `DROP TABLE` command. There is no name conflict when several users create temporary tables with the same name.

BDL REPORTs can create a temporary table when the rows are not sorted externally (by the source SQL statement).

Informix® allows you to create indexes on temporary tables. No name conflict occurs when several users create an index on a temporary table by using the same index identifier.
When creating temporary tables in Informix®, the WITH NO LOG clause can be used to avoid the overhead of recording DML operations in transaction logs.

**Oracle® MySQL and MariaDB**

MySQL support temporary tables with the following syntax:

```sql
CREATE TEMPORARY TABLE tablename ( coldef [, ...] )
```

and:

```sql
CREATE TEMPORARY TABLE tablename LIKE other-table
```

**Solution**

In BDL, Informix® temporary tables instructions are converted to generate native SQL Server temporary tables. The general FGLPROFILE entry to control temporary table emulation is:

```sql
dbi.database.dsname.ifxemul.temptables = [ true | false ]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Temporary tables on page 575

Syntax for temporary table creation is not unique across all database engines.

**Substrings in SQL**

**Informix®**

Informix® SQL statements can use subscripts on columns defined with the character data type:

```sql
SELECT ... FROM tab1 WHERE col1[2,3] = 'RO'
SELECT ... FROM tab1 WHERE col1[10] = 'R' -- Same as col1[10,10]
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ... 
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

**Important:** With other database servers as Informix®, when the subscript notation is used to modify column values in UPDATE statement, or as ORDER BY element, you will get an SQL error:

```sql
UPDATE tab1 SET col1[2,3] = 'RO' WHERE ...
SELECT ... FROM tab1 ORDER BY col1[1,3]
```

**Oracle® MySQL and MariaDB**

MySQL and MariaDB provide the function, to extract a substring from a string expression:

```sql
SELECT .... FROM tab1 WHERE SUBSTRING(col1,2,3) = 'RO'
SELECT SUBSTRING('Some text',6,3) ... -- Gives 'tex'
```

**Solution**

Replace all Informix® col[x,y] right-value expressions by SUBSTRING(col,x,y-x+1).

Rewrite UPDATE and ORDER BY clauses using col[x,y] expressions.
The translation of \texttt{col[x,y]} expressions can be controlled with the following FGLPROFILE entry:

\begin{verbatim}
dbi.database.dsnname.ifxemul.colsubs = \texttt{true} \rightarrow \texttt{false}
\end{verbatim}

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

**Related concepts**

Substring expressions on page 577
Handle substrings expressions with different database engines.

**The \texttt{LENGTH()} function**

**Informix\textsuperscript{®}**

Informix\textsuperscript{®} provides the \texttt{LENGTH()} function to count the number of bytes of a character string expression:

\begin{verbatim}
SELECT \texttt{LENGTH("aaa"), \texttt{LENGTH(c1)} FROM table}
\end{verbatim}

Informix\textsuperscript{®} \texttt{LENGTH()} does not count the trailing blanks for \texttt{CHAR} or \texttt{VARCHAR} expressions, while Oracle counts the trailing blanks.

Informix\textsuperscript{®} \texttt{LENGTH()} returns 0 when the given string is empty. That means, \texttt{LENGTH('')} = 0.

**Oracle\textsuperscript{®} MySQL**

MySQL supports the \texttt{LENGTH()} function, which is similar to Informix\textsuperscript{®} \texttt{LENGTH()}.

The MySQL \texttt{LENGTH()} function ignores trailing blanks.

When passing \texttt{NULL} as parameter, the MySQL \texttt{LENGTH()} function returns \texttt{NULL}.

**Solution**

The SQL \texttt{LENGTH()} function name can be used with MySQL.

**Related concepts**

The \texttt{LENGTH()} function in SQL on page 581
The semantics of the \texttt{LENGTH()} SQL function differs according to the database engine.

**MATCHES and LIKE**

**Informix\textsuperscript{®}**

Informix\textsuperscript{®} supports MATCHES and LIKE operators in SQL statements.

\texttt{MATCHES} expects * and ? wild-card characters, while \texttt{LIKE} uses the \% and _ wild-cards as equivalents.

\begin{verbatim}
(col MATCHES 'Smi*' AND col NOT MATCHES 'R?x')
(col LIKE 'Smi%' AND col NOT LIKE 'R_x')
\end{verbatim}

\texttt{MATCHES} accepts also brackets notation, to specify a set of matching characters at a given position:

\begin{verbatim}
(col MATCHES '[Pp]aris')
(col MATCHES '[0-9][a-z]*')
\end{verbatim}

**Oracle\textsuperscript{®} MySQL and MariaDB**

MySQL and MariaDB do not provide an equivalent of the Informix\textsuperscript{®} MATCHES operator.

The \texttt{LIKE} operator is supported.
**Solution**

The database driver is able to translate Informix® MATCHES expressions to LIKE expressions, when no [ ] bracket character ranges are used in the MATCHES operand.

The MATCHES to LIKE expression translation is controlled by the following FGLPROFILE entry:

```
dbi.database.dbname.ifxemul.matches = { true | false }
```

**Important:** Only [NOT] MATCHES followed by a search pattern provided as a string literal can be converted by ODI drivers. A [NOT] MATCHES followed by a question mark parameter place holder is not translated!

For maximum portability, consider replacing the MATCHES expressions with LIKE expressions in all SQL statements.

Avoid using CHAR (N) types for variable length character data (such as name, address).

**Related concepts**

MATCHES and LIKE operators on page 579

Use the standard LIKE operator instead of the MATCHES operator.

**BDL programming**

Oracle® MySQL related programming topics.

