</tbody>
</table>
**util.Strings.base64Decode**
Decodes a Base64 encoded string and writes the bytes to a file.

**Syntax**

```plaintext
util.Strings.base64Decode(
    base64 STRING,
    filename STRING
)
```

1. `base64` is the Base64 encoded string.
2. `filename` is the name of the file to write to.

**Usage**
The `util.Strings.base64Decode()` method converts the Base64 encoded string passed as first parameter, and writes the bytes to file specified as second parameter.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE base64 STRING
    LET base64 = util.Strings.base64Encode( "picture1.png" )
    DISPLAY base64
    CALL util.Strings.base64Decode( base64, "picture2.png" )
END MAIN
```

**Related concepts**

- **util.Strings.base64Encode** on page 2754
  Converts the content of a file to a Base64 encoded string.

- **util.Strings.base64Encode**
  Converts the content of a file to a Base64 encoded string.

**Syntax**

```plaintext
util.Strings.base64Encode(
    filename STRING
)
```

1. `filename` is the name of the file to read from.

**Usage**
The `util.Strings.base64Encode()` method reads the content of the file passed as parameter, and converts the bytes to a Base64 encoded string.

**Example**

```plaintext
IMPORT util
MAIN
    DISPLAY util.Strings.base64Encode( "picture.png" )
END MAIN
```

**Related concepts**

- **util.Strings.base64Decode** on page 2754
Decodes a Base64 encoded string and writes the bytes to a file.

**util.Strings.base64DecodeToHexString**
Decodes a base64 encoded string and returns the corresponding hexadecimal string.

**Syntax**

```plaintext
util.Strings.base64DecodeToHexString(
    base64 STRING
)  
RETURNS STRING
```

1. `base64` is the Base64 encoded string.

**Usage**

The `util.Strings.base64DecodeToHexString()` method converts the Base64 encoded string passed as parameter to an array of bytes, then it converts the byte array to the hexadecimal representation of this array of bytes, and returns that string.

**Tip:** After converting the Base64 string to an hexadecimal string, use the `util.parseHexString()` method to convert bytes of the hexadecimal string to integers.

**Example**

```plaintext
IMPORT util
MAIN
DEFINE hexa VARCHAR(50)
    DISPLAY util.Strings.base64DecodeToHexString( "AA==" )
    DISPLAY util.Strings.base64DecodeToHexString( "AAAAAA==" )
    DISPLAY util.Strings.base64DecodeToHexString( "AQ==" )
    DISPLAY util.Strings.base64DecodeToHexString( "/=8=" )
    DISPLAY util.Strings.base64DecodeToHexString( "QUJDRA==" )
    LET hexa = util.Strings.base64DecodeToHexString( "QUJDRA==" )
    DISPLAY util.Integer.parseHexString( hexa[1,2] )
    DISPLAY util.Integer.parseHexString( hexa[3,4] )
    DISPLAY util.Integer.parseHexString( hexa[5,6] )
    DISPLAY util.Integer.parseHexString( hexa[7,8] )
END MAIN
```

**Output:**

```
00
00000000
01
ffff
41424344
65
66
67
68
```

**Related concepts**

`util.Strings.base64EncodeFromHexString` on page 2756
Converts the hexadecimal string passed as parameter to a Base64 encoded string.

**util.Strings.base64DecodeToString**
Decodes a base64 encoded string and returns the corresponding string.

**Syntax**

```plaintext
util.Strings.base64DecodeToString(
  base64 STRING
)  
RETURNS STRING
```

1. `base64` is the Base64 encoded string.

**Usage**

The `util.Strings.base64DecodeToString()` method converts the Base64 encoded string passed as parameter to an array of bytes, then it converts the byte array to a string representation in the current locale, and returns that string.

If the Base64 source string contains a sequence of bytes that does not represent a valid character in the current application locale, the function returns NULL.

**Note:** In contrast to `util.Strings.urlDecode()`, the original string is not converted from UTF-8 to the application character encoding: The Base64 source string must represent valid characters in the current application locale.

**Example**

(Character encoding is UTF-8)

```plaintext
IMPORT util
MAIN
  DEFINE base64 STRING
  LET base64 = util.Strings.base64EncodeFromString( "Forêt" )
  DISPLAY base64
  DISPLAY util.Strings.base64DecodeToString( base64 )
END MAIN
```

Output:

```
Rm9yw6p0
Forêt
```

**Related concepts**

- **util.Strings.base64EncodeFromString** on page 2757
  Converts the string passed as parameter to a Base64 encoded string.

- **util.Strings.base64EncodeFromHexString**
  Converts the hexadecimal string passed as parameter to a Base64 encoded string.

**Syntax**

```plaintext
util.Strings.base64EncodeFromHexString(
  s STRING
)  
RETURNS STRING
```

1. `s` is the source hexadecimal string to convert in Base64.
Usage

The `util.Strings.base64EncodeFromHexString()` method first converts the hexadecimal string passed as parameter to an array of bytes, then it converts the array of bytes to a Base64 representation, and returns the resulting Base64 encoded string.

Tip: Use the `util.Integer.toHexString()` method to build an hexadecimal string from a set of integer/byte values, then convert the hexadecimal string to a Base64 representation.

Example

```sql
IMPORT util

DEFINE hexa VARCHAR(50)
DISPLAY util.Strings.base64EncodeFromHexString( "00" )
DISPLAY util.Strings.base64EncodeFromHexString( "0000" )
DISPLAY util.Strings.base64EncodeFromHexString( "FFFF" )
DISPLAY util.Strings.base64EncodeFromHexString( "42EFB3E5" )
LET hexa = util.Integer.toHexString(65)
|       | util.Integer.toHexString(66)
|       | util.Integer.toHexString(67)
DISPLAY hexa
DISPLAY util.Strings.base64EncodeFromHexString( hexa )
END MAIN
```

Output:

```
AA==
AAA=
//8=
Qu+z5Q==
414243
QUJD
```

Related concepts

`util.Strings.base64DecodeToHexString` on page 2755
Decodes a base64 encoded string and returns the corresponding hexadecimal string.

`util.Strings.base64EncodeFromString`
Converts the string passed as parameter to a Base64 encoded string.

Syntax

```sql
util.Strings.base64EncodeFromString(
    s STRING
) RETURNS STRING
```

1. `s` is the source string to convert in Base64.

Usage

The `util.Strings.base64EncodeFromString()` method first converts the string passed as parameter (in the current character encoding of the application) to an array of bytes, then it converts the array of bytes to a Base64 representation, and returns the resulting Base64 encoded string.

Note: In contrast to `util.Strings.urlEncode()`, the original string is not converted from the application locale to UTF-8, before performing the encoding to Base64: The resulting Base64 encoded string will contain byte sequences representing characters in the current application locale.
**Example**

(Characteristic encoding is UTF-8)

```
IMPORT util
MAIN
    DISPLAY util.Strings.base64EncodeFromString("Forêt")
END MAIN
```

Output:

```
Rm9yw6p0
```

**Related concepts**

`util.Strings.base64DecodeToString` on page 2756
Decodes a base64 encoded string and returns the corresponding string.

`util.Strings.urlDecode`
Converts the URL-encoded string to a string in the current application locale.

**Syntax**

```
util.Strings.urlDecode(
    s STRING
)
RETURNS STRING
```

1. *s* is the URL-encoded source string (UTF-8 bytes).

**Usage**

The `util.Strings.urlDecode()` method converts the URL-encoded string passed as parameter to a character string.

The source string must contain ASCII characters and/or %xx hexadecimal representation of UTF-8 encoding bytes.

The decoder is error tolerant:

- Alphabetical characters of a %xx element can be uppercase or lowercase (%b2 = %B2).
- If the source string contains a set of %xx elements that represent a UTF-8 encoded character which is not existing in the current application locale, it will be converted to a ? question mark.
- If the percent character is not followed by two hexadecimal digits, then a "%" is copied to the result string and the decoder continues at the next character.

**Example**

```
IMPORT util
MAIN
    DISPLAY util.Strings.urlDecode("abc%C3%84%E2%82%AC")
END MAIN
```

Output:

```
abcĀ€
```

**Related concepts**

`Defining the application locale` on page 519
This section describes the settings defining the application locale, changing the behavior of the compilers and runtime system.

`util.Strings.urlEncode` on page 2759
Converts a string from the current codeset to a URL-encoded string.

util.Strings.urlEncode
Converts a string from the current codeset to a URL-encoded string.

Syntax

```plaintext
util.Strings.urlEncode(
   source STRING
)
RETURNS STRING
```

1. `source` is the source string to url-encode.

Usage

The `util.Strings.urlEncode()` method converts the character string passed as parameter to a URL-encoded string.

All characters not matching `[-_.~a-zA-Z0-9]` are "percent encoded": Percent-encoding involves converting those characters to UTF-8 and representing its corresponding byte values by a percent sign ("%") and a pair of hexadecimal digits.

Example

```plaintext
IMPORT util
MAIN
   DISPLAY util.Strings.urlEncode("abcĀ")
END MAIN

Output:
abc%C3%84%E2%82%AC
```

Related concepts

Defining the application locale on page 519

<td>Computes the sine of the passed value, measured in radians.</td>
</tr>
<tr>
<td><code>util.Math.sqrt</code> (x FLOAT)</td>
<td>Returns the square root of the argument provided.</td>
</tr>
<tr>
<td><code>util.Math.srand</code>()</td>
<td>Initializes the pseudo-random numbers generator.</td>
</tr>
<tr>
<td><code>util.Math.tan</code> (x FLOAT)</td>
<td>Computes the tangent of the passed value, measured in radians.</td>
</tr>
</tbody>
</table>
**util.Math.acos**
Computes the arc cosine of the passed value, measured in radians.

**Syntax**

```
util.Math.acos(
    x FLOAT )
RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage**

Returns NULL if the argument provided is invalid.

**util.Math.asin**
Computes the arc sine of the passed value, measured in radians.

**Syntax**

```
util.Math.asin(
    x FLOAT )
RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage**

Returns NULL if the argument provided is invalid.

**util.Math.atan**
Computes the arc tangent of the passed value, measured in radians.

**Syntax**

```
util.Math.atan(
    x FLOAT )
RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage**

Returns NULL if the argument provided is invalid.

**util.Math.cos**
Computes the cosine of the passed value, measured in radians.

**Syntax**

```
util.Math.cos(
    x FLOAT )
RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage:**

Returns NULL if the argument provided is invalid.
**util.Math.exp**
Computes the base-e exponential of the value passed as parameter.

**Syntax**
```
util.Math.exp(
   x FLOAT )
RETURNS FLOAT
```

1. *x* is a floating point value.

**Usage**
Returns **NULL** if the argument provided on error.

**util.Math.pi**
Returns the FLOAT value of PI.

**Syntax**
```
util.Math.pi()
RETURNS FLOAT
```

**util.Math.pow**
Computes the value of *x* raised to the power *y*.

**Syntax**
```
util.Math.pow(
   x FLOAT,
   y FLOAT )
RETURNS FLOAT
```

1. *x* is the value to be raised.
2. *y* is the power operand.

**Usage**
The function returns **NULL** if one of the arguments provided is invalid.
If *x* is negative, the caller must ensure that *y* is an integer value.

**util.Math.rand**
Returns a positive pseudo-random number.

**Syntax**
```
util.Math.rand(
   max INTEGER )
RETURNS INTEGER
```

1. *max* is the maximum random number that can be generated.

**Usage**
The `rand()` function returns a pseudo-random integer number between zero and *max*.

**Important:**
The `srand()` function initializes the pseudo-random numbers generator. It must be called before subsequent calls to the `rand()` function. If you do not call the `srand()` function, the `rand()` function will generate the same sequence of numbers for every program execution. The numbers generated by `rand()` can vary depending on the operating system.

The maximum random number returned by the `rand()` function is 2,147,483,646.

The `rand()` function returns zero if the argument is lower or equal to 0.

**Example**

```plaintext
IMPORT util
MAIN
  DEFINE i SMALLINT
  DISPLAY "Before srand() call:"
  FOR i=1 TO 3
    DISPLAY util.Math.rand(100)
  END FOR
  CALL util.Math.srand()
  DISPLAY "After srand() call:"
  FOR i=1 TO 3
    DISPLAY util.Math.rand(100)
  END FOR
END MAIN
```

(run this example several times)

**util.Math.sin**

Computes the sine of the passed value, measured in radians.

**Syntax**

```plaintext
util.Math.sin(  
  x FLOAT )  
RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage**

Returns NULL if the argument provided is invalid.

**util.Math.sqrt**

Returns the square root of the argument provided.

**Syntax**

```plaintext
util.Math.sqrt(  
  x FLOAT )  
RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage**

The function returns NULL if the argument provided is invalid.
**util.Math.srand**
Initializes the pseudo-random numbers generator.

**Syntax**

```javascript
util.Math.srand()
```

**Usage**
The `srand()` function initializes the pseudo-random numbers generator. It must be called before subsequent calls to the `rand()` function. If you do not call the `srand()` function, the `rand()` function will generate the same sequence of numbers for every program execution. The numbers generated by `rand()` can vary depending on the operating system.

**util.Math.tan**
Computes the tangent of the passed value, measured in radians.

**Syntax**

```javascript
util.Math.tan(
    x FLOAT
) RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage**
Returns NULL if the argument provided is invalid.

**util.Math.log**
Computes the natural logarithm of the passed value.

**Syntax**

```javascript
util.Math.log(
    x FLOAT
) RETURNS FLOAT
```

1. `x` is a floating point value.

**Usage**
Returns NULL if the argument provided is invalid.

**util.Math.toDegrees**
Converts an angle measured in radians to an approximately equivalent angle measured in degrees.

**Syntax**

```javascript
util.Math.toDegrees(
    x FLOAT
) RETURNS FLOAT
```

1. `x` is a floating point value to be converted to degrees.
**util.Math.toRadians**
Converts an angle measured in degrees to an approximately equivalent angle measured in radians.

**Syntax**

```plaintext
util.Math.toRadians(
    x  FLOAT )
RETURNS FLOAT
```

1. `x` is a floating point value to be converted to radians.

**The util.JSON class**
The `util.JSON` class provides a basic interface to convert program variable values to/from JSON data.

The `util.JSON` class is provided in the `util C-Extension` library. To use the `util.JSON` class, you must import the `util` package in your program:

```plaintext
IMPORT util
```

This class does not have to be instantiated; it provides class methods for the current program.

The purpose of the `util.JSON` class is to convert a JSON string from/to a BDL variable, to interface with other software based on the JSON format.

The BDL variable can be:

- a simple variable (defined with a primitive type such as `DATE`, `INTEGER`, `VARCHAR(20)`)  
- a structured variable (`RECORD ... END RECORD`) 
- a dynamic array (`DYNAMIC ARRAY OF ...`) 
- a dictionary (`DICTIONARY OF ...`) 

It is not possible to modify JSON elements with this class. In order to manipulate JSON objects, use the `util.JSONObject` and `util.JSONArray` classes.

**Related concepts**

- [JSON support on page 575](#)
  Genero BDL supports JSON data manipulation.

- [IMPORT C-Extension on page 481](#)
The IMPORT instruction imports c extension module elements to be used by the current module.

**util.JSON methods**
Methods for the util.JSON class.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>util.JSON.format (s STRING )</code>&lt;br&gt;RETURNS STRING</td>
<td>Formats a JSON string with indentation.</td>
</tr>
<tr>
<td>`util.JSON.parse (s STRING, variableRef { primitive-type</td>
<td>record-type</td>
</tr>
<tr>
<td><code>util.JSON.proposeType (s STRING )</code>&lt;br&gt;RETURNS STRING</td>
<td>Describes the record structure that can hold a given JSON data string.</td>
</tr>
<tr>
<td>`util.JSON.stringify (value { primitive-type</td>
<td>record-type</td>
</tr>
<tr>
<td>`util.JSON.stringifyOmitNulls (value { primitive-type</td>
<td>record-type</td>
</tr>
</tbody>
</table>

**util.JSON.format**
Formats a JSON string with indentation.

**Syntax**

```plaintext
util.JSON.format (s STRING )
RETURNS STRING
```

1. `s` is a string value that contains JSON formatted data.
Usage

The `util.JSON.format()` class method takes a JSON string as parameter and reorganizes the JSON data for better readability.

If the provided string is not valid JSON, the `format()` method will raise error `-8109`. Consider enclosing the `format()` method call in a `TRY/CATCH` block, if the source string can be malformed JSON.

The main purpose of this method is to beautify a JSON data string that is on a single line, by adding line breaks and indentation.

Example

```plaintext
IMPORT util
MAIN
    DISPLAY "1: ", util.JSON.format('{}')
    DISPLAY "2: ", util.JSON.format({'pkey':8374,"name":"John"}')
    DISPLAY "3: ", util.JSON.format({'ids':[234,3452,9845] })
    DISPLAY "4: ", util.JSON.format({'pkey':8374,"orders":[{}]}')
END MAIN
```

Output:

```
1: {}
2: {
    "pkey": 8374,
    "name": "John"
}
3: {
    "ids": [
        234,
        3452,
        9845
    ]
}
4: {
    "pkey": 8374,
    "orders": []
}
```

Related concepts

Records on page 408
Records allow structured program variables definitions.

`util.JSON.parse`

Parses a JSON string and fills program variables with the values.

Syntax

```plaintext
util.JSON.parse(
    s STRING,
    variableRef | primitive-type
                  | record-type
                  | array-type
                  | dictionary-type
)
```

1. `s` is a string value that contains JSON formatted data.
2. `variableRef` is the variable to be initialized with values of the JSON string.

   **Important:** The `variableRef` parameter is passed by reference to the method.
3. *primitive-type* is a primitive data type of Genero (INTEGER, DATE, VARCHAR)
4. *record-type* is a RECORD ... END RECORD type.
5. *array-type* is a DYNAMIC ARRAY OF ... or ARRAY[n] OF ... type.
6. *dictionary-type* is a DICTIONARY OF ... type.

**Usage**

The `util.JSON.parse()` class method scans the JSON source string passed as parameter and fills the destination variable members by name.

If the provided string is not valid JSON, the `parse()` method will raise error -8109. Consider enclosing the `parse()` method call in a TRY/CATCH block, if the source string can be malformed JSON.

The destination variable is expected to have the same structure as the JSON source data, it can be a RECORD, DYNAMIC ARRAY or a DICTIONARY.

The `parse()` method initializes the target variable to NULL before the parsing starts.

See [JSON support](#) on page 575 for details on how the destination variable is populated when the structures are not identical.

**Note:** When parsing a JSON string to fill a TEXT or BYTE variable, if the data storage for the LOB variable has not been defined with the LOCATE instruction, the JSON methods will automatically locate the TEXT or BYTE in memory. This applies also to TEXT and BYTE elements of records, arrays and dictionaries.

**Example**

```plaintext
IMPORT util
MAIN
  DEFINE cust_rec RECORD
    cust_num INTEGER,
    cust_name VARCHAR(30),
    order_ids DYNAMIC ARRAY OF INTEGER
  END RECORD
  DEFINE js STRING
  LET js='{ "cust_num":2735, "cust_name":"McCarlson",
         "order_ids":[234,3456,24656,34561] }'
  TRY
    CALL util.JSON.parse( js, cust_rec )
    DISPLAY cust_rec.cust_name
    DISPLAY cust_rec.order_ids[4]
  CATCH
    DISPLAY "ERROR:", STATUS
  END TRY
END MAIN
```

**Related concepts**

*Records* on page 408
Records allow structured program variables definitions.

*util.JSON.proposeType*
Describes the record structure that can hold a given JSON data string.

**Syntax**

```plaintext
util.JSON.proposeType(
  s STRING)
RETURNS STRING
```

1. *s* is a string value that contains JSON formatted data.
Usage

The `util.JSON.proposeType()` class method takes a JSON formatted string as parameter and generates the RECORD definition that can be used as base record definition hold the source JSON string.

If the provided string is not valid JSON, the `proposeType()` method will raise error -8109. Consider enclosing the `proposeType()` method call in a TRY/CATCH block, if the source string can be malformed JSON.

In order to respect the BDL syntax, and match exactly the JSON source structure, the type generated by `proposeType()` may need to be reviewed.

For example, if the JSON property name contains characters not allowed in a BDL identifiers, use the `json_name` variable definition attribute to map the JSON property name to the RECORD element. Furthermore, the type DICTIONARY will not be proposed. As result, a source JSON string like ("First Name": "John", "Last Name": "Piper") will produce:

```plaintext
RECORD
   First Name STRING,
   Last Name STRING
END RECORD
```

That needs to be adapted to use `json_name` attributes:

```plaintext
RECORD
   first_name STRING ATTRIBUTES(json_name="First Name"),
   last_name  STRING ATTRIBUTES(json_name="Last Name")
END RECORD
```

Or to a DICTIONARY type:

```plaintext
DICTIONARY OF STRING
```

Example

```plaintext
IMPORT util
MAIN
   DEFINE js STRING
   LET js='{ "cust_num":2735, "cust_name":"McCarlson",
           "orderids":\[234,3456,24656,34561\] }'
   DISPLAY util.JSON.proposeType( js )
END MAIN
```

Displays:

```plaintext
RECORD
   cust_num FLOAT,
   cust_name STRING,
   orderids DYNAMIC ARRAY OF FLOAT
END RECORD
```

Related concepts

Records on page 408
Records allow structured program variables definitions.

`util.JSON.stringify`
Transforms a record variable to a flat JSON formatted string, by including empty records and empty arrays.

Syntax

```plaintext
util.JSON.stringify()
```
value | $ primitive-type 
| record-type 
| array-type 
| dictionary-type 

) 

RETURNS STRING

1. value is the program variable to be converted to a JSON string.
2. primitive-type is a primitive data type of Genero (INTEGER, DATE, VARCHAR)
3. record-type is a RECORD ... END RECORD type.
4. array-type is a DYNAMIC ARRAY OF ... or ARRAY[n] OF ... type.
5. dictionary-type is a DICTIONARY OF ... type.

Usage

The util.JSON.stringify() class method takes a variable as parameter, and generates the corresponding data string in JSON format, as defined in the [RFC4627] specification.

Important: Unlike util.JSON.stringifyOmitNulls(), empty records (where all members are NULL), and empty arrays will be written in the JSON string. For detailed control on null and empty variables when serializing to JSON elements, use the json_null variable definition attribute.

The method raises error -8110 if the JSON string cannot be generated.

For more details about FGL to JSON conversion, see JSON support on page 575.

Example

IMPORT util
MAIN
DEFINE rec RECORD
   field1 INTEGER,
   field2 CHAR(1),
   subrec1 RECORD
      field11 INTEGER,
      field12 VARCHAR(30)
   END RECORD,
   subarr1 DYNAMIC ARRAY OF INTEGER
END RECORD
INITIALIZE rec.* TO NULL
LET rec.field1 = 999
LET rec.subarr1[3] = 888
DISPLAY "stringify() : ", util.JSON.stringify(rec)
END MAIN

Output:

stringify() : {"field1":999,"subrec1":{},"subarr1":[null,null,888]}

Related concepts

util.JSON.stringifyOmitNulls on page 2772
Transforms a record variable to a flat JSON formatted string, by excluding empty records and empty arrays.

Records on page 408
Records allow structured program variables definitions.

*util.JSON.stringifyOmitNulls*

Transforms a record variable to a flat JSON formatted string, by excluding empty records and empty arrays.

**Syntax**

```plaintext
util.JSON.stringifyOmitNulls(
  value { primitive-type
    | record-type
    | array-type
    | dictionary-type
  }
)
RETURNS STRING
```

1. `value` is the program variable to be converted to a JSON string.
2. `primitive-type` is a primitive data type of Genero (INTEGER, DATE, VARCHAR)
3. `record-type` is a `RECORD ... END RECORD` type.
4. `array-type` is a `DYNAMIC ARRAY OF ...` or `ARRAY[n] OF ...` type.
5. `dictionary-type` is a `DICTIONARY OF ...` type.

**Usage**

The `util.JSON.stringifyOmitNulls()` class method takes a variable as parameter, and generates the corresponding data string in JSON format, as defined in the [RFC4627] specification.

**Important:** Unlike `util.JSON.stringify()`, empty records (where all members are NULL), and empty arrays will **NOT** be written in the JSON string. For detailed control on null and empty variables when serializing to JSON elements, use the `json_null` variable definition attribute and the `stringify()` method. The method `stringifyOmitNulls()` behaves like `stringify()`, when all variable elements are defined with the `json_null="undefined"` attribute.

The method raises error `-8110` if the JSON string cannot be generated.

For more details about FGL to JSON conversion, see JSON support on page 575.

**Example**

```plaintext
IMPORT util
MAIN
  DEFINE rec RECORD
    field1 INTEGER,
    field2 CHAR(1),
    subrec1 RECORD
      field11 INTEGER,
      field12 VARCHAR(30)
    END RECORD,
    subarr1 DYNAMIC ARRAY OF INTEGER
  END RECORD
  INITIALIZE rec.* TO NULL
  LET rec.field1 = 999
  DISPLAY "stringify()   : ", util.JSON.stringify(rec)
  DISPLAY "stringifyOmitNulls(): ", util.JSON.stringifyOmitNulls(rec)
END MAIN
```

Output:

```
stringify()         : {"field1":999,"subrec1":{},"subarr1":[]}
stringifyOmitNulls(): {"field1":999}
```
**Related concepts**
util.JSON.stringify on page 2770
Transforms a record variable to a flat JSON formatted string, by including empty records and empty arrays.

Records on page 408
Records allow structured program variables definitions.

**Examples**
util.JSON usage examples.

*Example 1: Reading a JSON file*

This program reads JSON data from customers.json, then parses the file content to fill the program array custlist, converts the array back to a JSON string and writes a formatted JSON string to the standard output.

**Note:** The parse() method is enclosed in a TRY/CATCH block, to detect potential JSON format errors in the source file.

```c
IMPORT util
MAIN
  DEFINE jsondata TEXT,
  custlist DYNAMIC ARRAY OF RECORD
    num INTEGER,
    name VARCHAR(40)
  END RECORD,
  tmp STRING
  LOCATE jsondata IN FILE "customers.json"
  TRY
    CALL util.JSON.parse( jsondata, custlist )
    DISPLAY "Array length = ", custlist.getLength()
    LET tmp = util.JSON.stringify(custlist)
    DISPLAY util.JSON.format( tmp )
  CATCH
    DISPLAY "ERROR:", STATUS
  END TRY
END MAIN
```

The file customers.json:

```json
[
  {
    "num": 823,
    "name": "Mark Renbing"
  },
  {
    "num": 234,
    "name": "Clark Gambler"
  }
]
```

**Note** that the JSON file does not contain the name of the dynamic array (custlist), but starts directly with the JSON array in [ ] square brackets.

**The util.JSONObject class**
The util.JSONObject class provides methods to handle an structured data object following the JSON string syntax.

The util.JSONObject class is provided in the util C-Extension library. To use the util.JSONObject class, you must import the util package in your program:

```c
IMPORT util
```
A JSONObject is an unordered collection of name/value pairs. The format of a JSON object string is a comma-separated "name":value pairs, wrapped in curly brackets. The value can be simple numeric or string value, but it can also be an array of values enclosed in square brackets, or a sub-element enclosed in curly brackets:

```json
{
  "cust_num":2735,
  "cust_name":"McCarlson",
  "order_ids":[234,3456,24656,34561],
  "address": {
    "street":"34, Sunset Bld",
    "city":"Los Angeles",
    "state":"CA"
  }
}
```

A JSONObject object must be created before usage with one of the class methods like `util.JSONObject.create()`. The JSONObject class provides methods for accessing, adding/replacing or deleting the values by name with the `get()`, `put()` and `remove()` methods.

The `get()` method can return a simple value, a `util.JSONObject` or a `util.JSONArray` object reference. The `put()` method can take a simple value, a RECORD, or an ARRAY as parameter.

If the structure of the JSON object is not known at compile time, you can introspect the elements of the object with the `getLength()`, `getType()` and `name()` methods.

**Related concepts**

**JSON support** on page 575
Genero BDL supports JSON data manipulation.

**IMPORT C-Extension** on page 481
The IMPORT instruction imports C extension module elements to be used by the current module.

**util.JSONObject methods**
Methods for the util.JSONObject class.

</tbody>
</table>

#### `util.JSONObject.create`

Creates a new JSON object.

#### Syntax

```plaintext
util.JSONObject.create()
RETURNS util.JSONObject
```

#### Usage

The `util.JSONObject.create()` method creates a new JSON object.

The created object must be assigned to a program variable defined with the `util.JSONObject` type.
Example

```plaintext
IMPORT util
MAIN
  DEFINE cust_rec RECORD
    cust_num INTEGER,
    cust_name VARCHAR(30),
    order_ids DYNAMIC ARRAY OF INTEGER
  END RECORD
  DEFINE obj util.JSONObject
  LET cust_rec.cust_num = 345
  LET cust_rec.cust_name = "McMaclum"
  LET cust_rec.order_ids[1] = 4732
  LET cust_rec.order_ids[2] = 9834
  LET cust_rec.order_ids[3] = 2194
  LET obj = util.JSONObject.fromFGL(cust_rec)
  DISPLAY obj.toString()
END MAIN
```

Related concepts

util.JSONObject.fromFGL on page 2776
Creates a new JSON object from a RECORD.

util.JSONObject.parse on page 2777
Parses a JSON string and creates a JSON object from it.

util.JSONObject.fromFGL
Creates a new JSON object from a RECORD.

Syntax

```plaintext
util.JSONObject.fromFGL(
  record record-type )
RETURNS util.JSONObject
```

1. `record` is the record variable used to create the JSON object.
2. `record-type` is a RECORD ... END RECORD type.

Usage

The `util.JSONObject.fromFGL()` method creates a new JSON object from the RECORD variable passed as parameter.

The created object must be assigned to a program variable defined with the `util.JSONObject` type.

The members of the RECORD are converted to name/value pairs in the JSON object.

For more details about FGL to JSON conversion, see JSON support on page 575.

Example

```plaintext
IMPORT util
MAIN
  DEFINE cust_rec RECORD
    cust_num INTEGER,
    cust_name VARCHAR(30),
    order_ids DYNAMIC ARRAY OF INTEGER
  END RECORD
  DEFINE obj util.JSONObject
  LET cust_rec.cust_num = 345
  LET cust_rec.cust_name = "McMaclum"
  LET cust_rec.order_ids[1] = 4732
  LET cust_rec.order_ids[2] = 9834
  LET cust_rec.order_ids[3] = 2194
  LET obj = util.JSONObject.fromFGL(cust_rec)
  DISPLAY obj.toString()
END MAIN
```

Related concepts

Records on page 408
Records allow structured program variables definitions.

*util.JSONObject.create* on page 2775
Creates a new JSON object.

*util.JSONObject.parse* on page 2777
Parses a JSON string and creates a JSON object from it.

### Syntax

```c
util.JSONObject.parse(
    s STRING
) RETURNS util.JSONObject
```

1. `s` is a string value that contains JSON formatted data.

### Usage

The `util.JSONObject.parse()` method scans the JSON source string passed as parameter and creates a JSON object from it.

The created object must be assigned to a program variable defined with the `util.JSONObject` type.

The source string must follow the JSON format specification. It can contain multi-level structured data, but it must start with a curly brace.

The method raises error `-8109` if the JSON source string is not properly formatted. Consider enclosing the `parse()` method call in a `TRY/CATCH` block, if the source string can be malformed JSON.

### Example

```c
IMPORT util
MAIN
    DEFINE js STRING
    DEFINE obj util.JSONObject
    LET js='{ "cust_num":2735, "cust_name":"McCarlson", "orderids":[234,3456,24656,34561] }'
    LET obj = util.JSONObject.parse( js )
    DISPLAY obj.get("cust_name")
END MAIN
```

### Related concepts

*util.JSONObject.create* on page 2775
Creates a new JSON object.

*util.JSONObject.fromFGL* on page 2776
Creates a new JSON object from a RECORD.

*util.JSONObject.get*
Returns the value corresponding to the specified entry name.

### Syntax

```c
util.JSONObject.get(
    name STRING
) RETURNS result-type
```

1. `name` is the string identifying the JSON object property.
2. **result-type** can be a simple type, a `util.JSONObject` or a `util.JSONArray` object reference.

**Usage**

The `get()` method returns the value or JSON object corresponding to the element name passed as parameter.

If the element identified by the name is a simple value, the method returns a string. If the element is structured, the method returns a `util.JSONObject` instance and the returned object must be assigned to a program variable defined with the `util.JSONObject` type. If the element is a list of values, the method `util.JSONArray` instance and the returned object must be assigned to a program variable defined with the `util.JSONArray` type.

**Note:** If the element is a simple value, pay attention to the data format when directly assigning the result of the `get()` method to a program variable. For example, if the JSON string value represents a date, it will use the ISO format (YYYY-MM-DD). Assigning this ISO-formatted date string to a `DATE` variable will fail, if `DBDATE` format does not match.

A name/value pair can be set with the `put()` method.

**Example**

```hll
IMPORT util
MAIN
    DEFINE obj, sub util.JSONObject
    DEFINE jarr util.JSONArray
    DEFINE rec RECORD
        id INTEGER,
        name STRING
    END RECORD
    DEFINE arr DYNAMIC ARRAY OF INTEGER
    DEFINE x INT
    LET obj = util.JSONObject.create()
    -- Simple value
    CALL obj.put("simple", 234)
    LET x = obj.get("simple")
    -- Sub-element
    LET rec.id = 234
    LET rec.name = "Barton"
    CALL obj.put("record", rec)
    LET sub = obj.get("record")
    -- Array
    LET arr[1] = 234
    LET arr[2] = 2837
    CALL obj.put("array", arr)
    LET jarr = obj.get("array")
END MAIN
```

**Related concepts**

- **`util.JSONObject.put`** on page 2781
  Sets a name-value pair in the JSON object.

- **`util.JSONObject.getLength`**
  Returns the number of name-value pairs in the JSON object.

**Syntax**

```hll
util.JSONObject.getLength()
RETURNS INTEGER
```

**Usage**

The `getLength()` method returns the number of name-value pairs in the JSON object.
This method can be used along with the `name()` and `getType()` methods to read the entries of a JSON object.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    DEFINE i INTEGER
    LET obj = util.JSONObject.parse('{"id":123,"name":"Scott"}')
    FOR i=1 TO obj.getLength()
        DISPLAY i, " ", obj.name(i), " ", " = ", obj.get(obj.name(i))
    END FOR
END MAIN
```

**Related concepts**

- `util.JSONObject.name` on page 2780
  Returns the name of a JSON object entry by position.
- `util.JSONObject.getType` on page 2779
  Returns the type of a JSON object element.
- `util.JSONObject.getType`
  Returns the type of a JSON object element.

**Syntax**

```plaintext
util.JSONObject.getType(
    name STRING
) RETURNS STRING
```

1. `name` is the name of the element.

**Usage**

The `getType()` method returns the JSON data type name corresponding to the element name passed as parameter. This method can be used along with the `name()` and `getLength()` methods, to read the entries of a JSON object. Possible values returned by this method are:

- **NUMBER**: A numeric value.
- **STRING**: A string value delimited by double quotes.
- **BOOLEAN**: A boolean value (true/false)
- **NULL**: A non-existing element.
- **OBJECT**: A structured object.
- **ARRAY**: An ordered list of elements.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    LET obj = util.JSONObject.create()
    CALL obj.put("id", 8723)
    DISPLAY obj.getType("id") -- NUMBER
    CALL obj.put("name", "Brando")
    DISPLAY obj.getType("name") -- STRING
    DISPLAY obj.getType("undef") -- NULL
END MAIN
```
**Related concepts**

*util.JSONObject.getLength* on page 2778
Returns the number of name-value pairs in the JSON object.

*util.JSONObject.name* on page 2780
Returns the name of a JSON object entry by position.

*util.JSONObject.has*
Checks if the JSON object contains a specific entry name.

**Syntax**

```
util.JSONObject.has(
  name STRING
) RETURNS BOOLEAN
```

1. *name* is a string identifying a JSON object property.

**Usage**

The `has()` method determines if the JSON object holds a property identified by the element name passed as parameter.

The method returns `TRUE` if the name/value pair exists in the JSON object.

A name/value pair can be set with the `put()` method.

**Related concepts**

*util.JSONObject.put* on page 2781
Sets a name-value pair in the JSON object.

*util.JSONObject.name*
Returns the name of a JSON object entry by position.

**Syntax**

```
util.JSONObject.name(
  index INTEGER
) RETURNS STRING
```

1. *index* is the index of the name-value pair in the JSON object.

**Usage**

The `name()` method returns the entry name in the JSON object at the given position.

The index corresponding to the first name-value pair is 1.

If no entry exists at the given index, the method returns `NULL`.

This method can be used along with the `getLength()` and `getType()` methods to read the entries of a JSON object.

**Example**

```
IMPORT util
MAIN
  DEFINE obj util.JSONObject
  DEFINE i INTEGER
  LET obj = util.JSONObject.parse('"id":123,"name":"Scott"')
  FOR i=1 TO obj.getLength()
    DISPLAY i, ": ", obj.name(i)
```
Related concepts

util.JSONObject.getLength on page 2778
Returns the number of name-value pairs in the JSON object.

util.JSONObject.getType on page 2779
Returns the type of a JSON object element.

util.JSONObject.put
Sets a name-value pair in the JSON object.

Syntax

```java
util.JSONObject.put(
    name STRING,
    value value-type
)
```

1. `name` is a string defining the entry name.
2. `value` is the value to be associated to the name.
3. `value-type` can be a simple string or numeric type, a RECORD or a DYNAMIC ARRAY.

Usage

The `put()` method adds a name-value pair to the JSON object.

The first parameter is the name of the element. The second parameter can be a simple string or numeric value, or a complex variable defined as RECORD or DYNAMIC ARRAY.

If the element exists, the existing value is replaced.

Example

```java
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    DEFINE rec RECORD
        id INTEGER,
        name STRING
    END RECORD
    DEFINE arr DYNAMIC ARRAY OF INTEGER
    LET obj = util.JSONObject.create()
    CALL obj.put("simple", 234)
    LET rec.id = 234
    LET rec.name = "Barton"
    CALL obj.put("record", rec)
    LET arr[1] = 234
    LET arr[2] = 2837
    CALL obj.put("array", arr)
    DISPLAY obj.toString()
END MAIN
```

Related concepts

util.JSONObject.get on page 2777
Returns the value corresponding to the specified entry name.

`util.JSONObject.remove`
Removes the specified element in the JSON object.

**Syntax**

```
util.JSONObject.remove(
   name STRING )
```

1. `name` is the string identifying the JSON object property.

**Usage**

The `remove()` method deletes a name-value pair identified by the name passed as parameter.

**Example**

```plaintext
IMPORT util
MAIN
   DEFINE obj util.JSONObject
   LET obj = util.JSONObject.create()
   CALL obj.put("address", "5 Brando Street")
   CALL obj.remove("address")
   DISPLAY obj.get("address")
END MAIN
```

**Related concepts**

- `util.JSONObject.put` on page 2781
  Sets a name-value pair in the JSON object.
- `util.JSONObject.get` on page 2777
  Returns the value corresponding to the specified entry name.
- `util.JSONObject.toFGL`
  Fills a record variable with the entries contained in the JSON object.

**Syntax**

```
util.JSONObject.toFGL(
   recordRef record-type )
```

1. `recordRef` is the variable to be set with values of the JSON string.
   
   **Important:** The `recordRef` is a RECORD variable is passed by reference to the method.

2. `record-type` is a RECORD ... END RECORD type.

**Usage**

The `toFGL()` method fills the RECORD variable passed as parameter with the corresponding values defined in the JSON object.

The destination record must have the same structure as the JSON source data. For more details see JSON support on page 575.

**Example**

```plaintext
IMPORT util
MAIN
   DEFINE cust_rec RECORD
   cust_num INTEGER,
```
cust_name VARCHAR(30),
    order_ids DYNAMIC ARRAY OF INTEGER
END RECORD

DEFINE js STRING
DEFINE obj util.JSONObject
LET js='{"cust_num":2735, "cust_name":"McCarlson",
"order_ids":[234,3456,24656,34561]}'
LET obj = util.JSONObject.parse( js )
CALL obj.toFGL( cust_rec )
DISPLAY cust_rec.cust_name
DISPLAY cust_rec.order_ids[4]
END MAIN

Related concepts

util.JSONObject.toString on page 2783
Builds a JSON string from the values contained in the JSON object.

util.JSONObject.toString
Builds a JSON string from the values contained in the JSON object.

**Syntax**

```plaintext
util.JSONObject.toString()
RETURNS STRING
```

**Usage**

The `toString()` method produces a JSON formatted string from the name-value pairs contained in the JSON object.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE obj util.JSONObject
    LET obj = util.JSONObject.create()
    CALL obj.put("num", "75263")
    CALL obj.put("name", "Ferguson")
    CALL obj.put("address", "12 Marylon Street")
    DISPLAY obj.toString()
END MAIN
```

Related concepts

util.JSONObject.toFGL on page 2782
Fills a record variable with the entries contained in the JSON object.

The **util.JSONArray class**

The `util.JSONArray` class provides methods to handle an array of values, following the JSON string syntax.

The `util.JSONArray` class is provided in the `util` C-Extension library. To use the `util.JSONArray` class, you must import the `util` package in your program:

```plaintext
IMPORT util
```

A JSONArray is a sequence of unnamed values. The format of a JSON array string is a list of values wrapped in square brackets with commas between the values:

```plaintext
[123, 546, "abc", "def", "xyz"]
```
A JSONArray object must be created before usage with one of the class methods like
util.JSONArray.create().

The JSONArray class provides methods for accessing, adding/replacing or deleting the array values by index with
the get(), put() and remove() methods.

If the structure of the JSON array is not known at compile time, you can introspect the elements of the array with the
getLength() and getType() methods.

Related concepts
JSON support on page 575
Genero BDL supports JSON data manipulation.

IMPORT C-Extension on page 481
The IMPORT instruction imports C extension module elements to be used by the current module.

</tr>
</tbody>
</table>

util.JSONArray.create

Creates a new JSON array object.

Syntax

```plaintext
util.JSONArray.create ()
RETURNS util.JSONArray
```

Usage

The `util.JSONArray.create ()` method create a new JSON array object.

The created object must be assigned to a program variable defined with the `util.JSONArray` type.

Example

```plaintext
IMPORT util
MAIN
  DEFINE arr util.JSONArray
  LET arr = util.JSONArray.create ()
  ...
END MAIN
```
**Related concepts**

- `util.JSONArray.fromFGL` on page 2786
  Creates a new JSON array object from a **DYNAMIC ARRAY**.

- `util.JSONArray.parse` on page 2786
  Parses a JSON string and creates a JSON array object from it.

**util.JSONArray.fromFGL**

Creates a new JSON array object from a **DYNAMIC ARRAY**.

**Syntax**

```plaintext
util.JSONArray.fromFGL(
    array dynamic-array-type )
RETURNS util.JSONArray
```

1. `array` is the dynamic array variable used to create the JSON array object.
2. `dynamic-array-type` is a **DYNAMIC ARRAY OF ...** type.

**Usage**

The `util.JSONArray.fromFGL()` method creates a new JSON array from the **DYNAMIC ARRAY** variable passed as parameter.

The created object must be assigned to a program variable defined with the `util.JSONArray` type.

The members of the **DYNAMIC ARRAY** are converted to a list of name / value pairs in the JSON array object.

The dynamic array can be structured with a **RECORD** definition: the elements of the array will be converted individually.

For more details about FGL to JSON conversion, see **JSON support** on page 575.

**Example**

```plaintext
IMPORT util
MAIN
    DEFINE da DYNAMIC ARRAY OF INTEGER
    DEFINE arr util.JSONArray
    LET da[1] = 123
    LET da[2] = 972
    LET arr = util.JSONArray.fromFGL(da)
    DISPLAY arr.toString()
END MAIN
```

**Related concepts**

- **Arrays** on page 418
  Arrays (static or dynamic) allow you to handle an ordered collection of elements.

- `util.JSONArray.parse`  
Parses a JSON string and creates a JSON array object from it.

**Syntax**

```plaintext
util.JSONArray.parse(
    s STRING )
RETURNS util.JSONArray
```

1. `s` is a string value that contains JSON formatted data as a list of elements delimited by square brackets.
Usage

The `util.JSONArray.parse()` method scans the JSON source string passed as parameter and creates a new
JSON array object from it.

The created object must be assigned to a program variable defined with the `util.JSONArray` type.

The source string must follow the JSON format specification. Elements of the list can contain multi-level structured
data, but the string must follow the JSON array string syntax `[ element, ... ]` with square brackets.

The method raises error -8109 if the JSON source string is not properly formatted. Consider enclosing the `parse()` method call in a `TRY/CATCH` block, if the source string can be malformed JSON.

Example

```import util
main
  define da dynamic array of integer
  define arr util.JSONArray
  let arr = util.JSONArray.parse("[1,2,3,4,5]"
  display arr.toString()
end main```

Related concepts

`util.JSONArray.fromFGL` on page 2786
Creates a new JSON array object from a `DYNAMIC ARRAY`.

`util.JSONArray.create` on page 2785
Creates a new JSON array object.

`util JSONArray.get`
Returns the value of a JSON array element.

Syntax

```util JSONArray.get(
  index integer )
returns result-type```

1. `index` is the index of the element in the JSON array object.
2. `result-type` can be a simple type, a `util.JSONObject` or a `util.JSONArray` object reference.

Usage

The `get()` method returns the value or JSON object corresponding to the element at the given position.

The index corresponding to the first element is 1.

If no element exists at the given index, the method returns `NULL`.

If the element identified by the name is a simple value, the method returns a string. If the element is structured, the
method returns a `util.JSONObject` instance and the returned object must be assigned to a program variable
defined with the `util.JSONObject` type. If the element is a list of values, the method `util.JSONArray`
instance and the returned object must be assigned to a program variable defined with the `util.JSONArray` type.

Note: If the element is a simple value, pay attention to the data format when directly assigning the result of the
`get()` method to a program variable. For example, if the JSON string value represents a date, it will use the ISO
format (YYYY-MM-DD). Assigning this ISO-formatted date string to a `DATE` variable will fail, if `DBDATE` format
does not match.

A name/value pair can be set with the `put()` method.
Example

```
IMPORT util
MAIN
  DEFINE arr util.JSONArray
  LET arr = util.JSONArray.parse('"[123,"abc",null]"
  DISPLAY arr.get(2) -- abc
END MAIN
```

Related concepts

`util.JSONArray.put` on page 2789
Sets an element by position in the JSON array object.

`util.JSONArray.getLength`
Returns the number of elements in the JSON array object.

Syntax

```
util.JSONArray.getLength()
RETURNS INTEGER
```

Usage

The `getLength()` method returns the number of elements in the JSON array object.
This method can be used along with the `get()` and `getType()` method to read elements of a JSON array object.

Example

```
IMPORT util
MAIN
  DEFINE arr util.JSONArray
  DEFINE i INTEGER
  LET arr = util.JSONArray.parse('[123,8723,9232]
  FOR i=1 TO arr.getLength()
    DISPLAY i, ", ", arr.get(i)
  END FOR
END MAIN
```

Related concepts

`util.JSONArray.getType` on page 2788
Returns the type of a JSON array element.

`util.JSONArray.getType`
Returns the type of a JSON array element.

Syntax

```
util.JSONArray.getType(
  index INTEGER )
RETURNS STRING
```

1. `index` is the ordinal position of the element.

Usage

The `getType()` method returns the data type name corresponding to the JSON array element at the given position.
The index corresponding to the first element is 1.
This method can be used along with the `getLength()` method to read the entries of a JSON array object.

Possible values returned by this method are:

- **NUMBER**: A numeric value.
- **STRING**: A string value delimited by double quotes.
- **BOOLEAN**: A boolean value (true/false)
- **NULL**: A non-existing element.
- **OBJECT**: A structured object.
- **ARRAY**: An ordered list of elements.

**Example**

```plaintext
IMPORT util
MAIN
  DEFINE arr util.JSONArray
  LET arr = util.JSONArray.parse('[123,"abc",null]')
  DISPLAY arr.getType(1) -- NUMBER
  DISPLAY arr.getType(2) -- STRING
  DISPLAY arr.getType(3) -- NULL
END MAIN
```

**Related concepts**

- **util.JSONArray.getLength** on page 2788
  Returns the number of elements in the JSON array object.

- **util.JSONArray.put**
  Sets an element by position in the JSON array object.

**Syntax**

```plaintext
util.JSONArray.put(  
  index INTEGER,  
  value value-type )
```

1. **index** is the index of the element in the JSON array object.
2. **value** is the value to be associated to the index.
3. **value-type** can be a simple string or numeric type, a **RECORD** or a **DYNAMIC ARRAY**.

**Usage**

The `put()` method sets an element value by position in the JSON array object.

The first parameter is the index of the element. The second parameter can be a simple string or numeric value, or a complex variable defined as **RECORD** or **DYNAMIC ARRAY**.

The index corresponding to the first element is 1.

If the element exists, the existing value is replaced.

**Example**

```plaintext
IMPORT util
MAIN
  DEFINE ja util.JSONArray
  DEFINE rec RECORD
  id INTEGER,
  name STRING
  END RECORD
  DEFINE arr DYNAMIC ARRAY OF INTEGER
  LET ja = util.JSONArray.create()
```
CALL ja.put(1, 234)
LET rec.id = 234
LET rec.name = "Barton"
CALL ja.put(2, rec)
LET arr[1] = 234
LET arr[2] = 2837
CALL ja.put(3, arr)
DISPLAY ja.toString()
END MAIN

Related concepts

util.JSONArray.get on page 2787
Returns the value of a JSON array element.

util.JSONArray.remove
Removes the specified entry in the JSON array object.

Syntax

util.JSONArray.remove(
  index INTEGER )

1. index is the index of the element in the JSON array object.

Usage

The remove() method deletes an element in the JSON array object at the given position.
The index corresponding to the first element is 1.
If no element exists at the specified index, the method returns silently.

Example

IMPORT util
MAIN
  DEFINE arr util.JSONArray
  LET arr = util.JSONArray.parse('["aa","bb","cc"]')
  CALL arr.remove(2)
  DISPLAY arr.get(2) -- cc
END MAIN

Related concepts

util.JSONArray.put on page 2789
Sets an element by position in the JSON array object.

util.JSONArray.toFGL
Fills a dynamic array variable with the elements contained in the JSON array object.

Syntax

util.JSONArray.toFGL(
  arrayRef dynamic-array-type )

1. arrayRef is the array variable to be set with values of the JSON string.
   Important: The arrayRef is a dynamic array passed by reference to the method.
2. dynamic-array-type is a DYNAMIC ARRAY OF ... type.
| Library reference | 2791

Usage
The toFGL() method fills the DYNAMIC ARRAY passed as parameter with the corresponding values defined in the
JSON array object.
The destination array must have the same structure as the JSON source data. For more details see JSON support on
page 575.
Example
IMPORT util
MAIN
DEFINE ja util.JSONArray
DEFINE arr DYNAMIC ARRAY OF STRING
LET ja = util.JSONArray.parse('["aa","bb","cc"]')
CALL ja.toFGL(arr)
DISPLAY arr[2] -- bb
END MAIN
Related concepts
Arrays on page 418
Arrays (static or dynamic) allow you to handle an ordered collection of elements.
Records on page 408
Records allow structured program variables definitions.
util.JSONArray.toString on page 2791
Builds a JSON string from the elements contained in the JSON array object.
util.JSONArray.toString
Builds a JSON string from the elements contained in the JSON array object.
Syntax
util.JSONArray.toString()
RETURNS STRING
Usage
The toString() method produces a JSON formatted string from the elements contained in the JSON array object.
Example
IMPORT util
MAIN
DEFINE ja util.JSONArray
LET ja = util.JSONArray.create()
CALL ja.put(1,"aa")
CALL ja.put(2,"bb")
CALL ja.put(3,"cc")
DISPLAY ja.toString() -- ["aa","bb","cc"]
END MAIN
Related concepts
util.JSONArray.toFGL on page 2790


Fills a dynamic array variable with the elements contained in the JSON array object.

**The os package**

These topics cover the classes of the os package.

**The os.Path class**

The os.Path class provides functions to manipulate files and directories on the machine where the program executes.

This class is provided in the util C-Extension library. To use the os.Path extension, you must import the os package in your program:

```python
IMPORT os
```

In order to manipulate files, this API gives you access to low-level system functions. Pay attention to operating system specific conventions like path separators.

**Important:** Some methods are OS specific, like os.Path.rwx() which works only on UNIX® systems. Other methods may behave differently, depending on the OS. For example, the os.Path.rename() method cannot rename a file across file systems on a UNIX® platform.

**Related concepts**

IMPORT C-Extension on page 481
The **IMPORT** instruction imports C extension module elements to be used by the current module.
## os.Path methods

### Table 597: Class methods

<table>
<thead>
<tr>
<th>Name</th>

<td>Returns all components of a path excluding the last one.</td>
</tr>
<tr>
<td><code>os.Path.dirNext(dirHandle INTEGER)</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Reads the next entry in the directory opened with <code>os.Path.diropen()</code>.</td>
</tr>
</tbody>
</table>
**os.Path.atime**

Returns the time of the last file access.

**Syntax**

```sql
os.Path.atime(
    path STRING
) RETURNS STRING
```

1. *path* is the path to a file.

**Usage**

The function returns a string containing the last access time for the specified file, in the standard format 'YYYY-MM-DD HH:MM:SS'.

If the function fails, it returns **NULL**.

**os.Path.baseName**

Returns the last element of a path.

**Syntax**

```sql
os.Path.baseName(
    path STRING
) RETURNS STRING
```

1. *path* is the name of the file.

**Usage**

This method extracts the last component of a path provided as argument.

For example, if you pass "/root/dir1/file.ext" as the parameter, it will return "file.ext".

See [Example 1: Extracting the parts of a file name](page 2809) on page 2809 for more examples.

**os.Path.copy**

Creates a new file by copying an existing file.

**Syntax**

```sql
os.Path.copy(
    fromPath STRING, 
    toPath STRING 
) RETURNS INTEGER
```

1. *fromPath* is the name of the file to copy.
2. *toPath* is the destination filename.

**Usage**

The function returns **TRUE** if the file has been successfully copied, **FALSE** otherwise.

**Example**

```sql
IF NOT os.Path.copy("/tmp/result.txt","/tmp/result-backup.txt") THEN
    DISPLAY "Could not copy the file."
END IF
```
**os.Path.chDir**
Changes the current working directory.

**Syntax**

```plaintext
os.Path.chDir(
    path STRING,
) RETURNS INTEGER
```

1. `path` is the path to the directory to select.

**Usage**
Use this function to change the current working directory.
The function returns `TRUE` if the current directory is successfully selected, `FALSE` otherwise.

**os.Path.chRwx**
Changes the UNIX™ permissions of a file.

**Syntax**

```plaintext
os.Path.chRwx(
    path STRING,
    mode INTEGER )
RETURNS INTEGER
```

1. `path` is the name of the file.
2. `mode` is the UNIX™ permission combination in decimal (not octal!).

**Usage**
This method can only be used on UNIX™!
Function returns `TRUE` on success, `FALSE` otherwise.
The `mode` must be a decimal value which is the combination of read, write and execution bits for the user, group and other part of the UNIX™ file permission. Make sure to pass the `mode` as the decimal version of permissions, not as octal (the chrwx UNIX™ command takes an octal value as parameter). For example, to set `-rw-r--r--` permissions, you must pass `((4+2)*64) + (4*8) + 4 = 420` to this method.

**os.Path.chOwn**
Changes the UNIX™ owner and group of a file.

**Syntax**

```plaintext
os.Path.chOwn(
    path STRING,
    uid INTEGER,
    gui INTEGER )
RETURNS INTEGER
```

1. `path` is the name of the file.
2. `uid` is the user id.
3. `gui` is the group id.

**Usage**
This method can only be used on UNIX™!
Function returns TRUE on success, FALSE otherwise.

**os.Path.chVolume**
Changes the current working volume.

**Syntax**

```plaintext
os.Path.chVolume(
    volume STRING)
RETURNS INTEGER
```

1. `volume` is the name of the volume to select as the new current working volume.

**Usage**

To change the current volume to C:

```plaintext
LET result = os.Path.chVolume("C:\")
```

The function returns TRUE if the current working volume is successfully changed, FALSE otherwise.

**os.Path.delete**
Deletes a file or a directory.

**Syntax**

```plaintext
os.Path.delete(
    path STRING)
RETURNS INTEGER
```

1. `path` is the path to the file or directory to delete.

**Usage**

A directory can only be deleted if it is empty.

The function returns TRUE if the file has been successfully deleted, FALSE otherwise.

**os.Path.dirClose**
Closes the directory referenced by the directory opened by `os.Path.diropen()`.

**Syntax**

```plaintext
os.Path.dirClose(
    dirHandle INTEGER)
```

1. `dirHandle` is the directory handle of the directory to close.

**Usage**

This function closes the directory search handle opened with `os.Path.diropen()`.

**os.Path.dirFMask**
Defines a filter mask for `os.Path.diropen()`.

**Syntax**

```plaintext
os.Path.dirFMask(
    mask INTEGER)
```
1. *mask* defines the filter mask.

**Usage**

When you call this function, you define the filter mask for any subsequent `os.Path.dirOpen()` call. By default, all kinds of directory entries are selected by the `dirOpen()` function. You can restrict the number of entries by using a filter mask.

The parameter of the `os.Path.dirFMask()` function must be a combination of the following bits:

- 0x01 = Exclude hidden files (.*)
- 0x02 = Exclude directories
- 0x04 = Exclude symbolic links
- 0x08 = Exclude regular files

For example, to retrieve only regular files, you must call:

```java
CALL os.Path.dirFMask( 1 + 2 + 4 )
```

**os.Path.dirName**

Returns all components of a path excluding the last one.

**Syntax**

```java
os.Path.dirName(
    path STRING)
RETURNS STRING
```

1. *path* is the path to a file or directory.

**Usage**

This method removes the last component of a path provided as argument.

For example, if you pass "/root/dir1/file.ext" as the parameter, it will return "/root/dir1".

See [Example 1: Extracting the parts of a file name](#) on page 2809 for more examples.

**os.Path.dirNext**

Reads the next entry in the directory opened with `os.Path.dirOpen()`.

**Syntax**

```java
os.Path.dirNext(
    dirHandle INTEGER)
RETURNS STRING
```

1. *dirHandle* is the directory handle of the directory to read.

**Usage**

This function returns the next entry of the directory opened with `os.Path.dirOpen()`.

Returns NULL if all entries have been read.
**os.Path.dirOpen**

Opens a directory and returns an integer handle to this directory.

**Syntax**

```c
os.Path.dirOpen(  
    path STRING)  
RETURNS INTEGER
```

1. *path* is the name of the directory.
2. *handle* is the directory handle.

**Usage**

This function creates a handle to scan the elements of a directory.

The function returns a value of 0 if it fails to open the directory.

Before calling the `dirOpen()` method, you can define a filter with `os.Path.dirFMask()`, and a sort order with `os.Path.dirSort()`.

**os.Path.dirSort**

Defines the sort criteria and sort order for `os.Path.dirOpen()`.

**Syntax**

```c
os.Path.dirSort(  
    criteria STRING,  
    order INTEGER )
```

1. *criteria* is the sort criteria.
2. *order* defines ascending (1) or descending (-1) order.

**Usage**

When you call this function, you define the sort criteria and sort order for any subsequent `os.Path.dirOpen()` call.

The *criteria* parameter must be one of the following strings:

- "undefined" = No sort. This is the default. Entries are read as returned by the OS functions.
- "name" = Sort by file name.
- "size" = Sort by file size.
- "type" = Sort by file type (directory, link, regular file).
- "atime" = Sort by access time.
- "mtime" = Sort by modification time.
- "extension" = Sort by file extension.

When sorting by name, directory entries will be ordered based on the current locale.

When sorting by any criteria other than the file name, entries having the same value for the given criteria are ordered by name following the value of the *order* parameter.

**os.Path.executable**

Checks if a file is executable.

**Syntax**

```c
os.Path.executable(  
    path STRING)
```
1. *path* is the path to a file.

**Usage**
The function returns **TRUE** if the file is executable, **FALSE** otherwise.

*os.Path.exists*
Checks if a file exists.

**Syntax**

```python
os.Path.exists(path STRING) RETURNS INTEGER
```

1. *path* is the path to a file.

**Usage**
The function returns **TRUE** if the file exists, **FALSE** otherwise.

*os.Path.extension*
Returns the file extension.

**Syntax**

```python
os.Path.extension(path STRING) RETURNS STRING
```

1. *path* is the path to a file.

**Usage**
The function returns the string following the last dot found in *path*.
If *path* does not have an extension, the function returns **NULL**.

*os.Path.fullPath*
Returns the canonical equivalent of a path.

**Syntax**

```python
os.Path.fullPath(path STRING) RETURNS STRING
```

1. *path* is the path to complete.

**Usage**
The *os.path.fullPath()* class method takes a path as parameter and resolves extra path separator characters (/ on UNIX™, \ on Windows®), as well as references to current (.) and parent directory (..). The result is called a canonical path.

On UNIX™, symbolic links **are not** followed. Use the *os.Path.isLink()* method to identify symbolic links.
Example

```display
os.Path.fullPath("/home/usr//scott/tmp/../images")
```

Resolves to:

```
/home/usr/scott/images
```

`os.Path.gid`

Returns the UNIX™ group id of a file.

Syntax

```python
os.Path.gid(path STRING)
RETURNS INTEGER
```

1. `path` is the path to a file.

Usage

This function returns the group id of the file.

This method can only be used on UNIX™!

Function returns -1 if it fails to get the user id.

`os.Path.glob`

Returns a list of files matching the specified pattern.

Syntax

```python
os.Path.glob(pattern STRING)
RETURNS DYNAMIC ARRAY OF STRING
```

1. `pattern` is a string representing file names, using wildcard characters *, ?, and [] as the MATCHES operator.

Usage

The `glob()` method produces a DYNAMIC ARRAY OF STRING containing a list of pathnames of the file system that match the pattern provided as parameter.

If no file or directory path matches the pattern, the `glob()` method returns an empty array.

The pattern can contain wildcard as follows:

- `?`: matches any single char at this position (except the path separator).
- `*`: matches any string (not including the path separator).
- `[ set-of-chars ]`: matches any character enclosed by the brackets. Can define a range of characters with the hyphen ( `[a-z]` ). The matching is inverted when starting with a `^`: `[^0-9]` matches any non digit.

Globbing is applied on each of the components of a pathname separately. The path separator (Unix `/`, Windows `\` or `\`) splits the pattern in subpatterns. A pattern in the form `"pattern1/pattern2"` finds files matching `pattern2` in each directory matching `pattern1`. Thus `glob()` limits the result to directory-names if the pattern ends with a path separator.
Table 598: Examples of glob() patterns

<table>
<thead>
<tr>
<th>glob pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*.4gl</td>
<td>Files in current dir ending with '.4gl'</td>
</tr>
<tr>
<td>m*</td>
<td>Files in current dir starting with the character 'm'</td>
</tr>
<tr>
<td>[Mm]akefile</td>
<td>The file Makefile or makefile in current dir</td>
</tr>
<tr>
<td>[0-9]*</td>
<td>Files in current dir starting with a digit</td>
</tr>
<tr>
<td>subdir/*.4gl</td>
<td>Files ending with '.4gl' in the directory 'subdir'</td>
</tr>
<tr>
<td>subdir[12]/*.4gl</td>
<td>Files ending with '.4gl' in subdir1 or subdir2</td>
</tr>
<tr>
<td>..//*.4gl</td>
<td>Files ending with '.4gl' in the parent directory</td>
</tr>
<tr>
<td>/Users/Me/*.4gl</td>
<td>Files ending with '.4gl' in the directory 'Users/Me'</td>
</tr>
<tr>
<td>*/</td>
<td>All subdirectories (at level 1)</td>
</tr>
</tbody>
</table>

Example

```python
IMPORT os
MAIN
   DEFINE files DYNAMIC ARRAY OF STRING
   DEFINE x INTEGER
   LET files = os.Path.glob("[A-Z]*.4gl")
   FOR x=1 TO files.getLength()
      DISPLAY "File: ", files[x]
   END FOR
END MAIN
```

*os.Path.homeDir*

Returns the path to the HOME directory of the current user.

**Syntax**

```python
os.Path.homeDir()
RETURNS STRING
```

**Usage**

This function returns the home directory of the current user.

*os.Path.isDirectory*

Checks if a file is a directory.

**Syntax**

```python
os.Path.isDirectory(
   path STRING)
RETURNS BOOLEAN
```

1. *path* is the path to the directory.

**Usage**

The function returns TRUE if the file is a directory, FALSE otherwise.
**os.Path.isFile**  
Checks if a file is a regular file.

**Syntax**
```
os.Path.isFile(
    path STRING
)  
RETURNS BOOLEAN
```

1. `path` is the path to a file.

**Usage**
The function returns TRUE if the file is a regular file, FALSE otherwise.

**os.Path.isHidden**  
Checks if a file is hidden.

**Syntax**
```
os.Path.isHidden(
    path STRING
)  
RETURNS BOOLEAN
```

1. `path` is the file or directory path.

**Usage**
The function returns TRUE if the file is hidden, FALSE otherwise.

For example, on UNIX™, files starting with a dot in the file name are considered as hidden when using the `ls` command.

**os.Path.isLink**  
Checks if a file is an UNIX™ symbolic link.

**Syntax**
```
os.Path.isLink(
    path STRING
)  
RETURNS BOOLEAN
```

1. `path` is the file or directory path.

**Usage**
The function returns TRUE if the files is a symbolic link, FALSE otherwise.

This method can only be used on UNIX™!

**os.Path.isRoot**  
Checks if a file path is a root path.

**Syntax**
```
os.Path.isRoot(
    path STRING
)  
RETURNS BOOLEAN
```

1. `path` is the path to check.
**Usage**

The function returns TRUE if the path is a root path, FALSE otherwise.

On UNIX™ the root path is '/'.

On Windows® the root path matches "[a-zA-Z]:\".

**os.Path.join**

Joins two path segments adding the platform-dependent separator.

**Syntax**

```plaintext
os.Path.join(
    begin STRING,
    end STRING
) RETURNS STRING
```

1. `begin` is the beginning path segment.
2. `end` is the ending path segment.

**Usage**

Use this method to construct a path with no system-specific code to use the correct path separator:

```plaintext
LET path = os.Path.join(os.Path.homedir(), name)
```

This method returns the ending path segment if it is an absolute path.

If one of the arguments is NULL, the function returns NULL.

**os.Path.makeTempName**

Generates a temporary file name.

**Syntax**

```plaintext
os.Path.makeTempName() RETURNS STRING
```

**Usage**

This method creates a new temporary file path, with a unique file name, in the temporary directory of the process.

**Note:** The method just returns a new temporary file name. A file created with this name must be deleted by the programmer. It will not be deleted automatically when exiting the program.

The temporary directory can be defined with the DBTEMP environment variable. If the DBTEMP variable is not defined, the runtime system uses the temporary directory as defined by the operating system. For more details, see the DBTEMP environment variable.

**os.Path.mtime**

Returns the time of the last file modification.

**Syntax**

```plaintext
os.Path.mtime(
    path STRING
) RETURNS STRING
```

1. `path` is the path to a file.
Usage

The function returns a string containing the last modification time for the specified file, in the standard format 'YYYY-MM-DD HH:MM:SS'.

If the function fails, it returns NULL.

\textit{os.Path.mkDir}

Creates a new directory.

Syntax

\begin{verbatim}
\texttt{os.Path.mkDir(path STRING) RETURNS INTEGER}
\end{verbatim}

1. \textit{path} is the path of the directory to create.

Usage

The function returns TRUE if the directory has been successfully created, FALSE otherwise.

\textit{os.Path.pathSeparator}

Returns the character used in environment variables to separate path elements.

Syntax

\begin{verbatim}
\texttt{os.Path.pathSeparator() RETURNS STRING}
\end{verbatim}

Usage

You typically use this method to build a path from two components.

On UNIX™, the path separator is '\:'.

On Windows®, the path separator is '\;'.

\textit{os.Path.pathType}

Checks if a path is a relative path or an absolute path.

Syntax

\begin{verbatim}
\texttt{os.Path.pathType(path STRING) RETURNS STRING}
\end{verbatim}

1. \textit{path} is the path to check.

Usage

The function returns "absolute" if the path is an absolute path, or "relative" if the path is a relative path.

\textbf{Note:} On Unix-style platforms, an absolute path starts with a (/) slash. On Windows® platforms, an absolute path starts with a backslash (\), a slash (/), or starts with a drive letter followed by a colon (C:)

If the path is NULL, the function returns NULL.
**os.Path.pwd**  
Returns the current working directory.

**Syntax**

```
    os.Path.pwd()
    RETURNS STRING
```

**Usage**

This function returns the path of the current working directory.

On a mobile device, this front call returns the current application working directory:

- On Android™, it returns the directory where the program executes.
- On iOS, it returns the "Documents" directory under the application directory.

**os.Path.readable**  
Checks if a file is readable.

**Syntax**

```
    os.Path.readable(  
          path STRING) 
    RETURNS INTEGER
```

1. *path* is the path to a file or directory.

**Usage**

The function returns TRUE if the file is readable, FALSE otherwise.

**os.Path.rename**  
Renames a file or a directory.

**Syntax**

```
    os.Path.rename(  
          oldPath STRING,  
          newPath STRING ) 
    RETURNS INTEGER
```

1. *oldPath* is the current name of the file or directory to be renamed.
2. *newPath* is the new name to assign to the file or directory.

**Usage**

The function returns TRUE if the file or directory has been successfully renamed, FALSE otherwise.

On UNIX™ platforms, you can rename/move files and directories located on the same file system.

On Microsoft™ Windows® platforms only files can be renamed/moved. However, on Windows® you can move files across disks and directories.

**os.Path.separator**  
Returns the character used to separate path segments.

**Syntax**

```
    os.Path.separator()
```
Usage
Use this method to build a path from two components.
On UNIX™, the directory separator is '/'.
On Windows®, the directory separator is '\'.

__os.Path.size__
Returns the size of a file.

Syntax
```
__os.Path.size__(
    __path__ STRING)
RETURNS BIGINT
```

1. `path` is the path to a file.

Usage
The function returns the size in bytes for the specified file.
Large files sizes (> 2GB) are supported.

__os.Path.rootDir__
Returns the root directory of the current working path.

Syntax
```
__os.Path.rootDir__()
RETURNS STRING
```

Usage
This function returns the root directory of the current working path.
On UNIX™, it always returns "/".
On Windows® it returns the current working drive as "[a-zA-Z]:\"

__os.Path.rootName__
Returns the file path without the file extension of the last element of the file path.

Syntax
```
__os.Path.rootName__(
    __path__ STRING)
RETURNS STRING
```

1. `path` is the path to a file or directory.

Usage
This method removes the file extension from the path provided as parameter.
For example, if you pass "/root/dirl/file.ext" as the parameter it will return "/root/dirl/file".
See Example 1: Extracting the parts of a file name on page 2809 for more examples.
**os.Path.rwx**

Returns the UNIX™ file permissions of a file.

**Syntax**

```python
os.Path.rwx(
    path STRING)
RETURNS INTEGER
```

1. `path` is the path to a file or directory.

**Usage**

This function returns the combination of permissions for user, group and other.

This method can only be used on UNIX™!

Function returns -1 if it fails to get the permissions.

The `mode` is returned as a decimal value which is the combination of read, write and execution bits for the user, group and other part of the UNIX™ file permission. For example, if a file has the `-rwxr-xr-x` permissions, the method returns `((4+2+1) * 64 + (4+1) * 8) + (4+1) ) = 493`.

**os.Path.type**

Returns the file type as a string.

**Syntax**

```python
os.Path.type(
    path STRING)
RETURNS STRING
```

1. `path` is the path to file.

**Usage**

On UNIX™, this method follows symbolic links. Use the `os.Path.islink()` method to identify symbolic links.

The possible values returned by this method are:

1. `file`: the file is a regular file
2. `directory`: the file is a directory
3. `socket`: the file is a socket
4. `fifo`: the file is a fifo
5. `block`: the file is a block device
6. `char`: the file is a character device

**os.Path.uid**

Returns the UNIX™ user id of a file.

**Syntax**

```python
os.Path.uid(
    path STRING)
RETURNS INTEGER
```

1. `path` is the path to a file or directory.
Usage
This method can only be used on UNIX™!
Function returns -1 if it fails to get the user id.

*os.Path.volumes*
Returns the available volumes.

**Syntax**

```python
os.Path.volumes()
RETURNS STRING
```

Usage
The function returns the list of all available volumes separated by "|".
To display the list of available volumes, a volume is identified by its letter, followed by a colon and a backslash (:\).

```python
DISPLAY os.Path.volumes()
```

Output example:

```
C:\|E:\|F:\
```

*os.Path.writable*
Checks if a file is writable.

**Syntax**

```python
os.Path.writable(
    path STRING)
RETURNS INTEGER
```

1. *path* is the path to a file or directory.

Usage
The function returns TRUE if the file is writable, FALSE otherwise.

Examples
*os.Path usage examples.*

**Example 1: Extracting the parts of a file name**

This program uses the file functions to extract the directory name, the base name, the root name, and the file extension:

```python
IMPORT os
MAIN
    DISPLAY "Dir name  = ", os.Path.dirName(arg_val(1))
    DISPLAY "Base name  = ", os.Path.baseName(arg_val(1))
    DISPLAY "Root name  = ", os.Path.rootName(arg_val(1))
    DISPLAY "Extension = ", os.Path.extension(arg_val(1))
END MAIN
```

Example results:
Table 599: Example results

<table>
<thead>
<tr>
<th>Path</th>
<th>os.Path.dirname</th>
<th>os.Path.basename</th>
<th>os.Path.rootname</th>
<th>os.Path.extension</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>.</td>
<td>.</td>
<td>NULL</td>
<td></td>
</tr>
<tr>
<td>..</td>
<td>.</td>
<td>..</td>
<td>.</td>
<td>NULL</td>
</tr>
<tr>
<td>/</td>
<td>/</td>
<td>/</td>
<td>/</td>
<td>NULL</td>
</tr>
<tr>
<td>/usr/lib</td>
<td>/usr</td>
<td>lib</td>
<td>/usr/lib</td>
<td>NULL</td>
</tr>
<tr>
<td>/usr/</td>
<td>/</td>
<td>usr</td>
<td>/usr/</td>
<td>NULL</td>
</tr>
<tr>
<td>usr</td>
<td>.</td>
<td>usr</td>
<td>usr</td>
<td>NULL</td>
</tr>
<tr>
<td>file.xx</td>
<td>.</td>
<td>file.xx</td>
<td>file</td>
<td>xx</td>
</tr>
<tr>
<td>/tmp.yy/</td>
<td>/tmp.yy</td>
<td>file.xx</td>
<td>/tmp.yy/file</td>
<td>xx</td>
</tr>
<tr>
<td>/tmp.yy/</td>
<td>/tmp.yy</td>
<td>file.xx</td>
<td>/tmp.yy/file</td>
<td>/tmp.yy/file</td>
</tr>
<tr>
<td>/tmp.yy/</td>
<td>/</td>
<td>tmp.yy</td>
<td>/tmp.yy/</td>
<td>NULL</td>
</tr>
<tr>
<td>/tmp.yy/.</td>
<td>/tmp.yy</td>
<td>.</td>
<td>/tmp.yy/</td>
<td>NULL</td>
</tr>
</tbody>
</table>

These examples use UNIX™ file names. On Windows® the result would be different, as the file name separator is a backslash (\).

**Example 2: Browsing directories**

This program takes a directory path as an argument and scans the content recursively:

```
IMPORT os

MAIN
    CALL showDir(arg_val(1))
END MAIN

FUNCTION showDir(path)
    DEFINE path STRING
    DEFINE child STRING
    DEFINE h INTEGER

    IF NOT os.Path.exists(path) THEN
        RETURN
    END IF
```
IF NOT os.Path.isDirectory(path) THEN
  DISPLAY " ", os.Path.baseName(path)
  RETURN
END IF

DISPLAY "[", path, "]"
CALL os.Path.dirSort("name", 1)
LET h = os.Path.dirOpen(path)
WHILE h > 0
  LET child = os.Path.dirNext(h)
  IF child IS NULL THEN EXIT WHILE END IF
  IF child == "." OR child == ".." THEN CONTINUE WHILE END IF
  CALL showDir( os.Path.join( path, child ) )
END WHILE

CALL os.Path.dirClose(h)
END FUNCTION

The com package
The Genero Web Services com package provides classes and methods that allow you to perform tasks associated with creating Services and Clients, and managing the services.

Use the IMPORT statement at the top of the module using this library:

```
IMPORT com
```

Related concepts
Web services on page 3270
Create a Web service client or server with Genero BDL.

Web services classes
The Web services classes manage Web Services servers.

- The WebService class on page 2811
- The WebOperation class on page 2821
- The WebServiceEngine class on page 2828
- The HTTPServiceRequest class on page 2845

The WebService class
The com.WebService class provides an interface to create and manage Genero Web Services.

The com.WebServices class is used to implement a Web Service on the server.

Important: This Web Services class is not supported on GMI mobile devices.

Related concepts
Web services on page 3270
Create a Web service client or server with Genero BDL.

</tbody>
</table>

`com.WebService.createFault`
Creates a global fault for a Web Service object.

**Syntax**

```java
createFault(
    fault RECORD,
    encoded INTEGER
)
```

1. *fault* defines the Web Service fault.
2. *encoded* defines an integer value specifying the encoding mechanism.

**Usage**

The `createFault()` method creates a global fault for this Web Service object.

The *fault* parameter can be of any type that defines the SOAP fault in a SOAP response. In case of SOAP fault, the client for this Web Service will receive a variable with the same structure.

When the parameter *encoded* is true (1), the SOAP Section 5 encoding mechanism is used. False (0) indicates the XML Schema mechanism.

In case of error, the method throws an exception and sets the *STATUS* variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (*STATUS*) on page 3554.

**com.WebService.createHeader**

Defines the header for the Web Service object.

**Syntax**

```java
createHeader(
    header RECORD,
    encoded INTEGER
)
```

1. *header* defines the header for the Web Service object.
2. *encoded* defines an integer value specifying the encoding mechanism.

**Usage**

The `createHeader()` method creates a global header for the current Web Service object.

The Web Service header is defined by the first parameter. This will define SOAP headers exchanged by the client and server.

When the parameter *encoded* is true (1), the SOAP Section 5 encoding mechanism is used. False (0) indicates the XML Schema mechanism.

**Important:** Since Web Services headers are generally in Document Style, we recommend to set the *encoded* parameter to 0.

In case of error, the method throws an exception and sets the *STATUS* variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (*STATUS*) on page 3554.

**com.WebService.CreateWebService**

Creates a new object to implement a Web Service.

**Syntax**

```java
com.WebService.CreateWebService(
    name STRING,
```
ns STRING )  
RETURNS com.WebService

1. *name* defines the Web service identifier.
2. *ns* defines the namespace for the Web service.

**Usage**

The *name* and *ns* parameters must uniquely identify the Web service across the entire application, when multiple Web service programs run on the same server. In theory, the value of *ns*+*name* must be unique on the internet.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`com.WebService.CreateStatefulWebService`

Creates a new object to implement a stateful Web service.

**Syntax**

```java
com.WebService.CreateStatefulWebService(
  name STRING,
  ns STRING ,
  state RECORD )
RETURNS com.WebService
```

1. *name* defines the Web service identifier.
2. *ns* defines the namespace for the Web service.
3. *state* defines the state between the client and server.

**Usage**

The *name* and *ns* parameters must uniquely identify the Web service across the entire application, when multiple Web service programs run on the same server. In theory, the value of *ns*+*name* must be unique on the internet.

The *state* variable is used to identify the state between the client and the server:

- For a WS-Addressing stateful service, the *state* variable must be a RECORD with the following structure, with the `W3CEndpointReference` variable attribute:

  ```java
  RECORD ATTRIBUTES(W3CEndpointReference)
    address STRING, -- The location of the Web Service (for ex: URL)
    ref RECORD
    ... (other members defining the state)
  END RECORD
  END RECORD
  ```

- For a stateful service based on HTTP cookies, the *state* variable must be a simple variable defined with a basic data type.

It is up to the programmer to manage the *state* variable and to restore the service state from a database.

When creating a stateful Web service, all published Web operations require a session in the client request except those defined as 'initiateSession'.

```java
RECORD ATTRIBUTES(W3CEndpointReference)
  address STRING, -- The location of the Web Service (for ex: URL)
  ref RECORD
  ... (other members defining the state)
END RECORD
END RECORD
```
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

Stateful SOAP Web services on page 3283
The GWS provides support for stateful service. Different options for implementing SOAP stateful services are described.

com.WebService.generateWSDL

Creates an `xml.DomDocument` object with the WSDL corresponding to the Web Service object.

**Syntax**

```java
generateWSDL(
   location STRING )
RETURNS xml.DomDocument
```

1. `location` defines the URL where the Web Service will be deployed.

**Usage**

The `generateWSDL()` method creates a new `xml.DomDocument` object containing the WSDL data of the Web Service object.

The URL where the Web Service will be deployed must be specified.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

com.WebService.setComment on page 2820
Defines the comment for the Web Service object.

com.WebService.publishOperation

Publishes a Web Operation.

**Syntax**

```java
publishOperation(
   op com.WebOperation,
   role STRING )
```

1. `op` defines the Web Operation object.
2. `role` identifies uniquely the Web Operation.

**Usage**

The `publishOperation()` method publishes the Web Operation specified by the `com.WebOperation` object passed as parameter.

The `role` identifies the operation, if several operations have the same name, by setting the SOAPAction HTTP header. Usually this parameter is set to NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.WebService.registerInputHTTPVariable
Registers the record variable for HTTP input.

**Syntax**

```plaintext
registerInputHTTPVariable(
  headers RECORD )
```

1. *headers* defines the HTTP input record variable with the following structure:

```plaintext
RECORD
  verb STRING,
  url STRING,
  headers DYNAMIC ARRAY OF RECORD
    name STRING,
    value STRING
  END RECORD
END RECORD
```

**Usage**

The `registerInputHTTPVariable()` method registers a program variable with a specific structure, that will be filled with the HTTP request headers when a Web Operation arrives.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

- [com.WebService.registerOutputHTTPVariable](#) on page 2818
  Registers the record variable for HTTP output.

- [com.WebService.registerInputRequestHandler](#)
  Registers the function to be executed on incoming SOAP requests.

**Syntax**

```plaintext
registerInputRequestHandler(
  function STRING )
```

1. *function* has the name of a program function.

**Usage**

The `registerInputRequestHandler()` method registers a function to be called when an incoming SOAP request is received and before the SOAP engine has processed it.

The callback function must be defined with a unique parameter of type `xml.DomDocument`, and must return the reference to this object, or `NULL`:

```plaintext
FUNCTION myRequestInputHandler( in )
  DEFINE in xml.DomDocument
  ...
  RETURN in
END FUNCTION
```

The input callback function typically modifies the content of the SOAP input request DOM document object passed as parameter.

When returning `NULL` from the input callback function, the output callback function will be called with the default SOAP fault node, which can then be modified.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

*Server handlers* on page 3344  
Create and register your callback handlers (request, and response) to modify the WSDL.

**com.WebService.registerOutputRequestHandler**  
Registers the function to be executed just before the SOAP response is forwarded to the client.

**com.WebService.registerOutputHTTPVariable**  
Registers the record variable for HTTP output.

### Syntax

```
registerOutputHTTPVariable(  
    headers RECORD  
)
```

1. *headers* defines the HTTP input record variable with the following structure:

```
RECORD  
    code INTEGER,  
    desc STRING,  
    headers DYNAMIC ARRAY OF RECORD  
        name STRING,  
        value STRING  
    END RECORD  
END RECORD
```

**Usage**

The `registerOutputHTTPVariable()` method registers a program variable with a specific structure, that will be used to fill the HTTP response headers when a Web Operation is completed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

*com.WebService.registerInputHTTPVariable* on page 2816  
Registers the record variable for HTTP input.

**com.WebService.registerOutputRequestHandler**  
Registers the function to be executed just before the SOAP response is forwarded to the client.

### Syntax

```
registerOutputRequestHandler(  
    function STRING  
)
```

1. *function* has the name of a program function.

**Usage**

The `registerOutputRequestHandler()` method registers a function to be called just after the SOAP engine has processed the request and before the SOAP response is forwarded to the client.
The output callback function must be defined with a unique parameter of type `xml.DomDocument`, and must return the reference to this object:

```
FUNCTION myRequestOutputHandler( out )
    DEFINE out xml.DomDocument
    ...
    RETURN out
END FUNCTION
```

The output callback function typically modifies the content of the SOAP output request DOM document object passed as parameter.

If `NULL` was returned from the input callback function, the output callback function will be called with the default SOAP fault node.

When WS-Addressing is enabled, and the server side callback is triggered, the SOAP engine has already created the SOAP:Header node with the correct WS-Addressing entries. If other headers need to be added (for WS-Security for instance), it is recommended to add them as child nodes of the existing SOAP header node, instead of creating a new header node. Otherwise, you may get two SOAP headers in the same response, which is not allowed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

- **Server handlers** on page 3344
  Create and register your callback handlers (request, and response) to modify the WSDL.

  - `com.WebService.registerInputRequestHandler` on page 2817
    Registers the function to be executed on incoming SOAP requests.

- `com.WebService.registerWSDLHandler`
  Registers the function to be executed when a WSDL is generated.

**Syntax**

```
registerWSDLHandler( 
    function STRING )
```

1. `function` has the name of a program function.

**Usage**

The `registerWSDLHandler()` method registers a function to be called when the WSDL of the current Web Service object is generated.

The callback function must be defined with a unique parameter of type `xml.DomDocument`, and must return the reference to this object:

```
FUNCTION myWSDLHandler( wsdl )
    DEFINE wsdl xml.DomDocument
    ...
    RETURN wsdl
END FUNCTION
```

The callback function typically modifies the content of the WSDL DOM document object passed as parameter.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
**Related concepts**

**Server handlers** on page 3344
Create and register your callback handlers (request, and response) to modify the WSDL.

**com.WebService.saveWSDL**
Writes to a file the WSDL corresponding to the Web Service object.

**Syntax**

```java
saveWSDL(
    location STRING )
RETURNS INTEGER
```

1. *location* defines the URL where the Web Service will be deployed.

**Usage**
The `saveWSDL()` method writes the WSDL data corresponding to the Web Service object.

The URL where the Web Service will be deployed must be specified.

The name of the file will be the name of the Web Service defined by the *name* parameter passed to the `createWebService()` or `createStatefulWebService()` methods.

The method returns 0 if the file was saved, -1 in case of error.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See **Error handling in GWS calls (STATUS)** on page 3554.

**Related concepts**

**com.WebService.setComment** on page 2820
Defines the comment for the Web Service object.

**Syntax**

```java
setComment (
    comment STRING )
```

1. *comment* defines the comment to be set.

**Usage**
The `setComment()` method defines the comment associated with a `com.WebService` object.

The comment will be used when generating the WSDL file, as defined by the standard.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See **Error handling in GWS calls (STATUS)** on page 3554.

**com.WebService.setFeature**
Defines a feature for the current Web Service object.

**Syntax**

```java
setFeature(
    feature STRING,
    ...)
```

1. *feature* is a string that defines the feature to be set.
1. `feature` defines the name of the Web Service feature.
2. `value` defines the value of the feature.

**Usage**

The `setFeature()` method defines a feature for the current Web Service object by specifying a feature name and a value.

The features names are predefined. The second parameter must have a valid value for the specified feature.

**Table 602: Support Web Service features for the `setFeature()` method**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Soap1.1</td>
<td>Defines whether the Web Service supports the SOAP 1.1 protocol. Default value is <code>FALSE</code>.</td>
</tr>
<tr>
<td>Soap1.2</td>
<td>Defines whether the Web Service supports the SOAP 1.2 protocol. Default value is <code>FALSE</code>.</td>
</tr>
<tr>
<td>WS-Addressing1.0</td>
<td>Defines whether the Web Service supports WS-Addressing 1.0. Valid values include:</td>
</tr>
<tr>
<td></td>
<td>• <code>TRUE</code> - The service supports WS-Addressing 1.0 and accepts requests without WS-Addressing.</td>
</tr>
<tr>
<td></td>
<td>• <code>REQUIRED</code> - The service supports WS-Addressing 1.0 and accepts only requests with WS-Addressing.</td>
</tr>
<tr>
<td></td>
<td>• <code>FALSE</code> - WS-Addressing 1.0 is disabled (Default).</td>
</tr>
</tbody>
</table>

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**The `WebOperation` class**

The `com.WebOperation` class provides an interface to create and manage the operations of a Genero Web Service.

**Important:** This Web Services class is not supported on GMI mobile devices.

The Web Operation can be created as RPC Style or Document Style. Both RPC/Literal and Doc/Literal Styles are WS-I compliant (standards set by the Web Services Interoperability organization).

RPC Style Service (RPC/Literal) is generally used to execute a function, such as a service that returns a stock option. Document Style Service (Doc/Literal) is generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document; this is the MS.Net default. The input or output `RECORD` cannot have `XMLNamespace` attributes set on their members.

Calling the appropriate function to create the desired style is the only difference in your Genero code that creates the service. The remainder of the code that describes the service is the same, regardless of whether you want to create an RPC or Document style of service.

Do not use the `setInputEncoded()` and `setOutputEncoded()` methods, as they will specify the RPC/Encoded Style, which is not recommended (see Choosing a Web Service Style).

Since release 2.0 GWS allows you to create RPC Style and Document Style operations in the same Web service. However, we do not recommend this, as it is not WS-I compliant.
**com.WebOperation methods**
Methods for the `com.WebOperation` class.

</table>

com.WebOperation.addFault
Adds a fault to the current Web Operation definition.

Syntax
addFault (  
    fault RECORD ,  
    wsaaction STRING )

1. fault defines the program variable defining the fault.
2. wsaaction defines the type of action.

Usage
Adds a fault the Web Operation can throw during operation processing, where fault is any variable previously created as fault of the com.WebService object, and wsaaction the WS-Addressing action identifier if WS-Addressing is supported. If WS-Addressing is not supported, pass NULL as second parameter.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.WebOperation.addInputHeader

Adds an input header for the current Web Operation definition.

**Syntax**

```java
addInputHeader (  
    header RECORD )
```

1. `header` defines the program variable defining the header.

**Usage**

This method adds a header to the Web Operation object for input parameters.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.WebOperation.addOutputHeader

Adds an output header for the current Web Operation definition.

**Syntax**

```java
addOutputHeader (  
    header RECORD )
```

1. `header` defines the program variable defining the header.

**Usage**

This method adds a header to the Web Operation object for input parameters.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.WebOperation.CreateDOCStyle

Creates a new Web Operation object with Document style.

**Syntax**

```java
com.WebOperation.CreateDOCStyle (  
    function STRING,  
    operation STRING,  
    inputVar RECORD ,  
    outputVar RECORD )  
RETURNS com.WebOperation
```

1. `function` defines the program function to be called to process the XML operation.
2. `operation` defines the XML operation.
3. `inputVar` defines the variable defining the input parameters of the operation (or NULL if there is none).
4. `outputVar` defines the variable defining the output parameters of the operation (or NULL if there is none).
Usage

This method creates a Request-Response Document style `com.WebOperation` object, where `function` is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`com.WebOperation.CreateRPCStyle`

Creates a new Web Operation object with RPC style.

Syntax

```java
com.WebOperation.CreateRPCStyle(
    function STRING,
    operation STRING,
    inputVar RECORD,
    outputVar RECORD)
RETURNS com.WebOperation
```

1. `function` defines the program function to be called to process the XML operation.
2. `operation` defines the XML operation.
3. `inputVar` defines the variable defining the input parameters of the operation (or NULL if there is none).
4. `outputVar` defines the variable defining the output parameters of the operation (or NULL if there is none).

Usage

This method creates a Request-Response RPC style `com.WebOperation` object, where `function` is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`com.WebOperation.CreateOneWayDOCStyle`

Creates a new Web Operation object with One-Way Document style.

Syntax

```java
com.WebOperation.CreateOneWayDOCStyle(
    function STRING,
    operation STRING,
    inputVar RECORD)
RETURNS com.WebOperation
```

1. `function` defines the program function to be called to process the XML operation.
2. `operation` defines the XML operation.
3. `inputVar` defines the variable defining the input parameters of the operation (or NULL if there is none).

Usage

This method creates a One-Way DOC style `com.WebOperation` object, where `function` is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.
There is no output parameter to be returned to the client.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.WebOperation.CreateOneWayRPCStyle

Creates a new Web Operation object with One-Way RPC style.

Syntax

```java
com.WebOperation.CreateOneWayRPCStyle( 
  function STRING, 
  operation STRING, 
  inputVar RECORD 
) 
RETURNS com.WebOperation
```

1. `function` defines the program function to be called to process the XML operation.
2. `operation` defines the XML operation.
3. `inputVar` defines the variable defining the input parameters of the operation (or NULL if there is none).

Usage

This method creates a One-Way RPC Style `com.WebOperation` object, where `function` is the name of the program function that is executed to process the XML operation.

The function name must be a string literal, not a string variable, due to operation publication restrictions.

There is no output parameter to be returned to the client.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.WebOperation.initiateSession

Defines the Web Operation as session initiator.

Syntax

```java
initiateSession( 
  ok INTEGER 
)
```

1. `ok` must have an integer value of 1 to define a session initiator.

Usage

Pass the parameter with the value of 1 to `initiateSession()` in order to define the current Web Operation as a session initiator.

A new session must be instantiated in this operation, and must be returned to the client via the `state` variable defined at service creation.

This method works only for stateful web services.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.WebOperation.setComment
Sets the comment for the Web Operation object.

**Syntax**

```java
setComment(
    comment STRING )
```

1. *comment* defines the comment to be set.

**Usage**

The `setComment()` method defines a comment for the current Web Operation object. The comment will appear in the WSDL of the service.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

**com.WebOperation.setInputAction**

Sets the WS-Addressing action identifier of the input operation.

**Syntax**

```java
setInputAction(
    action STRING )
```

1. *action* defines the WSA action identifier.

**Usage**

When WS-Addressing is enabled, this method defines the WS-Addressing action identifier of the input operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

**com.WebOperation.setInputEncoded**

Defines the encoding mechanism for Web Operation input parameters.

**Syntax**

```java
setInputEncoded(
    val INTEGER )
```

1. *val* defines an integer value defining the encoding mechanism to be used.

**Usage**

When the parameter `encoded` is true (1), the SOAP Section 5 encoding mechanism is used. False (0) indicates the XML Schema mechanism.

The XML Schema mechanism (FALSE) is not recommended.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

**com.WebOperation.setOutputAction**
Sets the WS-Addressing action identifier of the output operation.

**Syntax**

```java
setOutputAction(
    action STRING )
```

1. `action` defines the WSA action identifier.

**Usage**

When WS-Addressing is enabled, this method defines the WS-Addressing action identifier of the output operation. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**com.WebOperation.setOutputEncoded**

Defines the encoding mechanism for Web Operation output parameters.

**Syntax**

```java
setOutputEncoded(
    val INTEGER  )
```

1. `val` defines an integer value defining the encoding mechanism to be used.

**Usage**

When the parameter `encoded` is true (1), the SOAP Section 5 encoding mechanism is used. False (0) indicates the XML Schema mechanism.

The XML Schema mechanism (FALSE) is not recommended.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**The WebServiceEngine class**

The `com.WebServiceEngine` class provides an interface to manage the Web Services engine.

**Important**: This Web Services class is not supported on GMI mobile devices.
com.WebServiceEngine methods
Methods for the com.WebServiceEngine class.
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>com.WebServiceEngine.Flush()</code></td>
<td>Forces the Web Service engine to immediately flush the response of the web service operation.</td>

</tr>
</tbody>
</table>
com.WebServiceEngine.Flush

Forces the Web Service engine to immediately flush the response of the web service operation.

Syntax

```markdown
com.WebServiceEngine.Flush()
RETURNS INTEGER
```

Usage

The `com.WebServiceEngine.flush()` class method allows for the return of the response inside a high-level web service operation, before the end of the web service function.

When this method is used, any other web operation output parameter changes are ignored.

The `status` returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of `com.WebServicesEngine` on page 2843

**Note:** The return status of the `com.WebServiceEngine.flush()` method has the same meaning as a status returned by `com.WebServiceEngine.ProcessServices()`, with the additional status code -32, meaning that the flush method was called outside of a web operation execution context.

**Note:** `com.WebServiceEngine.ProcessServices()` and `com.WebServiceEngine.HandleRequest()` can return the status code of -31, meaning that the flush function has been called in the last executed web operation.

Example

In this code example, the `flush()` method is used to force the response of the web service operation.