**INSERT cursors**

**Informix®**

Informix® provides insert cursors to optimize row creation in a database. An insert cursor is declared as a cursor, and rows as added with the PUT instruction. The rows are buffered and sent to the database server when executing a FLUSH instruction, or when the cursor is closed with CLOSE. When using transactions in Informix®, the OPEN, PUT and FLUSH instructions must be executed within a transaction block.

```
DECLARE c1 CURSOR FOR INSERT INTO tab1 ...
BEGIN WORK
    OPEN c1
    WHILE ...
        PUT c1 USING var-list
    END WHILE
    CLOSE c1
    COMMIT WORK
```

**Oracle® MySQL and MariaDB**

MySQL and MariaDB do not support insert cursors.

**Solution**

Insert cursors are emulated by the database interface, using basic INSERT SQL instructions.

The performances might be not as good as with Informix®, but the feature is fully supported.

**Related concepts**

Insert cursors on page 569
Using insert cursors with non-Informix databases.

**Cursors WITH HOLD**

**Informix®**

Informix® closes opened cursors automatically when a transaction ends, unless the WITH HOLD option is used in the DECLARE instruction:

```
DECLARE c1 CURSOR WITH HOLD FOR SELECT ...
OPEN c1
BEGIN WORK
FETCH c1 ...
COMMIT WORK
FETCH c1 ...
CLOSE c1
```

**Oracle® MySQL and MariaDB**

With MySQL and MariaDB, opened cursors using SELECT statements without a FOR UPDATE clause are not closed when a transaction ends. All MySQL cursors are WITH HOLD cursors, unless the FOR UPDATE clause is used in the SELECT statement.

Cursors declared FOR UPDATE and using the WITH HOLD option cannot be supported with MySQL because FOR UPDATE cursors are automatically closed by MySQL when the transaction ends.

**Solution**

BDL cursors that are not declared WITH HOLD are automatically closed by the database interface when a COMMIT WORK or ROLLBACK WORK is performed.

Since MySQL automatically closes FOR UPDATE cursors when the transaction ends, opening cursors declared FOR UPDATE and WITH HOLD option results in an SQL error; in the same conditions, this does not normally appear with Informix®.

Review the program logic in order to find another way to set locks.

**Related concepts**

- WITH HOLD and FOR UPDATE on page 568
  Hold cursors and not portable.

**SELECT ... FOR UPDATE**

**Informix®**

Legacy BDL programs typically use a cursor with SELECT FOR UPDATE to implement pessimistic locking and avoid several users editing the same rows:

```
DECLARE cc CURSOR FOR
SELECT ... FROM tab WHERE ... FOR UPDATE
OPEN cc
FETCH cc <-- lock is acquired
...
CLOSE cc <-- lock is released
```

The row must be fetched in order to set the lock.

If the cursor is local to a transaction, the lock is released when the transaction ends. If the cursor is declared WITH HOLD, the lock is released when the cursor is closed.
Informix® provides the SET LOCK MODE instruction to define the lock wait timeout:

```
SET LOCK MODE TO  ↓ WAIT ↓ NOT WAIT ↓ WAIT seconds ↓
```

The default mode is NOT WAIT.

**Oracle® MySQL and MariaDB**

MySQL and MariaDB support the FOR UPDATE clause in SELECT.

MySQL and MariaDB locking mechanism depends upon the transaction manager.  
The default locking granularity is per table when you use the default non-transactional configuration.  
Use the InnoDB Storage Engine to get transactions and locking mechanisms.  
Locks are released at the end of the transaction.

**Solution**

Check if the MySQL storage engine supports SELECT FOR UPDATE, otherwise review the program logic.

**Related concepts**

WITH HOLD and FOR UPDATE on page 568  
Hold cursors and not portable.

**UPDATE/DELETE ... WHERE CURRENT OF**

**Informix®**

Informix® allows positioned UPDATES and DELETEs with the "WHERE CURRENT OF cursor" clause, if the cursor has been DECLARED with a SELECT ... FOR UPDATE statement.

**Oracle® MySQL and MariaDB**

MySQL and MariaDB do not support UPDATE/DELETE with the WHERE CURRENT OF cursor clause.

**Solution**

UPDATE/DELETE ... WHERE CURRENT OF is not supported by MySQL; review your code for occurrences.

**Related concepts**

Positioned UPDATE/DELETE on page 567  
Using positioned updates/deletes with named database cursors.

**LOAD and UNLOAD**

**Informix®**

Informix® provides two SQL instructions to export / import data from / into a database table:

The UNLOAD instruction copies rows from a database table into a text file:

```
UNLOAD TO "filename.unl" SELECT * FROM tab1 WHERE ..
```

The LOAD instructions insert rows from a text file into a database table:

```
LOAD FROM "filename.unl" INSERT INTO tab1
```
Oracle® MySQL and MariaDB

MySQL does not provide LOAD and UNLOAD instructions.

Solution
LOAD and UNLOAD instruction are implemented in the Genero BDL runtime system with basic INSERT (for LOAD) or SELECT (for UNLOAD) SQL commands. The LOAD and UNLOAD instruction can be supported with various database servers.

However, LOAD and UNLOAD require the description of the column types in order to work, that can lead to some differences in the data formatting.

Note: If no transaction is started, the LOAD instruction will automatically execute a BEGIN WORK and COMMIT WORK when finished, or ROLLBACK WORK if a row insertion failed while loading. Terminating a transaction will automatically close cursors not defined WITH HOLD option. To workaround this situation, see more details in the LOAD on page 684 reference topic.

The LOAD and UNLOAD BDL instructions are supported with MySQL and MariaDB.

Related concepts
LOAD and UNLOAD instructions on page 574

The LOAD and UNLOAD instructions can produce different data formats depending on the database server type.

SQL Interruption

Informix®

With Informix®, it is possible to interrupt a long running query if the SQL INTERRUPT ON option.

Oracle® MySQL and MariaDB

MySQL and MariaDB provides the KILL QUERY command to interrupt a running query on the server.

Note: The database client program must open a second connection to execute the KILL QUERY statement.