```ada
DEFINE echoBoolean_in, echoBoolean_out RECORD
  a_boolean BOOLEAN ATTRIBUTES(XMLName="Boolean")
END RECORD

MAIN
  DEFINE ret INTEGER
  ...
  WHILE true
    LET ret = com.WebServiceEngine.ProcessServices(-1)
    CASE ret
      WHEN 0
        DISPLAY "Request automatically processed."
      WHEN -31
        DISPLAY "Operation has been flushed."
      ...
    END CASE
  END WHILE
  ...
END MAIN

FUNCTION echoBoolean()
  DEFINE ret INTEGER
  -- Assign output parameter with input parameter
  LET echoBoolean_out.a_boolean = echoBoolean_in.a_boolean
  -- Immediate flush of web operation
  LET ret = com.WebServiceEngine.flush()
  IF ret != 0 THEN
    DISPLAY "ERROR Code : ",ret
    EXIT PROGRAM (1)
  END IF
  -- Changing the output parameters after flush() would have no effect.
END FUNCTION
```
**Related concepts**

- `com.WebServiceEngine.HandleRequest` on page 2833
  - Get a handle for an incoming HTTP service request.

- `com.WebServiceEngine.ProcessServices` on page 2834
  - Specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

**com.WebServiceEngine.GetHTTPServiceRequest**

- Get a handle for an incoming HTTP service request.

**Syntax**

```java
com.WebServiceEngine.GetHTTPServiceRequest (timeout INTEGER)
RETURNS com.HTTPServiceRequest
```

1. `timeout` defines the timeout in seconds.

**Usage**

The `com.WebServiceEngine.GetHTTPServiceRequest()` class method returns a `com.HTTPServiceRequest` object to handle an incoming HTTP request, or `NULL` if there was no request during the given period of time.

The `timeout` parameter defines the time in seconds to wait for an incoming request. A value of `-1` means infinite wait. When the timeout occurs, the method returns `NULL`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 3554).

Any new call to this function will raise an error until the previous HTTP request is handled by sending a response back to the client, or destroyed.

The error `-15565` can be thrown if an invalid or unsupported HTTP request is sent. Supported methods are GET, PUT, POST, HEAD, and DELETE.

Even if the exception is trapped, the GWS HTTP server is not in a valid state anymore, and you must close the application properly before exiting the program.

**Note:** This is not an issue in production environments as the Genero Application Server (GAS) and GWSProxy will detect the ended DVM, return an HTTP error code to the client app, and any new request will start a new DVM in a clean state via GWS proxy and the pool configuration.

The error `-15575` can be thrown if the GAS disconnects the Web Services program.

URLs are sent in UTF-8 on the network, if the web services server is not able to convert UTF-8 URLs back to fglrun locale charset, error `-15552` will be thrown. As a general advice, run you WS server program in UTF-8.

**Example**

```java
DEFINE req com.HTTPServiceRequest
...
TRY
  WHILE TRUE
    LET req = com.WebServiceEngine.getHTTPServiceRequest(-1)
    IF req IS NULL THEN
      DISPLAY "HTTP request timeout...: ", CURRENT YEAR TO FRACTION
    ELSE
      CALL req.sendTextResponse(200,NULL,"It works")
    END IF
  END WHILE
CATCH
```
IF status == -15575 THEN
  DISPLAY "Disconnected : ",SQLCA.SQLERRM
ELSE
  DISPLAY "ERROR : ",status,SQLCA.SQLERRM
END IF
END TRY

Related concepts

com.WebServiceEngine.ProcessServices on page 2834
Specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

com.WebServiceEngine.HandleRequest on page 2833
Get a handle for an incoming HTTP service request.

com.WebServiceEngine.GetOption
Returns the value of a Web Service engine option.

Syntax

com.WebServiceEngine.GetOption (  
  option STRING  )  
RETURNS STRING

1.  option defines the option to be queried.

Usage

The com.WebServiceEngine.GetOption() class method returns the current value of the given Web Services engine option.

See WebServiceEngine options on page 2840 for the supported options.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.WebServiceEngine.HandleRequest
Get a handle for an incoming HTTP service request.

Syntax

com.WebServiceEngine.HandleRequest (  
  timeout INTEGER,  
  status RECORD  )  
RETURNS com.HTTPServiceRequest

1.  timeout defines the timeout in seconds.
2.  status defines the variable receiving the method execution status.

Usage

The com.WebServiceEngine.HandleRequest() class method returns a com.HTTPServiceRequest object to handle an incoming HTTP request, or NULL if there was no request during the given period of time.

The timeout parameter defines the time in seconds to wait for an incoming request. A value of -1 means infinite wait.

• If there is no request in the given period of time, or if there is an error, the status code is updated by reference, and a NULL object is returned.
• If the request is intended for a registered web service, it is processed automatically. The status code is updated by reference and a NULL object is returned.
• If the request isn't dedicated to a registered web service, a status code of value 1 is returned by reference, and a valid instance of a `com.HTTPServiceRequest` object, immediately usable to handle the incoming request, is returned.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

Any new call to this function will raise an error until the previous HTTP request was handled by sending a response back to the client, or destroyed.

The `status` returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of `com.WebServicesEngine` on page 2843.

A status of -8 or -10 is returned if an invalid or unsupported HTTP request is sent. Supported methods are GET, PUT, POST, HEAD, and DELETE.

Even if the exception is trapped, the GWS HTTP server is not in a valid state anymore, and you must close the application properly before exiting the program.

**Note:** This is not an issue in production environments as the Genero Application Server (GAS) and GWSProxy will detect the ended DVM, return an HTTP error code to the client app, and any new request will start a new DVM in a clean state via GWS proxy and the pool configuration.

**Note:** If the `com.WebServiceEngine.Flush()` method is used, the return status handling must be done in the web operation function, while `com.WebServiceEngine.HandleRequest()` will return the code -31, to indicated that a flush was done.

The error -15575 can be thrown if the GAS disconnects the Web Services program.

URLs are sent in UTF-8 on the network, if the web services server is not able to convert UTF-8 URLs back to fglrun locale charset, error -15552 will be thrown. As a general advice, run you WS server program in UTF-8.

**Related concepts**

- `com.WebServiceEngine.ProcessServices` on page 2834
  Specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

- `com.WebServiceEngine.GetHTTPServiceRequest` on page 2832
  Get a handle for an incoming HTTP service request.

- `com.WebServiceEngine.ProcessServices` specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

**Syntax**

```c
    timeout INTEGER
) RETURNS INTEGER
```

1. `timeout` defines the timeout in seconds.

**Usage**

The `com.WebServiceEngine.ProcessServices()` class method specifies the wait period for an HTTP input request, to process an operation of one of the registered Web Services.

The `timeout` parameter defines the wait period for an HTTP input request, to process an operation of one of the registered Web Services. The value -1 specifies an infinite waiting time.

The `status` returned by the method provides information about the execution of the last web operation. A return status of zero means OK. For a complete list of error codes, see Error codes of `com.WebServicesEngine` on page 2843.

A status of -8 or -10 is returned if an invalid or unsupported HTTP request is sent.
Even if the exception is trapped, the GWS HTTP server is not in a valid state anymore, and you must close the application properly before exiting the program.

**Note:** This is not an issue in production environments as the Genero Application Server (GAS) and GWSProxy will detect the ended DVM, return an HTTP error code to the client app, and any new request will start a new DVM in a clean state via GWS proxy and the pool configuration.

The execution status is typically handled in a `CASE / END CASE` block, to treat all possible execution cases. For a complete example of execution status handling, see [Process the requests](#) on page 3351.

**Note:** If the `com.WebServiceEngine.Flush()` method is used, the return status handling must be done in the web operation function, while `com.WebServiceEngine.ProcessServices()` will return the code `-31`, to indicated that a flush was done.

**Related concepts**

- `com.WebServiceEngine.HandleRequest` on page 2833
  Get a handle for an incoming HTTP service request.

- `com.WebServiceEngine.GetHTTPServiceRequest` on page 2832
  Get a handle for an incoming HTTP service request.

- `com.WebServiceEngine.RegisterService`
  Registers a service in the engine.

  **Syntax**

  ```java
  com.WebServiceEngine.RegisterService(
      ws com.WebService 
  )
  ```

  1. `ws` defines the name of the service object to register.

  **Usage**

  The `com.WebServiceEngine.RegisterService()` class method registers the `com.WebService` object passed as parameter.

  In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](#) on page 3554.

- `com.WebServiceEngine.RegisterRestService`
  Registers a REST service in the engine.

  **Syntax**

  ```java
  com.WebServiceEngine.RegisterRestService on page 2835(
      module STRING
      basePath STRING
  )
  ```

  1. `module` registers the module of the REST service.

  2. `basePath` defines the base path to the Web service as it appears in the URL.

  **Usage**

  You use this method to register all the public functions in the `module` of your Web service with the Genero Web Service engine and publish them for users on the internet.

  It is recommended to import the Rest service module with the `IMPORT FGL` statement. Alternatively, you can link `.42r` files using the `fgllink` command.
The `basePath` sets the base path to the Web service in the Genero Web Service engine as it appears in the URL for the service. For instance, if you want your 4GL module called "accounts" to be published as a Rest service with the name "Accounts" (uppercase "A") you must call the function as shown:

```java
CALL com.WebServiceEngine.RegisterRestService("accounts","Accounts")
```

Then the URL is: `http://host:port/gas/ws/r/group/xcf/Accounts`

**Note:** Typically, you deploy the service behind a Genero Application Server, and therefore you have also the `group` name (if not the default) and the service `xcf` file name in the URL.

In direct mode on a localhost, the URL is just: `http://localhost:port/ws/r/Accounts`

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls](STATUS) on page 3554.

**com.WebServiceEngine.SetFaultCode**

Get a handle for an incoming HTTP service request.

**Syntax**

```java
com.WebServiceEngine.SetFaultCode(
    code STRING,
    ns STRING
)
```

1. `code` defines the fault code.
2. `ns` defines the namespace of the fault code.

**Usage**

The `com.WebServiceEngine.SetFaultCode()` class method defines a user SOAP Fault code to be returned to the client, where `code` is the mandatory SOAP Fault code and `ns` is the mandatory code namespace.

This method must be called inside a Web Service operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls](STATUS) on page 3554.

**com.WebServiceEngine.SetFaultDetail**

Defines the published SOAP Fault.

**Syntax**

```java
com.WebServiceEngine.SetFaultDetail(
    fault RECORD
)
```

1. `fault` defines the published fault.

**Usage**

The `com.WebServiceEngine.SetFaultDetail()` class method defines the published SOAP Fault to be returned to the client when operation has finished, where `fault` is one of the published variables defined as Fault for that operation.

This method must be called inside a Web Service operation.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls](STATUS) on page 3554.
com.WebServiceEngine.SetFaultString
Defines the description of a SOAP Fault.

Syntax

```java
com.WebServiceEngine.SetFaultString(
    str STRING )
```

1. `str` defines the description of the fault.

Usage
The `com.WebServiceEngine.SetFaultString()` class method defines a user SOAP Fault description to be returned to the client, where `str` contains the description of the fault.

This method must be called inside a Web Service function.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

com.WebServiceEngine.SetOption
Sets an option for the Web Service engine.

Syntax

```java
com.WebServiceEngine.SetOption(
    optionName STRING,
    optionValue STRING )
```

1. `optionName` defines the option to set.
2. `optionValue` defines the value of the option to set.

Usage
The `com.WebServiceEngine.SetOption()` class method configures the Web Services engine with options. See WebServiceEngine options on page 2840 for the supported options.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

com.WebServiceEngine.SetRestError
Manages error handling for a REST high-level Web Service function.

Syntax

```java
com.WebServiceEngine.SetRestError on page 2837(
    code INTEGER
    error RECORD )
```

1. `code` defines a standard HTTP response status code (400 - 599) as defined in RFC 2616 Section 10.4 and RFC 2616 Section 10.5
2. `error` defines details of the error. It can reference a variable of a suitable Genero BDL type; for example, simple type, or record. It can return a NULL value.
**Usage**

You use this method to set the HTTP status code and details of the error to be returned to the client when the request to the resource has finished. `SetRestError` accepts the HTTP code, a Genero BDL variable (if any), or a text description to be returned. This method must be called inside a Web Service REST high-level function.

If the `SetRestError()` method `error` parameter references a variable, the variable must be specified in the `WSThrows` on page 3484 declaration of the function, otherwise the method fails and returns an error code of -15570.

Variables referenced by `WSThrows`, must be defined as `PUBLIC` at the modular level and specified with the `WSError` on page 3483 attribute.

If `WSThrows` does not reference a variable, just a message string (for example "404:my error message"), you must call the method with the NULL value (`SetRestError(404,NULL)`) to send the "my error message" as the HTTP reason phrase. Ultimately, this will depend on whether the web server allows you to change the standard protocol message or not.

It is recommended that if you need to ensure an error description other than the standard protocol message is returned to the client, you must use `WSThrows` with "code:@variable" option and call the method with a reference to the variable, for example `SetRestError(400,myError)`.

In the examples Example 1: managing expected errors on page 2838 and Example 2: managing unexpected errors on page 2838 different uses of the method are shown.

**Example 1: managing expected errors**

In this example, common application level type errors, like resource not found, are expected. Instead of the standard HTTP status code (400 bad request), the call to `SetRestError(400,myerror)` will send the description set on the `myError.message` variable as the reason for the error.

```plaintext
PUBLIC DEFINE myError RECORD ATTRIBUTE(WSError="user error")
message STRING
END RECORD

PUBLIC
FUNCTION queryAccountById(id VARCHAR(10) ATTRIBUTE(WSParam))

  ATTRIBUTES(WSGet,
  WSPATH="/accounts/{id}",
  WSThrows="400:@myError,500:Internal Server Error")
  RETURNS accountType ATTRIBUTES(WSName="body")

  DEFINE thisAccount RECORD LIKE accounts.*
  # ... retrieve user id from database ...
  CASE sqlca.sqlcode
  WHEN 0
    EXIT CASE
  WHEN NOTFOUND
    LET myError.message = SFMT("Could not find account id :%1",id)
    CALL com.WebServiceEngine.SetRestError(400,myError)
  OTHERWISE
    CALL com.WebServiceEngine.SetRestError(500,NULL)
  END CASE
  RETURN thisAccount.*
END FUNCTION
```

**Example 2: managing unexpected errors**

**Warning:** In general, the recommended option is to list all the expected errors as shown in Example 1, in order to get them generated in the OpenAPI specification file and trapped on the client side.
In this example you code to trap a status code not defined in the WSThrows list. In the call to the SetRestError() method the status code and optionally the error variable is returned.

PUBLIC DEFINE myError RECORD ATTRIBUTE(WSError="user error")
   message STRING
END RECORD

PUBLIC
FUNCTION queryAccountById(id VARCHAR(10) ATTRIBUTE(WSParam))
   ATTRIBUTES(WSGet,
      WSPath="/accounts/{id}",
      WSThrows="400:@myError,500:Internal Server Error")
   RETURNS accountType ATTRIBUTES(WSName="body")

DEFINE thisAccount RECORD LIKE accounts.*
# ... retrieve user id from database ...

CASE sqlca.sqlcode
WHEN 0 # success
   EXIT CASE
WHEN NOTFOUND
   LET myError.message = SFMT("Could not find account id :%1",id)
   CALL com.WebServiceEngine.SetRestError(400,myError)
WHEN < 0
   CALL com.WebServiceEngine.SetRestError(500,NULL)
otherwise
   CALL com.WebServiceEngine.SetRestError(505,NULL)
END CASE
RETURN thisAccount.*
END FUNCTION

Related concepts
Handling application level errors on page 3399
There are many situations in which you need to notify an error to a client using your REST Web service.

Define functions in a module on page 3376
A GWS REST service is defined in a single module.

Related reference
High-level RESTful Web service attributes on page 3463

com.WebServiceEngine.Start
Starts the Web Service engine.

Syntax

com.WebServiceEngine.Start()

Usage
The com.WebServiceEngine.Start() class method starts the engine for all registered Web Services.

If you run the Web Services server program in standalone mode, port 80 is used unless FGLAPPSERVER is set. We recommend that you set FGLAPPSERVER, as port 80 may already be in use by other Web servers. If you run the Web Services server program through the Genero Application Server, the FGLAPPSERVER variable is automatically set by the Genero Application Server. Do NOT manually set FGLAPPSERVER in this case.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
Related concepts
FGLAPPSERVER on page 274
Defines the listening TCP port of the Web service in development context.

WSDL generation options notes
If you are planning to work with WSDL generation, you are advised to review these notes.

1. For the DECIMAL(5, 2) data type, when wsdl_decimalsize is TRUE, the generated WSDL file contains the total size and the size of the fractional part of the decimal:

```xml
<types>
    <schema xmlns="http://www.w3.org/2001/XMLSchema"
        targetNamespace="http://www.mycompany.com/types/">
        <simpleType name="echoDecimal5_2_a_dec5_2_out_FGLDecimal">
            <restriction base="decimal">
                <totalDigits value="5" />
                <fractionDigits value="2" />
            </restriction>
        </simpleType>
    </schema>
</types>
```

When wsdl_decimalsize is FALSE, the total size and the size of the fractional part are not mentioned:

```xml
<message name="echoDecimal5_2">
    <part name="dec5_2" type="f:echoDecimal5_2_a_dec5_2_in_FGLDecimal" />
</message>
```

2. If the WSDL file does not contain the size, the client application has no way of knowing the size. In this case, a default value for the size is generated. For example, the exported server type DECIMAL(5, 2) becomes a DECIMAL(32) on the client side.

3. It is better to keep the options wsdl_arraysize, wsdl_stringsize and wsdl_decimalsize set to TRUE so that the client program can do exact type mapping. The default for all three options is TRUE.

4. When setting a facet constraint attribute on a simple data type, the generation of the WSDL will take this attribute into account even if an option has been set to perform the opposite.

5. When setting one facet constraint attribute, all of the default constraint attributes won’t be generated anymore unless you specify them as facet constraint attributes.

WebServiceEngine options

Table 606: Options for the com.WebServiceEngine

<table>
<thead>
<tr>
<th>Flag</th>
<th>Client or Server</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>autocookiesmanagement</td>
<td>Client</td>
<td>If set to TRUE, it activates the automatic cookies management for any HTTPRequest. It is the same as calling <code>req.setAutoCookies(TRUE)</code> for all HTTPRequest to a single instance of fglrun. By setting to TRUE, the program does not need to call <code>req.setAutoCookies(true)</code> on any HTTPRequest in its code. The global option is called once at the start of the program, and all cookies received from a server are automatically sent back according to the cookie definition (path, expiration date, domain). Default value is FALSE.</td>
</tr>
<tr>
<td>Flag</td>

         You need to debug your application. Check the message with FGLWSDEBUG or display  
         `SQLCA.SQLERRM`. |
| -21    | SOAP Version mismatch  
         Your client SOAP version does not match your server SOAP version, amend either your client  
         or your server code. |
| -22    | SOAP header not understood  
         Modify your server code to handle the `mustUnderstand` attribute. Use the incoming request  
         handler. |
| -23    | Deserialization error  
         Check the message with FGLWSDEBUG or display `SQLCA.SQLERRM`. |
| -24    | Reserved error code  
         This error code is reserved for future use. |
| -25    | Web Services Addressing action is mandatory  
         Check that the WSA action is specified in the SOAP message. |
| -26    | Web Services Addressing message header is invalid  
         Check that the WSA header is correct in the SOAP message. |
| -27    | Web Services Addressing message header is mandatory  
         Check that the WSA header is specified in the SOAP message. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -28    | Web Services Addressing message protocol does not match  
Check that the WSA message uses the protocol version of the client matches the version expected by the server. |
| -29    | Cookie error  
Check that the HTTP request contains a valid cookie. |
| -30    | No active web operation  
The method was called outside the context of a web operation process. |
| -31    | Web Operation was flushed  
This code is returned by the `ProcessServices()` or the `HandlerRequest()` method, to indicated that the `Flush()` method was called during the last web operation execution. |
| -32    | Serialization error  
Check the message with FGLWSDEBUG or display SQLCA.SQLERRM. |
| -33    | XOP Not Supported  
The Web service does not implement the XML-binary Optimized Packaging (XOP) packaging specification for serializing binary data. |
| -34    | XOP Error  
Handing of XML-Binary Optimized Packaging failed, check the error with FGLWSDEBUG. |
| -35    | No Matching Rest Operation Found  
Check the URL of the resource and the REST web service function parameters. |
| -36    | Unexpected Rest Parameter  
Check that the number and type of input and return parameters match the service function. |
| -37    | WADL Error  
Generation of Web Application Description Language (WADL) failed, check error with FGLWSDEBUG. |
| -38    | Open API Error  
Generation of OpenAPI specification failed, check error with FGLWSDEBUG. |
| -39    | Content Type Ctx Incompatible  
Runtime Content-Type set via `WSContext` does not match the `WSMedia` of the REST operation, check `WSMedia` and `WSContext` values. |
| -40    | Scope Missing  
Service is secured, and a user token is required to authenticate access. Check that you are providing a scope. |

**The HTTPServiceRequest class**

The `com.HTTPServiceRequest` class provides an interface to process incoming XML and TEXT requests over HTTP on the server side, with an access to the HTTP layer and additional XML streaming possibilities.

**Important:** This Web Services class is not supported on GMI mobile devices.
**Table 608: Object methods: Request URLs**

<table>

</tbody>
</table>

**com.HTTPServiceRequest.addResponsePart**

Adds a new part to the HTTP root part response.

**Syntax**

```java
addResponsePart(
    part com.HTTPPart
)
```

1. `part` defines `com.HTTPPart` used to manage the HTTP attachment.

**Usage**

Adds a new part to the HTTP root part response. It will be sent after root part has been processed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

Examples using `com.HTTPServiceRequest` methods on page 2870

These examples use methods of the `com.HTTPServiceRequest` class.

Examples: Using the `com.HTTPPart` class on page 2910

Examples using methods of the `com.HTTPPart` class.

**com.HTTPServiceRequest.beginXmlRequest**

Starts an HTTP streaming request.

**Syntax**

```java
beginXmlRequest() RETURNS xml.StaxReader
```

**Usage**

The `beginXmlRequest()` method starts the streaming of HTTP request and returns a `xml.StaxReader` object ready to read the XML from the client.

Supported methods are PUT and POST.

The request Content-Type header must be of the form */xml or */+xml. For example: application/xhtml+xml.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555

Related concepts
Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.
Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.beginTransaction
Starts an HTTP streaming response.

Syntax

```
beginTransaction(
    code INTEGER,
    description STRING )
RETURNS xml.StaxWriter
```

1. `code` defines the status code of the response.
2. `description` defines the description of the response.

Usage
The `beginTransaction()` method starts an HTTP streaming response by sending a status (`code`) and description (`desc`), followed by the headers previously set, and returns a `xml.StaxWriter` object ready to send XML as the HTTP body.

If the request fails to be read, its content will be discarded; for example, when a request is not well formatted.

The default Content-Type header is `text/xml`, but it can be changed if of the form `/*xml` or `*/*+xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is `NULL`, a default description based on the status code is sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.endRequest
Terminates an HTTP streaming request.

Syntax

```
endRequest(
    stax xml.StaxReader )
```

1. `stax` defines the `xml.StaxReader` object used for streaming.
Usage

The `endXmlRequest()` method ends the streaming HTTP request by closing the `xml.StaxReader` object passed as parameter.

The `stax` object must be created with the `beginXmlRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555

Related concepts

Examples using `com.HTTPServiceRequest` methods on page 2870
These examples use methods of the `com.HTTPServiceRequest` class.

Examples: Using the `com.HTTPPart` class on page 2910
Examples using methods of the `com.HTTPPart` class.

com.HTTPServiceRequest.endXmlResponse

Terminates an HTTP streaming response.

Syntax

```
endXmlResponse(
    stax xml.StaxWriter
)
```

1. `stax` defines `xml.StaxWriter` used to write the HTTP body.

Usage

The `endXmlResponse()` method terminates the HTTP streaming response by closing the `xml.StaxWriter` object created by `beginXmlResponse`.

The body of the request is discarded.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555

These examples use methods of the `com.HTTPServiceRequest` class.

Examples: Using the `com.HTTPPart` class on page 2910
Examples using methods of the `com.HTTPPart` class.

com.HTTPServiceRequest.findRequestCookie

Enables the server to retrieve a cookie sent by the client by name.

Syntax

```
findRequestCookie(
    name STRING
)
```
**Usage**

Enables the server to retrieve a cookie sent by the client by name.

The method returns the value of the cookie, or NULL if the named cookie does not exist.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

- Examples using com.HTTPServiceRequest methods on page 2870
  These examples use methods of the com.HTTPServiceRequest class.
- Examples: Using the com.HTTPPart class on page 2910
  Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.getMethod

Returns the HTTP method of the service request.

**Syntax**

```java
getMethod()
  RETURNS STRING
```

**Usage**

The `getMethod()` method returns the HTTP method of the request, Supported methods are GET, PUT, POST, HEAD, and DELETE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

- Examples using com.HTTPServiceRequest methods on page 2870
  These examples use methods of the com.HTTPServiceRequest class.
- Examples: Using the com.HTTPPart class on page 2910
  Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.getRequestVersion

Returns the HTTP version of the service request.

**Syntax**

```java
getRequestVersion()
  RETURNS STRING
```

**Usage**

The `getRequestVersion()` method returns the HTTP version of the request (1.0 or 1.1).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
Related concepts

Examples using com.HTTPServiceRequest methods on page 2870

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

**com.HTTPServiceRequest.getRequestHeader**

Returns the value of an HTTP header.

**Syntax**

```
getRequestHeader (  
   name STRING  
)  
RETURNS STRING
```

1. *name* defines an HTTP header.

**Usage**

The `getRequestHeader()` method returns the value of the HTTP header specified by the *name* parameter, or NULL if there is none found.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2870

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

**com.HTTPServiceRequest.getRequestHeaderCount**

Returns the number of request headers.

**Syntax**

```
getRequestHeaderCount ()  
RETURNS INTEGER
```

**Usage**

The `getRequestHeaderCount()` method returns the entire URL request containing the host, port, document and query string.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

**com.HTTPServiceRequest.getRequestHeaderName**
Returns a request header name by position.

Syntax

```
getRequestHeaderName (  
    ind INTEGER  
)  
RETURNS STRING
```

1. `ind` defines the ordinal position of the header.

Usage

The `getRequestHeaderName()` method returns the name of the header at the given position.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the `com.HTTPServiceRequest` class.

Examples: Using the `com.HTTPPart` class on page 2910
Examples using methods of the `com.HTTPPart` class.

com.HTTPServiceRequest.getRequestHeaderValue
Returns a request header value by position.

Syntax

```
getRequestHeaderValue (  
    ind INTEGER  
)  
RETURNS STRING
```

1. `ind` defines the ordinal position of the header.

Usage

The `getRequestHeaderValue()` method returns the value of the header at the given position.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the `com.HTTPServiceRequest` class.

Examples: Using the `com.HTTPPart` class on page 2910
Examples using methods of the `com.HTTPPart` class.

com.HTTPServiceRequest.getRequestMultipartType
Returns the multipart type of an incoming request.

Syntax

```
getRequestMultipartType (  
)  
RETURNS STRING
```
Usage

Returns the multipart type of an incoming request, returns NULL if not a multipart request.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.getRequestPart

Returns the HTTPPart object at the specified index position.

Syntax

```java
getRequestPart (  
    pos INTEGER)  
RETURNS com.HTTPPart
```

1. pos defines the index position.

Usage

Returns the HTTPPart object at the specified index position. The file part is stored in the temporary directory as defined by the DVM environment or the system. If the DVM DBTEMP on page 273 environment variable is set, this is used. Otherwise the temporary directory as defined by the system is used. On Windows® the system temporary directory is set by TEMP. On UNIX® the /tmp directory is used.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Can raise error -15554 (Index is out of bounds).

Related concepts

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.getRequestPartCount

Returns the number of additional multipart elements.

Syntax

```java
getRequestPartCount ()  
RETURNS INTEGER
```

Usage

The root multipart is handled via standard readTextRequest(), readXmlRequest(), readDataRequest() and beginXmlRequest().

The number of parts is only available when the entire request has been read.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

**com.HTTPServiceRequest.getRequestPartFromID**

Returns the HTTPPart object of the given Content-ID value.

**Syntax**

```java
getRequestPartFromID(
    id STRING)
RETURNS com.HTTPPart
```

1. *id* defines the Content-ID value.

**Usage**

Returns the HTTPPart object of the given Content-ID value, returns NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

**com.HTTPServiceRequest.getURL**

Returns the URL of the HTTP service request. The URL may consists of a host name, a port number, a path, and a query.

**Syntax**

```java
getURL()
RETURNS STRING
```

**Usage**

The `getURL()` method returns the entire URL request containing the host, port, document and query string.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

URLs are sent in UTF-8 on the network. If the query part of the URL cannot be converted from UTF-8 to the fglrun locale charset, STATUS will be set to -15552. Is this case, the document part of the URL is available, but the query string must be retrieved through `HTTPServiceRequest.readFormEncodedRequest()`. As a general advice, run your WS server program in UTF-8.
Related concepts

These examples use methods of the com.HTTPServiceRequest class.
Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.getURLHost
Returns the host name contained in the URL of an HTTP service request.

Syntax

```
getURLHost ()
RETURNS STRING
```

Usage
Returns the host name contained in the URL of an HTTP service request.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts
Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.
Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.getURLPath
Returns the path contained in the URL of an HTTP service request.

Syntax

```
getURLPath ()
RETURNS STRING
```

Usage
Returns the path contained in the URL of an HTTP service request.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts
Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.
Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.getURLPort
Returns the port number contained in the URL of an HTTP service request.

Syntax

```
getURLPort ()
```
**Usage**

Returns the port number contained in the URL of an HTTP service request.

The method returns NULL if there is no port.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

### com.HTTPServiceRequest.getURLQuery

Takes a dynamic array of RECORD of two strings and fills that array with the decoded query string of an HTTP service request.

**Syntax**

```plaintext
getURLQuery(
    query RECORD)
```

1. `query` defines a record with the following structure:

   ```plaintext
   DEFINE query DYNAMIC ARRAY OF RECORD
   name STRING,
   value STRING
   END RECORD
   ```

   The WSHelper library provides the WSHelper.WSQueryType variable for your use. See WSHelper variables and records on page 3500.

**Usage**

Takes a dynamic array of RECORD of two strings and fills that array with the decoded query string of an HTTP service request. If there is no query string, the dynamic array size will be zero (0).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

If the given array is not of the expected type, it raises exception -15535.

If there is an encoding issue, the STATUS is set to -15552. No exception is raised. You can process the query parts that do not have any UTF-8 conversion issues.

**Related concepts**

### com.HTTPServiceRequest.hasRequestKeepConnection

...
Returns TRUE if the connection remains open after sending a response.

**Syntax**

```java
hasRequestKeepConnection ()
RETURNS INTEGER
```

**Usage**

The `hasRequestKeepConnection()` method returns if the request expects the connection to stay open after sending the response.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

- Examples using com.HTTPServiceRequest methods on page 2870
  These examples use methods of the com.HTTPServiceRequest class.

- Examples: Using the com.HTTPPart class on page 2910
  Examples using methods of the com.HTTPPart class.

---

**com.HTTPServiceRequest.readDataRequest**

Returns the body of a request in a `BYTE`.

**Syntax**

```java
readDataRequest (b BYTE)
```

1. `b` defines a variable of type `BYTE` that will be filled with the request body.

**Usage**

The `readDataRequest()` method returns the body of the request in a `BYTE`.

Supported methods are PUT and POST.

The `BYTE` variable must be located in memory, and will be filled with the request body. The existing content of the `BYTE` will be discarded.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

**Related concepts**

- Examples using com.HTTPServiceRequest methods on page 2870
  These examples use methods of the com.HTTPServiceRequest class.

- Examples: Using the com.HTTPPart class on page 2910
  Examples using methods of the com.HTTPPart class.

---

**com.HTTPServiceRequest.readFileRequest**
Returns the body of a request in a file.

Syntax

```java
readFileRequest()
RETURNS STRING
```

Usage

The `readFileRequest()` method returns the body of the request to a file on disk.

The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file is the basename found in the HTTP Content-Disposition Header. If this basename is not specified, the file name is created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form: `/tmp/ABC/filename_index.ext`, where `index` represents the number of files with the same name on disk.

Supported methods are PUT and POST.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555

Related concepts

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.readFormEncodedRequest

Returns the string of a GET request with UTF-8 conversion option.

Syntax

```java
readFormEncodedRequest(
    utf8 INTEGER)
RETURNS STRING
```

1. `utf8` specifies if the string must be decoded to the current charset.

Usage

The `readFormEncodedRequest()` method returns the query of a POST "application/x-www-form-urlencoded" request or the query string of a GET request, decoded depending on HTML4 or XFORM if `utf8` is TRUE.

Note: If the result string contains & or = XForms special characters, these are doubled as follows:

na&me=va=ue

If the `utf8` parameter is TRUE, the decoded query string is translated from UTF-8 to the current character set. This may lead to a conversion error.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555
Related concepts
Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.
Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.readTextRequest
Returns the request body as a plain string.

Syntax

```java
readTextRequest ()
RETURNS STRING
```

Usage

The `readTextRequest()` method returns the body of the request as a string.

Supported methods are PUT and POST.

The request Content-Type header can be of any form */*. For example: `application/json`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

Related concepts
Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.
Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.readXmlRequest
Returns the request body as an XML document.

Syntax

```java
readXmlRequest ()
RETURNS xml.DomDocument
```

Usage

The `readXmlRequest()` method returns the request as an entire XML document, contained in a `xml.DomDocument` object.

Supported methods are PUT and POST.

The request Content-Type header must be of the form */xml or */+xml. For example: `application/xhtml+xml`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.
Related concepts

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.sendDataResponse
Sends an HTTP response with data of a BYTE variable.

Syntax

```java
sendDataResponse(
    code INTEGER,
    description STRING,
    b BYTE )
```

1. `code` specifies the status code of the response.
2. `description` specifies the description of the response.
3. `b` defines a BYTE type containing the data to be sent.

Usage

The `sendDataResponse()` method performs the HTTP response by sending the status (`code`) and description (`description`), followed by the headers previously set and binary data contained in the `b` program variable as body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server is expected to send an HTTP response with the code of 400 (Bad Request). See HTTP status codes (wikipedia) for more details about common HTTP response codes.

The `b` parameter is defined as a BYTE and must be located in memory and not NULL, otherwise the operation fails.

The default Content-Type header is `application/octet-stream`, but it can be changed to any other mime type. For example: `image/jpeg`.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is NULL, a default description according to the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.sendFileResponse
Sends an HTTP response with the data contained in a file.

**Syntax**

```java
sendFileResponse(
    code INTEGER,
    description STRING,
    filename STRING )
```

1. `code` specifies the status code of the response.
2. `description` specifies the description of the response.
3. `filename` specifies the path of the file containing the data to be send.

**Usage**

The `sendFileResponse()` method performs the HTTP response by sending the status (`code`) and description (`description`), followed by the headers previously set and the data contained in the specified file as body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server is expected to send an HTTP response with the code of 400 (Bad Request). See HTTP status codes (wikipedia) for more details about common HTTP response codes.

If not defined by the programmer, the HTTP headers are automatically set as follows:

- **Content-Type** is defined based on the file name extension. If the file extension is not recognized, `Content-Type` defaults to `application/octet-stream`.
  
  **Note:** File extensions to `Content-Type` mapping can be customized in the file `$FGLDIR/lib/wse/mime.cfg`.

- **Content-Disposition** is set with the base name of the given `filename` as follows: `attachment; filename="basename"`.

For example, when calling the method as follows:

```java
CALL server.sendFileResponse( 200, NULL, "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP headers of the response will look like:

```text
Content-Type: image/jpeg
Content-Disposition: attachment; filename="logo.jpg"
```

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is `NULL`, a default description according to the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

`com.HTTPServiceRequest.sendResponse`
Sends an HTTP response without body.

**Syntax**

```java
sendResponse(
    code INTEGER,
    description STRING )
```

1. `code` specifies the status code of the response.
2. `description` specifies the description of the response.

**Usage**

The `sendResponse()` method performs the HTTP response by sending a status (`code`) and description (`description`), followed by the headers previously set, without a body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server is expected to send an HTTP response with the code of 400 (Bad Request). See [HTTP status codes](https://en.wikipedia.org/wiki/List_of_HTTP_status_codes) for more details about common HTTP response codes.

If the description is `NULL`, a default description based on the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](https://www.ibm.com/support/knowledgecenter/SSSHWH_14.1.0/com.ibm.db2.luw.ur.doc/doc/docx/erradm.htm) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see [ Interruption handling in GWS calls (INT_FLAG) ](https://www.ibm.com/support/knowledgecenter/SSSHWH_14.1.0/com.ibm.db2.luw.ur.doc/doc/docx/erradm.htm) on page 3555.

`com.HTTPServiceRequest.sendTextResponse`
Sends an HTTP response with data from a plain string.

**Syntax**

```java
sendTextResponse(
    code INTEGER,
    description STRING,
    txt STRING )
```

1. `code` specifies the status code of the response.
2. `description` specifies the description of the response.
3. `txt` defines the string containing the data to be sent.
Usage

The `sendTextResponse()` method performs the HTTP response by sending the a status (`code`) and description (`description`), followed by the headers previously set, and text data contained in the string as body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server is expected to send an HTTP response with the code of 400 (Bad Request). See [HTTP status codes (wikipedia)](https://en.wikipedia.org/wiki/List_of_HTTP_status_codes) for more details about common HTTP response codes.

The default Content-Type header is `text/plain`, but it can be changed if of the form `*/*`. For example: `application/json`.

Automatic conversion from locale to user-defined charset is performed when possible, otherwise throws an exception.

In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is `NULL`, a default description based on the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls](page 3554) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see [Interruption handling in GWS calls (INT_FLAG)](page 3555) on page 3555.

### Syntax

```java
sendTextResponse(
    code INTEGER,
    desc STRING,
    doc xml.DomDocument)
```

1. `code` specifies the status code of the response.
2. `description` specifies the description of the response.
3. `doc` specifies the XML document containing the data to be sent.

Usage

The `sendTextResponse()` method performs the HTTP response by sending a status (`code`) and description (`description`), followed by the headers previously set, and the XML data contained in the passed `xml.DomDocument` object as body.

It is important for the server to return a correct status `code`, following the HTTP standards, otherwise the client may fail to interpret the response. For instance, if the request is malformed, the server is expected to send an HTTP response with the code of 400 (Bad Request). See [HTTP status codes (wikipedia)](https://en.wikipedia.org/wiki/List_of_HTTP_status_codes) for more details about common HTTP response codes.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `*/+xml`. For example: `application/xhtml+xml`.
In HTTP 1.1, if the body size is greater than 32k, the response will be sent in several chunks of the same size.

If the description is NULL, a default description based on the status code is sent.

New incoming requests can be retrieved again with the `com.WebServiceEngine.GetHTTPServiceRequest()` method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

**Related concepts**

  - These examples use methods of the `com.HTTPServiceRequest` class.
- Examples: Using the `com.HTTPPart` class on page 2910
  - Examples using methods of the `com.HTTPPart` class.

**Syntax**

```java
com.HTTPServiceRequest.setResponseCharset
```

Defines the HTTP response character set.

**Usage**

The `setResponseCharset()` method defines the character set to use when sending an HTTP response.

The server must send a response in a character set that the client understands.

If the response character set is not defined by `setResponseCharset()`, the same character set as the client request is used, or the implicit ISO-8859-1 charset is used if the character is not defined by the client request.

The method must be called before sending the response with one of `sendResponse`, `sendTextResponse`, `sendXMLResponse`, or `beginXMLResponse` and `endXMLResponse` methods.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

- Localization on page 512
  - Localization support allows you to implement programs that follow specific language and cultural rules.
- Examples using com.HTTPServiceRequest methods on page 2870
  - These examples use methods of the `com.HTTPServiceRequest` class.

**Syntax**

```java
com.HTTPServiceRequest.setResponseCookies
```

Allows the server to return cookies to be set on the client application sending the request.

**Usage**

The `setResponseCookies()` method allows the server to return cookies to be set on the client application sending the request.

The method must be called before sending the response with one of `sendResponse`, `sendTextResponse`, `sendXMLResponse`, or `beginXMLResponse` and `endXMLResponse` methods.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
1. *cookies* defines a dynamic array for the cookies to be set. See WSHelper variables and records on page 3500 for more information regarding WSServerCookiesType.

**Usage**

Allows the server to return cookies to be set on the client application sending the request.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Setting cookies example**

```plaintext
IMPORT FGL WSHelper

DEFINE cookies WSHelper.WSServerCookiesType

# Set first cookie named 'CookieName'
LET cookies[1].name = "CookieName"
LET cookies[1].value = "AnyValue"
LET cookies[1].expires = now + INTERVAL (5) MINUTE TO MINUTRE

# Set second cookie named 'SecondCookie'
LET cookies[2].name = "SecondCookie"
LET cookies[2].value = "AnotherValue"

# Set all cookies defined in the cookie array
CALL req.setResponseCookies(cookies)
CALL req.sendTextResponse(200, NULL, "Hello world")
```

**Related concepts**

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

**Syntax**

```plaintext
setResponseHeader (  
    name STRING,  
    value STRING )
```

1. *name* specifies the name of a header.
2. *value* defines the value of a header.

**Usage**

The setResponseVersion() method sets (or replaces) the name and value of an HTTP response header.

The Content-Length header cannot be set, because it is computed internally according to the body size.

The method must be called before sending the response with one of sendResponse, sendTextResponse, sendXmlResponse, or beginXmlResponse and endXmlResponse methods.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
Related concepts

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.setResponseMultipartType
Sets HTTP response in multipart mode of given type.

Syntax

```java
setResponseMultipartType(
    type STRING,
    start STRING,
    boundary STRING )
```

1. `type` defines one of the following:
   - form-data: Browser Xform with attachment
   - mixed: Parts are independent
   - related: Parts are dependent (Required for SOAP)
   - alternative: Parts are different types of the same document
   - *or any other type*
   - NULL: switch multipart mode off

2. `start` specifies the Content-ID value of root multipart document. Must be ASCII (optional)
3. `boundary` specifies the string used as multipart boundary. Must be ASCII (optional)

Usage

Sets HTTP response in multipart mode of given type. Calling one of the standard request methods will send the HTTP response as the given multipart type, even if no other part has been set.

The root HTTP part must be handled via the standard HTTPServiceRequest methods such as sendTextRequest(), sendXmlRequest(), sendDataRequest() and BeginXmlResponse().

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts

Examples using com.HTTPServiceRequest methods on page 2870
These examples use methods of the com.HTTPServiceRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPServiceRequest.setResponseVersion
Defines the HTTP response version.

Syntax

```java
setResponseVersion(
    version STRING )
```

1. `version` specifies the HTTP response version.
Usage

The `setResponseVersion()` method defines the HTML response version (1.0 or 1.1). If not set, the same version as the request is used.

The method must be called before sending the response with one of `sendResponse`, `sendTextResponse`, `sendXmlResponse`, or `beginXmlResponse` and `endXmlResponse` methods.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the $\text{SQLCA.SQLERRM}$ register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts

Server-side example

```java
IMPORT COM
IMPORT Security
IMPORT FGL WSHelper

CONSTANT C_5_MINUTES = INTERVAL(5) MINUTE TO MINUTE

MAIN
  DEFINE expires DATETIME DAY TO SECOND
  DEFINE req com.HTTPServiceRequest
  DEFINE query WSHelper.WSQueryType
  DEFINE ind INTEGER
  DEFINE url, host, port, path, myCookie STRING
  DEFINE cookies WSHelper.WSServerCookiesType

  CALL com.WebServiceEngine.Start()
  WHILE true
    LET req = com.WebServiceEngine.GetHTTPServiceRequest(-1)
    LET url = req.getURL()
    DISPLAY "URL is ":url
    LET host = req.getURLHost()
    DISPLAY "Host is ":host
    LET port = req.getURLPort()
    DISPLAY "Port is ":port
    LET path = req.getURLPath()
    DISPLAY "Path is ":path
    CALL req.getUrlQuery(query)
    FOR ind = 1 TO query.getLength()
      DISPLAY "Query ":ind
      DISPLAY " key ":query[ind].name
      DISPLAY " val ":query[ind].value
    END FOR

    LET myCookie = req.findRequestCookie("UserIDCookie")
    IF myCookie IS NULL THEN
      DISPLAY "New user"
    ELSE
      DISPLAY "User id is ":myCookie
    END IF
```
# Compute Set-Cookies
DISPLAY "Now is ":, CURRENT
LET expires = CURRENT + C_5_MINUTES

LET cookies[1].name = "AnotherCookie"
LET cookies[1].value = "security.RandomGenerator.CreateUUIDString()"
LET cookies[1].domain = ".strasbourg.4js.com"
LET cookies[1].expires = expires
LET cookies[1].httpOnly = TRUE
CALL req.setResponseCookies(cookies)
# Send response with cookie
CALL req.sendTextResponse(200, NULL, "IT WORKS.")
END WHILE
END MAIN

HTTP classes
The HTTP classes manage HTTP client network operations on the client side.

The HTTPRequest class
The com.HTTPRequest class provides an interface to perform asynchronous XML and TEXT requests over HTTP for a specified URL, with additional XML streaming possibilities, on the client side.

The STATUS variable is set to zero after a successful method call.

`com.HTTPRequest.addPart`  
Adds a new part to the HTTP root part request.

**Syntax**

```plaintext
addPart ( part com.HTTPPart )
```

1. `part` defines the HTTPPart object.

**Usage**

Adds a new part to the HTTP root part request. This part is sent after root part has been processed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

**Related concepts**

Examples using com.HTTPRequest methods on page 2891  
These examples use methods of the `com.HTTPRequest` class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the `com.HTTPRequest` class.

`com.HTTPRequest.beginXmlRequest`
Starts a streaming HTTP request.

**Syntax**

```java
beginXmlRequest ()
RETURNS xml.StaxWriter
```

**Usage**

The `beginXmlRequest()` starts a streaming HTTP request and returns an `xml.StaxWriter` object ready to send to the server.

Supported methods are PUT and POST.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `*/+xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

**Related concepts**

- Examples using `com.HTTPRequest` methods on page 2891
- These examples use methods of the `com.HTTPRequest` class.

`com.HTTPRequest.clearAuthentication`
Removes user-defined authentication.

**Syntax**

```java
clearAuthentication()
```

**Usage**

Removes user-defined authentication.

If an `authenticate` entry exists in the FGLPROFILE file, it will be used for authentication, even if the user-defined authentication was removed.

**Important:** The iOS HTTP stack doesn't provide a simple way to handle authentication. The GMI front-end uses the global iOS credential management system, that keeps credential values of previous request based on host and realm, until the keep-alive session is closed. Therefore, doing a `clearAuthentication()` on iOS devices does not take effect immediately.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

- Examples using `com.HTTPRequest` methods on page 2891
These examples use methods of the `com.HTTPRequest` class.

**Examples: Using the `com.HTTPPart` class** on page 2910
Examples using methods of the `com.HTTPPart` class.

**com.HTTPRequest.clearHeaders**
Removes all user-defined HTTP request headers.

**Syntax**

```java
clearHeaders()
```

**Usage**
Removes all user-defined HTTP request headers defined with the `setHeader()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

**Related concepts**

- Examples using `com.HTTPRequest` methods on page 2891
- These examples use methods of the `com.HTTPRequest` class.

**Examples: Using the `com.HTTPPart` class** on page 2910
Examples using methods of the `com.HTTPPart` class.

**com.HTTPRequest.Create**
Creates a new `HTTPRequest` object from an URL.

**Syntax**

```java
com.HTTPRequest.Create(
    url STRING )
RETURNS com.HTTPRequest
```

1. `url` defines the URL for the HTTP request.

**Usage**
Creates a `com.HTTPRequest` object by providing a mandatory URL with HTTP or HTTPS as protocol.

The `url` parameter can be an identifier of an URL mapping with an optional `alias://` prefix. See FGLPROFILE Configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

**Related concepts**

- Examples using `com.HTTPRequest` methods on page 2891
- These examples use methods of the `com.HTTPRequest` class.

**Examples: Using the `com.HTTPPart` class** on page 2910
Examples using methods of the `com.HTTPPart` class.

**com.HTTPRequest.doDataRequest**
Performs the request by sending binary data.

**Syntax**

```
doDataRequest (  
   b BYTE  )
```

1. `b` defines the binary data.

**Usage**

Performs the request by sending binary data contained in the `b` variable.

Supported methods are PUT and POST.

The `b` must be located in memory and not NULL otherwise the operation fails.

The default Content-Type header is `application/octet-stream`, but it can be changed to any other mime type. For example: `image/jpeg`.

In HTTP 1.1, if the body size is greater than 32k, the request will be sent in several chunks of the same size.

This HTTP request method is non-blocking. It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2882 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going, use the `com.HTTPRequest.getAsyncResponse` on page 2881 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555

**Related concepts**

- Examples using `com.HTTPRequest` methods on page 2891
  These examples use methods of the `com.HTTPRequest` class.
- Examples: Using the `com.HTTPPart` class on page 2910
  Examples using methods of the `com.HTTPPart` class.

`com.HTTPRequest.doFileRequest`

Performs the request by sending data contained in a file.

**Syntax**

```
doFileRequest (  
   filename STRING  )
```

1. `filename` defines the file containing the data to be send.

**Usage**

Performs the request by sending data contained in the file passed as parameter. The data is sent as is without any further conversion.

Supported methods are PUT and POST.

If not defined by programmer, the HTTP headers are automatically set as follows:

- `Content-Type` is defined based on the file name extension. If the file extension is not recognized, `Content-Type` defaults to `application/octet-stream`. 
Note: File extensions to Content-Type mapping can be customized in the file $FGGLDIR/lib/wse/mime.cfg.

- Content-Disposition is set with the base name of the given filename as follows: attachment; filename="basename".

For example, when calling the method as follows:

```java
CALL request.doFileRequest( "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP headers of the POST or PUT will look like:

```
Content-Type: image/jpeg
Content-Disposition: attachment; filename="logo.jpg"
```

In HTTP 1.1, if the body size is greater than 32k, the request will be sent in several chunks of the same size.

This HTTP request method is non-blocking. It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2882 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going, use the `com.HTTPRequest.getAsyncResponse` on page 2881 method, to check if a response is available.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555

Related concepts

These examples use methods of the com.HTTPRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

`com.HTTPRequest.doFormEncodedRequest`
Performs an "application/x-www-form-urlencoded forms" encoded query.

**Syntax**

```java
doFormEncodedRequest ( 
    query STRING,
    utf8 INTEGER )
```

1. `query` defines a list of name/value pairs separated by an &.
2. `utf8` defines if the query string is UTF-8 encoded.

**Usage**

The `doFormEncodedRequest()` method performs a request with an "application/x-www-form-urlencoded forms" encoded query.

Supported methods are GET and POST.

The `query` string is a list of name/value pairs separated by an ampersand (&). For example:

```java
name1=value1&name2=value2&name3=value3
```

**Note:** If you need to URL-encode the separator characters & and =, double them as following: na&&me=va==lue.
If the `utf8` parameter is `TRUE`, the query string is encoded in UTF-8 as specified in `XForms1.0`, otherwise in ASCII as specified in `HTML4`.

This HTTP request method is non-blocking. It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2882 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going, use the `com.HTTPRequest.getAsyncResponse` on page 2881 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See `Error handling in GWS calls (STATUS)` on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see `Interruption handling in GWS calls (INT_FLAG)` on page 3555

**com.HTTPRequest.doRequest**
Performs the HTTP request.

### Syntax

```java
doRequest()
```

### Usage

The `doRequest()` method performs the HTTP request.

Supported methods are GET, HEAD, POST, PUT and DELETE.

**Note:** For POST and PUT requests, the body will be empty.

This HTTP request method is non-blocking. It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2882 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going, use the `com.HTTPRequest.getAsyncResponse` on page 2881 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See `Error handling in GWS calls (STATUS)` on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see `Interruption handling in GWS calls (INT_FLAG)` on page 3555

**Related concepts**

Examples using `com.HTTPRequest` methods on page 2891
These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2910
Examples using methods of the `com.HTTPPart` class.

**com.HTTPRequest.doTextRequest**
Performs the request by sending an entire string at once.

### Syntax

```java
doTextRequest()
```
1. *str* defines a string containing the request.

**Usage**

Performs the request by sending an entire string at once.

Supported methods are PUT and POST.

The default Content-Type header is `text/plain`, but it can be changed if of the form `*/*`. For example: `application/json`.

Automatic character set conversion from the application locale to the user-defined charset is performed. In case of conversion error, the method throws an exception.

**Note:** To avoid character conversion problems when sending text over HTTP, consider setting the same user-defined character set as the program defined by the application locale (assuming that the server understands the client application character set).

In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.

This HTTP request method is non-blocking. It returns immediately after the call. Use the `com.HTTPRequest.getResponse` method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going, use the `com.HTTPRequest.getAsyncResponse` method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

**Related concepts**

Examples using com.HTTPRequest methods on page 2891

These examples use methods of the `com.HTTPRequest` class.

Examples: Using the com.HTTPPart class on page 2910

Examples using methods of the `com.HTTPPart` class.

**Syntax**

```java
doXmlRequest (doc xml.DomDocument )
```

1. *doc* defines the XML document containing the data to be sent.

**Usage**

The `doXmlRequest()` method performs the request by sending the entire passed `xml.DomDocument` at once.

Supported methods are PUT and POST.

The default Content-Type header is `text/xml`, but it can be changed if of the form `*/xml` or `*//*.xml`. For example: `application/xhtml+xml`.

In HTTP 1.1, if the body size is greater than 32 KB, the request will be sent in several chunks of the same size.
The character set used to send the XML data is defined by the encoding attribute in the XML document prolog. It is recommended that you define the HTTP request character set to NULL with the `setCharSet()` method, or that you use the same character set that was set in the XML Document.

This HTTP request method is non-blocking. It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2882 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going, use the `com.HTTPRequest.getAsyncResponse` on page 2881 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555

**Related concepts**

Examples using com.HTTPRequest methods on page 2891
These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2910
Examples using methods of the `com.HTTPPart` class.

```java
com.HTTPRequest.endXmlRequest
Terminates a streaming HTTP request.

Syntax

```
endXmlRequest(
    stax xml.StaxWriter
)
```

1. `stax` defines the `xml.StaxWriter` object used to write the HTTP request.

**Usage**

The `endXmlRequest()` method terminates a streaming HTTP request by closing the `xml.StaxWriter` object that was created with the `beginXmlRequest()` method.

This HTTP request method is non-blocking. It returns immediately after the call. Use the `com.HTTPRequest.getResponse` on page 2882 method, to perform a synchronous HTTP request, suspending the program flow until the response returns from the server. If the program must keep going, use the `com.HTTPRequest.getAsyncResponse` on page 2881 method, to check if a response is available.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555

**Related concepts**

Examples using com.HTTPRequest methods on page 2891
These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2910
Examples using methods of the `com.HTTPPart` class.
When available, returns the response produced by one of request methods.

Syntax

```
getAsyncResponse()
RETURNS com.HTTPResponse
```

**Usage**

If a response is available, the `getAsyncResponse()` method returns a `com.HTTPResponse` object corresponding to the response that was produced by a call to one of the request methods: `doRequest()`, `doTextRequest()`, `doXmlRequest()`, `doFormEncodedRequest()`, or `beginXmlRequest()` and `endXmlRequest()`.

Unlike `getResponse()`, the `getAsyncResponse()` method is non-blocking: it returns immediately and does not stop the program flow when waiting for a response.

The method returns `null` if the HTTP response was not yet received from the server.

This method is typically called just after a `do*Request()` call, and if the returned value is `null`, it is called again after a short period of time, to check for a response. Within a dialog, use an `ON IDLE` block to issue a `getAsyncRequest()` every seconds for example.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (`INT_FLAG`) on page 3555.

**Related concepts**

- `com.HTTPRequest.getResponse` on page 2882
  Waits for and returns the response produced by one of request methods.
  
  **Examples using `com.HTTPRequest` methods** on page 2891
  These examples use methods of the `com.HTTPRequest` class.

**Syntax**

```
getResponse()
RETURNS com.HTTPResponse
```

**Usage**

The `getResponse()` method waits for a response from the server and returns a `com.HTTPResponse` object corresponding to the response that was produced by a call to one of the request methods: `doRequest()`, `doTextRequest()`, `doXmlRequest()`, `doFormEncodedRequest()`, or `beginXmlRequest()` and `endXmlRequest()`.

**Note:** On iOS, a long running HTTP request will display a message box, to allow the user to cancel the request. If the user cancels the HTTP request, the error `-15578` will be raised. This error can be trapped with `TRY/CATCH`.

Unlike `getAsyncResponse()`, the `getResponse()` method is blocking: it stops program flow until an HTTP response is received from the server.

Define a response timeout with the `com.HTTPRequest.setTimeOut` on page 2890 method.
**Note:** On iOS devices, when using this method, it is not possible to distinguish different timeouts for the connection and for read/write operation, defined respectively by the `setConnectionTimeOut()` and `setTimeOut()` methods. If both timeouts are defined, the longest timeout will be used for the connection and read/write operations.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see * Interruption handling in GWS calls (INT_FLAG)* on page 3555.

**Related concepts**

- [com.HTTPRequest.getAsyncResponse](#) on page 2881
  - When available, returns the response produced by one of request methods.

- [Examples using com.HTTPRequest methods](#) on page 2891
  - These examples use methods of the `com.HTTPRequest` class.

**Syntax**

```java
removeHeader(
    name STRING
)
```

1. `name` defines the HTTP header name.

**Usage**

The `removeHeader()` method deletes an HTTP header identified by `name`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See *Error handling in GWS calls (STATUS)* on page 3554.

**Related concepts**

- [Examples using com.HTTPRequest methods](#) on page 2891
  - These examples use methods of the `com.HTTPRequest` class.

**Examples: Using the com.HTTPPart class** on page 2910
- Examples using methods of the `com.HTTPPart` class.

**Syntax**

```java
setAuthentication(
    login STRING,
    pass STRING,
    scheme STRING,
    realm STRING
)
```

1. `login` defines the login to use for authentication.
2. `pass` specifies the password to use for authentication.
3. `scheme` defines the method to be used during authentication. This is optional; it can be set to NULL.
4. `realm` defines the realm. This is optional; it can be set to NULL.
**Usage**

The `setAuthentication()` method defines the mandatory user login and password to authenticate to the server.

**Note:** If the server uses the Windows® NT (New Technology) LAN Manager (NTLM) protocol, authentication requires the request to keep the connection open via a call to `setKeepConnection(TRUE)`, otherwise authentication will fail.

The `scheme` parameter defines the method to be used during authentication. The supported values for the `scheme` parameter are `Anonymous`, `Basic`, `Digest`, and `NTLM`. The default is `Anonymous`.

An optional `realm` can be specified.

With `Anonymous`, `Digest`, or `NTLM` authentication, you must re-send the request if you get a 401 or 407 HTTP return code (authorization required). In the case of NTLM, the request must be re-sent one more time.

If a user-defined authentication is set and there is an `authenticate` entry for this URL in the FGLPROFILE file, the user-defined authentication has priority.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

Examples using `com.HTTPRequest` methods on page 2891

These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2910

Examples using methods of the `com.HTTPPart` class.

`com.HTTPRequest.setAutoCookies`

Enables automatic cookie management for a given request.

**Syntax**

```java
setAutoCookies(val INTEGER)
```

1. `val` defines the cookie management flag.

**Usage**

Set to `TRUE` to activate automatic cookie management.

If set to `TRUE`, it activates the automatic cookies management for that request. For the `com.HTTPRequest` instance:

- If the server returns session cookies (with no expiration date), they will be automatically sent again for the next request.
- If the server returns persistent cookies (with an expiration date), those cookies will be registered globally for the current `fglrn` process, and any other `HTTPRequest` (including the current one) will automatically send those cookies according to the request path and domain, as long as the expiration date has not expired.

The `autocookiesmanagement` option of the `com.WebServiceEngine.SetOption` on page 2837 method activates the automatic cookies management for any `HTTPRequest`.

The `maximumpersistentcookies` option of the `com.WebServiceEngine.SetOption` on page 2837 method sets the maximum number of cookies that can be handled by an `fglrn` process.

Default value is `FALSE`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
com.HTTPRequest.setAutoReply

Defines the auto reply option for response methods.

Syntax

```plaintext
setAutoReply( 
  val INTEGER )
```

1. `val` defines auto-reply when `TRUE`.

Usage

The `setAutoReply()` method defines whether `getResponse()` or `getAsyncResponse()` will automatically perform another HTTP GET request if the response contains HTTP Authentication, Proxy Authentication or HTTP redirect data.

Available for GET method and the HTTP HEAD method.

The default is `TRUE`.

**Important:** On iOS devices, `setAutoReply()` is ignored for redirection in synchronous requests. The iOS HTTP stack does not allow you to set an auto reply option when doing synchronous requests.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts

- `com.HTTPRequest.getResponse` on page 2882
  Waits for and returns the response produced by one of request methods.
- `com.HTTPRequest.getAsyncResponse` on page 2881
  When available, returns the response produced by one of request methods.
- Examples using `com.HTTPRequest methods` on page 2891
  These examples use methods of the `com.HTTPRequest` class.

com.HTTPRequest.setCharset

Defines the charset used when sending text or XML.

Syntax

```plaintext
setCharset( 
  charset STRING )
```

1. `charset` defines the character set to use.

Usage

Defines the character set used when sending an HTTP request.

By default, no character set information will be transmitted in the HTTP header. This is also the case when specifying `NULL` as parameter for this method.

If no character set is specified in HTTP headers, ISO8859-1 will implicitly be used as defined by the HTTP standards.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts

Localization on page 512
Localization support allows you to implement programs that follow specific language and cultural rules.

Examples using com.HTTPRequest methods on page 2891
These examples use methods of the com.HTTPRequest class.

com.HTTPRequest.setConnectionTimeOut
Defines the timeout for the establishment of the connection.

Syntax

```
setConnectionTimeOut(
    timeout INTEGER
)
```

1. `timeout` defines the number of seconds.

Usage

The `setConnectionTimeOut()` method sets the time value in seconds to wait for the establishment of the connection, before a break.

The value of -1 means infinite wait.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts

Examples using com.HTTPRequest methods on page 2891
These examples use methods of the com.HTTPRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPRequest.setHeader
Sets an HTTP header for the request.

Syntax

```
setHeader(
    name STRING,
    value STRING
)
```

1. `name` defines the HTTP header name.
2. `value` defines the HTTP header value.

Usage

The `setHeader()` method defines an HTTP header with a `name` and `value` for the request.

If a header exists with the same name, it is replaced with the new value.

Setting a header after the body has been sent, or if a streaming operation has been started, will not take effect. It will only be set when a new request is reissued.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

  These examples use methods of the `com.HTTPRequest` class.
- Examples: Using the `com.HTTPPart` class on page 2910
  Examples using methods of the `com.HTTPPart` class.

**com.HTTPRequest.setKeepConnection**
Defines whether a connection is kept open if a new request occurs.

**Syntax**

```java
setKeepConnection(
  keep INTEGER )
```

1. `keep` defines if the connection is kept.

**Usage**
The `setKeepConnection()` method defines whether the connection stays open when a new HTTP request occurs.

The default is `FALSE`.

**Note:** If the server uses the Windows® NT (New Technology) LAN Manager (NTLM) protocol, authentication requires the request to keep the connection open via a call to `setKeepConnection(TRUE)`, otherwise authentication will fail.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**
- Examples using `com.HTTPRequest` methods on page 2891
  These examples use methods of the `com.HTTPRequest` class.
- Examples: Using the `com.HTTPPart` class on page 2910
  Examples using methods of the `com.HTTPPart` class.

**com.HTTPRequest.setMaximumResponseLength**
Defines the maximum size in Kbytes of a response.

**Syntax**

```java
setMaximumResponseLength(
  length INTEGER )
```

1. `length` defines the maximum size in Kbytes.

**Usage**
The `setMaximumResponseLength()` method sets the maximum authorized size in Kbytes of the whole response (including headers, body and all control characters), before a break.

The value of -1 means no limit.
Note: Setting the maximum response length is ignored for synchronous requests in a Genero Mobile for iOS (GMI) app. The iOS HTTP stack does not allow you to set a maximum response length when doing synchronous requests.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts
Examples using com.HTTPRequest methods on page 2891
These examples use methods of the com.HTTPRequest class.
Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPRequest.setMethod
Sets the HTTP method of the request.

Syntax

```
setMethod(
    method STRING
)
```

1. `method` defines the HTTP method of the request.

Usage

The `setMethod()` method defines the HTTP method of the request.

Supported methods are GET, PUT, POST, HEAD, and DELETE.

The default is GET.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts
Examples using com.HTTPRequest methods on page 2891

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPRequest.setMultipartType
Switch HTTPRequest in multipart mode of a given type.

Syntax

```
setMultipartType(
    type STRING,
    start STRING,
    boundary STRING
)
```

1. `type` defines one of the following:
   - form-data: Browser Xform with attachment
   - mixed: Parts are independent
   - related: Parts are dependent (Required for SOAP)
   - alternative: Parts are different types of the same document
   - or any other type
   - NULL: switch multipart mode off
2. *start* defines the Content-ID value of root multipart document. (optional)
3. *boundary* defines a string used as multipart boundary. (optional)

**Usage**

Switch HTTPRequest in multipart mode of a given type. Calling one of the standard request methods will send the HTTP request as the given multipart type, even if no other part has been set.

**Important:** Multipart HTTP requests are not supported on GMI mobile devices.

The root HTTP part is the part handled via the standard HTTPRequest methods such as `doTextRequest()`, `doXmlRequest()`, `doDataRequest()` and `beginXmlRequest()`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

Examples using com.HTTPRequest methods on page 2891
These examples use methods of the com.HTTPRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

**Syntax**

```java
setProxy(
    host STRING,
    port INTEGER )
```

1. *host* defines the host of the proxy.
2. *port* defines the port number of the proxy.

**Usage**

Defines the proxy URL to be used for the current HTTPRequest request. Even if a proxy URL is configured in FGLPROFILE, the proxy set by the `setProxy()` method will be used.

If `proxy_host` is NULL or `proxy_port` is < 0, error -15535 (Invalid parameter) is raised.

If `proxy_host` is unreachable, error -15579 (COM_PROXY_ERROR) is raised.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

Examples using com.HTTPRequest methods on page 2891
These examples use methods of the com.HTTPRequest class.

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPRequest.setProxyAuthentication
Define the login and password to use for proxy authentication.

Syntax

```
setProxyAuthentication (  
  login STRING,  
  password STRING,  
  scheme STRING,  
  realm STRING )
```

1. `login` defines the login to use for authentication.
2. `password` specifies the password to use for authentication.
3. `scheme` defines the method to be used during authentication. This is optional; it can be set to NULL.
4. `realm` defines the realm. This is optional; it can be set to NULL.

Usage

Defines the login and password to use for proxy authentication for the current `HTTPRequest` request.

The `scheme` parameter defines the method to be used during authentication. The supported values for the `scheme` parameter are `Anonymous`, `Basic`, `Digest`, and `NTLM`. The default is `Anonymous`.

If `setProxy()` is called, the login and password will be used to authenticate against the proxy set by this API, regardless of whether a proxy is configured in FGLPROFILE.

If `setProxy()` has not been called and a proxy is configured in FGLPROFILE, the login and password set by this method will be used to authenticate against the proxy defined by FGLPROFILE.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts

Examples using `com.HTTPRequest` methods on page 2891
These examples use methods of the `com.HTTPRequest` class.

Examples: Using the `com.HTTPPart` class on page 2910
Examples using methods of the `com.HTTPPart` class.

c.com.HTTPRequest.setTimeOut
Defines the timeout for a reading or writing operation.

Syntax

```
setTimeOut (  
  timeout INTEGER )
```

1. `timeout` defines the number of seconds.

Usage

The `setTimeOut()` method defines a delay in seconds, to wait for an HTTP request read or write operation. If the operation is not terminated after the timeout, it returns immediately with an error.

Use the value of -1 to define an infinite timeout.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
Related concepts

com.HTTPRequest.setVersion
Sets the HTTP version of the request.

Syntax

```plaintext
define
      setVersion ( version STRING )
```

1. `version` defines the HTTP version of the request.

Usage
The `setVersion()` method defines the HTTP version of the request.

Accepted versions are 1.0 and 1.1 (only these two versions are supported).

The default is 1.1.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

HTTP request cookie management

The com.HTTPResponse class provides an interface to perform XML and TEXT responses over HTTP, with additional XML streaming possibilities, on the client side.

The STATUS variable is set to zero after a successful method call.
*com.HTTPResponse methods*
Methods for the `com.HTTPResponse` class.

**Table 623: Object methods**

<tbody>
<tr>
<td><code>getServerCookies(cookies RECORD)</code></td>
<td>Returns all cookies set as response from a server.</td>
</tr>
</tbody>
</table>

com.HTTPResponse.beginXmlResponse
Starts a streaming HTTP response.

**Syntax**

```java
beginXmlResponse()
RETURNS xml.StaxReader
```

**Usage**

The `beginXmlResponse()` method starts a streaming HTTP response and returns a `xml.StaxReader` object ready to read XML from the server.

The Content-Type header must be of the form */xml or */+xml. For example: application/xhtml+xml. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

com.HTTPResponse.endXmlResponse
Performs the HTTP request.

**Syntax**

```java
endXmlResponse()
```
1. *stax* defines an *xml.StaxReader* object used to read the HTTP response.

**Usage**

The `endXmlResponse()` method ends the streaming HTTP response by closing the *xml.StaxReader* object that was created with the `beginXmlResponse()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 3554).

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see [Interruption handling in GWS calls (INT_FLAG)](page 3555).

**com.HTTPResponse.getDataResponse**

- Returns the entire HTTP response in a BYTE.

**Syntax**

```java
getDataResponse ( 
    b BYTE )
```

1. `b` defines a BYTE variable receiving the HTTP response data.

**Usage**

The `getDataResponse()` method returns the body of an HTTP response into a BYTE variable.

The BYTE variable must be located in memory, otherwise operation fails.

Returns binary data as response from a server into a BYTE.

Previous content is discarded.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 3554).

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see [Interruption handling in GWS calls (INT_FLAG)](page 3555).

**com.HTTPResponse.getFileResponse**

- Returns the entire HTTP response to a file on the disk.

**Syntax**

```java
getFileResponse ( )
RETURNS STRING
```

**Usage**

Reads an HTTP response and creates a file from it.

The method returns the absolute path to the file containing the HTTP response.

The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file is the basename found in the HTTP Content-Disposition Header. If this basename is not specified, the file name is created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form: `/tmp/ABC/filename_index.ext`, where `index` represents the number of files with the same name on disk.
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

The \texttt{INT\_FLAG} variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (\texttt{INT\_FLAG}) on page 3555.

\begin{verbatim}
com.HTTPResponse.getHeader
Returns the value of an HTTP header.

\textbf{Syntax}

\begin{verbatim}
getHeader ( name STRING )
  RETURNS STRING
\end{verbatim}

1. \texttt{name} is the name of the parameter that defines the HTTP header.

\textbf{Usage}

The \texttt{getHeader()} method returns the value of the HTTP header specified by the \texttt{name} parameter, or \texttt{NULL} if not found.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

com.HTTPResponse.getHeaderCount
Returns the number of headers.

\textbf{Syntax}

\begin{verbatim}
getHeaderCount ()
  RETURNS INTEGER
\end{verbatim}

\textbf{Usage}

The \texttt{getHeaderCount()} method returns the number of headers of the HTTP response.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

com.HTTPResponse.getHeaderName
Returns the name of a header by position.

\textbf{Syntax}

\begin{verbatim}
getHeaderName ( pos INTEGER )
  RETURNS STRING
\end{verbatim}

1. \texttt{pos} specifies the ordinal position of the header.

\textbf{Usage}

The \texttt{getHeaderName()} method returns the name of the HTTP response header depending on the position passed as parameter.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.HTTPResponse.getHeaderValue
Returns the value of a header by position.

**Syntax**

```java
getHeaderValue ( 
   pos INTEGER )
RETURNS STRING
```

1. *pos* specifies the ordinal position of the header.

**Usage**

The `getHeaderValue()` method returns the value of the HTTP response header based on the position passed as parameter.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.HTTPResponse.getMultipartType
Returns whether a response is multipart or not, and the kind of multipart if any.

**Syntax**

```java
getMultipartType ()
RETURNS STRING
```

**Usage**

Returns whether a response is multipart or not, and the kind of multipart if any.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

Examples: Using the com.HTTPPart class on page 2910
Examples using methods of the com.HTTPPart class.

com.HTTPResponse.getPartCount
Returns the number of additional parts in the HTTP response.

**Syntax**

```java
getPartCount ()
RETURNS INTEGER
```

**Usage**

Returns the number of additional parts in the HTTP response. The root part element must be handled via `getXmlResponse().getTextResponse().getDataResponse()` and `beginXmlResponse()`. In other words, there are `getPartCount() +1` parts if `getMultipartType()` does not return NULL.
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

**Related concepts**
- Examples: Using the \texttt{com.HTTPPart} class on page 2910
- Examples using methods of the \texttt{com.HTTPPart} class.

\texttt{com.HTTPResponse.getPart}

Returns the HTTP part object at the specified index of the current HTTP response.

**Syntax**

\begin{verbatim}
getPart (  
pos INTEGER )  
RETURNS \texttt{com.HTTPPart}
\end{verbatim}

1. \texttt{pos} is the input parameter that specifies the index number.

**Usage**

Returns the HTTP part object at the specified index of the current HTTP response.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

Can raise error -15554 (Index is out of bounds).

**Related concepts**
- Examples: Using the \texttt{com.HTTPPart} class on page 2910
- Examples using methods of the \texttt{com.HTTPPart} class.

\texttt{com.HTTPResponse.getPartFromContentID}

Returns the HTTP part object marked with the given Content-ID value as identifier, or NULL if none.

**Syntax**

\begin{verbatim}
getPartFromContentID (  
id STRING )  
RETURNS \texttt{com.HTTPPart}
\end{verbatim}

1. \texttt{id} defines the HTTP header.

**Usage**

Returns the HTTP part object marked with the given Content-ID value as identifier, or NULL if none.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

\texttt{com.HTTPResponse.getServerCookies}

Returns all cookies set as response from a server.

**Syntax**

\begin{verbatim}
getServerCookies (  
cookies RECORD )
\end{verbatim}
1. *cookies* defines the dynamic array of all cookies sent as a response from a server. See WSHelper variables and records on page 3500 for more information regarding WSServerCookiesType.

**Usage**

This method returns all cookies set as response from a server, in a dynamic array. All cookies are returned, even those that have already expired.

If the method `setAutoCookies()` is enabled, cookies are automatically send back if they have not expired. In other words, the `setAutoCookies(true)` handles all cookies for you; however, you can still check them with the `getServerCookies()` method if needed.

If `setAutoCookies(false)` (the default), you must handle the cookies and not send the expired ones.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

This method may raise exception -15535 if the given dynamic array is not a dynamic array of RECORD with seven (7) members as defined by WSHelper.WSServerCookiesType.

**Related concepts**

- com.HTTPRequest.setAutoCookies on page 2884
  Enables automatic cookie management for a given request.

- com.HTTPResponse.getStatusCode
  Returns the HTTP status code.

  **Syntax**

  ```java
  getStatusCode()
  RETURNS INTEGER
  ```

  **Usage**

  The `getStatusCode()` method returns the status code for the HTTP response.

  When the returned HTTP status code is 401 or 407, authorization is required.

  In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

  **Related concepts**

  - com.HTTPRequest.setAuthentication on page 2883
    Defines the user login and password to authenticate to the server.

- com.HTTPResponse.getStatusDescription
  Returns the HTTP status description.

  **Syntax**

  ```java
  getStatusDescription()
  RETURNS STRING
  ```

  **Usage**

  The `getStatusDescription()` method returns a description of the HTTP response status.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.HTTPResponse.getTextResponse
Returns the entire HTTP response in a string.

**Syntax**

```java
getTextResponse ()
   RETURNS STRING
```

**Usage**

The `getTextResponse()` method returns a HTTP response as an entire string.

- The Content-Type header can be of the form */* or */*. For example: application/json.
- Automatic conversion to the locale charset is performed when possible, otherwise throws an exception.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

com.HTTPResponse.getXmlResponse
Returns the entire HTTP response in a DOM document.

**Syntax**

```java
getXmlResponse ()
   RETURNS xml.DomDocument
```

**Usage**

The `getXmlResponse()` method returns an HTTP response in a `xml.DomDocument` object.

The Content-Type header must be of the form */xml or *//*+xml. For example: application/xhtml+xml.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

**Examples**

Examples using methods of the `com.HTTPResponse` class.

For examples, see Examples using `com.HTTPRequest` methods on page 2891.

**The HTTPPart class**

The `com.HTTPPart` class provides an interface to manage the HTTP attachment sent or received in HTTP.

The STATUS variable is set to zero after a successful method call.
**com.HTTPPart methods**
Methods for the `com.HTTPPart` class.

**Table 626: Class methods of com.HTTPPart**

<tr>
<td>setHeader( name STRING, value STRING )</td>
<td>Setter to handle HTTP multipart headers.</td>
</tr>
</tbody>
</table>

com.HTTPPart.CreateFromString

Creates a new HTTPPart object based on given string.

**Syntax**

```
CreateFromString(
    str STRING )
RETURNS com.HTTPPart
```

1. `str` specifies a string value.

**Usage**

Creates a new HTTPPart object based on given string. To be used via the `addPart()` method.

Defaults HTTP multipart headers:

- Content-Type: text/plain
- Content-Transfer-Encoding: 8bits

Notice that the string will be converted during request sending into ISO-8859-1 by default, unless a different charset has been set via `setHeader("Content-Type","text/plain; charset=UTF-8")` for instance.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.HTTPPart.CreateFromDomDocument
Creates a new HTTPPart object based on given XML document.

**Syntax**

```java
CreateFromDomDocument (doc xml.DomDocument )
RETURNS com.HTTPPart
```

1. `doc` specifies an XML document.

**Usage**

Creates a new HTTPPart object based on given XML document. To be used via the `addPart()` method.

Defaults HTTP multipart headers:

- Content-Type: text/xml; charset=UTF-8
- Content-Transfer-Encoding: 8bits

A different charset can be set with the `setHeader` method. For example, `setHeader("Content-Type","text/plain; charset=ISO-8859-1")` sets the charset to ISO-8859-1.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

- **com.HTTPPart.setHeader** on page 2909
  Setter to handle HTTP multipart headers.

com.HTTPPart.CreateFromData
Creates a new HTTPPart object based on given BYTE located in memory.

**Syntax**

```java
CreateFromData (b BYTE )
RETURNS com.HTTPPart
```

1. `b` defines a BYTE object located in memory.

**Usage**

Creates a new HTTPPart object based on given BYTE located in memory. To be used via the `addPart()` method.

Defaults HTTP headers:

- Content-Type: application/octet-stream
- Content-Transfer-Encoding: binary

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.HTTPPart.CreateAttachment
Creates a new HTTPPart object based on a given file name located on disk.

**Syntax**

```java
CreateAttachment(
    filename STRING )
RETURNS com.HTTPPart
```

1. *filename* specifies the name of a file.

**Usage**

Creates a new HTTPPart object based on a given file name located on disk. To be used via the `addPart()` method.

The `com.HTTPPart.CreateAttachment()` method automatically sets the following headers for the created HTTPPart object:

- **Content-Type** is defined based on the file name extension. If the file extension is not recognized, `Content-Type` defaults to `application/octet-stream`.
  
  **Note:** File extensions to `Content-Type` mapping can be customized in the file `$FGLDIR/lib/wse/mime.cfg`.

- **Content-Transfer-Encoding** is set to "binary".

- **Content-Disposition** is set with the base name of the given `filename` as follows: `attachment; filename="basename"`.

For example, when calling the method as follows:

```java
LET part = com.HTTPPart.CreateAttachment( "/opt/myapp/resources/logo.jpg" )
```

The resulting HTTP part headers will look like:

```
Content-Type: image/jpeg
Content-Transfer-Encoding: binary
Content-Disposition: attachment; filename="logo.jpg"
```

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

- Examples: Using the `com.HTTPPart` class on page 2910
- Examples using methods of the `com.HTTPPart` class.

**clearHeaders**

Remove all headers from the HTTP part.

**Syntax**

```java
clearHeaders()
```

**Usage**

This method removes all headers from an HTTP multipart object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
Example

```call
CALL req.clearHeaders()
```

Related concepts

- com.HTTPPart.removeHeader on page 2909
  - Remove the header of given name from the current HTTPPart object.

- com.HTTPPart.getAttachment
  - Returns the absolute path to the HTTP part.

Syntax

```call
getAttachment ()
RETURNS STRING
```

Usage

Returns the absolute path location of the received part file.

The file is created in the temporary directory used by the runtime system (DBTEMP). The name of the file is the basename found in the HTTP Content-Disposition Header. If this basename is not specified, the file name is created with a UUID. If a file with the same name already exists in the temporary directory, the API prefixes the new file with a number. It is then of the form: `/tmp/ABC/filename_index.ext`, where `index` represents the number of files with the same name on disk.

If the file is encoded in base64, you can use the Genero Web Services `fglpass -dec64` command to convert it back to binary.

It is up to the programmer to remove the file from the disk when it is no longer needed.

To be used via methods: com.HTTPResponse.getPart on page 2900, com.HTTPResponse.getPartCount on page 2899, and com.HTTPResponse.getPartFromID on page 2900

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

- com.HTTPPart.getContentAsData
  - Returns the HTTP part as a BYTE.

Syntax

```param
getContentAsData ( 
  b BYTE )
```

1. `b` defines a variable holding the BYTE data.

Usage

Returns the HTTP part as a BYTE. BYTE data cannot be returned from a function with a RETURN statement. Therefore, the `b` parameter must be handled by reference.

To be used via methods: com.HTTPResponse.getPart on page 2900, com.HTTPResponse.getPartCount on page 2899, and com.HTTPResponse.getPartFromID on page 2900

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The `error -15573` is raised if the part cannot be converted to a Genero BYTE.
com.HTTPPart.getContentAsDomDocument
Returns the HTTP part as an XML document.

Syntax
```
getContentAsDomDocument ()
  RETURNS xml.DomDocument
```

Usage
Returns the HTTP part as an XML document.

To be used via methods: com.HTTPResponse.getPart on page 2900, com.HTTPResponse.getPartCount on page 2899, and com.HTTPResponse.getPartFromID on page 2900

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The error -15573 is raised if the part cannot be converted to a XML DomDocument.

com.HTTPPart.getContentAsString
Returns the HTTP part as a string.

Syntax
```
getContentAsString ()
  RETURNS STRING
```

Usage
Returns the HTTP part as a string.

To be used via methods: com.HTTPResponse.getPart on page 2900, com.HTTPResponse.getPartCount on page 2899, and com.HTTPResponse.getPartFromID on page 2900

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The error -15573 is raised if the part cannot be converted to a Genero string or if the charset is not supported.

com.HTTPPart.getHeader
Setter to handle HTTP multipart headers.

Syntax
```
getHeader ()
  name STRING
  RETURNS STRING
```

1.  name specifies the name of the header part.

Usage
Getter to handle HTTP multipart headers.

The method returns the value for the header part specified by name.

Note: In case of related multipart (i.e., the part is multipart/related and set via the com.HTTPRequest.setMultipartType("related",NULL,NULL)), it is mandatory
to set a unique Content-ID header. To set up a unique Content-ID header, you can use the
security.RandomGenerator.CreateUUIDString on page 3128 method for that.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Example

```
LET val = req.getHeader("MyClientHeader")
```

Related concepts

com.HTTPPart.setHeader on page 2909
Setter to handle HTTP multipart headers.

com.HTTPPart.removeHeader
Remove the header of given name from the current HTTPPart object.

Syntax

```
removeHeader (  
    name STRING  )
```

1. `name` is the name of the header to remove.

Usage

With an HTTP multipart object, the "Content-Type" header may be optional for each part:

```
https://tools.abc.org/html/rfc1234#section-1.1
```

A request might be rejected by some providers if the "Content-Type" header is set for a part. This method allows you to remove headers from an HTTPPart object based on the header name.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Example

```
CALL req.removeHeader("Content-Type")
```

Related concepts

com.HTTPPart.clearHeaders on page 2906
Remove all headers from the HTTP part.

com.HTTPPart.setHeader
Setter to handle HTTP multipart headers.

Syntax

```
setHeader (  
    name STRING,  
    value STRING  )
```

1. `name` specifies the multipart header name.
2. `value` specifies the multipart header value (such as HTTP headers).
Usage
Setter to handle HTTP multipart headers.

For instance, when you send a multipart image, it is recommended that you specify the image mime type with this header method. If the image is a .png, you have to do `part.setHeader("Content-Type","image/png")`, which allows the peer to know the format of the attached file it has to process.

**Note:** In case of related multipart (i.e., the part is multipart/related and set via the `com.HTTPRequest.setMultipartType("related",NULL,NULL)`), it is mandatory to set a unique Content-ID header. To set up a unique Content-ID header, you can use the `security.RandomGenerator.CreateUUIDString` on page 3128 method for that.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

Example

```java
CALL req.setHeader("MyClientHeader","Hello")
```

Related concepts

`com.HTTPPart.getHeader` on page 2908
Setter to handle HTTP multipart headers.

**Examples: Using the `com.HTTPPart` class**
Examples using methods of the `com.HTTPPart` class.

This example consists of two applications: a client and server exchanging an XML document in multipart with an image as an attachment.

**Client Application**

```java
IMPORT com
IMPORT xml

CONSTANT SERVER_URL = "http://localhost:8090/MultipartMixed/Sample"

MAIN

DEFINE req com.HTTPRequest
DEFINE resp com.HTTPResponse
DEFINE doc xml.DomDocument
DEFINE p com.HTTPPart
DEFINE type STRING
DEFINE ind INTEGER

LET req = com.HTTPRequest.Create(SERVER_URL)
CALL req.setMethod("POST")
CALL req.setHeader("MyClientHeader","Hello")
TRY
  # Set multipart type
  CALL req.setMultipartType("mixed",NULL,NULL)
  # Add filename as part
  LET p = com.HTTPPart.CreateAttachment("my_picture.png")
  # Set attachment Content-Type
  CALL p.setHeader("Content-Type","image/png")
  # Add part to the request
  CALL req.addPart(p)
  # Perform XML request
```
CALL req.doXmlRequest(doc)
# Check response
LET resp=req.getResponse()
IF resp.getStatusCode() != 200 THEN
  DISPLAY "HTTP Error ("||resp.getStatusCode()||") ",
  resp.getStatusDescription()
  EXIT PROGRAM (-1)
END IF
IF resp.getStatusDescription() != "OK" THEN
  DISPLAY "HTTP Error ("||resp.getStatusCode()||") ",
  resp.getStatusDescription()
  EXIT PROGRAM (-1)
END IF
# Check whether multipart response or not
LET type = resp.getMultipartType()
IF type IS NULL THEN
  DISPLAY "Failed : Expected multipart in response"
  EXIT PROGRAM (-1)
ELSE
  DISPLAY "Response is multipart of ":,type
END IF
# Check response
LET doc = resp.getXmlResponse()
IF doc IS NULL THEN
  DISPLAY "Expected XML document as response"
  EXIT PROGRAM (-1)
ELSE
  DISPLAY "Response is ":,doc.saveToString()
END IF
# Process additional parts
FOR ind = 1 TO resp.getPartCount()
  LET p = resp.getPart(ind)
  IF p.getAttachment() IS NOT NULL THEN
    DISPLAY "Attached file at ":,p.getAttachment()
  ELSE
    DISPLAY "Attached part is ":,p.getContentAsString()
  END IF
END FOR
CATCH
  DISPLAY "unexpected exception ":,STATUS," ("||SQLCA.SQLERRM||")"
END TRY
END MAIN

Server Application

IMPORT com
IMPORT xml
MAIN
DEFINE req com.HTTPServiceRequest
DEFINE url STRING
DEFINE method STRING
DEFINE doc xml.DomDocument
DEFINE type STRING
DEFINE ind INTEGER

<tr>
<td><code>setTimeOut(timeout INTEGER)</code></td>
<td>Defines the time out for read/write operations.</td>
</tr>
</tbody>
</table>

**Syntax**

```java
com.TCPRequest.beginXmlRequest
   Starts a streaming XML request.
```

```java
beginXmlRequest()
   RETURNS `xml.StaxWriter`
```
**Usage**

The `beginXmlRequest()` method begins a streaming HTTP request and returns an `xml.StaxWriter` object ready to send XML to the server.

After sending all the XML data to the server, you must call the `endXmlRequest()` method with the `xml.StaxWriter` object created by the `beginXmlRequest()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

**com.TCPRequest.Create**

Creates a new TCP request object.

**Syntax**

```java
com.TCPRequest.Create(
    uri STRING )
RETURNS com.TCPRequest
```

1. `uri` specifies the URL of the TCP request.

**Usage**

This class method creates a new `com.TCPRequest` object based on the URL passed as parameter.

The URL must use the TCP or TCPS protocol. Examples of valid URLs include:

- `tcp://localhost:4242/`
- `tcps://localhost:4343/`

The URL can be an identifier of an URL mapping with an optional `alias://` prefix. See FGLPROFILE configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**com.TCPRequest.doDataRequest**

Performs the request by sending binary data.

**Syntax**

```java
doDataRequest(
    data BYTE )
```

1. `data` defines the binary data to be send for a TCP request. The `data` variable must be located IN MEMORY.

**Usage**

Performs the TCP request by sending binary data contained in the `BYTE` variable.

**Note:** The `data` variable must be located IN MEMORY.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**com.TCPRequest.doRequest**
Performs a TCP request.

**Syntax**

```java
doRequest ()
```

**Usage**

The `doRequest()` method performs the TCP request.

The connection is shutdown for writing, to confirm that no data will be sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

**Example**

```java
IMPORT com
IMPORT XML

MAIN
  DEFINE url STRING
  LET url = "tcp://localhost:4242"
  CALL an_example(url)
END MAIN

FUNCTION an_example(url)
  DEFINE url STRING
  DEFINE req com.TCPRequest
  DEFINE resp com.TCPResponse
  DEFINE ret xml.DomDocument
  TRY
    LET req = com.TCPRequest.create(url)
    CALL req.doRequest()
    LET resp = req.getResponse()
    LET ret = resp.getXmlResponse()
  CATCH
    DISPLAY "ERROR : ", STATUS, SQLCA.SQLERRM
    EXIT PROGRAM(-1)
  END TRY
END FUNCTION
```

**com.TCPRequest.doXmlRequest**

Performs a request with a DOM document.

**Syntax**

```java
doXmlRequest (  
  doc xml.DomDocument  )
```

1. `doc` specifies the DOM document describing the request.
**Usage**

The `doXmlRequest()` method performs the TCP request by using the information defined in the `xml.DomDocument` object passed as parameter.

The connection is shutdown for writing, to confirm that no data will be sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

```
com.TCPRequest.doTextRequest
Performs a request with a string.
```

**Syntax**

```
doTextRequest ( str STRING )
```

1. `str` defines the string describing the request.

**Usage**

The `doTextRequest()` method performs the TCP request by using the information defined in the string passed as parameter.

The connection is shutdown for writing, to confirm that no data will be sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

```
com.TCPRequest.endXmlRequest
Terminates a streaming TCP request.
```

**Syntax**

```
endXmlRequest ( stax xml.StaxWriter )
```

1. `stax` specifies the `xml.StaxWriter` object used for streaming.

**Usage**

The `endXmlRequest()` method terminates a streaming TCP request performed with the `xml.StaxWriter` object that was created by the `beginXmlRequest()` method.

The connection is shutdown for writing, to confirm that no data will be sent.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

```
com.TCPRequest.getResponse
```
Returns the response after performing a TCP request.

Syntax

```java
getResponse()
RETURNS com.TCPResponse
```

Usage

The `getResponse()` method returns a TCP response as a `com.TCPResponse` object, after a call to `doRequest()`, `doXmlRequest()`, `doTextRequest()`, or `beginXmlRequest() / endXmlRequest()` calls.

A call to this method will stop the program flow until the response is received.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

com.TCPRequest.getAsyncResponse

Returns the response after performing a TCP request, asynchronously.

Syntax

```java
getAsyncResponse()
RETURNS com.TCPResponse
```

Usage

The `getAsyncResponse()` method returns a TCP response as a `com.TCPResponse` object, after a call to `doRequest()`, `doXmlRequest()`, `doTextRequest()`, or `beginXmlRequest() / endXmlRequest()` calls.

Unlike `getResponse()`, the `getAsyncResponse()` method does not stop the program flow: The method returns `NULL` if the response was not yet received.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

com.TCPRequest.setTimeOut

Defines the time out for read/write operations.

Syntax

```java
setTimeout (timeout INTEGER )
```

1. `timeout` specifies a time out value in seconds.

Usage

This method defines a value in seconds to wait for a read or write operation to complete, before a break.
If the time out is set to -1, it waits indefinitely.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.TCPRequest.setConnectionTimeOut
Defines the connection time out.

**Syntax**

```
setConnectionTimeOut(
  timeout INTEGER )
```

1. `timeout` specifies a time out value in seconds.

**Usage**

This method defines the time in seconds to wait for a connection, before a break.

If the time out is set to -1, it waits indefinitely.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.TCPRequest.setKeepConnection
Defines if the TCP connection is kept open after sending a request.

**Syntax**

```
setKeepConnection(
  keep INTEGER )
```

1. `keep` indicates if the TCP connection must be kept open.

**Usage**

This method can be used to force the TCP socket to remain open after a send operation, in order to perform subsequent do*Request() calls, without closing the connection (in write mode).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

com.TCPRequest.setMaximumResponseLength
Defines the maximum size in Kbyte of the response.

**Syntax**

```
setMaximumResponseLength(
  length INTEGER )
```

1. `length` specifies the max size of a response in Kbytes.

**Usage**

This method sets the maximum authorized size in Kbyte of the whole response, before a break.

A length of -1 defines no limit.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The TCPResponse class
The com.TCPResponse class provides an interface to perform XML and TEXT responses over TCP, with additional XML streaming possibilities.

Important: This Web Services class is not supported on GMI mobile devices.

com.TCPResponse methods
Methods of the com.TCPResponse class.

Table 630: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>beginXmlResponse()</td>
<td>Starts a streaming TCP response.</td>
</tr>
<tr>
<td></td>
<td>RETURNS xml.StaxReader</td>
</tr>
<tr>
<td>endXmlResponse()</td>
<td>Ends a streaming TCP response.</td>
</tr>
<tr>
<td></td>
<td>stax xml.StaxReader</td>
</tr>
<tr>

<td></td>
<td>RETURNS STRING</td>
</tr>
<tr>
<td>getXmlResponse()</td>
<td>Returns an entire DOM document as TCP response.</td>
</tr>
<tr>
<td></td>
<td>RETURNS xml.DomDocument</td>
</tr>
</tbody>
</table>

com.TCPResponse.beginXmlResponse
Starts a streaming TCP response.

Syntax

beginXmlResponse()
RETURNS xml.StaxReader

Usage

 Begins the streaming TCP response and returns an xml.StaxReader object ready to read XML from the server.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

com.TCPResponse.endXmlResponse
Ends a streaming TCP response.

**Syntax**

```java
endXmlResponse(  
    stax xml.StaxReader  )
```

1. `stax` defines the `xml.StaxReader` object created with `beginXmlResponse()`.

**Usage**

Terminates the streaming TCP response identified by the `xml.StaxReader` object passed as parameter. This object must have been created with the `beginXmlResponse()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

**com.TCPResponse.getDataResponse**

Returns a TCP response in binary format.

**Syntax**

```java
dataGetResponse(  
    data BYTE  )
```

1. `data` defines a `BYTE` variable that will hold the response data in binary format. The `BYTE` variable must be located IN MEMORY.

**Usage**

This method retrieves the TCP response in binary format into the `data` variable passed as parameter. The method will read the TCP stream, until the peer closes the connection.

**Note:** The `data` variable must be located IN MEMORY.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

The `INT_FLAG` variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555.

**com.TCPResponse.getTextResponse**

Returns a TCP response in string format.

**Syntax**

```java
getTextResponse()  
    RETURNS STRING
```

**Usage**

This method returns a complete streaming TCP response from the server as a string.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555

com.TCPResponse.getTransaction
Returns an entire DOM document as TCP response.

Syntax

getXmlResponse()
RETURNS xml.DomDocument

Usage

This method returns a complete xml.DomDocument as streaming TCP response from the server.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

The INT_FLAG variable is checked during GWS API call to handle program interruptions, for more details, see Interruption handling in GWS calls (INT_FLAG) on page 3555

Helper classes

The Helper classes provide utility classes.

- The Util class on page 2922

The Util class

The com.Util class provides static helper methods.

This class does not have to be instantiated.

Important: This Web Services class is not supported on GMI mobile devices.

com.Util methods

Methods of the com.Util class.

Table 631: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>com.Util.UniqueApplicationInstance(file STRING)</td>
<td>Checks that the calling application is the only one to run.</td>
</tr>
<tr>
<td>_returns INTEGER</td>
<td></td>
</tr>
</tbody>
</table>

com.Util.UniqueApplicationInstance
Checks that the calling application is the only one to run.

Syntax

com.Util.UniqueApplicationInstance(file STRING)
>Returns INTEGER

1. file specifies the string for the lock file.
Usage
This method checks that the calling application is the only one to run, by trying to get an exclusive lock on the given
file.

If the lock could be set, the method returns TRUE. Otherwise, it returns FALSE and updates STATUS with an error
code.

Specific classes
Several classes support specific features.

• The APNS class on page 2923

The APNS class
The com.APNS class implements Apple® Push Notification Service APIs.

The com.APNS class implements a set of methods to build and handle push messages to be broadcast by the Apple
Push Notification service.

Related concepts
Apple Push Notification Service (APNs) on page 3625
Follow this procedure to implement push notification with APNs.

APNs SSL/TLS certificate
Get and configure an SSL/TLS certificate to establish secure connections to the Apple Push Notification service.

Basics
The Apple® Push Notification Certificate identifies the push notification service for a given mobile app. This
certificate is created from an App ID (also known as Bundle ID) and is used by the APNs system to dispatch the
notification message to the registered devices.

You can create two types of APN certificates for a given App ID:

• Sandbox (for development and test purpose)
• Production (for deployment)

An APNS push notification provider or an APNS feedback handler needs to establish a secure connection to Apple's
APNs server.

Get an APNs certificate for your app
In this section we will produce the myapp.cer file and myapp-key.p12 file.

To create an Apple® Push Notification Certificate:

1. Log in to Apple's Member Center with you iOS developer or enterprise account.
2. Select Certificates, Identifiers & Profiles.
3. Under App IDs, make sure that you have created an App ID with the Push Notification service enabled, for
development and/or distribution.
4. Under Certificates, select the + symbol.
5. Select Apple® Push Notification service SSL (Sandbox) for development, or Apple® Push Notification service
SSL (Sandbox & Production) for production.
6. Choose the App ID with push notifications service enabled.
7. Follow the instructions to create a Certificate Signing Request (CSR) file from your Mac, then click Continue.
8. Back in the web browser and IOS Certificate page, upload the CSR file you have generated.
9. Generate the certificate.
10. Once the certificate is generated, download it. The certificate will be downloaded into your Downloads folder, as a
    .cer file (for example, myapp.cer).
11. Double-click this file to import the certificate into the Mac® Keychain®.
12. The new certificate is now listed in the Certificates list.
13. Open your Keychain® app and locate the certificate you created, export the private key in p12 format (for example, myapp-key.p12). Note that you will be asked for a password to encode the .p12 file, and for your session password, to exported Keychain® files.

**Configure Genero to use the APNs certificate**

On the Genero push provider server, you will need the public certificate (myapp.crt file) and the private key (myapp-key.pem file) for your app. These files will be referenced in the security.global.certificate and security.global.privatekey entries of FGLPROFILE.

In order to authenticate the APNs server, you will also need the root certificate authority (apple_entrust_root_certification_authority.pem), that can be downloaded from Apple's web site. This file will be referenced by the security.global.ca entry in FGLPROFILE.

**Note:** When executing on a Mac, the root certificate (security.global.ca entry) is not required: The Web Services library reads the Keystore of the Mac® computer, to authenticate the APNs server.

Create the myapp.crt file (public certificate) from the myapp.cer file, with the openssl x509 command:

```
$ openssl x509 -in myapp.cer -inform der -out myapp.crt
```

Convert the myapp-key.p12 file (containing the private key) to a myapp-key.pem format, with the openssl pkcs12 command:

```
$ openssl pkcs12 -nocerts -in myapp-key.p12 -out myapp-key.pem
```

**Note:** You need to enter the passphrase for the .p12 file so that openssl can read it. Then you need to enter a new passphrase that will be used to encrypt the .pem file.

The FGLPROFILE entry security.global.privatekey expects unencrypted private key files. Therefore, you need to remove the passphrase from the myapp-key.pem file, with the openssl rsa command:

```
$ openssl rsa -in myapp-key.pem -out myapp-key-noenc.pem
```

Set up your FGLPROFILE with the appropriate **security.* entries:**

```
security.global.ca                   = "apple_entrust_root_certification_authority.pem"
security.global.certificate        = "myapp.crt"
security.global.privatekey          = "myapp-key-noenc.pem"
```

In the above example:

1. apple_entrust_root_certification_authority.pem is the HTTPS root certificate authenticating the APNs server (if the computer is not a Mac).
2. myapp.crt is the public certificate for your app.
3. myapp-key-noenc.pem is the unencrypted private key file for your app.

**Note:** If you want to keep the private key encrypted, you need to configure a password agent, as described in Using the password agent
**com.APNS methods**

Methods of the **com.APNS** class.

**Table 632: Class methods**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>com.APNS.DecodeError</strong> (data BYTE)</td>
<td>Decodes content of BYTE data returned from the APNS server in case of error.</td>

<td><strong>com.APNS.EncodeMessage</strong> (data BYTE, deviceIdBase64 STRING, json STRING, uuidBase64 STRING, expiration INTEGER, priority INTEGER)</td>
<td>Encodes an APNS specific push notification message into a BYTE.</td>
</tr>
<tr>
<td>Returns INTEGER</td>
<td></td>
</tr>
</tbody>
</table>

**com.APNS.DecodeError**

Decodes content of BYTE data returned from the APNS server in case of error.

**Syntax**

```java
com.APNS.DecodeError(data BYTE)
RETURNS (uuid STRING, error INTEGER)
```

1. *data* is the BYTE variable containing the error data. This BYTE variable must be located IN MEMORY.
2. *uuid* is a Base64 encoded string containing the push notification identifier.
3. *error* is the APNS error code returned by the server.

**Usage**

This method decodes the content of the BYTE variable passed as a parameter and received as response for a push notification message in the event of an error from the APNs server.

**Note:** This BYTE variable must be located IN MEMORY.

The *uuid* is a binary value that identifies the push notification message. It is returned as a Base64-encoded string.

The *error* returned value defines the APNs error code. For example, error will be set to 10 if the APNs server was shutdown. See the Apple® Push Notification Service error reference for more details.

In the case of a decoding error, the method will raise the exception -15566, with details in the SQLCA.SQLERRM register.

**Example**

```sql
DEFINE error_data BYTE,
    uuid STRING,
```
error INTEGER
LOCATE error_data IN MEMORY

-- Send push notification message TCP request
...
CALL req.doDataRequest(data)
LET resp = req.getResponse()
TRY
  CALL resp.getDataResponse(error_data)
  CALL com.APNS.DecodeError(error_data)
RETURNING uuid, ecode
...

For a complete example, see APNs push provider on page 2929.

com.APNS.DecodeFeedback
Decodes content of BYTE data returned from the APNS feedback service.

Syntax

com.APNS.DecodeFeedback(
  data BYTE,
  unregs RECORD
)

1.  data defines a BYTE variable containing the feedback data. This BYTE variable must be located IN MEMORY.
2.  unregs defines a structured dynamic array that contains the list of unregistered device tokens.
   a. timestamp is the number of seconds since UNIX® Epoch (in UTC)
   b.  deviceToken is an APNS device token that has been unregistered (encoded in Base-64)

Usage

Apple® recommends connecting frequently to the APNS feedback server in order to verify that your applications are still registered for push notifications.

To get APNS feedback, you must perform a TCP request (using SSL/TLS), to the following specific URI:

tcps://feedback.push.apple.com:2196

The DecodeFeedback() method decodes the content of the BYTE variable, which was passed as a parameter and received as response for the TCP request to the APNS feedback server.

Note: This BYTE variable must be located IN MEMORY.

For the second parameter, this method takes a structured dynamic array that will be filled with the list of unregistered APNS device tokens. It is up to the push program to stop sending push notification messages for these unregistered device tokens.

The timestamp member of an unregs dynamic array element can be used to verify that device tokens have not been re-registered since the feedback entry was generated. This timestamp is returned as a number of seconds since the UNIX® epoch, in UTC. Use the util.Datetime.fromSecondsSinceEpoch on page 2730 utility API to convert timestamp to a DATETIME value in the current local time.

The deviceToken member of an unregs dynamic array element identifies iOS devices that have been unregistered from the APNS server. Note that these identifier is encoded in Base64.

In the event of a decoding error, the method will raise the exception -15566, with details in the SQLCA.SQLERRM register.
Example

DEFINE feedback_data BYTE,
   unregs DYNAMIC ARRAY OF RECORD
      timestamp  INTEGER,
      deviceToken STRING
   END RECORD,
   i INTEGER

LOCATE feedback_data IN MEMORY

... TCP request to APNS feedback server ...

CALL com.APNS.DecodeFeedback(feedback_data, unregs)

FOR i=1 TO unregs.getLength()
   DISPLAY i, " ", unrefs[i].deviceToken
END FOR

For a complete example, see APNs feedback handler on page 2930.

com.APNS.EncodeMessage

Encodes an APNS specific push notification message into a BYTE.

Syntax

com.APNS.EncodeMessage (      
data BYTE, 
   deviceIdBase64 STRING, 
   json STRING, 
   uuidBase64 STRING, 
   expiration INTEGER, 
   priority INTEGER)       
RETURNS INTEGER

1. data defines a BYTE variable holding the APNs message. This BYTE variable must be located IN MEMORY.
2. deviceIdBase64 defines an APNs device token (encoded in Base-64).
3. json defines a JSON string containing the APNs push message data.
4. uuidBase64 defines the 4 bytes-long push message identifier (encoded in Base64).
5. expiration defines a number of seconds since UNIX® Epoch defining the expiration date of the message.
6. priority defines an integer as the priority of the message.

Usage

This method builds the APNS push notification message into a BYTE variable, for a given device token.

Note: This BYTE variable must be located IN MEMORY.

Note: The size of an APNs notification payload cannot exceed 2 Kilobytes. Make sure that the resulting BYTE variable does not exceed this size limitation. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The APNS push notification message protocol requires some binary data to be encoded in the message content before it is sent to the APNS server with a TCP (over SSL/TLS) request, to specific URIs, namely:

• "tcps://gateway.sandbox.apple.com:2195" (for development)
• "tcps://gateway.push.apple.com:2195" (for production)

You need to provide several parameters in order to build the push notification message:
The `deviceToken` parameter is an APNS device token encoded in Base-64. It's used to identify the target device that must receive the push message. The device token identifies a single iOS device: If you have N devices registered to your push notification provider, you will have N different device tokens. If you want to send one push notification message to all the devices, you must send N different messages, where the only difference between the messages is the device token.

**Note:** It's in your hands to handle the list of registered device tokens. A device token is assigned to a physical iOS device when the mobile app issues a `registerForRemoteNotifications` call. The app must then provide its device token to the push provider program using a method such as a web service mechanism.

Fill the `json` parameter with a JSON string containing the APNS push message data. For example:

```plaintext
LET json = '{"aps":{"alert":"Hello, world","sound":"default","badge":1,"content-available":1}}'
```

See APNS documentation for more details about the JSON content of a message.

The `uuid` parameter is the 4 bytes-long push message identifier, encoded in Base64. This parameter can be used later to identify the message in push notification errors (`com.APNS.DecodeError` on page 2925). This parameter can be `NULL`. To create the `uuid` parameter, use the `security.RandomGenerator.CreateRandomString` API, with a size of 4:

```plaintext
LET uuid = security.RandomGenerator.createRandomString(4)
```

The `expiration` parameter is a number of seconds since UNIX® Epoch. It defines the expiration date of the message if it cannot be sent by the APNS server to the target devices. This parameter can be `NULL`, to indicate that there is no expiration date:

```plaintext
LET dt = CURRENT + INTERVAL (10) MINUTE TO MINUTE
LET expiration = util.Datetime.toSecondsSinceEpoch(dt)
```

The `priority` parameter can be used to define a priority for the push notification message. Typically, use a value of 10 for immediate, 5 for delayed. This parameter can be `NULL`. See APNS documentation for more details.

If there's an encoding error, the method will raise the exception `-15566`, with details in the `SQLCA.SQLERRM` register.

**Example**

```plaintext
DEFINE push_data BYTE,
    deviceTokenHexa STRING,
    dt DATETIME YEAR TO FRACTION(3),
    expiration INTEGER,
    json_data STRING,
    uuid STRING

LOCATE push_data IN MEMORY

LET deviceTokenHexa = "84e3................."

LET dt = CURRENT + INTERVAL (10) MINUTE TO MINUTE
LET expiration = util.Datetime.toSecondsSinceEpoch(dt)

LET json_date = util.JSON.stringify(...)
LET uuid = security.RandomGenerator.createRandomString(4)

CALL com.APNS.EncodeMessage(
    push_data,
    security.HexBinary.ToBase64(deviceTokenHexa),
    json_data,
    uuid,
```
IF LENGTH(push_data) > 2000 THEN
   -- Must reduce the message content...
   RETURN FALSE
END IF

-- Do the TCP request with the push_data variable

For a complete example, see APNs push provider on page 2929.

**APNs examples**

**APNs push provider**

The `com.APNS` class can be used to implement an APNs push provider.

The following code example implements a push program using the `com.APNS` API to send a notification message to devices by using the TCP request API. See also `com.APNS methods` on page 2925 for more details about the APNs API.

**Note:** An SSL/TLS certificate needs to be defined in FGLPROFILE, as described in APNs SSL/TLS certificate on page 2923.

**Note:** The size of the resulting BYTE variable containing the APNS payload cannot exceed 2 Kilobytes.

**Important:** In order to check that the push message was properly handled by the APNs server, you need to define a TCP request timeout (2 seconds in this example). In case of error, the APNs server will return a response immediately. In case of success, there is no response from the APNs server. For more details about this protocol, see Apple's APNs documentation.

```
IMPORT com

Apple Push Notification Service (APNs) on page 3625
Follow this procedure to implement push notification with APNs.

APNs feedback handler

The com.APNS class can be used to implement a server application to query the APNs feedback service.

Implement an APNs feedback handler to get a list of unregistered device tokens in order to stop sending push notification messages to these apps.

Note: An SSL/TLS certificate needs to be defined in FGLPROFILE, as described in APNs SSL/TLS certificate on page 2923.
LET req = com.TCPRequest.create( "tcps://feedback.push.apple.com:2196" )
CALL req.setKeepConnection(true)
CALL req setTimeout(2)
CALL req.doRequest()
LET resp = req.getResponse()
CALL resp.getDataResponse(data)
DISPLAY "Feedback service has responded"
CALL com.APNS.DecodeFeedback(data, feedback)
FOR i=1 TO feedback.getLength()
    LET timestamp =
        util.Datetime.fromSecondsSinceEpoch(feedback[i].timestamp)
        DISPLAY "Device Token :", feedback[i].deviceToken, " Timestamp :",
        timestamp
END FOR
CATCH
    CASE STATUS
        WHEN -15553 DISPLAY "Timeout: No feedback message"
        WHEN -15566 DISPLAY "Operation failed :", SQLCA.SQLERRM
        WHEN -15564 DISPLAY "Server has shutdown"
        OTHERWISE DISPLAY "ERROR :", STATUS
    END CASE
END TRY
END MAIN

Related concepts
Implementing a token maintainer on page 3631
The token maintainer is a BDL Web Services server program that handles push token registration from mobile apps.

The xml package
The Genero Web Services XML package provides classes and methods to handle any kind of XML documents, including documents with namespaces.

The library provides a W3C-compatible DOM API, integrating additional XML Schema and DTD validation methods. There is also an API compatible with StAX for writing or reading XML documents where performance and speed are important.

Use the IMPORT statement at the top of the module using this library:

IMPORT xml

Note: The DOM API of the om package is designed to handle specific FGL files and to manipulate the user interface tree (the AUI tree). For all other cases, we recommend that you use the DOM API of the Web Services xml package.

The Document Object Modeling (DOM) classes
The Document Object Modeling (DOM) classes manage XML documents entirely in memory with support for XML Schema and DTD validation.

The DomDocument class
The xml.DomDocument class provides methods to manipulate a data tree, following the DOM standards.

The STATUS variable is set to zero after a successful method call.
**xml.DomDocument methods**
Methods for the xml.DomDocument class.

</tr>
<tr>
<td>xml.DomDocument.create</td>
<td></td>
</tr>
</tbody>
</table>
Constructor of an empty DomDocument object.

Syntax

```java
xml.DomDocument.create()
RETURNS xml.DomDocument
```

Usage

Constructor of an empty DomDocument object.

Returns a DomDocument object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Example

Create a DomDocument without a root node:

```java
xml.domDocument.create()
```

Create a DomDocument with an initial root node named ARoot:

```java
xml.domDocument.create("ARoot")
```

xml.DomDocument.createAttribute

Creates a XML Attribute DomNode object for a DomDocument object.

Syntax

```java
createAttribute( 
   elt STRING ) 
RETURNS xml.DomNode
```

1. `elt` defines the name of the XML attribute.

Usage

Creates a XML Attribute DomNode object for a DomDocument object, where `elt` is the name of the XML attribute. It cannot be NULL.

Returns the XML element DomNode object, or NULL.

To create a default namespace declaration attribute use xmlns as the name. (Using declareNamespace instead is recommended)

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.createAttributeNS

Creates a XML namespace-qualified Attribute DomNode object for a DomDocument object.

Syntax

```java
createAttributeNS( 
   prefix STRING, 
   elt STRING, 
   ns STRING )
```
RETURNS xml.DomNode

1. *prefix* defines the prefix of the XML attribute.
2. *elt* defines the name of the XML attribute.
3. *ns* defines the namespace URI of the XML attribute.

**Usage**

Creates a XML namespace-qualified Attribute DomNode object for this DomDocument object where *prefix* is the prefix of the XML attribute, it cannot be NULL; *elt* is the name of the XML attribute; it cannot be NULL; *ns* is the namespace URI of the XML attribute, it cannot be NULL.

Returns the XML element DomNode object, or NULL.

To create a namespace declaration attribute use *xmlns* as the prefix and http://www.w3.org/XML/1998/namespace as the namespace. Using declareNamespace instead is recommended.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.createCDATASection

Creates an XML CDATA DomNode object for a DomDocument object.

**Syntax**

```
cREATECDATASECTION(  
data STRING  )  
RETURNS xml.DomNode
```

1. *data* defines the data of the XML CDATA node.

**Usage**

Creates a XML CDATA DomNode object for this DomDocument object, where *data* is the data of the XML CDATA node, or NULL.

Returns the XML element DomNode object, or NULL.

Only the characters #x9, #xA, #xD, [#x20-#xD7FF], [#xE000-#xFFFD] and [#x10000-#x10FFFF] are allowed in the content of an XML CDATASection node.

The character sequence (Double-Hyphen) ‘--’ is not allowed in the content of a XML CDATASection node. The save and normalize methods will fail if the sequence of characters other than those allowed exist in a CDATASection node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.createComment

Creates a XML Comment DomNode object for a DomDocument object.

**Syntax**

```
cREATECOMMENT(  
cmt STRING  )  
RETURNS xml.DomNode
```

1. *cmt* defines the data of the XML Comment node.
Usage

Creates a XML Comment DomNode object for this DomDocument object, where \textit{cmt} is the data of the XML Comment node, or NULL.

Returns the XML element DomNode object, or NULL.

Only the characters 
$\#x9$, \$\#xA$, \$\#xD$, \$[\#x20-\#xD7FF]$, \$[\#xE000-\#xFFFD]$ and \$[\#x10000-\#x10FFFF]$ are allowed in the content of an XML Comment node.

The character sequence (Double-Hyphen) ‘--’ is not allowed in the content of a XML CDATASection node.

The \texttt{save} and \texttt{normalize} methods will fail if the sequence of characters other than those allowed exist in a CDATASection node.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

\texttt{xml.DomDocument.createDocument}

Constructor of a DomDocument with a XML root element.

Syntax

\begin{verbatim}
xml.DomDocument.createDocument(
   name STRING
) RETURNS xml.DomDocument
\end{verbatim}

1. \texttt{name} defines the XML element.

Usage

Constructor of a \texttt{xml.DomDocument} with a XML root element; where \texttt{name} is the name of the XML Element.

Returns a \texttt{xml.DomDocument} object or NULL.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

\texttt{xml.DomDocument.createDocumentFragment}

Creates a XML Document Fragment DomNode object for a DomDocument object.

Syntax

\begin{verbatim}
createDocumentFragment ()
RETURNS xmlDOMNode
\end{verbatim}

Usage

Creates a XML Document Fragment DomNode object for this DomDocument object.

Returns the XML element DomNode object, or NULL.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

\texttt{xml.DomDocument.createDocumentNS}
Constructor of a DomDocument with a root namespace-qualified XML root element

Syntax

```javascript
xml.DomDocument.createDocumentNS(
    prefix STRING,
    name STRING,
    ns STRING )
RETURNS xml.DomDocument
```

1. `prefix` defines the prefix of the XML Element or NULL.
2. `name` defines the XML element.
3. `ns` is the namespace of the XML Element.

Usage

Constructor of a `xml.DomDocument` with a root namespace-qualified XML root element where `prefix` is the prefix of the XML element or NULL, `name` is the name of the XML element, and `ns` is the namespace of the XML element. Returns a `xml.DomDocument` object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

Example

Create a DomDocument with an initial root node named "List" with `abc` as the prefix and `http://www.mysite.com/xmlapi` as the namespace:

```javascript
xml.domdocument.createDocumentNS("abc","List","http://www.mysite.com/xmlapi")
```

Produces:

```xml
<abc:List xmlns:abc="http://www.mysite.com/xmlapi">
[...]
</abc:List>
```

`xml.DomDocument.createDocumentType`

Creates a XML Document Type (DTD) DomNode object for a DomDocument object.

Syntax

```javascript
createDocumentType( 
    name STRING,
    publicID STRING,
    systemID STRING,
    internalSubset STRING )
RETURNS xml.DomNode
```

1. `name` defines the name of the document type.
2. `publicID` defines the URI of the public identifier.
3. `systemID` defines the URL of the system identifier (Specifies the file location of the external DTD subset).
4. `internalSubset` defines the internal DTD subset.
Usage

Creates a XML Document Type (DTD) DomNode object for this DomDocument object; name is the name of the document type; publicID is the URI of the public identifier or NULL; systemID is the URL of the system identifier or NULL (Specifies the file location of the external DTD subset); internalSubset is the internal DTD subset or NULL.

Returns a xml.DomNode object, or NULL if internalSubset is malformed.

Important: This method is not part of W3C standard API.

Only internal DTDs are supported.

The public identifier cannot be set without the system identifier.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.createElement

Creates a XML Element DomNode object for a DomDocument object

Syntax

```javascript
createElement ( 
  elt STRING ) 
RETURNS xml.DomNode
```

1. elt defines the name of the XML element.

Usage

Creates a XML Element DomNode object for this DomDocument object, where elt is the name of the XML element, which cannot be NULL.

Returns the XML element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.createElementNS

Creates a XML namespace-qualified Element DomNode object for a DomDocument object.

Syntax

```javascript
createElementNS ( 
  prefix STRING, 
  elt STRING, 
  ns STRING ) 
RETURNS xml.DomNode
```

1. prefix defines the prefix of the XML element, or NULL to use the default namespace.
2. elt defines the name of the XML element.
3. ns defines the namespace URI of the XML element.

Usage

Creates a XML namespace-qualified Element DomNode object for this DomDocument object, where prefix is the prefix of the XML element, or NULL to use the default namespace. elt is the name of the XML element, this cannot be NULL. ns is the namespace URI of the XML element, this cannot be NULL.

Returns the XML element DomNode object, or NULL.
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3554.

\texttt{xml.DomDocument.createEntityReference}

Creates a XML EntityReference \texttt{DomNode} object for a \texttt{DomDocument} object

\textbf{Syntax}

\begin{verbatim}
createEntityReference(
    entity STRING )
RETURNS xml.DomNode
\end{verbatim}

1. \textit{entity} defines the name of the entity reference.

\textbf{Usage}

Creates a XML EntityReference \texttt{DomNode} object for this \texttt{DomDocument} object, where \textit{entity} is the name of the entity reference.

Returns the XML element \texttt{DomNode} object, or NULL.

An Entity Reference node is read-only and cannot be modified.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3554.

\texttt{xml.DomDocument.createNode}

Creates a XML \texttt{DomNode} object from a string for a \texttt{DomDocument} object.

\textbf{Syntax}

\begin{verbatim}
createNode(
    str STRING )
RETURNS xml.DomNode
\end{verbatim}

1. \textit{str} defines the string representation of the \texttt{DomNode} to be created.

\textbf{Usage}

Creates a XML \texttt{DomNode} object from a string for this \texttt{DomDocument} object; \textit{str} is the string representation of the \texttt{DomNode} to be created.

Returns the XML element \texttt{DomNode} object, or NULL.

\textbf{Important}: This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3554.

\texttt{xml.DomDocument.createProcessingInstruction}

Creates a XML Processing Instruction \texttt{DomNode} object for this \texttt{DomDocument} object.

\textbf{Syntax}

\begin{verbatim}
createProcessingInstruction(
    target STRING, 
    data STRING )
RETURNS xml.DomNode
\end{verbatim}
1. **target** defines the target part of the XML Processing Instruction.
2. **data** defines the data part of the XML Processing Instruction.

**Usage**

Creates a XML Processing Instruction DomNode object for this DomDocument object, where **target** is the target part of the XML Processing Instruction, cannot be NULL; **data** is the data part of the XML Processing Instruction, or NULL.

Returns the XML element DomNode object, or NULL.

Only the characters #x9, #xA, #xD, [#x20-#xD7FF], [#xE000-#xFFFFD] and [#x10000-#x10FFFF] are allowed in the content of an XML Processing Instruction node.

The character sequence (Double-Hyphen) ‘--’ is not allowed in the content of an XML Processing Instruction. The **save()** and **normalize()** methods will fail if this sequence or characters other than those allowed exist in a Processing Instruction node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomDocument.createTextNode**

Creates a XML Text DomNode object for a DomDocument object.

**Syntax**

```sql
createTextNode( 
    txt STRING 
) RETURNS xml.DomNode
```

1. **txt** defines the data of the XML Text node.

**Usage**

Creates a XML Text DomNode object for this DomDocument object, where **txt** is the data of the XML Text node, or NULL.

Returns the XML element DomNode object, or NULL.

Only the characters #x9, #xA, #xD, [#x20-#xD7FF], [#xE000-#xFFFFD] and [#x10000-#x10FFFF] are allowed in the content of an XML Text node. The **save()** and **normalize()** methods will fail if characters other than those allowed exist in a Text node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomDocument.declareNamespace**

Forces namespace declaration to a XML Element DomNode for a DomDocument object.

**Syntax**

```sql
declareNamespace( 
    node xml.DomNode, 
    alias STRING, 
    ns STRING )
```

1. **node** defines the XML Element DomNode that carries the namespace definition.
2. **alias** defines the alias of the namespace to declare.
3. **ns** defines the URI of the namespace to declare.
Usage
Forces namespace declaration to a XML Element **DomNode** for this DomDocument object; *node* is the XML Element DomNode that carries the namespace definition; *alias* is the alias of the namespace to declare, or NULL to declare the default namespace; *ns* is the URI of the namespace to declare (can only be NULL if alias is NULL).

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.getDocumentElement
Returns the root XML Element DomNode object for this DomDocument object.

**Syntax**

```java
getElement() 
RETURNS xml.DomNode
```

Usage
Returns the root XML Element DomNode object for this DomDocument object.

Returns the XML element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.getDocumentNodesCount
Returns the number of child DomNode objects for a DomDocument object.

**Syntax**

```java
getDocumentNodesCount() 
RETURNS INTEGER
```

Usage
Returns the number of child DomNode objects in this DomDocument object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.getDocumentNodeItem
Returns the child DomNode object at a given position for this DomDocument object.

**Syntax**

```java
getNodeItem(index INTEGER) 
RETURNS xml.DomNode
```

1. *index* defines the position of the node to return (index starts at 1).
Usage

Returns the child xmlDOMNode object at a given position for this DomDocument object where index is the position of the node to return (index starts at 1), or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.getElementById

Returns the element that has an attribute of type ID with the given value.

Syntax

getElementById (id STRING)
RETURNS xmlDOMNode

1. id defines the Id value.

Usage

Use this method to return the xmlDOMNode element that has an attribute of type ID with the given value, or NULL if there is none.

Attributes with the name "ID" or "id" are not of type ID unless so defined with setIdAttribute or setIdAttributeNS. However, there is a specific attribute called xml:id belonging to the namespace http://www.w3.org/XML/1998/namespace that is always of type ID even if not set with setIdAttributeNS.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.getElementsByTagName

Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name in the entire document.

Syntax

getElementsByTagName (tag STRING)
RETURNS xmlDOMNodeList

1. tag defines the name of the XML Element tag to match or "*" to match all tags.

Usage

Use this method to return a DomNodeList object containing all XML Element DomNode objects with the same tag name in the entire document. The tag string contains the name of the XML Element tag to match, or use "*" to match all tags.

Returns a DomNodeList object, or NULL.

The returned list is ordered using a Depth-First pass algorithm.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.getElementsByTagNameNS
Returns a DomNodeList object containing all namespace qualified XML Element DomNode objects with the same tag name and namespace in the entire document.

**Syntax**

```vbnet
getElementsByTagNameNS (tag STRING, ns STRING )
RETURNS xml.DomNodeList
```

1. *tag* defines the name of the XML Element tag to match or "*" to match all tags.
2. *ns* defines the namespace URI of the XML Element tag to match, or "*" to match all namespaces.

**Usage**

Use this method to return a `xml.DomNodeList` object containing all namespace qualified XML Element DomNode objects with the same tag name and namespace in the entire document. The *tag* string contains the name of the XML Element tag to match, or use "*" to match all tags. *ns* is the namespace URI of the XML Element tag to match, or use "*" to match all namespaces.

Returns a `DomNodeList` object, or `NULL`. The returned list is ordered using a Depth-First pass algorithm.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Example error management**

```vbnet
FOR i=1 TO doc.getErrorsCount()  
  DISPLAY "[", i, "] ", doc.getErrorDescription(i)  
END FOR
```

Displays all the errors encountered in the save, load, or validate of the `doc` `DomDocument`.

To display other errors, use the global variable `STATUS` to get the error code and `err_get(status)` or `SQLCA.SQLERRM` to get the description of the error. See error code for more details.

**Syntax**

```vbnet
getErrorDescription (index INTEGER )
RETURNS STRING
```

1. *index* defines the position of the error description (index starts at 1).

**Usage**

This method returns the error description at the given position. *index* is the position of the error description (index starts at 1). It returns a string with an error description.

**Important:** This method is not part of W3C standard API.

**Example error management**

```vbnet
xml.DomDocument.getErrorDescription
```

Returns the error description at the given position.

**Syntax**

```vbnet
xml.DomDocument.getErrorDescription
```

Returns the error description at the given position.
Returns the number of errors encountered during the loading, saving or validation of a XML document.

**Syntax**

```java
getErrorsCount ()
RETURNS INTEGER
```

**Usage**

This method returns the number of errors encountered during the loading, saving, or the validation of a XML document.

Returns the number of errors, or zero if there are none.

**Important:** This method is not part of W3C standard API.

**Example error management**

```java
FOR i=1 TO doc.getErrorsCount()
    DISPLAY "[", i, "] ", doc.getErrorDescription(i)
END FOR
```

Displays all the errors encountered in the save, load, or validate of the `doc` DomDocument.

To display other errors, use the global variable STATUS to get the error code and `err_get (status)` or `SQLCA.SQLERRM` to get the description of the error. See error code for more details.

**xml.DomDocument.getFirstDocumentNode**

Returns the first child DomNode object for a DomDocument object.

**Syntax**

```java
getFirstDocumentNode ()
RETURNS xml.DomNode
```

**Usage**

Use this method to return the first child `xml.DomNode` object for this `DomDocument` object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomDocument.getFeature**

Gets a feature for a DomDocument object.

**Syntax**

```java
getFeature (property STRING)
RETURNS STRING
```

1. `property` is the name of the input parameter defining the name of a DomDocument feature.

**Usage**

This method returns the name of a feature for the `DomDocument` object, where `property` is the name of the `DomDocument` feature.

Returns the value of the feature.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.getLastDocumentNode

    Returns the last child DomNode object in a DomDocument object.

**Syntax**

```
getLastDocumentNode ()
RETURNS xml.DomNode
```

**Usage**

Use this method to return the last child xml.DomNode object in this DomDocument object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.getXmlEncoding

    Returns the document encoding as defined in the XML document declaration.

**Syntax**

```
getXmlEncoding ()
RETURNS STRING
```

**Usage**

This method returns the document encoding as defined in the XML document declaration, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.getXmlVersion

    Returns the document version as defined in the XML document declaration.

**Syntax**

```
getXmlVersion ()
RETURNS STRING
```

**Usage**

This method returns the document version as defined in the XML document declaration, which is 1.0. No other versions are supported.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.importNode

    Imports a DomNode from a DomDocument object into its new context (attached to a DomDocument object).

**Syntax**

```
importNode (
```

```
n xml.DomNode
  deep INTEGER )
RETURNS xml.DomNode

1. n defines the node to import.
2. deep defines a boolean identifying whether to import the node only or the node and all its child nodes.

Usage
Imports a xml.DomNode object from a DomDocument object into its new context (attached to this DomDocument object), where n is the node to import. When deep is FALSE only the node is imported; when TRUE the node and all its child nodes are imported.

Returns the xml.DomNode object that has been imported to this DomDocument, or NULL.

Document and Document Type nodes cannot be imported.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Inserts a child DomNode object before another child DomNode for this DomDocument object.

Syntax
insertBeforeDocumentNode (  
  newNode xml.DomNode,  
  ref xml.DomNode )

1. newNode defines the node to insert.
2. ref defines the reference node (the node before which the new node must be inserted).

Usage
Inserts a child xml.DomNode object before another child DomNode for this DomDocument object; newNode is the node to insert, ref is the reference node (the node before which the new node must be inserted).

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node, and one Document Type node allowed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.insertAfterDocumentNode
Inserts a child DomNode object after another child DomNode in a DomDocument object.

Syntax
insertAfterDocumentNode (  
  newNode xml.DomNode,  
  ref xml.DomNode )

1. newNode defines the node to insert.
2. ref defines the reference node (the node after which the new node must be inserted).
**Usage**

Inserts a child `xml.DomNode` object after another child `DomNode` in this `DomDocument` object; `newNode` is the node to insert; `ref` is the reference node (the node after which the new node must be inserted).

**Important:** This method is not part of W3C standard API.

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node, and one Document Type node allowed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomDocument.isXmlStandalone**

Checks whether the XML standalone attribute is set in the XML declaration.

**Syntax**

```
isXmlStandalone()  RETURNS INTEGER
```

**Usage**

Use this method to check if the XML standalone attribute is set in the XML declaration or not. It returns `TRUE` if set to yes, `FALSE` if not.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomDocument.load**

Loads a XML Document into a `DomDocument` object from a file or an URL.

**Syntax**

```
load(filename STRING )
```

1. `filename` defines a valid URL or the name of the file.

**Usage**

This method loads a XML Document into a `DomDocument` object from a file or an URL, where `filename` is a valid URL or the name of the file.

Use `setFeature()` to specify how the document can be loaded. HTML parsing is possible when `enable-html-compliancy` is enabled.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

**Note:** When loading a document, if `xml.DomNode` objects are still referenced in other variables of the program, the entire document is kept in memory. Otherwise, the DOM nodes of the document are deleted before loading the new document. For more details about object references and garbage collection in BDL, see Working with objects on page 571.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Important:** On Mac® OS X versions prior to 10.9, the libxml library (used by Genero Web Services classes) has a bug when parsing HTML documents. If you set the HTML compliancy option with CALL doc.setFeature("enable-html-compliancy",TRUE), loading an HTML document with xml.DomDocument.load() may produce additional blank TEXT nodes, because the libxml library loads some ignorable white-space nodes from the HTML document. Starting with Mac® OS X 10.9, the libxml library of the system has fixed this bug.

xml.DomDocument.loadFromPipe
Loads a XML Document into a DomDocument object from a PIPE.

**Syntax**

```
loadFromPipe(
    name STRING )
```

1. `name` defines the command to read from the PIPE.

**Usage**

Use this method to load a XML Document into a DomDocument object from a PIPE, where `name` is the command to read from the PIPE.

**Important:** This method is not part of W3C standard API.

Use `setFeature()` to specify how the document can be loaded. HTML parsing is possible when `enable-html-compliancy` is enabled.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

**Note:** When loading a document, if xml.DomNode objects are still referenced in other variables of the program, the entire document is kept in memory. Otherwise, the DOM nodes of the document are deleted before loading the new document. For more details about object references and garbage collection in BDL, see Working with objects on page 571.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.loadFromstring
Loads a XML Document into a DomDocument object from a string.

**Syntax**

```
loadFromString(
    xmlstr STRING )
```

1. `xmlstr` defines the string to load.

**Usage**

Use this method to load a XML Document into a DomDocument object from a string, where `xmlstr` is the string to load.

**Important:** This method is not part of W3C standard API.

Use `setFeature()` to specify how the document can be loaded. HTML parsing is possible when `enable-html-compliancy` is enabled.
See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

**Note:** When loading a document, if `xml.DomNode` objects are still referenced in other variables of the program, the entire document is kept in memory. Otherwise, the DOM nodes of the document are deleted before loading the new document. For more details about object references and garbage collection in BDL, see Working with objects on page 571.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

### `xml.DomDocument.normalize`  
Normalizes the entire Document.

**Syntax**

```java
normalize()
```

**Usage**

Normalizes the entire Document. This method merges adjacent text nodes, removes empty text nodes, and sets namespace declarations as if the document had been saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

### `xml.DomDocument.prependDocumentNode`  
Adds a child `xml.DomNode` object to the beginning of the `DomNode` children of a `DomDocument` object

**Syntax**

```java
prependDocumentNode (  
  n xml.DomNode  
)
```

1. `n` defines the node to add.

**Usage**

Adds a child `xml.DomNode` object to the beginning of the `DomNode` children in this `DomDocument` object; `n` is the node to add.

**Important:** This method is not part of W3C standard API.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

### `xml.DomDocument.removeDocumentNode`  
Removes a child `DomNode` object from the `DomNode` children in a `DomDocument` object

**Syntax**

```java
removeDocumentNode (  
  n xml.DomNode  
)
```

1. `n` defines the node to remove.
**Usage**

Removes a child DomNode object from the DomNode children in this DomDocument object, where \( n \) is the node to remove.

Only Text nodes, Processing Instruction nodes, Document Fragment nodes, one Element node, and one Document Type node allowed.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

```java
xml.DomDocument.save()
```

Saves a DomDocument object as a XML Document to a file or URL.

**Syntax**

```
save(
    filename STRING )
```

1. `filename` defines a valid URL or the name of a file.

**Usage**

Saves a DomDocument object as a XML Document to a file or URL, where `filename` is a valid URL or the name of the file.

Only the following kinds of URLs are supported:

- `http://`
- `https://`
- `tcp://`
- `tcps://`
- `file:///
- `alias://`

See fglprofile Configuration for more details about URL mapping with aliases, and for proxy and security configuration.

See `setFeature()` to specify how the document can be saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

```java
xml.DomDocument.saveToPipe()
```

Saves a DomDocument object as an XML Document to a PIPE.

**Syntax**

```
saveToPipe(
    name STRING )
```

1. `name` defines the command to start the pipe.

**Usage**

Saves a DomDocument object as a XML Document to a PIPE, where `name` is the command to start the pipe.

See `setFeature()` to specify how the document can be saved.
See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

```java
xml.DomDocument.saveToString
Saves a DomDocument object as a XML Document to a string.

Syntax
```saveToString()
RETURNS STRING```

Usage
Saves a DomDocument object as a XML Document to a string. Returns the string that will contain the resulting document.

**Important:** This method is not part of W3C standard API.

See `setFeature()` to specify how the document can be saved.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

```java
xml.DomDocument.selectByXPath
Returns a DomNodeList object containing all DomNode objects matching a XPath 1.0 expression.

Syntax
```selectByXPath(
   expr STRING,
   args ...)
RETURNS xml.DomNodeList```

1. `expr` defines the XPath1.0 expression
2. `args` defines a list of prefixes bound to namespaces in order to resolve qualified names in the XPath expression.

**Usage**
Returns a `xml.DomNodeList` object containing all DomNode objects matching a XPath 1.0 expression. `expr` is the XPath1.0 expression, `args` is a list of prefixes bound to namespaces in order to resolve qualified names in the XPath expression. This list must be filled with an even number of arguments, representing the prefix and its corresponding namespace.

**Important:** This method is not part of W3C standard API.

Valid example:
```java
selectByXPath("//d:Record",
   "d",
   "http://defaultnamespace")
selectByXPath(""/ns1:Record",
   NULL)
selectByXPath(""/ns1:Records/ns2:Record",
   ...)"
"ns1",
"http://namespace1",
"ns2",
"http://namespace2")

Invalid example:

```java
selectByXPath("//ns1:Record", "ns1")
```

This example is invalid because the namespace definition is missing.

If the namespaces list is NULL, the prefixes and namespaces defined in the document itself are used if available.

A namespace must be an absolute URI (for example, 'http://', 'file://').

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.setFeature
Sets a feature for a DomDocument object.

**Syntax**

```java
setFeature(
    property STRING,
    value STRING)
```

1. `property` is the name of the input parameter defining the name of a DomDocument feature.
2. `value` is the value of a feature.

**Usage**

Use this method to set a feature for the DomDocument object, where `property` is the name of a DomDocument feature, and `value` is the value of a feature.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.setXmlEncoding
Sets the XML document encoding in the XML declaration.

**Syntax**

```java
setXmlEncoding(
    encoding STRING)
```

1. `encoding` defines the XML document encoding.

**Usage**

Sets the XML document encoding in the XML declaration, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomDocument.setXmlStandalone
Sets the XML standalone attribute in the XML declaration to "yes" or "no" in the XML declaration, or removes the standalone attribute.

Syntax

```plaintext
setXmlStandalone(
    alone INTEGER )
```

1. `alone` defines a boolean flag.
   - `1` sets the standalone attribute to "yes".
   - `0` sets the standalone attribute to "no".
   - `-1` removes the standalone attribute.

Usage

This sample sets the standalone attribute to "no":

```plaintext
IMPORT XML
MAIN
    DEFINE doc xml.DomDocument
    LET doc = xml.DomDocument.Create()  
        CALL doc.setXmlStandalone(0)
    DISPLAY doc.saveToString()
END MAIN
```

The output displayed by the above example is

```xml
<?xml version="1.0" encoding="UTF-8" standalone="no"?>
```

This sample sets the standalone attribute to "yes":

```plaintext
IMPORT XML
MAIN
    DEFINE doc xml.DomDocument
    LET doc = xml.DomDocument.Create()  
        CALL doc.setXmlStandalone(1)
    DISPLAY doc.saveToString()
END MAIN
```

The output displayed by the above example is

```xml
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
```

This sample removes the standalone attribute:

```plaintext
IMPORT XML
MAIN
    DEFINE doc xml.DomDocument
    LET doc = xml.DomDocument.Create()  
        CALL doc.setXmlStandalone(-1)
    DISPLAY doc.saveToString()
END MAIN
```
The output displayed by the above example is 

```xml
<?xml version="1.0" encoding="UTF-8"?>.
```

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomDocument.validate**

Performs a DTD or XML Schema validation for a DomDocument object.

**Syntax**

```java
validate() 
RETURNS INTEGER
```

**Usage**

Performs a DTD or XML Schema validation for this DomDocument object. Returns the number of validation errors, or zero if there are none.

**Important:** This method is not part of W3C standard API.

See `setFeature()` to specify what kind of validation to do.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomDocument.validateOneElement**

Performs a DTD or XML Schema validation of a XML Element DomNode object.

**Syntax**

```java
validateOneElement( 
   elt xml.DomNode 
) 
RETURNS INTEGER
```

1. *elt* defines the XML element DomNode to validate.

**Usage**

Performs a DTD or XML Schema validation of a XML Element DomNode object; *elt* is the XML Element DomNode to validate.

Returns the number of validation errors, or zero if there are none.

**Important:** This method is not part of W3C standard API.

See `setFeature()` to specify what kind of validation to do.

See `getErrorsCount()` and `getErrorDescription()` to retrieve error messages related to XML document.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
**Navigation methods usage examples**

Examples using the navigation methods of the xml.DomDocument class.

DomDocument navigation functions deal with nodes immediately under the DomDocument object, except for search features. To navigate through all the nodes, you can refer to the navigation functions of the class xml.DomNode.

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
<?xml-stylesheet type="text/xsl" href="card.xsl"?>
<!-- demo card -->
<CardList xml:id="1" >[...]
</CardList>
```

In the example the first node of the document is xml-stylesheet. Use `getFirstDocumentNode` to get the node. The element at position 2 is the comment `<!-- demo card -->`. Use `getDocumentNodeItem` function to get the node.

The last node of the document is CardList. Use `getLastDocumentNode` to get the node.

The number of nodes in the document is 3. This is the result of the function `getDocumentNodesCount`. This function only counts the number of children immediately under the DomDocument.

**Note:** The first line of the example, `<?xml version="1.0" encoding="ISO-8859-1"?>`, is not considered as a node. To access the information of the first line, use `getXmlVersion()` and `getXmlEncoding` functions.

Caution, if the example is in pretty printed format, the results are not the same. There are additional text nodes representing the carriage returns.

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
<?xml-stylesheet type="text/xsl" href="card.xsl"?>
<!-- demo card -->
<CardList xml:id="1" > [...
</CardList>
```

See **Cautions** section for more details.

You can select nodes using their tag names, by XPath, or by their attributes value (if of type ID, xml:id for example). The `getElementsbyTagName` and `getElementsbyTagNameNS` methods return a DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is restricted to containing objects with the same tag name and/or namespace. The `selectByXPath` method also returns a DomNodeList object, but each node can have a different name.

```javascript
getElementsByTagNameNS("message","http://schemas.xmlsoap.org/wsd1/")
```

Get the message nodes that have `http://schemas.xmlsoap.org/wsd1/` as the namespace.

```javascript
getElementsByTagNameNS("message","*")
```

Get all the message nodes, regardless of the namespace they have.

```javascript
getElementsByTagName("message")
```

Get all the message nodes that do not have any namespace.

```javascript
selectByXPath("//xs:element",NULL)
```

Get all the xs:element nodes that have a namespace corresponding to the prefix `xs`.
Get all the Card nodes that do not have any namespace.

```javascript
getElementById("1")
```

Get the unique node whose attribute of type ID has a value of "1".

**Node creation methods usage examples**

Node creation methods usage examples for the `xml.DomDocument` class.

Creating a node for the `DomDocument` is done in two steps:

- Create the node.
- Add the node to the `DomDocument`.

Each time you create a node, you need to append it at the right place in the `DomDocument`. To add a node to the document use the `DomDocument` management methods or the `DomNode` manipulation methods.

```javascript
createNode("<LastName>PATTERSON</LastName><FirstName>Andrew</FirstName>")
```

Creates a structure of nodes.

```javascript
createElement("CardList")
```

Produces

```xml
<CardList/>
```

```javascript
createElementNS("cny", "Company", "http://www.mysite.com/")
```

```javascript
createAttribute("Country")
```

Creates a `Country` attribute node.

- To set a value to the attribute, use the method `setNodeValue` of the `xml.DomNode` class.
- To add the attribute to an element node, use the method `setAttributeNode` of the `xml.DomNode` class.

```javascript
createAttributeNS("tw","Town","http://www.mysite.com/cities")
```

Produces `xmlns:tw="http://www.mysite.com/cities" tw:Town=""`

- To set a value to the attribute use the method `setNodeValue` of the `xml.DomNode` class.
- To add the attribute to an element node use the method `setAttributeNodeNS` of the `xml.DomNode` class.
- For optimization reasons, the namespace is not written beside the attribute until the saving of the `DomDocument`.
- When accessing the element node, the namespace is not listed in the list of children. In the example above, `tw:Town=""` is in the list of children, not `xmlns:tw="http://www.mysite.com/cities"`.
- To access the namespace during the `DomDocument` building, use the method `normalize` first. Normalize writes the namespace declaration at the appropriate place. If there is no previous declaration, it will be accessible as an attribute of this element, otherwise it will be an attribute of one of the ancestors of the element.

```javascript
createTextNode("My Company")
```

Creates a text node.

```javascript
createComment("End of the card")
```
Produces <!--End of the card-->

createCDATASection("<website><a href="www.mysite.com">My Company</a></website>")

Produces <![CDATA[<website><a href="www.mysite.com">My Company</a></website>]]>

createEntityReference("title")

Creates the entity reference &title.

createProcessingInstruction("xml-stylesheet", "type="text/xsl" href="card.xsl""")

Produces <?xml-stylesheet type="text/xsl" href="card.xsl"?>

createDocumentType("Card", NULL, NULL,"<!ELEMENT Card (lastname, firstname, company, location)>")

Produces <!DOCTYPE Card [ <!ELEMENT Card (lastname, firstname, company, location)>]

• Only inline DTD are supported. The DTD has to been inserted in the DomDocument at an appropriate place.

createDocumentFragment

Is a method that creates a lightweight DomDocument. It represents a subtree of nodes that do not need to conform to well-formed XML rules. This makes DocumentFragment easier to manipulate than a DomDocument.

for i=1 to 5
  let node = doc.createElement("Card")
  call root.appendChild(node) end for

This produces a subtree with 5 Card nodes that do not have any root node. Once the subtree is completed, it can be added to the DomDocument object like any other node.

**HTML document usage example**
The HTML language provides tags that allow the user to provide an embedded style sheet (the "style" tag) and to write embedded client side script (the "script" tag). According to the HTML 4.0 specification, the content of these tags must be managed as CDATA section.

**Note:** For more information, see the HTML 4.0 specification.

Because HTML document management via the xml.DomDocument object provides HTML compliancy only (and not strict HTML management), there is a specific way to add these nodes inside a loaded HTML document:

1. Create an element node with the name of the tag to be created.
2. Append the element node to its parent.
3. Create a CDATASection node with the required embedded piece of style sheet or piece of script content.
4. Append the CDATASection node to the previously-created element node.

By following this procedure, the "script" and "style" tags content are recognized as CDATA section content and not TEXT section content and will be preserved. Other methods for adding nodes to the document manage text and therefore will not treat these types of content properly, resulting in invalid HTML code.

**Example**

```ruby
IMPORT xml
MAIN
  DEFINE myDoc xml.DomDocument
  DEFINE myEltNode, myAttrNode, bodyNode, myCdataNode xml.DomNode
```
DEFINE nodeLst xml.DomNodeList
TRY
LET myDoc = xml.DomDocument.create()
CALL myDoc.setFeature("enable-html-compliancy", 1)
CALL myDoc.load("testHtml.html")
LET myEltNode = myDoc.createElement("script")
LET myCdataNode = myDoc.createCDATASection("document.write("CDATA");")
LET myAttrNode = myDoc.createAttribute("type")
CALL myAttrNode.setNodeValue("text/javascript")
LET nodeLst = myDoc.getElementsByTagName("body")
LET bodyNode = nodeLst.getItem(1)
CALL bodyNode.appendChild(myEltNode)
CALL myEltNode.setAttributeNode(myAttrNode)
CALL myEltNode.appendChild(myCdataNode)
CATCH
DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
EXIT PROGRAM(-1)
END TRY
END MAIN

Load and save methods usage examples
Load and save method usage examples for the xml.DomDocument class.
You can load an existing XML document. Before loading an XML document you need to create the DomDocument object.
A DomDocument can load files using different URI: http://, https://, tcp://, tcps://, file:// and alias://.
See getErrorsCount() and getErrorDescription() to retrieve error messages related to XML document.

load("data.xml")
load("http://www.w3schools.com/xml/cd_catalog.xml")
load("https://localhost:6394/ws/r/calculator?WSDL")
load("file:///data/cd_catalog.xml")
load("tcp://localhost:4242/")
load("tcps://localhost:4243/")
load("alias://demo")

In the example the demo alias is defined in fglprofile as ws.demo.url = "http://www.w3schools.com/xml/cd_catalog.xml"

loadfromstring("<List> <elt>First element</elt> <elt>Second element</elt> <elt>Third element</elt> </List>")
The example, produces a subtree with a root node List and three nodes elt and three textnode.
A DomDocument can be saved at different URI beginning with: http://, https://, tcp://, tcps://, file:// and alias://.

save("myfile.xml")
save("http://myserver:8080/data/save1.xml")
save("file:///data/save.xml")
save("tcp://localhost:4242/")
save("alias://test")

In the example the test alias is defined in fglprofile as ws.test.url = "http://localhost:8080/data/save3.xml"
The saveToString method saves the DomDocument in a string.
See getErrorsCount() and getErrorDescription() to retrieve error messages related to XML document.
The normalize function emulates a DomDocument save and load. It can be called at any stage of the DomDocument building. This removes empty Text nodes and sets namespace declarations as if the document had been saved.

**Cautions**

Some things you need to be aware of when working with the xml.DomDocument class.

Whitespaces, line feeds and carriage returns between elements are represented as text nodes in memory. A XML document written in a single line and a human readable (pretty printed format) do not have the same representation in the DomDocument. Take this into account when navigating in the document.

If a xml.DomNode is not attached to a DomDocument and not referenced by any variable it can be destroyed. If one child of this node is still referenced, this child is not destroyed but its parent and the other nodes of the subtree are destroyed. To check if a node is attached to a DomDocument use isAttached method.

The DomDocument remains in memory if any of its nodes are still referenced in a variable.

**DomDocument Features**

A list of features for the xml.DomDocument class.

**DomDocument features**

**Table 641: DomDocument Features**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>format-pretty-print</td>
<td>Formats the output by adding whitespace to produce a pretty-printed, indented,</td>
</tr>
<tr>
<td></td>
<td>human-readable form. Possible values are TRUE or FALSE. Default value is</td>
</tr>
<tr>
<td></td>
<td>FALSE.</td>
</tr>
<tr>
<td>comments</td>
<td>Defines whether the XML comments are kept during the loading of a document</td>
</tr>
<tr>
<td></td>
<td>into a DomDocument object. Possible values are TRUE or FALSE. Default</td>
</tr>
<tr>
<td></td>
<td>value is TRUE.</td>
</tr>
<tr>
<td>whitespace-in-element-content</td>
<td>Defines whether XML Text nodes that can be considered &quot;Ignorable&quot; are kept</td>
</tr>
<tr>
<td></td>
<td>during the loading of an XML document into a DomDocument object. Possible</td>
</tr>
<tr>
<td></td>
<td>values are TRUE or FALSE. Default value is TRUE.</td>
</tr>
<tr>
<td>cdata-sections</td>
<td>Defines whether XML CDATA nodes are kept or replaced by XML Text nodes</td>
</tr>
<tr>
<td></td>
<td>during the loading of an XML document into a DomDocument object. Possible</td>
</tr>
<tr>
<td></td>
<td>values are TRUE or FALSE. Default value is TRUE.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>expand-entity-references</td>
<td>Defines whether XML EntityReference nodes are kept or replaced during the loading of an XML document into a DomDocument object. Possible values are TRUE or FALSE. Default value is FALSE.</td>
</tr>
<tr>
<td>validation-type</td>
<td>Defines what kind of validation is performed. Possible values are: DTD, Schema. Default is Schema.</td>
</tr>
<tr>
<td>external-schemaLocation</td>
<td>Defines a list of namespace-qualified XML schemas to use for validation on a DomDocument object. Value is a space-separated string of one or several pairs of strings representing the namespace URI of the schema, followed by its location.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td>external-noNamespaceSchemaLocation</td>
<td>Defines a list of XML schemas to use for validation on a DomDocument object. Value is a space-separated string of one or several strings representing the location of a schema.</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>&quot;mySchema1.xsd mySchema2.xsd&quot;</td>
</tr>
<tr>
<td>schema-uriRecovery</td>
<td>Changes the schema location of an XML schema referenced by import tags in other schemas. Value is a space-separated string of one or several pairs of strings representing the original schema location followed by the new schema location</td>
</tr>
<tr>
<td></td>
<td>Example:</td>
</tr>
<tr>
<td></td>
<td>&quot;<a href="http://www.w3.org/2001/xml.xsd">http://www.w3.org/2001/xml.xsd</a> myXML.xsd <a href="http://www.mycompany.com/">http://www.mycompany.com/</a> GWS.xsd myGWS.xsd&quot;</td>
</tr>
<tr>
<td>load-save-base64-string</td>
<td>Changes methods loadFromString() and saveToString() to handle Base64 strings. Parsing an XML document is done from a BASE64 encoded string, and saving an XML document results in a BASE64 encoded string. Possible values are TRUE or FALSE. Default is FALSE.</td>
</tr>
</tbody>
</table>
### Name | Description
--- | ---
**auto-id-attribute** | Changes the parsing of an XML document in order to set all unqualified attributes named ID, Id, iD or id to be of type ID.

They can then be retrieved with method `getElementById()` or with an XPath expression without calling `setIdAttribute()`.

Possible values are TRUE or FALSE.

Default is FALSE.

**auto-id-qualified-attribute** | Changes the parsing of an XML document in order to set all qualified attributes named ID, Id, iD or id to be of type ID.

They can then be retrieved with method `getElementById()` or with an XPath expression without calling `setIdAttributeNS()`.

Possible values are TRUE or FALSE.

Default is FALSE.

**enable-html-compliancy** | Changes methods to parse, normalize and save HTML document via the `DomDocument` object.

Possible values are TRUE or FALSE.

Default value is FALSE.

The HTML parsing isn't namespace qualified, and document is considered as an XML document after loading.

**Note:** This feature works only for HTML 4, it is not supported for HTML 5.

### Security issues with expand-entity-references

For example, in its DTD, the following XML file defines the `myref` ENTITY element referencing the `/etc/passwd` file:

```xml
<?xml version="1.0" encoding="ISO-8859-1"?>
<!DOCTYPE foo [ 
  <!ELEMENT foo ANY >
  <!ENTITY myref SYSTEM "file:///etc/passwd" >
]>
<foo>&myref;</foo>
```

When loading this XML file with `expand-entity-references` set to TRUE, the resulting DOM document will have a `<foo>` node containing a text node with the content of `/etc/passwd`. 
Examples
xml.DomDocument usage examples.
Example 1 : Create a namespace qualified document with processing instructions

To create the following XML document on disk:

```xml
<?Target1 This is my first PI ?>
<MyPre:RootNode xmlns:MyPre="http://www.tempuri.org" >
<MyPre:Element />
</MyPre:RootNode>
<?Target2 This is my last PI ?>
```

Write the following code:

```xml
IMPORT xml

MAIN
  DEFINE doc xml.DomDocument
  DEFINE pi xml.DomNode
  DEFINE node xml.DomNode
  DEFINE elt xml.DomNode

  # Create a document with an initial namespace qualified root node
  # Create a Processing instruction
  LET pi = doc.createProcessingInstruction("Target1", "This is my first PI")
  # And add it at the begining of the document
  CALL doc.prependDocumentNode(pi)
  # Create another Processing instruction
  LET pi = doc.createProcessingInstruction("Target2", "This is my last PI")
  # And add it at the end of the document
  CALL doc.appendDocumentNode(pi)
  # Retrieve initial root node of the document
  LET elt = doc.getDocumentElement()
  # Create a new Element node
  LET node = doc.createElementNS("MyPre", "Element", "http://www.tempuri.org")
  # And add it as child of the rootNode
  CALL elt.appendChild(node)
  # Then save the document on disk
  CALL doc.save("MyFile.xml")
END MAIN
```

Example 2 : Validating a document against XML schemas or a DTD

This code example loads one or more XML schemas or uses an embedded DTD to validate against a XML document:

```xml
IMPORT xml

MAIN
  DEFINE location STRING
  DEFINE xmlfile STRING
  DEFINE doc xml.DomDocument
  DEFINE ind INTEGER

  IF num_args()<2 THEN
    # Checks the number of arguments
    CALL ExitHelp()
  ELSE
    LET doc = xml.DomDocument.Create()
    LET xmlfile = arg_val(num_args())
    IF num_args() == 2 AND arg_val(1) == "-dtd" THEN
```
# User chose DTD validation
CALL doc.setFeature("validation-type", "DTD")
ELSE
# User chose XML Schema validation
IF arg_val(1) == "-ns" THEN
    # Handle namespace qualified XML schemas
    IF num_args() MOD 2 != 0 THEN
        CALL ExitHelp()
    END IF
    FOR ind = 2 TO num_args()-1 STEP 2
        IF location IS NULL THEN
            LET location = arg_val(ind) || " " || arg_val(ind+1)
        ELSE
            LET location = location || " " || arg_val(ind) || " " || arg_val(ind+1)
        END IF
    END FOR
    TRY
        CALL doc.setFeature("external-schemaLocation", location)
    CATCH
        FOR ind = 1 TO doc.getErrorsCount()
            DISPLAY "Schema error (" || ind || ") :", doc.getErrorDescription(ind)
        END FOR

# Display help
FUNCTION ExitHelp()
    DISPLAY "Validator < -dtd | -ns [namespace schema]+ | [schema]+ > xmlfile"
    EXIT PROGRAM
END FUNCTION

Example

$ fglrun Validator -dtd MyFile.xml
Validates XML file using DTD embedded in the XML file.

$ fglrun Validator Schema1.xsd Schema2.xsd MyFile.xml
Validates unqualified XML file using two unqualified XML schemas.

Validates namespace qualified XML file using two namespace qualified XML schemas.

The **DOMNode** class
The **xmlDOMNode** class provides methods to manipulate a node of a DomDocument object.

You can create a DomNode object using creation methods in the **DomDocument** class.

The **STATUS** variable is set to zero after a successful method call.
### xmlDOMNode methods
Methods for the xmlDOMNode class.

#### Table 642: Object methods: Navigation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getChildrenCount()</code></td>
<td>RETURNS INTEGER Returns the number of child DomNode objects for a DomNode object.</td>
</tr>
<tr>
<td><code>getChildNodeItem(index)</code></td>
<td>RETURNS xmlDOMNode Returns the child DomNode object at a given position for a DomNode object.</td>
</tr>
<tr>
<td><code>getFirstChild()</code></td>
<td>RETURNS xmlDOMNode Returns the first child DomNode object for this XML Element DomNode object.</td>
</tr>
<tr>
<td><code>getFirstChildElement()</code></td>
<td>RETURNS xmlDOMNode Returns the first XML Element child DomNode object for this DomNode object.</td>
</tr>
<tr>
<td><code>getLastChild()</code></td>
<td>RETURNS xmlDOMNode Returns the last child DomNode object for a XML Element DomNode object.</td>
</tr>
<tr>
<td><code>getLastChildElement()</code></td>
<td>RETURNS xmlDOMNode Returns the last child XML element DomNode object for this DomNode object.</td>
</tr>
<tr>
<td><code>getNextSibling()</code></td>
<td>RETURNS xmlDOMNode Returns the DomNode object immediately following a DomNode object.</td>
</tr>
<tr>
<td><code>getNextSiblingElement()</code></td>
<td>RETURNS xmlDOMNode Returns the XML Element DomNode object immediately following a DomNode object.</td>
</tr>
<tr>
<td><code>getParentNode()</code></td>
<td>RETURNS xmlDOMNode Returns the parent DomNode object for this DomNode object.</td>
</tr>
<tr>
<td><code>getPreviousSibling()</code></td>
<td>RETURNS xmlDOMNode Returns the DomNode object immediately preceding a DomNode object.</td>
</tr>
<tr>
<td><code>getPreviousSiblingElement()</code></td>
<td>RETURNS xmlDOMNode Returns the XML Element DomNode object immediately preceding a DomNode object.</td>
</tr>
<tr>
<td><code>hasChildNodes()</code></td>
<td>RETURNS INTEGER Returns TRUE if a node has child nodes.</td>
</tr>
</tbody>
</table>
### Table 643: Object methods: Manipulation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| clone(  
  deep INTEGER )  
  RETURNS xml.DomNode | Returns a duplicate DomNode object of a node. |
| appendChild(  
  newNode xml.DomNode ) | Adds a child DomNode object to the end of the child list for a DomNode object. |
| appendChildElement(  
  name STRING )  
  RETURNS xml.DomNode | Creates and adds a child XML Element node to the end of the list of child nodes for an XML Element DomNode object. |
| appendChildElementNS(  
  prefix STRING,  
  name STRING,  
  ns STRING )  
  RETURNS xml.DomNode | Creates and adds a child namespace qualified XML Element node to the end of the list of child nodes for an XML Element DomNode object. |
| addNextSibling(  
  newNode xml.DomNode ) | Adds a DomNode object as the next sibling of a DomNode object. |
| addPreviousSibling(  
  newNode xml.DomNode ) | Adds a DomNode object as the previous sibling of a DomNode object. |
| insertBeforeChild(  
  newNode xml.DomNode,  
  refChild xml.DomNode ) | Inserts a DomNode object before an existing child DomNode object. |
| insertAfterChild(  
  newNode xml.DomNode,  
  refChild xml.DomNode ) | Inserts a DomNode object after an existing child DomNode object. |
| prependChild(  
  newNode xml.DomNode ) | Adds a child DomNode object to the beginning of the child list for a DomNode object. |
| prependChildElement(  
  name STRING )  
  RETURNS xml.DomNode | Creates and adds a child XML Element node to the beginning of the list of child nodes for this XML Element DomNode object. |
| prependChildElementNS(  
  prefix STRING,  
  name STRING,  
  ns STRING )  
  RETURNS xml.DomNode | Creates and adds a child namespace-qualified XML Element node to the beginning of the list of child nodes for an XML Element DomNode object. |
| removeAllChildren() | Removes all child DomNode objects from a DomNode object. |
| removeChild(  
  oldChild xml.DomNode ) | Removes a child DomNode object from the list of child DomNode objects. |
### Table 644: Object methods: Access

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getLocalName()</code></td>
<td>GETS the local name for a DomNode object.</td>
</tr>
<tr>
<td><code>getNamespaceURI()</code></td>
<td>Returns the namespace URI for a DomNode object.</td>
</tr>
<tr>
<td><code>getNodeName()</code></td>
<td>GETS the name for a DomNode object.</td>
</tr>
<tr>
<td><code>getNodeType()</code></td>
<td>GETS the XML type for this DomNode object.</td>
</tr>
<tr>
<td><code>getNodeValue()</code></td>
<td>Returns the value for a DomNode object.</td>
</tr>
<tr>
<td><code>getPrefix()</code></td>
<td>Returns the prefix for a DomNode object.</td>
</tr>
<tr>
<td><code>isAttached()</code></td>
<td>Returns whether the node is attached to the XML document.</td>
</tr>
</tbody>
</table>

### Table 645: Object methods: Modifier

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>setNodeValue()</code></td>
<td>Sets the node value for a DomNode object.</td>
</tr>
<tr>
<td><code>setPrefix()</code></td>
<td>Sets the prefix for a DomNode object.</td>
</tr>
<tr>
<td><code>toString()</code></td>
<td>Returns a string representation of a DomNode object.</td>
</tr>
</tbody>
</table>
Table 646: Object methods: Attribute

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hasAttribute</code> (name STRING )</td>
<td>Checks whether an XML Element DomNode object has the XML Attribute specified by a specified name.</td>
</tr>
<tr>

</tbody>
</table>

xml.DomNode.addPreviousSibling

Adds a DomNode object as the previous sibling of a DomNode object.

**Syntax**

```
addPreviousSibling(
    newNode xml.DomNode  )
```

1. `newNode` defines the node to add.

**Usage**

Adds a DomNode object as the previous sibling of this DomNode object; `newNode` is the node to add.

**Important:** This method is not part of W3C standard API.

The DomNode object node must be the child of an element or document node; otherwise the operation fails.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.addNextSibling
Adds a DomNode object as the next sibling of a DomNode object.

**Syntax**

```plaintext
addNextSibling(
    newNode xml.DomNode
)
```

1. `newNode` defines the node to add.

**Usage**

Adds a DomNode object as the next sibling of this DomNode object; `newNode` is the node to add.

**Important:** This method is not part of W3C standard API.

The DomNode object node must be the child of an element or document node; otherwise the operation fails.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.appendChild**

Adds a child DomNode object to the end of the child list for a DomNode object.

**Syntax**

```plaintext
appendChild(
    newChild xml.DomNode
)
```

1. `newChild` defines the node to add.

**Usage**

Adds a child DomNode object to the end of the child list for this DomNode object.

The DomNode object node must be the child of an element or document node; otherwise the operation fails.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.appendChildElement**

Creates and adds a child XML Element node to the end of the list of child nodes for an XML Element DomNode object.

**Syntax**

```plaintext
appendChildElement(
    name STRING
)
RETURNS xml.DomNode
```

1. `name` defines the XML Element name.

**Usage**

Creates and adds a child XML Element node to the end of the list of child nodes for this XML Element DomNode object.

**Important:** This method is not part of W3C standard API.

Returns the XML element DomNode object, or NULL.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.appendChildElementNS**

Creates and adds a child namespace qualified XML Element node to the end of the list of child nodes for an XML Element DomNode object.

**Syntax**

```java
appendChildElementNS (prefix STRING, name STRING, ns STRING) RETURNS xml.DomNode
```

1. prefix defines the prefix of the XML Element to add.
2. name defines the name of the XML Element to add.
3. ns defines the namespace URI of the XML Element to add.

**Usage**

Creates and adds a child namespace qualified XML Element node to the end of the list of child nodes for this XML Element DomNode object.

**Important:** This method is not part of W3C standard API.

Returns the XML element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.clone**

Returns a duplicate DomNode object of a node.

**Syntax**

```java
clone (deep INTEGER) RETURNS xml.DomNode
```

1. deep defines a boolean. If deep is TRUE, child DomNode objects are cloned too; otherwise only the DomNode itself is cloned.

**Usage**

Returns a duplicate DomNode object of this node. If deep is TRUE, child DomNode objects are cloned too; otherwise only the DomNode itself is cloned.

Returns a copy of this xml.DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.getAttribute**
Returns the value of a XML Attribute for an XML Element DomNode object

Syntax

```java
getAttribute(
    name STRING )
RETURNS STRING
```

1. `name` defines the name of the XML attribute to retrieve.

Usage

Returns the value of a XML Attribute for this XML Element DomNode object, where `name` is the name of the XML attribute to retrieve.

Returns the XML attribute value, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getAttributeNode

Returns an XML Attribute DomNode object for an XML Element DomNode object

Syntax

```java
getAttributeNode(
    name STRING )
RETURNS xml.DomNode
```

1. `name` defines the name of the attribute to retrieve.

Usage

Returns an XML attribute DomNode object for this XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getAttributeNodeItem

Returns the XML Attribute DomNode object at a given position on this XML Element DomNode object.

Syntax

```java
getAttributeNodeItem(
    index INTEGER )
RETURNS xml.DomNode
```

1. `index` defines the position of the node to return.

Usage

Returns the XML Attribute DomNode object at a given position on this XML Element DomNode object, where `index` is the position of the node to return (Index starts at 1).

Returns the XML Attribute DomNode object at the given position, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
xml.DomNode.getAttributeNodeNS
Returns a namespace-qualified XML Attribute DomNode object for an XML Element DomNode object

Syntax
```java
getAttributeNodeNS (        
    name STRING,        
    ns STRING )        
RETURNS xml.DomNode
```

1. `name` defines the name of the XML Attribute to retrieve.
2. `ns` defines the namespace URI of the XML Attribute to retrieve.

Usage
Returns a namespace-qualified XML Attribute DomNode object for this XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getAttributeNS
Returns the value of a namespace qualified XML Attribute for an XML Element DomNode object

Syntax
```java
getAttributeNS (        
    name STRING,        
    ns STRING )        
RETURNS STRING
```

1. `name` defines the name.
2. `ns` defines the namespace URI of the XML Attribute to retrieve

Usage
Returns the value of a namespace qualified XML Attribute for this XML Element xml.DomNode object, where `name` is the name and `ns` is the namespace URI of the XML Attribute to retrieve.

Returns the XML attribute value, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getAttributesCount
Returns the number of XML Attribute DomNode objects on this XML Element DomNode object.

Syntax
```java
getAttributesCount ()        
RETURNS INTEGER
```

Usage
Returns the number of XML Attribute xml.DomNode objects on this XML Element DomNode object.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getChildNodeItem
Returns the child DomNode object at a given position for a DomNode object.

Syntax

```plaintext
getChildNodeItem(
   index INTEGER )
RETURNS xml.DomNode
```

1. *index* defines the position of the child node in the collection.

Usage

Returns the child DomNode object at a given position for this DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getChildrenCount
Returns the number of child DomNode objects for a DomNode object.

Syntax

```plaintext
getChildrenCount ()
RETURNS INTEGER
```

Usage

Returns the number of child xml.DomNode objects for this DomNode object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getElementsByTagName
Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name.

Syntax

```plaintext
getElementsByTagName (tag STRING )
RETURNS xml.DomNodeList
```

1. *tag* defines the name of the XML Element tag to match or "*" to match all tags.

Usage

Returns a DomNodeList object containing all XML Element DomNode objects with the same tag name, or NULL; *tag* is the name of the XML Element tag to match, or "*" to match all tags.

The getElementsByTagName and getElementsByTagNameNS methods return a xml.DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is restricted to objects with the same tag name and/or namespace.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getElementsByTagNameNS

Returns a DomNodeList object containing all namespace-qualified XML Element DomNode objects with the same tag name and namespace.

**Syntax**

```java
getElementsByTagNameNS (  
tag STRING,  
ns STRING  )  
RETURNS xml.DomNodeList
```

1. *tag* defines the name of the XML Element tag to match or "*" to match all tags.
2. *ns* defines the namespace URI of the XML Element tag to match or "*" to match any namespace.

**Usage**

Returns a DomNodeList object containing all namespace-qualified XML Element DomNode objects with the same tag name and namespace, or NULL. *tag* is the name of the XML Element tag to match, or "*" to match all tags; *ns* is the namespace URI of the XML Element tag to match, or "*" to match any namespace.

The `getElementsByTagNameNS` and `getElementsByTagName` methods return a DomNodeList object, unlike the other methods that return a DomNode object. The DomNodeList is restricted to contain objects with the same tag name and/or namespace.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getFirstChild

Returns the first child DomNode object for this XML Element DomNode object.

**Syntax**

```java
getFirstChild ()  
RETURNS xml.DomNode
```

**Usage**

Returns the first child DomNode object for this XML Element DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getFirstChildElement

Returns the first XML Element child DomNode object for this DomNode object.

**Syntax**

```java
getFirstChildElement ()  
RETURNS xml.DomNode
```

**Usage**

Returns the first XML Element child DomNode object for this DomNode object, or NULL.
**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.getLastChild**

Returns the last child `DomNode` object for a XML Element `DomNode` object.

**Syntax**

```java
getLastChild()
RETURNS xml.DomNode
```

**Usage**

Returns the last child `DomNode` object for this XML Element `DomNode` object, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.getLastChildElement**

Returns the last child XML element `DomNode` object for this `DomNode` object.

**Syntax**

```java
getLastChildElement()
RETURNS xml.DomNode
```

**Usage**

Returns the last child XML element `DomNode` object for this `DomNode` object, or NULL.

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.getLocalName**

Gets the local name for a `DomNode` object.

**Syntax**

```java
getLocalName()
RETURNS STRING
```

**Usage**

Gets the local name for this `DomNode` object. If `xml.DomNode` has a qualified name, only the local part is returned.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.getNamespaceURI**
Returns the namespace URI for a DomNode object.

**Syntax**

```plaintext
getNamespaceURI ()
RETURNS STRING
```

**Usage**

This method returns the namespace URI for this xml.DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.getNextSibling**

Returns the DomNode object immediately following a DomNode object.

**Syntax**

```plaintext
getNextSibling ()
RETURNS xml.DomNode
```

**Usage**

Returns the xml.DomNode object immediately following this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.getNextSiblingElement**

Returns the XML Element DomNode object immediately following a DomNode object.

**Syntax**

```plaintext
getNextSiblingElement ()
RETURNS xml.DomNode
```

**Usage**

Returns the XML Element xml.DomNode object immediately following this DomNode object, or NULL.

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.getNodeName**

Gets the name for a DomNode object.

**Syntax**

```plaintext
getNodeName ()
RETURNS STRING
```
Usage

Gets the name for this `xml.DomNode` object. This method returns the qualified name of the `DomNode` object, or NULL. If `DomNode` does not have a qualified name, the local part is returned.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.DomNode.getNodeType`

Gets the XML type for this `DomNode` object.

**Syntax**

```
getNodeType()
RETURNS STRING
```

Usage

This method returns the XML type for this `DomNode` object; it returns one of the XML `DomNode` types, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.DomNode.getNodeValue`

Returns the value for a `DomNode` object.

**Syntax**

```
getNodeValue()
RETURNS STRING
```

Usage

Use this method to return the value for this `xml.DomNode` object, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.DomNode.getOwnerDocument`

Returns the `DomDocument` object containing this `DomNode` object.

**Syntax**

```
getOwnerDocument()
RETURNS `xml.DomDocument`
```

Usage

This method returns the `xml.DomDocument` object containing this `DomNode` object, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.DomNode.getParentNode`
Returns the parent DomNode object for this DomNode object.

**Syntax**

```java
getParentNode()
RETURNS xml.DomNode
```

**Usage**

This method returns the parent xml.DomNode object for this DomNode object, or NULL. In the case of a xml.DomDocument node, this method will return NULL (parent is not a DomNode object) but `isAttached()` will return TRUE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getPrefix

Returns the prefix for a DomNode object.

**Syntax**

```java
getPrefix()
RETURNS STRING
```

**Usage**

This method returns the prefix for this xml.DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getPreviousSibling

Returns the DomNode object immediately preceding a DomNode object.

**Syntax**

```java
getPreviousSibling()
RETURNS xml.DomNode
```

**Usage**

Use this method to return the xml.DomNode object immediately preceding this DomNode object, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.getPreviousSiblingElement

Returns the XML Element DomNode object immediately preceding a DomNode object.

**Syntax**

```java
getPreviousSiblingElement()
RETURNS xml.DomNode
```
Usage

Use this method to return the XML Element `DomNode` object immediately preceding this `DomNode` object, or NULL.

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

xml.DomNode.hasAttribute

Checks whether an XML Element `DomNode` object has the XML Attribute specified by a specified name.

Syntax

```plaintext
hasAttribute(
    name STRING
) RETURNS INTEGER
```

1. `name` defines the object name to check.

Usage

Checks whether this XML Element `DomNode` object has the XML Attribute specified by `name`. Returns TRUE if an XML Attribute with the given name is carried by this XML Element `DomNode` object, otherwise returns FALSE.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

xml.DomNode.hasAttributeNS

Checks whether a namespace qualified XML Attribute of a given name is carried by an XML Element `DomNode` object.

Syntax

```plaintext
hasAttributeNS(
    name STRING,
    ns STRING
) RETURNS INTEGER
```

1. `name` defines the name of the XMLAttribute to check
2. `ns` defines the namespace URI of the XML Attribute to check.

Usage

Use this method to check whether a namespace qualified XML Attribute of a given name is carried by this XML Element `DomNode` object, where `name` is the name of the XMLAttribute to check; `ns` the namespace URI of the XML Attribute to check. Returns TRUE if an XML Attribute with the given name and namespace URI is carried by this XML Element `DomNode` object, otherwise returns FALSE.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

xml.DomNode.hasAttributes
Identifies whether a node has XML Attribute nodes.

Syntax

```java
hasAttributes ()
RETURNS INTEGER
```

Usage

This method returns `TRUE` if this node has XML Attribute nodes; otherwise returns `FALSE`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

```
xml.DomNode.hasChildNodes
```

Returns `TRUE` if a node has child nodes.

Syntax

```java
hasChildNodes ()
RETURNS INTEGER
```

Usage

Use this method to check if a node has child nodes. It returns `TRUE` if this node has child nodes; otherwise, returns `FALSE`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

```
xml.DomNode.insertAfterChild
```

Inserts a `DomNode` object after an existing child `DomNode` object.

Syntax

```java
insertAfterChild (  
    newChild xml.DomNode,  
    refChild xml.DomNode  
)
```

1. `newChild` defines the node to insert.
2. `refChild` defines the reference node (the node before which the new node must be inserted).

Usage

Use this method to inserts a `DomNode` object after an existing child `DomNode` object; `newChild` is the node to insert, `refChild` is the reference node (the node before which the new node must be inserted).

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

```
xml.DomNode.insertBeforeChild
```

Inserts a `DomNode` object before an existing child `DomNode` object in the order of the children list.

Syntax

```java
insertBeforeChild (  
    newChild xml.DomNode,  
    refChild xml.DomNode  
)
```

1. `newChild` defines the node to insert.
2. `refChild` defines the reference node (the node before which the new node must be inserted).

Usage

Use this method to inserts a `DomNode` object before an existing child `DomNode` object; `newChild` is the node to insert, `refChild` is the reference node (the node before which the new node must be inserted).

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
Inserts a DomNode object before an existing child DomNode object.

**Syntax**

```csharp
insertBeforeChild(
    newNode xml.DomNode,
    refChild xml.DomNode )
```

1. `newChild` defines the node to insert.
2. `refChild` defines the reference node (the node before which the new node must be inserted).

**Usage**

Use this method to insert a DomNode object before an existing child DomNode object; `newChild` is the node to insert, `refChild` is the reference node (the node before which the new node must be inserted).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.isAttached**

Returns whether the node is attached to the XML document.

**Syntax**

```csharp
isAttached ()
RETURNS INTEGER
```

**Usage**

The returned integer indicates whether the node is attached to the XML document or not.

**Important:** This method is not part of W3C standard API.

This method returns TRUE if the DomNode object is attached to a xml.DomDocument object as a child; otherwise it returns FALSE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.isDefaultNamespace**

Checks whether the specified namespace URI is the default namespace.

**Syntax**

```csharp
isDefaultNamespace (  
    ns STRING )
RETURNS INTEGER
```

1. `ns` defines the namespace URI to look for.

**Usage**

Use this method to check whether the specified namespace URI is the default namespace, where `ns` is the namespace URI to look for. Returns TRUE if the given namespace is the default namespace, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
xml.DomNode.lookupNamespaceURI

Looks up the namespace URI associated to a prefix, starting from a specified node.

**Syntax**

```sql
lookupNamespaceURI(
    prefix STRING
)
RETURNS STRING
```

1. `prefix` defines the prefix to look for.

**Usage**

Use this method to look up the namespace URI associated with a prefix, starting from this node, where `prefix` is the prefix to look for. If NULL, the default namespace URI will be returned. A namespace URI, or NULL, is returned.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.lookupPrefix

Looks up the prefix associated to a namespace URI, starting from the specified node.

**Syntax**

```sql
lookupPrefix(
    ns STRING
)
RETURNS STRING
```

1. `ns` defines the namespace URI to look for.

**Usage**

Use this method to look up the prefix associated with a namespace URI, starting from this node, where `ns` is the namespace URI to look for. Returns the prefix associated with this namespace URI, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.prependChild

Adds a child DomNode object to the beginning of the child list for a DomNode object.

**Syntax**

```sql
prependChild(
    newChild xml.DomNode
)
```

1. `newChild` defines the node to add.

**Usage**

Use this method to add a child DomNode object to the beginning of the child list for this DomNode object; `newChild` is the node to add.

**Important:** This method is not part of W3C standard API.

The DomNode object node must be the child of an element or document node, otherwise the operation fails.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.prependChildElement**

Creates and adds a child XML Element node to the beginning of the list of child nodes for this XML Element DomNode object.

**Syntax**

```java
prependChildElement (
    name STRING )
RETURNS xml.DomNode
```

1. `name` defines the name of the XML element to add.

**Usage**

Use this method to create and add a child XML Element node to the beginning of the list of child nodes for this XML Element DomNode object; `name` is the name of the XML element to add.

It returns the XML Element DomNode object, or NULL.

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.prependChildElementNS**

Creates and adds a child namespace-qualified XML Element node to the beginning of the list of child nodes for an XML Element DomNode object.

**Syntax**

```java
prependChildElementNS ( 
    prefix STRING,  
    name STRING,  
    ns STRING )
RETURNS xml.DomNode
```

1. `prefix` defines the prefix of the XML Element to add.
2. `name` defines the name of the XML Element to add.
3. `ns` defines the namespace URI of the XML Element to add.

**Usage**

Use this method to create and add a child namespace-qualified XML Element node to the beginning of the list of child nodes for this XML Element DomNode object.

It returns the XML Element DomNode object, or NULL.

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.DomNode.removeAllChildren**
Removes all child DomNode objects from a DomNode object.

**Syntax**

```
removeAllChildren()
```

**Usage**

Use this method to remove all child xml.DomNode objects from this DomNode object. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.removeAttribute

Removes an XML Attribute for an XML Element DomNode object.

**Syntax**

```
removeAttribute( 
    name STRING 
)
```

1. `name` defines the name of the XML attribute to remove.

**Usage**

Use this method to remove an XML Attribute for this XML Element DomNode object, where `name` is the name of the XML attribute to remove. Status is updated with an error code. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.removeAttributeNS

Removes a namespace qualified XML Attribute for an XML Element DomNode object.

**Syntax**

```
removeAttributeNS( 
    name STRING, 
    ns STRING 
)
```

1. `name` defines the name of the XML Attribute to remove.
2. `ns` defines the namespace URI of the XML Attribute to remove.

**Usage**

Use this method to remove a namespace qualified XML Attribute for this XML Element DomNode object, where `name` is the name and `ns` is the namespace URI of the XML Attribute to remove. In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.removeChild
Removes a child DomNode object from the list of child DomNode objects.

Syntax

```java
removeChild(
    oldChild xml.DomNode
)
```

1. `oldChild` defines the node to remove.

Usage

Use this method to remove a child DomNode object from a list of child DomNode objects, where `oldchild` is the node to remove.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.DomNode.replaceChild`

Replaces an existing child DomNode with another child DomNode object.

Syntax

```java
replaceChild(
    newChild xml.DomNode,
    oldChild xml.DomNode
)
```

1. `newChild` defines the replacement child.
2. `oldChild` defines the child to be replaced.

Usage

Use this method to replace an existing child DomNode with another child DomNode object, where `oldChild` is the child to be replaced and `newChild` is the replacement child.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.DomNode.selectByXPath`

Returns a DomNodeList object containing all DomNode objects matching an XPath 1.0 expression.

Syntax

```java
selectByXPath(
    expr STRING,
    args ...)
RETURNS xml.DomNodeList
```

1. `expr` defines the XPath 1.0 expression.
2. `args` defines a list of prefixes bound to namespaces in order to resolve qualified names in the XPath expression.

Usage

This method returns a DomNodeList object containing all DomNode objects matching an XPath 1.0 expression; `expr` is the XPath 1.0 expression, `args` is a list of prefixes bound to namespaces in order to resolve qualified names in the XPath expression. This list must be filled with an even number of arguments, representing the prefix and it corresponding namespace.
**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Example**

```xml
selectByXPath("../../d:Record/*[last()]", "d",
"http://defaultnamespace")
```

```xml
selectByXPath("ns:Record", NULL)
```

```xml
selectByXPath("ns1:Records/ns2:Record",
"ns1",
"http://namespace1",
"ns2",
"http://namespace2")
```

```xml
selectByXPath("ns1:Record", "ns1") is invalid because the namespace definition is missing.
```

If the namespaces list is NULL, the prefixes and namespaces defined in the document itself are used if available.

A namespace must be an absolute URI (ex 'http://', 'file://').

xml.DomNode.setAttribute

Sets (or resets) an XML Attribute for an XML Element DomNode object.

**Syntax**

```xml
setAttribute (  
  name STRING,  
  value STRING )
```

1. `name` defines the name of the XML Attribute.
2. `value` defines the value of the XML Attribute.

**Usage**

Use this method to set (or reset) an XML Attribute for this XML Element DomNode object, where `name` is the name of the XML Attribute and `value` is the value of the XML Attribute.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNode.setAttributeNode

Sets (or resets) an XML Attribute DomNode object to an XML Element DomNode object.

**Syntax**

```xml
setAttributeNode (  
  attr xml.DomNode  )
```

1. `attr` defines the XML Attribute DomNode object to set.
**Usage**

Use this method to set (or reset) an XML Attribute `DOMNode` object to an XML Element `DOMNode` object, where `attr` is the XML Attribute `DOMNode` object to set.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.DomNode.setAttributeNodeNS`

Sets (or resets) a namespace-qualified XML Attribute `DOMNode` object to an XML Element `DOMNode` object.

**Syntax**

```java
setAttributeNodeNS (
    attr xml.DomNode
)
```

1. `attr` defines the XML Attribute `DOMNode` object to set.

**Usage**

Use this method to set (or reset) a namespace-qualified XML Attribute `DOMNode` object to an XML Element `DOMNode` object, where `attr` is the XML Attribute `DOMNode` object to set.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.DomNode.setAttributeNS`

Sets (or resets) a namespace-qualified XML Attribute for an XML Element `DOMNode` object.

**Syntax**

```java
setAttributeNS (
    prefix STRING,
    name STRING,
    ns STRING,
    value STRING
)
```

1. `prefix` defines the prefix of the XML Attribute.
2. `name` defines the name of the XML Attribute.
3. `ns` defines the namespace URI of the XML Attribute.
4. `value` defines the value of the XML Attribute.

**Usage**

Use this method to set (or reset) a namespace-qualified XML Attribute for this XML Element `DOMNode` object, where `prefix` is the prefix of the XML Attribute, `name` is the name of the XML Attribute, `ns` is the namespace URI of the XML Attribute, and `val` is the value of the XML Attribute.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.DomNode.setIdAttribute`

Set the XML Attribute of given name to be of type ID. Declare (or undeclare) the ID as user-determined.

**Syntax**

```java
setIdAttribute (
)
```
name STRING,
   isId INTEGER )

1. *name* defines the name of the XML Attribute to set.
2. *isId* declares whether the attribute is a user-determined ID attribute.

**Usage**

Use this method to set (or reset) the XML Attribute of given name to be of type ID. Use the value TRUE for the parameter *isId*, to declare the attribute as a user-determined ID attribute, otherwise use FALSE.

This affects the behavior of `getElementById`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml DomNode.setIdAttributeNS**

Set the namespace-qualified XML Attribute of given name and namespace to be of type ID. Declare (or undeclare) the ID as user-determined.

**Syntax**

```
setIdAttributeNS (  
    name STRING,  
    ns STRING,  
    isId INTEGER )
```

1. *name* defines the name of the XML Attribute to set.
2. *ns* defines the namespace URI of the XML Attribute to set.
3. *isId* declares whether the attribute is a user-determined ID attribute.

**Usage**

This method sets the namespace-qualified XML Attribute of given name and namespace to be of type ID. Use the value TRUE for the parameter *isId*, to declare that attribute as a user-determined ID attribute, otherwise use FALSE.

This affects the behavior of `getElementById`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml DomNode.getNodeValue**

Sets the node value for a DomNode object.

**Syntax**

```
getNodeValue (  
    value STRING  
)
```

1. *value* defines the node value.

**Usage**

This method sets the node value for this DomNode object, where *value* is the node value.

Use of this method is only recommended for nodes that are not parents of other nodes, which means it can be used for a node of type:

- ATTRIBUTE_NODE
• TEXT_NODE
• CDATA_SECTION_NODE
• PROCESSING_INSTRUCTION_NODE
• COMMENT_NODE

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DonNode.setPrefix
Sets the prefix for a DomNode object.

**Syntax**

```
setPrefix(
    prefix STRING )
```

1. `prefix` defines the prefix for this DomNode object.

**Usage**

Use this method to set the prefix for this xml.DonNode object.

This method is only valid on namespace qualified Element or Attribute nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DonNode.toString
Returns a string representation of a DomNode object.

**Syntax**

```
toString()
RETURNS STRING
```

**Usage**

This method returns a string representation of this DomNode object, or NULL.

**Important:** This method is not part of W3C standard API.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**DomNode types**
List of types for the xml.DonNode class.

**Table 648: DomNode types**

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ELEMENT_NODE</td>
<td>The DomNode is an XML Element node.</td>
</tr>
<tr>
<td>ATTRIBUTE_NODE</td>
<td>The DomNode is an XML Attribute node.</td>
</tr>
<tr>
<td>TEXT_NODE</td>
<td>The DomNode is an XML Text node.</td>
</tr>
<tr>
<td>CDATA_SECTION_NODE</td>
<td>The DomNode is an XML CData Section node.</td>
</tr>
</tbody>
</table>
### Type vs. Description

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENTITY_REFERENCE_NODE</td>
<td>The DomNode is an XML Entity Reference node.</td>
</tr>
<tr>
<td>PROCESSING_INSTRUCTION_NODE</td>
<td>The DomNode is an XML Processing Instruction node.</td>
</tr>
<tr>
<td>COMMENT_NODE</td>
<td>The DomNode is an XML Comment node.</td>
</tr>
<tr>
<td>DOCUMENT_TYPE_NODE</td>
<td>The DomNode is an XML DTD node.</td>
</tr>
<tr>
<td>DOCUMENT_FRAGMENT_NODE</td>
<td>The DomNode is an XML Document Fragment node.</td>
</tr>
</tbody>
</table>

#### Examples

**xml.DomNode usage examples.**

**Example Counting the number of nodes in an XML document**

This code example counts the number of nodes of each type.

```xml
IMPORT XML

DEFINE nbElt INTEGER
DEFINE nbAttr INTEGER
DEFINE nbComment INTEGER
DEFINE nbPI INTEGER
DEFINE nbTxt INTEGER
DEFINE nbCData INTEGER

MAIN
  DEFINE document xml.DomDocument
  DEFINE ind INTEGER
  # Handle arguments
  IF num_args() !=1 THEN
    CALL ExitHelp()
  END IF
  # Create document, load it, and count the nodes
  LET document = xml.DomDocument.Create()
  CALL document.load(arg_val(1))
  CALL CountDoc(document)
  # Display result
  DISPLAY "Results: ",nbElt
  DISPLAY " Elements: ",nbAttr
  DISPLAY " Attributes:"nbAttr
  DISPLAY " Comments: ",nbComment
  DISPLAY " PI: ",nbPI
  DISPLAY " Texts: ",nbElt
  DISPLAY " CDat: ",nbCData
END MAIN

FUNCTION CountDoc(d)
  DEFINE d xml.DomDocument
  DEFINE n xml.DomNode
  LET n = d.getFirstDocumentNode()
  WHILE (n IS NOT NULL) |
    CALL Count(n)
    LET n = n.getNextSibling()
  END WHILE
END FUNCTION

FUNCTION Count(n)
  DEFINE n xml.DomNode
  DEFINE child xml.DomNode
  DEFINE next xml.DomNode
  DEFINE node xml.DomNode
  DEFINE ind INTEGER
```
DEFINE name STRING
IF n IS NOT NULL THEN
  IF n.getNodeType() == "COMMENT_NODE" THEN
    LET nbComment = nbComment + 1
  END IF
  IF n.getNodeType() == "ATTRIBUTE_NODE" THEN
    LET nbAttr = nbAttr + 1
  END IF
  IF n.getNodeType() == "PROCESSING_INSTRUCTION_NODE " THEN
    LET nbPI = nbPI + 1
  END IF
  IF n.getNodeType() == "ELEMENT_NODE" THEN
    LET nbElt = nbElt + 1
  END IF
  IF n.getNodeType() == "TEXT_NODE" THEN
    LET nbTxt = nbTxt +1
  END IF
  IF n.getNodeType() == "CDATA_SECTION_NODE" THEN
    LET nbCData = nbCData + 1
  END IF
  IF n.hasChildNodes() THEN
    LET name = n.getLocalName()
    LET child = n.getFirstChild()
    WHILE (child IS NOT NULL )
      CALL Count(child)
      LET child = child.getNextSibling()
    END WHILE
  END IF
  IF n.hasAttributes() THEN
    FOR ind = 1 TO n.getAttributesCount()
      LET node = n.getAttributeNodeItem(ind)
      CALL Count(node)
    END FOR
  END IF
END IF
END FUNCTION

FUNCTION ExitHelp()
  DISPLAY "DomCount <xml>"
  EXIT PROGRAM
END FUNCTION

The DomNodeList class
The xml.DomNodeList class provides methods to manipulate a list of DomNode objects.

You can create a DomNodeList object using selection methods in the DomDocument and DomNode classes. The relationship between the DomNode objects in the list depends on the method used to create the DomNodeList object.

The STATUS variable is set to zero after a successful method call.
xml.DomNodeList methods
Methods for the xml.DomNodeList class.

Table 649: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getCount()</td>
<td>Returns the number of DomNode objects in a DomNodeList object.</td>
</tr>
<tr>
<td>getItem(index)</td>
<td>Returns the DomNode object at a given position in a DomNodeList object.</td>
</tr>
</tbody>
</table>

xml.DomNodeList.getCount
Returns the number of DomNode objects in a DomNodeList object.

Syntax

getCount()  
RETURNS INTEGER

Usage
Use this method to return the number of xml.DomNode objects in this DomNodeList object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.DomNodeList.getItem
Returns the DomNode object at a given position in a DomNodeList object.

Syntax

getItem(index INTEGER)  
RETURNS xml.DomNode

1. index defines the position of the DomNode object to return (index starts at 1).

Usage
Use this method to return a DomNode object at the given position in this DomNodeList object, where index is the position of the DomNode object to return (Index starts at 1).

Returns NULL when no DomNode object is at the given position.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
The streaming API for XML (StAX) classes

The streaming API for XML (StAX) classes use streaming while managing XML documents.

The StaxWriter class

The `xml.StaxWriter` class provides methods compatible with Streaming API for XML (StAX) for writing XML documents.

The `STATUS` variable is set to zero after a successful method call.

xml.StaxWriter methods

Methods for the `xml.StaxWriter` class.

Table 650: Class methods: Creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.StaxWriter.create()</code></td>
<td>Constructor of a StaxWriter object.</td>
</tr>
<tr>
<td>RETURNS <code>xml.StaxWriter</code></td>
<td></td>
</tr>
</tbody>
</table>

Table 651: Object methods: Configuration

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getFeature()</code></td>
<td>Gets a feature of a StaxWriter object.</td>
</tr>
<tr>
<td><code>property STRING</code></td>
<td>RETURNS <code>STRING</code></td>
</tr>
<tr>
<td><code>setFeature()</code></td>
<td>Sets a feature of a StaxWriter object.</td>
</tr>
<tr>
<td><code>property STRING, value STRING</code></td>
<td></td>
</tr>
</tbody>
</table>

Table 652: Object methods: Output

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>close()</code></td>
<td>Closes the StaxWriter streaming, and releases all associated resources.</td>
</tr>
<tr>
<td><code>writeTo(name STRING)</code></td>
<td>Sets the output stream of the StaxWriter object to a file or an URL, and starts the streaming.</td>
</tr>
<tr>
<td><code>writeToPipe(name STRING)</code></td>
<td>Sets the output stream of the StaxWriter object to a PIPE, and starts the streaming.</td>
</tr>
<tr>
<td><code>writeToText(txt TEXT)</code></td>
<td>Sets the output stream of the StaxWriter object to a TEXT large object, and starts the streaming.</td>
</tr>
</tbody>
</table>
Table 653: Object methods: Document

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dtd</code> (</td>
<td>Writes a DTD to the StaxWriter stream.</td>
</tr>
<tr>
<td><code>dtd</code> STRING )</td>
<td></td>
</tr>
<tr>
<td><code>endDocument()</code></td>
<td>Closes any open tags and writes corresponding end tags.</td>
</tr>
<tr>
<td><code>startDocument</code> (</td>
<td>Writes a XML declaration to the StaxWriter stream.</td>
</tr>
<tr>
<td><code>encoding</code> STRING,</td>
<td></td>
</tr>
<tr>
<td><code>version</code> STRING,</td>
<td></td>

</tr>
<tr>
<td><code>ns</code> STRING )</td>
<td></td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| attribute (  
   name STRING,  
   value STRING ) | Writes a XML attribute to the StaxWriter stream. |
| attributeNS (  
   name STRING,  
   ns STRING,  
   value STRING ) | Writes a XML namespace qualified attribute to the StaxWriter stream. |
| cdata (  
   cdata STRING ) | Writes a XML CData to the StaxWriter stream. |
| characters (  
   characters STRING ) | Writes a XML text to the StaxWriter stream. |
| comment (  
   comment STRING ) | Writes a XML comment to the StaxWriter stream. |
| emptyElement (  
   name STRING ) | Writes an empty XML element to the StaxWriter stream. |
| emptyElementNS (  
   name STRING,  
   ns STRING ) | Writes an empty namespace qualified XML element to the StaxWriter stream. |
| endElement () | Writes an end tag to the StaxWriter stream. |
| entityRef (  
   name STRING ) | Writes a XML EntityReference to the StaxWriter stream. |
| processingInstruction (  
   target STRING,  
   data STRING ) | Writes a XML ProcessingInstruction to the StaxWriter stream. |
| startElement (  
   name STRING ) | Writes a XML start element to the StaxWriter stream. |
| startElementNS (  
   name STRING,  
   ns STRING ) | Writes a namespace-qualified XML start element to the StaxWriter stream. |
Writes a XML attribute to the StaxWriter stream.

Syntax

```java
attribute(
    name STRING,
    value STRING )
```

1. `name` defines the local name of the XML attribute. It cannot be NULL.
2. `value` defines the value of the XML attribute. It cannot be NULL.

Usage

Attributes can only be written on the StaxWriter stream if it points to a START_ELEMENT or an EMPTY_ELEMENT, otherwise the operation fails with an exception. This method can only be called after a startElement, startElementNS, emptyElement, emptyElementNS, or attribute and attributeNS.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.attributeNS

Writes a XML namespace qualified attribute to the StaxWriter stream.

Syntax

```java
attributeNS(
    name STRING,
    ns STRING,
    value STRING )
```

1. `name` defines the local name of the XML attribute, cannot be NULL.
2. `ns` defines the namespace URI of the XML attribute, cannot be NULL.
3. `value` defines the value of the XML attribute, cannot be NULL.

Usage

Attributes can only be written on the StaxWriter stream if it points to a START_ELEMENT or an EMPTY_ELEMENT, otherwise the operation fails with an exception. This method can only be called after a startElement, startElementNS, emptyElement, emptyElementNS, or attribute and attributeNS.

If namespace URI has not been bound to a prefix with one of the methods setPrefix, declareNamespace, setDefaultNamespace or declareDefaultNamespace, the operation fails with an exception.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.cdata

Writes a XML CData to the StaxWriter stream.

Syntax

```java
cdata(
    cdata STRING )
```

1. `cdata` defines the data contained in the CData section, or NULL.
Usage
This method writes XML character data passed as parameter as a CData.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.characters
Writes a XML text to the StaxWriter stream.

Syntax

```java
characters (characters STRING )
```

1. `characters` defines the value to write.

Usage
This method writes the character string passed as parameter as a text element.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.close
Closes the StaxWriter streaming, and releases all associated resources.

Syntax

```java
close ()
```

Usage
This method closes the stream.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.comment
Writes a XML comment to the StaxWriter stream.

Syntax

```java
comment (comment STRING )
```

1. `comment` defines the data in the XML comment, or NULL.

Usage
This method writes a XML comment to the stream.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.create
Constructor of a StaxWriter object.

Syntax

```java
xml.StaxWriter.create()
RETURNS xml.StaxWriter
```

Usage

This method returns a StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.declareDefaultNamespace

Binds a namespace URI to the default namespace, and forces the output to the StaxWriter stream.

Syntax

```java
declareDefaultNamespace(
   ns STRING
)
```

1. `ns` defines the URI to bind to the default namespace. It cannot be NULL.

Usage

This method binds a namespace URI to the default namespace, and forces the output of the default XML namespace definition to the StaxWriter stream.

The stream must point to a START_ELEMENT, and the prefix scope is the current START_ELEMENT / END_ELEMENT pair.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.declareNamespace

Binds a namespace URI to a prefix, and forces the output of the XML namespace definition to the StaxWriter stream.

Syntax

```java
declareNamespace(
   prefix STRING,
   ns STRING
)
```

1. `prefix` defines the prefix to bind to the URI, cannot be NULL.
2. `ns` defines the URI to bind to the default namespace, cannot be NULL.

Usage

This method binds a namespace URI to a prefix, and forces the output of the XML namespace definition to the StaxWriter stream.

The stream must point to a START_ELEMENT, and the prefix scope is the current START_ELEMENT / END_ELEMENT pair.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
xml.StaxWriter.dtd
Writes a DTD to the StaxWriter stream.

Syntax

```
dtd ( 
    dtd STRING )
```

1. `dtd` defines a string representing a valid DTD, cannot be NULL.

Usage

This method writes a document type definition (DTD) for the StaxWriter stream, where `dtd` represents a valid DTD.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.emptyElement
Writes an empty XML element to the StaxWriter stream.

Syntax

```
emptyElement ( 
    name STRING )
```

1. `name` defines the local name of the XML empty element, cannot be NULL.

Usage

This method writes an empty XML element to the StaxWriter stream, where `name` defines the local name of the empty element. It cannot be NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.emptyElementNS
Writes an empty namespace qualified XML element to the StaxWriter stream.

Syntax

```
emptyElementNS ( 
    name STRING, 
    ns STRING )
```

1. `name` defines the local name of the XML empty element, cannot be NULL.
2. `ns` defines the namespace URI of the XML empty element, cannot be NULL.

Usage

This method writes an empty namespace qualified XML element to the StaxWriter stream.

If namespace URI has not been bound to a prefix with one of the functions `setPrefix`, `setDefaultNamespace`, or `declareDefaultNamespace`, the operation fails with an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
xml.StaxWriter.endDocument
Closes any open tags and writes corresponding end tags.

Syntax

```java
endDocument()
```

Usage

This method closes any open tags and writes corresponding ending tags.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.endElement
Writes an end tag to the StaxWriter stream.

Syntax

```java
endElement()
```

Usage

This method writes an end tag to the StaxWriter stream relying on the internal state to determine the prefix and local name of the last START_ELEMENT.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.entityRef
Writes a XML EntityReference to the StaxWriter stream.

Syntax

```java
entityRef(
    name  STRING
)
```

1. `name` defines the name of the entity, cannot be NULL.

Usage

This method writes a XML EntityReference, specified by `name`, to the StaxWriter stream.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.getFeature
Gets a feature of a StaxWriter object.

Syntax

```java
getFeature(
    property  STRING
)
```

1. `property` defines the name of a feature.
Usage

This method returns the name of a feature, specified in property, of the StaxWriter stream.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.processingInstruction

Writes a XML ProcessingInstruction to the StaxWriter stream

Syntax

```java
processingInstruction(
    target STRING,
    data STRING )
```

1. target defines the target of the Processing Instruction, cannot be NULL.
2. data defines the data of the Processing Instruction, or NULL.

Usage

This method writes a XML ProcessingInstruction to the StaxWriter stream, where target is the target of the Processing Instruction, which cannot be NULL. data is the data of the Processing Instruction, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.setDefaultNamespace

Binds a namespace URI to the default namespace.

Syntax

```java
setDefaultNamespace(
    ns STRING )
```

1. ns defines the URI to bind to the default namespace, cannot be NULL.

Usage

This method binds a namespace URI to the default namespace. The default namespace scope is the current START_ELEMENT / END_ELEMENT pair; ns is the URI to bind to the default namespace. It cannot be NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.setFeature

Sets a feature of a StaxWriter object.

Syntax

```java
setFeature(
    property STRING,
    value STRING )
```

1. property defines the name of a feature.
2. value is the value of the feature.
Usage

Use this method to set a feature of a StaxWriter object, where `property` is the name of a feature, and `value` is the value of the feature. The features can be changed at any time, but will only be taken into account at the beginning of a new stream (see `writeTo` or `writeToDocument`).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

```java
xml.StaxWriter.setPrefix
Binds a namespace URI to a prefix.
```

Syntax

```java
setPrefix(
    prefix STRING,
    ns STRING
)
```

1. `prefix` defines the prefix to be bind to the URI, cannot be NULL.
2. `ns` defines the namespace URI to be bind to the prefix, cannot be NULL.

Usage

Use this method to bind a namespace URI, specified in `ns`, to a prefix defined in `prefix`.

The prefix scope is the current `START_ELEMENT` / `END_ELEMENT` pair.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

```java
xml.StaxWriter.startDocument
Writes a XML declaration to the StaxWriter stream.
```

Syntax

```java
startDocument(
    encoding STRING,
    version STRING,
    standalone INTEGER
)
```

1. `encoding` defines the encoding declaration in the XML declaration. Passing a NULL value will use the default UTF-8 encoding.
2. `version` defines the XML version in the XML declaration. Passing a NULL value will use the default 1.0 version.
3. `standalone` defines the XML standalone declaration. Possible values are:
   - 1: Set `standalone="yes"`.
   - 0: Set `standalone="no"`.
   - -1: Do not set the `standalone` attribute.

Usage

This method writes a XML declaration to the StaxWriter stream to specify the encoding, the version, and whether the document is standalone.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
**Example**

This call:

```java
startDocument("utf-8","1.0",1)
```

Produces:

```xml
<?xml version="1.0" encoding="UTF-8" standalone="yes" ?>
dtd("note [<!ENTITY writer "Donald Duck.">]")
```

**xml.StaxWriter.startElement**

Writes a XML start element to the StaxWriter stream.

**Syntax**

```java
startElement (name STRING )
```

1. *name* defines the local name of the XML start element, cannot be NULL.

**Usage**

This method writes a XML start element to the StaxWriter stream. All `startElement` methods open a new scope and set the stream to a `START_ELEMENT`. Writing the corresponding `endElement` ( ) causes the scope to be closed.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.StaxWriter.startElementNS**

Writes a namespace-qualified XML start element to the StaxWriter stream.

**Syntax**

```java
startElementNS (name STRING, ns STRING )
```

1. *name* defines the local name of the XML start element, cannot be NULL.
2. *ns* defines the namespace URI of the XML start element, cannot be NULL.

**Usage**

All `startElementNS` methods open a new scope and set the stream to a `START_ELEMENT`. Writing the corresponding `endElement` causes the scope to be closed.

If namespace URI has not been bound to a prefix with one of the functions `setPrefix`, `setDefaultNamespace`, or `declareDefaultNamespace`, the operation fails with an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.StaxWriter.writeTo**
Sets the output stream of the StaxWriter object to a file or an URL, and starts the streaming.

Syntax

```java
writeTo(
    name STRING
)
```

1. `name` defines a valid URL or the name of the file that will contain the resulting XML document.

Usage

This method sets the output stream of the StaxWriter object to a file or an URL specified in `name`, and starts the streaming.

Only the following kinds of URLs are supported:

- `http://`
- `https://`
- `tcp://`
- `tcps://`
- `file:///
- `alias://`

See `fglprofile Configuration` for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See `Error handling in GWS calls (STATUS)` on page 3554.

Examples

```java
writeTo("printerList.xml")
writeTo("http://myserver:1100/documents/printerList.xml")
writeTo("https://myserver:1100/documents/printerList.xml")
writeTo("alias://printerlist")
```

In the example `printerlist` alias is defined in `fglprofile` as `ws.printerlist.url = "http://myserver:1100/documents/ptinterList.xml"`.

xml.StaxWriter.writeToDocument

Sets the output stream of the StaxWriter object to an xml.dom.Document object, and starts the streaming.

Syntax

```java
writeToDocument(
    doc xml.dom.Document
)
```

1. `doc` defines the empty `DomDocument` object that will contain the resulting XML document.

Usage

This method sets the output stream of the StaxWriter object to a `DomDocument` specified in `doc`, and starts the streaming.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.writeToPipe
Sets the output stream of the StaxWriter object to a PIPE, and starts the streaming.

**Syntax**

```java
writeToPipe(  
   name STRING )
```

1. `name` defines the command to start the PIPE that will get the resulting XML document.

**Usage**

This method sets the output stream of the StaxWriter object to a PIPE command specified in `name`, and starts the streaming.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxWriter.writeToText
Sets the output stream of the StaxWriter object to a TEXT large object, and starts the streaming.

**Syntax**

```java
writeToText(  
   txt TEXT )
```

1. `txt` defines a TEXT lob located in memory that will contain the resulting XML document.

**Usage**

This method sets the output stream of the StaxWriter object to a text large object in memory, specified in `txt`, and starts the streaming.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**StaxWriter Features**

Features of the `xml.StaxWriter` class.

**Table 656: StaxWriter features**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>format-pretty-print</td>
<td>Formats the output by adding whitespace to produce a pretty-printed, indented, human-readable form. Default value is FALSE.</td>
</tr>
<tr>
<td>smart-ending-elements</td>
<td>Outputs each tag closed with an <code>endElement()</code> call as empty element if it has no children. Default value is FALSE.</td>
</tr>
</tbody>
</table>
Example
This example uses methods from the xml.StaxWriter class.