Solution
SQL interruption is supported with MySQL.

The database driver opens a second connection to the server and sends a KILL QUERY command, with the MySQL process id of the current connection.

Important: Opening a second connection does not work when using Unix sockets, connect to MySQL with a host name and TCP port.

Related concepts
Using SQL interruption on page 539

Interrupt long running SQL queries, or interrupt queries waiting for locked data.

Scrollable cursors

Informix®

Informix® SQL and Genero BDL support scrollable cursors when you specify the SCROLL clause in the DECLARE cursor instruction:

```
DECLARE c1 SCROLL CURSOR FOR SELECT ...
```

Oracle® MySQL and MariaDB

MySQL and MariaDB do not support scrollable cursors.
Solution
The MySQL and MariaDB database drivers emulate scrollable cursors by fetching rows in a temporary file.

Related concepts
Scrollable cursors on page 560
How scrollable cursors can be supported on different databases.

Oracle® Database

Supported versions
Genero BDL supports the following Oracle Database versions:

- Oracle Database 11.x
- Oracle Database 12.x

Installation (Runtime Configuration)
Oracle Database related installation topics.

Install Oracle and create a database - database configuration/design tasks
If you are tasked with installing and configuring the database, here is a list of steps to be taken:

1. Install the ORACLE database software on your computer.
2. Create and setup the Oracle instance and database. Consider creating a multitenant database when using Oracle 12c and higher, to create several pluggable databases (PDB) in the same Oracle instance.
   Specify the database character set when creating the database instance. If you plan to use UTF-8, use also character length semantics (See NLS_LENGTH_SEMANTICS session parameter).
3. Create a database context dedicated to your application.
   According the Oracle version, define a db user / schema to hold application tables, or create a pluggable database (starting with Oracle 12c).
   a) With Oracle version 11g and lower, group application tables in a schema by creating a dedicated database user.
      Connect as system user with:
      ```
      $ sqlplus / AS SYSDBA
      ```
      and execute the following SQL command to create the db user:
      ```
      CREATE USER appadmin IDENTIFIED BY password;
      Grant privileges to the application administrator user:
      ```
      GRANT CONNECT, RESOURCE, UNLIMITED TABLESPACE TO appadmin;
      b) With Oracle version 12c and higher, group application tables in a pluggable database (PDB).
      Connect as system user with:
      ```
      $ sqlplus / AS SYSDBA
      ```
      and create a pluggable database and its PDB administrator user. This is a basic PDB creation example using Oracle Managed Files, consider planing the PDB creation with the person in charge of Oracle database administration:
      ```
      CREATE PLUGGABLE DATABASE mypdb
      ADMIN USER pdbadmin IDENTIFIED BY password ROLES = (DBA)
      DEFAULT TABLESPACE mypdb_01
      DATAFILE 'path_01' SIZE 250M AUTOEXTEND ON ;
      ```
For now the PDB is only mounted, it must be opened for regular usage:

```
ALTER PLUGGABLE DATABASE mypdb OPEN;
```

PDBs must be identified as separate database services (i.e. different from the CDB service). By default Oracle creates a database service with the same name as the PDB. To access the PDB through TNS, create the mypdb record in TNSNAMES.ORA file in addition to the default database service (ORC*):

```
tnsname =
(DESCRIPTION =
 (ADDRESS = (PROTOCOL = TCP)(HOST = localhost)(PORT = 1521))
 (CONNECT_DATA =
 (SERVER = DEDICATED)
 (SERVICE_NAME = mypdb)
 )
)
```

By default when Oracle starts, the PDBs are mounted but are not open for regular usage. With Oracle 12c, you can create a database trigger to open all PDBs automatically:

```
CREATE OR REPLACE TRIGGER open_pdb
AFTER STARTUP ON DATABASE
BEGIN
 EXECUTE IMMEDIATE 'ALTER PLUGGABLE DATABASE ALL OPEN';
 END open_pdb;
 /
```

Re-connect as PDB administrator and create a user dedicated to application tables administration:

```
CONNECT pdbadmin/password@mypdb
CREATE USER appadmin IDENTIFIED BY password;
GRANT CONNECT, RESOURCE, UNLIMITED TABLESPACE TO appadmin;
```

4. If programs create temporary tables, you must create a dedicated tablespace and schema depending on the type of temporary table emulation used.

   For more details about temporary table emulations, see Temporary tables on page 872.

5. Create the application tables by connecting to the database context as the application administrator:

   ```
   $ sqlplus appadmin/password@tnsname
   ```

Convert Informix® data types to Oracle data types. See issue data type Conversion Tables for more details.

6. If you plan to use SERIAL emulation, you must choose a serial emulation method.

   Select the best emulation technique that matches your needs. You need to prepare the database depending on the emulation type. For more details, see SERIAL data types on page 861.

Prepare the runtime environment - connecting to the database

1. In order to connect to Oracle®, you must have a database driver "dbmora" in FGLDIR/dbdrivers.

2. If you want to connect to a remote Oracle® server from an application server, you must install the Oracle® Client Software on your application server and configure this.

3. Make sure that the ORACLE client environment variables are properly set.

   Check variables such as ORACLE_HOME (the path to the installation directory), ORACLE_SID (the server identifier when connecting locally), etc. See the Oracle® documentation for more details.

4. Verify the environment variable defining the search path for database client shared libraries (libclntsh.so on UNIX™, OCI.DLL on Windows®)
5. Check the database client locale settings (NLS_LANG, NLS_DATE_FORMAT, etc).
   The database client locale must match the locale used by the runtime system (LC_ALL, LANG).

6. If you are using the TNS protocol, verify if the Oracle listener is started on the server.

7. To test the client environment settings, you can try to connect to the Oracle server with the SQL*Plus tool:

   `$ sqlplus username/password@service`

8. Disable installation of signal handlers for the OCI diagnostic framework.

   By default, the OCI client library installs signal handlers for the OCI diagnostic framework. These signal handlers are registered when connecting to the database, and can conflict with the signal handlers installed by the fglrun runtime system.