```plaintext
IMPORT xml

FUNCTION save(file)
    DEFINE file STRING
    DEFINE writer xml.StaxWriter
    TRY
        LET writer = xml.StaxWriter.Create()
        CALL writer.setFeature("format-pretty-print", TRUE)
        CALL writer.writeTo(file)
        CALL writer.startDocument("utf-8","1.0",true)
        CALL writer.comment("This is my first comment using a stax writer")
        CALL writer.setPrefix("c","http://www.mycompany.com/c")
        CALL writer.setPrefix("d","http://www.mycompany.com/d")
        CALL writer.startElementNS("root","http://www.mycompany.com/d")
        CALL writer.attribute("attr1","value1")
        CALL writer.attribute("attr2","value2")
        CALL writer.attributeNS("attr3","http://www.mycompany.com/d","value3")
        CALL writer.comment("This is a comment using a stax writer")
        CALL writer.startElementNS("eltA","http://www.mycompany.com/d")
        CALL writer.CData("<this is a CData section>")
        CALL writer.setDefaultNamespace("http://www.mycompany.com/d")
        CALL writer.startElementNS("eltB","http://www.mycompany.com/c")
        CALL writer.characters("Hello world, I'm from the development team")
        CALL writer.entityRef("one")
        CALL writer.endElement()
        CALL writer.startElementNS("eltA","http://www.mycompany.com/d")
        CALL writer.startElementNS("eltB","http://www.mycompany.com/c")
        CALL writer.characters("Hello world, I'm from the development team")
        CALL writer.startElementNS("eltA","http://www.mycompany.com/d")
        CALL writer.CData("<this is a CData section>")
        CALL writer.setDefaultNamespace("http://www.mycompany.com/d")
        CALL writer.startElementNS("eltB","http://www.mycompany.com/c")
        CALL writer.characters("Hello world, I'm from the development team")
        CALL writer.entityRef("one")
        CALL writer.endElement()
        CALL writer.startElementNS("eltA","http://www.mycompany.com/d")
        CALL writer.CData("<this is a CData section>")
        CALL writer.setDefaultNamespace("http://www.mycompany.com/d")
        CALL writer.startElementNS("eltB","http://www.mycompany.com/c")
        CALL writer.characters("Hello world, I'm from the development team")
        CALL writer.entityRef("one")
        CALL writer.endElement()
        RETURN TRUE
    CATCH
        DISPLAY "StaxWriter ERROR ":,STATUS, SQLCA.SQLERRM
        RETURN FALSE
    END TRY
END FUNCTION
```

The StaxReader class
The StaxReader class provides methods compatible with Streaming API for XML(StAX) for reading XML documents.

The STATUS variable is set to zero after a successful method call.

Syntax

```
xml.StaxReader
```

xml.StaxReader methods
Methods for the xml.StaxReader class.

Table 657: Class methods: Creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml.StaxReader.Create()</td>
<td>Constructor of a StaxReader object.</td>
</tr>
</tbody>
</table>
### Table 658: Object methods: Configuration

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>setFeature(property STRING, value STRING)</code></td>
<td>Sets a feature of a StaxReader object.</td>
</tr>
<tr>
<td><code>getFeature(property STRING)</code></td>
<td>Gets a feature of a StaxReader object.</td>
</tr>
</tbody>
</table>

### Table 659: Object methods: Input

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>readFrom(name STRING)</code></td>
<td>Sets the input stream of the StaxReader object to a file or an URL and starts the streaming.</td>
</tr>
<tr>
<td><code>readFromDocument(_doc xml.DomDocument)</code></td>
<td>Sets the input stream of the StaxReader object to a DomDocument object and starts the streaming.</td>
</tr>
<tr>
<td><code>readFromText(_txt TEXT)</code></td>
<td>Sets the input stream of the StaxReader object to a TEXT large object and starts the streaming.</td>
</tr>
<tr>
<td><code>readFromPipe(name STRING)</code></td>
<td>Sets the input stream of the StaxReader object to a PIPE and starts the streaming.</td>
</tr>
<tr>
<td><code>close()</code></td>
<td>Closes the StaxReader streaming and releases all associated resources.</td>
</tr>
</tbody>
</table>
### Table 660: Object methods: Access

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getEventType()</code></td>
<td>Returns a string that indicates the type of event the cursor of the StaxReader object is pointing to.</td>
</tr>
<tr>
<td><code>hasName()</code></td>
<td>Checks whether the StaxReader cursor points to a node with a name.</td>
</tr>
<tr>
<td><code>hasText()</code></td>
<td>Checks whether the StaxReader cursor points to a node with a text value.</td>
</tr>
<tr>
<td><code>isEmptyElement()</code></td>
<td>Checks whether the StaxReader cursor points to an empty element node.</td>
</tr>
<tr>
<td><code>isStartElement()</code></td>
<td>Checks whether the StaxReader cursor points to a start element node.</td>
</tr>
<tr>
<td><code>isEndElement()</code></td>
<td>Checks whether the StaxReader cursor points to an end element node.</td>
</tr>
<tr>
<td><code>isCharacters()</code></td>
<td>Checks whether the StaxReader cursor points to a text node.</td>
</tr>
<tr>
<td><code>isIgnorableWhitespace()</code></td>
<td>Checks whether the StaxReader cursor points to ignorable whitespace.</td>
</tr>
</tbody>
</table>

### Table 661: Object methods: Document

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getEncoding()</code></td>
<td>Returns the document encoding defined in the XML Document declaration, or NULL.</td>
</tr>
<tr>
<td><code>getVersion()</code></td>
<td>Returns the document version defined in the XML Document declaration, or NULL.</td>
</tr>
<tr>
<td><code>isStandalone()</code></td>
<td>Checks whether the document standalone attribute defined in the XML Document declaration is set to yes.</td>
</tr>
<tr>
<td><code>standaloneSet()</code></td>
<td>Checks whether the document standalone attribute is defined in the XML Document declaration.</td>
</tr>
</tbody>
</table>
Table 662: Object methods: Nodes

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getPrefix()</code></td>
<td>Returns the prefix of the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getLocalName()</code></td>
<td>Returns the local name of the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getName()</code></td>
<td>Returns the qualified name of the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getNamespace()</code></td>
<td>Returns the namespace URI of the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getText()</code></td>
<td>Returns as a string the value of the current XML node, or NULL.</td>
</tr>
</tbody>
</table>

Table 663: Object methods: Processing Instructions

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getPITarget()</code></td>
<td>Returns the target part of a XML Processing Instruction node, or NULL.</td>
</tr>
<tr>
<td><code>getPIData()</code></td>
<td>Returns the data part of a XML Processing Instruction node, or NULL.</td>
</tr>
</tbody>
</table>
### Table 664: Object methods: Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getAttributeCount()</code></td>
<td>Returns the number of XML attributes defined on the current XML node, or zero.</td>
</tr>
<tr>
<td><code>getAttributeLocalName()</code></td>
<td>Returns the local name of a XML attribute defined at a given position on the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getAttributeNamespace()</code></td>
<td>Returns the namespace URI of a XML attribute defined at a given position on the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getAttributePrefix()</code></td>
<td>Returns the prefix of a XML attribute defined at a given position on the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getAttributeValue()</code></td>
<td>Returns the value of a XML attribute defined at a given position on the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>findAttributeValue()</code></td>
<td>Returns the value of an XML attribute of a given name and/or namespace.</td>
</tr>
</tbody>
</table>
### Table 665: Object methods: Namespace

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>lookupNamespace (prefix STRING )</code></td>
<td>LOOKS up the namespace URI associated with a given prefix starting from the current XML node the StaxReader cursor is pointing to.</td>
</tr>
<tr>
<td><code>lookupPrefix (ns STRING )</code></td>
<td>LOOKS up the prefix associated with a given namespace URI, starting from the current XML node the StaxReader cursor is pointing to.</td>
</tr>
<tr>
<td><code>getNamespaceCount ()</code></td>
<td>RETURNS the number of namespace declarations defined on the current XML node, or zero.</td>
</tr>
<tr>
<td><code>getNamespacePrefix (index INTEGER )</code></td>
<td>RETURNS the prefix of a namespace declaration defined at a given position on the current XML node, or NULL.</td>
</tr>
<tr>
<td><code>getNamespaceURI (index INTEGER )</code></td>
<td>RETURNS the URI of a namespace declaration defined at a given position on the current XML node, or NULL.</td>
</tr>
</tbody>
</table>

### Table 666: Object methods: Navigation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>hasNext ()</code></td>
<td>CHECKS whether the StaxReader cursor can be moved to a XML node next to it.</td>
</tr>
<tr>
<td><code>next ()</code></td>
<td>MOVES the StaxReader cursor to the next XML node.</td>
</tr>
<tr>
<td><code>nextTag ()</code></td>
<td>MOVES the StaxReader cursor to the next XML open or end tag</td>
</tr>
<tr>
<td><code>nextSibling ()</code></td>
<td>MOVES the StaxReader cursor to the immediate next sibling XML Element of the current node, skipping all its child nodes.</td>
</tr>
</tbody>
</table>

xml.StaxReader.close
Closes the StaxReader streaming and releases all associated resources.

**Syntax**

```
close()
```

**Usage**

This method closes the stream.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.Create

Constructor of a StaxReader object.

**Syntax**

```java
xml.StaxReader.Create()
RETURNS xml.StaxReader
```

**Usage**

Use this method to create and return a StaxReader object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.findAttributeValue

Returns the value of an XML attribute of a given name and/or namespace.

**Syntax**

```java
findAttributeValue(
    name STRING,
    ns STRING )
RETURNS STRING
```

1. **name** defines the name of the attribute to retrieve. It cannot be NULL.
2. **ns** defines the namespace URI of the attribute to retrieve, or NULL if the attribute is not namespace-qualified.

**Usage**

This method returns the value of an XML attribute of a given name and/or namespace on the current XML node, where **name** is the name of the attribute and **ns** is the namespace or is NULL if not namespace-qualified.

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getAttributeCount

Returns the number of XML attributes defined on the current XML node, or zero.

**Syntax**

```java
getAttributeCount()
RETURNS INTEGER
```

**Usage**

Use this method to return the number of XML attributes defined on the current XML node.

This method is only valid on a START_ELEMENT node.
In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See **Error handling in GWS calls (STATUS)** on page 3554.

**xml.StaxReader.getAttributeLocalName**

Returns the local name of a XML attribute defined at a given position on the current XML node, or NULL.

**Syntax**

```java
getAttributeLocalName(
    index INTEGER )
RETURNS STRING
```

1. *index* defines the position of the attribute to return (index starts at 1).

**Usage**

Gets the local name of a XML attribute defined at *index* position on the current XML node. It returns the local name or NULL.

This method is only valid on a **START_ELEMENT** node.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See **Error handling in GWS calls (STATUS)** on page 3554.

**xml.StaxReader.getAttributeNamespace**

Returns the namespace URI of a XML attribute defined at a given position on the current XML node, or NULL.

**Syntax**

```java
getAttributeNamespace(
    index INTEGER )
RETURNS STRING
```

1. *index* defines the position of the attribute to return (index starts at 1).

**Usage**

This method returns the value of a namespace URI attribute at *index* position on the current XML node, or NULL.

This method is only valid on a **START_ELEMENT** node.

In case of error, the method throws an exception and sets the **STATUS** variable. Depending on the error, a human-readable description of the problem is available in the **SQLCA.SQLERRM** register. See **Error handling in GWS calls (STATUS)** on page 3554.

**xml.StaxReader.getAttributePrefix**

Returns the prefix of a XML attribute defined at a given position on the current XML node, or NULL.

**Syntax**

```java
getAttributePrefix(
    index INTEGER )
RETURNS STRING
```

1. *index* defines the position of the attribute to return (index starts at 1).

**Usage**

This method returns the prefix attribute at *index* position on the current XML node, or NULL.
This method is only valid on a \texttt{START\_ELEMENT} node.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

\texttt{xml.StaxReader.getAttributeValue}

Returns the value of a XML attribute defined at a given position on the current XML node, or NULL.

\textbf{Syntax}

\begin{verbatim}
getAttributeValue(index INTEGER )
RETURNS STRING
\end{verbatim}

1. \textit{index} defines the position of the attribute to return (index starts at 1).

\textbf{Usage}

Use this method to return the value of a XML attribute at \textit{index} position, or NULL.

This method is only valid on a \texttt{START\_ELEMENT} node.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

\texttt{xml.StaxReader.getEncoding}

Returns the document encoding defined in the XML Document declaration, or NULL.

\textbf{Syntax}

\begin{verbatim}
getEncoding()
RETURNS STRING
\end{verbatim}

\textbf{Usage}

This method returns the document encoding as defined in the XML document declaration, or NULL if there is none.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

\texttt{xml.StaxReader.getEventType}

Returns a string that indicates the type of event the cursor of the StaxReader object is pointing to.

\textbf{Syntax}

\begin{verbatim}
getEventType()
RETURNS STRING
\end{verbatim}

\textbf{Usage}

This method returns the name of the event type the StaxReader object cursor is pointing to. See StaxReader Event Types on page 3031 for the full list of StaxReader event types.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.
xml.StaxReader.getFeature

Gets a feature of a StaxReader object.

**Syntax**

```java
getFeature (
    property STRING
) 
RETURNS STRING
```

1. `property` defines the name of a feature.

**Usage**

This method returns the name of a feature for the StaxReader object, where `property` is the name of the StaxReader feature.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getLocalName

Returns the local name of the current XML node, or NULL.

**Syntax**

```java
getLocalName ()
RETURNS STRING
```

**Usage**

Use this method to return the local name of the current XML node, or NULL if there is none.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getName

Returns the qualified name of the current XML node, or NULL.

**Syntax**

```java
getName ()
RETURNS STRING
```

**Usage**

This method returns the qualified name of the current XML node, or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getNamespace

Returns the namespace URI of the current XML node, or NULL.

**Syntax**

```java
getNamespace ()
```
Usage

This method returns the namespace URI of the current XML node, or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getNamespaceCount

Returns the number of namespace declarations defined on the current XML node, or zero.

Syntax

```java
getNamespaceCount ()
RETURNS INTEGER
```

Usage

This method returns the number of namespace declarations in the current XML node, or zero if none.

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getNamespacePrefix

Returns the prefix of a namespace declaration defined at a given position on the current XML node, or NULL.

Syntax

```java
getNamespacePrefix ( 
 index INTEGER )
RETURNS STRING
```

1. `index` defines the position of the namespace declaration (index starts at 1).

Usage

This method returns the prefix of a namespace declaration at `index` position on the current XML node, or NULL.

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getNamespaceURI

Returns the URI of a namespace declaration defined at a given position on the current XML node, or NULL.

Syntax

```java
getNamespaceURI ( 
 index INTEGER )
RETURNS STRING
```

1. `index` defines the position of the namespace declaration (index starts at 1).
Usage

This method returns the URI of a namespace declaration defined at index position on the current XML node, or NULL.

This method is only valid on a START_ELEMENT node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getPIData
Returns the data part of a XML Processing Instruction node, or NULL.

Syntax

getPIData ()
RETURNS STRING

Usage

Use this method to return the data part of a XML PROCESSING_INSTRUCTION node, or NULL.

This method is only valid on a PROCESSING_INSTRUCTION node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getPITarget
Returns the target part of a XML Processing Instruction node, or NULL.

Syntax

getPITarget ()
RETURNS STRING

Usage

This method returns the target part of a XML Processing Instruction node, or NULL.

This method is only valid on a PROCESSING_INSTRUCTION node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getPrefix
Returns the prefix of the current XML node, or NULL.

Syntax

getPrefix ()
RETURNS STRING

Usage

This method returns the prefix of the current XML node, or NULL.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getText

Returns as a string the value of the current XML node, or NULL.

Syntax

```
getText()
RETURNS STRING
```

Usage

Use this method to return a string containing text in the current XML node, or NULL if there is none.

This method is only valid on CHARACTERS, CDATA, SPACE, COMMENT, DTD, and ENTITY_REFERENCE nodes. For an ENTITY_REFERENCE, this method returns the replacement value, or NULL if none. See StaxReader Event Types on page 3031.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.getVersion

Returns the document version defined in the XML Document declaration, or NULL.

Syntax

```
getVersion()
RETURNS STRING
```

Usage

This method returns the document version as defined in the XML document declaration, or NULL if not defined.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.hasName

Checks whether the StaxReader cursor points to a node with a name.

Syntax

```
hasName()
RETURNS INTEGER
```

Usage

This method returns TRUE if the current XML node has a name, FALSE otherwise. It returns TRUE for START_ELEMENT and END_ELEMENT, FALSE for all other nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.hasNext
Checks whether the StaxReader cursor can be moved to a XML node next to it.

**Syntax**

```java
hasNext ()
RETURNS INTEGER
```

**Usage**

Use this method to check if there is still a XML node in the stream. It returns TRUE if there is, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.hasText
Checks whether the StaxReader cursor points to a node with a text value.

**Syntax**

```java
hasText ()
RETURNS INTEGER
```

**Usage**

Use this method to check if the StaxReader cursor is pointing to a node with a text value. It returns TRUE if the current XML node has a text value, FALSE otherwise. This method returns TRUE for CHARACTERS, SPACE, CDATA, COMMENT, ENTITY_REFERENCE, and DTD nodes, FALSE for all other nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.isCharacters
Checks whether the StaxReader cursor points to a text node.

**Syntax**

```java
isCharacters ()
RETURNS INTEGER
```

**Usage**

Use this method to check if the StaxReader cursor is pointing to a text node. It returns TRUE if the current XML node is a text node, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.isEmptyElement
Checks whether the StaxReader cursor points to an empty element node.

**Syntax**

```java
isEmptyElement ()
RETURNS INTEGER
```
**Usage**

Use this method to check if the StaxReader cursor is pointing to an XML element node that has no children. It returns TRUE if the node has no children, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.isEndElement

Checks whether the StaxReader cursor points to an end element node.

**Syntax**

```java
isEndElement()
RETURNS INTEGER
```

**Usage**

Use this method to check if the StaxReader cursor is pointing to an end element node. It returns TRUE if the current XML node is an end element node, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.isIgnorableWhitespace

Checks whether the StaxReader cursor points to ignorable whitespace.

**Syntax**

```java
isIgnorableWhitespace()
RETURNS INTEGER
```

**Usage**

Use this method to check if the StaxReader cursor is pointing to a text node with ignorable whitespace. It returns TRUE if there is ignorable whitespace, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.isStandalone

Checks whether the document standalone attribute defined in the XML Document declaration is set to yes.

**Syntax**

```java
isStandalone()
RETURNS INTEGER
```

**Usage**

Use this method to check if the document standalone attribute defined in the XML Document declaration is set to yes. It returns TRUE if set to yes, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
xml.StaxReader.isStartElement
Checks whether the StaxReader cursor points to a start element node.

**Syntax**

```plaintext
isStartElement()
RETURNS INTEGER
```

**Usage**

Use this method to check if the StaxReader cursor is pointing to a start element node. It returns TRUE if the current XML node is a start element node, FALSE otherwise.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.lookupNamespace
Looks up the namespace URI associated with a given prefix starting from the current XML node the StaxReader cursor is pointing to.

**Syntax**

```plaintext
lookupNamespace(  
  prefix STRING  
)  
RETURNS STRING
```

1. prefix defines the prefix to look for; if NULL the default namespace URI will be returned.

**Usage**

Use this method to return the namespace URI associated with the prefix specified by prefix at the current XML node. It returns a string with the namespace URI associated with the prefix, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.lookupPrefix
Looks up the prefix associated with a given namespace URI, starting from the current XML node the StaxReader cursor is pointing to.

**Syntax**

```plaintext
lookupPrefix(  
  ns STRING  
)  
RETURNS STRING
```

1. ns defines the namespace URI to look for. It cannot be NULL.

**Usage**

Use this method to return the prefix associated with the namespace specified by ns at the current XML node. It returns the prefix, or NULL if there is none.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
xml.StaxReader.next

Moves the StaxReader cursor to the next XML node.

**Syntax**

```java
next ()
```

**Usage**

Use this method to move the StaxReader cursor to the next XML node in the stream.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.nextSibling

Moves the StaxReader cursor to the immediate next sibling XML Element of the current node, skipping all its child nodes.

**Syntax**

```java
nextSibling ()
```

**Usage**

Use this method to move the StaxReader cursor to the next sibling of the current XML Element node in the stream, skipping all its child nodes. The cursor points to the parent end tag if there are no siblings.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.nextTag

Moves the StaxReader cursor to the next XML open or end tag

**Syntax**

```java
nextTag ()
```

**Usage**

Use this method to move the StaxReader cursor to the next XML open or end tag. The cursor points to the end of the document if there is no next XML open or end tag.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.readFrom

Sets the input stream of the StaxReader object to a file or an URL and starts the streaming

**Syntax**

```java
readFrom( 
    name STRING )
```

1. **name** defines a valid URL or the name of the file to read.
Usage
This method sets the input stream of the StaxReader object to a file or an URL, where name is a valid URL or the name of the file.

Only the following kinds of URLs are supported:

- http://
- https://
- tcp://
- tcps://
- file:////
- alias://

See fglprofile Configuration for more details about URL mapping with aliases, and for proxy and security configuration.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.readFromDocument
Sets the input stream of the StaxReader object to a DomDocument object and starts the streaming.

Syntax

```java
readFromDocument(
    _doc xml.DomDocument
)
```

Usage
Use this method to set the input stream of the StaxReader object to a xml.DomDocument object, where _doc is a valid object containing an XML document.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.readFromPipe
Sets the input stream of the StaxReader object to a PIPE and starts the streaming.

Syntax

```java
readFromPipe(
    name STRING
)
```

1. name defines the command to start the PIPE and where the reader will get the XML from.

Usage
Use this method to set the input stream of the StaxReader object to a PIPE, where name is the command to read from the PIPE.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.StaxReader.readFromText
Sets the input stream of the StaxReader object to a TEXT large object and starts the streaming.

**Syntax**

```java
readFromText (
    _txt TEXT )
```

1. `_txt` defines a TEXT lob located in memory and containing the XML to read.

**Usage**

Use this method to set the input stream of the StaxReader object to a TEXT large object, where `_txt` is the text to read.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

**xml.StaxReader.setFeature**

Sets a feature of a StaxReader object.

**Syntax**

```java
setFeature (   
    property STRING,   
    value STRING )
```

1. `property` defines the name of a feature.
2. `value` defines the value of the feature.

**Usage**

Use this method to set a feature for the StaxReader object, where `property` is the name of a `XmlStaxReader` feature, and `value` is the value of a feature.

The features can be changed at any time, but they will only be taken into account at the beginning of a new stream (see `readFrom` or `readFromDocument`).

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

**xml.StaxReader.standaloneSet**

Checks whether the document standalone attribute is defined in the XML Document declaration.

**Syntax**

```java
standaloneSet ()
RETURNS INTEGER
```

**Usage**

Use this method to check if the document standalone attribute is defined in the XML Document declaration. It returns `TRUE` if the standalone attribute is set, `FALSE` otherwise.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.
StaxReader Features
Features of the xml.StaxReader class.

</tbody>
</table>
**Type** | **Description** | **XML sample**
---|---|---
ERROR | StaxReader cursor points to an unexpected XML node. | |

**Example**
Example using methods of the `xml.StaxReader` class.

```
IMPORT xml

FUNCTION parse(file)
DEFINE file STRING
DEFINE event STRING
DEFINE ind INTEGER
DEFINE reader xml.StaxReader
TRY
  LET reader=xml.StaxReader.Create()
  CALL reader.readFrom(file)
  WHILE (true)
    LET event=reader.getEventType()
    CASE event
      WHEN "START_DOCUMENT"
        DISPLAY "Document reading started"
        DISPLAY "XML Version : ",reader.getVersion()
        DISPLAY "XML Encoding : ",reader.getEncoding()
        IF reader.standaloneSet() THEN
          IF reader.isStandalone() THEN
            DISPLAY "Standalone : yes"
          ELSE
            DISPLAY "Standalone : no"
          END IF
        END IF
      WHEN "END_DOCUMENT"
        DISPLAY "Document reading finished"
      WHEN "START_ELEMENT"
        IF reader.isEmptyElement() THEN
          DISPLAY "<"||reader.getName()||"/>
        ELSE
          DISPLAY "<"||reader.getName()||">
          FOR ind=1 TO reader.getNamespaceCount()
            DISPLAY "xmlns:"||reader.getNamespacePrefix(ind)||"=
            ||reader.getNamespaceURI(ind)
          END FOR
          FOR ind=1 TO reader.getAttributeCount()
            IF reader.getAttributePrefix(ind) THEN
              DISPLAY reader.getAttributePrefix(ind)||":"
            ELSE
              DISPLAY reader.getAttributeLocalName(ind)||"=
            END IF
            ||reader.getAttributeValue(ind)
          END FOR
          DISPLAY "</"||reader.getName()||">
      WHEN "CHARACTERS"
        IF reader.hasText() AND NOT reader.isIgnorableWhitespace() THEN
          DISPLAY "CHARACTERS :",reader.getText()
        END IF
      WHEN "COMMENT"
        IF reader.hasText() THEN
          DISPLAY "Comment :",reader.getText()
        END IF
    END CASE
  END WHILE
END TRY
```
XML serialization classes
The XML serialization classes convert BDL variables to XML and XML to BDL variables.

The Serializer class
The xml.Serializer class provides methods to manage options for the serializer engine, and to use the serializer engine to serialize variables and XML element nodes.

This class is a static class and does not have to be instantiated.

The STATUS variable is set to zero after a successful method call.
xml.Serializer methods
Methods for the xml.Serializer class.
Table 669: Class methods

</tbody>
</table>
xml.Serializer.CreateXmlSchemas

Creates XML schemas corresponding to the given variable, and fills a dynamic array with xml.DomDocument objects each representing a XML schema.

**Syntax**

```plaintext
xml.Serializer.CreateXmlSchemas (  
    var RECORD,  
    schemas RECORD )
```

1. `var` is a given variable.
2. `schemas` is a dynamic array of xml.DomDocument objects, each representing an XML schema.

**Usage**

Use this method to create XML schemas corresponding to the given variable `var`, and fill the dynamic array `schemas` with xml.DomDocument objects each representing a XML schema.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Serializer.DomToStax

Serializes a XML DomNode object to a StaxWriter object.

**Syntax**

```plaintext
xml.Serializer.DomToStax (  
    node xml.DomNode,  
    stax xml.StaxWriter )
```

1. `node` is a DomNode object.
2. `stax` is a StaxWriter object.

**Usage**

Use this method to serialize a xml.DomNode object to a StaxWriter object.

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Serializer.DomToVariable

Serializes a XML element node into a BDL variable using a DomNode object.

**Syntax**

```plaintext
xml.Serializer.DomToVariable (  
    node xml.DomNode,  
    var RECORD )
```

1. `node` is a DomNode object of type ELEMENT_NODE.
2. `var` is any Genero BDL variable with optional XML mapping attributes.
Usage
Use this method to serialize a XML element node defined by `node` as a DomNode object into a BDL variable.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Serializer.getOption
Gets a global option value from the serializer engine.

Syntax
```
xml.Serializer.GetOption(
    str STRING )
RETURNS STRING
```

1. `str` defines the option flag.

Usage
This method gets an option value from the serializer engine for an option defined by `str`. It returns the value of the flag.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Serializer.OptimizedDomToVariable
Serializes a XML element node into a BDL variable using a DomNode object.

This API implements the XML-binary Optimized packaging specification. See https://www.w3.org/TR/xop10/.

Syntax
```
xml.Serializer.OptimizedDomToVariable(
    node xml.DomNode,
    var RECORD,
    xopTable RECORD )
```

1. `node` is a `DomNode` object of type `ELEMENT_NODE`.
2. `var` is any Genero BDL variable with optional XML mapping attributes.
3. `xopTable` is a dynamic array, defined as follows:
```
DEFINE XOPTable DYNAMIC ARRAY OF RECORD
    cid STRING, # Content-ID to identify the part in a XML Optimized document
    data BYTE, # Blob handled as part in a XML Optimized document
    file STRING # Name of the file handled as part in an XML Optimized document
END RECORD
```

The `XOPTable` dynamic array is necessary to keep the relation between the data to be handled as separate part in an XML Optimized document via an `href` attribute containing the Content-ID value. This parameter can be NULL.

Usage
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
Optimized APIs

Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the XOPTable (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<ms:data xmlns:m='http://example.org/stuff'>
  <m:photo>
    <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include' href='cid:myref@tempuri.org'/>
  </m:photo>
</m:data>
```

If you have NOT used XMLOptimizedContent, the XOPTable will contain one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains the BYTE to be sent or to be received as an attachment.
- `file` contains NULL.

If you have used XMLOptimizedContent, the XOPtable contains one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains NULL.
- `file` contains the file name to be sent or to be received as an attachment.

xml.Serializer.OptimizedSoapSection5ToVariable

Serializes an XML element node into a BDL variable in Soap Section 5 encoding.

This API implements the XML-binary Optimized packaging specification. See [https://www.w3.org/TR/xop10/](https://www.w3.org/TR/xop10/).

Syntax

```c
xml.Serializer.OptimizedSoapSection5ToVariable(
    node xml.DomNode,
    var RECORD,
    xopTable RECORD)
```

1. `node` is a DomNode object of type ELEMENT_NODE.
2. `var` is any Genero BDL variable with optional XML mapping attributes.
3. `xopTable` is a dynamic array, defined as follows:

   ```c
   DEFINE XOPTable DYNAMIC ARRAY OF RECORD
   cid STRING,  # Content-ID to identify the part in a XML Optimized document
   data BYTE,   # Blob handled as part in a XML Optimized document
   file STRING  # Name of the file handled as part in an XML Optimized document
   END RECORD
   ```

   The XOPTable dynamic array is necessary to keep the relation between the data to be handled as separate part in an XML Optimized document via an href attribute containing the Content-ID value. This parameter can be NULL.
Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Optimized APIs

Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the XOPTable (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<m:data xmlns:m='http://example.org/stuff'>
  <m:photo>
    <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include' href='cid:myref@tempuri.org'/>
  </m:photo>
</m:data>
```

If you have NOT used XMLOptimizedContent, the XOPTable will contain one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains the BYTE to be sent or to be received as an attachment.
- `file` contains NULL.

If you have used XMLOptimizedContent, the XOPtable contains one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains NULL.
- `file` contains the file name to be sent or to be received as an attachment.

xml.Serializer.OptimizedStaxToVariable

Serializes an XML element node into a BDL variable using a StaxReader object.

This API implements the XML-binary Optimized packaging specification. See https://www.w3.org/TR/xop10/.

Syntax

```sql
xml.Serializer.OptimizedStaxToVariable (  
  stax xml.StaxReader,  
  var RECORD,  
  xopTable RECORD )
```

1. `stax` is a StaxReader object where the cursor points to an XML Element node.
2. `var` is any Genero BDL variable with optional XML mapping attributes.
3. `xopTable` is a dynamic array, defined as follows:

```
DEFINE XOPTable DYNAMIC ARRAY OF RECORD
  cid STRING, # Content-ID to identify the part in a XML Optimized document
  data BYTE, # Blob handled as part in a XML Optimized document
  file STRING # Name of the file handled as part in an XML Optimized document
END RECORD
```
The XOPTable dynamic array is necessary to keep the relation between the data to be handled as separate part in an XML Optimized document via an href attribute containing the Content-ID value. This parameter can be NULL.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Optimized APIs

Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the XOPTable (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<m:photo xmlns:m='http://example.org/stuff'>
  <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include'
    href='cid:myref@tempuri.org'/>
</m:photo>
</m:data>
```

If you have NOT used XMLOptimizedContent, the XOPTable will contain one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains the BYTE to be sent or to be received as an attachment.
- `file` contains NULL.

If you have used XMLOptimizedContent, the XOPtable contains one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains NULL.
- `file` contains the file name to be sent or to be received as an attachment.

xml.Serializer.OptimizedVariableToDom

Serializes a BDL variable into a XML element node using a DomNode object.

This API implements the XML-binary Optimized packaging specification. See https://www.w3.org/TR/xop10/.

Syntax

```haskell
xml.Serializer.OptimizedVariableToDom(
  var fgl-type,
  node xml.DomNode,
  xopTable RECORD )
```

1. `var` is any Genero BDL variable with optional XML mapping attributes.
2. `node` is a DomNode object of type ELEMENT_NODE or DOCUMENT_FRAGMENT_NODE.
3. `xopTable` is a dynamic array, defined as follows:

```
DEFINE XOPTable DYNAMIC ARRAY OF RECORD
  cid STRING, # Content-ID to identify the part in a XML Optimized document
  data BYTE, # Blob handled as part in a XML Optimized document
```
The XOPTable dynamic array is necessary to keep the relation between the data to be handled as separate part in an XML Optimize document via an href attribute containing the Content-ID value. This parameter can be NULL.

**Usage**

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLErrorM register. See Error handling in GWS calls (STATUS) on page 3554.

**Optimized APIs**

Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the XOPTable (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<data xmlns:m='http://example.org/stuff'>
  <m:photo>
    <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include' href='cid:myref@tempuri.org'/>
  </m:photo>
</data>
```

If you have NOT used XMLOptimizedContent, the XOPTable will contain one element where:

1. cid contains "myref@tempuri.org".
2. data contains the BYTE to be sent or to be received as an attachment.
3. file contains NULL.

If you have used XMLOptimizedContent, the XOPtable contains one element where:

1. cid contains "myref@tempuri.org".
2. data contains NULL.
3. file contains the file name to be sent or to be received as an attachment.

xml.Serializer.OptimizedVariableToSoapSection5

Serializes a BDL variable into a XML element node in Soap Section 5 encoding.

This API implements the XML-binary Optimized packaging specification. See https://www.w3.org/TR/xop10/.

**Syntax**

```bsh
xml.Serializer.OptimizedVariableToSoapSection5( var ,
  node xml.DomNode, 
  xopTable RECORD)
```

1. var is any Genero BDL variable with optional XML mapping attributes.
2. node is a DomNode object of type ELEMENT_NODE or DOCUMENT_FRAGMENT_NODE.
3. **xopTable** is a dynamic array, defined as follows:

```plaintext
DEFINE XOPTable DYNAMIC ARRAY OF RECORD
    cid STRING,  # Content-ID to identify the part in a XML Optimized document
    data BYTE,   # Blob handled as part in a XML Optimized document
    file STRING  # Name of the file handled as part in an XML Optimized document
END RECORD
```

The XOPTable dynamic array is necessary to keep the relation between the data to be handled as separate part in an XML Optimized document via an href attribute containing the Content-ID value. This parameter can be NULL.

**Usage**

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Optimized APIs**

Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the XOPTable (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<m:data xmlns:m='http://example.org/stuff'>
    <m:photo>
        <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include' href='cid:myref@tempuri.org'/>
    </m:photo>
</m:data>
```

If you have NOT used XMLOptimizedContent, the XOPTable will contain one element where:

- **cid** contains "myref@tempuri.org".
- **data** contains the BYTE to be sent or to be received as an attachment.
- **file** contains NULL.

If you have used XMLOptimizedContent, the XOPtable contains one element where:

- **cid** contains "myref@tempuri.org".
- **data** contains NULL.
- **file** contains the file name to be sent or to be received as an attachment.

```plaintext
xml.Serializer.OptimizedVariableToStax
```

Serializes a BDL variable into a XML element node using a StaxWriter object.

This API implements the XML-binary Optimized packaging specification. See [https://www.w3.org/TR/xop10/](https://www.w3.org/TR/xop10/).

**Syntax**

```plaintext
xml.Serializer.OptimizedVariableToStax (var RECORD, stax xml.StaxWriter,
```
1. `var` is any Genero BDL variable with optional XML mapping attributes.
2. `stax` is a StaxWriter object.
3. `xopTable` is a dynamic array, defined as follows:

```gdscript
DEFINE XOPTable DYNAMIC ARRAY OF RECORD
    cid STRING, # Content-ID to identify the part in a XML Optimized document
    data BYTE, # Blob handled as part in a XML Optimized document
    file STRING # Name of the file handled as part in an XML Optimized document
END RECORD
```

The `XOPTable` dynamic array is necessary to keep the relation between the data to be handled as separate part in an XML Optimized document via an href attribute containing the Content-ID value. This parameter can be NULL.

**Usage**

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Optimized APIs**

Optimized APIs work in the same method as the non-Optimized APIs, with the addition that the optimized API supports XML-binary Optimized format, and return in the `XOPTable` (if not NULL) the BYTE or the file on disk to handle as a separate part based on the Content-ID.

For instance, if a BYTE has to be sent as an attachment via MTOM, the API will create an XML Optimized node with an href containing the Content-ID returned in the XOP table. This node will include a reference to that BYTE.

For example, given this example of an XML-optimized document:

```xml
<m:data xmlns:m='http://example.org/stuff'>
    <m:photo>
        <xop:Include xmlns:xop='http://www.w3.org/2004/08/xop/include'
                     href='cid:myref@tempuri.org'/>
    </m:photo>
</m:data>
```

If you have NOT used XMLOptimizedContent, the `XOPTable` will contain one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains the BYTE to be sent or to be received as an attachment.
- `file` contains NULL.

If you have used XMLOptimizedContent, the `XOPtable` contains one element where:

- `cid` contains "myref@tempuri.org".
- `data` contains NULL.
- `file` contains the file name to be sent or to be received as an attachment.
Sets a global option value for the serializer engine

**Syntax**

```xml
xml.Serializer.SetOption(
    optionName STRING,
    optionValue STRING )
```

1. `optionName` specifies the name of the option flag.
2. `optionValue` defines the value of the flag.

**Usage**

This method sets the specified option value for the serializer engine for an option defined by `optionName`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.Serializer.SoapSection5ToVariable**

Serializes an XML element node into a BDL variable in Soap Section 5 encoding.

**Syntax**

```xml
xml.Serializer.SoapSection5ToVariable(
    node xml.DomNode,
    var RECORD )
```

1. `node` is a `DomNode` object of type `ELEMENT_NODE`.
2. `var` is any Genero BDL variable with optional XML mapping attributes.

**Usage**

Use this method to serialize a XML element node defined by `node` as a `DomNode` object into a BDL variable in Soap Section 5 encoding.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.Serializer.StaxToDom**

Serializes an XML element node into a `DomNode` object using a StaxReader object.

**Syntax**

```xml
xml.Serializer.StaxToDom(
    stax xml.StaxReader,
    node xml.DomNode )
```

1. `stax` is a `StaxReader` object where the cursor points to an XML Element node.
2. `node` is a `DomNode` object of type `ELEMENT_NODE` or `DOCUMENT_FRAGMENT_NODE`.

**Usage**

This method serializes a XML element node into a `DomNode` object using a StaxReader object. The resulting XML element node of the serialization process will be appended to the last child of the given node.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.Serializer.StaxToVariable`  
Serializes an XML element node into a BDL variable using a StaxReader object.  

**Syntax**  

```java  
xml.Serializer.StaxToVariable(  
    stax xml.StaxReader,  
    var RECORD  
)  
```

1. `stax` is a `StaxReader` object where the cursor points to an XML Element node.  
2. `var` is any Genero BDL variable with optional XML mapping attributes.  

**Usage**  
This method serializes a XML element node into a BDL variable using a StaxReader object. 

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.Serializer.VariableToDom`  
Serializes a BDL variable into a XML element node using a DomNode object.  

**Syntax**  

```java  
xml.Serializer.VariableToDom(  
    var RECORD,  
    node xml.DomNode  
)  
```

1. `var` is any Genero BDL variable with optional XML mapping attributes.  
2. `node` is a `DomNode` object of type `ELEMENT_NODE` or `DOCUMENT_FRAGMENT_NODE`.  

**Usage**  
This method serializes a BDL variable into a XML element node using a DomNode object. The resulting XML element node of the serialization process will be appended to the last child of the given node.  

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.Serializer.VariableToSoapSection5`  
Serializes a BDL variable into a XML element node in Soap Section 5 encoding.  

**Syntax**  

```java  
xml.Serializer.VariableToSoapSection5(  
    var fgl-type,  
    node xml.DomNode  
)  
```

1. `var` is any Genero BDL variable with optional XML mapping attributes.  
2. `node` is a `DomNode` object of type `ELEMENT_NODE` or `DOCUMENT_FRAGMENT_NODE`.  

Usage

Use this method to serialize a BDL variable into a XML element node defined by node as a DomNode object using Soap Section 5 encoding. The resulting XML element node of the serialization process will be appended to the last child of the given node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Serializer.VariableToStax
Serializes a BDL variable into a XML element node using a StaxWriter object.

Syntax

```plaintext
xml.Serializer.VariableToStax(
    var RECORD,
    stax xml.StaxWriter
)
```

1. `var` is any Genero BDL variable with optional XML mapping attributes.
2. `stax` is a StaxWriter object.

Usage

This method serializes a BDL variable into a XML element node using a StaxReader object.

The resulting XML element node of the serialization process will be added at the current cursor position of the StaxWriter object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Serialization option flags
Serialization option flags for the xml.Serializer class.

Table 670: Serialization option flags

**XML security classes**

XML Security classes handle encryption and signature of XML documents entirely in memory with keys and certificates.

**The CryptoKey class**

The `xml.CryptoKey` class provides methods to manipulate HMAC, symmetric and asymmetric keys needed for signing, verifying, encrypting and decrypting XML documents or document fragments.

It follows the XML-Signature and XML-Encryption specifications.

The `STATUS` variable is set to zero after a successful method call.
**xml.CryptoKey methods**  
Methods for the xml.CryptoKey class.

### Table 672: Class methods: Creation

<td>Sets or resets the value of a feature for a CryptoKey object.</td>
</tr>
</tbody>
</table>

xml.CryptoKey.compareTo

Comparis a CryptoKey object to a second key.

**Syntax**

```plaintext
compareTo(toCompare xml.CryptoKey )
RETURNS INTEGER
```

1. `toCompare` defines the `xml.CryptoKey` object to use for comparison to the current CryptoKey object.

**Usage**

The method verifies if the key's URL, type, size, usage and value are the same. If they are the same, the two identical keys will produce the same encryption cipher.

The key features are not taken into account during comparison.

Returns `TRUE` if they are identical, `FALSE` if they are not identical.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related reference**

CryptoKey Features on page 3065
Features of the `xml.CryptoKey` class.

xml.CryptoKey.computeKey

Computes the shared secret based on the given modulus, generator, the private key, and the other peer's public key.

The returned key can be any symmetric/HMAC or symmetric/encryption key type. It can be used for symmetric signature or symmetric encryption.

**Syntax**

```plaintext
computeKey( 
  pub xml.CryptoKey, 
  url STRING 
) 
RETURNS xml.CryptoKey
```

1. `pub` defines the other peer's public key (`xml.CryptoKey`).
2. `url` defines the shared secret key type as an URL identifier (`STRING`).
Usage

Important: This method is for Diffie-Hellman key-agreement algorithm only.

Returns a `xml.CryptoKey sharedSecret`: a `xml.CryptoKey` object of the specified type.

In the 3DES case, no key weakness test is done. If the compound shared secret is weak, the other peer involved in the communication may raise an error. It depends on the language used on the other side.

In order to be able to compute an AES256 shared secret of the Java side, you need to add or replace the files `local_policy.jar` and `US_export_policy.jar` located in `$JDK_HOME/jre/lib/security` by the Java Cryptographic Extension corresponding to your JDK version. You can find this extension at [http://www.oracle.com/technetwork/java/javase/downloads/index.html](http://www.oracle.com/technetwork/java/javase/downloads/index.html).

If the shared secret key length is less than the Diffie-Hellman key length, only the first needed bytes will be taken. For example, if the Diffie-Hellman is 512 bits length and the shared secret is a 3DES key, then only the first 192 bits will be used by the computation. In a 3DES shared secret case, `xml.CryptoKey.computeKey()` is calculated, whereas in AES shared secret case, the Diffie-Hellman key is truncated.

If the shared secret key length is bigger than the Diffie-Hellman key length, an error is raised.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 3554).

xml.CryptoKey.Create

Initializes a `xml.CryptoKey` object. Constructor of an empty CryptoKey object based on a URL.

**Syntax**

```java
xml.CryptoKey.Create (url STRING )
RETURNS xml.CryptoKey
```

1. `url` defines a key identifier based on the XML-Signature and XML-Encryption specification or the Diffie-Hellman specification.

**Usage**

Returns a `xml.CryptoKey` object or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See [Error handling in GWS calls (STATUS)](page 3554).

xml.CryptoKey.CreateDerivedKey

Constructor of an empty CryptoKey object based on an URL. The crypto key must be derived before use.

**Syntax**

```java
xml.CryptoKey.CreateDerivedKey (url STRING )
RETURNS xml.CryptoKey
```

1. `url` defines a key identifier based on the XML-Signature and XML-Encryption specification.

**Usage**

Returns a `xml.CryptoKey` object or NULL. Only symmetric and HMAC keys can be derived.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

`xml.CryptoKey.deriveKey` on page 3053

Derives the symmetric or HMAC CryptoKey object using the given `method` identifier and concatenating the optional `label`, the mandatory `seed` value and the optional `created` date as initial random value.

`xml.CryptoKey.CreateFromNode`  
Constructor of a new CryptoKey object based on a URL, from a XML node based on the XML-Signature and XML-Encryption specification.

**Syntax**

```ruby
define CreateFromNode (  
  url STRING,  
  node xml.DomNode  
)  
RETURNS xml.CryptoKey
```

1. `url` defines a key identifier restricted to PUBLIC/PRIVATE keys.  
2. `node` defines an `ELEMENT` node whose local name is either:  
   - `DSAKeyValue` or `RSAKeyValue` belonging to the XML-Signature namespace `http://www.w3.org/2000/09/xmldsig#`  
   - `RSAKeyPair` belonging to the XKMS 2.0 namespace `http://www.w3.org/2002/03/xkms#`

**Usage**

Returns a CryptoKey object or NULL.

If the local name is RSAKeyValue or RSAKeyPair, the URL must be a RSA key. If the local name is DSAKeyValue, the URL must be a DSA key.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.CryptoKey.deriveKey`  
Derives the symmetric or HMAC CryptoKey object using the given `method` identifier and concatenating the optional `label`, the mandatory `seed` value and the optional `created` date as initial random value.

**Syntax**

```ruby
define deriveKey (  
  url STRING,  
  label STRING,  
  seed STRING,  
  created STRING,  
  offset INTEGER,  
  bytes INTEGER  
)
```

1. `url` defines the `identifier` of the algorithm to apply to the password and its inputs.  
2. `label` defines the optional label input.  
3. `seed` defines the mandatory seed input as a valid Base64 string representing random binary data obtained with the `security.RandomGenerator.CreateRandomNumber` on page 3127 helper method.  
4. `created` defines the optional created date input.  
5. `offset` defines the number of bytes the resulting octet stream must be shifted to obtain the derived key.  
6. `bytes` defines the number of bytes of the resulting derived key.
**Usage**

If it is a symmetric key, the size can be 0, or must match the original key depending on the identifier of the key type. See Derived keys on page 3065 for more details.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoKey.generateKey
Generates a random key of given size (in bits).

**Syntax**

```plaintext
generateKey(
    keySize INTEGER
)
```

1. **keySize** defines the size of the key to generate.

**Usage**

For symmetric keys, the size is fixed by the key identifier and cannot be changed. The only authorized values are the real key size or NULL.

For Diffie-Hellman, the input parameter (size INTEGER) is the size of the Diffie-Hellman modulus. If the given size is greater than zero (0), it populates the Diffie-Hellman object by randomly generating a modulus of the given size and a private key, and computes the public key. The used generator is two (2). If the given size is zero (0), it completes the Diffie-Hellman object by choosing a private key and computing the public key based on the previously loaded parameters. For more details on loading parameters, see Table 683: Object methods: Load and save on page 3069.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoKey.getFeature
Returns the value of the given feature for this CryptoKey object, or NULL.

**Syntax**

```plaintext
getFeature(
    feature STRING
) RETURNS STRING
```

1. **feature** defines the CryptoKey feature.

**Usage**

Returns NULL if the feature is not set.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related reference**

CryptoKey Features on page 3065
Features of the xml.CryptoKey class.

xml.CryptoKey.getSHA1
Returns the SHA1 encoded key identifier in a base64 encoded STRING.

**Syntax**

```
getSHA1()
RETURNS STRING
```

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoKey.getSize

Returns the size of the key in bits.

**Syntax**

```
getSize()
RETURNS INTEGER
```

**Usage**

For a Diffie-Hellman key, it returns the size of the key; the size of a Diffie-Hellman key is actually the size of the modulus. If the modulus is not available (null or equal to zero), the method returns zero. In this situation, a return of zero does NOT mean the key is corrupt or unusable.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related reference**

[Supported kind of keys](#) on page 3061
Types of keys supported by the xml.CryptoKey class.

xml.CryptoKey.getType

Returns the type of the key.

**Syntax**

```
getType()
RETURNS STRING
```

**Usage**

This method returns the key type. It corresponds to the key type used by the identifier.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related reference**

[Supported kind of keys](#) on page 3061
Types of keys supported by the xml.CryptoKey class.

xml.CryptoKey.getUrl
Returns the key identifier as an URL.

**Syntax**

```
getUrl() 
RETURNS STRING
```

**Usage**

This method returns the cryptographic key as an URL. The key is defined in the XML-Signature and XML-Encryption specification.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related reference**

Supported kind of keys on page 3061

Types of keys supported by the `xml.CryptoKey` class.

xml.CryptoKey.getUsage

Returns the usage of the key.

**Syntax**

```
geUsage() 
RETURNS STRING
```

**Usage**

This method returns the usage of the key as defined by the `identifier`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related reference**

Supported kind of keys on page 3061

Types of keys supported by the `xml.CryptoKey` class.

xml.CryptoKey.loadBIN

Loads a symmetric or HMAC key from a file in raw format.

**Syntax**

```
loadBIN( 
    filename STRING )
```

1. `filename` defines the file name or an entry in the FGLPROFILE file.

**Usage**

Raw format means that data in the file is read without any transformation, and will be stored as is in the key.

For instance, if your file contains "hello", it has the same effect as calling `xml.CryptoKey.setKey()` with "hello" as parameter.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoKey.loadDER

Loads an asymmetric DSA key, an asymmetric RSA key, or Diffie-Hellman parameters from a file in DER format.

**Syntax**

```
loadDER(
    filename STRING )
```

1. *filename* defines the file name or an entry in the FGLPROFILE file.

**Usage**

If the DSA or RSA private key or Diffie-Hellman parameters is protected with a password, the recommended way is to unprotect it with the openssl tool and to put the key file on a restricted file system. However, you can use a script or the fglpass agent to provide the password to the application.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoKey.loadFromString

Loads the given key in BASE64 string format into a CryptoKey object.

**Syntax**

```
loadFromString(
    str STRING )
```

1. *str* defines the string to load.

**Usage**

For Diffie-Hellman, the input parameter is a base64 encoded string containing the Diffie-Hellman parameters. This method populates the Diffie-Hellman key with the modulus and generator in the base64 encoded string. This is useful for the parameters exchange step between two peers.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoKey.loadPEM

Loads an asymmetric DSA key, an asymmetric RSA key, or Diffie-Hellman parameters from a file in PEM format.

**Syntax**

```
loadPEM(
    filename STRING )
```

1. *filename* defines the file name or an entry in the FGLPROFILE file.

**Usage**

If the DSA or RSA private key or Diffie-Hellman parameters are protected with a password, the recommended way is to unprotect it with the openssl tool and to put the key file on a restricted file system. However, you can use a script or the fglpass agent to provide the password to the application.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.CryptoKey.loadPrivate**

Loads the private asymmetric RSA key from the given XML document.

**Syntax**

```
loadPrivate(
    doc xml.DomDocument  )
```

1. `doc` defines a `xml.DomDocument` object.

**Usage**

This method loads the private asymmetric RSA key contained in the given `xml.DomDocument` into the private key element of the CryptoKey object. The RSA private key is based on the **XKMS2.0 specification**.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.CryptoKey.loadPublic**

Loads the public part of an asymmetric RSA or DSA CryptoKey object, or the parameters and the public key of the Diffie-Hellman object from a XML document.

**Syntax**

```
loadPublic(
    doc xml.DomDocument  )
```

1. `doc` defines a `xml.DomDocument` object.

**Usage**

This method populates the RSA or DSA CryptoKey object with the public key parts contained in the given `xml.DomDocument`.

The asymmetric RSA CryptoKey object public key part is based on the XML-Signature specification for **RSA**. The DSA CryptoKey object public key part is based on the **DSA** specification.

For Diffie-Hellman, the input parameter is a `xml.DomDocument` object containing a representation of the Diffie-Hellman key based on the XML-Signature specification for the Diffie-Hellman key values. This method populates the Diffie-Hellman object with the parameters and the public key contained in the given `xml.DomDocument`.

If the public key node exists in the `xml.DomDocument` but is empty, it won't be possible to use the key unless the document contains valid modulus and generator parameters and you call `xml.CryptoKey.generateKey` with a size of zero (0). In this case, you won't be in possession of the other peer's public key.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.CryptoKey.loadPublicFromString**

Populate the current CryptoKey object with the passed public key.

**Syntax**

```
loadPublicFromString(
    key string )
```

1. `key` is a string containing the public key.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
1. *str* defines the public part of the key in base64 form.

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See [Error handling in GWS calls (STATUS)](page 3554).

```java
xml.CryptoKey.savePublic
Saves the public part of an asymmetric RSA CryptoKey object into a XML document according to the XKMS2.0 specification.
```

**Syntax**

```java
savePublic()
RETURNS xml.DomDocument
```

**Usage**

Returns a xml.DomDocument object containing the private key part of an asymmetric RSA key.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See [Error handling in GWS calls (STATUS)](page 3554).

```java
xml.CryptoKey.savePrivate
Saves the private key part of an asymmetric RSA CryptoKey object into a XML document according to the XKMS2.0 specification.
```

**Syntax**

```java
savePrivate()
RETURNS xml.DomDocument
```

**Usage**

This method saves the public key parts of an RSA or DSA CryptoKey object in an xml.DomDocument.

The asymmetric RSA CryptoKey object public key part is based on the XML-Signature specification for RSA. The DSA CryptoKey object public key part is based on the DSA specification.

For Diffie-Hellman, the method is used for the public key exchanged between the two peers.

See also the CryptoKey RetrievalMethod feature.

Returns a xml.DomDocument object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See [Error handling in GWS calls (STATUS)](page 3554).

```java
xml.CryptoKey.savePublicToString
Save the current xml.CryptoKey's public part in the returned base64 string.
```

**Syntax**

```java
savePublicToString()
RETURNS STRING
```
**Usage**

Returns the public part of the key in base64 form (STRING).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

```java
xml.CryptoKey.saveToString
```

Saves the CryptoKey object into a BASE64 string format.

**Syntax**

```java
saveToString()
RETURNS STRING
```

**Usage**

For Diffie-Hellman, this method returns the Diffie-Hellman key's modulus and generator in a base64 encoded string. This is used for the parameters exchange step between the two peers.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

```java
xml.CryptoKey.setFeature
```

Sets or resets the value of a feature for a CryptoKey object.

**Syntax**

```java
setFeature(
    feature STRING,
    value STRING )
```

1. `feature` defines the name of the feature.
2. `value` defines the value to set for the named feature.

**Usage**

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Related reference**

CryptoKey Features on page 3065
Features of the xml.CryptoKey class.

```java
xml.CryptoKey.setKey
```

Defines the value of a HMAC or Symmetric key.

**Syntax**

```java
setKey(
    key STRING )
```

1. `key` defines the value.
**Usage**

The value can be a password and must be of the size corresponding to the key identifier.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Supported kind of keys**

Types of keys supported by the `xml.CryptoKey` class.

</table>

**Derived keys**

Key derivation is used on symmetric or HMAC keys to avoid the direct usage of a shared secret password in secured operations. If two parties share a secret password that is successfully hacked by a third party, any future operations become insecure, and the initial two parties do not even realize that their exchanges are unsafe. However, if a different password based on that shared secret password is used for each new secured operation, even if one operation is compromised, it will only be insecure for that operation, but not other operations.

The derivation consists of applying an algorithm with some additional inputs (such as a random seed value) to a password in order to obtain another password that is then used in one secured operation. Of course, the algorithm and its additional inputs must also be shared to enable the computation of the same derived key for the decryption of the message by the person it is intended for.

Note that passwords are often only composed of alphanumeric characters, which makes the job of a hacker a little bit easier, whereas a derived key is composed of any binary data produced by the algorithm used for the derivation.

**Table 678: Derived keys methods**

</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>KeyValue</strong></td>
<td>Defines or returns whether the public part of the asymmetric key is added during a XML signature or encryption. Only for RSA and DSA keys. The default value is FALSE, meaning that no key value is used.</td>
</tr>
</tbody>
</table>
| **RetrievalMethod** | Defines or returns the URL where the XML form of:  
- a DSA or RSA public key will be set during a XML signature, and loaded during a XML verification process.  
- a RSA public key will be set and used to encrypt a XML node during XML encryption  
- a symmetric key with encryption usage will be used to encrypt a XML node or decrypt it back  
The default value is NULL, meaning that no retrieval method is used.  
The XML form of a DSA or RSA public key can be obtained by the `xml.CryptoKey.savePublic` method.  
The XML form of a symmetric key can be obtained by the `xml.Encryption.encryptKey` method. |

### Examples

**xml.CryptoKey usage examples.**

**Loading an asymmetric RSA key**

```xml
IMPORT xml

MAIN
DEFINE key xml.CryptoKey
LET key = xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#rsa-1_5")
TRY
CALL key.loadPEM("RSA1024Key.pem")
CALL key.setFeature("KeyName","MyRsaKey")
DISPLAY "Key size (in bits) : ",key.getSize() # displays 1024 (bits)
DISPLAY "Key type : ",key.getType() # displays PRIVATE or PUBLIC
DISPLAY "Key usage : ",key.getUsage() # displays KEYENCRYPTION
CATCH
DISPLAY "Unable to load key :",STATUS
END TRY
END MAIN
```

**Note:** All keys in PEM or DER format were created with the OpenSSL tool.

**Generating a symmetric AES256 key**

```xml
IMPORT xml

MAIN
DEFINE key xml.CryptoKey
LET key = xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#aes256-cbc")
```
TRY
    CALL key.generateKey(NULL)
    DISPLAY "Key size (in bits) : ",key.getSize() # displays 256 (bits)
    DISPLAY "Key type : ",key.getType() # displays SYMMETRIC
    DISPLAY "Key usage : ",key.getUsage() # displays ENCRYPTION
CATCH
    DISPLAY "Unable to generate key :",STATUS
END TRY
END MAIN

Note: All keys in PEM or DER format were created with the OpenSSL tool.

Setting a HMAC key

IMPORT xml

MAIN
    DEFINE key xml.CryptoKey
    LET key = xml.CryptoKey.Create("http://www.w3.org/2000/09/xmldsig#hmac-sha1")
    TRY
        CALL key.setKey("secretpassword")
        # displays 112 (size of secretpassword in bits)
        DISPLAY "Key size (in bits) : ",key.getSize()
        DISPLAY "Key type : ",key.getType() # displays HMAC
        DISPLAY "Key usage : ",key.getUsage() # displays SIGNATURE
CATCH
    END TRY
END MAIN

Note: All keys in PEM or DER format were created with the OpenSSL tool.

Deriving a HMAC key

IMPORT xml
IMPORT security

MAIN
    DEFINE key xml.CryptoKey
    # will contain a random binary data encoded in Base64
    DEFINE seedBase64 STRING
    LET key = xml.CryptoKey.CreateDerivedKey("http://www.w3.org/2000/09/xmldsig#hmac-sha1")
    TRY
        # Creates a random 24 bytes long binary data encoded into a Base64 form string
        CALL key.setKey("secretpassword")
        # Derives the 14 bytes long "secretpassword" into a 64 bytes long key
        # from a random 24 bytes long seed value and shifting the resulting key
        # from 255 bytes
        LET seedBase64 = security.RandomGenerator.CreateRandomString(24)
        CALL key.deriveKey("http://schemas.xmlsoap.org/ws/2005/02/sc/dk/p_sha1",
        NULL,seedBase64,NULL,255,64)
        # Displays 512 (size of 'secretpassword' derivation in bits)
        DISPLAY "Key size (in bits) : ",key.getSize()
        # Note: Key is derived and can be used in
        # any encryption or signature function
CATCH
    END TRY
END MAIN
Note: All keys in PEM or DER format were created with the OpenSSL tool.

Computing the shared secret with Diffie-Hellman

Load the Diffie-Hellman parameters from a PEM file, the other peer's public key from an XML file, and compute the shared secret.

Function `generateKey` is called with a 0, parameters are already filled.

```
IMPORT xml

FUNCTION BuildSharedSecret(DHdoc)
    DEFINE myKey, othersPubKey, sharedSecret xml.CryptoKey
    DEFINE DHdoc xml.DomDocument
    LET myKey =
        xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#DHKeyValue")
    LET othersPubKey =
        xml.CryptoKey.Create("http://www.w3.org/2001/04/xmlenc#DHKeyValue")
    TRY
        CALL othersPubKey.loadPublic(DHdoc)
        # populate myKey with the parameters previously generated by the
        # other peer.
        CALL myKey.loadPEM("DHParam.pem")
        # Randomly generate a private key and compute the public key. Key
        # length is the parameters length.
        CALL myKey.generateKey(0)
        LET sharedSecret = myKey.computeKey(othersPubKey,
            "http://www.w3.org/2000/09/xmldsig#hmac-sha1")
    CATCH
        DISPLAY "ERROR : should not raise exception"
        EXIT PROGRAM (-1)
    END TRY
END FUNCTION
```

The CryptoX509 class

The `xml.CryptoX509` class provides methods to manipulate X509 certificates needed for identification of individual persons, groups or any entities during XML encryption or signature process.

It also provides additional load and save functions to interact with other applications in XML or in BASE64, such as in WS-Security compliant applications. It follows the `XML-Signature` and `XML-Encryption` specifications.

The `STATUS` variable is set to zero after a successful method call.

**xml.CryptoX509 methods**

Methods for the `xml.CryptoX509` class.

<tr>
<td><code>setFeature</code></td>
<td>Sets or resets the given feature for this CryptoX509 object.</td>
</tr>
</tbody>
</table>

xml.CryptoX509.Create

Constructor of an empty CryptoX509 object.

**Syntax**

```java
xml.CryptoX509.Create() 
RETURNS xml.CryptoX509
```

**Usage**

Returns a xml.CryptoX509 object or NULL.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoX509.CreateFromNode

Constructor of a new CryptoX509 object from a XML X509 certificate node.

**Syntax**

```java
xml.CryptoX509.CreateFromNode( 
   node xml.DomNode  ) 
RETURNS xml.CryptoX509
```

1. `node` defines an element in xml.DomNode node with `X509Data` as local name, which is based on the XML-Signature specification namespace "http://www.w3.org/2000/09/xmldsig#".

**Usage**

Returns a xml.CryptoX509 object or NULL.

If the X509 certificate is incomplete, the certificate will be created from the application global certificate list if one of `SubjectName` or `Issuer` matches. (See xml.KeyStore.addCertificate for more details.)

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoX509.createPublicKey

Creates a new public CryptoKey object for the given URL.

**Syntax**

```java
createPublicKey(
```
url STRING )
RETURNS xml.CryptoX509

1. url defines the given url.

Usage
This method creates a new public CryptoKey object for the given URL, from the public key embedded in this certificate if any; NULL otherwise.
Returns a CryptoX509 object.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoX509.getFeature
Get the value of a given feature of a CryptoX509 object.

Syntax
getFeature ( feature STRING )
RETURNS STRING

1. feature defines a feature of the CryptoX509 object.

Usage
This method returns the value of the given feature for the CryptoX509 object, or NULL if feature is not set.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related reference
CryptoX509 Features on page 3074
Features of the xml.CryptoX509 class.

xml.CryptoX509.getIdentifier
Gets the identification part of a X509 certificate

Syntax
getIdentifier ()
RETURNS STRING

Usage
Returns the identification part of the X509 certificate in a string.
Example: /C=FR/ST=France/L=Schiltigheim/O=MC/OU=My Company Name/CN=cert
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoX509.getThumbprintSHA1
Gets the SHA1 encoded thumbprint identifying the X509 certificate.

**Syntax**

```java
getThumbprintSHA1()
RETURNS STRING
```

**Usage**

This method returns the SHA1 encoded thumbprint identifying the X509 certificate in a BASE64-encoded string.

Example: CM4y6z7zzLmTGMelIE46RKIKAPI=

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

---

**xml.CryptoX509.load**

Loads the given XML document with ds:X509Data as root node in a CryptoX509 object.

**Syntax**

```java
load(
    doc xml.DomDocument
)
```

1. `doc` defines a `xml.DomDocument` object.

**Usage**

This method loads an XML document with ds:X509Data based on the XML-Signature specification as root node in a CryptoX509 object. See the w3.org site for more information on the XML-Signature specification for ds:X509Data as root node.

If the X509 certificate is incomplete, the certificate will be created from the application global certificate list if one of SubjectName or Issuer matches. (See `xml.KeyStore.addCertificate` for more details.)

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

---

**xml.CryptoX509.loadDER**

Loads a X509 certificate from a file in DER format.

**Syntax**

```java
loadDER(
    filename STRING
)
```

1. `filename` defines the file name or an entry in the FGLPROFILE file.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

---

**xml.CryptoX509.loadFromString**
Loads the given X509 certificate in BASE64 string format into this CryptoX509 object.

**Syntax**

```java
loadFromString(
    str STRING )
```

1. `str` defines the X509 certificate in BASE64 string format to load.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoX509.loadPEM

Loads a X509 certificate from a file in PEM format.

**Syntax**

```java
loadPEM(
    filename STRING )
```

1. `filename` defines the file name or an entry in the FGLPROFILE file.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoX509.save

Saves the CryptoX509 certificate into a XML document with ds:X509Data element as root node.

**Syntax**

```java
save()
RETURNS xml.DomDocument
```

**Usage**

This method saves a CryptoX509 certificate in an XML document with the ds:X509Data element as root node. See the w3.org site for more information on the XML-Signature specification for ds:X509Data as root node.

(See also the RetrievalMethod feature)

Returns a `xml.DomDocument` object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoX509.saveToString

Saves the CryptoX509 certificate into a BASE64 string format.

**Syntax**

```java
saveToString()
RETURNS STRING
```
Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.CryptoX509.setFeature

Sets or resets the given feature for this CryptoX509 object.

Syntax

```java
setFeature(
    feature STRING,
    value STRING
)
```

1. `feature` defines the feature to be set.
2. `value` defines the value to set.

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

</tbody>
</table>
### Feature Description

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
</table>
| RetrievalMethod | Defines or returns the URL where the XML form of the X509 certificate will be set during a XML signature, and loaded during a XML verification process, and based on that CryptoX509 object. Default value is NULL, meaning that no retrieval method is used.

**Note:** The XML form of a X509 certificate can be obtain by the `xml.CryptoX509.save()` method.

#### Examples

**xml.CryptoX509 usage examples.**

**Loading a certificate from a PEM file**

```plaintext
IMPORT xml

MAIN
  DEFINE x509 xml.CryptoX509
  LET x509 = xml.CryptoX509.Create()
  TRY
    CALL x509.loadPEM("Certificate.crt");
    DISPLAY "Id : ", x509.getIdentifier()
  CATCH
    DISPLAY "Unable to load certificate : ", STATUS
  END TRY
END MAIN

**Note:** All certificates in PEM format were created with the OpenSSL tool.

**Creating a public key for signature verification from a certificate**

```plaintext
IMPORT xml

MAIN
  DEFINE x509 xml.CryptoX509
  DEFINE key xml.CryptoKey
  LET x509 = xml.CryptoX509.Create()
  TRY
    CALL x509.loadPEM("RSA1024Certificate.crt");
    CATCH
      DISPLAY "Unable to load certificate : ", STATUS
      EXIT PROGRAM
  END TRY
  TRY
    LET key = x509.createPublicKey("http://www.w3.org/2000/09/xmldsig#rsa-shal")
    DISPLAY "Key size (in bytes) : ", key.getSize() # displays 1024 (bits)
    DISPLAY "Key type : ", key.getType() # displays PUBLIC
    DISPLAY "Key usage : ", key.getUsage() # displays SIGNATURE
    CATCH
      DISPLAY "Unable to create public key : ", STATUS
  END TRY
END MAIN

**Note:** All certificates in PEM format were created with the OpenSSL tool.

**Saving the subjectName of a certificate in XML**

```plaintext
IMPORT xml
```
MAIN
DEFINE x509 xml.CryptoX509
DEFINE doc xml.DomDocument
LET x509 = xml.CryptoX509.Create()
TRY
  CALL x509.loadPEM("RSA1024Certificate.crt");
  CATCH
    DISPLAY "Unable to load certificate :",STATUS
    EXIT PROGRAM
END TRY
TRY
  CALL x509.setFeature("X509SubjectName",TRUE)
  LET doc = x509.save()
  CALL doc.setFeature("format-pretty-print",TRUE)
  CALL doc.save("RSAX509SubjectName.xml")
  CATCH
    DISPLAY "Unable to save certificate :",STATUS
END TRY
END MAIN

Note: All certificates in PEM format were created with the OpenSSL tool.

The Signature class
The xml.Signature class provides methods to create detached, enveloped or enveloping XML signatures of one or more references of XML documents or document fragments, and to determine whether a signed referenced document has been modified afterwards.

It follows the XML-Signature specifications.

The STATUS variable is set to zero after a successful method call.

xml.Signature methods
Methods for the xml.Signature class.

Table 686: Class methods: Creation

<table>
<thead>
<tr>

<tr>
<td><code>signString(key xml.CryptoKey, str STRING )</code></td>
<td>Sign the passed string according to the specified key.</td>
</tr>
<tr>
<td><code>verify(doc xml.DomDocument )</code></td>
<td>Verifies that all references in this signature object have not changed.</td>
</tr>
<tr>
<td><code>verifyString(key xml.CryptoKey, originalStr STRING, signature STRING )</code></td>
<td>Verify the signature is consistent with the given key and the original message.</td>
</tr>
</tbody>
</table>

`xml.Signature.appendObjectData`
Append a copy of a XML DomNode to the signature object index.

**Syntax**

```java
appendObjectData(
    index INTEGER,
    node xml.DomNode
)
```

1. `index` defines the index in this Signature object.
2. `node` defines the `xml.DomNode`.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`xml.Signature.appendReferenceTransformation`
Appends transformations related to the specified reference index.

**Syntax**

```java
appendReferenceTransformation(
    referenceIndex INTEGER,
    method STRING,
    args ...
)
```

1. `referenceIndex` defines the index in this Signature object.
2. `method` represents an URL as identifier of the transformation algorithm.
3. `args` defines a list of transformations.
Usage

This method appends a reference transformation that is executed before any computation.

A transformation modifies the reference URI before signing or validating it. Several transformations are executed one after another, and only once the last transformation has been applied, is the reference really signed or verified.

Depending on the transformation identifier, additional parameters are necessary.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.compute

Computes the signature of all references set in this Signature object.

Syntax

```java
compute(
    doc xml.DomDocument )
```

1. `doc` defines the XML document.

Usage

If the signature type is:

- Enveloping: then `doc` must be NULL because all document fragment references are inside the Signature itself
- Enveloped: then `doc` must be the XML document where the signature must be added afterwards to get a valid enveloped signature
- Detached: then `doc` can be NULL if all references are absolute, otherwise it can be the XML document fragment references that are referencing

See XML Signature concepts for more details.

Also, see Windows®.NET special recommendation.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.Create

Constructor of a blank Signature object.

Syntax

```java
xml.Signature.Create() 
RETURNS xml.Signature
```

Usage

Returns a XML Signature object or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.CreateFromNode
Constructor of a new Signature object from a XML Signature node, based on the XML-Signature specification.

Syntax

```
xml.Signature.CreateFromNode(
    node xml.DomNode )
RETURNS xml.Signature
```

1. `node` defines the XML Signature node.

Usage

Returns a XML Signature object or NULL.

The `node` must be an element node with Signature as the local name, and it must belong to the XML-Signature namespace http://www.w3.org/2000/09/xmldsig#, as defined in www.w3.org.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.createObject

Creates a new object that will embed additional XML nodes.

Syntax

```
createObject ()
RETURNS INTEGER
```

Usage

The returned value represents the index for any further manipulation of this signature object.

Note: An object is enveloping additional XML nodes, but is not necessarily signed unless there is a reference on it.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.createReference

Creates a new reference that will be signed with the `compute()` method.

Syntax

```
createReference (
    uri STRING,
    digest STRING )
RETURNS INTEGER
```

1. `uri` represents the data to be signed.
2. `digest` defines a URL as identifier for the hash algorithm.

Usage

The returned value represents the index for any further manipulation of this reference.

The `uri` can be:
• An absolute URL such as http://, https://, tcp://, tcps://, file:/// and alias:// (see FGLPROFILE Configuration for more details about URL mapping with aliases), and where the data can be a XML document or any kind of data such as images or HTML pages.
• NULL to sign the whole document, but only one NULL is allowed in the entire signature.
• A fragment like #tobesigned. Note that a DOM node fragment is identified via the value of an attribute of type ID such as xml:id or any attribute whose type was changed to ID with xml.DomNode.setIdAttribute() or xml.DomNode.setIdAttributeNS().

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Related concepts
xml.Signature.compute on page 3081
Computes the signature of all references set in this Signature object.

xml.Signature.getCanonicalization
Returns the canonicalization identifier of the signature.

Syntax

getCanonicalization()  
RETURNS STRING

Usage
Returns one of the four canonicalization identifiers of the signature.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.getDocument
Returns a new DomDocument object representing the signature in XML.

Syntax

getDocument()  
RETURNS xml.DomDocument

Usage
Returns a xml.DomDocument object.

If the signature type is enveloped, it's up to the user to add it at the right place in the XML document it is intended to sign.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.getID
Returns the ID value of the signature.

Syntax

getID()  
RETURNS STRING
Usage

This method returns the ID value of the signature.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.getObjectCount

Returns the number of objects in this Signature object.

Syntax

```java
getObjectCount ()
RETURNS INTEGER
```

Usage

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.getObjectId

Returns the ID value of the signature object.

Syntax

```java
getObjectId (index INTEGER )
RETURNS STRING
```

1. `index` defines the index in this Signature object.

Usage

This method returns the ID value of the index (index) in this signature object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.getReferenceCount

Returns the number of references in this Signature object.

Syntax

```java
getReferenceCount ()
RETURNS INTEGER
```

Usage

This method returns the number of references in the specified signature object.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.getReferenceDigest
Returns the digest algorithm identifier of the reference.

### Syntax

```java
getReferenceDigest (  
    index INTEGER  
)  
RETURNS STRING
```

1. `index` defines the index in this signature object.

#### Usage

Returns the digest algorithm identifier of the reference of index (`index`) in this signature object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

xml.Signature.getReferenceID

Returns the ID value of the reference in this signature object.

### Syntax

```java
getReferenceID (  
    index INTEGER  
)  
RETURNS STRING
```

1. `index` is the index in this Signature object.

#### Usage

This method returns the ID value of the reference of index (`index`) in this signature object, or NULL if there is none.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

xml.Signature.getReferenceTransformation

Gets the transformation identifier related to the reference of index `referenceIndex`.

### Syntax

```java
getReferenceTransformation (  
    referenceIndex INTEGER,  
    index INTEGER  
)  
RETURNS STRING
```

1. `referenceIndex` is the index in this Signature object.
2. `index` defines the position in the list of transformations.

#### Usage

Returns the transformation identifier related to the reference of index `referenceIndex`, at the position specified by `index` in the list of transformations.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

xml.Signature.getReferenceTransformationCount
Returns the number of transformations referenced in this signature object.

**Syntax**

```plaintext
getReferenceTransformationCount ( referenceIndex INTEGER )
RETURNS INTEGER
```

1. `referenceIndex` defines the index in this signature object.

**Usage**

This method returns the number of transformations related to the reference of index `referenceIndex` in this signature object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.Signature.getReferenceURI**

Returns the URI of the reference in this signature object.

**Syntax**

```plaintext
getReferenceURI ( index INTEGER )
RETURNS STRING
```

1. `index` defines the index in this signature object.

**Usage**

This method returns the URI of the reference specified in the index `index` in this signature object.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.Signature.getSignatureMethod**

Returns the algorithm method of the signature.

**Syntax**

```plaintext
getSignatureMethod ()
RETURNS STRING
```

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**xml.Signature.getType**

Returns a string with the type of the signature object.

**Syntax**

```plaintext
getType ()
```
xml.Signature.RetrieveObjectDataListFromSignatureNode

Returns a DomNodeList containing all embedded XML nodes related to the signature object.

Syntax

```xml
xml.Signature.RetrieveObjectDataListFromSignatureNode(
    signNode xml.DomNode,
    index INTEGER
) RETURNS xml.DomNodeList
```

1. `signNode` defines the XML Signature xml.DomNode.
2. `index` defines the index of the signature object.

Usage

This method returns a xml.DomNodeList containing all embedded XML nodes related to the signature object specified by the index `index` within the XML signature node, `signNode`.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.setCanonicalization

Sets the canonicalization method to use for the signature.

Syntax

```xml
setCanonicalization(
    url STRING
)
```

1. `url` defines one of the four canonicalization identifier.

Usage

This method sets the canonicalization method to use for the signature. The default value is the `c14n` method.

**Note:** Windows®.NET default `c14n` canonicalization method is not compatible with the W3C standard, therefore it is recommended to use the `exc-c14n` method when interoperating with a Windows® system.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.setCertificate

Defines the X509 certificate to be added to the signature object when signing a document.

Syntax

```xml
setCertificate(
)
```
1. `cert defines the X509 certificate to be added.``

**Usage**

If NULL, no certificate is added.

During the computation of the signature, some certificate information can be added based on the `feature` set on that CryptoX509 object. If no features are set, the complete X509 certificate is automatically added.

During the verification of a signature the certificate set with the `setCertificate` method isn't used. See **XML Signature concepts** for more details.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See **Error handling in GWS calls (STATUS)** on page 3554.

**xml.Signature.setID**

Sets an ID value for the signature.

**Syntax**

```plaintext
setId(id STRING )
```

1. `id` defines the ID value to be set.

**Usage**

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See **Error handling in GWS calls (STATUS)** on page 3554.

**xml.Signature.setKey**

Defines the key used for signing or validation.

**Syntax**

```plaintext
setKey(key xml.CryptoKey )
```

1. `key` defines the `key` to be used for signing or validation.

**Usage**

Only RSA, DSA or HMAC keys intended for `SIGNATURE` are allowed.

During the computation of the signature, some key information can be added depending on the `feature` set on that CryptoKey object. If no features are set, nothing is added. See **XML Signature concepts** for more details.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See **Error handling in GWS calls (STATUS)** on page 3554.

**xml.Signature.setObjectID**

Sets an ID for the signature object.

**Syntax**

```plaintext
setObjectID(
```
xml.Signature.setReferenceID
Sets an ID for the signature reference in the specified signature object.

Syntax

```java
setReferenceID(
    index INTEGER,
    id STRING )
```

1. `index` defines the index value.
2. `id` defines the value to be set.

Usage
This method sets the ID defined by `id` value for the signature object specified in the index (`index`).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.signString
Sign the passed string according to the specified key.

Syntax

```java
signString(
    key xml.CryptoKey,
    str STRING
) RETURNS STRING
```

1. `key` defines the key to be used for the signature.
2. `str` defines the string to be signed.

Usage
The key can be a HMAC key, a RSA private key, or a DSA private key. The signing process is performed with SHA-1 digest, as recommended by the XMLSec specification.

Returns `sig`, or the signature in base64 format.

This method does not belong to the XML encryption specification.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
xml.Signature.verify

Verifies that all references in this signature object have not changed.

**Syntax**

```plaintext
verify(
    doc xml.DomDocument
)
RETURNS INTEGER
```

1. `doc` defines the XML document.

**Usage**

Returns TRUE if valid, FALSE otherwise.

If the signature type is:

- Enveloping: then `doc` must be NULL because all document fragment references are inside the Signature itself
- Enveloped: then `doc` must be the XML document where the signature was enveloped
- Detached: then `doc` can be null if all references are absolute, otherwise it can be the XML document the fragment references are referencing

See XML Signature concepts for more details.

By default, the validation process uses the CryptoKey set with `xml.Signature.setKey()` to verify the signature. However, if the signature contains a X509 certificate or a X509 retrieval method, it uses the list of trusted certificates, or if the signature contains a RSA or DSA retrieval method, it uses the RSA or DSA public key automatically loaded.

**Note:** See Windows® .NET special recommendation.

Before loading the XML document to verify the signature, you might need to set some options to retrieve the "id" nodes with the `xml.DomDocument.setFeature()` method:

```plaintext
DEFINE doc xml.DomDocument
...
CALL doc.setFeature(feature, TRUE)
...
```

Here `feature` must be "auto-id-attribute" if the "id" attribute has no namespace, or "auto-id-qualified-attribute", when "id" has a namespace.

This is especially needed when you encounter error messages such as:

```plaintext
Xml security operation failed : libxml2 library function failed : expr=xpointer(id('id-1436767651')).
```

Meaning that the parser was unable to find the "id" attribute in the XML document.

Note that the "auto-id-*" features will declare all XML attributes where the name is "id", "ID", "Id" or "iD" to be of type ID, and thus be usable via `xml.DomDocument.getElementById()` method used during signature validation.

If needed, you can also set features for a specific attribute with the `xmlDOMNode.setIdAttribute()` method, or with the `xmlDOMNode.setIdAttributeNS()` method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Signature.verifyString
Verify the signature is consistent with the given key and the original message.

**Syntax**

```java
verifyString(
    key xml.CryptoKey,
    originalStr STRING,
    signature STRING )
RETURNS INTEGER
```

1. `key` defines the key to use for verification.
2. `originalStr` defines the signed string in its clear form.
3. `toBeVerifiedStr` defines the signature to be verified.

**Usage**

The key can be a HMAC key, a RSA private key or a DSA private key. The HMAC key must be the same as the one used for signing. The public RSA and DSA key must be the public key corresponding to the private key used for signing.

Returns 1 when verification is successful; 0 (zero) is returned if verification fails.

This method does not belong to the XML encryption specification.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**XML Signature concepts**

The purpose of a signature is to guarantee the integrity of a XML document, that it was not altered, and that it still contains the same data as when it was created. An additional purpose of a signature is to authenticate the author of the document. There are different ways to achieve this guarantee.

Sign and verify with a common shared HMAC key

Use if the sender of the XML document and the receiver share a common secret key.

**How to sign**

1. Create a HMAC key with the constructor of the CryptoKey class.
2. Set or load the common shared key value in the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

**How to verify**

1. Create a HMAC key with the constructor of the CryptoKey.
2. Set or load the common shared key value in the CryptoKey object.
3. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
4. Assign the CryptoKey object to the Signature object.
5. Verify the signature validity.

**Related concepts**

Examples on page 3099
xml.Signature usage examples.

Sign with the originator private RSA or DSA key, and verify with the originator public RSA or DSA key
Use if the receiver of the XML document has the RSA or DSA public key of the sender.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign
1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

How to verify
1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA public key into the CryptoKey object.
3. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
4. Assign the CryptoKey object to the Signature object.
5. Verify the signature validity.

Related concepts

xml.Signature usage examples.

Sign with the originator private RSA or DSA key, and verify with a RSA or DSA retrieval method
Use if the sender of the XML document provides the public RSA or DSA key in XML form (and via http, tcp or a file protocol).

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign
1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Set the RetrievalMethod feature on the CryptoKey object with the URL where the XML form of the public RSA or DSA key is available.
4. Create a blank signature with the constructor of the Signature class.
5. Assign the CryptoKey object to the Signature object.
6. Create one or more references to be signed.
7. Compute the signature.
8. Retrieve the XML signature document from the Signature object.

How to verify
1. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
2. Verify the signature validity.

Note: There is no key nor certificate to set in the Signature object during validation.
Sign with the originator private RSA or DSA key, and verify with the originator X509 certificate associated to the private RSA or DSA key.

Use if the receiver of the XML document has the X509 certificate associated to the RSA or DSA private key.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

**How to sign**

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a blank signature with the constructor of the Signature class.
4. Assign the CryptoKey object to the Signature object.
5. Create one or more references to be signed.
6. Compute the signature.
7. Retrieve the XML signature document from the Signature object.

**How to verify**

1. Create a X509 certificate with the constructor of the CryptoX509 class.
2. Load the X509 certificate into the CryptoKey object.
3. Create the RSA or DSA public key from the X509 certificate of the CryptoX509 object.
4. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
5. Assign the CryptoKey object containing the public key to the Signature object.
6. Verify the signature validity.

Sign with the originator private RSA or DSA key, and verify with trusted X509 certificates.

Use if the sender of the XML document adds a X509 certificate that was signed by another trusted X509 certificate.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

**How to sign**

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a X509 certificate with the constructor of the CryptoX509 class.
4. Load the X509 certificate associated to the RSA or DSA private key into the CryptoKey object.
5. Create a blank signature with the constructor of the Signature class.
6. Assign the CryptoKey object to the Signature object.
7. Assign the CryptoX509 object to the Signature object.
8. Create one or more references to be signed.
9. Compute the signature.
10. Retrieve the XML signature document from the Signature object.
How to verify

1. Create a X509 certificate with the constructor of the CryptoX509 class.
2. Load the X509 certificate that was used to sign the originator X509 certificate into the CryptoX509 object.
3. Add the X509 certificate as trusted certificate to the application.
4. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
5. Verify the signature validity.

Note: Point 1 to 3 can be omitted if entry xml.application.calist has been set in FGLPROFILE file with the trusted certificate.

Note: There is no key nor certificate to set in the Signature object during validation.

Related concepts

Examples on page 3099
xml.Signature usage examples.

Sign with the originator private RSA or DSA key, and verify with a X509 certificate retrieval method and trusted X509 certificates

Use if the sender of the XML document adds a X509 retrieval method that was signed by another trusted X509 certificate.

Only the originator can sign a message with this specific pair of keys. Any other peer needs the corresponding public key and does not have access to the private key.

How to sign

1. Create a RSA or DSA key with the constructor of the CryptoKey class.
2. Load the RSA or DSA private key into the CryptoKey object.
3. Create a X509 certificate with the constructor of the CryptoX509 class.
4. Set the RetrievalMethod feature on the CryptoX509 object with the URL where the XML form of the originator X509 certificate is available.
5. Create a blank signature with the constructor of the Signature class.
6. Assign the CryptoKey object to the Signature object.
7. Assign the CryptoX509 object to the Signature object.
8. Create one or more references to be signed.
9. Compute the signature.
10. Retrieve the XML signature document from the Signature object.

How to verify

1. Create a X509 certificate with the constructor of the CryptoX509 class.
2. Load the X509 certificate that was used to sign the originator X509 certificate into the CryptoX509 object.
3. Add the X509 certificate as trusted certificate to the application.
4. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
5. Verify the signature validity.

Note: Steps 1 - 3 can be omitted if entry xml.application.calist has been set in FGLPROFILE file with the trusted certificate.

Note: There is no key or certificate to set in the Signature object during validation.

Related concepts

Examples on page 3099
xml.Signature usage examples.

Sign with a named key and verify using the keystore

Use if the sender and the receiver exchange multiple XML documents signed with different keys.

How to sign

1. Create a HMAC, RSA or DSA key with the constructor of the CryptoKey class.
2. Set the HMAC key or load the RSA or DSA key in the CryptoKey object.
3. Set the KeyName feature with the name identifying the key.
4. Create a blank signature with the constructor of the Signature class.
5. Assign the CryptoKey object to the Signature object.
6. Create one or more references to be signed.
7. Compute the signature.
8. Retrieve the XML signature document from the Signature object.

How to verify

1. Create a HMAC, RSA or DSA key with the constructor of the CryptoKey.
2. Set the HMAC key or load the RSA or DSA key in the CryptoKey object.
3. Set the KeyName feature with the name identifying the key.
4. Register the key to be used by key name for any signature verification.
5. Create a signature with the constructor of the Signature class and from a XML signature node obtained after the above compute operation.
6. Verify the signature validity.

Note: It is recommended that steps 1 to 4 are done once at application start-up for each key used in the application. Steps 5 - 6 can then be executed quickly for any XML signature to be checked.