   Unless you are explicitly asked to use OCI diagnostic framework, there is no need to let OCI use these signals.

   To disable OCI client library signal handlers, define the following parameters in the sqlnet.ora file:

   ```
   DIAG_ADR_ENABLED=FALSE
   DIAG_DDE_ENABLED=FALSE
   DIAG_SIGHANDLER_ENABLED=FALSE
   ```

   For more details, search Oracle OCI documentation about "Fault Diagnosability in OCI".

9. Set up the fglprofile entries for database connections.
   a) Set up fglprofile for the SERIAL emulation method.

      The following entry defines the SERIAL emulation method. You can use the SEQUENCE based trigger or the SERIALREG based trigger method:

      ```
      dbi.database.dbname.ifxemul.datatype.serial.emulation = "(native|regtable)"
      ```

      The value 'native' selects the SEQUENCE based method, and the value 'regtable' selects the SERIALREG based method. This entry has no effect if dbi.database.dbname.ifxemul.datatype.serial is set to 'false'.

      The default is SERIAL emulation enabled with native method (SEQUENCE-based). See issue SERIAL data types on page 861 for more details.

   b) The "source" parameter defines the TNS name of the Oracle database.

      ```
      dbi.database.dbname.source = "stock"
      ```

   c) Define the database schema selection if needed.

      The following entry defines the database schema to be used by the application. The database interface automatically executes an "ALTER SESSION SET CURRENT_SCHEMA owner" instruction to switch to a specific schema:

      ```
      dbi.database.dbname.ora.schema = "name"
      ```

      Here dbname identifies the database name used in the BDL program (DATABASE dbname) and name is the schema name to be used in the ALTER SESSION instruction. If this entry is not defined, no ALTER SESSION instruction is executed and the current schema defaults to the user's name.

   d) Define pre-fetch parameters.
Oracle® offers high performance by pre-fetching rows in memory. The pre-fetching parameters can be tuned with the following entries:

```
  dbi.database.dbname.ora.prefetch.rows = integer
  dbi.database.dbname.ora.prefetch.memory = integer # in bytes
```

These values will be applied to all application cursors.

The interface pre-fetches rows up to the `prefetch.rows` limit unless the `prefetch.memory` limit is reached, in which case the interface returns as many rows as will fit in a buffer of size `prefetch.memory`.

By default, pre-fetching is on and defaults to 10 rows; the memory parameter is set to zero, so the memory size is not included in computing the number of rows to prefetch.

e) If needed, define a specific command to generate session identifiers with this fglprofile setting:

```
  dbi.database.dbname.ora.sid.command = "SELECT ..."
```

This unique session identifier will be used to create table names for temporary table emulation.

By default, the database driver will use "SELECT USERENV('SESSIONID') FROM DUAL".

f) If needed, define a specific command to generate session identifiers with this fglprofile setting:

```
  dbi.database.dbname.ora.sid.command = "SELECT ..."
```

This unique session identifier will be used to create table names for temporary table emulation.

By default, the database driver will use "SELECT USERENV('SESSIONID') FROM DUAL".

g) The default temporary table emulation uses regular permanent tables.

If this does not fit your needs, you can use GLOBAL TEMPORARY TABLES with this fglprofile setting:

```
  dbi.database.dbname.ifxemul.temptables.emulation = "global"
```

h) By default, the tablespace for the default temporary table emulation is TEMPTABS. For global temporary table emulation, there is no tablespace used by default.

If required, define the tablespace to be used for temporary table emulations (note that this parameter applies to all temporary table emulation methods):

```
  dbi.database.dbname.ora.temptables.tablespace = "mytemptabs"
```

i) By default, no schema is used for the default temporary table emulation. For global temporary table emulation, the schema TEMPTABS is used by default.

If required, define the schema to be used for temporary table emulations (note that these parameters applies to all temporary table emulation methods). Define the "source" parameter to use the current user login, or a SELECT command to produce the schema name:

```
# Get the schema from the current user name specified in connection command:
  dbi.database.dbname.ora.temptables.schema.source = "login"
# or, get the schema from a SELECT statement:
  dbi.database.dbname.ora.temptables.schema.source = "command"
  dbi.database.dbname.ora.temptables.schema.command = "SELECT SYS_CONTEXT('USERENV','SESSION_USER') FROM DUAL"
```

Database concepts
Oracle Database related database concepts topics.

Database concepts
Informix® servers can handle multiple database entities. By default an ORACLE instance can only handle one database entity. Starting with Oracle 12c, you can use a multi-tenant database to define several pluggable databases.
ORACLE can manage multiple schemas, but by default other users must give the owner name as prefix to the table name:

```
SELECT * FROM stores.customer
```

**Solution 1: With Oracle 12c and higher**

Oracle 12c introduced the multi-tenant database concept, where you can create several pluggable databases in a root container. Consider using this feature, if you need to create several copies of the same database entity, that can be accessed/seen as individual data sources.

**Solution 2: With Oracle 10g and 11g**

In an Oracle database, each user can manage his own database schema. You can dedicate a database user to administer each occurrence of the application database.

Any user can select the current database schema with the following SQL command:

```
ALTER SESSION SET CURRENT_SCHEMA = "schema"
```

Using this instruction, any user can access the tables without giving the owner prefix as long as the table owner has granted the privileges to access the tables.

You can make the database interface select the current schema automatically with the following fglprofile entry:

```
dbi.database.dbname.schema = "schema"
```

When using multiple database schemas, it is recommended that you create them in separated tablespaces to enable independent backups and keep logical sets of tables together. The simplest way is to define a default tablespace when creating the schema owner:

```
CREATE USER user IDENTIFIED BY password
DEFAULT TABLESPACE deftablespace
TEMPORARY TABLESPACE tmptablespace
```

**Data storage concepts**

When converting from Informix® to Oracle® the aim is to try to preserve as much of the data storage information as possible in the process. The most important storage decisions made for Informix® database objects (like initial sizes and physical placement) can be applied to the Oracle® database.

Storage concepts are quite similar in Informix® and in Oracle®, but the names are different.

This table compares Informix® storage concepts to Oracle® storage concepts:

**Table 228: Physical units of storage**

<table>
<thead>
<tr>
<th>Informix®</th>
<th>ORACLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>The largest unit of physical disk space is a &quot;chunk&quot;, which can be allocated either as a cooked file (I/O is controlled by the OS) or as raw device (=UNIX® partition, I/O is controlled by the database engine). A &quot;dbspace&quot; uses at least one &quot;chunk&quot; for storage. You must add &quot;chunks&quot; to &quot;dbspaces&quot; in order to increase the size of the logical unit of storage.</td>
<td>One or more &quot;data files&quot; are created for each &quot;tablespace&quot; to physically store the data of all logical structures. Like Informix® &quot;chunks&quot;, a &quot;data file&quot; can be an OS file or a raw device. You can add &quot;data files&quot; to a &quot;tablespace&quot; in order to increase the size of the logical unit of storage or you can use the AUTOEXTEND option when using OS files.</td>
</tr>
</tbody>
</table>
A "page" is the smallest physical unit of disk storage that the engine uses to read from and write to databases. A "chunk" contains a certain number of "pages". The size of a "page" must be equal to the operating system's block size.

An "extent" consists of a collection of contiguous "pages" that the engine uses to allocate both initial and subsequent storage space for database tables. When creating a table, you can specify the first extent size and the size of future extents with the EXTENT SIZE and NEXT EXTENT options. For a single table, "extents" can be located in different "chunks" of the same "dbspace".

At the finest level of granularity, Oracle® stores data in "data blocks" which size corresponds to a multiple of the operating system's block size. You set the "data block" size when creating the database.

An "extent" is a specific number of contiguous "data blocks", obtained in a single allocation. When creating a table, you can specify the first extent size and the size of future extents with the STORAGE() option. For a single table, "extents" can be located in different "data files" of the same "tablespace".

Table 229: Logical units of storage

<table>
<thead>
<tr>
<th>Informix®</th>
<th>ORACLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>A &quot;table&quot; is a logical unit of storage that contains rows of data values.</td>
<td>Same concept as Informix®.</td>
</tr>
<tr>
<td>A &quot;database&quot; is a logical unit of storage that contains table and index data. Each database also contains a system catalog that tracks information about database elements like tables, indexes, stored procedures, integrity constraints and user privileges.</td>
<td>Same concept as Informix®, but one Oracle® instance can manage only one database, in the same way that Informix® does.</td>
</tr>
</tbody>
</table>

Database tables are created in a specific "dbspace", which defines a logical place to store data. If no dbspace is given when creating the table, Informix® defaults to the current database dbspace.

The total disk space allocated for a table is the "tblspace ", which includes "pages" allocated for data, indexes, blobs, tracking page usage within table extents.

Do not confuse the Informix® "tblspace" concept and Oracle® "tablespaces".

Database tables are created in a specific "tablespace", which defines a logical place to store data. If no tablespace is given when creating the table, Oracle® defaults to the user's default tablespace.

A "segment" is a set of "extents" allocated for a certain logical structure. There are four different types of segments, including data segments, index segments, rollback segments and temporary segments.

Table 230: Other concepts related to storage

<table>
<thead>
<tr>
<th>Informix®</th>
<th>ORACLE</th>
</tr>
</thead>
<tbody>
<tr>
<td>When initializing an Informix® engine, a &quot;root dbspace&quot; is created to store information about all databases, including storages information (chunks used, other dbspaces, etc.)</td>
<td>Each Oracle® database has a &quot;control file&quot; that records the physical structure of the database, like the database name, location and names of &quot;data files&quot; and &quot;redo log&quot; files, and time stamp of database creation.</td>
</tr>
</tbody>
</table>
Informix®

The "physical log" is a set of continuous disk pages where the engine stores "before-images" of data that has been modified during processing.

The "logical log" is a set of "logical-log files" used to record logical operations during online processing. All transaction information is stored in the logical log files if a database has been created with transaction log.

Informix® combines "physical log" and "logical log" information when doing fast recovery. Saved "logical logs" can be used to restore a database from tape.

ORACLE

A "rollback segment" records the actions of SQL transactions that can be rolled back, and it records the data as it existed before an operation in a transaction.

The "redo log files" hold all changes made to the database, in case the database experiences an instance failure.

Each database has at least two "redo log files".

Redo entries record data that can be used to reconstruct all changes made to the database, including the rollback segments stored in the database buffers of the SGA. Therefore, the online redo log also protects rollback data.

Concurrence management

Data consistency and concurrency concepts

- **Data Consistency** applies to situations when readers want to access data currently being modified by writers.
- **Concurrent Data Access** applies to situations when several writers are accessing the same data for modification.
- **Locking Granularity** defines the amount of data concerned when a lock is set (for example, row, page, table).

**Informix®**

Informix® uses a locking mechanism to handle data consistency and concurrency. When a process changes database information with UPDATE, INSERT or DELETE, an exclusive lock is set on the touched rows. The lock remains active until the end of the transaction. Statements performed outside a transaction are treated as a transaction containing a single operation and therefore release the locks immediately after execution. SELECT statements can set shared locks, depending on isolation level. In case of locking conflicts (for example, when two processes want to acquire an exclusive lock on the same row for modification, or when a writer is trying to modify data protected by a shared lock), the behavior of a process can be changed by setting the lock wait mode.