**Examples**

xml.Signature usage examples.
Create a detached signature using a HMAC key

```xml
IMPORT xml

MAIN
DEFINE doc xml.DomDocument
DEFINE sig xml.Signature
DEFINE key xml.CryptoKey
DEFINE index INTEGER
# Create DomDocument object
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in cryptography, therefore it is recommended that you remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
    # Load document to be signed
    CALL doc.load("MyDocument.xml")
    # Create HMAC key
```
LET key = xml.CryptoKey.Create("http://www.w3.org/2000/09/xmldsig#hmac-sha1")
CALL key.setKey("secretpassword")
LET sig = xml.Signature.Create()
CALL sig.setKey(key)
LET index = sig.createReference('#code', "http://www.w3.org/2000/09/xmldsig#sha1")
CALL sig.appendReferenceTransformation(index, "http://www.w3.org/2001/10/xml-exc-c14n")
LET doc = xml.DomDocument.Create()
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
CALL doc.load("MyDocumentDetachedSignature.xml")
LET sig = xml.Signature.CreateFromNode(doc.getDocumentElement())
CALL key.setKey("secretpassword")
LET doc = xml.DomDocument.Create()
CALL doc.setFeature("whitespace-in-element-content",FALSE)
CALL doc.load("MyDocument.xml")
LET isVerified = sig.verify(doc)
IF isVerified THEN
DISPLAY "Signature OK"
ELSE
DISPLAY "Signature FAILED"
ENDIF
Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Create an enveloping signature using a DSA key

```plaintext
IMPORT xml

MAIN
DEFINE doc xml.DomDocument
DEFINE sig xml.Signature
DEFINE key xml.CryptoKey
DEFINE index INTEGER
DEFINE objInd INTEGER
# Create DomDocument object
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in cryptography,
# therefore it is recommended to remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
    # Load document to be signed
    CALL doc.load("MyDocument.xml")
    # Create DSA key and load it from file
    LET key = xml.CryptoKey.Create(
          "http://www.w3.org/2000/09/xmldsig#dsa-sha1")
    CALL key.loadPEM("DSAKey.pem")
    # Create signature object with the key to use
    LET sig = xml.Signature.Create()
    CALL sig.setKey(key)
    # Create an object inside the signature to envelop the root node
    LET objInd = sig.createObject()
    # Set the object id to get a reference
    CALL sig setObjectId(objInd,"data")
    # Copy the enveloping node from the document
    CALL sig.appendObjectData(objInd,doc.getDocumentElement())
    # Set the reference to be signed on the object node.
    # In our case, the object node with attribute 'data'
    LET index = sig.createReference("#data",
          "http://www.w3.org/2000/09/xmldsig#sha1")
    # Set canonicalization method on the enveloping object to be signed.
    CALL sig.appendReferenceTransformation(index,
          "http://www.w3.org/2001/10/xml-exc-c14n#")
    # Compute enveloping signature
    CALL sig.compute(NULL)
    # Retrieve signature document
    LET doc=sig.getDocument()
    # Save signature on disk
    CALL doc.setFeature("format-pretty-print",TRUE)
    CALL doc.save("MyDocumentEnvelopingSignature.xml")
CATCH
    DISPLAY "Unable to create an enveloping signature ":STATUS
END TRY
END MAIN
```

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Verify an enveloping signature using a X509 certificate

```plaintext
IMPORT xml

MAIN
```
MAIN
DEFINE doc xml.DomDocument
DEFINE sig xml.Signature
DEFINE cert xml.CryptoX509
DEFINE pub xml.CryptoKey
DEFINE isVerified INTEGER
# Create DomDocument object
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in cryptography,
# therefore it is recommended to remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
  # Load Signature into a DomDocument object
  CALL doc.load("MyDocumentEnvelopingSignature.xml")
  # Create signature object from DomDocument root node
  LET sig = xml.Signature.CreateFromNode(doc.getDocumentElement())
  # Create X509 certificate
  LET cert = xml.CryptoX509.Create()
  CALL cert.loadPEM("DSACertificate.crt")
  # Create public key from that X509 certificate
  LET pub = cert.createPublicKey("http://www.w3.org/2000/09/xmldsig#dsa-sha1")
  # Assign it to the signature
  CALL sig.setKey(pub)
  # Verify enveloping signature validity
  LET isVerified = sig.verify(NULL)
  # Notice that if something has been modified in the signature
  # or if the certificate isn't associated to the
  # private DSA key of example 3,
  # the program will display "FAILED".
  IF isVerified THEN
    DISPLAY "Signature OK"
  ELSE
    DISPLAY "Signature FAILED"
  END IF
CATCH
  DISPLAY "Unable to verify the enveloping signature :",STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Create an enveloped signature using a RSA key

IMPORT xml

MAIN
DEFINE doc xml.DomDocument
DEFINE doc2 xml.DomDocument
DEFINE root xml.DomNode
DEFINE node xml.DomNode
DEFINE signNode xml.DomNode
DEFINE sig xml.Signature
DEFINE key xml.CryptoKey
DEFINE index INTEGER
# Create DomDocument object
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in cryptography,
# therefore it is recommended to remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
  # Load document to be signed
  CALL doc.load("MyDocument.xml")

# Create rsa key
LET key = xml.CryptoKey.Create("http://www.w3.org/2000/09/xmldsig#rsa-sha1")
CALL key.loadPEM("RSAKey.pem")
# Create signature object with the key to use
LET sig = xml.Signature.Create()
CALL sig.setKey(key)
# Set XML node to be signed. In our case, the node with
# attribute 'xml:id="code"
LET index = sig.createReference("#code",
    "http://www.w3.org/2000/09/xmldsig#sha1")
# Add enveloped method to not take the XML signature node into account
# when computing the entire document.
CALL sig.appendReferenceTransformation(index,
# Set canonicalization method on the XML fragment to be signed.
CALL sig.appendReferenceTransformation(index,
    "http://www.w3.org/2001/10/xml-exc-c14n#")
# Compute enveloped signature
CALL sig.compute(doc)
# Retrieve signature document
LET doc2=sig.getDocument()()
# Append the signature node to the original document to get
# a valid enveloped signature
# Notice that the enveloped signature can be added anywhere in the
# original document
LET signNode = doc2.getDocumentElement() # Get Signature node
# Import it into the original document
LET node = doc.importNode(signNode,true)
# Retrieve the original document root node
LET root = doc.getDocumentElement()
# Append the signature node as last child of the original document
CALL root.appendChild(node)
# Save document with enveloped signature back to disk
CALL doc.setFeature("format-pretty-print",TRUE)
CALL doc.save("MyDocumentEnvelopedSignature.xml")
CATCH
    DISPLAY "Unable to create an enveloped signature ":,STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Verify an enveloped signature using a RSA key

IMPORT xml

MAIN
DEFINE doc xml.DomDocument
DEFINE node xml.DomNode
DEFINE sig xml.Signature
DEFINE key xml.CryptoKey
DEFINE list xml.DomNodeList
DEFINE isVerified INTEGER
# Create DomDocument object
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in cryptography,
# therefore it is recommended to remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",false)
TRY
    # Load original document with enveloped signature into a DomDocument object
CALL doc.load("MyDocumentEnvelopedSignature.xml")
# Because the signature can be anywhere in the original document,
# we must first retrieve it
LET list = doc.getElementsByTagNameNS("Signature",
    "http://www.w3.org/2000/09/xmldsig#")
IF list.getCount() != 1 THEN
    DISPLAY "Unable to find one Signature node"
    EXIT PROGRAM (-1)
ELSE
    LET node = list.getItem(1)
END IF
# Create RSA key
LET key = xml.CryptoKey.Create(
    "http://www.w3.org/2000/09/xmldsig#rsa-sha1")
CALL key.loadPEM("RSAKey.pem")
# Create signature object from DomNode object and set RSA key to use
LET sig = xml.Signature.CreateFromNode(node)
CALL sig.setKey(key)
# Verify enveloped signature validity of original document
LET isVerified = sig.verify(doc)
# Notice that if something has been modified in the node with
# attribute 'xml:id="code"' of the original XML document with the
# enveloped signature, the program will display "FAILED".
IF isVerified THEN
    DISPLAY "Signature OK"
ELSE
    DISPLAY "Signature FAILED"
END IF
CATCH
    DISPLAY "Unable to verify the enveloped signature :",STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

The Encryption class
The xml.Encryption class provides methods to encrypt and decrypt XML documents, nodes or symmetric keys.

It follows the XML-Encryption specifications.

The STATUS variable is set to zero after a successful method call.

xml.Encryption methods
Methods for the xml.Encryption class.

### Table 698: Class methods: Creation

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RETURNS xml.Encryption</td>
<td></td>
</tr>
</tbody>
</table>
### Table 699: Class methods: String encryption and decryption

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.Encryption.DecryptString(key xml.CryptoKey, str STRING)</code></td>
<td>Decrypts an encrypted string encoded in BASE64, using the specified symmetric key, and returns the string in clear text.</td>
</tr>
<tr>
<td><code>xml.Encryption.EncryptString(key xml.CryptoKey, str STRING)</code></td>
<td>Encrypts the specified string using the symmetric key, and returns the encrypted string encoded in BASE64.</td>
</tr>
<tr>
<td><code>xml.Encryption.RSADecrypt(filename STRING, str STRING)</code></td>
<td>Decrypts the BASE64 encrypted string using the RSA key and returns it in clear text</td>
</tr>
<tr>
<td><code>xml.Encryption.RSAEncrypt(filename STRING, str STRING)</code></td>
<td>Encrypts the specified string using the RSA key and returns it encoded in BASE64.</td>
</tr>
</tbody>
</table>

The methods listed in Table 699: Class methods: String encryption and decryption do not belong to the XML encryption specification, but are helper functions to allow BDL application to encrypt and decrypt short passwords with RSA keys, or big strings by using symmetric keys. Notice that a common way to encrypt data is to use symmetric keys, and to use RSA keys to encrypt the symmetric key value.

### Table 700: Object methods: Key and certificate setting

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getEmbeddedKey()</code></td>
<td>Get a copy of the embedded symmetric key that was used in the last decryption operation.</td>
</tr>
<tr>
<td><code>setCertificate(cert xml.CryptoX509)</code></td>
<td>Assigns a copy of the X509 certificate to this encryption object.</td>
</tr>
<tr>
<td><code>setKey(key xml.CryptoKey)</code></td>
<td>Assigns a copy of the symmetric key to this encryption object.</td>
</tr>
<tr>
<td><code>setKeyEncryptionKey(key xml.CryptoKey)</code></td>
<td>Assigns a copy of the key-encryption key to this encryption object.</td>
</tr>
</tbody>
</table>
### Table 701: Object methods: XML elements encryption and decryption

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>decryptElement</code></td>
<td>Decrypts the encrypted data DomNode using the symmetric key.</td>
</tr>
<tr>
<td><code>decryptElementContent</code></td>
<td>Decrypts the encrypted data DomNode using the symmetric key.</td>
</tr>
<tr>
<td><code>encryptElement</code></td>

<tr>
<td><code>encryptKey</code></td>
<td>Encrypts the given symmetric or HMAC key as an encrypted-key node and returns it as root node of a new XML document.</td>
</tr>
</tbody>
</table>
xml.Encryption.Create

Constructor of an Encryption object.

**Syntax**

```csharp
xml.Encryption.Create()
    RETURNS xml.Encryption
```

**Usage**

Returns an Encryption object or NULL.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Encryption.decryptElement

Decrypts the encrypted data DomNode using the symmetric key.

**Syntax**

```csharp
decryptElement (node xml.DomNode )
```

1. `node` defines the encrypted DomNode.

**Usage**

The EncryptedData DomNode node is replaced at the same place in the XML document with the resulting decrypted element DomNode and its children.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Encryption.decryptElementContent

Decrypts the encrypted data DomNode using the symmetric key.

**Syntax**

```csharp
decryptElementContent (node xml.DomNode )
```

1. `node` defines the encrypted DomNode.

**Usage**

The EncryptedData DomNode node is replaced at the same place in the XML document with the resulting child nodes.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
Decodes the encrypted data DomNode using the symmetric key, and returns all its children in one new document fragment type xml.DomNode.

Syntax

```
decryptElementContentDetached(
    node xml.DomNode
) RETURNS xml.DomNode
```

1. `node` defines the encrypted DomNode.

Usage

This method decrypts the EncryptedData DomNode referenced by `node` and returns all its children in one new DOCUMENT_FRAGMENT_NODE node.

The resulting child nodes are not added at any place in the XML document. It's up to the user to insert them in the right place, and to remove the encrypted node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Encryption.decryptElementDetached

Decrypts the specified encrypted data DomNode using the symmetric key, and returns it in a new element xml.DomNode.

Syntax

```
decryptElementDetached(
    node xml.DomNode
) RETURNS xml.DomNode
```

1. `node` defines the encrypted DomNode.

Usage

This method decrypts the EncryptedData DomNode `node`. The resulting element DomNode and its children are not added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the encrypted node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Encryption.decryptKey

Decrypts the EncryptedKey as root in the given XML document, and returns a new CryptoKey of the given kind.

Syntax

```
decryptKey(
    doc xml.DomDocument,
    url STRING
) RETURNS xml.CryptoKeY
```

1. `doc` defines the DomDocument object.
2. `url` defines the string.
Usage
Returns a new CryptoKey of the given kind.
Only symmetric or HMAC keys are allowed.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Encryption.DecryptString
Decrypts an encrypted string encoded in BASE64, using the specified symmetric key, and returns the string in clear text.

Syntax

```plaintext
xml.Encryption.DecryptString(
  key xml.CryptoKey,
  str STRING
) RETURNS STRING
```

1. `key` defines the symmetric key to use for decryption.
2. `str` defines the encrypted string for decryption.

Usage
This method decrypts the encrypted string `str` encoded in BASE64, using the symmetric key specified in `key`, and returns the string in clear text.
The key's usage must be for encryption, see Supported kind of keys on page 3061.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Encryption.encryptElement
Encrypts the element DomNode and all its children using the symmetric key.

Syntax

```plaintext
encryptElement(
  node xml.DomNode
)
```

1. `node` defines the ELEMENT DomNode to encrypt.

Usage
The element DomNode specified in `node` and all its children are replaced at the same place in the XML document with the resulting EncryptedData node.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.Encryption.encryptElementContent
Encrypts all child nodes of the element DomNode using the symmetric key.

Syntax

```plaintext
encryptElementContent(
  node xml.DomNode
)
```
1. `node` defines the element `DomNode` to encrypt.

**Usage**

The child nodes of the element `DomNode` specified in `node` are replaced at the same place in the XML document with the resulting `EncryptedData` node.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

```plaintext
xm.Encryption.encryptElementContentDetached
```

Encrypts all child nodes of the element `DomNode` using the symmetric key, and returns them as one new encrypted-data node.

**Syntax**

```plaintext
encryptElementContentDetached(
    node xml.DomNode
) RETURNS xml.DomNode
```

1. `node` defines the ELEMENT `DomNode` to encrypt.

**Usage**

Encrypts all child nodes of the element `DomNode` specified in `node` using the symmetric key, and returns them as one new `EncryptedData` node.

The resulting `DomNode` is not added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the nodes in clear form.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

```plaintext
xm.Encryption.encryptElementDetached
```

Encrypts the element `DomNode` and all its children using the symmetric key, and returns them as one new encrypted-data node.

**Syntax**

```plaintext
encryptElementDetached(
    node xml.DomNode
) RETURNS xml.DomNode
```

1. `node` defines the ELEMENT `DomNode` to encrypt.

**Usage**

Encrypts the element `DomNode` specified in `node` and all its children using the symmetric key, and returns them as one new `EncryptedData` node.

The resulting `DomNode` is not added at any place in the XML document. It's up to the user to insert it at the right place, and to remove the nodes in clear form.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

```plaintext
xm.Encryption.encryptKey
```
Encrypts the given symmetric or HMAC key as an encrypted-key node and returns it as root node of a new XML document.

**Syntax**

```plaintext
encryptKey(
    symkey xml.CryptoKey
) RETURNS xml.DomDocument
```

1. `symkey` defines the given symmetric or HMAC key as an EncryptedKey node.

**Usage**

This method encrypts the symmetric or HMAC key given in `symkey` as an encrypted-key node and returns it as root node of a new XML document. The encryption key must have been set otherwise it will fail.

Depending on the feature set on the key-encryption key, the returned XML document will contain an additional KeyInfo node.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

---

xml.Encryption.EncryptString

Encrypts the specified string using the symmetric key, and returns the encrypted string encoded in BASE64.

**Syntax**

```plaintext
xml.Encryption.EncryptString(
    key xml.CryptoKey,
    str STRING
) RETURNS STRING
```

1. `key` defines the key.
2. `str` defines the string to be encrypted.

**Usage**

This method encrypts the string specified in `str` using the symmetric key defined by `key`, and returns the encrypted string encoded in BASE64.

The key's usage must be for encryption, see Supported kind of keys on page 3061.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

---

xml.Encryption.getEmbeddedKey

Get a copy of the embedded symmetric key that was used in the last decryption operation.

**Syntax**

```plaintext
getEmbeddedKey() RETURNS xml.CryptoKey
```

**Usage**

Returns a copy of the embedded symmetric key that was used in the last decryption operation, or NULL if there is none.
An embedded symmetric key is always encrypted, and needs therefore a key-encryption key to be set in order to
decrypt it.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-
readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls
(STATUS) on page 3554.

xml.Encryption.RSADecrypt
Decysts the BASE64 encrypted string using the RSA key and returns it in clear text

Syntax

```java
xml.Encryption.RSADecrypt (  
    filename STRING,
    str STRING )
RETURNS STRING
```

1. filename defines the file name of a RSA private key in PEM format or an entry in the FGLPROFILE file.
2. str defines a string that was encrypted with the fglpass tool or with the xml.Encryption.RSAEncrypt
   method.

Usage

RSA decryption is only intended for short strings that cannot exceed the size of the RSA key minus 12 bytes. For
instance, if you have a RSA key of 512 bits, your password cannot exceed 512/8-12 = 52 bytes. If you need to handle
big strings, you must use symmetric keys and the DecryptString method. However, you can use RSA keys to
decrypt symmetric key values.

Important: You must ensure that access to the RSA private key file is restricted only to the authorized person or
group of persons.

If the RSA private key is protected with a password, the recommended way is to unprotect it with the openssl
 tool and to put the key file on a restricted file system. But you can also use a script or the fglpass agent to provide the
password to the application.

For example, you can encrypt a database password with the fglpass tool and store it in the FGLPROFILE
file, then you can decrypt it with the base.Application.getResourceEntry and the
xml.Encryption.RSADecrypt method to connect to the database.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-
readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls
(STATUS) on page 3554.

xml.Encryption.RSAEncrypt
Encrypts the specified string using the RSA key and returns it encoded in BASE64.

Syntax

```java
xml.Encryption.RSAEncrypt (  
    filename STRING,
    str STRING )
RETURNS STRING
```

1. filename defines the file name of a RSA public or private key in PEM format or an entry in the FGLPROFILE file.
2. str defines the string to be encrypted.

Usage

RSA encryption is only intended for short strings that cannot exceed the size of the RSA key minus 12 bytes. For
instance, if you have a RSA key of 512 bits, your password cannot exceed 512/8-12 = 52 bytes. If you need to handle
big strings, you must use symmetric keys and the `xml.Encryption.EncryptString` method. However, you can use RSA keys to encrypt symmetric key values.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

`xml.Encryption.setCertificate`

Assigns a copy of the X509 certificate to this encryption object.

**Syntax**

```java
setCertificate(
    cert xml.CryptoX509)
```

1. `cert` defines the copy of the X509 certificate.

**Usage**

The certificate will then be added to any further XML document or node encryption.

- NULL is allowed to avoid the certificate being added.
- To encrypt using a certificate, you must use the `createPublicKey` method of the X509 class to obtain the public key embedded in the certificate, and then provide it to the encryption object with `setKeyEncryptionKey` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

`xml.Encryption.setKey`

Assigns a copy of the symmetric key to this encryption object.

**Syntax**

```java
setKey(
    key xml.CryptoKey)
```

1. `key` defines the symmetric key.

**Usage**

Any further XML document or node encryption or decryption will use that symmetric key.

When decrypting a XML document that has an embedded symmetric key, the embedded key will be used instead.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (`STATUS`) on page 3554.

`xml.Encryption.setKeyEncryptionKey`

Assigns a copy of the key-encryption key to this encryption object.

**Syntax**

```java
setKeyEncryptionKey(
    key xml.CryptoKey)
```

1. `key` defines the key-encryption key.
Usage

Any further XML encryption will use that key-encryption key to encrypt the symmetric key set with $\text{setKey}()$ within the resulting XML, and any further XML decryption will use that key-encryption key to decrypt the embedded symmetric key.

- NULL is allowed, meaning that embedded symmetric keys will not be encrypted nor decrypted anymore, assuming that they have been exchanged in another way.
- Only public or private RSA keys, or key-wrap keys are allowed.
- Public RSA keys can encrypt but not decrypt.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

Examples

xml.Encryption usage examples.

Encrypt a XML node with a symmetric AES128 key

```java
IMPORT xml
MAIN
  DEFINE doc xml.DomDocument
  DEFINE root xml.DomNode
  DEFINE enc xml.Encryption
  DEFINE symkey xml.CryptoKey
  LET doc = xml.DomDocument.Create()
  # Notice that whitespaces are significant in cryptography,
  # therefore it is recommended that you remove unnecessary ones
  CALL doc.setFeature("whitespace-in-element-content",FALSE)
  TRY
    # Load XML file to be encrypted
    CALL doc.load("XMLFileToBeEncrypted.xml")
    LET root = doc.getDocumentElement()
    # Create symmetric AES128 key for XML encryption purposes
    LET symkey = xml.CryptoKey.Create( "http://www.w3.org/2001/04/xmlenc#aes128-cbc")
    CALL symkey.setKey("&secretpassword<") # password of 128 bits
    CALL symKey.setFeature("KeyName","MySecretKey") # Name the password
    # in order to identify the key (Not mandatory)
    # Encrypt the entire document
    LET enc = xml.Encryption.Create()
    CALL enc.setKey(symkey) # Set the symmetric key to be used
    CALL enc.encryptElement(root) # Encrypt
    # Save encrypted document back to disk
    CALL doc.setFeature("format-pretty-print",TRUE)
    CALL doc.save("EncryptedXMLFile.xml")
  CATCH
    DISPLAY "Unable to encrypt XML file :",STATUS
  END TRY
END MAIN
```

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Decrypt a XML node with a symmetric AES128 key

```java
IMPORT xml
MAIN
  DEFINE doc xml.DomDocument
  DEFINE node xml.DomNode
  DEFINE enc xml.Encryption
  DEFINE symkey xml.CryptoKey
```
DEFINE list xml.DomNodeList
DEFINE str String
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in cryptography, 
# therefore it is recommended to remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
# Load encrypted XML file
CALL doc.load("EncryptedXMLFile.xml")
# Retrieve encrypted node (if any) from the document
LET list = doc.getElementsByTagNameNS( 
   "EncryptedData","http://www.w3.org/2001/04/xmlenc#")
IF list.getCount()==1 THEN 
   LET node = list.getItem(1)
ELSE
   DISPLAY "No encrypted node found"
   EXIT PROGRAM
END IF
# Check if symmetric key name matches the expected "MySecretKey" 
   (Not mandatory)
LET list = node.selectByXPath("dsig:KeyInfo/dsig:KeyName[position()=1 and 
   text()="MySecretKey"]","dsig",http://www.w3.org/2000/09/xmldsig#")
IF list.getCount()!=1 THEN
   DISPLAY "Key name doesn't match"
   EXIT PROGRAM
END IF
# Create symmetric AES128 key for XML decryption purpose
LET symkey = xml.CryptoKey.Create(
   http://www.w3.org/2001/04/xmlenc#aes128-cbc")
CALL symkey.setKey(">secretpassword<") # password of 128 bits
# Decrypt the entire document
LET enc = xml.Encryption.Create()
CALL enc.setKey(symkey) # Set the symmetric key to be used
CALL enc.decryptElement(node) # Decrypt
# Save encrypted document back to disk
CALL doc.setFeature("format-pretty-print",TRUE)
CALL doc.save("DecryptedXMLFile.xml")
CATCH
   DISPLAY "Unable to decrypt XML file 
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.
Encrypt a XML node with a generated symmetric key protected with the public RSA key within a X509 certificate

IMPORT xml
MAIN
DEFINE doc xml.DomDocument
DEFINE root xml.DomNode
DEFINE enc xml.Encryption
DEFINE symkey xml.CryptoKey
DEFINE kek xml.CryptoKey
DEFINE cert xml.CryptoX509
LET doc = xml.DomDocument.Create()
# Notice that whitespaces are significant in cryptography, 
# therefore it is recommended to remove unnecessary ones
CALL doc.setFeature("whitespace-in-element-content",FALSE)
TRY
# Load XML file to be encrypted
CALL doc.load("XMLFileToBeEncrypted.xml")
LET root = doc.getDocumentElement()
# Load the X509 certificate and retrieve the public RSA key
# for key-encryption purpose
LET cert = xml.CryptoX509.Create()
CALL cert.loadPEM("RSA1024Certificate.crt")
LET kek = cert.createPublicKey(
    "http://www.w3.org/2001/04/xmlenc#rsa-1_5")
# Generate symmetric key for XML encryption purpose
LET symkey = xml.CryptoKey.Create(
    "http://www.w3.org/2001/04/xmlenc#aes256-cbc")
CALL symkey.generateKey(NULL)
# Encrypt the entire document
LET enc = xml.Encryption.Create()
CALL enc.setKey(symkey) # Set the symmetric key to be used
CALL enc.setKeyEncryptionKey(kek) # Set the key-encryption key to
    # be used for protecting the symmetric key
CALL enc.setCertificate(cert) # Set the certificate to be added
    # (not mandatory)
CALL enc.encryptElement(root) # Encrypt
# Save encrypted document back to disk
CALL doc.setFeature("format-pretty-print",TRUE)
CALL doc.save("EncryptedXMLFile.xml")
CATCH
  DISPLAY "Unable to encrypt XML file ",STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

Decrypt a XML node encrypted with a symmetric key protected with a private RSA key

IMPORT xml

MAIN
  DEFINE doc xml.DomDocument
  DEFINE node xml.DomNode
  DEFINE enc xml.Encryption
  DEFINE symkey xml.CryptoKey
  DEFINE kek xml.CryptoKey
  DEFINE list xml.DomNodeList
  LET doc = xml.DomDocument.Create()
  # Notice that whitespaces are significant in cryptography,
  # therefore it is recommended to remove unnecessary ones
  CALL doc.setFeature("whitespace-in-element-content",FALSE)
  TRY
    # Load encrypted XML file
    CALL doc.load("EncryptedXMLFile.xml")
    # Retrieve encrypted node (if any) from the document
    LET list = doc.getElementsByTagNameNS("EncryptedData",
        "http://www.w3.org/2001/04/xmlenc#")
    IF list.getCount()==1 THEN
      LET node = list.getItem(1)
    ELSE
      DISPLAY "No encrypted node found"
      EXIT PROGRAM
    END IF
    # Load the private RSA key
    LET kek = xml.CryptoKey.create(
        "http://www.w3.org/2001/04/xmlenc#rsa-1_5")
    CALL kek.loadPEM("RSA1024Key.pem")
    # Decrypt the entire document
    LET enc = xml.Encryption.Create()
CALL enc.setKeyEncryptionKey(kek) # Set the key-encryption key to decrypted the protected symmetric key
CALL enc.decryptElement(node) # Decrypt
# Retrieve the embedded symmetric key for further usage and display info about it
LET symkey = enc.getEmbeddedKey()
DISPLAY "Key size (in bytes) : ", symkey.getSize() # displays 1024
DISPLAY "Key type : ", symkey.getType() # displays SYMMETRIC
DISPLAY "Key usage : ", symkey.getUsage() # displays ENCRYPTION
# Encrypted document back to disk
CALL doc.setFeature("format-pretty-print", TRUE)
CALL doc.save("DecryptedXMLFile.xml")
CATCH
  DISPLAY "Unable to decrypt XML file : ", STATUS
END TRY
END MAIN

Note: All keys or certificates in PEM or DER format were created with the OpenSSL tool.

The KeyStore class
The xml.KeyStore class provides static methods to handle a key store that is global for the entire application. It enables you to register X509 and trusted certificates, and any kind of key by name for automatic XML signature validation or XML decryption.

The STATUS variable is set to zero after a successful method call.

xml.KeyStore methods
Methods for the xml.KeyStore class.

Table 704: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| xml.KeyStore.AddCertificate(  
  global xml.CryptoX509 ) | Registers in the keystore the given X509 certificate as a certificate for the application. |
| xml.KeyStore.AddKey(  
  global xml.CryptoX509 ) | Registers in the keystore the given key by name for the application. |
| xml.KeyStore.AddTrustedCertificate(  
  global xml.CryptoX509 ) | Registers in the keystore the given X509 certificate as a trusted certificate for the application. |

xml.KeyStore.AddCertificate
Registers in the keystore the given X509 certificate as a certificate for the application.

Syntax

xml.KeyStore.AddCertificate(  
  global xml.CryptoX509 )

1. **global** defines the X509 certificate to register.

Usage

This method registers a given X509 certificate to be used when an incomplete X509 certificate is detected during signature or encryption. To complete the process the certificate’s issuer name and serial number are checked.

The method has the same effect as the FGLPROFILE entry xml.keystore.x509list.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.KeyStore.AddKey
Registers in the keystore the given key by name for the application.

Syntax

```xml
xml.KeyStore.AddKey(
    global xml.CryptoX509
)
```

1. `global` defines the key object `xml.CryptoX509` to add to the keystore.

Usage

This method adds a key to the keystore to be used for XML signature verification or XML decryption when a key name has been specified in the XML KeyInfo node and no other key has been set in the Signature or Encryption object.

The CryptoKey must have the KeyName feature set, and the name must be unique in the application.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

xml.KeyStore.AddTrustedCertificate
Registers in the keystore the given X509 certificate as a trusted certificate for the application.

Syntax

```xml
xml.KeyStore.AddTrustedCertificate(
    global xml.CryptoX509
)
```

1. `global` defines the X509 certificate to register.

Usage

This method registers the given X509 certificate as a trusted certificate for the application. It will be used for signature verification if no other certificate was set for that purpose.

The method has the same effect as the FGLPROFILE entry xml.keystore.calist.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

XML transformation classes

The XML transformation classes transform XML.

Important: The XML transformation classes are not supported on GMI mobile devices.

The XSLTransformer class

The `xml.XSLTransformer` class handles XML transformation following the XSLT version 1.0 specification.

Important: This class is not available on iOS, as it is based on libxslt library, which is not allowed on the Apple® store.
xml.XSLTTransformer methods
Methods for the xml.XSLTTransformer class.

Table 705: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml.XSLTTransformer.CreateFromDocument (doc xml.DomDocument)</td>
<td>Returns a new instance of a XSLTTransformer object to be used to transform a XML document based on a given style sheet.</td>
</tr>
</tbody>
</table>

Table 706: Object methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml.XSLTTransformer.setParameter (param STRING, value STRING)</td>
<td>Set parameters in an instance of an XSLTTransformer corresponding to the XSLT entries named by param.</td>
</tr>
<tr>
<td>xml.XSLTTransformer.getParameter (param STRING)</td>
<td>Get the value of a given parameter in an instance of an XSLTTransformer corresponding to the XSLT entry named by param.</td>
</tr>
<tr>
<td>xml.XSLTTransformer.clearParameters ()</td>
<td>Clear all parameters in an instance of an XSLTTransformer object.</td>
</tr>
<tr>
<td>xml.XSLTTransformer.doTransform (doc xml.DomDocument)</td>
<td>Transforms the input source based on the XSLT style sheet used to create the XSLTTransformer instance and returns the transformed document.</td>
</tr>
<tr>
<td>xml.XSLTTransformer.getErrorDescription (index INTEGER)</td>
<td>Returns the exact description of the error referenced by the index.</td>
</tr>
<tr>
<td>xml.XSLTTransformer.getErrorsCount ()</td>
<td>Returns the number of errors.</td>
</tr>
</tbody>
</table>

xml.XSLTTransformer.clearParameters
Clear all parameters in an instance of an XSLTTransformer object.

Syntax

xml.XSLTTransformer.clearParameters()  

Usage

Clears all parameters corresponding to the XSLT entries named by param.

For example, this XSLT sample contains two param definitions:

```xml
<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform" >
```
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

\textbf{Related concepts}

\texttt{xml.XSLTTransformer.getParameter} on page 3123
Get the value of a given parameter in an instance of an \texttt{XSLTTransformer} corresponding to the XSLT entry named by \texttt{param}.

\texttt{xml.XSLTTransformer.setParameter} on page 3122
Set parameters in an instance of an \texttt{XSLTTransformer} corresponding to the XSLT entries named by \texttt{param}.

\texttt{xml.XSLTTransformer.CreateFromDocument}
Returns a new instance of a \texttt{XSLTTransformer} object to be used to transform a XML document based on a given style sheet.

\textbf{Syntax}

\begin{verbatim}
xml.XSLTTransformer.CreateFromDocument (  
doctor xml.DomDocument  )  
RETURNS xml.XSLTTransformer
\end{verbatim}

1. \texttt{doc} defines the given style sheet.

\textbf{Usage}

Returns a new instance of an \texttt{XSLTTransformer} object to be used to transform a XML document based on the given style sheet. It may raise a \texttt{XML_ERROR_LOAD_EXCEPTION} exception if the XML document is not loadable.

There may be non-critical errors when loading a given style sheet document; you can check with the \texttt{xml.XSLTTransformer.getErrorsCount()} method.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

To see these methods in a working example, see Example: Using xml.XSLTTransformer methods.

\texttt{xml.XSLTTransformer.doTransform}
Transforms the input source based on the XSLT style sheet used to create the \texttt{XSLTTransformer} instance and returns the transformed document.

\textbf{Syntax}

\begin{verbatim}
xml.XSLTTransformer.doTransform (  
doctor xml.DomDocument  )  
RETURNS xml.DomDocument
\end{verbatim}
1. *doc* defines the input source.

**Usage**

This method transforms the input source based on the XSLT style sheet used to create the XSLTTransformer instance and returns the transformed document. It raises a `XML_ERROR_FAILED` exception in case of critical error. The operation may return a new document that may be incomplete. You must check for errors that may occur during the transformation with the `xml.XSLTTransformer.getErrorsCount()` method.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

To see these methods in a working example, see Example: Using xml.XSLTTransformer methods.

**xml.XSLTTransformer.getErrorDescription**

Returns the exact description of the error referenced by the index.

**Syntax**

```java
xml.XSLTTransformer.getErrorDescription(
    index INTEGER
) RETURNS STRING
```

1. `index` defines the index of the error returned by `xml.XSLTTransformer.getErrorsCount()`.

**Usage**

This method returns the exact description of the error referenced by the index during the `doTransform()` call or during the `CreateFromDocument()` when the style sheet contains some errors.

This method is typically used in conjunction with `getErrorsCount()`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

To see these methods in a working example, see Example: Using xml.XSLTTransformer methods.

**Related concepts**

- `xml.XSLTTransformer.CreateFromDocument` on page 3120
  Returns a new instance of a XSLTTransformer object to be used to transform a XML document based on a given style sheet.

- `xml.XSLTTransformer.doTransform` on page 3120
  Transforms the input source based on the XSLT style sheet used to create the XSLTTransformer instance and returns the transformed document.

**xml.XSLTTransformer.getErrorsCount**

Returns the number of errors.

**Syntax**

```java
xml.XSLTTransformer.getErrorsCount()
RETURNS INTEGER
```

**Usage**

Return the number of errors during the `doTransform()` call or during the `CreateFromDocument()` when the style sheet contains errors.
It is recommended to check if errors have been encountered after both operations, because even with errors, it is possible to transform a document.

The errors count is reset between CreateFromDocument() and doTransform().

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

To see these methods in a working example, see Example: Using xml.XSLTTransformer methods.

Related concepts
xml.XSLTTransformer.getErrorDescription on page 3121
Returns the exact description of the error referenced by the index.

xml.XSLTTransformer.CreateFromDocument on page 3120
Returns a new instance of a XSLTTransformer object to be used to transform a XML document based on a given style sheet.

xml.XSLTTransformer.doTransform on page 3120
Transforms the input source based on the XSLT style sheet used to create the XSLTTransformer instance and returns the transformed document.

xml.XSLTTransformer.setParameter
Set parameters in an instance of an XSLTTransformer corresponding to the XSLT entries named by param.

Syntax

```
xm1.XSLTTransformer.setParameter(
    param STRING,
    value STRING )
```

1. param defines the name of the parameter.
2. value specifies the value to set the parameter.

Usage

Set parameters corresponding to the XSLT entries named by param.

For example, this XSLT sample contains two param definitions:

```
<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform" >

    <xsl:param name="QADIR" />
    <xsl:param name="NODE_NAME"/>
    ...
    <MyNode><xsl:value-of select="$QADIR" /></MyNode>
    ...
    <xsl:when test="name()=$NODE_NAME">
        <xsl:copy>
            <xsl:copy-of select="@*"/>
        </xsl:copy>
    </xsl:when>

</xsl:stylesheet>
```

To set the parameter QADIR:

```
CALL xslt.setParameter("QADIR","" | "/work/tmp" | "") # Literal
```

Note: If a parameter is a literal, you must quote it before calling the setParameter()
To set the parameter \texttt{NODE\_NAME}:

\begin{verbatim}
CALL xslt.setParameter("NODE\_NAME","BOOK")
\end{verbatim}

If the parameter is already set, the previous value will be replaced by the new one.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3554.

\textbf{Related concepts}

\texttt{xml.XSLTransformer.getParameter} on page 3123
Get the value of a given parameter in an instance of an \texttt{XSLTransformer} corresponding to the XSLT entry named by \texttt{param}.

\texttt{xml.XSLTransformer.clearParameters} on page 3119
Clear all parameters in an instance of an \texttt{XSLTransformer} object.

\texttt{xml.XSLTransformer.getParameter}
Get the value of a given parameter in an instance of an \texttt{XSLTransformer} corresponding to the XSLT entry named by \texttt{param}.

\textbf{Syntax}

\begin{verbatim}
xml.XSLTransformer.getParameter(
    param STRING)
RETURNS STRING
\end{verbatim}

1. \texttt{param} defines the name of the parameter.

\textbf{Usage}

Get parameters corresponding to the XSLT entries named by \texttt{param}.

For example, this XSLT sample contains two \texttt{param} definitions:

\begin{verbatim}
<xsl:stylesheet version="1.0" xmlns:xsl="http://www.w3.org/1999/XSL/Transform" >
  <xsl:param name="QADIR" />
  <xsl:param name="NODE\_NAME"/>
  ...
  <MyNode><xsl:value-of select="$QADIR" /></MyNode>
  ...
  <xsl:when test="name()=$NODE\_NAME">  
      <xsl:copy>
        <xsl:copy-of select="@*"/>
    </xsl:copy>
  </xsl:when>
</xsl:stylesheet>
\end{verbatim}

To get the parameter \texttt{QADIR}:

\begin{verbatim}
DEFINE dir STRING
SET dir=xslt.getParameter("QADIR")
\end{verbatim}

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3554.
To see these methods in a working example, see Example: Using xml.XSLTTransformer methods.

**Related concepts**

xml.XSLTTransformer.setParameter on page 3122

Set parameters in an instance of an XSLTTransformer corresponding to the XSLT entries named by param.

xml.XSLTTransformer.clearParameters on page 3119

Clear all parameters in an instance of an XSLTTransformer object.

**Example: Using xml.XSLTTransformer methods**

This Genero application provides a working example using methods from the XSLTTransformer class.

```genero
IMPORT XML

MAIN
   DEFINE ok BOOLEAN
   IF num_args() != 3 THEN
      DISPLAY "Usage : DoXslp <stylesheet> <source> <result>"
      EXIT PROGRAM 1
   ELSE
      LET ok = RunXSLP(arg_val(1), arg_val(2), arg_val(3))
      IF NOT ok THEN
         DISPLAY "Error: failed"
         EXIT PROGRAM 1
      ELSE
         DISPLAY "Done"
         EXIT PROGRAM
      END IF
   END IF
END MAIN

FUNCTION RunXSLP(style, src, ret)
   DEFINE style, src, ret STRING
   DEFINE ind INTEGER
   DEFINE xslt xml.XSLTTransformer
   DEFINE styleSheet xml.DomDocument
   DEFINE source xml.DomDocument
   DEFINE result xml.DomDocument

   # Load StyleSheet
   TRY
      LET styleSheet = xml.DomDocument.Create()
      CALL styleSheet.load(style)
   CATCH

      DISPLAY "Error : unable to create XSLT transformer from ", styleSheet
      RETURN false
   END TRY

   # Load Source
   TRY
      source = xml.DomDocument.Create()
      source.load(src)
   CATCH
      DISPLAY "Error: unable to load source", src
      RETURN false
   END TRY
```
OM to XML Migration

Code using the OM classes can be converted to XML classes in most cases.

The build-in om package provides basic XML handling. The Web Services extensions xml package provides full support for XML document processing. You may need to change code from om to xml classes. Before you convert code, make sure that you are using the classes from the appropriate package:

- Classes from the om package exist to manipulate the AUI tree and also provide basic XML handling.
- Classes from the xml package provides classes and methods to handle any kind of XML document processing, and are recommended for XML document manipulation.

Why would you migrate from om to xml classes and methods?

- You need to be able to utilize a feature (such as a StyleSheet) that requires use of methods from the xml library classes.

Note: The DOM API of the om package is designed to handle specific FGL files and to manipulate the user interface tree (the AUI tree). For all other cases, we recommend that you use the DOM API of the Web Services xml package.

OM - XML Mapping

A reference guide to the DOM APIs of the om and xml classes.

For more information on Genero built-in classes (such as the OM class), refer to Built-in packages on page 2378.

The security package

The Genero Web Services security package provides classes and methods to support basic cryptographic features.

Use the IMPORT statement at the top of the module using this library:

```fortran
IMPORT security
```

The RandomGenerator class

The security.RandomGenerator class includes methods for creating random strings or numbers.

security.RandomGenerator methods

Methods of the security.RandomGenerator class.

Table 708: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>security.RandomGenerator.CreateRandomNumber()</td>
<td>Generates an 8-byte strong random number.</td>
</tr>
<tr>
<td>security.RandomGenerator.CreateRandomString( size INTEGER ) RETURNS STRING</td>
<td>Creates a random base64 string.</td>
</tr>
</tbody>
</table>

**security.RandomGenerator.CreateRandomNumber**

Generates an 8-byte strong random number.

**Syntax**

```fortran
security.RandomGenerator.CreateRandomNumber() RETURNS BIGINT
```

**Usage**

This method generates an 8-byte strong random number and returns it as a BIGINT. The generated number can then be used for advanced cryptographic features.
This method is based on OpenSSL, using `/dev/random` on UNIX® and CryptGenRandom() on Microsoft® Windows®, which are based on the cryptographically secure pseudo-random number generator (CSPRNG) specifications.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

security.RandomGenerator.CreateRandomString
Creates a random base64 string.

Syntax

```
security.RandomGenerator.CreateRandomString(
    size INTEGER )
RETURNS STRING
```

1. `size` defines the size of the random string.

Usage

This method generates a random string of binary data of `size` bytes long and returns it in a STRING encoded in a Base64 form.

The size must be greater than 0.

Use this function when randomness is required, such as in xml.CryptoKey.deriveKey() or security.Digest.CreateDigestString().

This method is based on OpenSSL, using `/dev/random` on UNIX® and CryptGenRandom() on Microsoft® Windows®, which are based on the cryptographically secure pseudo-random number generator (CSPRNG) specifications.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

security.RandomGenerator.CreateUUIDString
Creates a new universal unique identifier (UUID).

Syntax

```
security.RandomGenerator.CreateUUIDString()
RETURNS STRING
```

Usage

This method generates an universal unique identifier and returns the value as STRING.

The generated string follows the UUID version 4 specification. Version 4 UUIDs have the form `xxxxxxxx-xxxx-4xxx-yxxx-xxxxxxxxxxxx` where `x` is any hexadecimal digit and `y` is one of 8, 9, A, or B.

Note: This method replaces com.Util.CreateUUIDString().

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
The Base64 class
The `security.Base64` class includes methods for encoding to base64 or decoding from base64.

security.Base64 methods
Methods of the `security.Base64` class.
Table 709: Class methods

<table>
<thead>
<tr>
<th>Name</th>

</tr>
<tr>
<td>security.Base64.Xor( clearVal1 STRING, clearVal2 STRING ) RETURNS STRING</td>
<td>Computes the exclusive disjunction between two base64 encoded strings.</td>
</tr>
</tbody>
</table>
security.Base64.FromByte
Encodes the given BYTE data in base64.

Syntax

```c
security.Base64.FromByte(
    data BYTE
) RETURNS STRING
```

1. `data` defines the data of type BYTE to be encoded.

Usage

This method encodes the given BYTE data in base64 and returns the string.

**Important:** The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

security.Base64.FromHexBinary
Decodes the given hexadecimal string to base64.

Syntax

```c
security.Base64.FromHexBinary(
    hexBinVal STRING
) RETURNS STRING
```

1. `hexBinVal` defines the string in hexadecimal form.

Usage

This method decodes the given hexadecimal string and returns it in base64.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

security.Base64.FromString
Encodes the given string in base64.

Syntax

```c
security.Base64.FromString(
    clearVal STRING
) RETURNS STRING
```

1. `clearVal` defines the string to be encoded.

Usage

This method encodes the given string, `clearVal`, and returns it in base64.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
**security.Base64.FromStringWithCharset**

Encodes the given string in base64, based on a given charset.

**Syntax**

```java
security.Base64.FromStringWithCharset(
    clearVal STRING,
    charset STRING
) RETURNS STRING
```

1. *clearVal* defines the string to be encoded.
2. *charset* defines the character set to be used.

**Usage**

This method encodes the string, *clearVal*, based on the specified charset, *charset*, and returns it in base64.

Before conversion, the string is converted from the local DVM charset to the specified encoding.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**security.Base64.LoadBinary**

Reads data from a file and encodes to base64.

**Syntax**

```java
security.Base64.LoadBinary(
    path STRING
) RETURNS STRING
```

1. *path* defines the path to the binary file.

**Usage**

Reads the file located at *path* and encodes this binary data in Base64 format.

For example, this method can be used to send images through a network.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**security.Base64.SaveBinary**

Decodes the given base64 string and writes the data to a file.

**Syntax**

```java
security.Base64.SaveBinary(
    path STRING,
    base64Data STRING
)
```

1. *path* defines the path to the binary file.
2. *base64Data* defines base64 string to be written.

**Usage**

Decodes the given Base64 string and writes the binary data to the file defined by *path*. 
This method can be used to save data from a network on the disk.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**security.Base64.ToHexBinary**

Decodes the given base64 string to hexadecimal.

**Syntax**

```plaintext
security.Base64.ToHexBinary ( 
    val64 STRING )
RETURNS STRING
```

1. `val64` defines a string encoded in base64.

**Usage**

Decodes the base64 string, `val64`, and returns it in its hexadecimal form.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**security.Base64.ToByte**

Decodes the given base64 string into a BYTE.

**Syntax**

```plaintext
security.Base64.ToByte ( 
    val64 STRING, 
    ret BYTE )
```

1. `val64` defines the string in base64.
2. `ret` defines a parameter of type BYTE to fill with data.

**Usage**

Decodes the base64 string specified in `val64` and fills the BYTE variable with binary data.

**Important:** The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**security.Base64.ToString**

Decodes the given base64 string.

**Syntax**

```plaintext
security.Base64.ToString ( 
    val64 STRING )
RETURNS STRING
```

1. `val64` defines the string in base64.
Usage
Decodes the given base64 string and returns it in its clear (human readable) form.
If the base64 string does not contain human readable data, the method will raise an exception.
If the base64 string contains bytes sequences that do not match a valid character in the current encoding, the method raises a conversion error.
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3554.

\texttt{security.Base64.ToStringWithCharset}
Decodes the given base64 string, based on a given charset.

Syntax

\begin{verbatim}
security.Base64.ToStringWithCharset ( 
    val64 STRING,
    charset STRING )
RETURNS STRING
\end{verbatim}

1. \texttt{val64} defines the string in base64.
2. \texttt{charset} defines the character set to be used.

Usage
Decodes the given base64 string and returns it in its clear human readable form, based on a given charset.
The original base64 encoded string is first decoded to a string that will be converted from the specified charset to the local DVM charset. In case of charset conversion error, the error -15700 is raised.
If the base64 string does not contain human readable data, the method will raise an exception.
If the base64 string contains bytes sequences that do not match a valid character in the current encoding, the method raises a conversion error.
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \textit{Error handling in GWS calls (STATUS)} on page 3554.

\texttt{security.Base64.Xor}
Computes the exclusive disjunction between two base64 encoded strings.

Syntax

\begin{verbatim}
security.Base64.Xor ( 
    clearVal1 STRING,
    clearVal2 STRING )
RETURNS STRING
\end{verbatim}

1. \texttt{clearVal1} defines the first string encoded in base64.
2. \texttt{clearVal2} defines the second string encoded in base64.

Usage
Decodes the two given strings and does an exclusive disjunction between the two binary inputs. The result is returned encoded in base64.
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
**The HexBinary class**

The `security.HexBinary` class includes methods for encoding to hexadecimal or decoding from hexadecimal.

**security.HexBinary methods**

Methods of the `security.HexBinary` class.

</tbody>
</table>
security.HexBinary.FromBase64
Converts a base64 string to the hexadecimal equivalent.

Syntax

```java
security.HexBinary.FromBase64(
    val64 STRING
) RETURNS STRING
```

1. `val64` defines a string encoded in base64.

Usage
This method decodes the given base64 string and returns it in its hexadecimal form.
In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

security.HexBinary.FromByte
Encodes BYTE data in hexadecimal.

Syntax

```java
security.HexBinary.FromByte(
    data BYTE
) RETURNS STRING
```

1. `data` defines the data of type BYTE to be encoded.

Usage
This method encodes the given BYTE data in hexadecimal and returns the string.

Important: The BYTE must be located in memory.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

security.HexBinary.FromString
Encodes a given string in hexadecimal.

Syntax

```java
security.HexBinary.FromString(
    clearVal STRING
) RETURNS STRING
```

1. `clearVal` defines the string to be encoded.

Usage
Encodes the given string and returns it in hexadecimal.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
**security.HexBinary.FromStringWithCharset**

Encodes a given string in hexadecimal, based on a given charset.

**Syntax**

```csharp
security.HexBinary.FromStringWithCharset(
    clearVal STRING,
    charset STRING )
RETURNS STRING
```

1. `clearVal` defines the string to be encoded.
2. `charset` defines the character set to be used.

**Usage**

Encodes the given string and returns it in hexadecimal.

Before conversion, the string is converted from the local DVM charset to the specified encoding.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**security.HexBinary.LoadBinary**

Reads binary data from a file and converts it to hexadecimal.

**Syntax**

```csharp
security.HexBinary.LoadBinary( 
    path STRING )
RETURNS STRING
```

1. `path` defines the path to the binary file.

**Usage**

Reads the file located at `path` and returns this binary data in hexadecimal format.

For example, this method can be used to send images through a network.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**security.HexBinary.SaveBinary**

Decodes an hexadecimal string and writes the binary data to a file.

**Syntax**

```csharp
security.HexBinary.SaveBinary(
    path STRING,
    hexBinData STRING )
```

1. `path` defines the path to the binary file.
2. `hexBinData` defines the hexadecimal string to be written.

**Usage**

Decodes the given hexadecimal string and writes the binary data to the file defined by `path`. 
This method can be used to save data from a network on the disk.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

`security.HexBinary.ToBase64`
Converts an hexadecimal string to the base64 equivalent

**Syntax**

```csharp
security.HexBinary.ToBase64(
    hexBinVal STRING )
RETURNS STRING
```

1. `hexBinVal` defines the string in hexadecimal form

**Usage**
Decodes the given hexadecimal string and returns it in base64.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

`security.HexBinary.ToByte`
Decodes an hexadecimal string into a BYTE variable.

**Syntax**

```csharp
security.HexBinary.ToByte(
    hex STRING,
    ret BYTE )
```

1. `hex` defines a string in hexadecimal.
2. `ret` defines the input parameter to fill with data of type BYTE.

**Usage**
Decodes the given hexadecimal string and fills the BYTE variable with binary data.

**Important:** The BYTE must be located in memory.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

`security.HexBinary.ToString`
Decodes an hexadecimal string to a clear, human-readable string.

**Syntax**

```csharp
security.HexBinary.ToString(
    hexVal STRING )
RETURNS STRING
```

1. `hexVal` defines the string in hexadecimal.
**Usage**

Decodes the given hexadecimal string and returns it in its clear, human-readable form. If the hexadecimal string does not contain a human-readable string, the method will raise an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`security.HexBinary.ToStringWithCharset`

Decodes an hexadecimal string to a clear, human-readable string, based on a given charset.

**Syntax**

```c
security.HexBinary.ToStringWithCharset ( 
    hexVal STRING, 
    charset STRING )
RETURNS STRING
```

1. `hexVal` defines the string in hexadecimal.
2. `charset` defines the character set to be used.

**Usage**

Decodes the given hexadecimal string and returns it in its clear human-readable form, based on a given charset.

The original hexadecimal encoded string is first decoded to a string that will then be converted from the specified charset to the local DVM charset. In case of charset conversion error, the error -15700 is raised.

If the hexadecimal string does not contain a human-readable string, the method will raise an exception.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

`security.HexBinary.Xor`

Computes the exclusive disjunction between two hexadecimal encoded strings.

**Syntax**

```c
security.HexBinary.Xor ( 
    hexVal1 STRING, 
    hexVal2 STRING )
RETURNS STRING
```

1. `hexVal1` defines the first string in hexadecimal.
2. `hexVal2` defines the second string in hexadecimal.

**Usage**

Decodes the two given strings and does an exclusive disjunction between the two binary inputs. The result is returned in hexadecimal.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.
The Digest class

The `security.Digest` class implements digest algorithms to process data.

The class implements several methods that allow you to add data piece by piece and process these data with a specified digest algorithm.

Steps to process data with a digest algorithm:

1. Define the digest algorithm with the `security.Digest.CreateDigest` method.
3. When all data pieces are added, the buffer can be processed by calling methods like `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

Alternatively, a simple data string can be processed with the `security.Digest.CreateDigestString` method.

**security.Digest methods**

Methods of the `security.Digest` class.

**Table 711: Class methods**

<table>
<thead>
<tr>
<th>Name</th>

<td><code>security.Digest.DoHexBinaryDigest ()</code></td>
<td>Creates a digest of the buffered data and returns the result in hexadecimal format.</td>
</tr>
</tbody>
</table>

**security.Digest.AddData**  
Adds data from a BYTE variable to the digest buffer.

**Syntax**

```plaintext
security.Digest.AddData ( 
    toDigest BYTE )
```

1. `toDigest` defines the binary data to be added to the digest buffer.

**Usage**

Adds the binary data contained in the given BYTE to the digest context.

After adding all the data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

**Important:** The BYTE must be located in memory.
In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \texttt{Error handling in GWS calls (STATUS)} on page 3554.

\texttt{security.Digest.AddBase64Data}

Adds data in base64 format to the digest buffer.

\textbf{Syntax}

\begin{verbatim}
security.Digest.AddBase64Data ( 
    toDigest STRING )
\end{verbatim}

1. \textit{toDigest} defines the base64 data string to be added to the digest buffer.

\textbf{Usage}

Use the method to decode the given base64 string and add the binary data to the digest buffer.

After adding all the data pieces, the buffer can be processed by calling \texttt{security.Digest.DoBase64Digest} or \texttt{security.Digest.DoHexBinaryDigest}.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \texttt{Error handling in GWS calls (STATUS)} on page 3554.

\texttt{security.Digest.AddHexBinaryData}

Adds data in hexadecimal format to the digest buffer.

\textbf{Syntax}

\begin{verbatim}
security.Digest.AddHexBinaryData ( 
    toDigest STRING )
\end{verbatim}

1. \textit{toDigest} defines the hexadecimal data string to be added to the digest buffer.

\textbf{Usage}

Use the method to decode the given hexadecimal string and add the binary data to the digest buffer.

After adding all the data pieces, the buffer can be processed by calling \texttt{security.Digest.DoBase64Digest} or \texttt{security.Digest.DoHexBinaryDigest}.

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See \texttt{Error handling in GWS calls (STATUS)} on page 3554.

\texttt{security.Digest.AddStringData}

Adds a data string to the digest buffer.

\textbf{Syntax}

\begin{verbatim}
security.Digest.AddStringData ( 
    toDigest STRING )
\end{verbatim}

1. \textit{toDigest} defines the human-readable character string to be added to the digest buffer.

\textbf{Usage}

This method adds the specified string data to the digest buffer.
After adding all the data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

- `security.Digest.AddStringDataWithCharset` on page 3145
  Adds a data string to the digest buffer, after converting to the specified character set.

**Syntax**

```java
security.Digest.AddStringDataWithCharset ( 
    toDigest STRING, 
    charset STRING ) 
```

1. `toDigest` defines the human-readable character string to be added to the digest buffer.
2. `charset` defines the charset to be used.

**Usage**

This method adds the specified string data based on the given charset to the digest buffer.

Before adding the string, it is converted from the local DVM charset to the specified encoding.

After adding all the data pieces, the buffer can be processed by calling `security.Digest.DoBase64Digest` or `security.Digest.DoHexBinaryDigest`.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

**Related concepts**

- `security.Digest.AddStringData` on page 3144
  Adds a data string to the digest buffer.

**Syntax**

```java
security.Digest.CreateDigest ( 
    algo STRING ) 
RETURNS security.Digest 
```

1. `algo` defines the digest algorithm to be used.

**Usage**

Use this method to create and initialize a digest context to compute data digest based on the specified algorithm.

Available digest algorithms are:

- "SHA1"
- "SHA224"
- "SHA256"
In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**security.Digest.CreateDigestString**

Creates a SHA1 digest from the given string.

**Syntax**

```java
security.Digest.CreateDigestString(
    toDigest STRING,
    randomBase64 STRING
) RETURNS STRING
```

1. `toDigest` defines the password to be digested.
2. `randomBase64` defines a random string in Base64.

**Usage**

Use this method to compute the SHA1 digest from the string in `toDigest` and an optional random Base64 form string, and return it in a string encoded in Base64 form.

The random value must be a valid Base64 string. You typically generate this value with the `security.RandomGenerator.CreateRandomString()` method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

**Example**

```
DEFINE password, digest STRING ...
LET digest =
    security.Digest.CreateDigestString(
        password,
        security.RandomGenerator.CreateRandomString(16) )
```

**security.Digest.DoBase64Digest**

Creates a digest of the buffered data and returns the result in base64 format.

**Syntax**

```java
security.Digest.DoBase64Digest ()
RETURNS STRING
```

**Usage**

This method processes the digest on all data previously added to the context and encodes it in base64.

After that call, the internal buffer is cleaned and ready to be populated again with new data to be digested.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.
security.Digest.DoHexBinaryDigest
Creates a digest of the buffered data and returns the result in hexadecimal format.

Syntax

```plaintext
security.Digest.DoHexBinaryDigest ()
RETURNS STRING
```

Usage

This method processes the digest on all data previously added to the context and returns it in hexadecimal.

After that call, the internal buffer is cleaned and ready to be populated again with new data to be digested.

In case of error, the method throws an exception and sets the `STATUS` variable. Depending on the error, a human-readable description of the problem is available in the `SQLCA.SQLERRM` register. See Error handling in GWS calls (STATUS) on page 3554.

Example

Computing a hash value of a string.

Program example `ComputeHash.4gl`:

```plaintext
IMPORT SECURITY

MAIN

DEFINE result STRING

IF num_args() != 2 THEN
    DISPLAY "Usage: ComputeHash <string> <hashcode>"
    DISPLAY "  string: the string to digest"
    DISPLAY "  hashcode: SHA1, SHA512, SHA384, SHA256, SHA224, MD5"
ELSE
    LET result = ComputeHash(arg_val(1), arg_val(2))
    IF result IS NOT NULL THEN
        DISPLAY "Hash value is :",result
    ELSE
        DISPLAY "Error"
    END IF
END IF

END MAIN

FUNCTION ComputeHash(toDigest, algo)

DEFINE toDigest, algo, result STRING
DEFINE dgst security.Digest

TRY
    LET dgst = security.Digest.CreateDigest(algo)
    CALL dgst.AddStringData(toDigest)
    LET result = dgst.DoBase64Digest()
CATCH
    DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
    EXIT PROGRAM(-1)
END TRY

RETURN result
END FUNCTION
```

Example execution:
$ fglrun ComputeHash "Hello World" SHA1
Hash value is: Ck1VqNd45QIvq3AZd8XYQLvEhtA=

The PBKDF2 class
The security.PBKDF2 class generates passwords using the Password-Based Key Derivation Function 2 (PBKDF2).

security.PBKDF2 methods
Methods of the security.PBKDF2 class.

Table 713: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>RETURNS BOOLEAN</td>
<td></td>
</tr>
</tbody>
</table>

security.PBKDF2.GenerateKey
Generates a password of a given size based on a human readable password using Password-Based Key Derivation Function 2 (PBKDF2)

Syntax

security.PBKDF2.GenerateKey (  
password STRING,  
salt STRING,  
hash STRING,  
iter INTEGER,  
keySize INTEGER )  
RETURNS STRING

1. *password* defines the human readable password to derive using the PBKDF2 method.
2. *salt* defines the base64 random value created using Security.RandomGenerator.CreateRandomString(). Can be NULL.
3. *hash* defines the hash operation. By default, it is "SHA1". Valid values include:
   - SHA1
   - SHA224
   - SHA256
   - SHA384
   - SHA512
   - MD5
4. \textit{iter} defines the number of iterations to compute the derived password. This value must be greater than or equal to zero (\(\geq 0\)).

5. \textit{keySize} defines the size in bytes of the returned key. Must be greater than zero (\(>0\))

\textbf{Usage}

This method generates a password of a given size based on a human readable password using \texttt{PBKDF2}.

In practice, with the same salt value and the same human readable password, the same key can be regenerated in another application and therefore used as symmetric key to decrypt data encrypted in the initial application.

This method may raise exception -15700 (operation failed) or -15701 (invalid parameter).

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.

For an example using \texttt{PBKDF2} methods, see Example: Using \texttt{security.PBKDF2} methods on page 3150.

\texttt{security.PBKDF2.CheckKey}

Validates a hashed key.

\textbf{Syntax}

\begin{verbatim}
security.PBKDF2.CheckKey (  
    password STRING,  
    salt STRING,  
    hash STRING,  
    iter INTEGER,  
    hashedkey STRING )  
RETURNS BOOLEAN
\end{verbatim}

1. \texttt{password} defines the human readable password to derive using the \texttt{PBKDF2} method.

2. \texttt{salt} defines the base64 random value created using \texttt{Security.RandomGenerator.CreateRandomString()}. Can be \texttt{NULL}.

3. \texttt{hash} defines the hash operation. By default, it is "SHA1". Valid values include:

   - SHA1
   - SHA224
   - SHA256
   - SHA384
   - SHA512
   - MD5

4. \texttt{iter} defines the number of iterations to compute the derived password. This value must be greater than or equal to zero (\(\geq 0\)).

5. \texttt{hashedkey} defines the key created by the \texttt{Security.PBKDF2.GenerateKey()} class method.

\textbf{Usage}

This method validates a hashed key produced by the \texttt{security.PBKDF2.GenerateKey} method.

The method returns \texttt{TRUE}, if the hashed key is valid, and returns \texttt{FALSE}, if the hashed key is not valid.

This method may raise exception -15700 (operation failed) or -15701 (invalid parameter).

In case of error, the method throws an exception and sets the \texttt{STATUS} variable. Depending on the error, a human-readable description of the problem is available in the \texttt{SQLCA.SQLERRM} register. See Error handling in GWS calls (\texttt{STATUS}) on page 3554.
Example: Using security.PBKDF2 methods
This example generates a key size of 128-bits based on a given password.

The 128-bits key can then be used in xml.CryptoKey, for instance.

```sql
IMPORT SECURITY

MAIN
DEFINE salt STRING
DEFINE result STRING
LET salt = Security.RandomGenerator.CreateRandomString(8)
TRY
    CALL Security.PBKDF2.GenerateKey(arg_val(1), salt, "sha1", 1000, 16)
RETURNING result
    DISPLAY "Generate Key of 128bits value is ":result # 128/8==16
CATCH
    IF status == -15700 THEN
        DISPLAY "Generation failed ":SQLCA.SQLERRM
    ELSE
        IF status == -15701 THEN
            DISPLAY "Invalid parameter ":SQLCA.SQLERRM
        ELSE
            DISPLAY "Unknown error ":STATUS
        END IF
    END IF
END TRY
END MAIN
```

The BCrypt class
The security.BCrypt class lets you save passwords as BCrypt results instead of clear text.

If you need to store passwords on a database for instance, you can save them as BCrypt results instead of clear text. This makes them difficult to hack, as the time to generate one is expensive.

security.BCrypt methods
Methods of the security.BCrypt class.

Table 714: Class methods

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>security.BCrypt.GenerateSalt</code> (&lt;i&gt;cost&lt;/i&gt; INTEGER) RETURNS STRING</td>
<td>Generates the encoded value needed as input to the HashPassword method.</td>
</tr>
<tr>
<td><code>security.BCrypt.HashPassword</code> (&lt;i&gt;password&lt;/i&gt; STRING, &lt;i&gt;salt&lt;/i&gt; STRING) RETURNS STRING</td>
<td>Creates a hash password.</td>
</tr>
<tr>
<td><code>security.BCrypt.CheckPassword</code> (&lt;i&gt;password&lt;/i&gt; STRING, &lt;i&gt;hashedPass&lt;/i&gt; STRING) RETURNS INTEGER</td>
<td>Checks the hash password.</td>
</tr>
</tbody>
</table>
**security.BCrypt.GenerateSalt**
Generates the encoded value needed as input to the HashPassword method.

**Syntax**

```sql
security.BCrypt.GenerateSalt(
    cost INTEGER
) RETURNS STRING
```

1. `cost` defines the number of rounds of hashing to apply. The default value is 10. This value must be between 4 and 30. It represents \(2^{\text{cost}}\) iteration. An iteration above 14 may take several minutes to compute.

   **Warning:** Using a high cost value for the salt is very CPU consuming, and can really slow down the application depending on the system it is running. Be forewarned that this is expected!

**Usage**

This method generates the encoded value needed as input to the HashPassword method.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

For an example using bcrypt methods, see Example: Using security.BCrypt methods on page 3152.

**Related concepts**

- **security.BCrypt.CheckPassword** on page 3152
  Checks the hash password.
- **security.BCrypt.HashPassword** on page 3151
  Creates a hash password.

**security.BCrypt.HashPassword**
Creates a hash password.

**Syntax**

```sql
security.BCrypt.HashPassword(
    password STRING,
    salt STRING
) RETURNS STRING
```

1. `password` defines the password to hash. The password is limited to 72 bytes.
2. `salt` defines an encoded value generated by GenerateSalt() that has a dedicated format. If the same hash value is computed again on another application, the same salt must be used. The format of the salt value follows this example: $2a$cost$modified_base64_encoded (random value of 16-byte length). If `salt` is NULL, the HashPassword method will generate one with a cost of 10.

**Usage**

The resulting hash password is composed of the version, the cost, and the salt+cipher separated by $, as in this example:

```
$2a$12$EXRkfkd9n2gzds2CSitu.MW9.qAVqa9eLS1/RYtYcmB1eLHg.9q
```

where:

- "2a" is the version of BCrypt. The current API supports 2a to 2z.
- "12" is the cost.
- The remainder is the salt + cipher result concatenated and encoded in "modified" base64:
• The first 22 characters ("EXRkfkdXn2gzs2SSitu." in our example) decode to a 16-byte value for the salt.
• The remaining characters ("MW9.gAVqa9eLS1//RYtYcmBleLHg.9q" in our example) are cipher text.

This method may raise exception -15700 (operation failed) or -15701 (invalid parameter).

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

For an example using BCrypt methods, see Example: Using security.BCrypt methods on page 3152.

Related concepts
security.BCrypt.CheckPassword on page 3152
Checks the hash password.

security.BCrypt.GenerateSalt on page 3151
Generates the encoded value needed as input to the HashPassword method.

security.BCrypt.CheckPassword
Checks the hash password.

Syntax

```
security.BCrypt.CheckPassword(
    password STRING,
    hashedPass STRING )
RETURNS  INTEGER
```

1. `password` defines the password to hash. The password is limited to 72 bytes.
2. `hashedPass` defines the hash password created by the HashPassword method.

Usage

The method returns TRUE, the hashed password is valid.

In case of error, the method throws an exception and sets the STATUS variable. Depending on the error, a human-readable description of the problem is available in the SQLCA.SQLERRM register. See Error handling in GWS calls (STATUS) on page 3554.

For an example using BCrypt methods, see Example: Using security.BCrypt methods on page 3152.

Related concepts
security.BCrypt.HashPassword on page 3151
Creates a hash password.

security.BCrypt.GenerateSalt on page 3151
Generates the encoded value needed as input to the HashPassword method.

Example: Using security.BCrypt methods

This example creates (and checks) a hash password as BCrypt results.

```
IMPORT SECURITY

MAIN
    DEFINE salt STRING
    DEFINE hashed_pass STRING
    LET salt = Security.BCrypt.GenerateSalt(12)
    CALL Security.BCrypt.HashPassword(arg_val(1), salt) RETURNING hashed_pass
    DISPLAY "Hashed password is ":hashed_pass
```
IF Security.BCrypt.CheckPassword(arg_val(1), hashed_pass) THEN
  DISPLAY "OK: password check done."
ELSE
  DISPLAY "KO: password check failed."
END IF
END MAIN

## Genero BDL errors

System error messages sorted by error number.

### Table 716: Genero system error messages

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -201   | A syntax error has occurred.  
This general SQL error message indicates mistakes in the syntax of an SQL statement.  
Look for missing or extra punctuation; keywords misspelled, misused, or out of sequence, or a reserved word used as an identifier. |
| -204   | An illegal floating point number has been found in the statement.  
A numeric constant that is punctuated like a floating-point number (with a decimal point and/or an exponent starting with e) is unacceptable. Possibly the exponent is larger than can be processed. |
| -206   | The specified table table-name is not in the database.  
The database server cannot find a table or view specified in the statement. The table or view might have been renamed or dropped from the database. |
| -213   | Statement interrupted by user.  
The database server received an interrupt signal from the user. The statement ended early. The program is expected to roll back the current transaction and terminate gracefully. |
| -217   | Column column-name not found in any table in the query.  
The column specified does not exist in the database tables used in this SQL statement. |
| -235   | Character column size is too big.  
The SQL statement specifies a width for a character data type that is greater than 65,534 bytes.  
If you need a column of this size, use the TEXT data type, which allows unlimited lengths. Otherwise, inspect the statement for typographical errors. |
| -236   | Number of columns in INSERT does not match number of VALUES.  
Each column that is named or implied in an INSERT statement must have a separate value expression. If the statement does not list specific columns, review the definition of the table for the number of columns and their data types. Also check that the list of expressions in the VALUES clause has no extra or missing comma that might result in an incorrect number of values. Be especially careful of long character strings and expressions with parentheses. |
| -239   | Could not insert new row - duplicate value in a UNIQUE INDEX column.  
The row that is being inserted (or being updated to have a new primary key) contains a duplicate value of some row that already exists, in a column or columns that are constrained to have unique values. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -244   | Could not do a physical-order read to fetch next row.  
The database server cannot read the data block for this SQL client program. The database server returns this error when a record is locked by another process, and the lock timeout defined by the current program has expired.  
Consider using the SET LOCK MODE TO WAIT instruction to define a lock timeout. By default, with most databases, this timeout is zero and error -244 is returned immediately when a lock conflict occurs. If all programs do short transactions (holding locks for a short period of time), it is usually safe to define a lock timeout of 5 to 10 seconds to avoid this SQL error. |
| -250   | Cannot read record from file for update.  
The database server cannot get a row of a table prior to update. |
| -251   | ORDER BY or GROUP BY column number is too big.  
The ORDER BY or GROUP BY clause uses column-sequence numbers, and at least one of them is larger than the count of columns in the select list. |
| -253   | Cannot read record from file for update.  
The database server cannot get a row of a table prior to update. |
| -254   | Too many or too few host variables given.  
The number of host variables that you named in the INTO clause of this statement does not match the number of columns that you referenced in the SQL statement. |
| -255   | Not in transaction.  
The database server cannot execute this COMMIT WORK or ROLLBACK WORK statement because no BEGIN WORK was executed to start a transaction. Because no transaction was started, you cannot end one. |
| -256   | Transaction not available.  
The database server does not support transactions. |
| -257   | System limit on maximum number of statements exceeded, maximum is count.  
The database server can handle only a fixed number of prepared SQL statements for each user. This limit includes statements that were prepared with the PREPARE statement and cursors that were declared with the DECLARE statement. |
| -259   | Cursor not open.  
The current statement refers to a cursor that has not been opened. Review the logic of the program to see how it failed to execute the OPEN statement before it reached this point. |
| -263   | Could not lock row for UPDATE.  
This statement, probably a FETCH statement that names a cursor declared FOR UPDATE, failed to get a lock on the row it tried to fetch. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -266   | There is no current row for UPDATE/DELETE cursor.  
The current statement uses the WHERE CURRENT OF cursor-name clause, but that cursor has not yet been associated with a current row. Either no FETCH statement has been executed since it was opened, or the most recent fetch resulted in an error so that no row was returned. Revise the logic of the program so that it always successfully fetches a row before it executes this statement. |
| -268   | Unique constraint constraint-name violated.  
The current statement uses the WHERE CURRENT OF cursor-name clause, but that cursor has not yet been associated with a current row. Either no FETCH statement has been executed since it was opened, or the most recent fetch resulted in an error so that no row was returned. Revise the logic of the program so that it always successfully fetches a row before it executes this statement. |
| -272   | No SELECT permission for table/column.  
The person who created this table has not granted SELECT privilege to your account name or to the public for the table or the column. The owner of the table or the DBA must grant this privilege before you can select data from the table or column. |
| -273   | No UPDATE permission for table/column.  
The person who created this table has not granted UPDATE privilege to your account name or to the public for the table or the column. The owner of the table or the DBA must grant this privilege before you can update a row in this table or update the column. |
| -274   | No DELETE permission for table.  
The person who created this table has not granted DELETE privilege to your account name or to the public. The owner of the table or the DBA must grant this privilege before you can delete a row in this table. |
| -275   | The Insert privilege is required for this operation.  
The Insert access privilege on this table or column is not currently held by your account name, nor by the PUBLIC group, nor by your current role. The owner of the table or the DBA must grant the Insert privilege before you can insert a row into this table. |
| -280   | A quoted string exceeds 256 bytes.  
A character literal in this statement exceeds the maximum length. Check the punctuation and length of all quoted strings in the statement. Possibly two missing quotes make a long string out of two short ones. You must revise the statement to use a shorter character string. |
| -282   | Found a quote for which there is no matching quote.  
Inspect the current statement, examining the punctuation of all quoted strings. |
A subquery has returned not exactly one row.

A subquery that is used in an expression in the place of a literal value must return only a single row and a single column. In this statement, a subquery has returned more than one row, and the database server cannot choose which returned value to use in the expression. You can ensure that a subquery will always return a single row. Use a WHERE clause that tests for equality on a column that has a unique index. Or select only an aggregate function. Review the subqueries, and check that they can return only a single row.

This error can also occur when you use a singleton SELECT statement to retrieve multiple rows. You must use the DECLARE/OPEN/FETCH series of statements or the EXECUTE INTO statement to retrieve multiple rows.

Invalid cursor received by sqlexec.

The cursor that this statement uses has not been properly declared or prepared, or the FREE statement has released it, or an automatic re-prepare has been attempted while opening the cursor but that operation failed, leaving the cursor unavailable. Review the program logic to ensure that the cursor has been declared. If it has, and if the DECLARE statement refers to a statement identifier, check that the referenced statement has been prepared.

Cursor not declared with FOR UPDATE clause.

This statement attempts to update with a cursor that was not declared for update. To use a cursor with the UPDATE or DELETE statements, you must declare it FOR UPDATE. Review the program logic to make sure that this statement uses the intended cursor.

The column column-name must be in the GROUP BY list.

In a grouping SELECT, you must list every nonaggregate column in the GROUP BY clause to ensure that a well-defined value exists for each selected column in each grouped row. A column contains either a single aggregate value or a value unique to that group. If a selected column were neither an aggregate nor in the list, two or more values for that column might possibly exist in some group, and the database server is unable to choose which value to display. Revise the query to include either the column name or its positional number in the clause.

Illegal subscript.

The substring values (two numbers in square brackets) of a character variable are incorrect. The first is less than zero or greater than the length of the column, or the second is less than the first. Review all uses of square brackets in the statement to find the error. Possibly the size of a column has been altered and makes a substring fail that used to work.

ORDER BY column or expression must be in SELECT list.

An expression or column name is in the ORDER BY clause of this SELECT statement, but the expression or column name is not in the select list (the list of values that follows the word SELECT). This action is not supported when a UNIQUE or DISTINCT operator is being used in a query.

Index index-name already exists in database.

This statement tries to create an index with the name shown, but an index of that name already exists. Only one index of a given name can exist in a single database.
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-324</td>
<td>Ambiguous column column-name. The column name appears in more than one of the tables that are listed in the FROM clause of this query. The database server needs to know which columns to use. Revise the statement so that this name is prefixed by the name of its table (table-name.column) wherever it appears in the query.</td>
</tr>
<tr>
<td>-329</td>
<td>Database not found or no system permission. The database you tried to connect to is not known by the db server. Check database client configuration settings and make sure that there is no spelling error in the name of the database.</td>
</tr>
<tr>
<td>-330</td>
<td>Cannot create or rename the database. Possibly you tried to create a database with the same name as one that already exists or rename a database to a name that already exists; if so, choose a different name.</td>
</tr>
<tr>
<td>-349</td>
<td>Database not selected yet. The SQL statement cannot be executed because no current database exists. You must issue a DATABASE or CONNECT TO instruction before executing other SQL statements.</td>
</tr>
<tr>
<td>-350</td>
<td>Index already exists on the column (or on the set of columns). This CREATE INDEX statement cannot be executed because an index on the same column or combination of columns already exists. For a given collation order, at most two indexes can exist on any combination of columns, one ascending and one descending.</td>
</tr>
<tr>
<td>-354</td>
<td>Incorrect database or cursor name format. This statement contains the name of a database or a cursor in some invalid format. If the statement is part of a program, the name might have been passed in a host variable.</td>
</tr>
<tr>
<td>-360</td>
<td>Cannot modify a table or view that is also used in subquery. The UPDATE, INSERT, or DELETE statement uses data taken from the same table in a subquery. Because of the danger of entering an endless loop, this action is not allowed, except in the case of an uncorrelated subquery in the WHERE clause of the DELETE or UPDATE statement.</td>
</tr>
<tr>
<td>-363</td>
<td>CURSOR not on SELECT statement. The cursor named in this statement (probably an OPEN) has been associated with a prepared statement that is not a SELECT statement. Review the program logic, especially the DECLARE for the cursor, the statement id specified in it, and the PREPARE that set up that statement. If you intended to use a cursor with an INSERT statement, you can only do that when the INSERT statement is written as part of the DECLARE statement. If you intended to execute an SQL statement, do that directly with the EXECUTE statement, not indirectly through a cursor.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -366   | The scale exceeds the maximum precision specified.  
A problem exists with the precision or scale of a DECIMAL or a MONEY data type usage, for example in a DEFINE statement. It is recommended to declare DECIMAL as DECIMAL(p) or DECIMAL(p,s), where p is the precision (total number of digits) between 1 and 32, and s, is the scale (number of digits to the right of the decimal point) greater or equal to zero and not greater than p. The MONEY type follows the same rules.  
Review the DECIMAL or MONEY type definition, and make sure that the precision is in the range [1,32] and that the scale is in the range [0,precision]. |
| -371   | Cannot create unique index on column with duplicate data.  
This CREATE UNIQUE INDEX statement cannot be completed because the column (or columns) contains one or more duplicate rows. |
| -382   | Same number of columns must be specified for view and select clause.  
In this VIEW statement, you have listed the names of the columns of the view; however, their number is different from the number of columns in the SELECT statement for the view. Check the punctuation of the two lists, and make sure that you have supplied a name for each item in the select list. |
| -387   | No connect permission.  
You cannot access the database that this statement requests because you have not been granted CONNECT privilege to it. Contact a person who has Database Administrator privilege to that database and ask to be granted CONNECT privileges to it. |
| -388   | No resource permission.  
If you issued a CREATE TABLE, CREATE INDEX, or CREATE PROCEDURE statement, you cannot execute this statement because your account has not been granted the RESOURCE privilege for this database. You need the RESOURCE privilege to create permanent tables, indexes on permanent tables, and procedures. |
| -389   | No DBA permission.  
This statement cannot be executed because you have not been granted DBA privilege for this database. Contact a person who has DBA privilege for the database and ask to be granted DBA privilege (or simply ask to have this statement executed for you). |
| -391   | Cannot insert a null into column column-name.  
This statement tries to put a null value in the noted column; however, that column has been defined as NOT NULL. Roll back the current transaction. If this is a program, review the definition of the table, and change the program logic to not use null values for columns that cannot accept them. |
| -400   | Fetch attempted on unopen cursor.  
This FETCH statement names a cursor that has never been opened or has been closed. Review the program logic, and check that it will open the cursor before this point and not accidentally close it. Unless a cursor is declared WITH HOLD, it is automatically closed by a COMMIT WORK or ROLLBACK WORK statement. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -404   | The cursor or statement is not available.  
You used a statement that names a cursor that is was destroyed. Review the program logic and check that the cursor specified is declared and opened, but not freed, prior to reaching this statement. |
| -410   | Prepare statement failed or was not executed.  
This EXECUTE statement refers to a statement id that has not been prepared. Either no PREPARE statement was done, or one was done but returned an error code. Review the program logic to ensure that a statement is prepared and the PREPARE return code is checked. A negative error code from PREPARE usually reflects an error in the statement being prepared. |
| -412   | Command pointer is NULL.  
This statement (probably an EXECUTE or DECLARE) refers to a dynamic SQL statement that has never been prepared or that has been freed. Review the program logic to ensure that the statement has been prepared, the PREPARE did not return an error code, and the FREE statement has not been used to release the statement before this point. |
| -413   | Insert attempted on unopen cursor.  
This INSERT statement names a cursor that has never been opened or that has been closed. Review the program logic, and check that it will open the cursor before this point and not accidentally close it. An insert cursor is automatically closed by a COMMIT WORK or ROLLBACK WORK statement. |
| -422   | Flush attempted on unopen cursor.  
This FLUSH statement names a cursor that has never been opened or has been closed. Review the program logic to ensure that it will open the cursor before this point and not accidentally close it. An insert cursor is automatically closed by a COMMIT WORK or ROLLBACK WORK. |
| -450   | Illegal ESQL locator, or uninitialized blob variable in BDL.  
An SQL statement is using a TEXT or BYTE variable that was not initialized with LOCATE IN FILE or MEMORY. LOCATE the TEXT or BYTE variable before using it in SQL statements. |
| -458   | Long transaction aborted.  
The database server ran out of log space in which to record this transaction. A transaction that is not fully recorded cannot be rolled back. To preserve database integrity, the operating system ended the transaction and rolled it back automatically. All changes made since the start of the transaction have been removed. Terminate the application, and replan it so that it modifies fewer rows per transaction. Alternatively, contact the database server administrator to discuss increasing the number or the size of the logical logs. Be prepared to talk about the number of rows being updated or inserted and the size of each row. |
| -481   | Invalid statement name or statement was not prepared.  
The statement has not been prepared, or the format of the statement name is not valid. A valid statement name does not exceed the maximum length, begins with a letter or underscore, does not contain any blanks or nonalphanumeric characters except underscores. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-482</td>
<td>Invalid operation on a non-SCROLL cursor. You cannot issue a FETCH PRIOR, FETCH FIRST, FETCH LAST, FETCH CURRENT, FETCH RELATIVE n, or FETCH ABSOLUTE n statement with a non-scroll cursor. To do so, you must first declare the cursor as a scroll cursor.</td>
</tr>
<tr>
<td>-507</td>
<td>Cursor cursor-name not found. The cursor that is named in the WHERE CURRENT OF clause in this UPDATE or DELETE statement does not exist. Review the spelling of the name. If it is as you intended, check the DECLARE statement to ensure that it has been executed. Also make sure that the cursor has not been freed with the FREE statement or during a failed automatic re-prepare attempt.</td>
</tr>
<tr>
<td>-513</td>
<td>Statement not available with this database server. The SQL statement used by the program is not valid for the target database server. Review the code, the SQL instruction cannot be used.</td>
</tr>
<tr>
<td>-517</td>
<td>The total size of the index is too large or too many parts in index. All database servers have limits on the number of columns that can be included in an index and on the total number of bytes in a key (the sum of the widths of the columns). This CREATE INDEX statement would exceed that limit for this database server.</td>
</tr>
<tr>
<td>-522</td>
<td>Table table-name not selected in query. The table name used in an expression (for example, in the WHERE clause) has not been listed in the clause defining the tables to be used in the query (typically the FROM clause in SELECT statements).</td>
</tr>
<tr>
<td>-526</td>
<td>Updates are not allowed on a scroll cursor. For a DECLARE statement, the clause FOR UPDATE is not allowed in conjunction with the SCROLL keyword.</td>
</tr>
<tr>
<td>-530</td>
<td>Check constraint constraint-name failed. The check constraint placed on the table column was violated.</td>
</tr>
<tr>
<td>-535</td>
<td>Already in transaction. This BEGIN WORK statement is redundant; a transaction is already in progress. If this is a program, review its logic to make sure it has not accidentally failed to end the previous transaction.</td>
</tr>
<tr>
<td>-551</td>
<td>The constraint contains too many columns. The total number of columns listed in a UNIQUE, PRIMARY KEY, or FOREIGN KEY clause is limited. The limit depends on the database server in use.</td>
</tr>
<tr>
<td>-611</td>
<td>Scroll cursor can't select TEXT or BYTE columns. Because of the bulk of TEXT and BYTE values, this action would require too much resources to be performed. Review the declaration of the cursor to select the desired columns of other types and also the primary key column. Use a secondary SELECT statement to fetch TEXT/BYTE columns for a given row, by using the primary key column value.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -674   | Routine routine-name cannot be resolved.  
You called a routine that does not exist in the database, you do not have permission to execute the routine, or you called the routine with too few or too many arguments. |
| -681   | Column specified more than once in the INSERT list.  
The error occurs if the user specifies a column name more than once in the INSERT column list. |
| -691   | Missing key in referenced table for referential constraint constraint-name.  
A referential constraint has been violated. This condition usually occurs when you are trying to insert a value into or update the value of a column that is part of a referential constraint. The value you are trying to enter does not exist in the referenced (parent-key) column. |
| -692   | Key value for constraint constraint-name is still being referenced.  
You have violated a referential constraint. This situation usually occurs when you are trying to delete a row in a column (parent key) that another row (child key) is referencing. If you are using cascading deletes, database logging must be on. |
| -743   | Object object_name already exists in database.  
You are trying to define an object that already exists in the database. |
| -768   | Internal error in routine routine-name.  
If this internal error recurs, note all circumstances and contact your technical support. |
| -805   | Cannot open file for load.  
The input file that is specified in this LOAD statement is unable to be opened.  
Check the statement. Possibly a more complete path name is needed, the file does not exist, or your account does not have read permission for the file or a directory in which it resides. |
| -806   | Cannot open file for unload.  
The output file that is specified in this UNLOAD statement is unable to be opened.  
Check the statement. Possibly a more complete path name is needed; the file exists, but your account does not have write permission for it; or the disk is full. |
| -809   | SQL Syntax error has occurred.  
The INSERT statement in this LOAD/UNLOAD statement has invalid syntax.  
Review it for punctuation and use of keywords. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-846</td>
<td>Number of values in load file is not equal to number of columns. The LOAD processor counts the delimiters in the first line of the file to determine the number of values in the load file. One delimiter must exist for each column in the table, or for each column in the list of columns if one is specified. Check that you specified the file that you intended and that it uses the correct delimiter character. An empty line in the text can also cause this error. If the LOAD statement does not specify a delimiter, verify that the default delimiter matches the delimiter that is used in the file. If you are in doubt about the default delimiter, specify the delimiter in the LOAD statement.</td>
</tr>
<tr>
<td>-930</td>
<td>Cannot connect to database server servername. The application is trying to access the database server but failed.</td>
</tr>
<tr>
<td>-942</td>
<td>Transaction commit failed - transaction will be rolled back. This error can occur at transaction-commit time if the database server is unable to commit the transaction.</td>
</tr>
<tr>
<td>-1102</td>
<td>Field name not found in form. A field name listed in an INPUT, INPUT ARRAY, CONSTRUCT, SCROLL or DISPLAY statement does not appear in the form specification of the screen form that is currently displayed. Review the program logic to ensure that the intended window is current, the intended form is displayed in it, and all the field names in the statement are spelled correctly.</td>
</tr>
<tr>
<td>-1107</td>
<td>Field subscript out of bounds. The subscript of a screen array in an INPUT, DISPLAY, or CONSTRUCT statement is either less than 1 or greater than the number of fields in the array. Review the program source in conjunction with the form specification to see where the error lies.</td>
</tr>
<tr>
<td>-1108</td>
<td>Record name not in form. The screen record that is named in an INPUT ARRAY or DISPLAY ARRAY statement does not appear in the screen form that is now displayed. Review the program source in conjunction with the form specification to see if the screen record names match.</td>
</tr>
<tr>
<td>-1109</td>
<td>List and record field counts differ. The number of program variables does not agree with the number of screen fields in a CONSTRUCT, INPUT, INPUT ARRAY, DISPLAY, or DISPLAY ARRAY statement. Review the statement in conjunction with the form specification to see where the error lies. Common problems include a change in the definition of a screen record that is not reflected in every statement that uses the record, and a change in a program record that is not reflected in the form design.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -1110  | Form file (file-name) not found.  
The form file that is specified in an OPEN FORM or OPEN WINDOW WITH FORM statement was not found.  
Inspect the form name used in the statement. The form file suffix is not required. If the form is not in the current directory, verify that FGLRESOURCEPATH / DBPATH environment variables contain the path to the form file. |
| -1112  | A form is incompatible with the current BDL version. Rebuild your form.  
The form file that is specified in an OPEN FORM statement is not acceptable. Possibly it was corrupted in some way, or it was compiled with a version of the Form Compiler that is not compatible with the version of the BDL compiler that compiled this program.  
Use a current version of the Form Compiler to recompile the form specification. |
| -1114  | No form has been displayed.  
The current statement requires the use of a screen form. For example, DISPLAY...TO or an INPUT statement must use the fields of a form; however, the DISPLAY FORM statement has not been executed since the current window was opened.  
Review the program logic to ensure that it opens and displays a form before it tries to use a form. |
| -1119  | NEXT FIELD name not found in form.  
This statement (INPUT or INPUT ARRAY) contains a NEXT FIELD clause that names a field that is not defined in the form.  
Review the form and program logic. Perhaps the form has been changed, but the program has not. |
| -1129  | Field (field-name) in BEFORE/AFTER clause not found in form.  
This statement includes a BEFORE FIELD clause or an AFTER FIELD clause that names a field that is not defined in the form that is currently displayed.  
Review the program to ensure that the intended form was displayed, and review this statement against the form specification to ensure that existing fields are named. |
| -1133  | The NEXT OPTION name is not in the menu.  
This MENU statement contains a NEXT OPTION clause that names a menu-option that is not defined in the statement.  
The string that follows NEXT OPTION must be identical to one that follows a COMMAND clause in the same MENU statement. Review the statement to ensure that these clauses agree with each other. |
| -1140  | NEXT OPTION is a hidden option.  
The option that is named in this NEXT OPTION statement has previously been hidden with the HIDE OPTION statement. Because it is not visible to the user, it cannot be highlighted as the next choice.  
Use the SHOW OPTION statement to unhide the menu option. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1141  | Cannot close window with active INPUT, DISPLAY ARRAY, or MENU statement.  
This CLOSE WINDOW statement cannot be executed because an input operation is still active in that window. The CLOSE WINDOW statement must have been contained in, or called from within, the input statement itself.  
Review the program logic, and revise it so that the statement completes before the window is closed. |
| -1143  | Window is already open.  
This OPEN WINDOW statement names a window that is already open.  
Review the program logic to see if it contains a CLOSE WINDOW statement. It may be possible that you simply need to use a CURRENT WINDOW statement to bring the open window to the top. |
| -1146  | PROMPT message is too long to fit in the window.  
Although BDL truncates the output of MESSAGE and COMMENT to fit the window dimensions, it does not do so for PROMPT and the user's response.  
Reduce the length of the prompt string, or make the window larger. Another option is to display most of the prompting text with DISPLAY and then prompt with a single space or colon. |
| -1150  | Window is too small to display this menu.  
The window must be at least two rows tall, and it must be wide enough to display the menu title, the longest option name, two sets of three-dot ellipses, and six spaces. Revise the program to make the window larger or to give the menu a shorter name and shorter options.  
Review the OPEN WINDOW statement for the current window in conjunction with this MENU statement. |
| -1168  | Command does not appear in the menu.  
The SHOW OPTION, HIDE OPTION, or NEXT OPTION statement cannot refer to an option (command) that does not exist.  
Check the spelling of the name of the option. |
| -1170  | The type of your terminal is unknown to the system.  
Check the setting of your TERM environment variable and the setting of your TERMCP or TERMINFO environment variable.  
Check with your system administrator if you need help with this action. |
| -1202  | An attempt was made to divide by zero.  
Zero cannot be a divisor.  
Check that the divisor is not zero. In some cases, this error arises because the divisor is a character value that does not convert properly to numeric. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1204  | Invalid year in date.  
The year in a DATE value or literal is invalid. For example, the number 0000 is not acceptable as the year.  
Check the value of year. |
| -1205  | Invalid month in date.  
The month in a DATE value or literal must be a one- or two-digit number from 1 to 12.  
Check the value of month. |
| -1206  | Invalid day in date.  
The day number in a DATE value or literal must be a one- or two-digit number from 1 to 28 (or 29 in a leap year), 30, or 31, depending on the month that accompanies it.  
Check the value of day. |
| -1210  | Date could not be converted to month/day/year format.  
The DATE type is compatible with the INTEGER type, but not all integer values are valid dates.  
The range of valid integer values for dates is from -693,594 to +2,958,464. Numbers that are outside this range have no representation as dates.  
Check the value of the number used to assign the date variable. |
| -1212  | Date conversion format must contain a month, day, and year component.  
**Note:** This error is non-trappable.  
When a date value is converted between internal binary format and display or entry format, a pattern directs the conversion. When conversion is done automatically, the pattern comes from the environment variable DBDATE. When it is done with an explicit call to the rfmtdate(), rdefmtdate(), or USING functions, a pattern string is passed as a parameter. In any case, the pattern string (the format of the message) must include letters that show the location of the three parts of the date: 2 or 3 letters d; 2 or 3 letters m; and either 2 or 4 letters y.  
Check the pattern string and the value of DBDATE. |
| -1213  | A character to numeric conversion process failed.  
A character value is being converted to numeric form for storage in a numeric column or variable; however, the character string cannot be interpreted as a number.  
Check the character string. It must not contain characters other than whitespace, digits, a sign, a decimal, or the letter e. Verify the parts are in the right order. If you are using NLS, the decimal character or thousands separator might be wrong for your locale. |
| -1214  | Value too large to fit in a SMALLINT.  
The SMALLINT data type can accept numbers with a value range from -32,767 to +32,767.  
To store numbers that are outside this range, redefine the column or variable to use INTEGER or DECIMAL type. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1215  | Value too large to fit in an INTEGER.  
The INTEGER data type can accept numbers with a value range from \(-2,147,483,647\) to \(+2,147,483,647\).  
Check the other data types available, such as DECIMAL. |
| -1218  | String to date conversion error.  
The data value does not properly represent a date: either it has non-digits where digits are expected, an unexpected delimiter, or numbers that are too large or are inconsistent.  
Check the value being converted. |
| -1222  | Value will not fit in a SMALLFLOAT.  
A statement tries to assign a value that exceeds the limits of the SMALLFLOAT data type.  
Review the code and consider using a FLOAT or DECIMAL type. |
| -1223  | Value will not fit in a FLOAT.  
A statement tries to assign a value that exceeds the limits of the FLOAT data type.  
Review the code and consider using a DECIMAL type. |
| -1226  | Decimal or money value exceeds maximum precision.  
The data value has more digits to the left of the decimal point than the declaration of the variable allows.  
Revise the program to define the variable with an appropriate precision. |
| -1260  | It is not possible to convert between the specified types.  
**Note:** This error is non-trappable.  
Data conversion does not make sense, or is not supported.  
Possibly you referenced the wrong variable or column. Check that you have specified the data types that you intended and that literal representations of data values are correctly formatted. |
| -1261  | Too many digits in the first field of datetime or interval.  
The first field of a DATETIME literal must contain 1 or 2 digits (if it is not a YEAR) or else 2 or 4 digits (if it is a YEAR). The first field of an INTERVAL literal represents a count of units and can have up to 9 digits, depending on the precision that is specified in its qualifier.  
Review the DATETIME and INTERVAL literals in this statement, and correct them. |
| -1262  | Non-numeric character in datetime or interval.  
A DATETIME or INTERVAL literal can contain only decimal digits and the allowed delimiters: the hyphen between year, month, and day numbers; the space between day and hour; the colon between hour, minute, and second; and the decimal point between second and fraction. Any other characters, or these characters in the wrong order, produce an error.  
Check the value of the literal. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1263</td>
<td>A field in a datetime or interval is out of range. At least one of the fields in a datetime or interval is incorrect. Inspect the DATE, DATETIME, and INTERVAL literals in this statement. In a DATE or DATETIME literal, the year might be zero, the month might be other than 1 to 12, or the day might be other than 1 to 31 or inappropriate for the month. Also in a DATETIME literal, the hour might be other than 0 to 23, the minute or second might be other than 0 to 59, or the fraction might have too many digits for the specified precision.</td>
</tr>
<tr>
<td>-1264</td>
<td>Extra characters at the end of a datetime or interval. Only spaces can follow a DATETIME or INTERVAL literal. Inspect this statement for missing or incorrect punctuation.</td>
</tr>
<tr>
<td>-1265</td>
<td>Overflow occurred on a datetime or interval operation. An arithmetic operation involving a DATETIME and/or INTERVAL produced a result that cannot fit in the target variable. Check if the data type can hold the result of the operation. For example, extend the INTERVAL precision by using YEAR(9) or DAY(9).</td>
</tr>
<tr>
<td>-1266</td>
<td>Intervals or datetimes are incompatible for the operation. An arithmetic operation mixes DATETIME and/or INTERVAL values that do not match. Check the data types of the variable used in the operation.</td>
</tr>
<tr>
<td>-1267</td>
<td>The result of a datetime computation is out of range. In this statement, a DATETIME computation produced a value that cannot be stored. This situation can occur, for example, if a large interval is added to a DATETIME value. This error can also occur if the resultant date does not exist, such as Feb 29, 1999. Review the expressions in the statement and see if you can change the sequence of operations to avoid the overflow.</td>
</tr>
<tr>
<td>-1268</td>
<td>Invalid datetime or interval qualifier. This statement contains a DATETIME or INTERVAL qualifier that is not acceptable. These qualifiers can contain only the words YEAR, MONTH, DAY, HOUR, MINUTE, SECOND, FRACTION, and TO. A number from 1 to 5 in parentheses can follow FRACTION. Inspect the statement for missing punctuation and misspelled words. A common error is adding an s, as in MINUTES.</td>
</tr>
<tr>
<td>-1279</td>
<td>Value exceeds string column length. You attempted to insert into a CHAR, NCHAR, VARCHAR, NVARCHAR or LVARCHAR column using a string host variable, but the string is too long.</td>
</tr>
<tr>
<td>-1284</td>
<td>Value will not fit in a BIGINT or INT8. The BIGINT data type can accept numbers with a value range from -9223372036854775807 to +9223372036854775807. To store numbers that are outside this range, redefine the column or variable to use the DECIMAL type.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -1301  | This value is not among the valid possibilities.  
A list or range of acceptable values has been established for this column in the form-specification file.  
You must enter a value within the acceptable range. |
| -1302  | The two entries were not the same -- please try again.  
To guard against typographical errors, this field has been designated VERIFY in the form-specification file. You must enter the value in this field twice, identically.  
Carefully reenter the data. Alternatively, you can cancel the form entry with the Interrupt key. |
| -1303  | You cannot use this editing feature because a picture exists.  
This field is defined in the form-specification file with a PICTURE attribute to specify its format.  
You cannot use certain editing keys (for example, CTRL-A, CTRL-D, and CTRL-X) while you are editing such a field. Use only printable characters and backspace to enter the value. |
| -1304  | Error in field.  
You entered a value in this field that cannot be stored in the program variable that is meant to receive it.  
Possibly you entered a decimal number when the application provided only an integer variable, or you entered a character string that is longer than the application expected. |
| -1305  | This field requires an entered value.  
The cursor is in a form field that has been designated REQUIRED.  
You must enter some value before the cursor can move to another field. To enter a null value, type any printable character and then backspace. Alternatively, you can cancel the form entry with the Interrupt key. |
| -1306  | Please type again for verification.  
The cursor is in a form field that has been designated VERIFY. This procedure helps to ensure that no typographical errors occur during data entry.  
You must enter the value twice, identically, before the cursor can move to another field. Alternatively, you can cancel the form entry with the Interrupt key. |
| -1307  | Cannot insert another row -- the input array is full.  
You are entering data into an array of records that is represented in the program by a static array of program variables. That array is now full; no place is available to store another record.  
Press the ACCEPT key to process the records that you have entered. |
| -1308  | Cannot delete row -- it has no data.  
You try to delete a row in an empty row. Nothing was deleted. |
| -1309  | There are no more rows in the direction you are going.  
You are attempting to scroll an array of records farther than it can go, either scrolling up at the top or scrolling down at the bottom of the array. Further attempts will have the same result. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1312  | FORMS statement error number error-num.  
An error occurred in the form at runtime.  
Edit your source file: go to the specified line, correct the error, and recompile the file. |
| -1313  | SQL statement error number error-num.  
The current SQL statement returned this error code number. |
| -1314  | Program stopped at 'filename', line number line-number.  
At runtime an error occurred in the specified file at the specified line. No .err file is generated.  
Edit your source file, go to the specified line, correct the error, and recompile the file. |
| -1318  | A parameter count mismatch has occurred between the calling function and the called function.  
Either too many or too few parameters were given in the call to the function.  
The call is probably in a different source module from the called functions. Inspect the definition of the function, and check all places where it is called to ensure that they use the number of parameters that it declares. |
| -1320  | A function has not returned the correct number of values expected.  
Note: This error is non-trappable.  
A function that returns several variables has not returned the correct number of parameters.  
Check your source code and recompile. |
| -1321  | A validation error has occurred as a result of the VALIDATE command.  
The VALIDATE LIKE statement tests the current value of variables against rules that are stored in the syscolval table. It has detected a mismatch.  
Ordinarily, the program would use the WHENEVER statement to trap this error and display or correct the erroneous values. Inspect the VALIDATE statement to see which variables were being tested and find out why they were wrong. |
| -1322  | A report output file cannot be opened: description  
The file that the REPORT TO statement specifies cannot be opened. See the description for more details.  
Check that your account has permission to write such a file, that the disk is not full, and that you have not exceeded some limit on the number of open files. |
| -1323  | A report output pipe cannot be opened.  
The pipe that the REPORT TO PIPE statement specifies is unable to be started.  
Check that all programs that are named in it exist and are accessible from your execution path.  
Also look for operating-system messages that might give more specific errors. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1324  | A report output file cannot be written to.  
The file that the REPORT TO statement specifies was opened, but an error occurred while writing to it.  
Possibly the disk is full. Look for operating-system messages that might give more information. |
| -1326  | An array variable has been referenced outside of its specified dimensions.  
**Note:** This error is non-trappable.  
The subscript expression for an array has produced a number that is either less than one or greater than the number of elements in the array.  
Review the program logic that leads up to this statement to determine how the error was made. |
| -1327  | An insert statement could not be prepared for inserting rows into a temporary table used for a report.  
Within the report function, BDL generated an SQL statement to save rows into a temporary table. The dynamic preparation of the statement (see the reference material on the PREPARE statement) produced an error.  
Probably the database tables are not defined now, at execution time, as they were when the program was compiled. Either the database has been changed, or the program has selected a different database than the one that was current during compilation. Possibly the database administrator has revoked SELECT privilege from you for one or more of the tables that the report uses. Look for other error messages that might give more details. |
| -1328  | A temporary table needed for a report could not be created in the selected database.  
**Note:** This error is non-trappable.  
Within the report definition, BDL generated an SQL statement to save rows into a temporary table, but is unable to create the temporary table.  
You must have permission to create tables in the selected database, and there must be sufficient disk space left in the database. You may already have a table in your current database with the same name as the temporary table that the report definition is attempting to create as a sorting table; the sorting table is named "t_reportname". Another possible cause with some database servers is that you have exceeded an operating-system limit on open files. |
| -1329  | A database index could not be created for a temporary database table needed for a report.  
Within the report definition, BDL generated SQL statements to save rows into a temporary table; however, an index failed to be created on the temporary table.  
Probably an index with the same name already exists in the database. (The sorting index is named "i_reportname"; for example, "i_order_rpt".) Possibly no disk space is available in the file system or dbspace. Another possibility with some database servers is that you have exceeded an operating-system limit on open files. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1330  | A row could not be inserted into a temporary report table.  
Within the report definition, BDL generated SQL statements that would save rows into a temporary table; however, an error occurred while rows were being inserted.  
Probably no disk space is left in the database. Look for other error messages that might give more details. |
| -1331  | A row could not be fetched from a temporary report table.  
Within the report definition, BDL generated SQL statements to select rows from a temporary table. The table was built successfully but now an error occurred while rows were being retrieved from it.  
Almost the only possible cause is a hardware failure or an error in the database server. Check for operating-system messages that might give more details. |
| -1332  | A character variable has referenced subscripts that are out of range.  
**Note:** This error is non-trappable.  
In the current statement, a variable that is used in taking a substring of a character value contains a number less than one or a number greater than the size of the variable, or the first substring expression is larger than the second.  
Review the program logic that leads up to this statement to find the cause of the error. |
| -1335  | A report is accepting output or being finished before it has been started.  
The program executed an OUTPUT TO REPORT or FINISH REPORT statement before it executed a START REPORT.  
Review the program logic that leads up to this statement to find the cause of the error. |
| -1337  | The variable variable-name has been redefined with a different type or length, definition in module-name-1.4gl, redefinition in module-name-2.4gl.  
**Note:** This error is non-trappable.  
The variable that is shown is defined in the GLOBALS section of two or more modules, but it is defined differently in some modules than in others.  
Possibly modules were compiled at different times, with some change to the common GLOBALS file between. Possibly the variable is declared as a module variable in some module that does not include the GLOBALS file. |
| -1338  | The function 'function-name' has not been defined in any module in the program.  
**Note:** This error is non-trappable.  
The named function is called from at least one module of the program, but it is defined in none.  
Verify that the module containing the function is a part of the program, and that the function name is correctly spelled. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1340  | The error log has not been started.  
**Note:** This error is **non-trappable**.  
The program called the errorlog() function without first calling the startlog() function.  
Review the program logic to find out the cause of this error. |
| -1349  | Character to numeric conversion error.  
A character value is being converted to numeric form for storage in a numeric column or variable; however, the character string cannot be interpreted as a number. It contains some characters other than whitespace, digits, a sign, a decimal, or the letter e, or else the parts are in the wrong order so that the number cannot be deciphered. |
| -1353  | Use '!' to edit TEXT and BYTE fields.  
This is a normal message text used outside an error context. |
| -1355  | Cannot build temporary file.  
A TEXT or BYTE variable has been located in a temporary file using the LOCATE statement.  
The current statement assigns a value into that variable, so BDL attempted to create the temporary file, but an error occurred.  
Possibly no disk space is available, or your account does not have permission to create a temporary file. Look for operating-system error messages that might give more information. |
| -1359  | Read error on blob file 'file-name'.  
The operating system signaled an error during output to a temporary file in which a TEXT or BYTE variable was being saved.  
Possibly the disk is full, or a hardware failure occurred. For more information, look for operating-system messages. |
| -1360  | No PROGRAM= clause for this field.  
No external program has been designated for this field using the PROGRAM attribute in the form-specification file (For Text User Interface mode on ASCII terminals only) |
| -1373  | The field 'field-name' is not in the list of fields in the CONSTRUCT/INPUT statement.  
The built-in function get fldbuf() or field_touched() has been called with the field name shown; however, input from that field was not requested in this CONSTRUCT or INPUT statement. As a result, the function cannot return any useful value.  
Review all uses of these functions, and compare them to the list of fields at the beginning of the statement. |
| -1374  | SQL character truncation or transaction warning.  
The program set WHENEVER WARNING STOP, and a warning condition arose. If the statement involved is a DATABASE statement, the condition is that the database that was just opened uses a transaction log. On any other statement, the condition is that a character value from the database had to be truncated to fit in its destination. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -1375  | SQL NULL value in aggregate or mode ANSI database warning.  
The program set WHENEVER WARNING STOP, and a warning condition arose. If the statement that is involved is a DATABASE statement, the condition is that the database that was just opened is ANSI compliant. On any other statement, the condition is that a null value has been used in the computation of an aggregate value. |
| -1376  | SQL, database server, or program variable mismatch warning.  
The program set WHENEVER WARNING STOP, and a warning condition arose. If the statement that is involved is a DATABASE or CREATE DATABASE statement, the condition is that the database server opened the database. On any other statement, the condition is that a SELECT statement returned more values than there were program variables to contain them. |
| -1377  | SQL float-to-decimal conversion warning.  
The program set WHENEVER WARNING STOP, and a warning condition arose. The condition is that in the database that was just opened, the database server will use the DECIMAL data type for FLOAT values. |
| -1378  | SQL non-ANSI extension warning.  
A database operation was performed that is not part of ANSI SQL, although the current database is ANSI compliant. This message is informational only. |
| -1396  | A report PRINT FILE source file cannot be opened for reading.  
The file that is named in a PRINT FILE statement cannot be opened.  
Review the file name. If it is not in the current directory, you must specify the full path. If the file exists, make sure your account has permissions to read it. |
| -2017  | The character data value does not convert correctly to the field type.  
You have entered a character value (a quoted string) into a field that has a different data type (for example INTEGER); however, the characters that you entered cannot be converted to the type of the field.  
Re-enter the data. |
| -2021  | An illegal color has been specified. Colors 0 through 7 are white, yellow, magenta, red, cyan, green, blue, and black.  
Use one of the color names allowed by the COLOR attribute syntax. |
| -2024  | There is already a record 'record-name' specified.  
A screen record is automatically defined for each table that is used in the ATTRIBUTES section to define a field. If you define a record with the name of a table, it is seen as a duplicate.  
Check that the record-name of every screen record and screen array is unique in the form specification. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -2028  | The symbol 'symbol-name' does not represent a table prefix used in this form.  
In a SCREEN RECORD statement, each component must be introduced by the name of the table as defined in the TABLES section or by the word FORMONLY.  
Review the spelling of the indicated name against the TABLES section, and check the punctuation of the rest of the statement. |
| -2029  | Screen record array 'record-name' has different component sizes.  
The screen record array name has component sizes which either differ from the specified dimension of the array or differ among themselves. This error message appears when one or more of the columns appear a different number of times.  
The dimension of the screen array is written in square brackets that follow its name. Verify that the dimensions of the screen array match the screen fields. |
| -2039  | The attributes AUTONEXT, DEFAULT, INCLUDE, VERIFY, RIGHT and ZEROFILL are not supported for BLOB fields.  
Columns of the data type specified cannot be used in the ways that these attributes imply.  
Check that the table and column names are as you intended, and verify the current definition of the table in the database that the DATABASE statement names. |
| -2041  | The form 'form-name' cannot be opened.  
The form filename cannot be opened. This is probably because it does not exist, or the user does not have read permission.  
Check the spelling of filename. Check that the form file exists in your current directory. If it is in another directory, check that the correct pathname has been provided. On a UNIX™ system, if these things are correct, verify that your account has read permission on the file. |
| -2045  | The conditional attributes of a field cannot depend on the values of other fields.  
The boolean expression in a WHERE clause of a COLOR attribute can use only the name of that field and constants.  
Revise this attribute, and recompile the form. |
| -2100  | Field 'field-name' has validation string error, String = string.  
One of the formatting or validation strings that is stored in the syscolval or syscolatt tables is improperly coded. The string is shown as is the field to which it applies.  
Update the string in the tables. |
| -2810  | The name 'database-name' is not an existing database name.  
This name, which was found in the DATABASE statement at the start of the form specification, is not a database that can be found.  
Check the spelling of the database name and the database entries in the FGLPROFILE file. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -2820  | The label name between brackets is incorrectly given or the label is missing.  
In the layout section of a form specification, it is recommended that brackets contain a simple name. Instead, they contain spaces or an invalid name.  
Check the layout section of the form for invalid form item labels. |
| -2830  | A left square bracket has been found on this line, with no right square bracket to match it.  
Every left square bracket field delimiter must have a right square bracket delimiter on the same line.  
Review the form definition file to make sure all fields are properly marked. |
| -2840  | The field label 'label-name' was not defined in the form.  
The indicated name appears at the left of this ATTRIBUTES statement, but it does not appear within brackets in the SCREEN section.  
Review the field tags that have been defined to see why this one was omitted. |
| -2843  | The column 'column-name' does not appear in the form specification.  
A name in this ATTRIBUTES statement has not been defined in the form specification.  
Check that all names in the statement are spelled correctly and defined properly. |
| -2846  | The field 'field-name' is not a member of the table 'table-name'.  
Something in this statement suggests that the name shown is part of this table, but that is not true in the current database.  
Review the spelling of the two names. If they are as you intended, check that the correct database is in use and that the table has not been altered. |
| -2859  | The column 'column-name' is a member of more then one table -- you must specify the table name.  
Two or more tables that are named in the TABLES section have columns with the name shown.  
You must make clear which table you mean. To do this, write the table name as a prefix of the column name, as table.column, wherever this name is used in the form specification. |
| -2860  | There is a column/value type mismatch for 'column-name'.  
This statement assigns a value to the field with the DEFAULT clause or uses its value with the INCLUDE clause, but it does so with data that does not agree with the data type of the field.  
Review the data type of the field (which comes from the column with which it is associated), and make sure that only compatible values are assigned. |
| -2862  | The table 'table-name' cannot be found in the database.  
The indicated table does not exist in the database that is named in the form.  
Check the spelling of the table name and database name. If they are as you intended, either you are not using the version of the database that you expected, or the database has been changed. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -2863  | The column 'column-name' does not exist among the specified tables.  
The tables that are specified in the TABLES section of the form exist, but column-name, which is named in the ATTRIBUTES section, does not.  
Check its spelling against the actual table. Possibly the table was altered, or the column was renamed. |
| -2864  | The table 'table-name' is not among the specified tables.  
The indicated table is used in this statement but is not defined in the TABLES section of the form specification.  
Check its spelling; if it is as you intended, add the table in the TABLES section. |
| -2865  | The column 'column-name' does not exist in the table 'table-name'.  
Something in this statement implies that the column shown is part of the indicated table (most likely the statement refers to table-name.column-name); however, it is not defined in that table.  
Check the spelling of both names. If they are as you intended, then make sure that the database schema (.sch) is up to date; possibly the table has been altered or the column renamed, and thus needs a new db schema extraction with the fgldbsch tool. |
| -2892  | The column 'column-name' appears more than once. If you wish a column to be duplicated in a form, use the same display field label.  
The same column name is listed in the ATTRIBUTES section more than once.  
The expected way to display the same column in two or more places is to put two or more fields in the screen layout, each with the same tag-name. Then put a single statement in the ATTRIBUTES section to associate that tag-name with the column name. The current column value will be duplicated in all fields. If you intended to display different columns that happen to have the same column-names, prefix each column with its table-name. |
| -2893  | The display field label 'label-name' appears more than once in this form, but the lengths are different.  
You can put multiple copies of a field in the screen layout (all will display the same column), but all copies must be the same length.  
Review the form definition to make sure that, if you intended to have multiple copies of one field, all copies are the same. |
| -2975  | The display field label 'label-name' has not been used.  
A field tag has been declared in the screen section of the form- specification file but is not defined in the attributes section.  
Check your form-specification file. |
| -2992  | The display label 'label-name' has already been used.  
The forms compiler indicates that name has been defined twice. These names must be defined uniquely in the form specification.  
Review all uses of the name to see if one of them is incorrect. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -2997  | See error number error-num.  
The database server returned an error that is shown.  
Look up the shown error in the database server documentation. |
| -4303  | A blob variable or cursor name expected.  
The argument to the FREE statement must be the name of a cursor or prepared statement or, in BDL, the name of a variable with the BYTE or TEXT data type.  
Check the name used after the FREE keyword. |
| -4307  | The number of variables and/or constants in the display list does not match the number of form fields in the display destination.  
There must be exactly as many items in the list of values to display as there are fields listed following the TO keyword in this statement.  
Review the statement. |
| -4308  | The number of input variables does not match the number of form fields in the screen input list.  
Your INPUT statement must specify the same number of variables as it does fields.  
When checking this, keep in mind that when you refer to a record using an asterisk or THRU, it is the same as listing each record component individually. |
| -4309  | Printing cannot be done within a loop or CASE statement contained in report headers or trailers.  
BDL needs to know how many lines of space will be devoted to page headers and trailers; otherwise, it does not know how many detail rows to allow on a page. Since it cannot predict how many times a loop will be executed, or which branch of a CASE will be executed, it forbids the use of PRINT in these contexts within FIRST PAGE HEADER, PAGE HEADER, and PAGE TRAILER sections.  
Re-arrange the code to place the PRINT statement where it will always be executed. |
| -4319  | The symbol 'symbol-name' has been defined more than once.  
The variable that is shown has appeared in at least one other DEFINE statement before this one.  
Review your code. If this DEFINE is within a function or the MAIN section, the prior one is also. If this DEFINE is outside any function, the prior one is also outside any function; however, it might be within the file included by the GLOBALS statement. |
| -4320  | The symbol 'symbol-name' is not the name of a table in the specified database.  
The named table does not appear in the database.  
Review the statement. The table name may be spelled wrong in the program, or the table might have been dropped or renamed since the last time the program was compiled. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -4322  | The symbol 'symbol-name' is not the name of a column in the specified database.  
      The preceding statement suggests that the named column is part of a certain table in the specified database. The table exists, but the column does not appear in it.  
      Check the spelling of the column name. If it is spelled as you intended, then either the table has been altered, or the column renamed, or you are not accessing the database you expected. |
| -4323  | The variable 'variable-name' is too complex to be used in an assignment statement.  
      The named variable is a complex variable like a record or an array, which cannot be used in a LET statement.  
      You must assign groups of components to groups of components using asterisk notation. |
| -4324  | The variable 'variable-name' is not a character type, and cannot be used to contain the result of concatenation.  
      This statement attempts to concatenate two or more character strings (using the comma as the concatenation operator) and assign the result to the named variable. Unfortunately, it is not a character variable, and automatic conversion from characters cannot be performed in this case.  
      Assign the concatenated string to a character variable; then, if you want to treat the result as numeric, assign the string as a whole to a numeric variable. |
| -4325  | The source and destination records in this record assignment statement are not compatible in types and/or length.  
      This statement uses asterisk notation to assign all components of one record to the corresponding components of another; however, the components do not correspond. Note that BDL matches record components strictly by position, the first to the first, second to second, and so on; it does not match them by name.  
      If the source and destination records do not have the same number and type of components, you will have to write a simple assignment statement for each component. |
| -4328  | The variable 'variable-name' is too complex to be used as the destination of a return from a function.  
      The named variable is too complex to be assigned directly in a RETURNING clause.  
      Individual members of the complex variable must be returned separately. |
| -4330  | RETURN statements can be executed only within functions.  
      This error occurs when the RETURN clause is used in an invalid context such as MAIN, REPORT or DIALOG blocks. |
| -4333  | The function 'function-name' has already been called with a different number of parameters.  
      Earlier in the program, there is a call to this same function or event with a different number of parameters in the parameter list. At least one of these calls must be in error.  
      Examine the FUNCTION statement for the named function to find out the correct number of parameters. Then examine all calls to it, and make sure that they are written correctly. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -4334  | The variable 'variable-name' in its current form is too complex to be used in this statement.  
The variable has too many component parts. Only simple variables (those that have a single component) can be used in this statement.  
If variable-name is an array, you must provide a subscript to select just one element. If it is a record, you must choose just one of its components; however, if this statement permits a list of variables, as in the INITIALIZE statement, you can use asterisk or THRU notation to convert a record name into a list of components. |
| -4335  | The symbol 'field-name' is not an element of the record 'record-name'.  
The field name used in a record.field expression is not identified as a member of the record variable.  
Find the definition of the record (it may be in the GLOBALS file), verify the names of its fields, and correct the spelling of field-name. |
| -4336  | The parameter 'param-name' has not been defined within the function or report.  
The name variable-name appears in the parameter list of the FUNCTION statement for this function; however, it does not appear in a DEFINE statement within the function. All parameters must be defined in their function before use.  
Review your code. Possibly you wrote a DEFINE statement but did not spell variable-name the same way in both places. |
| -4338  | The symbol 'symbol-name' has already been defined once as a parameter.  
The name that is shown appears in the parameter list of the FUNCTION statement and in at least two DEFINE statements within the function body.  
Review your code. Only one appearance in a DEFINE statement is permitted. |
| -4340  | The variable 'variable-name' is too complex a type to be used in an expression.  
In an expression, only simple variables (those that have a single component) can be used.  
If the variable indicated is an array, you must provide a subscript to select just one element. If it is a record or object, you must choose just one of its components. |
| -4341  | Aggregate functions are only allowed in reports and SELECT statements.  
Aggregate functions such as SUM, AVG, and MAX can only appear in SQL statements and within certain statements that you use in the context of a report body. They are not supported in ordinary expressions in program statements.  
Review the code and check that the aggregate functions are in an SQL statement or in the correct blocks of the REPORT routine. |
<table>

<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>-4361</td>
<td>Group aggregates can occur only in AFTER GROUP clauses. The aggregate functions that apply to a group of rows (GROUP COUNT/PERCENT/SUM/AVG/MIN/MAX) can only be used at the point in the report when a complete group has been processed, namely, in the AFTER GROUP control block. Make sure that the AFTER GROUP block exists and was recognized. If you need the value of a group aggregate at another time (for instance, in a PAGE TRAILER control block), you can save it in a module variable with a LET statement in the AFTER GROUP block.</td>
</tr>
<tr>
<td>-4363</td>
<td>The report cannot skip lines while in a loop within a header or trailer. BDL needs to know how many lines of space will be devoted to the page header and trailer (otherwise it does not know how many detail rows to allow on the page). It cannot predict how many times a loop will be executed, so it has to forbid the use of SKIP statements in loops in the PAGE HEADER, PAGE TRAILER, and FIRST PAGE HEADER sections. Review the report header or trailer to avoid SKIP in loops.</td>
</tr>
<tr>
<td>-4369</td>
<td>The symbol 'symbol-name' does not represent a defined variable. The name shown appears where a variable would be expected, but it does not match any variable name in a DEFINE statement that applies to this context. Check the spelling of the name. If it is the name you intended, look back and find out why it has not yet been defined. Possibly the GLOBALS statement has been omitted from this source module, or it names an incorrect file. Possibly this code has been copied from another module or another function, but the DEFINE statement was not copied also.</td>
</tr>
<tr>
<td>-4371</td>
<td>Cursors must be uniquely declared within one program module. In the statement DECLARE cursor-name CURSOR, the identifier cursor-name can be used in only one DECLARE statement in the source file. This is true even when the DECLARE statement appears inside a function. Although a program variable made with the DEFINE statement is local to the function, a cursor within a function is still global to the whole module Search for duplicated cursor names and change the name to have unique identifiers.</td>
</tr>
<tr>
<td>-4372</td>
<td>The cursor 'cursor-name' has not yet been declared in this program. The name shown appears where the name of a declared cursor or a prepared statement is expected; however, no cursor (or statement) of that name has been declared (or prepared) up to this point in the program. Check the spelling of the name. If it is the name you intended, look back in the program to see why it has not been declared. Possibly the DECLARE statement appears in a GLOBALS file that was not included.</td>
</tr>
<tr>
<td>-4374</td>
<td>This type of statement can only be used within a MENU statement. This statement only makes sense within the context of a MENU statement. Review the program in this vicinity to see if an END MENU statement has been misplaced. If you intended to set up the appearance of a menu before displaying it, use a BEFORE MENU block within the scope of the MENU.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -4375  | The page length is too short to cover the specified page header and trailer lengths.  

A REPORT defines page header and trailer sections with a total number of lines that is not sufficiently less than the specified page length in order to print some detail lines.  

Review the [FIRST] PAGE HEADER and PAGE TRAILER blocks to use less lines or increase the page length. |
| -4379  | The input file 'file-name' cannot be opened.  

Either the file does not exist, or, on UNIX™, your account does not have permission to read it.  
Possibly the filename is misspelled, or the directory path leading to the file was specified incorrectly. |
| -4380  | The listing file 'file-name' cannot be created.  

The file cannot be created.  
Check that the directory path leading to the file is specified correctly and, on UNIX™ systems, that your account has permission to create a file in that directory. Look for other, more explicit, error messages from the operating system. Possibly the disk is full, or you have reached a limit on the number of open files. |
| -4382  | Record variables that contain array type elements may not be referenced by the ".*" or THROUGH shorthand, or used as a function parameter.  

The .* and THROUGH/THRU notation is used to expand a record with an array member.  
It is allowed to define a record with an array member, but this element must always be used with its full designation of record.array[n]. The .* or THROUGH/THRU notation only expands simple members of the record. |
| -4383  | The elements 'name-1' and 'name-2' do not belong to the same record.  

The two names shown are used where two components of one record are required; however, they are not components of the same record.  
Check the spelling of both names. If they are spelled as you intended, go back to the definition of the record and see why it does not include both names as component fields. |
| -4402  | In this type of statement, subscripting may be applied only to array.  

The statement contains a name followed by square brackets, but the name is not that of an array variable.  
Check the punctuation of the statement and the spelling of all names. Names that are subscripted must be arrays. If you intended to use a character substring in this statement, you will have to revise the program. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -4403  | The number of dimensions for the variable 'variable-name' does not match the number of subscripts.  

In this statement, the array whose name is shown is subscripted by a different number of dimensions than it was defined to have.  

Check the punctuation of the subscript. If it is as you intended, then review the DEFINE statement where variable-name is defined. |
| -4410  | There is a numeric constant in the previous line that is too large or too small.  

The compiler is unable to process a numeric constant because it is too big or too small to represent a valid SMALLINT, INTEGER, BIGINT or DECIMAL constant.  

Check the number of digits and the punctuation of the numeric constant. Make sure you have not typed a letter for a digit for example. |
| -4414  | The label 'label-name' has been used but has never been defined within the above main program or function.  

A GOTO or WHENEVER statement refers to the label shown, but there is no corresponding LABEL statement in the current function or main program.  

Check the spelling of the label. If it is as you intended it, find and inspect the LABEL statement that defines it. You cannot transfer out of a program block with GOTO; labels must be defined in the same function body where they are used. |
| -4415  | An ORDER BY or GROUP item specified within a report must be one of the report parameters.  

The names used in a ORDER BY, AFTER GROUP OF, or BEFORE GROUP OF statement must also appear in the parameter list of the REPORT statement. It is not possible to order or group based on a global variable or other expression.  

Check the spelling of the names in the statement and compare them to the REPORT statement. |
| -4416  | There is an error in the validation string: 'validation-string'.  

The validation string in the syscolval table is not correct.  

Change the appropriate DEFAULT or INCLUDE value in the syscolval table. |
| -4417  | This type of statement can be used only in a report.  

Statements such as PRINT, SKIP, or NEED are meaningful only within the body of a report function, where there is an implicit report listing to receive output.  

Remove the report specific statement from the code which is not in a report body. |
| -4418  | The variable used in the INPUT ARRAY or DISPLAY ARRAY statement must be an array.  

The name following the words DISPLAY ARRAY or INPUT ARRAY must be that of an array of records.  

Check the spelling of the name. If it is as you intended, find and inspect the DEFINE statement to see why it is not an array. (If you want to display or input a simple variable or a single element of an array, use the DISPLAY or INPUT statement.) |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -4420  | The number of lines printed in the IF part of an IF-THEN-ELSE statement of a header or trailer clause must equal the number of lines printed in the ELSE part.  
   The runtime system needs to know how many lines will be filled in header and trailer sections (otherwise it does not know how many detail rows to put on the page). Because it cannot tell which part of an IF statement will be executed, it requires that both produce the same number of lines of output.
   Use the same number of occurrences of PRINT statements in each block of the IF statement. |
| -4425  | The variable 'variable-name' has not been defined like the table 'table-name'.  
   The named variable has been used in the SET clause of an UPDATE statement or in the VALUES clause of an INSERT statement, but it was not define LIKE the table being modified.  
   As a result, then runtime system cannot associate record components with table columns.
   Make sure the schema file is up to date and check that the variable was defined like the table. You can also rewrite the UPDATE or INSERT statement with a different syntax to show the explicit relationship between column names and record components. |
| -4440  | The field 'field-name-1' precedes 'field-name-2' in the record 'record-name' and must also precede it when used with the THROUGH shorthand.  
   The THROUGH or THRU shorthand requires you to give the starting and ending fields as they appear in physical sequence in the record.
   Check the spelling of the names; if they are as you intended, then refer to the VARIABLE statement where the record was defined to see why they are not in the sequence you expected. |
| -4447  | 'key-name' is not a recognized key value.  
   The key name used in an ON KEY clause is not known by the compiler.
   Search the documentation for possible key names (F1-F255, Control-?). |
| -4448  | Cannot open the file 'file-name' for reading or writing.  
   Note: This error is non-trappable.  
   The file cannot be opened because:
   • You do not have permissions. Verify that your account has permission to read or write to the file.
   • The file cannot be found. Verify that the file name is correctly spelled and that it exist. Also the source of the file path, such as an environment or program variable, that would give you the proper path may not be set properly. Check your environment configuration and review your code. |
| -4452  | The function (or report) 'function-name' has already been defined.  
   Each function (or report, which is similar to a function) must have a unique name within the program.
   Change the function or report name. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -4457  | You may have at most 4 keys in the list.  
          An interactive instruction defines a ON KEY() clause with more that 4 keys.  
          Remove keys from the list. |
| -4458  | One dimension of this array has exceeded the limit of 65535.  
          The program is using a static array with a dimension that exceeds the limit.  
          Use a dimension below the 65535 limit. |
| -4463  | The NEXT FIELD statement can only be used within an INPUT or CONSTRUCT statement.  
          The NEXT FIELD statement is used outside an INPUT, INPUT ARRAY or CONSTRUCT statement.  
          Remove the NEXT FIELD statement from that part of the code. |
| -4464  | The number of columns must match the number of values in the SET clause of an UPDATE statement.  
          In an UPDATE statement, the number of values used does not match the number of columns.  
          Check for the table definition, then either add or remove values or columns from the UPDATE statement. |
| -4476  | Record members may not be used with database column substring.  
          This statement has a reference of the form name1.name2[...]. This is the form in which you would refer to a substring of a column: table.column[...] ; however, the names are not a table and column in the database, so BDL presumes they refer to a field of a record.  
          Inspect the statement and determine what was intended: a reference to a column or to a record.  
          If it is a column reference, verify the names of the table and column in the database. If it is a record reference, verify that the record and component are properly defined. |
| -4477  | The variable 'variable-name' is an array. You must specify one of its elements in this statement.  
          You tried to use an array without element specification in a SQL statement.  
          Use one of the members of the array. |
| -4485  | Only blob variables of type BYTE or TEXT may be used in a LOCATE statement.  
          The LOCATE statement is using a variable defined with a data type different from BYTE or TEXT.  
          Make sure the variables used with LOCATE are defined as BYTE or TEXT. |
| -4488  | The program cannot CONTINUE or EXIT statement-type at this point because it is not immediately within statement-type statement.  
          This CONTINUE or EXIT statement is not appropriate in its context.  
          Review your code. Possibly the statement is misplaced, or the statement type was specified incorrectly. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -4489  | A variable used in the above statement must be a global variable.  
A REPORT routine is defining an OUTPUT REPORT TO using a local function variable or report parameter.  
Review the report clause to use a global or module variable instead. |
| -4490  | You cannot have multiple BEFORE clauses for the same field.  
You cannot specify more than one BEFORE FIELD clause for the same field.  
Review your code to eliminate multiple BEFORE FIELD clauses. |
| -4491  | You cannot have multiple AFTER clauses for the same field.  
You cannot specify more than one AFTER FIELD clause for the same field.  
Review your code to eliminate multiple AFTER FIELD clauses. |
| -4534  | Wordwrap may not be used within report headers or trailers.  
The report routine uses the WORDWRAP clause in the FIRST PAGE HEADER, PAGE HEADER or PAGE TRAILER sections.  
Remove the WORDWRAP clause from the expression. |
| -4631  | Startfield of DATETIME or INTERVAL qualifiers must come earlier in the time-list than its endfield.  
The qualifier for a DATETIME or INTERVAL consists of start TO end, where the start and end are chosen from this list: YEAR MONTH DAY HOUR MINUTE SECOND FRACTION.  
The keyword for the start field must come earlier in the list than, or be the same as, the keyword for the end field.  
Check the order of the startfield and endfield qualifiers. For example, qualifiers of DAY TO FRACTION and MONTH TO MONTH are valid but one of MINUTE TO HOUR is not. |
| -4632  | Parenthetical precision of FRACTION must be between 1 and 5. No precision can be specified for other time units.  
In a DATETIME qualifier only the FRACTION field may have a precision in parentheses, and it must be a single digit from 1 to 5.  
Check the DATETIME qualifiers in the current statement; one of them violates these rules. The first field of an INTERVAL qualifier may also have a parenthesized precision from 1 to 5. |
| -4652  | The function 'function-name' can only be used within an INPUT or CONSTRUCT statement.  
The function shown is being used outside of an INPUT or CONSTRUCT statement; however, it returns a result that is only meaningful in the context of INPUT or CONSTRUCT.  
Review the code to make sure that an END INPUT or END CONSTRUCT statement has not been misplaced. Review the operation and use of the function to make sure you understand it. |
-4653
No more than one BEFORE or AFTER INPUT/CONSTRUCT clause can appear in an INPUT/CONSTRUCT statement.

There may be only one BEFORE block of statements to initialize each of these statement types. Make sure that the scope of all your INPUT, CONSTRUCT and MENU statements is correctly marked with END statements. Then combine all the preparation code into a single BEFORE block for each one.

-4656
CANCEL INSERT can only be used in the BEFORE INSERT clause of an INPUT ARRAY statement.

The CANCEL INSERT statement is being used outside of the BEFORE INSERT clause of an INPUT ARRAY.

Review the code to make sure that CANCEL INSERT has not been used anywhere except in the BEFORE INSERT clause.

-4657
CANCEL DELETE can only be used in the BEFORE DELETE clause of an INPUT ARRAY statement.

The CANCEL DELETE statement is being used outside of BEFORE DELETE clause of an INPUT ARRAY.

Review the code to make sure that CANCEL DELETE has not been used anywhere except in the BEFORE DELETE clause.

-4668
The report output, specified by a START REPORT statement, is not any of file, pipe, screen, printer, pipe in line mode, or pipe in form mode.

The output of a report can be sent only to any of file, pipe (in form or line modes), screen, or printer.

Check the START REPORT instruction and make sure that the OUTPUT clause specifies one of the supported values.

-4900
This syntax is not supported here. Use [screenrecordname.]screenfieldname.

The field name specification in a BEFORE FIELD or AFTER FIELD is not valid.

Check for the field name and use [screenrecordname.]screenfieldname syntax.

-4901
Fatal internal error: description ( line-number ).

This generic error occurs when the fglcomp compiler cannot identify the problem and must stop processing the source.

Check the code near the line displayed in the error message.

-6001
The license manager daemon cannot be started.

Note: This error is non-trappable.

This error occurs when a process creation fails during the start of the license manager.

Increase the maximum number of processes allowed (ulimit)

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6178  | Your machine is not allowed to be connected on any of your authorized licenses.  
Note: This error is non-trappable.  
The CPU license rejects the connection of a new host. All CPU licenses are consumed.  
Contact your support center. |
| -6179  | License validity time is reached. The users control is reactivated.  
Note: This error is non-trappable.  
The CPU license is time limit is reached. The CPU license is degraded and user control is reactivated.  
Contact your support center. |
| -6180  | CPU limit exceeded. The users control is reactivated.  
Note: This error is non-trappable.  
The CPU license has less CPUs available than the number of CPUs on the connected host, resulting in one or more hosts running in degraded mode. When running in degraded mode, the number of users allowed is the number of available CPUs in the license * 100 users. User control is activated for license request coming from that host.  
For example, if you have a 5 CPU license and are using the license manager.  
• Host A with 2 CPUs connects. It consumes 2 CPUs of the 5 CPU license. 3 CPUs remain free on the license.  
• Host B with 2 CPUs connects. It consumes 2 CPUs of the 5 CPU license. 1 CPU remains free on the license.  
• Host C with 2 CPU connects. It expects to be able to consume 2 CPUs, but only 1 CPU remains on the license. User control for Host C is enabled, with 1 CPU (the remaining free CPU) * 100 users allowed.  
• Host D connects with N CPU, however there are no CPUs free on the license. Host D is rejected.  
In summary, Host A and B can have unlimited sessions, Host C is limited to 100 sessions as the license is degraded by CPU, and any other host is rejected.  
In the case of a single host, user control applies to local licenses as well. If Host A has 6 CPUs, yet has a 5 CPU license, it consumes all of the CPUs for the license and runs in degraded mode. That means 5 * 100 users are allowed.  
Contact your support center. |
| -6181  | Cannot get license extension information. Check your environment, the license (run 'fglWrt -a info') and the fglWrt version ('fglWrt -V' should give version-number or higher).

| -6202  | filename 'file-name': Bad magic: Code cannot run with this p code machine.  
You have compiled your program with an old version. The new compiled version of your program is not supported. You might also have a file with the same name as the .42r. You used the fglrun 42r-Name without specifying the extension.  
To resolve this problem, call fglrun with the .42r extension or recompile your application. |
| -6203  | Module 'module-name-1': The function 'function-name' has already been defined in module 'module-name-2'.  
**Note:** This error is non-trappable.  
The specified function is defined for the second time in the application. The second occurrence of the function is in the specified module.  
Eliminate one of the two function definitions from your source code. |
| -6204  | Module 'module-name': Unknown op-code.  
**Note:** This error is non-trappable.  
An unknown instruction was found in the compiled BDL application.  
Check that the version of the Genero Business Development Language package executing the compiled application is the same as the one that compiled the application. It is also possible that the compiled module has been corrupted. If so, you will need to recompile your application. |
| -6205  | INTERNAL ERROR: Alignment.  
**Note:** This error is non-trappable.  
This error is internal, and does not normally occur.  
Contact your Technical Support. |
| -6206  | The 42m module 'module-name' could not be loaded, check FGLLDPATH environment variable.  
**Note:** This error is non-trappable.  
The .42m module is not in the current directory or in one of the directories specified by the FGLLDPATH environment variable.  
Set the environment variable FGLLDPATH with the path to the .42m modules to be loaded. |
| -6207  | The dynamic loaded module 'module-name' does not contain the function 'function-name'.  
**Note:** This error is non-trappable.  
A BDL module has been changed and recompiled, but the different modules of the application have not been linked afterward.  
Link the new modules together before you execute your application. |
<table>
<thead>
<tr>

</tr>
</thead>
</table>
| -6208  | Module 'module-name' already loaded.  
     **Note:** This error is non-trappable.  
A module was loaded twice at runtime. This can occur because one module has been concatenated with another.  
Recompile and re-link your BDL modules. |
| -6210  | INTERNAL ERROR: exception 2 raised before invoking the exception handler for exception 1.  
A module was loaded twice at runtime. This can occur because one module has been concatenated with another.  
Check for function names, recompile and re-link your BDL modules. |
| -6211  | Link has failed.  
A problem occurred while linking the BDL program.  
Check for function names, recompile and re-link your BDL modules. |
| -6212  | Function function-name : local variables size is too large - Allocation failed.  
A local function variable is too large and runtime is unable to allocate memory.  
Review the variable data types in the function. |
| -6213  | Module module-name : Module's variable size is too large - Allocation failed.  
A module variable is too large and runtime is unable to allocate memory.  
Review the variable data types in the module. |
| -6214  | Global variable variable-name size is too large - Allocation failed.  
A global variable is too large and runtime is unable to allocate memory.  
Review the variable data types in the globals. |
| -6215  | Memory allocation failed. Ending program.  
Runtime is unable to allocate memory.  
Check for system resources and verify if the OS user is allowed to allocate as much memory as the program needs (check for `ulimits` on UNIX™ systems). |
| -6216  | The global 'constant-name' has been redefined with a different constant-value.  
**Note:** This error is non-trappable.  
A global constant has been defined twice with a different value.  
A global constant may have only one value. Review your code. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6217  | The global 'variable-name' has been defined as a constant and a variable.  
**Note:** This error is **non-trappable.**  
The same symbol was used to define a constant and a variable.  
Use a different name for the constant and the variable. Review your code. |
| -6218  | No runtime. You must call fgl_start() before calling fgl_call().  
This error occurs when a C extension has redefined the main() routine, but then does not call fgl_start() to initialize the BDL runtime environment.  
Check the C extension and call fgl_start() before any other operation. |
| -6219  | WHENEVER ERROR CALL: The error-handler recursively calls itself.  
The function specified with the WHENEVER ERROR CALL instruction raises an error that would call itself recursively.  
Review the function called by the WHENEVER ERROR CALL and make sure it does not produce a runtime error. |
| -6220  | Could not load C extension library 'library-name'. Reason: description  
**Note:** This error is **non-trappable.**  
Runtime system is unable to find the shared library for the reason given.  
Check if the C extension library exists in one of the directories defined by FGLLDPATH. If the C extension module depends on other shared libraries, make sure that these libraries can be found by the library loader of the operating system (check the LD_LIBRARY_PATH environment variable on UNIX™ or the PATH environment variable on Windows®). |
| -6221  | C extension initialization failed with status number.  
**Note:** This error is **non-trappable.**  
C extension failed to initialize and returned the status shown in the error message.  
Check the C extension source or documentation. |
| -6222  | class-name class not found.  
**Note:** This error is **non-trappable.**  
The program was compiled with the built-in class class-name but at execution time the class is not found.  
Check you installation, it is possible that you are executing program that was compiled with a younger version as the version used in the execution context, which certainly is missing that class in the runtime library. |
| -6223  | No such symbol: symbol-name.  
**Note:** This error is **non-trappable.**  
The runtime system loads a module dynamically (on demand) and searches for the symbol in a given module. But the symbol is not found, for example, because of an invalid FGLLDPATH, or because the installed module no longer contains the symbol (after a recompilation). |

|-6307   | GUI server autostart: can not identify workstation.  
GUI Server autostart configuration is wrong. Either DISPLAY, FGLSERVER or FGLPROFILE settings are invalid.  
Set the required environment variables and check for FGLPROFILE autostart entries. |
|-6308   | GUI server autostart: unknown workstation: check gui.server.autostart entries.  
The computer described by the X11 DISPLAY environment variable is neither the local host, nor is it listed in the FGLPROFILE entries.  
Check if the X11 DISPLAY name is correctly set, or review the FGLPROFILE entries. |
|-6309   | Not connected. Cannot write to GUI.  
For unknown reasons there was an attempt to write on the GUI socket before the connection was initiated.  
Check the program for invalid GUI operations. |
|-6310   | Not connected. Cannot read from GUI.  
For unknown reasons there was an attempt to read on the GUI socket before the connection was initiated.  
Check the program for invalid GUI operations. |
|-6311   | No current window.  
The program tries to issue a MENU instruction with no current window open.  
Review the program logic and make sure a window is open before MENU. |
|-6312   | The type of the user interface (FGLGUI) is invalid.  
**Note:** This error is **non-trappable**.  
While initiating the user interface, the runtime system did not recognize the GUI type and stopped.  
Make sure the FGLGUI environment variable has a correct value. |
|-6313   | The UserInterface has been destroyed.  
**Note:** This error is **non-trappable**.  
The error occurs when the front-end sends a DestroyEvent event, indicating some inconsistency with the starting program. This can happen, for example, when multiple StartMenus are used, or when you try to run an MDI child without a parent container, or when two MDI containers are started with the same name, etc.  
Check for inconsistency and fix it. |
|-6314   | Wrong connection string. Check client version.  
While starting the program, the runtime received a wrong or incorrectly constructed answer from the front-end.  
Make sure you are using a front-end that is compatible with the runtime system. |
<table>
<thead>
<tr>
<th>Number</th>

An unexpected error occurred while writing to the channel. See the description for more details. |
| -6346 | Cannot read from unopened file, pipe or socket.  
You try to read from a channel object which is not open.  
First open the channel, then read. |
| -6360 | This runner cannot execute any SQL.  
The runtime system is not ready for database connections.  
Check the configuration of BDL. |
| -6361 | Dynamic SQL: type unknown: type-name .  
The database driver does not support this SQL data type.  
You cannot use this SQL data type, review the code. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6364  | Cannot connect to sql back end.  
The runtime system is unable to initialize the database driver to establish a database connection.  
Make sure the database driver exists. |
| -6365  | Database driver not connected yet.  
There is an attempt to execute an SQL statement, but no database connect is established.  
First connect, then execute SQL statements. |
| -6366  | Could not load database driver driver-name.  
**Note:** This error is non-trappable.  
The runtime system failed to load the specified database driver. The database driver shared object (.so or .DLL) or a dependent library could not be found.  
Make sure that the name of the specified driver is spelled correctly. If the driver name is correct, there is probably an environment problem. Make sure the database client software is installed. Check the UNIX™ LD_LIBRARY_PATH environment variable or the PATH variable on Windows®. These must point to the database client libraries. |
| -6367  | Incompatible database driver interface.  
**Note:** This error is non-trappable.  
The database driver interface does not match the interface expected by the runtime system. This can occur if you copy an old database driver into a younger FGLDIR installation.  
Call the support to get a valid database driver. |
| -6368  | SQL driver initialization function failed.  
**Note:** This error is non-trappable.  
The runtime system failed to initialize the database driver, program must stop because no database connection can be established.  
There is probably an environment problem (for example, INFORMIXDIR or ORACLE_HOME is not set). Check your environment and try to connect with a database vendor tool (dbaccess, sqlplus) to identify the problem. |
| -6369  | Invalid database connection mode.  
You try to mix DATABASE and CONNECT statements, but this is not allowed.  
Use either DATABASE or CONNECT. |
| -6370  | Unsupported SQL feature.  
This SQL command or statement is not supported with the current database driver.  
Review the code and use a standard SQL feature instead. |
| -6371  | SQL statement error number error-num (native-error).  
An SQL error has occurred having the specified error number.  
You can query SQLERRMESSAGE or the SQLCA record to get a description of the error. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>

</tbody>
</table>
| -6605  | The module 'module-name' does not contain function 'function-name'.  
The module shown in the error message does not hold the function name as expected.  
The specified function needs to be defined in this module. |
| -6606  | No member function 'function-name' for class 'class-name' defined.  
**Note:** This error is non-trappable.  
The function name is misspelled or is not a method of the class for which it is called.  
Review your code and the documentation for the method you are attempting to use. If the function is an object method, make sure the referenced object in your code is of the correct class. |
| -6608  | Resource error: entry-name :parameter expected  
This is a generic error message for resource file problems. |
| -6609  | A grammatical error has been found at 'seen-token' expecting: expected-token.  
A general syntax error message that indicates the location of the problem code and what code was expected.  
Review your code, particularly for missing END statements such as END FUNCTION or END INPUT, etc., and make the necessary corrections. |
| -6610  | The function 'function-name' has already been called with a different number of parameters.  
Earlier in the program, there is a call to this same function or event with a different number of parameters in the parameter list.  
Check the correct number of parameters for the specified function. Then examine all calls to it, and make sure that they are written correctly. |
| -6611  | Function 'function-name': unexpected number of returned values.  
The function shown returned a different number of values as expected.  
Check the body of the function for RETURN instructions. |
| -6612  | Redeclaration of function 'function-name'.  
The function shown was defined multiple times.  
Change the name of conflicting functions. |
| -6613  | The library function 'function-name' is not declared.  
The function shown was not declared.  
Change the name of the function. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6614    | The function 'function-name' may return a different number of values.  
The function shown contains multiple RETURN instructions which may return different number of values.  
Review the RETURN instructions to return the same number of values. |
| -6615    | The symbol-kind 'symbol-name' is unused.  
This is a warning indicating that the shown symbol is defined but never used. In this message,  
"symbol-kind" can be "symbol", "parameter", etc.  
Useless definition can be removed. |
| -6616    | The symbol 'symbol-name' does not represent a defined CONSTANT.  
The shown symbol is used as a CONSTANT, but it is not a constant.  
Review your code and check for this name. |
| -6617    | The symbol 'symbol-name' is a VARIABLE.  
The symbol shown is a VARIABLE which cannot be used in the current context.  
Review your code and check for this name. |
| -6618    | The symbol 'symbol-name' is a CONSTANT.  
The symbol shown is a CONSTANT which cannot be used in the current context.  
Review your code and check for this name. |
| -6619    | The symbol 'symbol-name' is not an INTEGER CONSTANT.  
The symbol shown is used as if it was an INTEGER constant, but it is not.  
Review your code and check for this name. |
| -6620    | The symbol 'symbol-name' is not a REPORT.  
The symbol shown is used as a REPORT, but it is not defined as a REPORT.  
Review your code and check for this name. |
| -6621    | The symbol 'symbol-name' is not a FUNCTION.  
The symbol shown is used as a FUNCTION, but it is not defined as FUNCTION.  
Review your code and check for this name. |
| -6622    | The symbol 'symbol-name' does not represent a valid variable type.  
The symbol shown is not known as a valid type to define a program variable.  
Review your code and check for the type name. |

|        | The current license is not valid for the product you have installed.  
Contact your support center to get a license corresponding to the current installed product. |
| -6802  | Can not open Database dictionary 'schema-name'. Run schema extraction tool.  
The schema file does not exist or cannot be found.  
If the schema file exists, verify that the filename is spelled correctly, and that the file is in the current directory or the FGLDBPATH environment variable is set to the correct path. If the file does not exist, run the database schema extraction tool to create a schema file. |
| -6803  | A grammatical error has been found at 'line-number', expecting 'token-name'.  
This is a generic message for errors. |
| -6804  | 'form-name' form compilation was successful.  
This is an information message indicating that the form was compiled without problem. |
You have compiled your form with a version of the form compiler that is not compatible with that used for compiling the other source code.  
Compile your form file and related source code files using the same or compatible versions of the compilers. |
| -6807  | The label 'label-name' could not be used as column-title.  
The form file defines an invalid TABLE column title.  
Check for column titles which are not corresponding to column positions. |
| -6808  | The widget 'widget-name' can not be defined as array.  
The form file defines an item which is used as a matrix column.  
Review your form definition. |
| -6809  | The layout tag 'tag-name' is invalid, expecting: 'token-name'.  
The form compiler detected an invalid layout tag specification.  
Review your form definition. |
| -6810  | The attribute 'attribute-name' is invalid for item type 'type-name'.  
The form compiler detected an invalid attribute definition for this item type.  
Review your form definition and check for invalid attributes. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6811  | Syntax error near 'token-1', expecting token-2.  
A general syntax error message that indicates the location of the problem code and what code was expected.  
Review your code and make the necessary corrections. |
| -6812  | Unterminated char constant.  
The form compiler detected an unterminated character constant.  
Review your form definition and check for missing quotes or double-quotes. |
| -6813  | The element 'element-name' conflicts with group-box 'group-name'.  
You have used the same name for an element and for a group-box.  
Review your form definition and ensure that the names used are unique. |
| -6814  | All members of the SCREEN RECORD 'screen-record-name' must reference the same Table or ScrollGrid.  
The shown screen record references multiple tables or scrollgrids in your form file.  
Review your form definition and use one unique table for a given screen record. |
| -6815  | Invalid indentation in between braces.  
The LAYOUT section of your form defines an invalid indentation.  
Review your form definition and check for corresponding indentations. |
| -6817  | TABLE container defined without a SCREEN RECORD in the INSTRUCTION section.  
The minimum value of the defined attribute must be lower than the maximum value.  
Review your code and make the necessary corrections. |
| -6818  | Min value must be lower that Max value.  
The minimum value of the defined attribute must be lower than the maximum value.  
Review your code and make the necessary corrections. |
| -6819  | Number of elements in the SCREEN RECORD must match the number of columns in TABLE container.  
The elements defined in the screen record differs from the columns used for the TABLE container.  
Review your form definition and add missing table columns to the screen record, order does not matter. |
| -6820  | ScrollGrid and/or Group layout tags cannot be nested.  
The form definition has nested ScrollGrid and/or Group layout tags. These tags cannot be nested.  
Review your form definition and make the necessary corrections. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6821  | HBOX tags cannot be used for ARRAYS.  
The form definition is using an HBOX tag for an array, which is not permitted.  
Review your form definition and make the necessary corrections. |
| -6822  | Escaped graphical characters are not accepted in GRID sections.  
You try to use Text User Interface graphics in the new GRID container.  
This is not allowed, use GROUPs instead. |
| -6823  | Close tag does not have a matching tag above.  
The form definition has a close tag without a prior matching open tag. Open tags and close tags must match.  
Review your form definition file and make the necessary corrections. |
| -6824  | The table 'table-name' is empty.  
The form layout defines a table layout tag identified by tablename, but nothing was found directly under this table that defines a column or a column title.  
Append columns to the table layout region. |
| -6825  | The tag 'tag-name' overlaps with table 'table-name'.  
In the form layout, tagname overlaps the layout region of tablename and makes it invalid.  
Move or remove tagname, or redefine the layout region of tablename. |
| -6826  | Checked value must be different from unchecked value for field 'field-name'.  
The VALUECHECKED and VALUEUNCHECKED attributes have the same value. This makes no sense because these attributes define the values corresponding to the checked and unchecked states of a checkbox.  
Use different values for these attributes. |
| -6827  | Duplicated item key found for field 'field-name'.  
The ITEMS attribute of field fieldname defines item keys with the same value.  
Check ITEMS attribute and use unique key values. Note that " and NULL are equivalent. |
| -6828  | The attribute attribute-name must belong to a column of a TABLE.  
A form item uses an attribute that references a form field which is not defined or does not belong to the TABLE.  
Check the ATTRIBUTES section for invalid column references. |
| -6829  | The column column-name referenced by the attribute-name attribute must belong to the TABLE.  
A form item uses an attribute that references a form field which is not defined or does not belong to the TABLE.  
Check the ATTRIBUTES section for invalid column references. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6830  | Not implemented (yet): feature-name  
The feature or syntax you are using is not implemented yet.  
This feature cannot be used in the Genero version you have installed. |
| -6831  | At least one member of the SCREEN RECORD 'screen-record-name'  
must not be a PHANTOM field.  
A screen record is defined with form fields that are all defined as PHANTOM fields.  
At least one screen record field must not be a PHANTOM field. |
| -6832  | Repeated screen tags 'tag-name' are misaligned, must align on X  
or Y.  
The layout defines multiple tags with the same name, but these are not properly aligned in the X  
or Y direction.  
Edit the form file and make sure that repeated tags are correctly aligned. |
| -6833  | Invalid TREE definition: the field 'field-name' must be an EDIT  
or LABEL.  
The form defines a TREE container with the field column defined with a wrong item type.  
Replace the item type by EDIT or LABEL. |
| -6834  | Invalid TREE definition: the field 'field-name' must be defined  
for the SCREEN RECORD.  
The form defines a TREE container with an invalid field set.  
Check that mandatory fields such as node name, parent id and node id fields are defined. |
| -6835  | The fields specified in the THRU option appear in the reverse  
order.  
The form defines a screen record by using the THRU or THROUGH keyword, but the first field  
is defined after the last field in the ATTRIBUTES section.  
Exchange the field names specified in the screen record definition, or review the declaration  
order in ATTRIBUTES. |
| -6836  | Invalid TREE definition: the attribute 'attribute-name'  
conflicts with id or parentid.  
The .per form defines a TREE with invalid configuration. You have probably used the same  
field for the named attribute and for IDCOLUMN or PARENTIDCOLUMN.  
Review the form definition and configure the TREE properly. You must use dedicated columns  
for the attributes mentioned. |
| -6837  | Invalid AGGREGATE definition: must be located below a table  
column.  
The .per form defines an AGGREGATE form item with a field tag that is not aligned under a  
table column field tag.  
Review the table layout and make sure that all aggregate fields are properly aligned and placed  
below column tags. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -6838  | This area is reserved for AGGREGATEs.  
The .per form defines a TABLE with aggregate fields, but not all aggregate fields are declared with the AGGREGATE item type.  
Review the field definitions in the ATTRIBUTES section. |
| -6839  | The screen tag 'tag-name' can not be defined in a TABLE.  
The .per form defines a TABLE with columns using different field tag names, an no AGGREGATE field is defined.  
Review columns of the TABLE, each field tag of a given column must use the same tag name, except if you want to define an AGGREGATE field. |
| -6841  | FORM not contain TOPMENU or TOOLBAR.  
The form layout includes an external form specification file containing a TOPMENU or a TOOLBAR. Remove these sections from the included form file. |
| -6842  | FORM is out of date.  
The form layout includes an external form specification file the was compiled with a older version. |
| -6843  | A resizable SCROLLGRID requires the definition of exactly one template.  
A resizable SCROLLGRID (WANTFIXEDPAGESIZE=NO) must define a single row template. |
| -6844  | INITIALPAGESIZE requires a resizable SCROLLGRID.  
When using the INITIALPAGESIZE attribute, the SCROLLGRID must be defined as resizable with the WANTFIXEDPAGESIZE=NO attribute. |
| -6845  | The display field label 'field-name' has already been defined.  
The field item tag is defined several times in different containers of the LAYOUT section. |
| -6846  | The screen tag 'tagname' can not be defined in a SCROLLGRID  
A SCROLLGRID contains a layout tag such as <TABLE > or <TREE >. This is not allowed. |
| -6847  | TABINDEX has to be unique  
Some elements of the form define the same TABINDEX. Review the ATTRIBUTE section and make sure that all TABINDEX values are unique. |
| -6848  | All TABLE columns must have the same size.  
In a TABLE or TREE container, all columns must be defined with the same width and height in the LAYOUT section. |
| -6849  | STRETCH=value conflicts with WANTFIXEDPAGESIZE.  
The STRETCH attribute values Y and BOTH are not consistent with WANTFIXEDPAGESIZE:  
The WANTFIXEDPAGESIZE attribute is equivalent to STRETCH=X.  
Remove the WANTFIXEDPAGESIZE attribute in favor of the STRETCH attribute. |
<table>

NULL cannot be used at this place.  
Review your code. |
| -8003  | Dom: A node is inserted somewhere it doesn't belong.  
**Note:** This error is non-trappable.  
You try to insert a node under a parent node which does not allow this type of nodes.  
Check for the possible nodes and review your code. |
| -8004  | Sax: Invalid hierarchy.  
The SAX handler encountered an invalid hierarchy.  
Make sure parent/child relations are respected. |
| -8005  | Deprecated feature: feature-name  
The feature you are using will be removed in a next version.  
A replacement for the feature is normally available. |
| -8006  | The string resource file 'file-name' cannot be found.  
**Note:** This error is non-trappable.  
The given string file was not found.  
Check if file exists and if path is valid. |
| -8007  | The string resource file 'file-name' cannot be read.  
**Note:** This error is non-trappable.  
The given string file was unable to be read.  
Check if file exists and if user has read permissions. |
| -8008  | There is no string text defined for the 'key-name' string key.  
The runtime system was unable to find a string resource corresponding to the shown key.  
Check if the key is defined in one of the resource files. |
| -8009  | String resource syntax error near 'token-name', expecting token.  
The string file compiler detected a syntax error.  
Check for invalid syntax in the .str file. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8012  | Duplicate string key 'key-name' (file-name : line) IGNORE LINE.  
The string file compiler detected duplicated string keys.  
Review the .str file and remove duplicated keys. |
| -8013  | The string file 'file-name' can not be opened for writing.  
The string file compiler was unable to write to the specified string file.  
Make sure the user has write permissions and file name is valid. |
| -8014  | The string file 'file-name' can not be read.  
The runtime system was unable to read from the specified string file.  
Make sure the user has read permissions. |
| -8015  | Field (field-name) in ON CHANGE clause not found in form.  
The field used in the ON CHANGE clauses was not found in the form specification file.  
Make sure the field name of the ON CHANGE clause matches a valid form field. |
| -8016  | You cannot have multiple ON CHANGE clauses for the same field.  
It is not possible to specify multiple ON CHANGE clauses using the same field.  
Remove unnecessary ON CHANGE clauses. |
| -8017  | SFMT: Invalid % index used.

</table>
| -8060  | Spacer items are not allowed inside a SCREEN sections.  
The form contains spacer items in a SCREEN section, while these are only allowed in LAYOUT.  
Review the form specification file. |
| -8061  | A TABLE row should not be defined on multiple lines.  
All columns of a row in a TABLE container must be in a single line.  
Use a SCROLLGRID if you want to show row cells on multiple lines. |
| -8063  | The client connection timed out.  
The runtime system failed to establish the connection with the front-end after a given time.  
This can for example happen during a file transfer, when the front-end takes too much time to respond to the runtime system.  
Check that your network connection is working properly. |
| -8064  | File transfer interrupted.  
An interruption was caught during a file transfer.  
File was not transferred, you need to redo the operation. |
| -8065  | Network error during file transfer.  
A socket error was caught during a file transfer.  
Check that your network connection is working properly. |
| -8066  | Could not write destination file for file transfer.  
The runtime system failed to write the destination file for a transfer.  
Make sure the file path is correct and check that user has write permissions. |
| -8067  | Could not read source file for file transfer.  
The runtime system was unable to read the source file to transfer.  
Make sure the file path is correct and check that user has read permissions. |
| -8068  | File transfer protocol error (invalid state).  
The runtime system encountered a problem during a file transfer.  
A network failure has probably raised this error. |
| -8069  | File transfer not available.  
File transfer feature is not supported.  
Make sure the front-end supports file transfer. |
<table>

</table>
| -8070  | The localized string file 'file-name' is corrupted.  
**Note:** This error is non-trappable.  
The shown string resource file is invalid (probably invalid multibyte characters corrupt the file).  
Check for locale settings (LANG), make sure the .str source uses valid characters and recompile it. |
| -8071  | 'symbol-name' is already defined.  
The form file defines several elements of the same type with the same name.  
Review the form file and use unique identifiers. |
| -8072  | Statement must terminate with ';'.  
An ESQL/C preprocessor directive is not terminated with a semicolon.  
Add a semicolon to the end of the directive. |
| -8073  | Invalid 'include' directive file name.  
An include preprocessor directive is using an invalid file name.  
Check the file name. |
| -8074  | A &elif directive found without corresponding &if, &ifdef or &ifndef directive.  
The preprocessor found an &elif directive with no corresponding &if.  
Add the &if directive before the &elif, or remove the &elif. |
| -8075  | The compiler plugin name could not be loaded.  
gflcomp failed to load the plugin because it was not found.  
Make sure the plugin exists and can be loaded. |
| -8076  | The compiler plugin name does not implement the required interface.  
gflcomp failed to load the plugin because the interface is invalid.  
Check if the plugin corresponds to the version of the compiler. |
| -8077  | The attribute 'attribute-name' has been defined more than once.  
The variable attribute shown in the error message was defined multiple times.  
Review the variable definition and remove duplicated attributes. |
| -8078  | The attribute 'attribute-name' is not allowed.  
The variable attribute shown in the error message is not allowed for this type of variable.  
Review the possible variable attributes. |

</tbody>
</table>
| -8088 | The dialog attribute 'attribute-name' is not supported.  
**Note:** This error is non-trappable.  
A dialog instruction was declared with an ATTRIBUTES clause containing an unsupported option.  
Review the ATTRIBUTES clause and remove unsupported option. |
| -8089 | Action 'action-name' not found in dialog.  
You try to use an action name that does not exist in the current dialog.  
Verify if name of the action is defined by an ON ACTION clause. |
| -8090 | Field 'field-name' already used in this DIALOG.  
The DIALOG instruction binds the same field-name or screen-record multiple times.  
Review all sub-dialog blocks and check the field-names / screen-records. |
| -8091 | The clause 'clause-name' appears more than once.  
You have defined the same dialog control block multiple times. For example, AFTER ROW was defined twice.  
Remove the un-necessary control blocks. |
| -8092 | At least one field for this INPUT ARRAY must be editable.  
**Note:** This error is non-trappable.  
An INPUT ARRAY is executed on fields that are read-only. At least one field must be editable and active.  
Review the form specification file or check that at least one field is active. |
| -8093 | Multi-range selection is not available in this context.  
You try to use multi-range selection but it is not possible in the current dialog type.  
Disable this feature. |
| -8094 | Multi-range selection is not available in this context.  
You try to use multi-range selection but it is not possible in the current dialog type.  
Disable this feature. |
| -8095 | Cannot change selection flag for this range of rows.  
An attempt of selection flag modification with DIALOG.setSelectionRange() failed because the range is out of bounds or because there is no multi-range selection available in this context.  
Make sure you can use multi-range selection, and check the start and end index of the range. |
| -8096 | General SQL Warning, check SQLCA.SQLERRD[2] or SQLSTATE.  
The last SQL statement has generated an SQL warning setting the SQLCA.SQLAWARN flags.  
Program execution can continue; however, it is recommended that you take care and check the native SQL code and the SQL message in SQLERRMESSAGE. |
<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
</table>
| -8097  | Value too large to fit in a TINYINT.  
The TINYINT data type can accept numbers with a value range from -128 to +127.  
To store numbers that are outside this range, redefine the column or variable to use the SMALLINT or INTEGER type. |
| -8098  | ON FILL BUFFER conflicts with DISPLAY ARRAY as a tree.  
The DISPLAY ARRAY instruction is using a treeview as decoration, but it implements also an ON FILL BUFFER trigger to do paged mode. The paged mode is not possible when using a treeview, because all rows of visible nodes are required (i.e. the dialog cannot display a tree only with a part of the dataset).  
To populate dynamically the array for a treeview, use the ON EXPAND to add new nodes and ON COLLAPSE to remove nodes. |
| -8099  | The form 'form-name' is incompatible with the current runtime version. Rebuild you forms.  
The .42f form was probably compiled with an earlier version as the current runtime system.  
Recompile the form with the fglform compiler corresponding to the current fglrune. |
| -8100  | Attempt to access a closed dialog.  
A call to a DIALOG class method is done with a dialog object that has terminated.  
Review the program logic and call the DIALOG methods only for active running dialogs. |
| -8101  | The TABLE column tag 'tag-name' appears multiple times in the row definition.  
A TABLE column can only be used once in the row definition, you have probably repeated the same screen tag by mistake.  
Modify the TABLE row definition in the layout section in order to use each column only once. |
| -8102  | Syntax error in preprocessor directive.  
The source file contains a preprocessor macro with an invalid syntax.  
Check the preprocessor manual page and fix the syntax error. |
| -8103  | The source and destination file name of a file transfer must not be NULL or empty.  
The program is doing an fgl_getfile() or fgl_putfile() and the source or destination file name is NULL or empty.  
Provide a valid file name for both source and destination parameters. |
| -8104  | Cannot read from TUI: system-error.  
A program running in text mode (FGGUI=0) failed to read from console input stream.  
Check the console/terminal settings. |

| -8300  | Cannot load java shared library. Reason: system-error  
  **Note:** This error is **non-trappable**.  
The runtime system failed to load the JVM shared library (or DLL).  
Make sure that a JRE is installed on the machine and check the environment  
(LD_LIBRARY_PATH on UNIX™ or PATH on Windows®). |
| -8301  | Cannot create java VM.  
  **Note:** This error is **non-trappable**.  
The runtime system loaded the JVM shared library (or DLL), but was unable to initialize the  
Java VM with a call to JNI_CreateJavaVM().  
Check that the Java requirements and resources needs to create a Java VM. |
| -8302  | Array element type is not a Java type.  
The fglcomp compiler detected a Java Array definition which is not using a Java type for the  
elements.  
Review the DEFINE statement and use a Java type. |
| -8303  | Java is not supported.  
The platform you are using does not support a recent Java version required by Genero.  
**Note:** This error is **non-trappable**.  
You cannot use the Java interface in this operating system, you must review your source code  
and remove all Java related parts. |
| -8304  | Cannot assign a value to final variable 'variable-name'.  
The program tries to set a Java class variable which is not writable.  
Review the program logic. |
| -8305  | The Java variable 'variable-name' can not be used here.  
The program tries to use a Java class variable in an invalid context. For example, a Java class  
variable is used in an INPUT instruction.  
Review the program logic and use a regular Genero BDL variable. |
| -8306  | Java exception thrown: java-exception-text.  
A Java exception has been thrown while executing Java code.  
Check the exception text and review the code. |
| -8307  | Java object required.  
A Java object reference is expected by the instruction. This error typically occurs in a CAST()  
or INSTANCEOF().  
Check the expression used in the instruction and make sure it references a Java object. |

<td>RECORD initializer expected.</td>
</tr>
<tr>
<td></td>
<td>The provided initialization value does not use the ( ) notation for RECORD variable definition.</td>
</tr>
<tr>
<td>Number</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| -8422  | ARRAY initializer expected.  
The provided initialization value does not use the [ ] notation for an ARRAY variable definition. |
| -8423  | Scalar initializer expected.  
The provided initialization value does not use a scalar value for the primitive-typed variable definition. |
| -8424  | Record member 'name' not exists.  
The provided initialization value specifies a member name that does not match the members of the RECORD variable definition. |
| -8425  | Duplicate field in RECORD initializer: 'name'.  
The provided initialization value defines duplicate RECORD member names. |
| -8426  | Imported symbol 'method-name' can not be qualified in a macro.  
Methods for types must be defined in the module where the TYPE is defined. |
| -8427  | >Imported symbol 'symbol-name' can not be qualified in an include file.  
An file included by the preprocessor &include instruction is referencing a symbol defined in an imported module. This practice is not recommended, reduce the dependencies between imported symbols and code produced by the preprocessor code. Move the code from included file into the imported module. |
| -8428  | A method definition requires a RECORD type defined locally in this module.  
A method is defined in the module for a RECORD type that is not defined in this module, or with a type that is not a RECORD. RECORD types and methods for this type must be defined in the same module. |
| -8429  | Method and field names must distinguish. Type type-name has field filed-name.  
A method for a type cannot use the same name as one of the fields of the RECORD type. |
| -8430  | The method method-name has already been defined.  
A method for type is defined twice in the module or in an interface definition. Rename one of the methods if it's not duplicated code, or remove one occurrence of the method listed in the interface. |
| -8431  | Method parameters or return values can not have anonymous types.  
A method defines a parameter with a RECORD, DYNAMIC ARRAY, DICTIONARY, etc, that defines an implicit anonymous type. This is not allowed in methods. First define a user type with the TYPE instruction, then use this type for the method parameter(s). |
| -8432  | An INOUT parameter requires a RECORD type.  
The INOUT keyword can only be used with a type name declared by TYPE definition. |

</table>
| -15553 | TCP runtime exception, see SQLCA.SQLERRM for more details. If detailed message is 'The TCP connection has been interrupted', then check that your network was working properly and that the INT_FLAG was not set to TRUE. When working with a Web Service application, this can be the result of a COM error. Check in FGLWSDEBUG to see whether it was shut down on the client or server side. For example:  
    WS-DEBUG (IO ERROR)  
    Class: TCPConection::atomicReceive()  
    Msg: TCP input stream shut down.  
    Code: 104  
    WS-DEBUG END=  
    You can find the 104 code in /usr/include/asm-i386/errno.h (depending on your system). In this example it corresponds to: #define ECONNRESET 104 /* Connection reset by peer */  
    • Review the WSDL and see if what we send to the server is correct  
    • Review the server log and see why it has ended the connection |
<p>| -15554 | Index is out of bound. Check your index maximum value. |

### Web services

Create a Web service client or server with Genero BDL.

The Genero APIs for creating Web services can be found in the Library section of this manual. See The com package on page 2811, The xml package on page 2931, and The util package on page 2726.

### General

These topics provide you with an introduction to Genero Web Services and the information needed to get working with the latest version of the software.

### Introduction to Web services

Web services are a standard way of communicating between applications over an intranet or Internet.

Web services can be invoked via the HyperText Transfer Protocol (HTTP), by requests for services, and information is returned in either JSON documents or XML documents. It does not matter if the platform that runs the Web Service is different to the platform that receives the JSON or XML document.

Genero Web Services supports Web services implemented by the Simple Object Access Protocol (SOAP) and Representational State Transfer (REST) architecture, which are defined standards for communicating with Web services. A Web service defines how to communicate between two entities:

- A server that exposes services
- A client that consumes services

### Server usage example

A server exposes, for example, a "StockQuotation" service that responds to an operation "getQuote". For the "getQuote" operation, the input message is a stock symbol as a string, and the output message is a stock value as a decimal number.

The "getQuote" operation is a function written in Genero BDL, and it is published on the server. This function retrieves the stock value for the stock symbol passed in, and returns it.

### Client usage example

The Web service client application calls the function as if it were a local function. It passes the stock symbol to the function, and stores the returned value in a variable.
SOAP

If the Web service operation is named `WebService_StockQuotation_getQuote` and the local variable is `svalue`, the Web service is called as follows:

```plaintext
LET svalue = WebService_StockQuotation_getQuote( "MyStockSymbol" )
```

REST

The Web service operation is requested using the URI with the required parameter that matches the function defined in the "StockQuotation" Web service server side. Therefore, `quotes` becomes the resource name part of the URI included in our example code. `req` is defined as an object of the `com.HTTPRequest` class.

```plaintext
```

Related concepts

REST Web services on page 3374

Genero Web Services allows you to write Web Services server and client applications for the REST Web standard architecture.

Service Oriented Architecture (SOA) and Web services

Service Oriented Architecture (SOA) is based on a philosophy of how to connect systems and exchange data to solve business problems.

Rather than concentrating on a specific task or transaction, SOA addresses how to use data from various sources, reduce human involvement, and mitigate the effects of change in a business process and its supporting systems.

SOA defines the services to be provided. Web services are the means of implementing those services. Web services provide a platform-neutral technology to connect multiple systems in a flexible manner, where the platform-neutrality helps insulate the SOA from changes to the underlying systems.

An SOA's resilience to change is accomplished by adhering to good Web services design practices:

- Building a Web service that performs a specific task
- Having a rigid structure for the data

Migrating to SOA and Web services

To migrate your application from an existing integration method to a Service Oriented Architecture (SOA) one and move to Web services requires an iterative and evolutionary approach.

It requires work and diligent design. When switching to Web services, it is recommended to initially focus on short-term business benefits, targeting an SOA and Web services project that has tangible goals with measurable benefits.

Once an SOA contains some useful services, these services can be arranged together in a workflow that automates a business process. Web services can be reused to answer new questions, and be implemented as new business services in an SOA.

A well-defined Web service does not contain business logic or business process information. Since each Web service in an SOA can be called individually to perform a specific task, they can be arranged (orchestrated) together to perform many different business functions. As a result, companies with a mature SOA in place can change business processes through configuring the orchestration software as opposed to programming individual links between systems.

Planning a Web service

Creating a Web service application requires planning for the future use and reuse of the service.

When creating a Web service, you not only have to think of the task at hand, but you must also consider growth. You likely want the Web service to be flexible; to be able to handle different types of input. Prepare the Web service for what is probable. Developers should think bigger than the needs of a single application. Consider how you might reuse existing services, and how your services might be reused by others.
Security will likely play a larger role than it did previously with existing in-house application infrastructures using programmed links between systems; you will need to become versed in security issues.

Decide which protocol is right for your requirements, Simple Object Access Protocol (SOAP) or Representational State Transfer (REST).

While both are similar, it is worth researching the advantages of one over the other in terms of the requirements and scope of your project. Keep in mind when designing and coding Web services that you need to have: Flexibility, Reusability, and Interoperability.

**Related concepts**

- **SOAP** on page 3273
  Simple Object Access Protocol (SOAP) is a communication protocol that defines an XML data flow between a server and a client.

- **REST** on page 3274
  Representational State Transfer (REST) is a Web standard architecture that provides a method for communication between a Web service and a client over HTTP.

- **Designing REST Web services** on page 3374
  Planning the resources that the client can interact with is essential to REST Web service design.

**Genero Web Services extension**

Applications providing Web services use special libraries of the Genero Business Development Language.

The Genero Web Services Extension (GWS) is an extension to the Genero Business Development Language. It installs within the Genero Business Development Language directory. The fglgws package includes both Genero Business Development Language and Genero Web Services.

The Genero Application Server is required to manage your Web services in a deployment environment. It is not required for Web services development, unless you are interested in testing deployment issues.

**Important:** When programming a Web service, your applications must include `IMPORT com` at the top of each module. This imports the Genero Web Services Extension library named `com`:

```
IMPORT com
```

**Web services standards**

Web services standards are defined by the World Wide Web and other organizations.

For more information about these standards, refer to the "Web services" section of [http://www.w3.org](http://www.w3.org). The Genero Web Services package supports the WSDL 1.1 specification of March 15, 2002 as well as some previous specifications.

Starting with FGLGWS version 3.20, the GWS supports the OpenAPI Specification (OAS), based on the original Swagger 2.0 specification, as the standard for defining and describing RESTful APIs. For more information see the web site at [http://www.openapis.org/](http://www.openapis.org/).

The standards involved in what is commonly called "Web services" include XML, JSON, XML Schema, SOAP, REST, WSDL, and HTTP.

**XML**

XML (eXtensible Markup Language) defines a machine-independent way of exchanging data.

For example, an XML representation of the following BDL data structure:

```bdl
DEFINE Person
RECORD Attribute (XMLName="Person")
    FirstName VARCHAR(32) Attribute (XMLName="FirstName"),
    LastName VARCHAR(32) Attribute (XMLName="LastName"),
    Age INTEGER Attribute (XMLName="Age")
END RECORD
```
Would be:

```xml
<Person>
  <FirstName>John</FirstName>
  <LastName>Smith</LastName>
  <Age>35</Age>
</Person>
```

The record definition allows you to specify XML attributes for data types. This feature was added with Genero 2.00.

**JSON**

JavaScript Object Notation (JSON) defines a machine-independent way of exchanging data.

For example, a JSON representation of the following BDL data structure:

```bdl
DEFINE Person
RECORD Attribute (XMLName="Person")
  FirstName  VARCHAR(32) Attribute (XMLName="FirstName"),
  LastName   VARCHAR(32) Attribute (XMLName="LastName"),
  Age        INTEGER Attribute (XMLName="Age")
END RECORD
```

Would be:

```
{
  "FirstName": "John",
  "LastName": "Smith",
  "Age": 27
}
```

**XML schema**

XML Schema defines the elements, entities, and content model of an XML document.

For example, for the example document shown in the topic **XML** on page 3272, the schema might indicate that the XML document contains an element "Person", and that each "Person" contains one and only one element "FirstName", "LastName", and "Age". The XML Schema has additional capabilities, such as data type control and content restrictions.

An XML Schema allows an XML document to be validated for correctness.

**SOAP**

Simple Object Access Protocol (SOAP) is a communication protocol that defines an XML data flow between a server and a client.

Web services using the Simple Object Access Protocol (SOAP) protocol provide information about their use that developers can invoke using the **Web services Descriptive Language (WSDL)** to generate a WSDL document.

Each SOAP Web service must have an associated WSDL document, so that developers and applications know what to expect from the Web service, and how to invoke it.

The "StockQuote" service mentioned in the **Introduction to Web services** on page 3270 exchanges messages using the following syntax:

**Response**

```xml
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/"
  xmlns:getQuoteResponse="http://www.sok.com/">
  <soap:Body>
    <getQuoteResponse>
      <stockValue>999.99</stockValue>
    </getQuoteResponse>
  </soap:Body>
</soap:Envelope>
```
SOAP relies on a lower-level protocol for the transport layer. Genero Web Services use SOAP over HTTP, and can also perform low-level XML and TEXT over HTTP communications on the client side. This allows communication between applications using the core Web technology, taking advantage of the large installed base of tools that can process XML delivered plainly over HTTP, as well as SOAP over HTTP.

REST
Representational State Transfer (REST) is a Web standard architecture that provides a method for communication between a Web service and a client over HTTP.

REST Web service resources are implemented through representations. Representations are the state of the resource transferred between the client and the server. Typically, these representations are sent and received in JSON or XML format.

If, for example, the client representation is to get some records from a database, the server does not send its database, instead it sends some JSON or XML that represents these records.

RESTful Web services are stateless. Each HTTP request–response message between the client and the server must be self-descriptive and include enough information to process the message.

The Web services client application request delivers state via body contents, query parameters, request headers, and the requested URI (the resource name).

The "StockQuote" service mentioned in the Introduction to Web services on page 3270 may receive a request for services, and information is returned in JSON as shown in the following:

**Request**

```
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/">
  <soap:Body>
    <getQuote>
      <stockSymbol>MyCompany</stockSymbol>
    </getQuote>
  </soap:Body>
</soap:Envelope>
```

**Response**

According to the HTTP request headers (Accept and Content-type), the response is delivered as JSON.

```
{
  "stockValue": "999.99"
}
```

**Related concepts**

REST Web services on page 3279
Special attributes in the BDL function provide for REST high-level Web services, while low level REST web services are implemented using standard HTTP classes.

**WSDL**
Web Services Description Language (WSDL) is an XML-based language that describes the services offered by a SOAP server.

A WSDL description or file containing that description is sufficient to provide all the information required to communicate with the server. It contains:

- The description of the operations offered by the server, and each operation's input and output messages.
- The location of the SOAP server.
- Internal connection and protocol details (transport layer, encoding, namespaces, and so on).

Genero Web Services package provides the fglwSDL tool that enables Genero client applications to obtain the WSDL description of a Web service.

**HTTP**
Hypertext Transfer Protocol (HTTP).

HTTP is the set of rules for exchanging files (text, graphic images, sound, video, and other multimedia files) on the World Wide Web.

**Web services style options**
Information on Web services Style options available for SOAP Genero Web services. There is no style concept in REST.

The Web services Style options available for created SOAP Genero Web services are WS-I (Web services Interoperability organization) compliant:

- **RPC Style Service (RPC/Literal)** is generally used to execute a function, such as a service that returns a stock option.
- **Document Style Service (Doc/Literal)** is generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document.
- **RPC Style Service (RPC/Encoded)** is the legacy style, now provided for backward compatibility. You most likely will not be using the RPC/Encoded style to create new Web services.

**Related concepts**
Choosing a web services style on page 3358

Genero Web Services contains style options for creating SOAP Web services. Your choice is dependent on the type of service, (Document or RPC), and the encoding mechanism (literal or encoded) required.

**GWS demos and examples**
Demos and examples are provided for both SOAP and RESTful Web services.

**Demos**
Web Services demos are located in $FGLDIR/demo/WebServices. Each demo sits in its own folder, and includes the code for both the client and the server. A readme.txt file provides details about the demo.

For SOAP demos, the description in the readme.txt file indicates a Web service such as: an RPC style Web service demonstration, a Document Style Web service demonstration, RPC encoded Web service demonstration, Stateful Web service demonstration, or Doc Literal Web service demonstration with XML-Security.

For RESTful demos, the description in the readme.txt file indicates a Web service such as a REST service demonstration, or a low-level Web service demonstration.

**Tutorials and Examples**
Examples are provided within this manual.
For a tutorial-style example of a SOAP Web service, start with Writing a Web Services client application on page 3321 and Writing a Web Services server application on page 3342.

For a tutorial-style example of a RESTful Web service, start with Writing a Web services client application on page 3418 and Writing a Web Services server application on page 3430. The full application code can be viewed at The RESTful calculator demo source on page 3436.

Debugging

Turn on the debug mode to log the data sent or received by your Web service application.

Debug information is written to the standard error stream of the console. If needed, it can be redirected to a file.

To turn on the debugging feature, set the FGLWSDEBUG environment variable before starting the application.

The level of debugging depends on the value set for the FGLWSDEBUG variable. See FGLWSDEBUG on page 283.

Note: To debug a Web Service application managed by the Genero Application Server (GAS), you have to modify the value of the FGLWSDEBUG environment variable in the GAS configuration file. To understand how environment variables are set within the GAS configuration file, see the ENVIRONMENT_VARIABLE topic in the Genero Application Server User Guide.

Platform-specific notes

Some platforms have specific requirements.

Web Services on IBM® AIX®

Requirements for IBM® AIX®.

• The "IBM® C++ Runtime Environment Components for AIX®" must be installed in order to use Genero Web Services. See the IBM® support center for more information about downloading the component.

  Note: If not installed, you will get the following error message:

  Could not load C extension library 'com'. Reason: A file or directory in the path name does not exist.

• Due to an IBM® issue on 64-bit platforms, the OpenSSL library is unable to open the system /dev/urandom device to generate a PRNG number.

  If you want to use security APIs in your GWS application (especially if you access a server in HTTPS), install Entropy Gathering Daemon (EGD).

Web Services on GMI (iOS)

Requirements to use Web services on iOS platforms (GMI).

Web services configuration options

GWS configuration FGLPROFILE entries related to SSL/TLS keys (security.*) are not supported (uses iOS native SSL/TLS).

Long running HTTP request

When executing an HTTP request (for example with com.HTTPRequest.doRequest()), if the request takes a long time to complete (for example, several minutes), the app will go into background mode. If the user taps the app icon to return to foreground mode, the program will get the runtime error -15553.

The XSLTTransformer class

The XSLTTransformer class is not available on iOS.
Web Services on GMA (Android™)
Requirements to use Web services on Android™ platforms.

V3 SSL Certificates
The SSL certificates for secured servers must be of type V3: Android™ does not support other types of SSL certificates. When creating your own self-signed certificates (to be installed in the "Install from storage" Keystore of Android), make sure that type V3 is used.

Known issues
There are some known issues when working with Web services.
These issues are specific to SOAP Web Services.

Forcing RPC style convention when no input message
In RPC style, the convention defines names for input messages and output messages, but if there is no input message, its name cannot be redefined.

To workaround this issue, respect RPC style convention in WSDL, or force RPC convention (on client and server side) by using the -fRPC option of the fglwsdl tool.

Variable names conflicts with library names
The fglwsdl tool can generate variable names conflicting with IMPORT library names.

For example:

```plaintext
DEFINE xml xml.DomDocument
```
will conflict with the xml library, if the code defines also the instruction:

```plaintext
IMPORT xml
```

Concepts
These topics cover various Genero Web Services concepts.

Genero Web Services APIs
This section provides overview information on the Web services Application Program Interfaces (APIs).

Web services work by responding to requests for data and returning JSON or XML documents. As JSON and XML are simple text formats, Web services are invoked via APIs over the Hypertext Transfer Protocol (HTTP).

Genero Web Services support SOAP and REST Web services.
SOAP Web services APIs
Special APIs are provided for use in creating SOAP Web services.

High-level and low-level SOAP APIs
High-level APIs use specially-designed classes to implement your Web service's function with minimal coding, while low-level APIs use standard HTTP classes that require you to code everything by hand.

SOAP high-level APIs
- The high-level APIs include the following:
  - The com.WebServices class is used to implement a Web service on the server. Instances of this class are used to create a Web service that can be stateless or stateful. Object methods for registering HTTP headers for request and response handling, and generating the WSDL are provided by this class.
  - The com.WebOperation class provides for the interface to create and manage the operations of a Web service. Instances of this class are used to create different style options (Document or RPC) and the encoding mechanism (literal or encoded) for the service. Object methods for this class are used to set the headers, action, and encoding. A stateful Web service can also be initiated by this class.
  - The com.WebServiceEngine class provides an interface to manage the Web Services engine. Instances of this class are used to start the service and handle HTTP requests. This class also handles request faults, timeout, and cookie options for both client and server.

If you have generated code via the fglwsdl tool (client and server side), these high-level APIs are automatically used.

SOAP low level APIs
Web services can be implemented with the HttpServletRequest, HttpServletResponse and HttpSessionRequest classes, but you have to write all the HTTP code of your services by hand.

Related concepts
Writing a Web Services server application on page 3342
Create a Genero Web Services server using the SOAP protocol.

Writing a Web Services client application on page 3321
Create, configure and deploy a Genero Web Services client using the SOAP protocol.

When to use high-level SOAP APIs
The recommendation is to use the high-level APIs wherever possible to implement SOAP Web services.

High-level APIs require less code in your application. They provide functionality that would otherwise need to be handled with many low-level API calls. They are therefore easier to use in comparison with low-level APIs.

You can perform a defined set of simple functions with one call to a high-level API. The global endpoint user-defined type (tGlobalEndpointType) generated by the WSDL stub, is used by the high-level API. For example, you can set variables for the interface, binding, etc., in the endpoint type record at runtime. For an example of this use see the Compression and a Web services client on page 3295.
Related concepts

Writing a Web Services server application on page 3342
Create a Genero Web Services server using the SOAP protocol.

Writing a Web Services client application on page 3321
Create, configure and deploy a Genero Web Services client using the SOAP protocol.

When to use low-level SOAP APIs
The recommendation is to use the high-level APIs wherever possible to implement SOAP Web services.

However, when there is need for more detailed and granular control, you may opt to use the low-level APIs. Low-level APIs may be needed in specific scenarios because a high-level implementation may not yet be available.

For example, a request to send an attached file in separate parts of the request requires a low-level implementation of a multipart style SOAP request. For an example of this implementation see SOAP multipart style requests in GWS on page 3297.

REST Web services
Special attributes in the BDL function provide for REST high-level Web services, while low level REST web services are implemented using standard HTTP classes.

High-level framework and low-level REST APIs
REST Web services implemented with the high-level framework outweigh a low-level solution in terms of ease of creation. Yet make sure you are aware of the differences, and when one or other is preferred, or both are needed.

REST high level

Web services implemented with the high-level REST framework use the Function attributes feature to define details of the Web service. Function attributes are specified in an ATTRIBUTES() clause of the function to define operation type, and path. Attributes also define parameters for path template, query strings, return values, etc., of your RESTful Web service function. These special attributes for REST high-level define the framework for creating REST web services.

Web service function attributes are identified with the WS* prefix. For example, the sample function add, is defined on the server side using the attributes, WSGET, WQUERY, WSPATH, and WSDESCRIPTION.

```
PUBLIC # Query sample
FUNCTION Add(a INTEGER ATTRIBUTES (WQUERY), b INTEGER ATTRIBUTES (WQUERY))
ATTRIBUTES (WSGET, WSPATH='/' add', WSDESCRIPTION='Simple query sample')
RETURNS (INTEGER)
RETURN a + b
END FUNCTION
```
When you need to determine what functions are available on the server, you can use the fglrestful tool (server side), to get all of the information necessary in an OpenAPI specification file (JSON or YAML). The fglrestful tool can also generate code automatically for the client.

REST low-level APIs

The standard HTTP classes HttpRequest, HTTPResponse, and HTTPServiceRequest are available if you need to code individual commands. Be aware that you have to write all the HTTP code of your services by hand.

The client stub generated by the fglrestful tool implements low-level APIs.

Related concepts
RESTful Web services with high-level framework on page 3375

To create a RESTful Genero Web services server application, there are a minimum of five steps that the server application must handle.

Writing a Web services client application on page 3418
Create, configure and deploy a RESTful Genero Web Services (GWS) client.

SOAP features
The GWS provides support for SOAP versions and for managing SOAP fault.

SOAP 1.1 and 1.2
GWS is able to communicate with Web services provided with SOAP 1.1 or SOAP 1.2.

Since 2.40, Genero Web Services (GWS) supports SOAP 1.2.
Server side

A Genero Web Services server can deliver a service in SOAP 1.1 or SOAP 1.2 using the `com.WebService.setFeature` function.

For example in $FGLDIR/demo/WebServices/calculator/server/calculatorServer.4gl, the calculator server offers the service in SOAP 1.1 and SOAP 1.2.

```plaintext
CALL serv.setFeature("Soap1.1",TRUE)
CALL serv.setFeature("Soap1.2",TRUE)
```

Client side

A GWS client can consume a service in SOAP 1.1 or SOAP 1.2.

For example:

- To create a client that consumes the Calculator service in SOAP 1.1 use command:
  ```bash
  ```
- To create a client that consumes the Calculator service in SOAP 1.2 use command:
  ```bash
  ```

Be aware that when generating different clients for each SOAP version, even if the same operations are provided, the services are using different protocols so the underlying generated stubs are also different.

SOAP Fault

Genero Web Services supports SOAP's built-in error handling.

Since 2.40, Genero Web Services supports SOAP fault.

For backward compatibility, the `fglwsdl` tool provides the `--ignoreFaults` option to disable SOAP fault management.

Server side

A Genero Web Services server can throw a SOAP fault when a processing error is encountered.

To generate a SOAP fault you need to:

- create the fault variable with `com.WebService.createFault()`
- add it to your operation with `com.WebOperation.addFault`
- use it with `com.WebServiceEngine.SetFaultDetail`

For example in $FGLDIR/demo/WebServices/calculator/server/calculatorServer.4gl, the calculator server has a `divide_by_zero` SOAP fault. The SOAP fault is raised when you try to divide a number by zero. To generate a SOAP fault proceed as follows:

Create a SOAP fault

You define the variable to send as a SOAP fault. It can be a simple string like in this example or a complex type. Remember to assign an XMLName to the variable.

```plaintext
DEFINE divide_by_zero STRING ATTRIBUTES (XMLName="DividedByZero")
```

Then you provide the fault variable to the service using the function `com.WebService.createFault()`.

```plaintext
CALL serv.createFault(divide_by_zero,FALSE)
```
Add the SOAP fault to an operation

A SOAP fault can be used by an operation in response to the client when an error has occurred in the service request. An operation can use different SOAP faults but **only one at a time**.

```plaintext
LET op = com.WebOperation.CreateRPCStyle("divide","Divide",divide_in,divide_out)
CALL op.addFault(divide_by_zero,NULL)
```

Here, the SOAP fault is added to the "divide" operation.

**Send the SOAP fault**

Set the values to the fault variable. The fault message is sent to the client at the end of the operation processing.

```plaintext
LET divide_by_zero = "Cannot divide "||divide_in.a||" by zero"
CALL com.WebServiceEngine.SetFaultDetail(divide_by_zero)
```

**Client side**

A Genero Web Services client can receive a SOAP fault number in the operation status and act accordingly.

If a SOAP fault occurs, the operation returns the SOAP fault number in the operation status. The SOAP fault number is defined in the generated stubs as a BDL constant prefixed with the string **FaultID_**.

**Note:** A SOAP fault can occur in case of HTTP error 200 and 500.

For example in `$FGLDIR/demo/WebServices/calculator/client/ws_calculator.inc`, the `Divide` operation has a SOAP fault that informs the client when a number is divided by zero.

```plaintext
# List of Soap fault constants
CONSTANT FaultID_DividedByZero = 1
...
# VARIABLE : DividedByZero
DEFINE DividedByZero STRING ATTRIBUTES(XMLName="DividedByZero",
   XMLNamespace="http://tempuri.org/")
...
# Operation: Divide
# FAULT #1: GLOBALS DividedByZero
```

You can test the operation status code accordingly and display the SOAP fault message.

For example in `$FGLDIR/demo/WebServices/calculator/client/calculatorClient.4gl`, when the divide operation status is 1, `DividedByZero` message is displayed.

```plaintext
ON ACTION divide
   CALL Divide(op1, op2) RETURNING wsstatus, result, remaind
   CASE wsstatus
      WHEN 0
         DISPLAY BY NAME result,remaind
         DISPLAY "OK" TO msg
      WHEN FaultID_DividedByZero
         DISPLAY DividedByZero TO msg
      OTHERWISE
         DISPLAY wsError.description TO msg
   END CASE
```
Stateful SOAP Web services

The GWS provides support for stateful service. Different options for implementing SOAP stateful services are described.

Concept
A stateful service is a service that maintains a context between a Web services client and server. It enables the service to keep track of previous requests from that context, in order to manage different states in the Web service server.

SOAP stateful Web service

Genero Web Services supports two kinds of stateful services:

- Based on the WS-Addressing 1.0 specification to define the XML format used to convey the context from the client to the server.
- Based on an HTTP session cookie to convey the context from the client to the server.

The Genero Web Service engine uses a BDL variable defined at stateful service creation via `createStatefulWebService()` as service context. Use that variable to hold a service state in a database.

It is up to the BDL programmer to create, store and remove the service state in the database.

The SOAP engine is responsible for:

- Deserializing the state variable when getting a new incoming request. The programmer can then read the state variable for any published BDL Web service operation and restore the service state corresponding to that variable.
- Serializing a new instance of the state variable in a Web service response for all BDL Web service operations set as session initiator via `initiateSession()`. The programmer must instantiate a new state by filling the state variable and storing it in a database for future use.

WS-Addressing 1.0 stateful services

WS-Addressing 1.0 uses the WS-Addressing EndpointReference type as a state variable to maintain a stateful service.

The `EndpointReference` type is independent from the transport layers. (See WS-Addressing 1.0 EndpointReferenceType). The session state is conveyed from the client to the server as WS-Addressing 1.0 reference parameters.

Server side

Perform these steps to create a WS-Addressing stateful service.

Step 1: Declare a W3C EndpointReference record to be used as state variable

This record MUST have:

- A mandatory member of type STRING, where you can define a different service end point URL, otherwise the current server URL will be used.
- A sub record to contain one or more BDL variables used as state variables and defined as reference parameter in the WS-Addressing 1.0 specification.

For example:

```bdl
DEFINE EndpointReferenceState RECORD ATTRIBUTES(W3CEndpointReference)
  address STRING, # Mandatory
  ref RECORD # Sub-record Reference parameters containing one # or more state variables
    OpaqueID STRING ATTRIBUTES(XMLName="OpaqueID"), # Unique ID to
    # identify the service state in the database
    Expiration DATE ATTRIBUTES(XMLName="Expiration",
    # Session state expiration date
    XMLNamespace="http://tempuri.org")
END RECORD
END RECORD
```

You can use a unique ID from a database table to manage the Web services sessions in place of `OpaqueID`. 
Related concepts
Step 2: Create a stateful WS-Addressing enabled web service with W3CEndpointReference record as a parameter on page 3284

**Step 2: Create a stateful WS-Addressing enabled web service with W3CEndpointReference record as a parameter**

The Genero Web Service extension provides a new Web service constructor called `createStatefulWebService()` to perform stateful services. This function works as the stateless constructor, but expects a W3CEndpointReference record as parameter.

For example:

```
DEFINE serv com.WebService
  EndpointReferenceState) # Create a stateful service
  # with a W3CEndpointReference state variable
CALL serv.setFeature("WS-Addressing1.0","REQUIRED") # enable
  # support of WS-Addressing 1.0
```

Related concepts
Step 3: Publish a web service operation returning the W3CEndpointReference state variable and set it as session initiator on page 3284

**Step 3: Publish a web service operation returning the W3CEndpointReference state variable and set it as session initiator**

You must define which Web service operation will initiate the session on your service and return the W3CEndpointReference state variable.

All other Web service operations (not defined as session initiator) will return an error if they don't get reference parameters defined in the W3CEndpointReference state variable as WS-Addressing 1.0 headers.

For example:

```
DEFINE op com.WebOperation
LET op = com.WebOperation.CreateDocStyle("GetInstance",
  "GetInstance",NULL,EndpointReferenceState)
CALL op.initiateSession(TRUE)
CALL serv.publishOperation(op,NULL)
```

There is no restriction regarding the input parameter of the Web service initiator function, but the output parameter must be the same W3CEndpointReference record passed to the service creation constructor.

It is not required to have a Web operation which initiates the session in the same service, but then you have to return the same W3CEndpointReference record in another Web service to instantiate the session, such as a Factory service that instantiates all sessions for other stateful services.