Control:

- Lock wait mode: SET LOCK MODE TO ...
- Isolation level: SET ISOLATION TO ...
- Locking granularity: CREATE TABLE ... LOCK MODE {PAGE|ROW}
- Explicit exclusive lock: SELECT ... FOR UPDATE

Defaults:

- The default isolation level is READ COMMITTED.
- The default lock wait mode is NOT WAIT.
- The default locking granularity is PAGE.

**ORACLE**

When data is modified, exclusive locks are set and held until the end of the transaction. For data consistency, ORACLE uses a multi-version consistency model: a copy of the original row is kept for readers before performing writer modifications. Readers do not have to wait for writers as in Informix®. The simplest way to think of Oracle's implementation of read consistency is to imagine each user accessing a private copy of the database, hence the multi-version consistency model. The lock wait mode cannot be changed session wide as in Informix®, the waiting behavior can be controlled with a SELECT FOR UPDATE NOWAIT only. Locks are set at the row level in ORACLE, and this cannot be changed.

Control:
• Lock wait mode (on `SELECT` only): `SELECT ... FOR UPDATE NOWAIT`
• Isolation level: `SET TRANSACTION ISOLATION LEVEL TO ...`
• Explicit exclusive lock: `SELECT ... FOR UPDATE [NOWAIT]`

Defaults:

• The default isolation level is `Read Committed` (readers cannot see uncommitted data, no shared lock is set when reading data).

The main difference between Informix® and ORACLE is that readers do not have to wait for writers in ORACLE.

**Solution**

The `SET ISOLATION TO ...` Informix® syntax is replaced by `ALTER SESSION SET ISOLATION_LEVEL ...` in Oracle. The next table shows the isolation level mappings done by the database driver:

**Table 231: Isolation level mappings done by the Oracle database driver**

<table>
<thead>
<tr>
<th>SET ISOLATION instruction in program</th>
<th>Native SQL command</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SET ISOLATION TO DIRTY READ</code></td>
<td><code>ALTER SESSION SET ISOLATION_LEVEL = READ COMMITTED</code></td>
</tr>
<tr>
<td><code>SET ISOLATION TO COMMITTED READ [READ COMMITTED] [RETAIN UPDATE LOCKS]</code></td>
<td><code>ALTER SESSION SET ISOLATION_LEVEL = READ COMMITTED</code></td>
</tr>
<tr>
<td><code>SET ISOLATION TO CURSOR STABILITY</code></td>
<td><code>ALTER SESSION SET ISOLATION_LEVEL = READ COMMITTED</code></td>
</tr>
<tr>
<td><code>SET ISOLATION TO REPEATABLE READ</code></td>
<td><code>ALTER SESSION SET ISOLATION_LEVEL = SERIALIZABLE</code></td>
</tr>
</tbody>
</table>

ORACLE does not provide a dirty read mode, the (session wide) lock wait mode cannot be changed and the locking precision is always at the row level. Based on this, it is recommended that you work with Informix® in the read committed isolation level (default), make processes wait for each other (lock mode wait), and use the default page-level locking granularity.

See the Informix® and ORACLE documentation for more details about data consistency, concurrency and locking mechanisms.

**Related concepts**

**Concurrent data access** on page 537
Understanding concurrent data access and data consistency.

**Optimistic locking** on page 561
Implementing optimistic locking to handle access concurrently to the same database records.

**WITH HOLD and FOR UPDATE** on page 568
Hold cursors and not portable.

**Transactions handling**

**Informix®**

With the Informix® native mode (non ANSI):

• Transactions blocks start with `BEGIN WORK` and terminate with `COMMIT WORK` or `ROLLBACK WORK`.
• Statements executed outside a transaction are automatically committed.
• DDL statements can be executed (and canceled) in transactions.

```
UPDATE tab1 SET ... -- auto-committed
BEGIN WORK -- start of TX block
```
**Informix**® version 11.50 introduces savepoints:

```sql
SAVEPOINT name [UNIQUE]
ROLLBACK [WORK] TO SAVEPOINT _name_ 1
RELEASE SAVEPOINT name
```

**ORACLE**

With ORACLE transactions:

- Beginnings of transactions are implicit.
- A transaction ends with a COMMIT or ROLLBACK statement.
- The current transaction is automatically committed when a DDL statement is executed.

```sql
UPDATE tab1 SET ... -- start of TX block
UPDATE tab2 SET ...
...  
COMMIT                -- end of TX block
```

ORACLE supports savepoints too. However, there are differences:

- Savepoints cannot be declared as UNIQUE
- Rollback must always specify the savepoint name
- You cannot release savepoints (RELEASE SAVEPOINT)

**Solution**

Regarding transaction control instructions, BDL applications do not have to be modified in order to work with ORACLE. The Informix® behavior is simulated with an autocommit mode in the ORACLE interface. A switch to the explicit commit mode is done when a BEGIN WORK is performed by the BDL program.

When executing a DDL statement inside a transaction, ORACLE automatically commits the transaction. Therefore, you must extract the DDL statements from transaction blocks.

If you want to use savepoints, do not use the UNIQUE keyword in the savepoint declaration, always specify the savepoint name in ROLLBACK TO SAVEPOINT, and do not drop savepoints with RELEASE SAVEPOINT.

See also **SELECT FOR UPDATE**

**Related concepts**

- Database transactions on page 538
  Database transactions define a set of SQL instructions to be executed as a whole, or rolled back as a whole.

**Database users**

**Informix**®

Until version 11.70.xC2, Informix® database users must be created at the operating system level and must be members of the 'informix' group.

Starting with 11.70.xC2, Informix® supports database-only users with the CREATE USER instruction, as in most other db servers.

Any database user must have sufficient privileges to connect and use resources of the database; user rights are defined with the GRANT command.
ORACLE

Oracle® users can be authenticated in different ways: as database users, as operating system users or by delegating authentication to another service, like Kerberos or LDAP.