Related concepts
Step 4: Create the BDL session initiator function and instantiate a new session on page 3284

**Step 4: Create the BDL session initiator function and instantiate a new session**

In your BDL function declared as session initiator, you have to:

- Handle the creation of the session
- Fill the state variable before returning from the function
- Store the new session in a database based on the state variable (in order to keep the session across consecutive requests from the same client).
For example:

FUNCTION GetInstance()
    LET EndpointReferenceState.address = NULL
    # Use default end point location
    LET EndpointReferenceState.ref.OpaqueID = com.Util.CreateUUIDString()
    # Generate an unique string (can come from a database table id)
    LET EndpointReferenceState.ref.Expiration = CURRENT + INTERVAL HOUR TO HOUR (1)
    # Create expiration date in one hour to discard request after that date
    ... Store OpaqueID into database or use directly a database table entry
    ... to hold the session
END FUNCTION

Related concepts
Step 5: Restore the session in any BDL web operation from the W3CEndpointReference record on page 3285

Step 5: Restore the session in any BDL web operation from the W3CEndpointReference record

In a published BDL Web function, the SOAP engine deserializes the WS-Addressing 1.0 reference parameter headers in the W3CEndpointReference sub-record so that you can retrieve the session from the state variable.

For example:

FUNCTION MyFunction()
    IF EndpointReferenceState.ref.OpaqueID IS NULL THEN
        CALL com.WebServiceEngine.SetFaultString("Invalid session id")
        RETURN
    ELSE
        ... Restore the service session based on the OpaqueID state
        ... variable from the database
    END IF
    ... Process the operation
END FUNCTION

Related concepts
Client side on page 3285
Perform these steps to communicate with a stateful Web service based on WS-Addressing 1.0.

Client side
Perform these steps to communicate with a stateful Web service based on WS-Addressing 1.0.

Step 1: Generate the client stub from your WS-Addressing stateful service

Use the fglwsdl tool as usual. It will detect that the service returns a W3CEndpointReference and generate the appropriate code.

The WSDL imports the WS-Addressing 1.0 schema, so the fglwsdl tool requires access to the W3C server. Use the option -proxy if you need to connect via a proxy server.

For example:

$ fglwsdl -o ws_stub http://localhost:8090/StatefulWSAddressingService?WSDL

The generated .inc file contains a variable of type tWSAGlobalEndpointType to be used to transmit the WS-Addressing 1.0 reference parameters.

Example of a global variable name

DEFINE
    StatefulWSAddressingService_StatefulWSAddressingServicePortTypeEndpoint
**Step 2: Create the MAIN application**

In your main application:

1. Import the XML library. This is due to the support of WS-Addressing 1.0 with `IMPORT XML`.
2. Import the generated `.inc` file with `GLOBALS "ws_stub.inc"`.
3. Manage the WS-Addressing 1.0 reference parameters representing the session state (if your client has to handle several instances of the same service).

For example:

```bdl
IMPORT XML # Import the XML library required for WS-Addressing 1.0
GLOBALS "ws_stub.inc" # Import service global definition

TYPE InstanceType DYNAMIC ARRAY OF xml.DomDocument
# End point WSA reference parameters

DEFINE instance1,instance2,instance3 InstanceType
# Store the different sessions the client will have to manage

MAIN
...
END MAIN
```

**Related concepts**

**Step 3: Instantiate a new session by calling the web service operation set as session initiator**

Call the BDL function generated from the WSDL that is defined as session initiator on the server. This function returns a `W3CEndpointReference` parameter that contains the WS-Addressing 1.0 reference parameters representing the new instance created on server side.

If your application handles several instances, you will have to copy and store those parameters in your application to identify a service instance for further requests.

As the WS-Addressing 1.0 reference parameters are defined as an XML document, they are represented as a dynamic list of `xml.DomDocument` in BDL.

For example:

```bdl
DISPLAY "Creating a new instance ..."
LET wsstatus = GetInstance_g() # call the service session initiator
# web function
IF wsstatus == 0 THEN
   FOR ind=1 TO
      ns1GetInstanceResponse.return.ReferenceParameters._LIST_0.getLength()
      LET instance1[ind]=
         ns1GetInstanceResponse.return.ReferenceParameters._LIST_0[ind].clone()
      # copy the service returned WS-Addressing 1.0 reference parameters
   END FOR
ELSE
   ... handle soap errors
END IF
```
**Important:** When creating a new instance, ensure that the Parameters member of the generated global variable of type `tWSAGlobalEndpointType` has been set to `NULL`, otherwise the server will throw an error.

**Related concepts**

*Step 4: Call any web service operation with previously returned WS-Addressing 1.0 reference parameters* on page 3287

*Step 4: Call any web service operation with previously returned WS-Addressing 1.0 reference parameters*

Before calling any Web service operation, you must set the WS-Addressing 1.0 reference parameters returned by a session initiator function to identify the session to the server.

For example:

```plaintext
LET StatefulWSAddressingService_StatefulWSAddressingServicePortTypeEndpoint.Address.Parameters.* = instance1.*
# assign WS-Addressing 1.0 reference parameters dynamic array by reference
CALL MyFunction("Hello") RETURNING wsstatus,ret
# Call web operation MyFunction of instance 1
```

**Stateful services based on HTTP cookies**

A stateful service based on HTTP cookies uses the HTTP transport protocol and its ability to transmit cookies, used as session context.

**Note:** This works only if the communication path between the client and the server is carried in HTTP, otherwise it is recommended to use WS-Addressing stateful services.

**Server side**

Perform these steps to create an HTTP cookie based stateful service.

*Step 1: Declare any BDL simple variable to be used as state variable*

For example:

```plaintext
DEFINE ServiceState STRING # Unique ID to identify the service state in the database
```

For instance, you can use a unique ID from a database table to manage the Web services sessions.

**Related concepts**

*Step 2: Create a stateful web service with state variable as parameter* on page 3287

*Step 2: Create a stateful web service with state variable as parameter*

The Genero Web Service extension provides a new Web service constructor called `createStatefulWebService()` to perform stateful services. This function works as the stateless constructor, but expects a simple state variable as parameter.

**Example**

```plaintext
DEFINE serv com.WebService
# Create a stateful service with a simple BDL variable as state variable
```

**Related concepts**

*Step 3: Publish a Web service operation defined as session initiator* on page 3287

*Step 3: Publish a Web service operation defined as session initiator*

Define which Web service operation will initiate the session on your service and instantiate a new session. All other Web service operations (not defined as session initiator) will return an error if they don't get an HTTP cookie called `GSESSIONID`. 
For example:

```plaintext
DEFINE op com.WebOperation
LET op =
CALL op.initiateSession(true)
CALL serv.publishOperation(op,NULL)
```

There is no restriction on the Web service session initiator function regarding the input and output parameters.

**Related concepts**

*Step 4: Create the BDL session initiator function and instantiate a new session* on page 3288

**Step 4: Create the BDL session initiator function and instantiate a new session**

In your BDL function declared as session initiator, you must:

- Handle the creation of the session.
- Fill the state variable before returning from the function.
- Store the state variable in a database based on the state variable (in order to keep the session across consecutive requests from the same client).

For example:

```plaintext
FUNCTION GetInstance()
    # Generate an unique string (can come from a database table id)
    LET ServiceState = com.Util.CreateUUIDString()
    ... Store ServiceState value into database or use directly a database table entry to hold the session
END FUNCTION
```

**Related concepts**

*Step 5: Restore the session in any BDL web operation from the state variable* on page 3288

**Step 5: Restore the session in any BDL web operation from the state variable**

In a published BDL web function, the SOAP engine deserializes the HTTP Cookie called `GSESSIONID` from the HTTP layer into the state variable. You can then retrieve the session in BDL via that state variable.

For example:

```plaintext
FUNCTION MyFunction()
    IF ServiceState IS NULL THEN
        CALL com.WebServiceEngine.SetFaultString("Invalid session id")
        RETURN
    ELSE
        ... Restore the service session based on the ServiceState variable from the database
    END IF
    ... Process the operation
END FUNCTION
```

**Related concepts**

*Step 6: Deployment recommendation* on page 3288

**Step 6: Deployment recommendation**

When deploying stateful Web services based on HTTP cookies, the complete server path will be added to the cookie when first instantiated, so you must pay attention to that URL. In other words, you MUST always call the service via the complete URL containing the service name.
For instance if your service is named **MyService** and if your GAS configuration file is called "Server.xcf", the stateful service is accessible at URL: http://localhost:6394/ws/r/group/Server/MyService.

**Client side**
Perform the following steps to communicate with a stateful Web service based on HTTP cookies.

*Step 1: Generate the client stub from your stateful service*

Use the fglwsdl tool as usual.

For example:

```bash
$ fglwsdl -o ws_stub http://localhost:8090/StatefulCookieService?WSDL
```

The generated `.inc` file contains a variable of type `tGlobalEndpointType` to be used to transmit the HTTP Cookie.

**Example of a global variable name**

```plaintext
DEFINE StatefulCookieService_StatefulCookieServicePortTypeEndpoint tGlobalEndpointType
```

**Related concepts**

*Step 2: Create the MAIN application* on page 3289

**Step 2: Create the MAIN application**

In your main application:

- Import the generated `.inc` file with `GLOBALS "ws_stub.inc"`.
- Manage the HTTP cookies representing the session state (if your client has to handle several instances of the same service).

For example:

```plaintext
GLOBALS "ws_stub.inc" # Import service global definition

# Store the different sessions the client will have to manage
# in a string
DEFINE instance1,instance2,instance3 String

MAIN
    ...
END MAIN
```

**Related concepts**

*Step 3: Instantiate a new session by calling the web service operation set as session initiator* on page 3289

**Step 3: Instantiate a new session by calling the web service operation set as session initiator**

Call the BDL function generated from the WSDL that was defined as session initiator on the server. This function returns a new HTTP Cookie saved in the `Binding.Cookie` member of the global service variable of type `tGlobalEndpointType`. If your application handles several instances, you will have to copy and store that cookie in your application to identify a service instance for further requests.

For example:

```plaintext
DISPLAY "Creating a new instance ..."
LET wsstatus = GetInstance_g() # call the service session
    # initiator web function
IF wsstatus == 0 THEN
    # copy the service returned HTTP cookie
    LET instance1 =
```
When creating a new instance, ensure that the Binding.Cookie member of the generated global variable of type tGlobalEndpointType has been set to NULL, otherwise the server will throw an error.

**Related concepts**

Step 4: Call any web service operation with previously returned HTTP cookie on page 3290

*Step 4: Call any web service operation with previously returned HTTP cookie*

Before calling any Web service operation, set the HTTP cookie returned by a session initiator function to identify the session to the server.

For example:

```plaintext
# use instance1
LET
  StatefulCookieService_StatefulCookieServicePortTypeEndpoint.Binding.Cookie = instance1
# Call web operation MyFunction of instance 1
CALL MyFunction("Hello") RETURNING wsstatus,ret
```

**Related concepts**

Step 5: Troubleshooting on page 3290

*Step 5: Troubleshooting*

If your Genero application doesn't set the HTTP cookie when accessing a stateful service via the GAS, it may be because you did not use the complete URL when accessing the service.

For instance if your service is named MyService and if your GAS configuration file is called Server.xcf, the stateful service is accessible at URL: http://localhost:6394/ws/r/group/Server/MyService.

**Encryption, BASE64 and password agent with fglpass tool**

Genero Web Services supports password encryption with fglpass as password agent.

For security reasons, it is recommended that you avoid storing clear passwords in a file. The Genero Web Services enables the password encryption of a HTTP Authenticate entry in the FGLPROFILE file. The encrypted password is decrypted by the Genero Web Services engine when required.

**The fglpass tool**

With the fglpass tool you can encrypt and decrypt passwords.

The Genero Web Services package provides a command line tool called fglpass, which can be used to encrypt a password from an X.509 certificate or a RSA private key. The encrypted password is displayed on the console in Base64 form, composed only of alphanumerical characters, and therefore easily usable in any text file.

See [fglpass](#) for more details.

**Encrypt a HTTP authenticate password for FGLPROFILE**

Use the fglpass tool to encrypt a password to store in the FGLPROFILE file.

1. Find the HTTP Authenticate entry with the password you want to encrypt:

```plaintext
authenticate.myentry.login = "mylogin"
authenticate.myentry.password = "mypassword"
```
2. Add the certificate and its private key in the FGLPROFILE file as follows:

```plaintext
security.mykey.certificate = "MyCertificate.crt"
security.mykey.privatekey  = "MyPrivateKey.pem"
```

3. Encrypt the password with fglpass:

```
$ fglpass -e -c MyCertificate.crt
Enter password :mypassword
```

The fglpass output looks like the following:

```
BASE64 BEGIN
dBy3E5JCxuoxsR+aOBVfp1j0SwQPt+hdjpMKriWvO2xM5rFnFEwv+sPPd4w
/onWV1GOM5mqubBeS7QUt/2KOD1aO9/R5RVa5wy1Qu//6vxfyd8NG/
SFJm1VH63kuyXf1Vfq6bHo5+n1Q2pVjSHF2msET3S9HTp2Ut4NbiP4=BASE64 END
```

**Note:** The encrypted password is enclosed between BASE64 BEGIN and BASE64 END. In the above example, the cyphertext is wrapped for display purposes only.

4. Replace the clear password with the encrypted one, and specify the key used to encrypt it (mykey in our example):

```
authenticate.myentry.login = "mylogin"
authenticate.myentry.password.mykey = "dBy3E5JCxuoxsR+aOBVfp1j0SwQPt+hdjpMKriWvO2xM5rFnFEwv+sPPd4w
/onWV1GOM5mqubBeS7QUt/2KOD1aO9/R5RVa5wy1Qu//6vxfyd8NG/
SFJm1VH63kuyXf1Vfq6bHo5+n1Q2pVjSHF2msET3S9HTp2Ut4NbiP4=
```

**Note:** Do not forget to put quotes around the base64 form; otherwise the '=' character is interpreted during the loading of FGLPROFILE. The long line of text is wrapped for display purposes only.

**Encrypt a HTTP authenticate password using a certificate in the Windows key store**

Use the fglpass tool to encrypt a password to store in the Windows® key store.

1. Find the HTTP authenticate entry with the password you want to encrypt:

```
authenticate.myentry.login    = "mylogin"
authenticate.myentry.password = "mypassword"
```

2. Add the subject of the certificate registered in the Windows® key store:

```
security.mykey.subject = "Georges"
```

3. Encrypt the password with fglpass:

```
$ fglpass -c Georges
Enter password :mypassword
```

The fglpass output looks like this:

```
BASE64 BEGIN
dBy3E5JCxuoxsR+aOBVfp1j0SwQPt+hdjpMKriWvO2xM5rFnFEwv+sPPd4w
/onWV1GOM5mqubBeS7QUt/2KOD1aO9/R5RVa5wy1Qu//6vxfyd8NG/
SFJm1VH63kuyXf1Vfq6bHo5+n1Q2pVjSHF2msET3S9HTp2Ut4NbiP4=BASE64 END
```

**Note:** The encrypted password corresponds to the string of alphanumeric characters between BASE64 BEGIN and BASE64 END. The long line of text is wrapped for display purposes only.
4. Replace the clear password with the encrypted one, and specify the key used to encrypt it (mykey in our example):

```plaintext
authenticate.myentry.login = "mylogin"
authenticate.myentry.password.mykey = "dBy3E5JCxuosxR+aOBVfpj0SWQPT+hdjphKriWv02zXnd5rFPEwv+spPd4w/onWvIgOM5mqubBeS7Q1Ut/ZK0DiAo9/R5RvA5wy1Qu/6vxyd8NG/SFJmltVGH63kuyXf1Fqq6bHo5+niQZpVJSfF2msEiT3S9HTpZUt4NbiP4="
```

**Note:** Do not forget to put quotes around the base64 form; otherwise the '=' character is interpreted. The long line of text is wrapped for display purposes only.

**Use the password agent**

Start the fglpass tool as the password agent.

The `fglpass` tool can be started as an agent with the `-agent:tcp-port` option, to allow BDL applications requiring passwords, to grant access to private keys without providing the passwords.

Passwords are provided once for each private key at the `fglpass` agent startup.

The `fglpass` agent has the following `fglrun` authentication methods:

- **By default,** the agent allows only `fglrun` to access the passwords, if the OS user executing `fglpass` and `fglrun` are the same.
- **On UNIX® platforms,** the `fglpass` agent can be started with the `-gid` option, to allow all users belonging to the OS group of users executing the `fglpass` program:

```plaintext
fglpass -gid -agent:4242 myprivate1.pem myprivate2.pem ...
```

For `fglrun` programs requiring the group-based agent authentication method, you need to set the following `FGLPROFILE` entry:

```plaintext
security.global.agent.gid=true
```

Authentication and data encryption are performed between the BDL application and the agent to guarantee passwords confidentiality, and the passwords are also stored in encrypted form in the agent memory.

1. To start the password agent at port number 4242 and to serve the BDL applications with the passwords of the private key RSAKey1.pem and DSAKey2.der, specify the option `-agent`, followed by a colon, followed by the port number where it will be reachable, followed by the list of private keys the agent will handle for all BDL applications.

```plaintext
fglpass -agent:4242 RSAKey1.pem DSAKey2.der
```

2. The agent prompts you to silently enter the password of the different keys (the passwords are not displayed to the console while being typed). In this example, you have:

```plaintext
Enter pass phrase for RSAKey1.pem:
```

Followed by:

```plaintext
Enter pass phrase for DSAKey2.der:
```

3. Once all keys have been processed, the following message is displayed to notify that the agent is ready.

```plaintext
Agent started
```

4. To enable one BDL application to use the password agent capability, set the entry called `security.global.agent` in the `FGLPROFILE` file with the port number of the agent.
In our example, with value 4242:

```
security.global.agent  = "4242"
```

**Encrypt a password from RSA key**

Use the `fglpass` tool to encrypt a password from a RSA key.

The `fglpass` tool can encrypt a password using an RSA key or certificate, and then encode it in BASE64 form. This allows you to easily add a protected password in the FGLPROFILE file for future use by any BDL application.

1. To encrypt a password from a RSA key and encoded in BASE64, enter:

   ```
   fglpass -e -k RSAPub.pem
   ```

2. You are prompted to enter the password you want to encrypt.

   ```
   Enter password : hello
   ```

   The `fglpass` tool outputs the BASE64 form of the encrypted password on the console.

   ```
   BASE64 BEGIN
   Pzk/fNRhetdJDZz5kjNg7P0XET4XsW6bys/fi0DvuqxrPh9d/s41oAws65JY0EPb2zytQjxzZ/dwaaRzJPYoQmA==
   BASE64 END
   ```

   **Note:** The BASE64 encrypted password is the string between the `BASE64 BEGIN` and `BASE64 END`.

**Related concepts**

- [Decrypt a password from BASE64](#)
  - The `fglpass` tool can decrypt a BASE64 encoded and encrypted password using a RSA private key.

**Decrypt a password from BASE64**

The `fglpass` tool can decrypt a BASE64 encoded and encrypted password using a RSA private key.

The `fglpass` tool uses the RSA private key that was used to encrypt it or that is associated to a certificate containing the public part of that private key.

1. To decrypt a BASE64 encoded and encrypted password from a RSA private key, enter:

   ```
   fglpass -d -k RSAPriv.pem
   ```

2. If the RSA key is protected with a password, you are prompted to enter that password (the password is not displayed to the console while being typed).

   ```
   Enter pass phrase for RSAPriv.pem:
   ```

3. You are prompted to enter the BASE64 encoded and encrypted password you want to decrypt.

   ```
   Enter password : Pzk/fNRhetdJDZz5kjNg7P0XET4XsW6bys/fi0DvuqxrPh9d/s41oAws65JY0EPb2zytQjxzZ/dwaaRzJPYoQmA==
   ```

   The `fglpass` tool outputs the password in clear text on the console.

   ```
   hello
   ```

**Related concepts**

- [Encrypt a password from RSA key](#)
Use the fglpass tool to encrypt a password from a RSA key.

**Encode a file in BASE64 form**
The fglpass tool can encode a file in BASE64 form.

1. To encode the file *MyFile* in BASE64, enter:

   ```
   fglpass -enc64 MyFile
   ```

   The fglpass tool outputs the BASE64 form of the file to the console.

   ```
   BASE64 BEGIN
c2VjdXJpdHkuZ2xvYmFsLmFnZW50ICAgICAgICAgICAgPSAiNDI0MiINCmNyeXB0by5pZDEua2V5ICAgICAgICAgICAgPSAiMjM5IzXkIGICAgICAgICAgICAgPSAiY2Vydml2ZSINCmNyeXB0by5pZDEua2V5ICAgICAgICAgICAgPSAiMTQWPSIyMzY0MmFyZSINCmNyeXB0by5pZDEua2V5ICAgICAgICAgICAgPSAiMjM5IzXkIGICAgICAgICAgICAgPSAiY2Vydml2ZSINCmNyeXB0by5pZDEua2V5ICAgICAgICAgICAgPSAiMjM5IzXkIGICAgICAgICAgICAgPSAiY2Vydml2ZSI=`

   Note:
   - The BASE64 encoded file is the string between BASE64 BEGIN and BASE64 END.
   - You can redirect the output of fglpass tool to a file. For example:

     ```
     fglpass -enc64 MyFile > Base64filename
     ```

   **Related concepts**
   - *Decode a file encoded in BASE64 form* on page 3294

**Decode a file encoded in BASE64 form**
The fglpass tool can decode a BASE64 encoded file.

1. To decode a file encoded in BASE64 form, enter:

   ```
   fglpass -dec64 Base64filename
   ```

   The fglpass tool outputs the file in clear form on the console.

   ```
   security.global.agent = "4242"
crypto.id1.key = "RSA1024Key.pem"
crypto.id2.key = "RSA2048Key.pem"
crypto.id3.key = "DSA1024Key.pem"
crypto.id4.key = "RSA512Protected.pem"
crypto.id5.key = "DSA512ReallyProtected.pem"
```

Note:
- You don't have to remove the BASE64 BEGIN and BASE64 END tags, if they are present in the file, because the fglpass tool detects and removes them automatically.
- You can redirect the output of the fglpass tool to a file. For example:

   ```
   fglpass -dec64 Base64MyFile > MyFile2
   ```

**Related concepts**
- *Encode a file in BASE64 form* on page 3294
The fglpass tool can encode a file in BASE64 form.

**HTTP compression in SOAP**

HTTP compression is a capability that can be built into web servers and web clients to make better use of available bandwidth, and provide greater transmission speeds between both.

There are a variety of places where you can set up HTTP compression.

- You can set up the Web services client to send and receive compressed requests. See Compression and a Web services client on page 3295.
- You can enable compression for the Web server. Refer to your Web server documentation for details.
- You can enable compression in the Genero Application Server. Compression is enabled by default in $FGLASDIR/etc/imt.cfg. Refer to the Compression in Genero Application Server page in Genero Application Server User Guide for more information.
- You can set up the Web services server to send and receive compressed requests. See Compression and a Web services server on page 3296.

**Compression and a Web services client**

Send and receive compressed requests from a Web services client.

When you create a low-level Web service and do not have any stubs created by fglwsdl, you need to manage it by setting the HTTP headers.

**Important:** HTTP request compression for POST/PUT is not supported on GMI mobile devices.

**Send a compressed request**

The method used to set up the client for sending a compressed request depends on whether the Genero Web Services client is a high-level or low-level Web services client. A high-level client is a Genero Web Services client that includes the stub files created by the fglwsdl tool. A low-level client is a Genero Web Services client that does not utilize stub files created by the fglwsdl tool.

Regardless of the type of client, the server must be set up to handle such compression, otherwise the request will be rejected.

**Send a compressed request from a high-level client**

Set the variable Binding.CompressRequest to either "gzip" or "deflate".

```plaintext
LET EchoDocStyle_EchoDocStylePortTypeEndpoint.Binding.CompressRequest = "gzip"
```

The Binding.CompressRequest variable is defined in the stub file, specifically the client's global (inc) file.

```plaintext
# Global Endpoint user-defined type definition

# End point

TYPE tGlobalEndPointType RECORD # End point
  Address RECORD # Address
    Uri STRING # URI
  END RECORD,
  Binding RECORD # Binding
    Version STRING, # HTTP Version (1.0 or 1.1)
    Cookie STRING, # Cookie to be set
    ConnectionTimeout INTEGER, # Connection timeout
    ReadWriteTimeout INTEGER, # Read write timeout
    CompressRequest STRING # HTTP request compression mode (gzip or deflate)
  END RECORD
END RECORD
```
Send a compressed request from a low-level client

A low-level client is a Genero Web Services client that does not utilize stub files created by the fglwsdl tool.

Set the Content-Encoding field in the request header to either "gzip" or "deflate".

This example sets the Content-Encoding field to "gzip", where the request is a com.HTTPRequest object.

```
CALL request.setHeader("Content-Encoding","gzip")
```

Accept a compressed response

A Genero Web Services client can accept a compressed request if it sets the Accept-Encoding field in the header to "gzip, deflate". These values represent supported compression schema names (called content-coding tokens) separated by commas.

This example sets the Accept-Encoding field with the setHeader method, where the request is a com.HTTPRequest object.

```
CALL request.setHeader("Accept-Encoding","gzip, deflate")
```

Compression and a Web services server

Send and receive compressed requests from a Web services server.

If the Genero Web Services client accepts compression, the Genero Web Services server will reply with a compressed response.

To disable compression, you must disable compression in the Genero Application Server $FGLASDIR/etc/imt.cfg file. See the Compression in Genero Application Server page in Genero Application Server User Guide for more information.

Send and receive compressed requests from a Web services client.

**SOAP multipart style requests in GWS**

This topic describes multipart support with Genero Web Services

**What is multipart style in SOAP?**

Multipart style SOAP is the ability to send and receive a SOAP request in multiple pieces. The sending of attached files in separate parts of the SOAP request is one example of a multipart style SOAP request.

**Multipart SOAP on the client**

When using a WSDL with multipart style, `fglwsdl` generates a client-side stub handling multipart requests. For more details, see *Multipart in the client stub* on page 3332.

**Multipart SOAP on the server**

Multipart style is not yet supported with the high-level WS API of Genero.

- It is not possible to write a GWS server handling multipart style SOAP requests with the high-level API.
- When generating code from a WSDL using multipart style, the `fglwsdl` will produce a warning message:
  
  **WARNING : Unable to manage MIME Mutlipart binding on message 'name', where name is the name of the message in XML.**

**Implementing multipart using the low-level APIs**

If required, you can implement a WS server handling multipart with the low-level APIs of Genero Web Services. For more details, see *com.HTTPServiceRequest.getRequestMultipartType* on page 2855.

**Related concepts**

*High-level and low-level SOAP APIs* on page 3278

High-level APIs use specially-designed classes to implement your Web service's function with minimal coding, while low-level APIs use standard HTTP classes that require you to code everything by hand.

*`fglwsdl` on page 2081*

The `fglwsdl` tool produces web services stub files for client or server programs (from WSDL / XSD).

**Message Transmission Optimization Mechanism (MTOM)**

Use MTOM to efficiently send binary data to and from SOAP Web services.

**When to use MTOM**

When you have a Web service transmitting large documents, it is recommended to use MTOM. MTOM must be used when you have to optimize the transfer of binary data located in a BLOB. Any BDL BYTE will be transferred as an HTTP part over the wire. Nothing changes from the programmer perspective: the program manipulates a BDL BLOB on the client side as well as on the server side. The programmer may not even know that an HTTP part was used.

**How to implement MTOM with a GWS server application**

If you are creating a server application from scratch, use `setFeature` to enable MTOM. See *Enabling MTOM on the server side* on page 3354.

If you are using the `-s` option of the `fglwsdl` command to generate the server stubs, you can also use the `-mtom` option of the `fglwsdl` command to override the WS-Policy; you normally do not have to override the WS-Policy. See *`fglwsdl` on page 2081*.
How to implement MTOM with a GWS client application

For a GWS client, if the Web service enabled MTOM, then the generated WSDL should include the MTOM policy and it should work transparently. If the MTOM policy is not included in the WSDL and you know that the Web service is using MTOM, you can force the generation of stubs with MTOM support with the -mtom option of the fglwsdl command. The -mtom option is only needed if you want to override the WS-Policy; you normally do not have to override the WS-Policy. See fglwsdl on page 2081.

Optimization Layer 1: Using MTOM

Optimization has layers.

When MTOM is used, GWS manages the large documents using BYTE variables. When MTOM is enabled, a BDL BLOB is transmitted transparently via a HTTP attachment. Your Genero program receives a BLOB variable, filled as before, oblivious to how the content was transmitted. It is “seen” as a BYTE, as if it was inline.

Optimization Layer 2: Using STRING variables

In addition to enabling MTOM, you can further optimize by using STRING variables instead of BYTE variables.

Note: A BYTE variable contains the data value, located in memory. A STRING variable contains the path to a file. The -hexb64AsString option of the fglwsdl command forces the stub generation with STRING instead of BYTE.

For example, you can avoid loading a big file into a BYTE entirely in memory. Instead of doing this:

```plaintext
DEFINE req RECORD
    data BYTE
END RECORD
DEFINE resp RECORD
    data2 BYTE
END RECORD
LOCATE req.data IN MEMORY
LOCATE resp.data2 IN MEMORY
CALL rec.data.readFile("myfile.jpg")
... Do SOAP Operation
CALL resp.data2.writeFile("retfile.jpg")
```

You can do this:

```plaintext
DEFINE req RECORD
    data STRING ATTRIBUTES(XMLOptimizedContent)
END RECORD
DEFINE resp RECORD
    data2 STRING ATTRIBUTES(XMLOptimizedContent)
END RECORD
LET rec.data = "myfile.jpg"
... Do SOAP Operation
handle returned file at resp.data2
```

Related information

https://www.w3.org/TR/soap12-mtom/

swaRef (SOAP with attachments using wsi:swaRef)

swaRef is a specific way for sending and receiving attachments in SOAP. It is used when you have to transfer files as attachment and locate on disk.

swaRef refers to "Soap with attachments using the wsi:swaRef XML type from WS-I". It is a specific case of the SoapWithAttachment specification.
Warning: Java handles swaRef automatically. Dot Net does not.

With swaRef, you can set an attribute with a dedicated value of "swaRef" on a STRING. When set, a Web service automatically sends the file in that string as an HTTP part or receives it as an HTTP part.

In the following example, a sendAttachment operation computes the MD5 of a file. The program sets XMLOptimizedContent="swaRef" on the DataIn string and the SOAP engine carries it over the wire as an HTTP part.

```plaintext
# Request Type
TYPE tsendAttachment RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="sendAttachment",XSTypeNamespace="http://4js.com/services/swa")
    Name STRING ATTRIBUTES(XMLName="Name",XMLOptional),
    DataIn STRING ATTRIBUTES(XMLOptimizedContent="swaRef",XMLAttribute,
    XMLName="DataIn",XMLOptional)
END RECORD

# Response Type
TYPE tsendAttachmentResponse RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="sendAttachmentResponse",XSTypeNamespace="http://4js.com/services/swa")
    return STRING ATTRIBUTES(XMLName="return",XMLOptional)
END RECORD

# VARIABLE : sendAttachment
DEFINE sendAttachment tsendAttachment
  ATTRIBUTES(XMLName="sendAttachment",XMLNamespace="http://4js.com/services/swa")

# VARIABLE : sendAttachmentResponse
DEFINE sendAttachmentResponse tsendAttachmentResponse
  ATTRIBUTES(XMLName="sendAttachmentResponse",XMLNamespace="http://4js.com/services/swa")

... # Publish Operation : sendAttachment
  LET operation = com.WebOperation.CreateDOCStyle("sendAttachment","sendAttachment",sendAttachment,sendAttachmentResponse)
  CALL service.publishOperation(operation,"")
...
```

XMLOptimizedContent on page 3552
Set on STRING or BYTE data type so that such string content represents a file on disk to be transmitted as base64 binary in SOAP via HTTP attachment.

Security
These topics cover security for Genero Web Services.

Encryption and authentication
A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

Secured communications
Secured communications are important. If an application wants to send or receive messages from a financial, business, or personnel application on the web, it must be able to authenticate the origin of the message, ensure that
no malicious application has altered the original message, and ensure that no third party application can intercept the message.

Suppose that a person named Georges wants to send a message to his bank to transfer some money on the Internet. In this scenario, he faces the following concerns:

1. **The privacy** of the message, since it includes his account number and the transfer amount.
2. **The integrity** of the message, since someone might try to modify the original message or substitute a different message in order to transfer the money to another account.
3. **The authentication** of the message, since the bank must ensure that the message was sent from the right person.

**Message privacy**

To keep a message private, use a cryptographic algorithm - a technique that transforms a message into an encrypted form unreadable except by those it is intended for. Once it is in this form, the message may only be interpreted through the use of a secret key. There are two kinds of cryptography algorithms: symmetric and asymmetric.

**Symmetric** means the sender and the receiver of a message have to share the same key used to encrypt a clear message into an encrypted form, and then to decrypt it back into the original message. If that key is kept secret, nobody other than the sender and the receiver can read the message. However, the task of choosing a private key before communicating can be problematic.

**Asymmetric** means that there are two different keys working as a key-pair. One key is used to encrypt a message, and the second one is used to decrypt the encrypted message back into its original form. This solves the problem of key sharing in the symmetric cryptography algorithm, and makes it possible to receive secure messages, simply by publishing the key used to encrypt messages (the **public key**), and keeping secret the key used to decrypt messages (the **private key**). Anyone can encrypt a message using the public key, but only the owner of the private key can read it.

**Important:** The use of an asymmetric key-pair (public and private key), allows Georges to send private messages to his bank, simply by using the bank's public key to encrypt a message. Only the owner of the corresponding private key (the bank in this scenario) is able to read it.

**Message integrity**

To guarantee the integrity of a message, send a concise summary of the original message. The receiver of the message can create its own summary and compare it to the sender's summary. If they are similar, the message is considered intact, meaning that no third party has modified the original message.

Such a summary is called a **message digest** and is based on hash algorithms that produce a fixed-length representation of variable-length messages. Message digests are designed to make it very difficult (if not impossible) to determine the original message from a summary.

The message digest must be sent to the receiver in a secure way to assure the message integrity. This is achieved with a digital signature authenticating the sender and containing the sender's message digest.

**Important:** The use of message digests allows Georges' bank to verify that no one has modified the original message he sent.

**Message authentication**

To authenticate a message, add a digital signature to that message.

**A digital signature** is another message, created by encrypting the message digest, along with some other information, with the sender's private key. Anyone with the corresponding public key can decrypt the digital signature. If an application is able to decrypt it, it means the owner of the private key was able to encrypt it, proving that the message comes from this sender and not from someone else.

Once the sender has been authenticated, the receiver can compare the message digest integrated into the digital signature to the one it created from the message it receives, in order to check the message integrity.

**Important:** The use of digital signatures allows Georges' bank to verify that the message really comes from him.
Certificates

An SSL/TLS certificate is a kind of digital identity card that associates the public key with a unique digital thumbprint identifying an individual, a server, or any other entity.

Now that Georges is able to send a secured message to his bank, there is still a problem. How can Georges be sure that the server he is connected to is really the bank's server and not a malicious server?

Georges must be sure that the public key he is using to encrypt his message corresponds to the bank's private key. Similarly, the bank needs to verify that the message signature it receives corresponds to Georges' signature.

To identify a remote peer, use a **certificate** - a kind of digital identity card that associates the public key with a unique digital thumbprint identifying an individual, a server, or any other entity (known as the **subject**). It also includes the identification and signature of the Certificate Authority that issued the certificate, and the period of time during which the certificate is valid. It may have additional information (or extensions) as well as administrative information for the Certificate Authority's use, such as a serial number.

A standard X.509 certificate contains the following standard fields:

- Certificate version
- Serial number of the certificate
- The distinguished name of the certificate issuer
- The distinguished name of the certificate owner
- The validity period of the certificate
- The public key
- The digital signature of the issuer
- Signature algorithm used
- Zero or more certificate extensions

**Note:**

1. An example of a distinguished name is: **CN=Georges,E=georges@mycompany.com,OU=Sales,O=My Company Name,C=FR,S=France**
2. The **CN** (Common Name) of the distinguished name of the certificate owner corresponds to the certificate subject, and identifies the owner of that certificate.

Certificate authorities

When a certificate authority signs a certificate, it is validating that the certificate is valid.

Each time Georges sends a message to his bank, he will present his own certificate to the bank, and will get the bank's certificate back. But as every one can create a certificate in the name of Georges, a higher authority that confirms the validity of a certificate is necessary. The bank must be sure it is Georges' certificate, and that no one else has taken his identity. Similarly, Georges needs an authority that confirms that the certificate coming from the server is really the bank's certificate.

The solution to validating a certificate is to sign it with a trusted certificate called **certificate authority**. This is a certificate in which an application has total confidence concerning the validity of the certificates it has signed. Before signing a certificate, a certificate authority must proceed with a strict identification of the owner of that certificate.

**Note:** The private key associated to a Certificate Authority must be managed with care, as it is the entity in charge of the validity of all other certificates it has signed.

There are several companies (such as *VeriSign*, *GlobalSign* or *RSA Security*) that have established themselves as certificate authorities and provide the following services over the Internet:

- Verifying certificate requests
- Processing certificate requests
- Issuing and managing certificates

**Note:** It is also possible to create your own Certificate Authority, but it is up to you to manage it securely.
Root Certificate Authority

A Certificate Authority signed by itself is called a Root Certificate Authority, meaning that the certificate issuer is the same as the certificate subject. Most of the time, such a certificate belongs to a company established as a Certificate Authority, and is used to sign certificate requests coming from different companies that want their own Certificate Authority. If a client certificate is signed by a Certificate Authority previously signed by a Root Certificate Authority, the client certificate can be validated by the Root Certificate Authority even if the Certificate Authority is not present.

For example, if a company wants to buy a Certificate Authority from VeriSign, VeriSign signs that Certificate Authority with its own Root Certificate Authority. The company can then create certificates with the Certificate Authority provided by VeriSign and connect to secure servers without providing them with their own Certificate Authority. The secure server, of course, has to know the VeriSign Root Certificate Authority.

Certificate Chains

A certificate authority may issue a certificate for another certificate authority. This means that when an application wants to examine the certificate of the issuer, it must check all parent certificates of that issuer until it reaches one in which it has confidence.

The certificate chain corresponds to the number of parent certificate authorities allowed to validate a certificate.

Certificate Authority List

A Certificate Authority List is a list of all certificate authorities considered as trusted by one application, classified by order of importance. Each of these certificates allows the authentication of a certificate presented to that application from a remote peer.

Note: With most applications, the Certificate Authority List is a concatenated file of all certificate authorities.

Certificates and private keys storage

The entire concept of security is based on the publication of the public key, and the privacy of the associated private key. For maximum security, it is critical to restrict the access of the private key to the owner of the certificate and associated private key.

Note: Some companies provide systems to manage certificates and private keys in complete security.

UNIX® systems

As the UNIX™ system is already able to restrict the access of a file to only one person, simply restrict access to the private key to the owner of that key to achieve a good level of security. This provides enough security to allow a Genero Web Services client to perform secured communications in the name of the certificate and private key owner, because access to the private key file is granted only if the correct user has logged in.

Windows® systems

Windows® has an integrated key store system to manage certificates and private keys. It allows the registration and the storage of X.509 certificate authorities, as well as personal X.509 certificates and their associated private keys.
keys accessible only if the correct user has logged in. It is recommended that you store the certificate and associated private key in the Windows® key store instead of in files on the disk.

**Related concepts**

- [Missing certificates](#) on page 3311
- Identifying missing certificates.

**Error: Peer certificate is issued by a company not in our CA list** on page 3310

When a client connects to a server using HTTPS, the client needs to trust the server it is in communication with. So the client needs to add the server's CAs (certificate authorities lists) to its trusted CAs.

### Accessing secured services

Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web service.

![Communications options for a client to connect to a Web Service](image)

- **HTTP**
  - Client connects to a Web Server (or a Web Service) using HTTP as the communication protocol. *(No security, No authentication).*

- **HTTP with Basic Authentication**
  - Client connects to a Web Server using HTTP as the communication protocol, but a valid login and password are required from the Web server to grant access to the Web Service. *(No security, Weak Authentication).* The login and password are sent in clear text on the communication layer.

- **HTTP with Digest Authentication**
  - Client connects to the Web Server using HTTP as the communication protocol, but a valid login and password are required from the Web server to grant access to the Web Service. *(No security, Authentication).* The login and password are encoded using a digest algorithm, requiring additional information from the Web server. This means that the first connection will always fail, but it is necessary in order to return Web server additional information back to the client.

- **HTTPS**
  - Client connects to a Web server using HTTPS as the communication protocol. *(Security, No authentication).* The communication channel is encrypted by SSL/TLS.

- **HTTPS with Basic Authentication**
  - Client connects to a Web server using HTTPS as the communication protocol, but a valid login and password are required from the Web server to grant access to the Web Service. *(Security, Weak Authentication).*
The login and password are sent in clear text on the communication layer, but the communication channel is encrypted by SSL/TLS.

**HTTPS with Digest Authentication**

Client connects to the Web Server using HTTPS as the communication protocol, but a valid login and password are required from the Web server to grant access to the Web Service. (Security, Authentication). The login and password are encoded using a digest algorithm, requiring additional information from the Web server. This means that the first connection will always fail, but it is necessary in order to return Web server additional information back to the client. The communication channel is encrypted by SSL/TLS.

To improve communication speed with the cache mechanism, or to restrict internet access to specific clients, Genero Web Services allows a client to connect via proxies. The proxy is in charge of dispatching the client request to the server, and uses the same protocol as that used by the server. So, when a client connects via a proxy to access a HTTP server, the configuration of the HTTP proxy is used, and when the client communicates in HTTPS, the HTTPS proxy configuration is used.

**HTTP proxy**

Client connects via a proxy using HTTP as the communication protocol.

**HTTP proxy with Basic Authentication**

Client connects via a proxy using HTTP as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. The login and password are sent in clear text on the communication layer between client and proxy.

**HTTP proxy with Digest Authentication**

Client connects via a proxy using HTTP as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. The login and password are encoded using a digest algorithm, requiring additional information from the proxy. This means that the first connection will always fail, but it is necessary in order to return proxy additional information back to the client.

**HTTPS proxy**

Client connects via a proxy using HTTPS as the communication protocol. The communication channel is encrypted by SSL/TLS.

**HTTPS proxy with Basic Authentication**

Client connects via a proxy using HTTPS as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. The login and password are sent in clear text on the communication layer between client and proxy, but the communication channel is encrypted by SSL/TLS.

**HTTPS proxy with Digest Authentication**

Client connects via a proxy using HTTPS as the communication protocol, but a valid login and password are required from the proxy to dispatch the request to the Web Service. The login and password are encoded using a digest algorithm, requiring additional information from the proxy. This means that the first connection will always fail, but it is necessary in order to return proxy additional information back to the client. The
Web services

communication channel between client and proxy is encrypted by SSL/TLS.

- Basic or digest HTTP authentication on page 3491
- Proxy configuration on page 3492

HTTPS configuration
If no client certificate is provided, Genero Web Services (GWS) does the HTTPS request transparently.

GWS can use an implicit certificate when no HTTPS configuration is provided. For stronger security, you can provide HTTPS configuration with your own certificates and CA list.

The implicit client certificate
For the implicit certificate, no configuration is required. GWS creates a temporary certificate for the HTTPS request. The temporary certificate is valid for the application session.

The explicit client certificate
For the explicit certificate, configure your certificate with entries for your HTTPS and password encryption on page 3489 settings of your FGLPROFILE file.

For access to a specific site, specify security.idsec.certificate and security.idsec.privatekey.

If you use the same certificate across all sites, specify security.global.certificate and security.global.privatekey.

Certificate authorities
Certificate authorities (file extension .crt) are usually provided by the system (the operating system keystore). If they are not provided by the system, the certificate authorities are searched for in the following locations:

1. The $FGLDIR/web_utilities/certs directory
2. The file specified by the FGLPROFILE file entry security.global.ca
3. The keystore specified by the FGLPROFILE file entry security.global.windowsca (Windows® systems) or security.global.systemca (all systems).
4. The directories listed in the FGLPROFILE file entry security.global.ca.lookuppath

Mobile platforms
On mobile platforms, no HTTPS configuration is required, because the Web Service library uses the SSL/TLS certificates installed in the key database of the device (Keystore for Android™ and Keychain® for iOS).

See also Web Services on GMA (Android) on page 3277.

Related concepts
- FGLPROFILE entries for Web Services on page 3489

The FGLPROFILE entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

Configure a WS client to access an HTTPS server
Configuration steps to access a server in HTTPS.

To configure access to an HTTPS server, you need a client certificate.

Important: On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain® typically holds the server certificate authority list. Therefore, the FGLPROFILE file security settings are ignored with the exception of the following: security.global.ca, security.global.ca.lookuppath, and security.global.systemca.
Before you begin, there are options to consider depending on how you wish to use the client certificate:

- If you do not have the certificate information in your FGLPROFILE file, Genero Web Services creates a certificate for you. This is an implicit or temporary certificate that is valid for a session only. For more information see HTTPS configuration on page 3305.

  **Note:** For the implicit certificate, no configuration is required.

- Alternatively, for stronger security, you generate a client certificate of your own, configure your application to use the client certificate generated, and add the configuration details to the FGLPROFILE file. Follow the steps outlined in this section.

  **Note:** In a production environment, some servers provide a client certificate and you use the certificate as provided, and add the configuration details to the FGLPROFILE file.

The **openssl command line tool** can be used to create your own certificates for the configuration of secured communication. The following steps outline the configuration process:

**Related concepts**
- Configuring the Apache Web server for HTTPS on page 3460
- Configuration steps to secure a Web service for Apache server in HTTPS.
- Certificates in practice on page 3313
- Procedures and tools for creating, importing, and viewing certificates and keys.
- Encryption and authentication on page 3299
- A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.
- Accessing secured services on page 3303
- Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web service.

**Create the client certificate**
Generate a root certificate authority that signs a client certificate.

In this task you create your own root certificate authority and client certificate using the OpenSSL command line tool.

1. Create the root certificate authority.

   a) Create the root certificate authority serial file.
   
   ```bash
   $ echo 01 > MyCompanyCA.srl
   ```

   This command creates a serial file with an initial HEX value 01. OpenSSL uses this file to track the serial numbers of certificates it creates. The serial file is typically given the same name as the CA with the extension .srl.

   b) Create the Certificate Signing Request (CSR) and private key.
   
   ```bash
   $ openssl req -new -out MyCompanyCA.csr -keyout MyCompanyCA.pem
   ```

   Follow the instructions to create the CSR.

   c) Create the Root Certificate Authority for a period of validity of 2 years.

   ```bash
   $ openssl x509 -trustout -in MyCompanyCA.csr -out MyCompanyCA.crt -req -signkey MyCompanyCA.pem -days 730
   ```

   **Note:** The private key file (MyCompanyCA.pem) of a Root Certificate Authority must be handled with care. This file is responsible for the validity of all other certificates it has signed. As a result, it must not be accessible by other users.

2. Create the client's X.509 certificate and private key.

   a) Create the client's Certificate Signing Request and private key.

   ```bash
   $ openssl req -new -out MyClientCA.csr -keyout MyClientCA.pem
   ```

   Follow the instructions to create the CSR.
$ openssl req -new -out MyClient.csr

**Note:** By default, openssl outputs the private key in the `privkey.pem` file. If you want to specify a different file name, or if your openssl version does not output the private key by default, add the `-keyout <myprivkey>.pem` to the command.

b) Remove the password from the RSA private key.

```
$ openssl rsa -in privkey.pem -out MyClient.pem
```

**Note:** The unprotected private key is output in `MyClient.pem`.

c) Create the client's certificate (self-signed X.509 certificate valid for a period of 1 year) trusted by the Root Certificate Authority created in step 1.

```
$ openssl x509 -in MyClient.csr -out MyClient.crt -req
-signtype MyClient.pem -CA MyCompanyCA.crt
-CAkey MyCompanyCA.pem -days 365
```

**Note:** Most servers do not check the identity of the clients. For these servers, the client's certificate does not necessarily need to be trusted; it is only used for data encryption purpose. If, however, the server performs client identification, you must trust a Certificate Authority in which it has total confidence concerning the validity of the client's certificates.

**Note:** The purpose of the client's certificate is to identify the client to any server; therefore the subject of the certificate must correspond to the client's identity as it is known by the servers.

**Note:** To import the certificate in a keystore you can create a pkcs12 certificate. See Import a certificate and its private key into the Windows key store on page 3315.

**What to do next**

Configure your FGLPROFILE file for the client certificate. See Configure for the client certificate on page 3307.

**Related concepts**

Encryption and authentication on page 3299
A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

The OpenSSL (openssl) tool on page 3313
The openssl command line tool creates certificates for the configuration of secured communications.

**Related tasks**

View a certificate on page 3316
This procedure allows you to view a certificate using the openssl command.

**Configure for the client certificate**

Configure your application to use the client certificate generated. For production systems, you add the configuration details to your FGLPROFILE file.

You have generated a client certificate as described in Create the client certificate on page 3306.

In this task you add the certificate information to your FGLPROFILE file.

Add the client's security configuration to your FGLPROFILE file.

The client security entry defines the certificate and the associated private key used by the Genero Web Services client during an HTTPS communication. The security entry must be defined with an unique identifier (id1 in this example).

```
security.id1.certificate = "MyClient.crt"
security.id1.privatekey = "MyClient.pem"
```
Note: If the private key is protected with a password, you must remove it or create a script that returns the password on demand. See Create the client certificate.

Your applications are configured to use the client certificate.

What to do next

Create the client's certificate authority list and configure the global certificate authority list (security.global.ca) in your FGLPROFILE file. See Configure for the certificate authority list on page 3308.

Related concepts

FGLPROFILE entries for Web Services on page 3489
The FGLPROFILE entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

FGLPROFILE: HTTP(S) Proxy Authentication on page 3496
FGLPROFILE entries can be used to define a connection to an HTTPS server via a proxy, and with HTTP and Proxy Authentication.

Encryption and authentication on page 3299
A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

Related tasks

View a certificate on page 3316
This procedure allows you to view a certificate using the openssl command.

Configure for the certificate authority list

The client needs to check to see if the server certificate is trusted. This is done using a certificate authority list.

In this task you create the client's certificate authority list using the OpenSSL command line tool, and set the global certificate authority list in your FGLPROFILE file.

Important: On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain® typically holds the server certificate authority list. Therefore, the FGLPROFILE file security settings are ignored with the exception of the following: security.global.ca, security.global.ca.lookuppath, and security.global.systemca.

1. Create the client's certificate authority list.
   a) Save the certificates of the HTTPS server to disk.
      Type the server's URL in your browser. When prompted, save all the certificates from the Certificate Hierarchy. For more information see, Selecting the certificate to add on page 3317 and Missing certificates on page 3311.
   b) Create the client's Certificate Authority List by running the following command for each of the certificates that you saved to disk.

      $ openssl x509 -in ServerCertificate.crt -text >> ClientCAList.pem

      Note: All trusted certificate authorities are listed. These are checked following a chain of child to parent certificates until a certificate is reached which is trusted. All other certificates that were trusted by the Root Certificate Authority will also be considered as trusted by the client. For more information see Certificate authorities on page 3301.

2. Set the global certificate authority list in your FGLPROFILE file.

   The global certificate authority list entry defines the file containing the certificate authority list used by the Genero Web Services client to validate all certificates coming from the different servers it will connect to.

   security.global.ca = "ClientCAList.pem"
**Note:** The file is located based on the current execution directory. If you use Genero Studio, for instance, *fglrun* may not be executed in the same directory as when you use the command line. The recommended practice therefore is to specify an absolute path for the .pem, for example:

```plaintext
security.global.ca = "/opt/usr/certs/ClientCAList.pem"
```

If `security.global.ca` is not defined, Genero Web Services will look to see whether the operating system has a keystore, otherwise `security.global.ca.lookuppath` will be used. For further information, see Certificate authorities in HTTPS configuration on page 3305.

The client application is configured to use the appropriate certificate authority list to validate a server's certificate.

**What to do next**

In your FGLPROFILE file ensure there are configuration entries (ws.*) for the HTTPS server URL and for the HTTP authentication when accessing the HTTPS server. See Add configuration entries in your FGLPROFILE file on page 3309.

**Related concepts**

**Error: Peer certificate is issued by a company not in our CA list** on page 3310

When a client connects to a server using HTTPS, the client needs to trust the server it is in communication with. So the client needs to add the server's CAs (certificate authorities lists) to its trusted CAs.

**Enable OCSP** on page 3310

To enable OCSP (Online Certificate Status Protocol), set the `security.global.ocsp.enable` and `security.global.ocsp.url` entries in FGLPROFILE.

**FGLPROFILE entries for Web Services** on page 3489

The FGLPROFILE entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

**FGLPROFILE: HTTP(S) Proxy Authentication** on page 3496

FGLPROFILE entries can be used to define a connection to an HTTPS server via a proxy, and with HTTP and Proxy Authentication.

**Accessing secured services** on page 3303

Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web service.

**Add configuration entries in your FGLPROFILE file**

Add a set of configuration entries that specify the security configuration for GWS clients accessing an HTTPS server.

In this task you add configuration entries (ws.*) in your FGLPROFILE file for the HTTPS server URL and for HTTP authentication when accessing the HTTPS server. For an example, see FGLPROFILE: HTTP(S) Proxy Authentication on page 3496.

**Important:** On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain typically holds the server certificate authority list. Therefore, the FGLPROFILE file security settings are ignored with the exception of the following: `security.global.ca`, `security.global.ca.lookuppath`, and `security.global.systemca`.

Add configuration entries for the server.

The following entries must be defined with an unique identifier (such as "myserver"):

   (Line breaks added for document readability)

b) `ws.myserver.security = "id1"

   Where the value (id1 in this example) must match the unique identifier defined by the client security entry created in Configure for the client certificate on page 3307.

**Tip:** The unique identifier "myserver" can be used in the BDL client code in place of the actual URL.

Troubleshoot certificate issues
You may encounter known (and common) issues when completing the Genero Web Services tutorials or when adding Web services of your own. These issues and their solutions are presented in the following topics.

Error: Peer certificate is issued by a company not in our CA list
When a client connects to a server using HTTPS, the client needs to trust the server it is in communication with. So the client needs to add the server's CAs (certificate authorities lists) to its trusted CAs.

This error means the client CA list is missing a certificate authority in its CA list.

To display the client CA list, use the following command:

```
openssl x509 -in ClientCAList.pem -noout -text
```

Solution:
1. Add the missing CA list to the client CA list.

```
openssl x509 -in MyCompanyCA.crt -text >> ClientCAList.pem
```

Theory
Usually certificates work in pairs: a public key and a private key.
Figure 122: Certificates working in pairs: a public key and a private key

The certificate which appears at the top of the list on the client and server side is the Certificate Authority (CA) root. This means that the client has a certificate that can be signed by an authority signed itself by a root authority. Likewise, the server has a certificate that can be signed by an authority signed itself by a root authority. In some instances, a certificate can be signed by itself.

Things to note:

- The server certificate is expected to have its host name set as CN (Common Name). For example, if you want to access the server https://www.mycompany.com the CN is expected to be "www.mycompany.com".
- In the client CA list it is recommended that you have all the CA of the server. In this example you need the server CA (5) and the server CA Root (4). If the server is self-signed then add the server certificate (6) to the client CA list.
- Sometimes, the needed CAs are not listed in the certificates hierarchy. Setting environment variable FGLWSDEBUG=3, will give you information about the missing CA.

Related concepts

Encryption and authentication on page 3299
A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

FGLWSDEBUG on page 283
The FGLWSDEBUG environment variable enables web services library debugging.

Related tasks

Configure for the certificate authority list on page 3308
The client needs to check to see if the server certificate is trusted. This is done using a certificate authority list.

Missing certificates
Identifying missing certificates.

Sometimes the CA hierarchy described in the server certificate is incomplete or needs another certificate (default ones used by browsers or private ones).
Figure 123: Certificate Viewer in Firefox Web Browser; Details Tab
When this occurs, you will get this kind of error message when you set FGLWSDEBUG:

```
WS-DEBUG (Security error)
Error with certificate at depth: 3
issuer = /C=US/O=VeriSign, Inc./OU=Class 3 Public Primary Certification Authority
subject = /C=US/O=VeriSign, Inc./OU=Class 3 Public Primary Certification Authority
err 19:self signed certificate in certificate chain
WS-DEBUG END
```

This means OpenSSL is looking for a third ancestor that is not listed in the hierarchy above. In this example, gatewaybeta.fedex.com only has two ancestors, and none are named "Class 3 Public Primary Certification Authority". You need to download the root certificates from VeriSign and add "Class 3 Public Primary Certification Authority" in your CA list.

If the certificate authorities are not found in the operating system keystore, you need to download them:

- If you store the CA certificates in $FGLDIR/web_utilities/certs directory, ensure they are named with the .crt extension.
- If you have configured the FGLPROFILE file using the global certificate authority list entry security.global.ca, you need to create the CA list with the .pem extension.

The Firefox browser allows you to download the CA list as a pem file; a PEM (cert) or PEM (chain). Use the PEM (chain) file in this case. Otherwise, you will need to download the certs individually and create the pem chain file as described in Create a certificate authority list on page 3315.

**Related concepts**

Error: Peer certificate is issued by a company not in our CA list on page 3310

When a client connects to a server using HTTPS, the client needs to trust the server it is in communication with. So the client needs to add the server's CAs (certificate authorities lists) to its trusted CAs.

**The OpenSSL (openssl) tool** on page 3313

The openssl command line tool creates certificates for the configuration of secured communications.

Certificates in practice

Procedures and tools for creating, importing, and viewing certificates and keys.

**The OpenSSL (openssl) tool**

The openssl command line tool creates certificates for the configuration of secured communications.

OpenSSL is provided in the FGLGWS package. To use it, you need to add its directory, $FGLDIR/web_utilities/tools, to your PATH environment variable.

The openssl tool has a default configuration file, openssl.cnf. It looks for the openssl.cnf file in the directory where it is executed; it stops if the file is not present. To use the openssl tool from any directory, set the OPENSSL_CONF environment variable to specify the location of the configuration file.

For information on how the openssl tool works, refer to the openssl documentation.

Create a root certificate authority

Generate a root certificate authority that signs a client certificate.

In this task you use the openssl command tool to create the root certificate authority.

1. Create the root certificate authority serial file:

```
$ echo 01 > MyRootCA.srl
```

This command creates a serial file with an initial HEX value 01. OpenSSL uses this file to track the serial numbers of certificates it creates. The serial file is typically given the same name as the root CA with the extension .srl.
2. Create a Certificate Signing Request (CSR):

   $ openssl req -new -out MyRootCA.csr

   Follow the instructions to create the CSR. Two files are created, the MyRootCA.csr and a file called privkey.pem, which contains the RSA private key of the CSR certificate protected by a password.

3. Remove the password of the private key (Optional):

   $ openssl rsa -in privkey.pem -out MyRootCA.pem

   Note: Removing the password of a certificate authority's private key is not recommended.

4. Create a self-signed certificate from the CSR and the unprotected private key for a validity period of 365 days:

   $ openssl x509 -trustout -in MyRootCA.csr -out MyRootCA.crt -req -signkey MyRootCA.pem -days 365

   Note: About the CSR and its private key:
   • If you want an official Certificate Authority, you must send the CSR file to one of the self-established Certificate Authority companies on the Internet (instead of creating it with openssl. See Encryption and authentication on page 3299).
   • The CSR file is also used to encrypt messages that only its corresponding private key can decrypt.

Configuration steps to access a server in HTTPS.

Create a certificate authority
This procedure allows you to create a certificate authority.

In this task you use the openssl command tool to create the certificate authority.

1. Create the certificate authority serial file:

   $ echo 01 > MyCA.srl

   This command creates a serial file with an initial HEX value 01. OpenSSL uses this file to track the serial numbers of certificates it creates. The serial file is typically given the same name as the CA with the extension .srl.

2. Create a certificate signing request (CSR):

   $ openssl req -new -out MyCA.csr

   Follow the instructions to create the CSR. This command also creates a private-key file, privkey.pem, containing the RSA private key of the CSR certificate and protected by a password.

3. Remove the private key password (Optional):

   $ openssl rsa -in privkey.pem -out MyCA.pem

   Note: Removing the password of a certificate authority's private key is not recommended.

4. Create a certificate from the Certificate Signing Request that is trusted by the Root Certificate Authority:

   $ openssl x509 -in MyCA.csr -out MyCA.crt -req -signkey MyCA.pem -CA MyRootCA.crt -CAkey MyRootCA.pem -days 365
**Note:** About the CSR and its private key:

- If you want an official Certificate Authority, you must send the CSR file to one of the self-established Certificate Authority companies on the Internet (instead of creating it with OpenSSL. See Encryption and authentication on page 3299).
- The CSR file is also used to encrypt messages that only its corresponding private key can decrypt.

**Related tasks**

Create a root certificate authority on page 3313
Generate a root certificate authority that signs a client certificate.

**Create a certificate**

This procedure allows you to create a certificate.

In this procedure you use the OpenSSL tool to perform the certificate creation tasks.

1. Create a Certificate Signing Request (CSR):

   ```
   $ openssl req -new -out MyCert.csr
   ```

   Follow the instructions to create the CSR. This command also creates a `privkey.pem` file containing the RSA private key of the CSR certificate that is protected by a password you provide.

2. Remove the private key password (Optional):

   ```
   $ openssl rsa -in privkey.pem -out MyCert.pem
   ```

   **Note:** The unprotected private key is output in `MyCert.pem`.

3. Create a certificate from the CSR that is trusted by the Certificate Authority:

   ```
   $ openssl x509 -in MyCert.csr -out MyCert.crt -req -signkey MyCert.pem -CA MyCA.crt -CAkey MyCA.pem -days 365
   ```

   **Note:** About the CSR and its private key:

   - If you want an official Certificate Authority, you must send the CSR file to one of the self-established Certificate Authority companies on the Internet (instead of creating it with OpenSSL. See Encryption and authentication on page 3299).
   - The CSR file is also used to encrypt messages that only its corresponding private key can decrypt.

Troubleshoot certificate issues on page 3310

You may encounter known (and common) issues when completing the Genero Web Services tutorials or when adding Web services of your own. These issues and their solutions are presented in the following topics.

**Examining certificates**

When you receive a URL in HTTPS, you are prompted to either accept a certificate or the certificate has already been accepted. In the second case, you can still check the server certificate.

**Check the server certificate using FireFox**

This procedure allows you to check the server certificate using FireFox.

1. Type the HTTPS URL.
2. Once the page is displayed, click on the padlock icon.
   The Page Info for the certificate displays.
3. In the Security tab, click on the View button.
   The Certificate Viewer opens.
4. In the Details tab, view the Certificate Hierarchy.
Check the server certificate using Internet Explorer
This procedure allows you to check the server certificate using Internet Explorer.

1. Type the HTTPS URL.
2. Once the page is displayed, click on the padlock icon.
   The Certificate window displays.
3. On the Certification Path, view the certificate hierarchy.

Selecting the certificate to add
The certificate authority (CA) is the authority that validates the server. The certificate to add to the CA list is the authority certificate, not the server certificate.

There are default certificates known by browsers like:

Get the server issuer certificate (and all the parents, grandparents, and so on).

For example, if your server is validated by Thawte, add the Thawte certificate to the list.

To check whether your certificate is the CA certificate, search for the CNs (Common Names) in the .cer files.
The CA Subject entry should be the Issuer CN in the server certificate. Running the openssl command as follows outputs the CN:

```
openssl x509 -in server.pem -noout -subject
```

```bash
subject=/C=ZA/ST=Western Cape/L=Cape Town/O=Thawte Consulting cc/OU=CertificationServices Division/CN=Thawte Server CA /emailAddress=server-certs@thawte.com
```
To convert a .cer certificate to the .pem format used by Genero Web Services run the following OpenSSL command:

```
openssl x509 -inform DER -in server.cer -outform PEM -out server.crt
```

Troubleshoot common issues

You may encounter known (and common) issues when completing the Genero Web Services tutorials or when adding Web services of your own. These issues and their solutions are presented in the following topics.

HTTP 401 error message

An HTTP 401 error message means the server is requesting, but not receiving, user authentication (login and password).

This error message means authenticate.xxx.login and authenticate.xxx.password are not correctly configured. The login and password should be provided in your FGLPROFILE file.

Solution:

1. Open the FGLPROFILE file used by the application.
2. Add entries for authenticate.xxx.login and authenticate.xxx.password.
3. Save your changes.

The Diffie-Hellman key agreement algorithm

Understand how Genero Web Services supports different key encryption methods for shared secret communication using the Diffie-Hellman key-agreement algorithm and the GWS XML security classes.

The Diffie-Hellman key agreement algorithm is a method that allows two devices to communicate over a network by establishing a shared secret without exchanging any secret data. Knowing the used key-agreement algorithm, the two devices only need to exchange their public keys. Then, using the other peer's public key and its own private key, each device performs the algorithm specific key generation operation to obtain the shared secret. The shared secret is a ready-to-use symmetric key for further signed or encrypted exchanges between the two peers.

Genero Web Services provides several shared secret type for signature, encryption, or key encryption purposes. Using the Diffie-Hellman key agreement algorithm, one of the following types of shared secrets can be computed:

- Symmetric AES128 encryption key
- Symmetric AES192 encryption key
- Symmetric AES256 encryption key
- Symmetric TripleDES encryption key
- Symmetric key wrap AES128 key encryption key
- Symmetric key wrap AES192 key encryption key
- Symmetric key wrap AES256 key encryption key
- Symmetric key wrap TripleDES key encryption key
- Symmetric HMAC-SHA1 signature key

In the Diffie-Hellman key agreement algorithm, two shared constants (called parameters) are used in addition to the private and public key. These two parameters are:

- The modulus (called P): A very big prime number chosen at random.
- The generator (called g): A prime number between two and five. Genero Web Services only uses two (2) for the generator.
If the private key (Priv) is a big number (not necessarily prime) chosen randomly, the public key (Pub) is calculated using P, g, and Priv as follows:

\[ \text{Pub} = g^{\text{Priv}} \mod P \]

Both devices need to use the same parameters for P and g. There are two ways to ensure this happens: Either P and g are chosen by a third party (such as a security authority) or one of the devices chooses them and sends them to the other peer with its public key.

Genero Web Services allows the Web service to generate the parameters itself, to load them from a string or from a PEM or DER file. The public key and the parameters can also be exchanged using an XML file.

This diagram shows the Diffie-Hellman algorithm steps between two devices, A and B, that need to communicate. Device A is in charge of generating the parameters. The shared secret is labeled K.
Figure 125: The Diffie-Hellman algorithm

For complete details about the mathematical basics underlying the Diffie-Hellman algorithm, see [RFC2631].
It is nearly impossible to get the private key from the public key, even knowing the values of parameters \( P \) and \( g \). Therefore, a middle man will not be able to obtain the shared secret \( K \). While devices \( A \) and \( B \) exchange their public key, and maybe the parameters as well, these values pass through different intermediate points. It is critical that \( A \) receives the correct public key from \( B \), and that \( B \) receives the correct public key from \( A \), in order to establish a common shared secret. It may be possible for a middle man to corrupt or replace one public key with his own. If that happens, \( A \) and \( B \) would be able to communicate because they don't compute the same shared secret. No secret data will be exchanged that is readable to the middle man. To avoid this situation, one can use Digital Certificate that helps to deliver the public key and the parameters in an authenticated method.

Once the shared secret is established, the Diffie-Hellman public key, private key and parameters are no longer useful. The Diffie-Hellman key agreement algorithm is achieved.

With the library provided as part of Genero Web Services, the shared secret has been computed to fit given specifications such as HMAC, 3DES, AES128, AES192, AES256, KW-3DES, KW-AES128, KW-AES192, or KW-AES256. The shared secret is actually a symmetric key ready to be used in a signature (HMAC) or cipher algorithm. It allows devices \( A \) and \( B \) to finally communicate via an authenticated (HMAC) or encrypted method.

**Related concepts**

XML security classes on page 3047
XML Security classes handle encryption and signature of XML documents entirely in memory with keys and certificates.

Supported kind of keys on page 3061
Types of keys supported by the `xml.CryptoKey` class.

---

**SOAP Web Services**

Write a Web Services client or server using the SOAP protocol.

The Genero APIs for creating Web services can be found in the Library section of this manual. See The com package on page 2811, The xml package on page 2931, and The util package on page 2726.

**Writing a Web Services client application**

Create, configure and deploy a Genero Web Services client using the SOAP protocol.

**Steps to write a WS client**

To access a SOAP Web service, you create a Genero BDL client application that requests the service's functions.

The Genero Web Services (GWS) package allows a BDL program to access Web services found on the Internet. GWS supports the WSDL1.1 specification of March 15, 2002. This example illustrates a client application that accesses the Add operation in the GWS Web Service `MyCalculator`.

See Writing a Web server application on page 3348 for information about the Service.

**Obtaining the WSDL information**

Before accessing a SOAP Web service, you must get the WSDL information from the service provider.

Sample services can be found through UDDI registries or on other sites such as XMethods (http://www.xmethods.net).

You can use the `fglwsdl` tool provided by the Genero Web Services package to obtain the necessary WSDL information. The following example obtains the WSDL information for the GWS Service `MyCalculator` created by the Writing a Web server application on page 3348:

```
fglwsdl -soap12 -o Example2Client http://localhost:8090/MyCalculator?WSDL
```

This generates two files:
- Example2Client.inc - the globals file containing the definitions of the input and output records, and the prototypes of the operations.
- Example2Client.4gl - a module containing the definitions of the functions that can be used in your GWS client application to perform the requested Web Service operation, and the code that manages the Web Service request.

Note: The MyCalculator GWS Service must be running on the specified port in order to provide the WSDL information.

The following definitions were generated in the globals file, Example2Client.inc:

### Input and Output records

```plaintext
DEFINE Add RECORD
  ATTRIBUTES( XMLName="Add",
    XMLNamespace="http://tempuri.org/webservices" )
  a INTEGER ATTRIBUTES( XMLName="a", XMLNamespace="" ),
  b INTEGER ATTRIBUTES( XMLName="b", XMLNamespace="" )
END RECORD

DEFINE AddResponse RECORD
  ATTRIBUTES( XMLName="AddResponse",
    XMLNamespace="http://tempuri.org/webservices" )
  r INTEGER ATTRIBUTES( XMLName="r",XMLNamespace="" )
END RECORD
```

The data types are defined as global or modular variables.

### Function prototypes for the Operations

This globals file contains the prototype of two functions for the Add operation.

The Add function uses input and output parameters, and returns the status and result. This function can only be used if the input and output parameters are not complex structures such as arrays or records. Using this function, developers do not access the global records directly.

The Add_g function can be used with the global input and output records. Before calling this function, you must set the values in the variables of the global input record.

```plaintext
Operation: Add
  #
  # FUNCTION: Add_g()
  # RETURNING: soapStatus
  # INPUT: GLOBAL Add
  # OUTPUT: GLOBAL AddResponse
  #
  # FUNCTION: Add(p_a, p_b)
  # RETURNING: soapStatus ,p_r
```

See fglwsdl on page 2081 and WS client stubs and handlers on page 3328 for more details regarding the fglwsdl tool, its output and the generated functions.

### Related concepts

SOAP 1.1 and 1.2 on page 3280
GWS is able to communicate with Web services provided with SOAP 1.1 or SOAP 1.2.

**Calling a web service**
Import the required libraries, specify globals, and write the program to call a SOAP Web Service.

**Step 1: Import the COM library of the GWS package**
The methods associated with creating and publishing a Web Service are contained in the classes that make up the Genero Web Services Library (com). If you use any of these methods in your client application, you must import the library. Since this example application sets the timeout period that the client will wait for the Service to respond, include the following line at the top of the module:

```plaintext
IMPORT com
```

If your generated .inc file uses XML class data types, you need to add `IMPORT xml.`

**Related concepts**
- The [com package](#) on page 2811
  The Genero Web Services com package provides classes and methods that allow you to perform tasks associated with creating Services and Clients, and managing the services.

**Step 2: Specify the globals file**
Use a GLOBALS statement to specify the globals file generated from the WSDL.

```plaintext
GLOBALS "Example2Client.inc"
```

**Related concepts**
- [Obtaining the WSDL information](#) on page 3321
  Before accessing a SOAP Web service, you must get the WSDL information from the service provider.

**Step 3: Write the MAIN program block**
Provide values for the input and output messages of the operation, and call one of the generated functions. Since the input and output messages are simple integers, we can call the Add function.

```plaintext
MAIN
  DEFINE op1 INTEGER
  DEFINE op2 INTEGER
  DEFINE result INTEGER
  DEFINE wsstatus INTEGER

  LET op1 = 1
  LET op2 = 2
  CALL Add(op1, op2) RETURNING wsstatus, result
  IF wsstatus = 0 THEN
    DISPLAY "Result: ", result
  ELSE
    -- Use the global wsError record
    DISPLAY "Error: ", wsError.description
  END IF
END MAIN
```

Alternatively, we can use the global input and output records directly, calling the Add_g function:

```plaintext
MAIN
  DEFINE wsstatus INTEGER

  LET Add.a = 1
  LET Add.b = 2
  LET wsstatus = Add_g()
  IF wsstatus != 0 THEN
```
-- Use the global wsError record
DISPLAY "Error ", wsError.Description
ELSE
  DISPLAY "Result: ", AddResponse.r
END IF
END MAIN

These examples are very basic versions of the code. For complete examples, see the code samples provided with the package in demo/WebServices.

Setting a time period for the response
To protect against remote server failure or unavailability, set a timeout value that indicates how long you are willing to wait for the server to respond to your request.

Use the SetOption() method of the WebServiceEngine class to set the readwritetimeout option.

For example, to wait no more than 10 seconds:

```
CALL com.WebServiceEngine.SetOption( "readwritetimeout", 10 )
```

A timeout value of -1 means "wait forever". This is the default value.

Related concepts
The WebServiceEngine class on page 2828
The com.WebServiceEngine class provides an interface to manage the Web Services engine.

Handling GWS server errors
When a Genero Web Services service operation returns a status that is non-zero, you can get a more detailed error description from the global record wsError.

This record is defined in the globals .inc file.

```
DEFINE wsError RECORD
  code STRING, -- Short description of the error
  codeNS STRING, -- The namespace of the error code
  description STRING, -- Long description of the error
  action STRING -- internal "SOAP action"
END RECORD
```

Compiling the client application
When compiling, remember to link in the WSHelper library.

It is recommended that the library file WSHelper.42m, included in the $FGLDIR/lib directory of the Genero Web Services package, is linked into every client or server program.

Assuming the example client code is in a module named clientmain.4gl, you can compile and link the client program:

```
fglcomp clientmain.4gl
fglcomp Example2Client.4gl
fgllink -o myclient.42r clientmain.42m Example2Client.42m WSHelper.42m
```

Related concepts
WSHelper library on page 3499
The WSHelper library.

Change WS client behavior at runtime
Various aspects of access to a Web Service may be implemented on the client side at runtime using global endpoint records.

Genero Web Services generates a global record called tGlobalEndpointType to change the client behavior at runtime without the need for modifying any generated client stub.
If WS-Addressing 1.0 is enabled, the global generated record is called tWSAGlobalEndpointType.

If needed, you can also access the HTTP layer via the Request and Response record of the binding record. See Access HTTP request and response headers for a service on page 3327.

**Global Endpoint type definition**
The client stub provides a global endpoint type, tGlobalEndpointType.

The following global type is used by any generated client stub to allow the programmer to change the client behavior at runtime.

```
TYPE tGlobalEndpointType RECORD # End point
  Address RECORD
    Uri STRING
  END RECORD,
  Binding RECORD
    Version STRING, # HTTP Version (1.0 or 1.1)
    Cookie STRING,
    ConnectionTimeout INTEGER,
    ReadWriteTimeout INTEGER
  END RECORD
END RECORD
```

Description of variables:

- **Address.Uri**: Represents the location of the server.

  **Important**: It replaces the global variable of type STRING generated prior to version 2.40, therefore it is mandatory to regenerate the client stub and to modify the location assignation in your application.

- **Binding.Version**: Represents the HTTP version to use for communication (only 1.0 or 1.1 allowed, default is 1.1).

- **Binding.Cookie**: Represents the HTTP cookie to use for communication (or NULL if there is no cookie to send).

- **Binding.ConnectionTimeout**: Represents the maximum time in seconds to wait for the establishment of the connection to the server.

- **Binding.ReadWriteTimeout**: Represents the maximum time in seconds to wait for a connection read or write operation before breaking the connection.

**Related concepts**

- Global Endpoint user-defined type definition on page 3329
- Bindings defined for the Web service can be changed at runtime.

**WS-Addressing 1.0 Global Endpoint type definition**
The client stub provides a global endpoint type for WS-Addressing, tWSAGlobalEndpointType.

The following global type is used by any generated client stub where support for WS-Addressing 1.0 is enabled. It allows the programmer to change the client behavior at runtime, and to send additional WS-Addressing 1.0 reference parameters to a server.

If this global type is used in your main application, you must add the IMPORT xml instruction.

```
TYPE tWSAGlobalEndpointType RECORD # End point
  Address RECORD # Address
    Uri STRING, # URI
  Parameters DYNAMIC ARRAY OF xml.DomDocument
    ATTRIBUTES(XMLNamespace="##any",XMLAny) # End point WSA reference parameters
  END RECORD,
  Binding RECORD # Binding
    Version STRING, # HTTP Version (1.0 or 1.1)
    Cookie STRING, # Cookie to be set
    ConnectionTimeout INTEGER,# Connection timeout
```

Description of variables:

- **Address.Parameters**: Represents the WS-Addressing 1.0 reference parameter to send to a WS-Addressing 1.0 compliant server.

  For a description of other parameters, see Global Endpoint type definition on page 3325.

**Related concepts**

- Global Endpoint user-defined type definition on page 3329
- Bindings defined for the Web service can be changed at runtime.

**Change server location**

If the Web service server location changes, you can update the address in the global endpoint record.

To change the server location at runtime, set the record `Uri` member with a valid URL of another service. All services must respect the same WSDL contract. If you leave the variable unset, the client will connect to the server URL defined in the WSDL at code generation time.

Example:

```plaintext
```

You can assign this variable with a URL set in the FGLPROFILE (see Logical Service location).

If you are migrating from a version prior to 2.40, see also Web Services changes on page 172.

**Change the HTTP protocol version**

The version parameter allows you to change the HTTP version binding if required.

To communicate with a service that communicates only on a given version of HTTP, set the record `Version` member with the desired value. If you leave the variable unset, the client will communicate in HTTP 1.1.

Example:

```plaintext
LET Calculator_CalculatorPortTypeEndpoint.Binding.Version = "1.0"
```

If you do not want the request to be split into chunks, set the HTTP protocol version to 1.0.

**Important**: On GMI mobile devices, the HTTP protocol version definition is ignored, it will always be version 1.1.

**Set an HTTP cookie**

Manage the cookie binding at runtime using the global endpoint record parameter.

To send an HTTP cookie to the service, set the record `Cookie` member with the cookie value. If you leave the variable unset, the client won't send any cookie.

Example:

```plaintext
LET Calculator_CalculatorPortTypeEndpoint.Binding.Cookie = "MyCookie=AValue"
```

Unset that variable if you don't need the cookie to be sent anymore.

**Set the connection timeout for a service**

A default connection timeout value is set, but you can configure the value at runtime, if required.

To change the default timeout value to establish a connection to the service, set the record member `ConnectionTimeout` with the timeout value in seconds. The `ConnectionTimeout` is a maximum time to establish the connection.
If the server is not available, you can get the response sooner than ConnectionTimeout. The ConnectionTimeout also avoids indefinitely waiting for a response when a server is reachable but not responding to requests.

Example:

```
LET Calculator_CalculatorPortTypeEndpoint.Binding.ConnectionTimeout = 15
```

**Important:** On GMI mobile devices, the max of ConnectionTimeout and ReadWriteTimeout will be used.

**Related concepts**

Set the read and write timeout for a service on page 3327

Set the ReadWriteTimeout value to indicate how long you are willing to wait for the server to respond to requests.

**Set the read and write timeout for a service**

Set the ReadWriteTimeout value to indicate how long you are willing to wait for the server to respond to requests.

To change the default time the application waits for a response from a service, set the ReadWriteTimeout parameter with a time out value in seconds.

Example:

```
LET Calculator_CalculatorPortTypeEndpoint.Binding.ReadWriteTimeout = 5
```

**Important:** On GMI mobile devices, the max of ConnectionTimeout and ReadWriteTimeout will be used.

**Related concepts**

Setting a time period for the response on page 3324

To protect against remote server failure or unavailability, set a timeout value that indicates how long you are willing to wait for the server to respond to your request.

Set the connection timeout for a service on page 3326

A default connection timeout value is set, but you can configure the value at runtime, if required.

**Access HTTP request and response headers for a service**

Configure additional headers for requests and responses by adding them to the globals endpoint record.

To access HTTP headers exchanged between the Genero client and a web service, you must use the following records in the binding section:

- one record called Request in order to customize HTTP headers to be sent to a web service
- one record called Response in order to retrieve all HTTP headers returned by a web service

```
TYPE tGlobalEndpointWithHttpLayerType RECORD # End point
  Address RECORD # Address
    Uri STRING # URI
  END RECORD,
  Binding RECORD # Binding
    Version STRING, # HTTP Version (1.0 or 1.1)
    Cookie STRING, # Cookie to be set
    Request RECORD
      Headers DYNAMIC ARRAY OF RECORD # HTTP Headers
        Name STRING,
        Value STRING
    END RECORD,
  Response RECORD
    Headers DYNAMIC ARRAY OF RECORD # HTTP Headers
        Name STRING,
        Value STRING
    END RECORD,
  ConnectionTimeout INTEGER,# Connection timeout
  ReadWriteTimeout INTEGER # Read write timeout
  CompressRequest STRING # HTTP compression mode (gzip or deflate)
```

Description of additional Request and Response variables:

- **Binding.Request.Headers**: Represents the additional HTTP headers to be sent to the web service. (Notice that client stub headers will replace user ones with the same name).
- **Binding.Response.Headers**: Represents the HTTP headers returned by a web service.

**Related reference**

- **Global Endpoint type definition** on page 3325
  The client stub provides a global endpoint type, tGlobalEndpointType.
- **WS-Addressing 1.0 Global Endpoint type definition** on page 3325
  The client stub provides a global endpoint type for WS-Addressing, tWSAGlobalEndpointType.

**WS client stubs and handlers**

To access a remote Web Service, you first must get the WSDL information from the service provider.

To access a remote Web service, you first must get the WSDL information from the service provider. Sample services can be found through UDDI registries (http://www.uddi.org), or on other sites such as XMethods.

**Generating stub files for a GWS Client**

Use the `fglwsdl` tool to generate the BDL stub from a WSDL URL or file.

This example requests the Calculator Web service information from the specified URL, and the output files will have the base name `ws_calculator`:

```
```

For a client application, `fglwsdl` generates two output files. It is not advised to modify these files:

- `filename.inc` - the globals file, containing declarations of global variables that can be used as input or output for functions accessing Web service operations, and the global `wsError` record. In our example, the file is `ws_calculator.inc`.
  
  This file must be listed in a GLOBALS statement at the top of any `.4gl` modules that you write for your GWS Client application.
- `filename.4gl` - containing the definitions of the functions that can be used in your GWS client application to perform the requested Web service operation, and the code that manages the Web service request. In our example, the file is `ws_calculator.4gl`.
  
  This file must be compiled and linked into your GWS Client application.

**Related concepts**

- **SOAP 1.1 and 1.2** on page 3280
  GWS is able to communicate with Web services provided with SOAP 1.1 or SOAP 1.2.

**Handling GWS server errors**

When a Genero Web Services service operation returns a status that is non-zero, you can get a more detailed error description from the global record `wsError`.

This record is defined in the globals `.inc` file.

```
DEFINE wsError RECORD
  code STRING,         -- Short description of the error
  codeNS STRING,       -- The namespace of the error code
  description STRING,  -- Long description of the error
  action STRING        -- internal "SOAP action"
END RECORD
```
Global Endpoint user-defined type definition

Bindings defined for the Web service can be changed at runtime.

The `fglwsdl` tool generates the globals (inc) file to use for a Web services client. Part of this globals file is a global endpoint user-defined type definition.

```plaintext
# Global Endpoint user-defined type definition

TYPE tGlobalEndpointType RECORD   # End point
    Address RECORD # Address
        Uri STRING                 # URI
    END RECORD,
    Binding RECORD # Binding
        Version STRING,             # HTTP Version (1.0 or 1.1)
        Cookie STRING,              # Cookie to be set
        ConnectionTimeout INTEGER,  # Connection timeout
        ReadWriteTimeout INTEGER,   # Read write timeout
        CompressRequest STRING      # HTTP request compression mode (gzip or deflate)
    END RECORD

# Location of the SOAP endpoint.
# You can reassign this value at run-time.
#
DEFINE EchoDocStyle_EchoDocStylePortTypeEndpoint tGlobalEndpointType
```

The `CompressRequest` entry is of type string. It is NULL by default, meaning that no request is compressed. To compress a request, set this variable to `gzip` or `deflate`. The server must support compression, otherwise the request will be rejected.

The generated functions

Defines the requirements for Genero Web Services (GWS) client functions.

Genero Web Services (GWS) client functions have the following requirements:

- The function cannot have input parameters.
- The function cannot have return values.
- The function's input message must be defined as a global or module RECORD.
- The function's output message must be defined as a global or module RECORD.

As a result, two types of GWS functions are generated for the Web Service operation that you requested:

- One function type uses global records for the input and output. The names of these functions end in "._g". Before calling the function in your GWS Client application, you must set the values in the global input record. After the function call, the status of the request is returned from the server, and the output message is stored in the global output record. In addition to performing the desired operation, this function handles the communication for the SOAP request and response, and sets the values in the `wsError` record as needed.
- The other function type serves as a "wrapper" for the "._g" function. It passes the values of input parameters to the "._g" function, and returns the output values and status received from the "._g" function. Your client application does not need to directly access the global records. This function can only be used if the parameters are simple variables (no records or arrays).
The generated .inc globals file contains comments that list the prototypes of the functions for the GWS operation, and the definitions of the global INPUT and OUTPUT records.

**The generated callback handlers**
Understand the function of callback handlers, and how to generate them in your client stub.

More and more Web services provide support for the different WS-* specifications. To enable a better interoperability with such services, the fglwssl on page 2081 tool allows the programmer to modify the SOAP request before it is sent, and to perform additional verifications of the SOAP response before it is returned from the BDL function.

When option -domHandler is used, the fglwssl tool performs the following two operations at once:

- It generates the client stub based entirely on the DOM API to ease the manipulation of the XML requests and responses.
- It generates additional calls for each operation of a service to execute one of the three callback handlers the programmer has to implement.

**Handler definition**
Describes the various callback handlers and how they are defined.

There are three kind of callbacks you must implement for each service generated with the -domHandler option.

- The request handler that allows the modification of the entire SOAP request before it is sent over the net.
  - It must be named `ServiceName_HandleRequest`, where `ServiceName` is the name of the service following the different prefix options used during generation.
  - It must return `TRUE` if you want the caller function to continue normally or `FALSE` to return from the caller function with a SOAP error you can define via the `wsError` record.

```plaintext
FUNCTION ServiceName_HandleRequest(operation, doc, header, body)
DEFINE operation STRING          -- Operation name of the
-- request to be modified.
DEFINE doc xml.DomDocument        -- Entire XML document of the request
DEFINE header xml.DomNode          -- XML node of the SOAP header
-- of the request
DEFINE body xml.DomNode           -- XML node of the SOAP body of the
-- request
CASE operation
  WHEN "Add"
    ... -- Use the DOM APIs to modify the request of the Add operation
  WHEN "Sub"
    ... -- Use the DOM APIs to modify the request of the Sub operation
  OTHERWISE
    DISPLAY "No modification for operation ":operation
END CASE
RETURN TRUE -- Continue normally in Add_g() or Sub_g()
END FUNCTION
```

- The response handler that allows the validation of the entire SOAP response before it is deserialized into the corresponding record.
  - It must be named `ServiceName_HandleResponse`, where `ServiceName` is the name of the service following the different prefix options used during generation.
  - It must return `TRUE` if you want the caller function to continue normally or `FALSE` to return from the caller function with a SOAP error you can define via the `wsError` record.

```plaintext
FUNCTION ServiceName_HandleResponse(operation, doc, header, body)
DEFINE operation STRING         -- Operation name of the
-- response to be checked.
DEFINE doc xml.DomDocument        -- Entire XML document of the response
DEFINE header xml.DomNode          -- XML node of the SOAP header of
-- the response
DEFINE body xml.DomNode           -- XML node of the SOAP body of the
```
The fault response handler that allows the verification of the entire SOAP fault response before it is de-serialized into the wsError record.

It must be named ServiceName_HandleResponseFault, where ServiceName is the name of the service according to the different prefix options used during generation. It must return TRUE if you want the caller function to continue normally or FALSE to return from the caller function with a SOAP error you can define via the wsError record.

```
FUNCTION ServiceName_HandleResponseFault(operation,doc,header,body)
  DEFINE operation STRING          -- Operation name of the fault response to be checked.
  DEFINE doc xml.DomDocument       -- Entire XML document of the fault response
  DEFINE header xml.DomNode        -- XML node of the SOAP header of the fault response
  DEFINE body xml.DomNode          -- XML node of the SOAP body of the fault response
  CASE operation
    WHEN "Add"
      ... -- Use the DOM APIs to verify the SOAP fault response of the Add operation
    WHEN "Sub"
      ... -- Use the DOM APIs to verify the SOAP fault response of the Sub operation
    OTHERWISE
      DISPLAY "No verification for operation :",operation
  END CASE
  RETURN TRUE -- Continue normally in Add_g() or Sub_g()
END FUNCTION
```

Example output
The example WSDL file for the Calculator Web Service provides information about the service.

The generated file ws_calculator.inc lists the prototype for the following functions: Add and Add_g functions, the asynchronous AddRequest_g and AddResponse_g functions, as well as the definitions of the global variables Add and AddResponse:

```
# Operation: Add## FUNCTION: Add_g() -- Function that uses the global input and output records## RETURNING: soapStatus -- An integer where 0 represents success## INPUT: GLOBAL Add## OUTPUT: GLOBAL AddResponse##
# FUNCTION: Add(p_a, p_b) -- Function with input parameters that correspond to the a and b variables## RETURNING: soapStatus ,p_r -- of the global INPUT record
```
--- Return values are the status
of the global OUTPUT record

# FUNCTION: AddRequest_g() -- Asynchronous function that uses the global input record
# RETURNING: soapStatus -- An integer where 0 represents success, -1 error and -2 means a previous request was sent and that a response is in progress.

# FUNCTION: AddResponse_g() -- Asynchronous function that uses the global output record
# RETURNING: soapStatus -- An integer where 0 represents success, -1 error and -2 means that the response was not yet received, and that a new call should be done later.

#VARIABLE : Add -- defines the global INPUT record
DEFINE Add RECORD ATTRIBUTES(XMLName="Add",
   XMLNamespace="http://tempuri.org/"
   a INTEGER ATTRIBUTES(XMLName="a",XMLNamespace=""),
   b INTEGER ATTRIBUTES(XMLName="b",XMLNamespace="")
END RECORD

# VARIABLE : AddResponse -- defines the global OUTPUT record
DEFINE AddResponse RECORD ATTRIBUTES(XMLName="AddResponse",
   XMLNamespace="http://tempuri.org/"
   r INTEGER ATTRIBUTES(XMLName="r",XMLNamespace="")
END RECORD

Multipart in the client stub
You can generate a client stub for a Web service that has multiple parts.

If the WSDL for a Web service indicates that the Web service uses multiple parts, the client stub generated will support multiple parts.

For the request
There are as many com.HTTPPart input parameters as parts defined for the input request, plus one AnyInputParts DYNAMIC ARRAY OF com.HTTPPart parameter, to manage the optional parts a user can add to the request.

For example:

FUNCTION xxx_g(InputHttpPart_1, ..., InputHttpPart_n, AnyInputParts)
   DEFINE InputHttpPart_1 com.HTTPPart
   ...
   DEFINE InputHttpPart_n com.HTTPPart
   DEFINE AnyInputParts DYNAMIC ARRAY OF com.HTTPPart
   ...
   RETURN wsstatus
END FUNCTION
For the response

There are as many `com.HTTPPart` variables as are described in the WSDL, plus one `AnyOutputParts` `DYNAMIC ARRAY OF com.HTTPPart` to handle the optional parts that may be returned by a service.

For example:

```gregated_code
FUNCTION xxx_g()
  DEFINE wsstatus INTEGER
  DEFINE OutputHttpPart_1 com.HTTPPart
  DEFINE AnyOutputParts DYNAMIC ARRAY OF com.HTTPPart
  ...
  RETURN wsstatus, OutputHttpPart_1, AnyOutputParts
END FUNCTION
```

Related concepts

**SOAP multipart style requests in GWS** on page 3297
This topic describes multipart support with Genero Web Services

**Using the generated functions**
Learn how to use the functions and global records in the stub file to write client applications that use the Web service.

The information about the Add function from the `ws_calculator.inc` file, for example, allows you to write code in your own `.4gl` module that uses this operation as part of your Client application.

**Using parameters and return values**
You call the Add function in your Client application, defining variables for the parameters and return values. The input variables for our example are simple integers.

```gregated_code
FUNCTION myWScall()
  DEFINE op1 INTEGER
  DEFINE op2 INTEGER
  DEFINE result INTEGER
  DEFINE wsstatus INTEGER
  ...
  LET op1 = 6
  LET op2 = 8
  CALL Add(op1, op2)
  RETURNING wsstatus, result ...
  DISPLAY result
```

**Using global records**
An alternative option is to call the `Add_g` function instead, using the global records `Add` and `AddResponse` directly. If the input variables are complex structures like records or arrays, you are required to use this function.

```gregated_code
FUNCTION myWScall()
  DEFINE wsstatus INTEGER
  ...
  LET Add.a = 6
  LET Add.b = 8
  LET wsstatus = Add_g()
  ...
  DISPLAY AddResponse.r
```

In this case, the status is returned by the function, which has also put the result in the `AddResponse` global record.

See **Tutorial: Writing a Client Application** for more information. The `demo/WebServices` subdirectory of your Genero installation directory contains complete examples of Client Applications.
Using asynchronous calls

If you don't want your application to be blocked when waiting for the response to a request, it is recommended that you first call `AddRequest_g();` this will send the request using the global `Add` record to the server. It returns a status of 0 (zero) if everything goes well, -1 in case of error, or -2 if you tried to resend a new request before the previous response was retrieved.

```bdl
FUNCTION sendMyWScall()
    DEFINE wsstatus INTEGER
    ...
    LET Add.a = 6
    LET Add.b = 8
    LET wsstatus = AddRequest_g()
    IF wsstatus <> 0 THEN
        DISPLAY "ERROR ", wsError.code
    END IF
    ...
```

You can then call `AddResponse_g` to retrieve the response in the `AddResponse` global record of the previous request. If the returned status is 0 (zero), the response was successfully received; -1 means that there was an error, and -2 means that the response was not yet received and that the function needs to be called later.

```bdl
FUNCTION retrieveMyWScall()
    DEFINE wsstatus INTEGER
    ...
    LET wsstatus = AddResponse_g()
    CASE wsstatus
        WHEN -2
            DISPLAY "No response available, try later"
        WHEN 0
            DISPLAY "Response is ", AddResponse.r
        OTHERWISE
            DISPLAY "ERROR ", wsError.code
    END CASE
    ...
```

You can mix the asynchronous call with the synchronous one as they are using two different requests. In other words, you can perform an asynchronous request with `AddRequest_g();` then a synchronous call with `Add_g();` and then retrieve the response of the previous asynchronous request with `AddResponse_g();`.

**Important:** In development mode, a single BDL Web Service server can only handle one request at a time, and several asynchronous requests in a row without retrieving the corresponding response will lead to a deadlock. To support several asynchronous requests in a row, it is recommended that you are in deployment mode with a GAS as the front-end.

**Using logical names for service locations**

Using a logical reference for the Web service, instead of the real URL, in your client application URL binding has advantages for working with and deploying applications.

Genero Web Services, starting with version 2.00, provides a repository for Web Service locations using FGLPROFILE. To achieve maximum flexibility, you can map a logical reference used by your Web Services client application to an actual URL. This is subject to the network configuration and access rights management of the deployment site.

**Important:** On GMI mobile devices, FGLPROFILE settings for logical names are not supported.

**FGLPROFILE entry**

FGLPROFILE entries can be used to define server URLs by using URL patterns.

The following entry in the FGLPROFILE file maps the logical reference "myservice" to an actual URL:

```plaintext
```
**Related concepts**

*FGLPROFILE: Server URL patterns* on page 3498

FGLPROFILE entries can be used to define multiple server URLs, by using URL patterns.

**Logical reference in the client application**

Specify a logical name for the Web service in the endpoint record of your client application.

When you generate a Client stub from WSDL information using the tool fglwsdl, a global variable for the URL of the Web Service is contained in the .inc file.

For example:

```plaintext
# Location of the SOAP server.
# You can reassign this value at run-time.
#
# DEFINE Calculator_CalculatorPortTypeEndpoint tGlobalEndpointType
```

You can assign a logical name, instead of the Web service URL, to this global variable in your Web Services client application:

```plaintext
LET Calculator_CalculatorPortTypeEndpoint.Address.Uri = "alias://myservice"
```

When the client application accesses the service, the actual location will be supplied by the entry in your FGLPROFILE file on the client machine. This allows you to provide the same compiled .42r application to different customers. The entries in the FGLPROFILE file on each customer's machine would customize the Web Service location for that customer.

If you are migrating from a version prior to 2.40, see also *Web Services changes* on page 172.

**Related concepts**

*Global Endpoint user-defined type definition* on page 3329

Bindings defined for the Web service can be changed at runtime.

**Logical reference in the URL**

Specify a Web service URL in the FGLPROFILE file.

When you deploy a Genero Web Service with a GAS behind a Web Server, the service can be accessed by two different URLs. You can use a logical name in the URL binding record, mapping the actual location of the Web Service in your FGLPROFILE file, depending on the location of the client machine.

For example:

- For internal clients: http://zeus:6394/ws/r/myservice
- For clients using the Web: http://www.myServer.com/...

These two URLs can be mapped in the FGLPROFILE file on the client machine, each specifying the location of the Service.

**Related concepts**

*Logical reference in the client application* on page 3335

Specify a logical name for the Web service in the endpoint record of your client application.

*FGLPROFILE entry* on page 3334

FGLPROFILE entries can be used to define server URLs by using URL patterns.

**Configure a WS client to access an HTTPS server**

Configuration steps to access a server in HTTPS.

To configure access to an HTTPS server, you need a client certificate.

**Important:** On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain® typically holds the server certificate authority list. Therefore, the FGLPROFILE file security settings are ignored
with the exception of the following: `security.global.ca`, `security.global.ca.lookuppath`, and `security.global.systemca`.

Before you begin, there are options to consider depending on how you wish to use the client certificate:

- If you do not have the certificate information in your FGLPROFILE file, Genero Web Services creates a certificate for you. This is an implicit or temporary certificate that is valid for a session only. For more information see HTTPS configuration on page 3305.
  
  **Note:** For the implicit certificate, no configuration is required.

- Alternatively, for stronger security, you generate a client certificate of your own, configure your application to use the client certificate generated, and add the configuration details to the FGLPROFILE file. Follow the steps outlined in this section.
  
  **Note:** In a production environment, some servers provide a client certificate and you use the certificate as provided, and add the configuration details to the FGLPROFILE file.

The openssl command line tool can be used to create your own certificates for the configuration of secured communication. The following steps outline the configuration process:

**Related concepts**

- Encryption and authentication on page 3299
  
  A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

- Accessing secured services on page 3303
  
  Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web service.

**Create the client certificate**

Generate a root certificate authority that signs a client certificate.

In this task you create your own root certificate authority and client certificate using the OpenSSL command line tool.

1. Create the root certificate authority.
   
   a) Create the root certificate authority serial file.
      
      ```
      $ echo 01 > MyCompanyCA.srl
      ```
      
      This command creates a serial file with an initial HEX value 01. OpenSSL uses this file to track the serial numbers of certificates it creates. The serial file is typically given the same name as the CA with the extension .srl.
      
      b) Create the Certificate Signing Request (CSR) and private key.
         
         ```
         $ openssl req -new -out MyCompanyCA.csr -keyout MyCompanyCA.pem
         ```
         
         Follow the instructions to create the CSR.
      
      c) Create the Root Certificate Authority for a period of validity of 2 years.
         
         ```
         $ openssl x509 -trustout -in MyCompanyCA.csr -out MyCompanyCA.crt -req -signkey MyCompanyCA.pem -days 730
         ```
         
         **Note:** The private key file (MyCompanyCA.pem) of a Root Certificate Authority must be handled with care. This file is responsible for the validity of all other certificates it has signed. As a result, it must not be accessible by other users.

2. Create the client's X.509 certificate and private key.
a) Create the client's Certificate Signing Request and private key.