Users must be created in the database with a CREATE USER command, to create a user authenticated by the database server:

```sql
CREATE USER username IDENTIFIED BY password
```

Oracle® users can also be created with the IDENTIFIED EXTERNALLY clause:

```sql
CREATE USER username IDENTIFIED EXTERNALLY
```

In this case, Oracle® trusts the operating system to authenticate the user. See the Oracle® documentation for OS user authentication configuration, especially the OS_AUTHENT_PREFIX (empty string) and REMOTE_OS_AUTHENT (true) server parameters. Note also that the Oracle® user name needs to be specified in uppercase in the CREATE USER instruction, and gets an additional prefix, depending on the operating system (domain name on Windows® platforms)

In Oracle®, users can also be defined in a central LDAP directory, with the IDENTIFIED GLOBALLY clause:

```sql
CREATE USER username IDENTIFIED GLOBALLY AS 'distinguished_name'
```

Global users are registered and managed by an external LDAP service, and are identified by the distinguished name (DN).

Oracle® supports also proxy authentication, by granting connection privileges through another "proxy user":

```sql
ALTER USER username GRANT CONNECT THROUGH proxy_user
```

Solution

Based on the application logic, you must create one or several Oracle® users. Use database or external authentication.

Connecting as an external user

If you want to keep the same Informix® OS users, you can configure Oracle® for OS authentication, and create users with the IDENTIFIED EXTERNALLY option. Consider using real RDBMS users instead, and ask for login/password when connecting a program to the database.

To connect to Oracle® as an external user, perform the CONNECT TO instruction without specifying the USER/USING clauses. You can check if external or RDBMS authentication takes place with the FGLSQLDEBUG output (check the line containing "Credential flag").

Tester with Oracle® 11.2 on a Linux® system (the Linux® user login name is "sf" in lowercase):

```
$ sqlplys / as sysdba

SQL> show parameter os_authentPrefix;
NAME                TYPE            VALUE
----------------------------------------------
os_authent_prefix   string
SQL> show parameter remote_os_authent;
NAME                TYPE            VALUE
----------------------------------------------
remote_os_authent   boolean         TRUE
SQL> create user "SF" identified externally;
User created.
```
SQL> grant connect, resource to "SF";
Grant succeeded.

To connect to Oracle® as an external user declared with IDENTIFIED EXTERNALLY (authenticated by the operating system), do not specify any login/password. For example, omit the USER/USING clause in the CONNECT TO instruction:

```
CONNECT TO "orc1fox+driver='dbmora'"
```

If no db login is specified, the Oracle® driver will open a database session with the OCI_CRED_EXT credentials.

**Switching to the application schema**

If several DB users are defined for the application, you might want to switch to a common schema with the following FGLPROFILE entry:

```
dbi.database.mydb.ora.schema = "app_owner"
```

**Connecting as SYSDBA or SYSOPER**

An Oracle® connection can also be established as SYSDBA or SYSOPER users. This is possible by specifying the /SYSDBA or /SYSOPER strings after the user name in the USER clause of the CONNECT TO instruction.

For example:

```
CONNECT TO "orc1fox+driver='dbmora'"
USER "orauser/SYSDBA" USING "fourjs"
```

**Using proxy authentication**

If Oracle® proxy authentication is required, specify the /PROXY_CLIENT:username string after the user name in the USER clause of the CONNECT TO instruction.

For example:

```
CONNECT TO "orc1fox+driver='dbmora'"
USER "orauser/PROXY_CLIENT:appuser" USING "fourjs"
```

In the above example, the credentials of the orauser login will be used to establish the connection, and then Oracle® will automatically switch to the user "appuser", assuming that the proxy connection has been granted with:

```
ALTER USER appuser GRANT CONNECT THROUGH orauser
```

**Related concepts**

- [Database users and security](#) on page 547
- Properly identifying database users allows to use database security and audit features.
- [Oracle DB specific FGLPROFILE parameters](#) on page 617

**Setting privileges**

**Informix®**

Informix® users must have at least the CONNECT privilege to access the database:

```
GRANT CONNECT TO username
```
Application administration users need the RESOURCE privilege to create tables:

```sql
GRANT RESOURCE TO username
```

Since version 7.20, Informix® supports database roles:

```sql
GRANT rolename TO username
```

### ORACLE

ORACLE supports the concept of *roles* to group privileges which then can be assigned to users.

ORACLE users do not have to explicitly set a role, they are assigned to a default privilege domain (set of roles). More than one role can be enabled at a time with ORACLE.

Informix® database privileges do NOT correspond exactly to ORACLE CONNECT, RESOURCE and DBA roles. However, roles can be created with equivalent privileges.

ORACLE users must have at least the CREATE SESSION privilege to access the database. This privilege is part of the CONNECT role:

```sql
GRANT CONNECT TO (PUBLIC|username)
```

### Solution

Create a role which groups Informix® CONNECT privileges, and assign this role to the application users:

```sql
CREATE ROLE ifx_connect IDENTIFIED BY oracle;
GRANT CREATE SESSION, ALTER SESSION, CREATE ANY VIEW, ... TO ifx_connect;
GRANT ifx_connect TO user1;
```

Notes:

1. For more details about serial emulation, see SERIAL data types on page 861.

**BOOLEAN data type**

Informix®

Informix® supports the BOOLEAN data type, which can store 't' or 'f' values.

Genero BDL implements the BOOLEAN data type in a different way: A BOOLEAN variable stores integer values 1 or 0 (for TRUE or FALSE). This type is designed to hold the result of a boolean expression.

**ORACLE**

Oracle does not implement a native BOOLEAN type in SQL types.

However, a BOOLEAN type exists in the PL/SQL language.

**Solution**

The Oracle database interface converts the BOOLEAN type to CHAR(1) columns and stores '1' or '0' values in the column.

The BOOLEAN type translation can be controlled with the following FGLPROFILE entry:

```
  dbi.database.dsnname.ifxemul.datatype.boolean = [ true | false ]
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.

Using portable data types on page 553
Only a limited set of data types are really portable across several database engines.

CHAR and VARCHAR data types

Informix®

Informix® supports the following character data types:

Table 233: Informix® character data types

<table>
<thead>
<tr>
<th>Informix® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>SBCS and MBCS character data (max is 32767 bytes)</td>
</tr>
<tr>
<td>VARCHAR (n, m)</td>
<td>SBCS and MBCS character data (max is 255 bytes)</td>
</tr>
<tr>
<td>NCHAR (n)</td>
<td>Same as CHAR, with specific collation order</td>
</tr>
<tr>
<td>NVARCHAR (n, m)</td>
<td>Same as VARCHAR, with specific collation order</td>
</tr>
<tr>
<td>LVARCHAR (n)</td>
<td>max size varies depending on the IDS version</td>
</tr>
</tbody>
</table>

With Informix®, both CHAR/VARCHAR and NCHAR/NVARCHAR data types can be used to store single-byte or multibyte encoded character strings. The only difference between CHAR/VARCHAR and NCHAR/NVARCHAR is in how they use sorting: N[VAR]CHAR types use the collation order, while [VAR]CHAR types use the byte order.

The character set used to store strings in CHAR/VARCHAR/NCHAR/NVARCHAR columns is defined by the DB_LOCALE environment variable.

The character set used by applications is defined by the CLIENT_LOCALE environment variable.

Informix® uses Byte Length Semantics (the size N that you specify in [VAR]CHAR (N) is expressed in bytes, not characters as in some other databases)

ORACLE

Oracle® supports the following data types to store character data:

Table 234: Oracle® character data types

<table>
<thead>
<tr>
<th>Oracle® data type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHAR (n)</td>
<td>SBCS or MBCS character data using the database character set, where n is specified in bytes or characters, based on the length semantics (max is 2000 bytes)</td>
</tr>
<tr>
<td>VARCHAR2 (n)</td>
<td>SBCS or MBCS character data using the database character set, where n is specified in bytes or characters, based on the length semantics (max is 4000 bytes)</td>
</tr>
<tr>
<td>NCHAR (n)</td>
<td>SBCS or MBCS character data using the national character set, where n is specified in bytes or characters, based on the length semantics (max is 2000 bytes)</td>
</tr>
<tr>
<td>NVARCHAR2 (n)</td>
<td>SBCS or MBCS character data using the national character set, where n is specified in bytes or characters, based on the length semantics (max is 4000 bytes)</td>
</tr>
</tbody>
</table>

Note: Oracle® 12c introduced extended character types with the MAX_STRING_SIZE=EXTENDED server parameter. Use VARCHAR2 type can get a size up to 32Kb when MAX_STRING_SIZE=EXTENDED is set.
However, the storage technique used by Oracle® 12c for such a large string type is different from the native/standard VARCHAR2 (4000) type. Large character strings will be stored as LOBs. Extended character types are not supported by Genero’s Oracle® database driver.

In Oracle® CHAR (N) / VARCHAR2 (N) types, the size N can be specified in character or byte units, depending on length semantics settings. See Length semantics settings on page 414 for more details.

When comparing CHAR and VARCHAR2 values in Oracle, the trailing blanks are significant; this is not the case when using Informix® VARCHAR columns. However, before comparing string values, Oracle® blank-pads CHAR (N) data to the maximum length of both operands. As result, it looks like trailing blanks are not significant in CHAR (N) comparison. For example, a column defined as CHAR(5) with the value 'abc ' (with 2 trailing blanks) will not be equal to 'abc', but when comparing (col = 'abc'), Oracle® will add 2 blanks to the right operand and values will match. Blank padding does not occur for VARCHAR2() data, as result, the expression (col = 'abc') will be false, if col VARCHAR2 does not exactly contain the value 'abc'. For more details, see blank-padded and non-padded comparison semantics in Oracle® documentation.

Oracle® treats empty strings like NULL values; Informix® doesn’t. See issue Empty Character Strings for more details.

With Oracle, you can define a Database Character Set and a National Character Set. Oracle® uses the Database Character Set to store string data in the CHAR/VARCHAR2 columns, and uses the National Character Set for NCHAR/ NVARCHAR2 columns.

**Solution**

Informix® CHAR (N) types must be mapped to Oracle® CHAR (N) types, and Informix® VARCHAR (N) or LVARCHAR (N) columns must be mapped to Oracle® VARCHAR2 (N).

Check that your database tables do not use CHAR, VARCHAR or LVARCHAR types with a length exceeding the Oracle® limits of CHAR/VARCHAR2.

When using a multibyte character set (such as UTF-8), configure Oracle® to use character length semantics, define CHAR/VARCHAR2 database columns with a size in character units, and use character length semantics in BDL programs with FGL_LENGTH_SEMANTICS=CHAR. See Length semantics settings on page 414 for more details.

When extracting a database schema from an Oracle® database, the fgldb sch schema extractor uses the size of the column in characters, not the octet length. If you have created a CHAR(10 (characters) ) column a in the database, the .sch file will get a size of 10, that will be interpreted according to FGL_LENGTH_SEMANTICS as a number of bytes or characters.

The Oracle® client character set must correspond to the Genero runtime system locale (LANG/LC_ALL). You can define the Oracle® client character set with the NLS_LANG environment variable.

See also the section about Localization.

The CHAR/VARCHAR type translation can be controlled with the following FGLPROFILE entries:

```
  dbi.database.dsname.ifxemul.datatype.char = { true | false }
  dbi.database.dsname.ifxemul.datatype.varchar = { true | false }
```

For more details see IBM Informix emulation parameters in FGLPROFILE on page 614.