```
$ openssl req -new -out MyClient.csr
```

**Note:** By default, openssl outputs the private key in the `privkey.pem` file. If you want to specify a different file name, or if your openssl version does not output the private key by default, add the `-keyout <myprivkey>.pem` to the command.

b) Remove the password from the RSA private key.

```
$ openssl rsa -in privkey.pem -out MyClient.pem
```

**Note:** The unprotected private key is output in `MyClient.pem`.

c) Create the client's certificate (self-signed X.509 certificate valid for a period of 1 year) trusted by the Root Certificate Authority created in step 1.

```
$ openssl x509 -in MyClient.csr -out MyClient.crt -req
-sigkey MyClient.pem -CA MyCompanyCA.crt
-CAkey MyCompanyCA.pem -days 365
```

**Note:** Most servers do not check the identity of the clients. For these servers, the client's certificate does not necessarily need to be trusted; it is only used for data encryption purpose. If, however, the server performs client identification, you must trust a Certificate Authority in which it has total confidence concerning the validity of the client's certificates.

**Note:** The purpose of the client's certificate is to identify the client to any server; therefore the subject of the certificate must correspond to the client's identity as it is known by the servers.

**Note:** To import the certificate in a keystore you can create a pkcs12 certificate. See Import a certificate and its private key into the Windows key store on page 3315.

**What to do next**

Configure your FGLPROFILE file for the client certificate. See Configure for the client certificate on page 3307.

**Related concepts**

Encryption and authentication on page 3299
A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

The OpenSSL (openssl) tool on page 3313
The openssl command line tool creates certificates for the configuration of secured communications.

**Related tasks**

View a certificate on page 3316
This procedure allows you to view a certificate using the openssl command.

**Configure for the client certificate**

Configure your application to use the client certificate generated. For production systems, you add the configuration details to your FGLPROFILE file.

You have generated a client certificate as described in Create the client certificate on page 3306.

In this task you add the certificate information to your FGLPROFILE file.

Add the client's security configuration to your FGLPROFILE file.

The client security entry defines the certificate and the associated private key used by the Genero Web Services client during an HTTPS communication. The security entry must be defined with an unique identifier (`id1` in this example).

```python
security.id1.certificate = "MyClient.crt"
security.id1.privatekey = "MyClient.pem"
```
Note: If the private key is protected with a password, you must remove it or create a script that returns the password on demand. See Create the client certificate.

Your applications are configured to use the client certificate.

What to do next

Create the client's certificate authority list and configure the global certificate authority list (security.global.ca) in your FGLPROFILE file. See Configure for the certificate authority list on page 3308.

Related tasks

View a certificate on page 3316
This procedure allows you to view a certificate using the openssl command.

Configure for the certificate authority list

The client needs to check to see if the server certificate is trusted. This is done using a certificate authority list.

In this task you create the client's certificate authority list using the OpenSSL command line tool, and set the global certificate authority list in your FGLPROFILE file.

Important: On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain typically holds the server certificate authority list. Therefore, the FGLPROFILE file security settings are ignored with the exception of the following: security.global.ca, security.global.ca.lookuppath, and security.global.systemca.

1. Create the client's certificate authority list.

   a) Save the certificates of the HTTPS server to disk.

      Type the server's URL in your browser. When prompted, save all the certificates from the Certificate Hierarchy. For more information see, Selecting the certificate to add on page 3317 and Missing certificates on page 3311.

   b) Create the client's Certificate Authority List by running the following command for each of the certificates that you saved to disk.

      $ openssl x509 -in ServerCertificate.crt -text >> ClientCAList.pem

      Note: All trusted certificate authorities are listed. These are checked following a chain of child to parent certificates until a certificate is reached which is trusted. All other certificates that were trusted by the Root Certificate Authority will also be considered as trusted by the client. For more information see Certificate authorities on page 3301.

2. Set the global certificate authority list in your FGLPROFILE file.

   The global certificate authority list entry defines the file containing the certificate authority list used by the Genero Web Services client to validate all certificates coming from the different servers it will connect to.

   security.global.ca = "ClientCAList.pem"
Note: The file is located based on the current execution directory. If you use Genero Studio, for instance, fglrun may not be executed in the same directory as when you use the command line. The recommended practice therefore is to specify an absolute path for the .pem, for example:

security.global.ca = "/opt/usr/certs/ClientCAList.pem"

If security.global.ca is not defined, Genero Web Services will look to see whether the operating system has a keystore, otherwise security.global.ca.lookuppath will be used. For further information, see Certificate authorities in HTTPS configuration on page 3305.

The client application is configured to use the appropriate certificate authority list to validate a server's certificate.

What to do next
In your FGLPROFILE file ensure there are configuration entries (ws.*) for the HTTPS server URL and for the HTTP authentication when accessing the HTTPS server. See Add configuration entries in your FGLPROFILE file on page 3309.

Related concepts
Error: Peer certificate is issued by a company not in our CA list on page 3310
When a client connects to a server using HTTPS, the client needs to trust the server it is in communication with. So the client needs to add the server's CAs (certificate authorities lists) to its trusted CAs.

Enable OCSP on page 3310
To enable OCSP (Online Certificate Status Protocol), set the security.global.ocsp.enable and security.global.ocsp.url entries in FGLPROFILE.

FGLPROFILE entries for Web Services on page 3489

FGLPROFILE: HTTP(S) Proxy Authentication on page 3496
FGLPROFILE entries can be used to define a connection to an HTTPS server via a proxy, and with HTTP and Proxy Authentication.

Accessing secured services on page 3303
Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web service.

Add configuration entries in your FGLPROFILE file
Add a set of configuration entries that specify the security configuration for GWS clients accessing an HTTPS server.

In this task you add configuration entries (ws.*) in your FGLPROFILE file for the HTTPS server URL and for HTTP authentication when accessing the HTTPS server. For an example, see FGLPROFILE: HTTP(S) Proxy Authentication on page 3496.

Important: On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain® typically holds the server certificate authority list. Therefore, the FGLPROFILE file security settings are ignored with the exception of the following: security.global.ca, security.global.ca.lookuppath, and security.global.systemca.

Add configuration entries for the server.
The following entries must be defined with an unique identifier (such as "myserver"):

   (Line breaks added for document readability)
b) ws.myserver.security = "id1"

Where the value (id1 in this example) must match the unique identifier defined by the client security entry created in Configure for the client certificate on page 3307.

Tip: The unique identifier "myserver" can be used in the BDL client code in place of the actual URL.
Related concepts

FGLPROFILE entries for Web Services on page 3489

The FGLPROFILE entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

Accessing secured services on page 3303

Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web service.

Troubleshoot certificate issues on page 3310

You may encounter known (and common) issues when completing the Genero Web Services tutorials or when adding Web services of your own. These issues and their solutions are presented in the following topics.

Configure a WS client to connect via an HTTP Proxy

Configuration steps to connect via a HTTP proxy.

Important: On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.

1. Add the location of the proxy to your FGLPROFILE file with the proxy.http.location entry.

   Add the entry proxy.http.location to your fglprofile. For the value, provide the IP address of the HTTP proxy and the port number where the HTTP proxy is listening, separated by a colon. For example, to have a client connect via a HTTP proxy located at the IP address "10.0.0.170" and listening on port number "8080", add this entry to your fglprofile:

   ```
   proxy.http.location = "10.0.0.170:8080"
   ```

   Note: To configure the client to connect via an HTTPS proxy, replace http with https.

2. Define the list of host names the client will not have to connect to via a proxy with the proxy.http.list entry.

   Add the entry proxy.http.list to your FGLPROFILE file. For the value, provide a semi-colon separated list of clients. For example, to exclude all hosts beginning with "www.mycompany.com" or "www.google." from connecting via a HTTP proxy, add this entry to your fglprofile:

   ```
   proxy.http.list = "www.mycompany.com;www.google."
   ```

Proxy configuration on page 3492

Configure a WS client to use IPv6

Configuration steps to customize IPv6 for a WS client.

A Web Services client program can access a WS server using IPv6.

URLs that map to IPv6 addresses will be automatically handled by the Web Services library. It is also possible to specify an IPv6 address directly as URL in your BDL code by enclosing the address in [] square brackets, for example:

```ruby
LET myURL = "http://[fe80::20c:29ff:fe05:9ca3]:80/index.html"
```

By default, the WS library will automatically use IPv6 addresses if available, and fallback to IPv4 if not. To overcome the default behavior, you can explicitly specify the IP version.

The platform where WS client programs execute must support IPv6.

1. If needed, force the IP version with the ip.global.version entry in your fglprofile file, by specifying "4" for IPv4 or "6" for IPv6.

   For example, to force IPv4 (when IPv6 is available):

   ```
   ip.global.version = "4"
   ```
2. When using IPv6 for link-local addresses, if several network interfaces exist on the machine, you can explicitly specify which interface must be used with the `ip.global.v6.interface.name` or `ip.global.v6.interface.id` entry in fglprofile.

In order to specify the IPv6 network interface by name, use:

```
ip.global.v6.interface.name = "eth0"
```

**Important:** The `ip.global.v6.interface.name` entry is not supported on Microsoft® Windows® platforms.

In order to specify the IPv6 network interface by id, use:

```
ip.global.v6.interface.id = "2"
```

**Related reference**
IPv6 configuration on page 3493

**Authenticate the WS client to a server (HTTP basic authentication)**
Configuration steps to authenticate the client to a server.

See [Basic or digest HTTP authentication](#) on page 3491. For an example, see FGLPROFILE: HTTP(S) Proxy Authentication on page 3496.

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: Use the `com.HTTPRequest.setAuthentication` API instead.

1. Add HTTP authenticate entries to your FGLPROFILE file.
   To connect to a server with HTTP Authentication, define the client login and password with the same values as registered on the server side. These entries must be defined with an unique identifier (`httpauth` in this example) to define a HTTP Authentication with "mylogin" as login and "mypassword" as password:

   ```
   authenticate.httpauth.login = "mylogin"
   authenticate.httpauth.password = "mypassword"
   ```

   See [RFC2617](#) for more details.

2. Encrypt the password.
   Due to security leaks, it is recommended that you NOT have a password in clear text. The Genero Web Services package provides the tool `fglpass`, which encrypts a password with a certificate that is readable only with the associated private key. To encrypt the HTTP authentication password:
   a) Encrypt the clear text password with `fglpass` using the client certificate.

   ```
   $ fglpass -e -c MyClient.crt
   Enter password :mypassword
   ```
   ```
   Note: fglpass outputs the encrypted password on the console but can be redirected to a file.
   ```
   ```
   b) Modify the HTTP authentication password entry by specifying the security configuration to use to decrypt it ("id1" in our example)

   ```
   authenticate.httpauth.password.id1="HWTFu8Q8E2t3e5D4joy7js8mB95oOGTzLmcAor9j5DS+CloillhGWzvZ9eWpflmIWSOn9IwoiJheYxfnu20uaGGmmiUGiHxT6341ePXNSicu32Nt1Vp9t6RcS0wN/p9a6D4XtiD9iHW7iQvXhqC9uamd3gI9Q3GhHwXOMM1Y/c8Y="
   ```
   ```
   Note: Hard returns have been added to the code sample above, for the purpose of printing and viewing within this document. The value for `authenticate.httpauth.password.id1` is a single string with no spaces.
   ```
   ```
   Note: The size of the encrypted password depends on the size of the public key, and can change based on the certificate used to encrypt it.
   ```
   ```
   3. Configure the client to authenticate to a server.
As a client is able to connect to different servers that do not know the client with the same login and password, it is necessary to specify the login and password that corresponds to each server. To authenticate the client known as "myclient" with the password passphrase by the server myserver, add the following entry:

```plaintext
ws.myserver.authenticate = "httpauth"
```

**Related tasks**

- Configure a WS client to access an HTTPS server on page 3305
- Configuration steps to access a server in HTTPS.

**Authenticate the WS client to a proxy**

Configuration steps to authenticate the client to a proxy (proxy authentication).

For an example, see FGLPROFILE: HTTP(S) Proxy Authentication on page 3496.

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.

1. Add an HTTP authenticate entry to your FGLPROFILE file.
   - To connect via a proxy with HTTP Proxy Authentication, it is necessary to define the client login and password as registered on the HTTP proxy.
   - The following two entries must be defined with an unique identifier (`proxyauth` for our example) to define a HTTP Proxy Authentication with `myapplication` as login and `mypassword` as password:

   ```plaintext
   authenticate.proxyauth.login = "myapplication"
   authenticate.proxyauth.password = "mypassword"
   ```

   See [RFC2617] for more details.

2. For proxy authentication, an entry must be made to the HTTP proxy configuration in order to authenticate a client.
   - To authenticate a client known as `myapplication` with `mypassword` as password by the HTTP Proxy, add the following entry to the HTTP proxy configuration:

   ```plaintext
   proxy.http.authenticate = "proxyauth"
   ```

   **Note:** To authenticate the client to a HTTPS proxy, replace `http` with `https`.

**Related reference**

- Proxy configuration on page 3492

**Writing a Web Services server application**

Create a Genero Web Services server using the SOAP protocol.

**Writing a Web services server function**

You create a standard Genero function and publish it as a Web function (Web services operation) using methods from the classes in the COM library.

There are some restrictions on the function - input and output parameters are not allowed. By using global or module variables, however, you can work around this exception.

See also Tutorial: Writing a GWS Server Application

The steps for writing a Web Services function:

**Define the input parameters**

Define a record for the input message of the Web function.

Even though input parameters are not allowed in Genero Web Service operations, each Web function can have one global variable or module variable that defines the input message of the function. This variable must be a record in which each field represents one of the input parameters of the Web function.
The name of each field corresponds to the name used in the SOAP request. These fields are filled with the contents of the SOAP request by the Web Services engine just before executing the corresponding BDL function.

**Example**

```plaintext
DEFINE add_in RECORD
    a INTEGER,
    b INTEGER
END RECORD
```

**Note:** Genero version 2.0 allows you to add optional attributes to the definition of data types. You can use attributes to map the BDL data types in a Genero application to their corresponding XML data types. See Attributes to Customize XML Mapping for additional information.

### Define the output parameters

Define a record for the output message of the function.

Even though output parameters in Genero Web functions are not allowed, each Web function can have one global variable or module variable that defines the output message of the function. This message must be a record where each field represents one of the output parameters of the Web function.

The name of each field corresponds to the name used in the SOAP request. These fields are retrieved from the Web Services engine immediately after executing the BDL function, and sent back to the client.

**Example**

```plaintext
DEFINE add_out RECORD
    r INTEGER
END RECORD
```

**Note:** GWS 2.0 allows you to add optional attributes to the definition of data types. You can use attributes to map the BDL data types in a Genero application to their corresponding XML data types. See Attributes to Customize XML Mapping for additional information.

### Write the BDL function

Your function defines an operation of the service.

A Web service function is a normal BDL function that uses the input and output records that you have defined.

**Example**

```plaintext
FUNCTION add()
    LET add_out.r = add_in.a + add_in.b
END FUNCTION
```

### Create and publish the Web services operation

Provide your Web service and its operation to users who can access it on the net.

Methods are available in the Genero Web Services library (com) to:

- Define the Web Service, by creating a WebService object
- Define the Web Services operation for your function, by creating a WebOperation object
- Publish the operation - associate it with the Web Service object that you defined.

The com library must be imported into each module of a Web Services Server application.

The following abbreviated example is from the Web Services Server tutorial:

```plaintext
IMPORT com
...
FUNCTION createservice()
    DEFINE serv com.WebService    # A WebService
    DEFINE op com.WebOperation    # Operation of a WebService
```
--Create WebService object
    "http://tempuri.org/webservices")

--Create WebOperation object
LET op = com.WebOperation.CreateRPCStyle("add", "Add", add_in, add_out)

--Publish the operation, associating it with the WebService object
CALL serv.publishOperation(op, NULL)
...
END FUNCTION

See the Writing a Web server application on page 3348 and Choosing a web services style on page 3358 for complete examples and explanations.

**WS server stubs and handlers**

Describes using a server stub from a compatible Web service that you can use in your GWS server application.

Sample Web services can be found through UDDI registries (http://uddi.xml.org), or on other sites such as XMethods.

**Generating files for a GWS server**

Use the fglwsdl -s tool server option to generate the BDL server stub from a WSDL.

You can write a Genero Web Services server application for a Web Service that you have created; see Tutorial: Writing a Server Application.

If you want to make sure your Web Service is compatible with that of a third-party (an accounting application vendor, for example), you can use the fglwsdl tool to obtain the WSDL information that complies with that vendor's standards, and to generate corresponding files that can be used in your GWS server application.

This example requests the Calculator Web Service information from the specified URL, and the output files will have the base name "ws_calculator".

```bash
```

For a server application, fglwsdl generates two files. It is not advised to modify these files:

- *filename*.inc - the globals file, containing declarations of global variables that can be used as input or output to functions accessing the Web Service operations. In our example, the file is *ws_calculatorService.inc*.
  
  This file must be listed in a GLOBALS statement at the top of any .4gl modules that you write for your GWS Server application.

- *filename*.4gl - containing a function that creates the service described in the WSDL, publishes the operations of the service, and registers the service. In our example, the file is *ws_calculatorService.4gl*.

  This file must be compiled and linked into your GWS Server application.

**Server handlers**

Create and register your callback handlers (request, and response) to modify the WSDL.

The COM library allows you to intercept high-level Web services operation on the server side. You can now define three BDL functions via the following methods of the Web service class. They will be executed at different steps of a web service request processing in order to modify the SOAP request, response or the generated WSDL document before or after the SOAP engine has processed it. This helps handle WS-* specifications not supported in the web service API.

- Method registerWSDLHandler()
- Method registerInputRequestHandler()
- Method registerOutputRequestHandler()
All three kinds of BDL callback functions must conform to this prototype:

```java
FUNCTION CallbackHandler( doc xml.DomDocument )
    RETURNING xml.DomDocument
```

Example 1: Modify the generation of a WSDL

Register your handler with:

```java
CALL serv.registerWsdlHandler("WSDLHandler")
```

where `serv` is of class `com.WebService` and `WSDLHandler` is the following function:

```java
FUNCTION WSDLHandler(wsdl)
    DEFINE wsdl Xml.DomDocument
    DEFINE node Xml.DomNode
    DEFINE list Xml.DomNodeList
    DEFINE ind INTEGER
    DEFINE name STRING
    # Add a comment
    LET node = wsdl.createComment("First modified WSDL via a BDL callback function")
    CALL wsdl.prependDocumentNode(node)
    # Rename input and output parameter in UPPERCASE
    -- first input parameter for selectByXPath above
    -- one string, no spaces!
    FOR ind=1 TO list.getCount()
        LET node = list.getItem(ind)
        LET name = node.getAttribute("name")
        LET name = name.toUpperCase()
        CALL node.setAttribute("name",name)
    END FOR
    RETURN wsdl
END FUNCTION
```

If NULL is returned from the callback function, an HTTP error will be sent and the `ProcessServices()` returns error code -20.

Example 2: Change the SOAP incoming request

Register your handler with:

```java
CALL serv.registerInputRequestHandler("InputRequestHandler")
```

where `serv` is of class `com.WebService` and `InputRequestHandler` is this function:

```java
FUNCTION InputRequestHandler(in)
    DEFINE in Xml.DomDocument
    DEFINE ind INTEGER
    DEFINE node Xml.DomNode
    DEFINE copy Xml.DomNode
    DEFINE tmp Xml.DomNode
    DEFINE parent Xml.DomNode
    DEFINE name STRING
    DEFINE list Xml.DomNodeList
    # Change input parameter below myrecord in lower case
    # to follow high-level web service
```
 FOR ind = 1 TO list.getCount()
 LET node = list.getItem(ind)
 LET parent = node.getParentNode()
 LET name = node.getLocalName()
 LET copy = in.createElementNS(node.getPrefix(), name.toLowerCase(), node.getNamespaceURI())
 LET tmp = node.getFirstChild()
 LET tmp = tmp.clone(true)
 CALL copy.appendChild(tmp)
 CALL parent.replaceChild(copy,node)
 END FOR
 RETURN in
END FUNCTION

If NULL is returned from the callback function, a SOAP fault will be sent (but can be changed from the output handler) and the ProcessServices() returns error code -18.

**Example 3: Modify the SOAP outgoing request**

Register your handler with:

CALL serv.registerOutputRequestHandler("OutputRequestHandler")

where serv is of class com.WebService and OutputRequestHandler is this function:

FUNCTION OutputRequestHandler(out)
 DEFINE out Xml.DomDocument
 DEFINE ind INTEGER
 DEFINE node Xml.DomNode
 DEFINE copy Xml.DomNode
 DEFINE tmp Xml.DomNode
 DEFINE parent Xml.DomNode
 DEFINE name STRING
 DEFINE list Xml.DomNodeList
 # Change output parameter below myrecord in uppercase
 # before sending back to the client
 FOR ind = 1 TO list.getCount()
 LET node = list.getItem(ind)
 LET parent = node.getParentNode()
 LET name = node.getLocalName()
 LET copy = out.createElementNS(node.getPrefix(),name.toUpperCase(), node.getNamespaceURI())
 LET tmp = node.getFirstChild()
 LET tmp = tmp.clone(true)
 CALL copy.appendChild(tmp)
 CALL parent.replaceChild(copy,node)
 END FOR
 RETURN out
END FUNCTION

If NULL is return from the callback function, a SOAP fault will be sent and the ProcessServices() returns error code -19.
Example output
What you can expect to find in the server stub files.

In the generated file `ws_calculatorService.inc`, the definitions of the variables for the input and output record are the same as those generated for the Web Service client application:

```plaintext
#VARIABLE : Add -- defines the global INPUT record
DEFINE Add RECORD ATTRIBUTES(XMLName="Add", 
XMLNamespace="http://tempuri.org/")
   a INTEGER ATTRIBUTES(XMLName="a",XMLNamespace=""),
   b INTEGER ATTRIBUTES(XMLName="b",XMLNamespace=""
END RECORD

# VARIABLE : AddResponse -- defines the global OUTPUT record
DEFINE AddResponse RECORD ATTRIBUTES(XMLName="AddResponse", 
XMLNamespace="http://tempuri.org/")
   r INTEGER ATTRIBUTES(XMLName="r",XMLNamespace=""
END RECORD
```

The generated file `ws_calculatorService.4gl` contains a single function that creates the Calculator service, creates and publishes the service operations, and registers the Calculator service:

```plaintext
FUNCTION Createws_calculatorService()
   DEFINE service com.WebService
   DEFINE operation com.WebOperation
   ...  # Create Web Service
   LET service = com.WebService.CreateWebService("Calculator", 
                "http://tempuri.org/")
   # Publish Operation : Add
   LET operation = com.WebOperation.CreateRPCStyle("Add","Add", 
                Add,AddResponse)
   CALL service.publishOperation(operation,"")  ...
   # Register Service
   CALL com.WebServiceEngine.RegisterService(service)
   RETURN 0
```

Writing your functions
Write functions that implement the functions in the stub modules. It allows you to create your own version of the function.

The `ws_calculator.inc` WSDL file provides you with the global input and output records and function names that allow you to write your own code implementing the operations.

Your new code should not be written in the generated modules. For example, do not add your own version of the Add function to the generated `ws_calculator.4gl` module; it can be included in your module containing the MAIN program block, or in a separate module to be included as part of the Web server application. The function must use the generated definitions for the global input and output records.

In your version of the Add operation, for example, this function adds 100 to the sum of the variables in the input record:

```plaintext
FUNCTION Add()
   LET AddResponse.r = (Add.a + Add.b) + 100
END FUNCTION
```

See Tutorial: Writing a Server application for more information. The demo/WebServices subdirectory of your Genero installation directory contains complete examples of Server Applications.
**Writing a Web server application**
Follow examples showing you how to write a complete Web service application for the SOAP protocol.

This tutorial guides you through the steps to create a server application for a Genero Web Service that can be accessed over the web by client applications. A complete example is provided at `$FGLDIR/demo/WebServices`.

You can write your server application based on input/output records that you have defined. Or, you can use the `fglwsdl` tool to include third-party WSDL information in your server application.

**Including the web services library**
Import the `com` class.

The methods associated with creating and publishing a Web Service are contained in the classes that make up the Genero Web Services Library (com). Include this line at the top of each module of your GWS server application to import the library:

```
IMPORT com
```

**Example 1: Writing the entire server application**
Design a simple Web service.

You can define a Web Service in your application and write definitions for the input and output records that will be used by the Service. This example illustrates a Service that has one operation, `Add`, to provide the sum of two numbers.

**Step 1: Define input and output records**
Define records for the input and output messages of the Web function.

Based on the desired functionality of the operations that you plan for the Service, define the input and output records for each operation. BDL functions that are written to implement a Web Service operation cannot have input parameters or return values. Instead, each function's input and output message must be defined as a global or module RECORD.

**The Input message**
The fields of the global or module record represent each of the input parameters of the Web function. The name of each field in the record corresponds to the name used in the SOAP request. These fields are filled with the contents of the SOAP request by the Web Services engine just before executing the corresponding BDL function.

**The Output message**
The fields of the global or module record represent each of the output parameters of the Web function. The name of each field in the record corresponds to the name used in the SOAP request. These fields are retrieved from the Web Services engine immediately after executing the BDL function, and sent back to the client.

Your Genero Web Services service has one planned operation that adds two integers and returns the result. The input and output records are defined as follows:

```
GLOBALS
DEFINE
    add_in RECORD   # input record
        a INTEGER,
        b INTEGER
    END RECORD,
    add_out RECORD  # output record
        r INTEGER
    END RECORD
END GLOBALS
```

**Related concepts**
Step 2: Write a BDL function for each service operation on page 3349
Each function defines an operation of the service.

**Step 2: Write a BDL function for each service operation**

Each function defines an operation of the service.

You will need to write a function to implement each operation, using the input and output global records.

To implement your **Add** operation:

```plaintext
#User Public Functions
FUNCTION add()
    LET add_out.r = add_in.a + add_in.b
END FUNCTION
```

**Related concepts**

**Step 3: Create the service and operations** on page 3349

Describes how you provide your Web service and its operations to users who can access it on the net.

**Step 3: Create the service and operations**

Describes how you provide your Web service and its operations to users who can access it on the net.

The Genero Web Services library (**com**) provides classes and methods that allow you to use Genero BDL to configure a Web Service and its operations.

- **WebService class** - this is a container for web operations.
- **WebOperation class** - describes the operation.

**Define variables for the WebService and WebOperation objects**

```plaintext
FUNCTION createservice()
    DEFINE serv  com.WebService    # A WebService
    DEFINE op    com.WebOperation  # Operation of a WebService
END FUNCTION
```

**Choose a Namespace**

**XML** uses namespaces to group element and attribute definitions, and to avoid conflicting names. In practice, a namespace must be a unique identifier (URI: Uniform Resource Identifier). If you do not know the unique identifier to use, your company's Web site domain name is guaranteed to be unique (such as "www.mycompany.com"); then, append any string.

Examples of valid namespaces for the fictional "My Company" company:

- "http://www.mycompany.com/MyServices"
- "http://www.mycompany.com/any_string"

Another option (for testing only) is to use the temporary namespace "http://tempuri.org/".

**Create the WebService object**

Call the constructor method of the **WebService** class. The parameters are:

1. Service name
2. Valid namespace

This example uses the temporary namespace and creates a service named "MyCalculator".

```plaintext
LET serv =
```
Create the WebOperation object

A WebService object can have multiple operations. The operations can be created in RPC or Document style by calling the corresponding constructor method of the WebOperation class. The parameters are:

1. the name of the BDL function that is executed to process the XML operation
2. the name you wish to assign to the XML operation
3. the input record defining the input parameters of the operation (or NULL if there is none)
4. the output record defining the output parameters of the operation (or NULL if there is none)

To create the operation for the previously defined `add` function in RPC style:

```plaintext
LET op = com.WebOperation.CreateRPCStyle("add", "Add", add_in, add_out)
```

To create the operation for the previously defined `add` function in Document style:

```plaintext
LET op = com.WebOperation.CreateDOCStyle("add", "Add", add_in, add_out)
```

Mixing RPC style and Document style operations in the same service is not recommended, as it is not WS-I compliant. See Web Services Styles for additional information about styles.

The rest of the code in your application is the same, regardless of the Web Services style that you have chosen.

Publish the operation

Once an operation is defined, it must be associated with its corresponding WebService (the operation must be published). The publishOperation method of the WebService object has the following parameters:

- The WebOperation to be published.
- A string to identify the operation if several operations have the same name; if this is NULL, the default value is an empty string.

For example, to publish the `Add` operation of the Calculator service, which was defined as `op`:

```plaintext
CALL serv.publishOperation(op, NULL)
```

Related concepts

Step 4: Register the service on page 3350
Register the service with the Genero Web Services (GWS) server.

Step 4: Register the service
Register the service with the Genero Web Services (GWS) server.

Once the Service and operations are defined and the operations are published, the WebService and WebOperation objects have completed their work. Registering a service puts the Genero DVM in charge of the execution of all the operations of that service - dispatching the incoming message to the right service, returning the correct output, and so on. The same service may be registered at different locations on the Web.

The WebServiceEngine is a global built-in object that manages the Server part of the Genero DVM. Use the RegisterService class method of the WebServiceEngine class. The parameter is:

1. The name of the WebService object

To register the "Calculator" service, for example, created in Step 3: Create the service and operations on page 3349:

```plaintext
CALL com.WebServiceEngine.RegisterService(serv)
END FUNCTION
```

Note: If you want to create a single GWS Server DVM containing multiple Web Services, define additional input and output records and repeat steps 2 through 6 for each Web Service. In Step 5: Start the GWS server and process requests on page 3351, a GWS Server DVM is started, containing as many Web Services as you have defined.
See Web services server program deployment on page 3459 for additional discussion of GWS Services and GWS Servers.

**Related concepts**

**Step 5: Start the GWS server and process requests**

Code to start the Genero Web Services (GWS) Server.

The GWS Server is located on the same physical machine where the application is being executed (in other words, where fglrun executes).

This is the MAIN program block of your application.

**Define a variable for status**

Define a variable to hold the returned status of the request:

```main
DEFINE ret INTEGER
```

Call the function that you created, which defined and registered the service and its operations:

```main
CALL createservice()
```

**Start the GWS Server**

Use the Start class method of the WebServiceEngine class to start the server.

```main
CALL com.WebServiceEngine.Start()
```

**Process the requests**

This example uses the ProcessServices method of the WebServiceEngine class to process each incoming request. It returns an integer representing the status. The parameter specifies the timeout period (in seconds) the method may wait to process a service. The value -1 specifies an infinite waiting time.

```main
WHILE TRUE
    # Process each incoming requests (infinite loop)
    LET ret = com.WebServiceEngine.ProcessServices(-1)
    CASE ret
        WHEN 0
            DISPLAY "Request processed."
        WHEN -1
            DISPLAY "Timeout reached."
        WHEN -2
            DISPLAY "Disconnected from application server."
            EXIT PROGRAM
        WHEN -3
            DISPLAY "Client Connection lost."
        WHEN -4
            DISPLAY "Server interrupted with Ctrl-C."
        WHEN -10
            DISPLAY "Internal server error."
            EXIT PROGRAM
        WHEN -15
            DISPLAY "Server was not started."
            EXIT PROGRAM
        OTHERWISE
```
Note: For testing purposes only, the GWS Server can be started in standalone mode. In a production environment, the Genero Application Server (GAS) is required to manage your application. For deployment, the GWS Server application must be added to the GAS configuration. See the Genero Application Server User Guide.

**Example 2: Writing a server using third-party WSDL (the fglwsdl tool)**

Describes using a server stub from a third-party Web service in your GWS server application.

To write a Web Service that is compatible with the specification of the input and output records defined by a third-party (for example, a vendor of manufacturing software, or a WSDL specialist in your company), you can use the fglwsdl tool to obtain the WSDL information and generate a part of the Server application. See fglwsdl on page 2081 for a complete description of the tool and its use.

**Step 1: Get the WSDL description and generate files**

Use the fglwsdl -s tool server option to generate the BDL server stub from a WSDL.

This tutorial uses fglwsdl and the Calculator Service defined in Example 1: Writing the entire server application on page 3348 to obtain the WSDL information and generate two corresponding BDL files:

- The **globals file**, containing declarations of global variables that can be used as input or output to functions accessing the Web Service operations.
- A **.4gl file** containing a function that creates the service described in the WSDL, publishes the operations of the service, and registers the service.

`fglwsdl -s -o example1 http://localhost:8090/MyCalculator?WSDL`

Note: The "MyCalculator" Genero Web Services service created in Example 1: Writing the entire server application on page 3348 must be running in order to obtain the WSDL information.

**The generated globals file**

The globals file `example1Service.inc` provides the definition of the global input and output records as described in Step 1: Define input and output records on page 3348 of the Example 1: Writing the entire server application on page 3348 GWS Server program. The names of the input and output records have been assigned by fglwsdl, in accordance with the Style of the Web Service "MyCalculator" (created as RPC Style in the Example1 program). Do not modify this file.

Input and output records:

```plaintext
# VARIABLE : Add
DEFINE Add RECORD
    ATTRIBUTES( XMLName="Add",
                XMLNamespace="http://tempuri.org/webservices" )
    a INTEGER ATTRIBUTES(XMLName="a",XMLNamespace=""),
    b INTEGER ATTRIBUTES(XMLName="b",XMLNamespace="")
END RECORD

# VARIABLE : AddResponse
DEFINE AddResponse RECORD
    ATTRIBUTES(XMLName="AddResponse",
                XMLNamespace="http://tempuri.org/webservices" )
```
The generated .4gl file

The example1Service.4gl file contains a single function that creates the service, publishes the operation, and registers the service. The Web Service Style that is created is determined by the style specified in the WSDL information. The functions in this file accomplish the same tasks as Step 3: Create the service and operations on page 3349 and Step 4: Register the service on page 3350 of Example 1. Do not modify this file.

```4gl
# example1Service.4gl
# Generated file containing the function Createexample1Service

IMPORT com
GLOBALS "example1Service.inc"

# FUNCTION Createexample1Service
#   RETURNING soapstatus
FUNCTION Createexample1Service()
DEFINE service com.WebService
DEFINE operation com.WebOperation
# Set ERROR handler
WHENEVER ANY ERROR GOTO error
# Create Web Service
LET service = com.WebService.CreateWebService(
    "MyCalculator",
    "http://tempuri.org/webservices")

# Operation: Add
# Publish Operation : Add
LET operation = com.WebOperation.CreateRPCStyle(
    "Add",
    "Add",
    Add,
    AddResponse)
CALL service.publishOperation(operation,"")
# Register Service
CALL com.WebServiceEngine.RegisterService(service)
RETURN 0
# ERROR handler
LABEL error:
RETURN STATUS
# Unset ERROR handler
WHENEVER ANY ERROR STOP
END FUNCTION
```

Related concepts

**Step 2: Write a BDL function for your service operation** on page 3353
Write functions that implement the functions in the stub file. This allows you to create your own version of the function.

**Step 2: Write a BDL function for your service operation**
Write functions that implement the functions in the stub file. This allows you to create your own version of the function.

Using the information from the files generated in Step 1: Get the WSDL description and generate files on page 3352, the Add operation from Example 1: Writing the entire server application on page 3348 is rewritten to have different functionality but to still be compatible with the WSDL description of the operation.
This step accomplishes the same thing as Step 2: Write a BDL function for each service operation on page 3349 in Example 1. In this version of the add operation, the sum of the two numbers in the input record is increased by 100.

```plaintext
# my_function.4gl -- file containing the function
IMPORT com -- definition
IMPORT the Web Services library
GLOBALs "example1Service.inc" -- use the generated globals file
#User Public Functions
FUNCTION add() -- new version of the add function
LET AddResponse.r = (Add.a + Add.b) + 100 -- the global input and output
END FUNCTION
```

Related concepts

Step 3: Create service, start server and process requests on page 3354
Code to start the Genero Web Services (GWS) Server.

Step 3: Create service, start server and process requests
Code to start the Genero Web Services (GWS) Server.

Create your own MAIN module that calls the function from the generated .4gl file to create the service, then starts the Genero Web Services Server and manages requests as in Step 5: Start the GWS server and process requests on page 3351 of Example 1: Writing the entire server application on page 3348.

```plaintext
# example2main.4gl file -- contains the MAIN program block
IMPORT com
GLOBALs "example1Service.inc"
MAIN
    DEFINE create_status INTEGER
    DEFER INTERRUPT
    CALL Createexample1Service() -- call the function generated
        RETURNING create_status -- in example1Service.4gl
        IF create_status <> 0 THEN
            DISPLAY "error"
        ELSE
            # Start the server and manage requests
            CALL ManageService()
        END IF
END MAIN

FUNCTION ManageService()
    DEFINE ret INTEGER
    CALL com.WebServiceEngine.start()
    WHILE TRUE
        # continue as in Step 5 of Example 1
        ...
END FUNCTION
```

Enabling MTOM on the server side
Enable the Message Transmission Optimization Mechanism (MTOM) feature to efficiently send binary data to and from Web services.

By default, MTOM is not enabled. As a result, any BYTE represented as xsd:base64 or xsd:hexbinary will be inlined in the SOAP request or response.
To enable MTOM on server side, set the MTOM feature to TRUE.

```
# Create Web Service
LET service =
CALL service.setFeature("MTOM",true)
```

With MTOM enabled on the server side, the generated WSDL includes the MTOM policy.

**Compiling GWS server applications**

When compiling, remember to link in the WSHelper library.

It is recommended that the library file WSHelper.42m, included in the $FGLDIR/lib directory of the Genero Web Services package, is linked into every GWS Server application.

If your application uses the fglwsdl tool to generate information, link the .4gl generated file into the application.

**Examples**

Compiling the Example 1: Writing the entire server application on page 3348 program:

```
fglcomp example1.4gl
fgllink -o example1.42r example1.42m WSHelper.42m
```

Compiling the Example 2: Writing a server using third-party WSDL (the fglwsdl tool) on page 3352 program:

```
fglcomp example2main.4gl my_function.4gl example1Service.4gl
fgllink -o example2.42r example2main.42m my function.42m example1Service.42m WSHelper.42m
```

**Testing the GWS service in stand-alone mode**

Test that your service is reachable and that it can generate the WSDL.

For testing and development purposes only, the Genero Web Services Server application can be executed directly, without using the Genero Application Server (GAS).

1. Use the Genero fglrun command to execute the GWS Server application. The application must reside on the same machine:

```
fglrun <gws-application>
```

This will start the GWS Server on the port specified by the FGLAPPSERVER environment variable. For example, if FGLAPPSERVER is set to 8090, the server will be started on that port. If this environment variable is not set for the user, port number 80 is used.

**Warning:** The user must not set the FGLAPPSERVER variable in production environments, since the port number is selected by the Genero Application Server.

2. Obtain the WSDL information for your Service and write a test Client application. For example, if the GWS Server in step 1 was started on your local machine and FGLAPPSERVER was set to 8090, the command to get the WSDL information would be:

```
fglwsdl -o <test-client> http://localhost:8090/<service-name>?WSDL
```

**Configuring the Genero Application Server for the GWS application**

Prepare for a production environment.

The final step is to configure the Genero Application Server (GAS) to handle the GWS application. In a production environment, Genero Web Services becomes a part of a global application architecture handled by the application server of the GAS package. See Web services server program deployment on page 3459, as well as Packaging web applications on page 2183 and Deploying apps with Genero Archive in the Genero Application Server User Guide.
Making the GWS service available
Provide your Web service to users who can access it on the net.

Once you compiled and deployed your Genero Web Services Server application (see Web services server program deployment on page 3459), it can be used by others to obtain the WSDL information and write a client application that accesses your Genero Web Service. See Steps to write a WS client on page 3321.

Your company can provide the location of the GWS Server to potential users of your Web Service in various ways. For example:

- Provide the location on a company web site
- Register the Web Service with UDDI (Universal Description, Discovery, and Integration) - the XML-based registry providing Internet listings for companies worldwide
- Communicate directly with your potential users

Get HTTP headers information at WS server side
To work with HTTP headers exchanged between the Genero client and a web service, you must register variables to receive and send them.

In high level (SOAP) Web services, we now give access to the HTTP headers request and response.

The Web service can get information from the request headers and reply with custom headers and status.

1. Declare variables to receive or send HTTP headers.
2. Register these variables to the Web service server.

Declare variables to receive or send HTTP headers
The variable for the request headers:

```
DEFINE http_in RECORD
    verb STRING,
    url STRING,
    headers DYNAMIC ARRAY OF RECORD
        name STRING,
        value STRING
    END RECORD
END RECORD
```

After the Web service operation has been processed, the variable is set to NULL.

The variable for the response headers:

```
DEFINE http_out RECORD
    code INTEGER,
    desc STRING,
    headers DYNAMIC ARRAY OF RECORD
        name STRING,
        value STRING
    END RECORD
END RECORD
```

After the Web service operation has been processed, the variable is set to NULL.

**Note:** While the variables must follow the structure shown, the variable name can be any name you choose.

The Web service engine headers have precedence. For example, if you set the "Content-Length" value, the one that is taken into account is the one defined by the Genero Web Services engine.

Register the variables to the server
This code example uses two methods, which use the defined variables:
• `com.WebService.registerInputHttpVariable(http_in)` where `http_in` is the RECORD variable for the request headers.

• `com.WebService.registerOutputHttpVariable(http_out)` where `http_out` is the RECORD variable for the response headers

Example

FUNCTION CreateService()

    DEFINE serv com.WebService # WebService
    DEFINE op com.WebOperation # Operation of a WebService

    TRY
        # Create a Web Service
        LET serv = com.WebService.CreateWebService("EchoHttpHeadersService", Namespace)

        # Create Document Style Operations
        # EchoDOCRecord
        LET op = com.WebOperation.CreateDOCStyle("echoDocRecord", "EchoDOCRecord", echoRecordDoc_in, echoRecordDoc_out)

        CALL serv.publishOperation(op,NULL)

        # Register HTTP input
        CALL serv.registerInputHttpVariable(http_in)

        # Register HTTP output
        CALL serv.registerOutputHttpVariable(http_out)

        # Register service
        CALL com.WebServiceEngine.RegisterService(serv)
        DISPLAY "EchoHttpHeadersService Service registered"
    CATCH
        DISPLAY "Unable to create 'EchoHttpHeadersService' Web Service : ", STATUS||"("||SQLCA.SQLERRM||")"
        EXIT PROGRAM (-1)
    END TRY

END FUNCTION

FUNCTION echoDocRecord()

    DEFINE ind INTEGER
    DEFINE ok BOOLEAN

    # Check incoming VERB
    IF http_in.verb != "POST" THEN
        LET http_out.code = 400
        LET http_out.desc = "Bad request: method should be POST"
        RETURN
    END IF

    # Check incoming query string
    IF http_in.url.getIndexOF("?MyQuery=OK",1)<=0 THEN
        LET http_out.code = 400
        LET http_out.desc = "Bad request: URL should have MyQuery=OK"
        RETURN
    END IF
# Check incoming header called MyPersonal
LET ok = FALSE
FOR ind = 1 TO http_in.headers.getLength()
    DISPLAY ind||" ",http_in.headers[ind].name,
    "=" http_in.headers[ind].value
    IF http_in.headers[ind].name == "MyPersonal" THEN
        IF http_in.headers[ind].value == "Header" THEN
            LET ok = TRUE
        END IF
    END IF
END FOR
IF NOT ok THEN
    LET http_out.code = 400
    LET http_out.desc = "Bad request: expected additional header called MyPersonal"
    RETURN
END IF

# assign the output record
LET echoRecordDoc_out.MyRecord.MyInt = echoRecordDoc_in.MyRecord.MyInt
LET echoRecordDoc_out.MyRecord.MyFloat = echoRecordDoc_in.MyRecord.MyFloat

# Add MyPersonalHeader=MyPersonalValue http headers
LET http_out.headers[1].name = "MyPersonalHeader"
LET http_out.headers[1].value = "MyPersonalValue"

END FUNCTION

Related concepts
The WebService class on page 2811
The com.WebService class provides an interface to create and manage Genero Web Services.

Choosing a web services style
Genero Web Services contains style options for creating SOAP Web services. Your choice is dependent on the type of service, (Document or RPC), and the encoding mechanism (literal or encoded) required.

Genero Web Services 2.0 allows you to create SOAP Web services operations in the following styles:

Table 717: Web Services Styles

<table>
<thead>
<tr>
<th>Web Services Style</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remote Procedure Call (RPC) Style Service (RPC/Literal)</td>
<td>Generally used to execute a function, such as a service that returns a stock option.</td>
</tr>
<tr>
<td>Document Style Service (Doc/Literal)</td>
<td>Generally used for more sophisticated operations that exchange complex data structures, such as a service that sends an invoice to an application, or exchanges a Word document; this is the MS.Net default.</td>
</tr>
<tr>
<td></td>
<td>Both RPC/Literal and Doc/Literal Styles are Web Services Interoperability (WS-I) organization compliant.</td>
</tr>
</tbody>
</table>
The style of service to be created is specified in the Genero application for the Web Service, using the following methods of the `WebOperation` class from the (Web Services COM Library). The parameters are the same for both methods:

1. The name of the BDL function that is executed to process the Web service operation
2. The name you wish to assign to the Web service operation
3. The `input` record defining the input parameters of the operation (or NULL if there is none)
4. The `output` record defining the output parameters of the operation (or NULL if there is none)

```
LET op = com.WebOperation.CreateRPCStyle("add","Add",add_in,add_out)
LET op = com.WebOperation.CreateDOCStyle("checkInvoice","CheckInvoice",invoice_in,invoice_out)
```

Calling the appropriate function for the desired style is the only difference in your Genero code that creates the service. The remainder of the code that describes the service is the same, regardless of whether you want to create an RPC or Document style of service.

**Important:** Do not use the `setInputEncoded()` and `setOutputEncoded()` methods of the `WebService` class from the Web Services COM Library (`com`), as they apply only to RPC/Encoded Style, which is not recommended.

**Note:** If you add headers to your RPC Style service, choose the Literal serialization mechanism by setting the `encoded` parameter of the `createHeader()` method to FALSE:

```
CALL serv.createHeader(var,FALSE)
```

**Note:** GWS release 2.0 allows you to create RPC Style and Document Style operations in the same Web service. However, we do not recommend this, as it is not WS-I compliant.

## How Do I ... ?

These topics provide you with the information needed to perform specific tasks related to Genero Web Services using the SOAP protocol.

**Tip:** See [here](#) for other Web services "How Do I … ?" topics.

### Fix Genero 2.10 to 2.11 WSDL generation issue

How to convert a WSDL generated from a Genero 2.11 (or later) application to a WSDL as generated by Genero 2.10.

Since Genero 2.11, each BDL variable generates an associated named complexType in the WSDL and references it. While this does not impact the Web service, some tools will generate additional client stubs to follow the WSDL definition with the named complexType. As a result, any client program written from a WSDL generated in 2.10 must be reviewed if it uses a WSDL generated in 2.11 or later.

If you do not want to modify your application, you can use the WSDL conversion tool program to remove the named complexType and add the unnamed equivalent as child node of the parameter variable of all Web service operations, as if the WSDL had been generated in 2.10.
**WSDL conversion tool**

This program reads a WSDL, looks for all named complexType used in all the web operation parameters and modifies them in order to have unnamed complexType instead.

```plaintext
IMPORT XML
MAIN
DEFINE
    doc xml.DomDocument,
    list, elist, tlist xml.DomNodeList,
    node, enode, nnode xml.DomNode,
    i, j, k, idx INTEGER,
    ename, tname STRING

IF num_args() <> 1 THEN
    CALL display_help()
    RETURN 0
END IF

TRY
    LET doc = xml.DomDocument.Create()
    CALL doc.setFeature("whitespace-in-element-content",FALSE)
    CALL doc.load(arg_val(1))
    # get the list of input/output message
    # check if their names (x) are defined as elements with types (y)
    # if yes then
    # copy the complextype y definition to element name x
    # and remove the complexe type y definition
    # for example:
    # message
    # <wsdl:message name="is_OKIn">
    #   <wsdl:part name="parameters" element="fjs:is_OKRequest" />
    # </wsdl:message>
    # <wsdl:message name="is_OKOut">
    #   <wsdl:part name="parameters" element="fjs:is_OKResponse" />
    # </wsdl:message>
    # element
    # <xsd:element name="is_OKResponse"
    #   type="s1:is_OKResponse_is_OKResponse" />
    # type
    # <xsd:complexType name="is_OKRequest_is_OKRequest">
    LET list =
        doc.selectByXPath("//wsdl:part[@name='parameters']/@element",
                         "wsdl","http://schemas.xmlsoap.org/wsdl/")
    IF list IS NULL THEN
        DISPLAY "Nothing to convert."
    END IF
    FOR i=1 TO list.getCount()
        LET node = list.getItem(i)
        LET ename = node.getNodeValue()
        LET idx = ename.getIndexOf(":",1)
        IF idx <> 0 THEN
            LET ename = ename.subString(idx+1,ename.getLength())
        END IF
        # get the element
        LET elist =
            doc.selectByXPath("//xsd:element[@name='" || ename || "]", "xsd","http://www.w3.org/2001/XMLSchema")
        IF elist IS NOT NULL THEN
            FOR j=1 TO elist.getCount()
                LET enode = elist.getItem(j)
                LET tname = enode.getAttribute("type")
                CALL enode.removeAttribute("type")
            END FOR
        END IF
    END FOR
```
Example of use:

$ fglrun Convert Genero2_21.wsdl
$ Document is saved in result.wsdl

How to handle WS security

The Genero Web Services engine does not entirely manage WS-Security; however, Genero BDL provides XML APIs to help the development of Web Services with security. Exploring the demo Web Service included with the FGLGWS installation will help you handle security in your own SOAP Web service.

These topics describe how to handle Web Services security using the wssecurermessage demo, located in $FGLDIR/demo/WebServices. See the readme.txt file provided with the demo for information and instructions on how to run the service.

You are encouraged to treat the demo as an example that you can adapt to your needs. It is based on the WS-Security (WSS) standard. For more information, refer to the WS-Security Policy documentation.

The demo demonstrates a secure messaging service using a WS-Security policy to exchange messages. It involves three clients exchanging secured messages. Those clients post and retrieve messages on a secured server. Each client is identified by a certificate that signs its messages.

The demo assumes that all the clients have sent their public keys to the other clients and to the server. Those keys are kept in each host's (server or clients) keystore.
As a prerequisite, we recommend that you become familiar with security concepts described in the Encryption and Authentication Concepts page.

**Important:** The certificates included in this package are provided for demonstration purposes only. As they are distributed with this package, anybody using this product can decrypt the messages exchanged. Do NOT use them in production.

**Server side**
Learn the steps the server uses to process messages it sends and receives. Identify the Genero handlers that help implement the security policy on the server side.

We provide 3 handlers to handle WS Security:

- Method `com.WebService.registerWSDLHandler()` to modify the WSDL to add WS policy.

In this demo (located in `$FGLDIR/demo/WebServices/wssecuritymessage`), a received message is processed:

1. Identify the sender and validate the sender (search in keystore)
2. Decrypt the symmetric key with the server private key
3. Decrypt the body
4. Check the signature with the sender public key
5. Store the message in the box (thanks to the "To" field, "subject" and "message")
6. Create the outgoing message
7. Sign the outgoing message
8. Encrypt the outgoing message with a generated symmetric key. This symmetric key is then encrypted with the client public key.

**Client side**
From the client side, identify the steps that need to be performed to send and receive secure messages.

The client function consists of sending a message and retrieving messages clients have sent to it.

Before you begin, create the client stub from the WDSL:

```
• fglwsdl -domHandler myservice.wsdl
```

The client stub references callback handlers:

- `SecureMessageBox_HandleRequest`
- `SecureMessageBox_HandleResponse`
- `SecureMessageBox_HandleResponseFault`

For more details about client SOAP handlers see Client stub and handlers.

What to do when a message is sent:

1. Sign and encrypt the request for the server (WS-Security)
   - sign with client private key
   - encrypt with server public key
2. Send key information in the request
   - key to identify the sender/client
   - key to identify the recipient/server
   - key used to encrypt the data (usually a symmetric key encrypted by the recipient public key)
3. If the message has to be encrypted for the final recipient (XML-Security)
   - sign the message
   - encrypt the message
What to do to retrieve messages:
1. Identify the sender and validate the sender (search in keystore)
2. Identify the recipient (should be the server itself)
3. Decrypt the request
4. Check the signature
5. Retrieve messages for the recipient

**SOAP security standards**
In this section read about the security policy standards, such as bindings, and the options for signing and encryption.

A Web service security policy requirements are included in the Web Services Description Language (WSDL) file. The policy is divided into these sections:

- Security bindings
- Security options
- Signed parts
- Encrypted parts

The following defines a policy:

```xml
```

The following section includes policy rules.

```xml
<wsp:ExactlyOne>
<wsp:All>
```

Only one assertion is fulfilled.

```xml
<wsp:All>
```

All the assertions included within this tag are fulfilled.

**Demo WSDL**
For a complete WS security policy document, see the WSDL file included with the demo "wssecuritymessage", located in `$FGLDIR/demo/WebServices`. For more information on the standard, refer to [WS-SecurityPolicy](#).

**Security bindings**
Understand the mechanism of bindings that allows the secure exchange of SOAP messages over HTTP. The demo application security policy is referenced to illustrate this.

There are 3 types of security bindings:

- TransportBinding
- SymmetricBinding
- AsymmetricBinding

The demo (located in `$FGLDIR/demo/WebServices/wssecuritymessage`) uses Asymmetric binding.

**Asymmetric Binding**
This section of the security policy is divided in sub sections:

- InitiatorToken
- RecipientToken
- AlgorithmSuite
- Layout
- Additional assertions
AsymmetricBinding is the root node of the security policy for protection description.

```xml

InitiatorToken
InitiatorToken is the message sender (client)
For example:

```xml
<sp:InitiatorToken>
  <wsp:Policy>
    <sp:X509Token sp:IncludeToken="http://schemas.xmlsoap.org/ws/2005/07/securitypolicy/IncludeToken/AlwaysToRecipient">
      <wsp:Policy>
        <sp:RequireThumbprintReference />
        <sp:WssX509V1Token10 />
      </wsp:Policy>
    </sp:X509Token>
  </wsp:Policy>
</sp:InitiatorToken>
```

**Note:** The value for the `sp:IncludeToken` attribute is one contiguous string with no spaces. For this document, it is shown covering two lines.

The token is used for the message signature from initiator to recipient and encryption from recipient to initiator.

The initiator key is a X509 certificate that is always sent to the recipient.

- `sp:IncludeToken` attribute indicates if the token must be included.
- `IncludeToken/AlwaysToRecipient` means each requests sent to the recipient must include the initiator token. But the token is not to be included in messages from recipient to initiator.

The token must send its Thumbprint Reference.

The token must be of type X509 version 1 as defined in "X509 token profile 1.0".

What needs to be done in BDL is described in **Client Side** section.

To retrieve the thumbprint reference you can use the API function `xml.CryptoX509.getThumbprintSHA1`

To create the x509 certificate, use an appropriate tool like `openssl`.

RecipientToken
RecipientToken is the message receiver (server)

```xml
<sp:RecipientToken>
  <wsp:Policy>
      <wsp:Policy>
        <sp:RequireThumbprintReference />
        <sp:WssX509V3Token10 />
      </wsp:Policy>
    </sp:X509Token>
  </wsp:Policy>
</sp:RecipientToken>
```

**Note:** The value for the `sp:IncludeToken` attribute is one contiguous string with no spaces. For this document, it is shown covering two lines.
The token is used for encryption from initiator to recipient, and for the message signature from recipient to initiator. The recipient key is a X509 certificate that is never sent to the initiator.

`sp:IncludeToken` attribute indicates if the token must be included.

Use of the `IncludeToken/Never` means the token is never to be included in any requests between the initiator and the recipient. This is the required and recommended setting.

Instead the recipient ThumbprintReference is sent.

The token must be of type X509 version 3 as defined in "X509 token profile 1.0"

What needs to be done in BDL is described in Server Side section. To retrieve the thumbprint reference you can use the API function `xml.CryptoX509.getThumbprintSHA1`. To create the appropriate certificate use an appropriate tool like `openssl`.

**AlgorithmSuite**

AlgorithmSuite specifies which algorithm is used to encrypt the data.

```xml
<sp:AlgorithmSuite>
   <wsp:Policy>
      <sp:TripleDesRsa15 />
   </wsp:Policy>
</sp:AlgorithmSuite>
```

`TripleDesRsa15` refers to key `http://www.w3.org/2001/04/xmlenc#tripledes-cbc`.

**Layout**

Layout describes the way information is added to the message header.

```xml
<sp:Layout>
   <wsp:Policy>
      <sp:Strict />
   </wsp:Policy>
</sp:Layout>
```

For example, with `Strict` layout, tokens that are included in the message must be declared before use. For more details on the rules to follow see the WS-SecurityPolicy specifications section 7.7.

**Additional Assertions**

PartsToSign

```xml
<sp:OnlySignEntireHeadersAndBody />```

The assertion means if there is any signature on the header or the body it applies to the entire header and the entire body not to their child element.

**SOAP message security options**

Describes the Wss10 SOAP Message Security 1.0 options that are supported.

```xml
   <sp:MustSupportRefKeyIdentifier />
   <sp:MustSupportRefIssuerSerial />
</sp:Wss10>
```

- `MustSupportRefKeyIdentifier` means that initiator and recipient are able to generate and process key identifier reference.
- `MustSupportRefIssuerSerial` means that initiator and recipient are able to generate and process issuer and token serial reference.
**SignedParts**
The SignedParts section of the policy specifies which part of the message should be signed.

```xml
  <sp:Body />
</sp:SignedParts>
```

- Only the body needs to be signed

**EncryptedParts**
The EncryptedParts section of the policy specifies which part of the message should be encrypted.

```xml
  <sp:Body />
</sp:EncryptedParts>
```

- `sp:Body` indicates the body message needs to be encrypted

Encrypt the body using the algorithm referenced in assertion **AlgorithmSuite**:

- Create an encryption key using TripleDesRsa15 algorithm (it generates a TripleDES symmetric key and then encrypts it with a RSA1.5 public key), like in example2 that uses AES256 in the CryptoKey chapter.
- Encrypt the body with the created key.

To find the exact syntax of security message read the specifications "Web Services Security: SOAP Message Security 1.0".

**Useful links**
For more information on SOAP message security, follow the links to the policy standards.

**How to migrate I4GL web service to Genero**
Provides instructions for migrating Web Services and client application from I4GL to Genero BDL.

**Migrate an I4GL web service provider to Genero**
Migrate a Web service from I4GL to Genero BDL using the SOAP protocol.

This section explains how to migrate an I4GL Web service provider to a Genero application providing the same Web service; allowing access to all clients already accessing that service - unmodified (excepted for the host name of course).

**Note:** The migration is based on the SOA zipcode demo in the I4GL package.

**Step 1: Use the I4GL function and the I4GL.4cf configuration file**
The I4GL .4cf configuration file has all the information you need about the I4GL Web service.

For example, the I4GL zipcode demo has the following .4cf configuration file:

```plaintext
[SERVICE]  TYPE            = publisher
          INFORMIXDIR    = /dbs/32bits/ifx/11.70.uc2
          DATABASE      = i4glsoa
          CLIENT_LOCALE = en_US.8859-1
          DB_LOCALE     = en_US.8859-1
          INFORMIXSERVER = ol_moscou1170uc2
          HOSTNAME      = moscou.strasbourg.4js.com
          PORTNO        = 9876
          I4GLVERSION   = 7.50.xC4
          WSHOME        = /dbs/32bits/ifx/11.70.uc2/AXIS2C
          WSVISION      = AXIS1.5
          TMPDIR        = /tmp/zipcodedemo
```
SERVICENAME = ws_zipcode

[FUNCTION]
NAME = zipcode_details

[INPUT]
[VARIABLE] NAME = pin TYPE = CHAR(10) [END-VARIABLE]
[END-INPUT]

[OUTPUT]
[VARIABLE] NAME = city TYPE = CHAR(100) [END-VARIABLE]
[VARIABLE] NAME = state TYPE = CHAR(100) [END-VARIABLE]
[END-OUTPUT]

[END-FUNCTION]

[DIRECTORY]
NAME = /home/f4gl/fg/i4gl
FILE = soademo.4gl,
[END-DIRECTORY]

[END-SERVICE]

Then simply copy your I4GL function without any modification into a new Genero file and add the Genero IMPORT com instruction at the beginning of the file.

For example, the I4GL SOA demo contains the zipcode_details service (soademo.4gl)

IMPORT com

FUNCTION zipcode_details(pin)
DEFINE state_rec RECORD
    pin CHAR(10),
    city CHAR(100),
    state CHAR(100)
END RECORD,

pin CHAR(10),
sel_stmt CHAR(512);

LET sel_stmt= "SELECT * FROM statedetails WHERE pin = ?";
PREPARE st_id FROM sel_stmt;
DECLARE cur_id CURSOR FOR st_id;
OPEN cur_id USING pin;
FETCH cur_id INTO state_rec.*;
CLOSE cur_id;
FREE cur_id;
FREE st_id;
RETURN state_rec.city, state_rec.state

END FUNCTION

Note: You may need to make some minor code modification for compatibility.

Step 2: Create a BDL RECORD for the input parameters

Define a BDL record for the input message of the Web function.

Add a new modular BDL record where all members map to one of your I4GL Web service input parameter, and keep the parameter order as defined in I4GL .4cf file.

You must then specify the Web service input message name via the Genero XML attribute called XMLName, and assign it to the FUNCTION NAME as defined in the I4GL .4cf file.

For example, in the I4GL zipcode demo there is only one parameter: pin. So add the following record at the beginning of the Genero file:

DEFINE zipcode_details_in RECORD ATTRIBUTES(XMLName="zipcode_details")
    pin CHAR(10)
END RECORD
**Note:** Genero Web Services supports complex data types as input parameters.

**Step 3: Create a BDL RECORD for the output parameters**
Define a BDL record for the output message of the Web function.

Add another modular BDL record where all members map to one of your I4GL Web service output parameter, and keep the parameter order as defined in I4GL .4cf file.

You must then specify the Web service output message name via the Genero XML attribute called `XMLName`, and assign it to the FUNCTION NAME as defined in the I4GL .4cf file concatenated to response.

For example, in the I4GL zipcode demo there are two parameters: `city` and `state`. So add the following record at the beginning of the Genero file:

```coffice
DEFINE zipcode_details_out RECORD
  ATTRIBUTES(XMLName="zipcode_detailsresponse")
  city CHAR(100),
  state CHAR(100)
END RECORD
```

**Note:** Genero Web Services supports complex data types as output parameters.

**Step 4: Create a BDL wrapper function**
Create the wrapper function that uses BDL records to call the I4GL function.

Create a Genero BDL wrapper function without any parameters that will then use the input and output record created at Step 2 and Step 3 to call the I4GL function passing it the parameters retrieved from the records.

For example, in the I4GL zipcode demo there are 1 input and 2 output parameters. So the BDL wrapper function must use these records to call the I4GL function as follows:

```coffice
FUNCTION zipcode_details_g()
  CALL zipcode_details(zipcode_details_in.pin)
  RETURNING zipcode_details_out.city,zipcode_details_out.state
END FUNCTION
```

**Step 5: Publish the wrapper function as a Genero web service**
Based on the details in the configuration file (.4cf) file, create a function that registers your Web service with the Genero Web Service server.

Use the COM APIs to publish the I4GL function as a Web service based on I4GL .4cf configuration file to get a compatible Genero Web service.

To create a new BDL function in charge of the service publication, you will need the following elements of the I4GL .4cf configuration file:

- The name of the service that is defined in the `SERVICENAME` entry
- The namespace of the service that is defined as `http://www.ibm.com/` concatenated to the `FUNCTION NAME`
- The name of the function to be published that is defined in the `FUNCTION NAME` entry

For example, the I4GL zipcode demo has one function published as a Doc/Literal service.

```coffice
FUNCTION create_zipcode_details_web_service()
  DEFINE serv com.WebService
  DEFINE op com.WebOperation
  # Create the web service based on the entries of the .4cf file
  # SERVICENAME: The name of service is 'ws_zipcode'
  # FUNCTION NAME: The namespace of the service is built from
  # the base url 'http://www.ibm.com/' concatenated to
  # the NAME of the I4GL function 'zipcode_details'
```
    "http://www.ibm.com/zipcode_details")

# Create and publish the Doc/Literal web function based on
# step 2, step 3 and step 4
# and from the FUNCTION NAME defined in the .4cf file
# LET op = com.WebOperation.CreateDOCStyle("zipcode_details_g",
#     "zipcode_details",
#     zipcode_details_in,
#     zipcode_details_out)
# CALL serv.publishOperation(op,NULL)
# Register the service into the SOAP engine
# CALL com.WebServiceEngine.RegisterService(serv)
END FUNCTION

Note: I4GL supports only Doc/Literal services.

Note: Genero Web Services can contain several BDL functions in the same service. In other words, you can group several I4GL services in the same Genero service.

Step 6: Create the server
Provide a file with a BDL function that starts your Web service with the Genero Web Service server instead of Axis.

I4GL uses Axis as server for its services, but Genero has its own server programmable via the COM library. Create a new file and add the IMPORT com instruction at the beginning of the server file, then simply create the main loop in BDL that will process any incoming HTTP request.

The port of the service defined in the I4GL .4cf configuration file (via the PORTNO entry) can be reused by setting the FGLAPPSERVER environment variable to the same value before running the server. However, only on development or for tests, on production Genero Web Services requires an application server called GAS in charge of load balancing. See the Genero Application Server User Guide for more details about port configuration for deployment purpose.

For example, to migrate the I4GL zipcode demo, the service must be created in the server before running the main loop as follows:

MAIN
    DEFINE ret INTEGER
    DEFER INTERRUPT

    # Create zipcode_details service
    CALL create_zipcode_details_web_service()

    # Start the server on port set in FGLAPPSERVER
    # (to be set to same value as PORTNO defined in the .4cf file)
    CALL com.WebServiceEngine.Start()

    # Handle any incoming request in a WHILE loop...
    WHILE TRUE
        LET ret = com.WebServiceEngine.ProcessServices(-1)
        CASE ret
            WHEN 0
                DISPLAY "Request processed."
            WHEN -1
                DISPLAY "Timeout reached."
            WHEN -2
                DISPLAY "Disconnected from application server."
EXIT PROGRAM  # The Application server has closed the connection
WHEN -3
  DISPLAY "Client Connection lost."
WHEN -4
  DISPLAY "Server interrupted with Ctrl-C."
WHEN -10
  DISPLAY "Internal server error."
END CASE
IF int_flag<>0 THEN
  LET int_flag=0
  EXIT WHILE
END IF
END WHILE
END MAIN

Note: With Genero Web Services, one server can contain several services. In other words, you can put all your I4GL services into one server.

Related information
Process the requests on page 3351

Step 7: Configure the database
Based on the DATABASE entry in the I4GL .4cf configuration file, use the Genero instruction to connect to the Informix® database at server startup.

For example, in the I4GL zipcode demo the service accesses the database called: "i4glsoa". So add the following instruction at the beginning of the server file created in step 6:

DATABASE i4glsoa
MAIN
...
END MAIN

Step 8: Compile and run the Genero service
Describes how to compile and run the service to test it.

Compile and link the 2 Genero files created and run your Genero service. It will be directly available for any client, and will provide the WSDL when requested via a HTTP GET with WSDL as query string.

Example
The Genero web service is accessible on URL: http://hostname:9876/ws_zipcode and can return the WSDL on URL: http://hostname:9876/ws_zipcode?WSDL.

$ fglcomp -M genero_service.4gl
$ fglcomp -M genero_server.4gl
$ fgllink -o genero_zipcode genero_service.42m genero_server.42m
$ export FGLAPPSEVER=9876
$ fglrun genero_zipcode.42r

Note: The host name depends on the machine your Genero application is started.

Note: For deploying the service on production sites you will need the Genero application server (GAS) to load-balance the service. See the Genero Application Server User Guide about Web services when deployment is required.

Migrate an I4GL web service consumer to Genero
Migrate a client application from I4GL to a Genero BDL application using the SOAP protocol.

This section explains how to migrate an I4GL Web service consumer to a Genero application accessing the same Web service.

Note: The migration is based on the SOA demo in the I4GL package.
Step 1: Generate the Genero web service stub from an I4GL WSDL

Use the fglwsdl tool to get the WSDL information from the service provider.

Use the I4GL WSDL located on the Axis server to generate the Genero Web service client stub via the tool called fglwsdl.

For example, the WSDL file of the I4GL zipcode demo is located on $INFORMIXDIR/AXIS2C/services/ws_zipcode/zipcode_details.wsdl. So run the following command:

```
$ fglwsdl -noFacets zipcode_details.wsdl
```

It will generate these two Genero files:

- `ws_zipcode_zipcode_detailsservice.4gl`
  - It contains the Genero functions to connect to the server in SOAP over HTTP.
  - Take a look at the file if you are interested in Genero HTTP and XML low-level APIs.
- `ws_zipcode_zipcode_detailsservice.inc`
  - It contains the Genero data types and variables used for XML serialization.
  - Take a look at the file if you are interested in Genero XML to BDL variable mapping.

Note: Option `-noFacets` is required for this demo because the I4GL CHAR data type will be generated as string in Genero, which can lead to an XML serialization error if not present.

Step 2: Modify the Genero .inc stubs to fix wrong I4GL WSDL

Remove the namespace attributes in the .inc file stub.

The I4GL WSDL contains namespace declaration for all I4GL Web service data types, but in practice the I4GL axis server doesn’t care about namespaces, but Genero does. So you have to open the generated Genero .inc file and remove all attributes called `XMLNamespace` and `XSTypeNamespace`.

For example, the generated .inc file from the I4GL WSDL must be modified as shown in the following sample:

```plaintext
# File: ws_zipcode_zipcode_detailsservice.inc
# GENERATED BY fglwsdl 101601
# THIS FILE WAS GENERATED. DO NOT MODIFY.

GLOBALS
...

# TYPE : tzipcode_details

TYPE tzipcode_details RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="zipcode_details")
  #,XSTypeNamespace="http://www.ibm.com/zipcode_details")
  pin STRING ATTRIBUTES(XMLName="pin")
END RECORD

# TYPE : tzipcode_detailsresponse

TYPE tzipcode_detailsresponse RECORD
  ATTRIBUTES(XMLSequence,XSTypeName="zipcode_detailsresponse")
  #,XSTypeNamespace="http://www.ibm.com/zipcode_details")
  city STRING ATTRIBUTES(XMLName="city")
  state STRING ATTRIBUTES(XMLName="state")
END RECORD
```
# Operation: zipcode_details

# FUNCTION: zipcode_details_g()
#   RETURNING: soapStatus
#   INPUT: GLOBAL zipcode_details
#   OUTPUT: GLOBAL zipcode_detailsresponse
#
# FUNCTION: zipcode_details(p_pin)
#   RETURNING: soapStatus ,p_city ,p_state
#
# FUNCTION: zipcode_detailsRequest_g()
#   RETURNING: soapStatus
#   INPUT: GLOBAL zipcode_details
#
# FUNCTION: zipcode_detailsResponse_g()
#   RETURNING: soapStatus
#   OUTPUT: GLOBAL zipcode_detailsresponse
#
# VARIABLE : zipcode_details
DEFINE zipcode_details tzipcode_details
ATTRIBUTES(XMLName="zipcode_details")
#,XMLNamespace="http://www.ibm.com/zipcode_details")
#--------------------------------------------------------------

# VARIABLE : zipcode_detailsresponse
DEFINE zipcode_detailsresponse tzipcode_detailsresponse
ATTRIBUTES(XMLName="zipcode_detailsresponse")
#,XMLNamespace="http://www.ibm.com/zipcode_details")
END GLOBALS

Note: For Genero Web Services options for mapping BDL and XML, see XML mapping attributes.

**Step 3: Include the generated stub in your I4GL application**

Use a GLOBALS statement to specify the Web service your application uses.

Add in all I4GL files calling a Web service in the generated .inc stub with a GLOBALS instruction.

For example, in the I4GL zipcode demo, only the clsoademo.4gl file uses Web services. So add the following line at the beginning of the file:

GLOBALs "ws_zipcode_zipcode_detailsservice.inc"
MAIN
...
END MAIN

Note: This allows access to the Genero global variables and data types used in the Web service call, so the Genero global wsError record can retrieve error codes if any.

**Step 4: Modify the I4GL web service function call**

Rename I4GL function name names to Genero Web service function names.

The Genero Web service function name is defined in the generated .4gl file and must be used instead of the I4GL function name.

For example, in the I4GL zipcode demo, the Web service function name is cons_ws_zipcode, which must be renamed to zipcode_details as follows:

FUNCTION func_cons_ws_zipcode()
  DEFINE state_rec RECORD
    pin CHAR(10),
    city CHAR(100),
    state CHAR(100)
  END RECORD;
# Genero web service status returning
# whether web function call was successful or not
# DEFINE soapstatus INTEGER
#
# I4GL web service function name is 'cons_ws_zipcode'
# CALL cons_ws_zipcode("97006")
# RETURNING state_rec.city, state_rec.state
# Genero web service function name is 'zipcode_details'
CALL zipcode_details("97006")
  RETURNING soapstatus, state_rec.city, state_rec.state
...
END FUNCTION

Note: In Genero Web Services there is an additional returned parameter, soapstatus. If it contains 0 the operation was a success, otherwise an error occurred.

Step 5: Handle Genero Web Services errors
Describes how to code to check the error status returned by the I4GL Web service, and get details of the error.

I4GL web service errors are returned on a non-conventional SOAP fault that cannot be handled in Genero. However, the errors are handled through the additional returned parameter soapstatus that must be checked after each Web service call. If its value is not zero, an error has occurred and can be retrieved via the global Genero wsError record defined in the generated .inc file.

Example

In the Genero Web Service you must check the soap status after each Web service call:

FUNCTION func_cons_ws_zipcode()
  DEFINE state_rec RECORD
    pin CHAR(10),
    city CHAR(100),
    state CHAR(100)
  END RECORD;
  # Genero web service status returning
  # whether web function call was successful or not
  # DEFINE soapstatus INTEGER
  # Genero web service function call
  CALL zipcode_details("97006")
    RETURNING soapstatus, state_rec.city, state_rec.state
  # Check soap status for errors after zipcode_details call
  IF soapstatus<>0 THEN
    # Display error information from the server
    DISPLAY "Error:
    DISPLAY " code :",wsError.code
    DISPLAY " ns :",wsError.codeNS
    DISPLAY " desc :",wsError.description
    DISPLAY " actor:"wsError.action
  ELSE
    # Display results
    DISPLAY "\n ------------------------- \n" 
    DISPLAY "SUPPLIED ZIP CODE: 97006 \n"
    DISPLAY " ------------------------- \n"
    DISPLAY "RESPONSE FROM WEB SERVICE \n"
    DISPLAY " ------------------------- \n"
    DISPLAY " CITY:"state_rec.city
    DISPLAY " \n STATE:"state_rec.state
    DISPLAY " \n ------------------------- \n"
**Step 6: Compile and run the Genero client**
Describes how to compile and run the client to test it.

Then simply compile your modified I4GL application for Genero and execute it. Your application will then connect to the Web service; passing and returning the parameters as if they were only simple BDL function calls.

For example, to compile your I4GL web service application for Genero, you must execute the following commands:

```
$ fglcomp -M ws_zipcode_zipcode_detailsservice.4gl
$ fglcomp -M clsoademo.4gl
$ fgllink -o clsoademo.42r clsoademo.42m
   ws_zipcode_zipcode_detailsservice.42m
$ fglrun clsoademo.42r
```

**Standalone Axis server is buggy**
Describes a bug you can expect using the I4GL standalone axis server.

The I4GL standalone axis server adds an extra CR LF after the body of the SOAP HTTP post response what leads the Genero client to return the error message: `Body content bigger than expected`. This is not allowed as defined in HTTP [RFC2616].

**Important:** Axis works as expected if loaded from Apache server.

---

**REST Web services**

Genero Web Services allows you to write Web Services server and client applications for the REST Web standard architecture.

**Designing REST Web services**

Planning the resources that the client can interact with is essential to REST Web service design.

Each component in a RESTful Web service is a resource that can be accessed using standard HTTP methods.

The starting point in identifying resources is to analyze your business domain and extract the nouns (and most appropriately pluralized nouns) that are relevant to your business needs. For example, “customers” and “accounts” are resources in a typical business domain.

Once the nouns (resources) have been identified, then the interactions with REST web services can be modeled as HTTP verbs against these nouns. REST relies on this resource/HTTP method combination.

For example, imagine you have a Web service like the "StockQuote" service mentioned in the Introduction to Web services on page 3270. In this simplification of the business domain, we can begin to identify some types of resources:

- quotes
  - /id
  - /price
  - /category
  - etc.
- companies
  - /id
  - /name
  - /rating
  - etc.
- users
Here's how you might begin to build resource identifiers. For example, "users" is a collection resource and "user" is a single resource in this domain. You can identify "users" using the URI with path "/users" to locate the resource. You can identify a single user resource using the path "/users/{id}". The path or endpoint is a logical not a physical URL that determines the resource you are requesting.

**Note:** You may find it helpful also to think of the resource in terms of CRUD, where each resource supports the action of Create, Read, Update, and Delete using the HTTP verbs PUT, GET, POST, DELETE.

For instance, the following may now represent endpoints to the StockQuote service for the users entity.

<table>
<thead>
<tr>
<th>Users</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET <a href="http://localhost:8090/StockQuote/users">http://localhost:8090/StockQuote/users</a>       - Return a list of all users (requires authentication)</td>
</tr>
<tr>
<td>GET <a href="http://localhost:8090/StockQuote/users/id">http://localhost:8090/StockQuote/users/id</a>    - Return the user with that id</td>
</tr>
<tr>
<td>POST <a href="http://localhost:8090/StockQuote/users">http://localhost:8090/StockQuote/users</a>      - Create a new user. Return a 201 status code and the newly created id</td>
</tr>
<tr>
<td>PUT   <a href="http://localhost:8090/StockQuote/users/id">http://localhost:8090/StockQuote/users/id</a>   - Update the user with that id</td>
</tr>
<tr>
<td>DELETE <a href="http://localhost:8090/StockQuote/users/id">http://localhost:8090/StockQuote/users/id</a> - Delete the user with that id</td>
</tr>
</tbody>
</table>

Functions in the REST Web service now need to be created to respond to requests for services based on those endpoints. For this it is recommended to always use the GWS REST high-level framework in your Web service. Functions require considerably less code in your application and are easier to use in comparison with low-level APIs.

**Related concepts**

**REST** on page 3274
Represenational State Transfer (REST) is a Web standard architecture that provides a method for communication between a Web service and a client over HTTP.

**Planning a Web service** on page 3271
Creating a Web service application requires planning for the future use and reuse of the service.

**RESTful Web services with high-level framework**
These topics give you the information you need to begin working with RESTful Web services applications using BDL function with support for attributes.

**Steps to writing a REST server application**
To create a RESTful Genero Web server application, you need to create a Genero BDL module that defines the service functions. When you publish it, a service description is available when required.

**Getting started with REST high-level**
Prepare an environment for testing, create the server application, and run and test the service.

If you are on a local server, you can start working with the GWS as follows:

1. Set the runtime environment. For example, run the script file envcomp in the Genero BDL installation directory to make sure that your FGLDIR and PATH are set correctly to run compiler and runtime system tools.
2. Set FGLAPPSERVER to 8090. This will start the GWS Server on port 8090. If this environment variable is not set, port number 80 is used.

**Warning:** The user must not set the FGLAPPSERVER variable in production environments, since the port number is selected by the Genero Application Server.
3. Set FGLWSDEBUG environment variable to 3. This ensures there is detail in the output of the HTTP requests and responses to see the interaction between the client and the server and for debugging purposes. See FGLWSDEBUG on page 283.

4. Create your application module. For example, create a file named `myService.4gl`. Add service functions using the GWS REST function attributes. See the examples in the Define functions in a module on page 3376 section.

5. Create the application’s main service module. See Publish a REST service on page 3404

6. Compile your main application and service module.

7. Publish the service, see Publish a REST service on page 3404.

8. To test, use the `fglrun` command to execute the GWS Server application in direct mode. The service and the runtime must reside on the same machine:

   ```
   fglrun <gws application>
   ```

   This will start the GWS Server on the port specified by the FGLAPPSERVER environment variable.

9. If the GWS Server in step 2 was started on your local machine, for example, the OpenAPI information would be at:

   ```
   http://localhost:8090/<service-name>?openapi.json
   ```

   or

   ```
   http://localhost:8090/<service-name>?openapi.yaml
   ```

**Define functions in a module**

A GWS REST service is defined in a single module.

You write a BDL function for each service function you wish to make public. In your functions input and output parameters you can set attributes. These attributes allow you to specify the communication between the server and the client in terms of HTTP:

- Path, query, header, cookie
- Request body
- Response body
- Multipart request and response

**Function REST parameters**

Through function parameters and their attributes, you define how the resources of your Web service are to be accessed and used:

- REST operation attributes define the REST behavior (such as the HTTP GET, or POST operation).
- Path templating parameters (with `WSParam`, `WSPath` attributes) define the location of a resource. The path parameter value is directly related to a resource and is part of the resources URL path.
- REST attributes on the input parameters and output return values that define how parameters are serialized. For example, parameter attributes specify if data is carried in the body or header, as a cookie, as a query, or as multipart.

For details of all available attributes and descriptions of their usage, see the High-level RESTful Web service attributes on page 3463 section.

See the examples for defining your REST Web service functions.

**Related concepts**

REST Web services on page 3374

Genero Web Services allows you to write Web Services server and client applications for the REST Web standard architecture.

**Related reference**

High-level RESTful Web service attributes on page 3463
**Define your resource operations**

Operations are the HTTP methods used to manipulate the resources of your Web service.

For each resource path, you define an operation (HTTP method) that can be used to access the resource. An HTTP operation such as GET, POST, PUT, or DELETE, must be represented in your REST function in order to provide its service.

The same resource path can support several operations, for example, GET /users to get a list of users and POST /users to add a new user, etc. However, only one operation is allowed per function and therefore you must provide separate functions for these operations.

In the OpenAPI specification the combination of resource path and an HTTP method defines a unique function. Two GET or two POST functions for the same path are not allowed; even if they have different parameters. Input parameters or return values do not effect the uniqueness of the function.

**Define functions with operation attributes**

In GWS REST the attributes that perform operations are identifiable by the HTTP verb in the name, for example, **WSGet** on page 3467, **WSDelete** on page 3466, **WSPost** on page 3467, and **WSPut** on page 3468, etc. Your REST function must have one of these attributes in order to define its service. You can use these attributes in the attributes clause of your function.

**Publishing operations**

When you generate the service description, the operations you declared are published in a node. For example, there is a "get" node if it describes a GET operation. You find the operation node under the path for that resource in your OpenAPI specification file.

**Related concepts**

- **Designing REST Web services** on page 3374
Planning the resources that the client can interact with is essential to REST Web service design.

- **Generate service description on demand** on page 3406
You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

Example: Get operation with WSGet

Example of methods you can use to get data from a resource with the WSGet attribute.

**Example using WSGet**

In this sample REST function the number of users from the users table of a database is returned.

```plaintext
PUBLIC FUNCTION getNumberUsers()
    ATTRIBUTES (WSGet,
                  WSPath="/users/count",
                  WSDescription="Returns a count of users")
    RETURNS INTEGER
    DEFINE cnt INTEGER
    SELECT COUNT(*) INTO cnt FROM users
    RETURN cnt
END FUNCTION
```

**Example using WSGet to return all users**

In this function all users are returned. An example of the resource URL is:

```plaintext
http://host:port/gas/ws/r/group/xcf/Account/users
```

```plaintext
IMPORT com

TYPE profileType RECORD ... END RECORD
```
PUBLIC FUNCTION getAllUsers()
    ATTRIBUTES (WSGet,
        WSPath="/users",
        WSDescription="Returns all user profiles",
        WSThrows="400:Invalid,404:Not found")
    RETURNS (DYNAMIC ARRAY ATTRIBUTE (WSName="All_users", WSMedia="application/xml") OF profileType
        ATTRIBUTE (XMLName="User") )

    DEFINE arr DYNAMIC ARRAY OF profileType
        # ... function code ...

    RETURN arr
END FUNCTION

The output as XML is customized by WSName on page 3475 and XMLName on page 3548

Related concepts
Resource operation attributes on page 3465
Attributes that map an HTTP operation in a function to a REST resource.

Example: create resource with WSPost
Create a new resource with the WSPost attribute.

Example creating resource with WSPost
In this sample REST function a new user resource is created. The user record is defined as a data type in the module. This is referenced in the input parameter thisUser.

IMPORT com

TYPE profileType RECORD ... END RECORD

PUBLIC DEFINE userError RECORD ATTRIBUTE (WSError="User error")
    message STRING
END RECORD

PUBLIC FUNCTION createUser( thisUser profileType )
    ATTRIBUTES (WSPost,
        WSPath="/users",
        WSDescription="Create a user profile",
        WSThrows="400:@userError")
    RETURNS STRING

    DEFINE ret STRING
    WHENEVER ERROR CONTINUE
        INSERT INTO users VALUES (thisUser.*)
        WHENEVER ERROR STOP
        CASE 
            WHEN SQLCA.SQLCODE == 0
                LET ret = SFMT("Created user: %1",thisUser.name)
            OTHERWISE 
                LET userError.message = SFMT("SQL error:%1 [%2]",SQLCA.SQLCODE, SQLERRMESSAGE)
                CALL com.WebServiceEngine.SetRestError(400,userError)
        END CASE
    END CASE

    RETURN ret
END FUNCTION

Related concepts
Resource operation attributes on page 3465
Attributes that map an HTTP operation in a function to a REST resource.

**Set a request body** on page 3383
Functions that create or update a resource need to set a request body for the incoming payload. You specify the request body in an input parameter.

**Example: Update resource with WSPut**
Update a resource with the WSPut attribute.

**Example updating a resource with WSPut**
In this sample REST function a user resource is updated.

```sql
IMPORT com

TYPE profileType RECORD ... END RECORD

PUBLIC DEFINE userError RECORD ATTRIBUTE(WSError="User error")
  message STRING
END RECORD

PUBLIC FUNCTION updateUsers(
  id INTEGER ATTRIBUTES(WSParam),
  thisUser profileType)
  ATTRIBUTES(
    WSPut,
    WSPATH="/users/{id}",
    WSDESCRIPTION="Update a user profile",
    WSThrows="400:@userError"
  )
  RETURNS STRING
  DEFINE ret STRING
  WHENEVER ERROR CONTINUE
  UPDATE users
    SET name = thisUser.name,
    email = thisUser.email
  WHERE @id = id
  WHENEVER ERROR STOP
  CASE
  WHEN SQLCA.SQLCODE = 0
    # test for processed rows
    IF SQLCA.SQLERRD[3] = 1 THEN
      LET ret = SFMT("Updated user with ID: %1",id)
    ELSE
      LET ret = SFMT("No user with ID: %1",id)
    END IF
  OTHERWISE
    LET ret=SFMT("Error updating user with ID: %1",id)
    LET userError.message = SFMT("SQL error:%1 [%2]",SQLCA.SQLCODE,
    SQLERRMESSAGE)
    CALL com.WebServiceEngine.SetRestError(400,userError)
  END CASE
  RETURN ret
END FUNCTION
```

**Related concepts**

**Resource operation attributes** on page 3465
Attributes that map an HTTP operation in a function to a REST resource.

**Example: Delete a resource with WSDelete**
Delete a resource with the WSDelete attribute.

**Example deleting a resource with WSDelete**

In this sample REST function a user resource is deleted.

```gws
PUBLIC FUNCTION deleteUsers( id INTEGER ATTRIBUTES(WSParam) )
    ATTRIBUTES(WSDelete,
        WSPATH="/users/{id}",
        WSDescription="Delete a user profile")
    RETURNS STRING
    DEFINE ret STRING
    DELETE FROM users WHERE @id = id
    LET ret = SFMT("Deleted user with ID: %1",id)
    RETURN ret
END FUNCTION
```

**Related concepts**

- [Resource operation attributes](#) on page 3465
  - Attributes that map an HTTP operation in a function to a REST resource.

- **Set resource path with WSParam and WSPATH**
  - Path parameters allow you to specify variables in the resource URL.

  Path parameters are variable parts of a resource path. You would use them if you needed in your function to point to a specific resource within a collection, such as a user identified by ID, and when a pattern could match many similar resources. This is an example of the format of a resource path with path template.

  `/users/{id}

  In the OpenAPI specification, the parts of the path that are replaceable with parameters are path templates. They are denoted with curly brackets `{}`. The path template is substituted with actual values when a GWS client makes a call to the resource.

  For instance, if a client requests data for a specific user, the user id (22) is provided in the URI:

  ```text
  http://host:port/gas/ws/r/group/xcf/Account/users/22
  ```

  A function in your web service with the path pattern above processes the request.

  In GWS REST the **WSPath** on page 3469 and **WSParam** on page 3469 attributes support path templating. Path parameters are set in the attributes clause of the function with the `WSPATH` attribute. For example:

  ```gws
  ATTRIBUTES (WSGet,WSPATH="/members/{membersId}/books/{bookId}")
  ```

  A call to the function with this path checks if a specified member checked out a book from the library. The input parameters that correspond to the templates in the path are described in **Table 718: Path parameters** on page 3380.

**Table 718: Path parameters**

<table>
<thead>
<tr>
<th>Parameter with WSParam attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>membersId INTEGER ATTRIBUTE(WSParam)</td>
<td>A unique identifier for a library user resource.</td>
</tr>
<tr>
<td>booksId INTEGER ATTRIBUTE(WSParam)</td>
<td>A unique identifier for a book resource.</td>
</tr>
</tbody>
</table>

Be aware that for each BDL function input parameter with a `WSParam` attribute, there must be a matching template value in the `WSPATH` attribute value. `fglcomp` checks to ensure that there is one template value per parameter, otherwise compilation `error-9111` is thrown.
Example path templating with WSPath and WSParam

```plaintext
IMPORT com

TYPE checkoutType RECORD
  booksId INT,
  title VARCHAR(100),
  author VARCHAR(100),
  m_name VARCHAR(100),
  checkout_date DATETIME YEAR TO SECOND
END RECORD

DEFINE myError RECORD ATTRIBUTE(WSError="My error")
  code INTEGER,
  reason STRING
END RECORD

PUBLIC FUNCTION getBooksCheckedOut(
  p_membersid INTEGER ATTRIBUTE(WSParam) )
  ATTRIBUTES (WSGet,
    WSPath="members/{p_membersid}/books/",
    WSDescription="Get books checked out by a given member of the
    library",
    WSThrows="400:Invalid,406:Should not happen" )
  RETURNS (  
    DYNAMIC ARRAY ATTRIBUTE(WSName="Books_checked_Out",WSMedia="application/xml") OF checkoutType
    ATTRIBUTE(XMLName="Book") )
  DEFINE bookList DYNAMIC ARRAY OF checkoutType
  INITIALIZE bookList TO NULL
  TRY
    DECLARE c1 CURSOR FOR SELECT b.booksid, b.title, b.author, m.name, 
    c.checkoutdate FROM books b 
    INNER JOIN checkouts c ON b.booksid = c.booksid AND c.membersid = m.membersid 
    INNER JOIN members m ON c.membersid = p_membersid 
    IF SQLCA.SQLCODE = 0 THEN 
      # ... function code
    END if
    CATCH 
    WHEN SQLCA.SQLCODE = NOTFOUND 
      LET myError.reason = SFMT("Nothing found for member: %1", p_membersid )
      CALL com.WebServiceEngine.SetRestError(400,myError) 
    OTHERWISE 
      LET myError.reason = SFMT("Error in SQL execution: %1 [%2]", SQLCA.SQLCODE, SQLERRMESSAGE )
      CALL com.WebServiceEngine.SetRestError(406,myError)
    END CASE
  END TRY
  FREE c1
  RETURN bookList
END FUNCTION
```

The variable part of the path is replaced by the value /48/ in this URL example:

```
http://host:port/gas/ws/r/group/xcf/MyLibrary/members/48/books
```

The XML output is customized by WName on page 3475 and XMLName on page 3548.
When to use WSPath or WSQuery

It is important to know when it is appropriate to use these attributes in your Web service. Basically the difference is that a path parameter is used to return a single entity given its id field, while a query parameter is used for any other field other than a resource id and a number of entities may be returned in the response.

For example, /users/{id} specifies the entity in the resource path. Usually you get a HTTP response code 404 (Not found) if an entity is not found by the id specified as path parameter.

On the other hand if you think in the case of a search or filter, you expect to return a number of entities in the response, unlike the single entity that you expect to get as the response for sending id as path parameter. Therefore, WSQuery on page 3471 is the logical attribute to use for filtering, searching, or sorting resources:

For example, in /users?lastname=smith the search criteria is specified in a query parameter of the URL.

Usually you get an HTTP response code 200 (OK) with an empty array as the response body, if no entities are found matching the search or filter parameters.

Related concepts

Designing REST Web services on page 3374
Planning the resources that the client can interact with is essential to REST Web service design.

Set query, header, or cookie parameters (if needed)

You define these parameters in your function if the resource needs data to be passed as query, cookie, or header.

The GWS REST engine provides support for the OpenAPI specification requirements for the following standard parameters:

1. Query parameters. These are set at the end of the resource URL after a question mark (?), with different name=value pairs separated by ampersands (&). Query parameters can be required and optional.
2. Header parameters, such as X-MyHeader:Value. These are custom headers to be sent with an HTTP request or response.
3. Cookie parameters, are passed in the Cookie header. For example, Cookie:ctoken=BUSE35dohU4O1MZxDCU.

Parameter attributes

You use the following attributes if there is requirement for them in your Web service function.

1. WSQuery on page 3471. You can specify this attribute only in an input parameter of your function. Its use is suited to filtering on resource collections, such as /users?country=france.
2. WSHeader on page 3472. Header attributes may be specified in an input parameter or in a return value of your function. The Content-Type:text/html header, for example, indicates the media type of the response sent to the client by the server. This helps the client in processing the response body correctly. Custom headers are commonly used for informational purposes, but you can also use them for passing data to implement logic on the server or client side.
3. WSCookie on page 3473. The cookie attribute is dedicated to the need for cookies in your function.

You can set these parameters as optional with the WSOptional on page 3476 attribute as shown in the sample function.

Example use of parameter attributes

```plaintext
TYPE profileType RECORD ...
END RECORD

PUBLIC FUNCTION getUsersStatus(
    stat STRING ATTRIBUTE(WSQuery, WSOptional, WSName="status"),
    sort_field STRING ATTRIBUTE(WSHeader, WSOptional, WSName="sortby"),
    country STRING ATTRIBUTE(WSCookie, WSOptional, WSName = "ccode" )
) ATTRIBUTES (WSGet,
    WSPath = "/users",
```
Your client application has the option of providing the custom header and cookie parameter with values in a call to the function.

The `WSQuery` parameter, if specified, forms the query string of the resource path, `status=active` in this example of the resource URL:

```
http://host:port/gas/ws/r/group/xcf/Accounts/users?status=active
```

The XML output is customized by `WSName` on page 3475 and `XMLName` on page 3548 attributes.

**Related concepts**

- **Designing REST Web services** on page 3374
- Planning the resources that the client can interact with is essential to REST Web service design.

- **Retrieve HTTP headers** on page 3385
- You can retrieve HTTP headers in your REST operation.

**Set a request body**

Functions that create or update a resource need to set a request body for the incoming payload. You specify the request body in an input parameter.

**Note:**

A message body is required when you perform an HTTP PUT, POST or PATCH request to a resource, otherwise the request results in the `error-9106`.

In your BDL function, you specify a request body by declaring an input parameter that does not have any `WSHeader`, `WSQuery`, `WSCookie`, or `WSParam` attributes.

In the example the single input parameter ("lname") is defined as a string. It is not defined with a REST attribute and its content is therefore sent in the body of the HTTP request.

**Note:** If you have more than one of such input parameters, it means your payload is delivered in a multipart body request.

If the data type is not a primitive data type, you may need to define a type suitable for the structure in your module. You reference the type in your input parameter. For an example, see Example: create resource with `WSPost` on page 3378. The function needs to receive data of the required structure for the resource in either a JSON or XML representation.

**Example specifying a request body**

```plaintext
IMPORT com
PUBLIC
DEFINE myerror RECORD ATTRIBUTE(WSError="My error")
    code INTEGER,
    reason STRING
END RECORD
PUBLIC FUNCTION updateUsersField(
```
id INTEGER ATTRIBUTES(WSParam, WSDescription="User id")
, lname STRING ATTRIBUTE(WSDescription="User's last name")

ATTRIBUTES(WSPut,
  WSPATH="/users/{id}",
  WSDescription="Update name of a given user",
  WSThrows="400:@myerror")

RETURNS STRING

DEFINE ret STRING
WHENEVER ERROR CONTINUE
UPDATE users SET
  user_name=lname
WHERE @user_id = id
WHENEVER ERROR STOP
CASE
  WHEN SQLCA.SQLCODE == 0
    LET ret = SFMT("Updated user: %1", lname)
  WHEN SQLCA.SQLCODE == NOTFOUND
    LET ret = SFMT("No row was found with ID: %1", id)
  OTHERWISE
    LET myerror.reason = SFMT("SQL error:%1 [%2]", SQLCA.SQLCODE, SQLERRMESSAGE)
    CALL com.WebServiceEngine.SetRestError(400, myerror)
  END CASE
RETURN ret
END FUNCTION

| PUT /courseGWS/users/1 HTTP/1.1 |
| Accept: text/plain, application/json, application/xml, text/xml |

**Figure 126: Output of the HTTP request**

**Related concepts**

HTTP verbs and attributes on page 3465
HTTP verbs are defined by the high-level RESTful attributes. Some verbs have requirements for request or response body and others do not.

**Set a response body and header**

Functions that create, update, delete, or get a resource need to set a response body. You specify this in a return parameter without an attribute. Other return values can be sent in headers, using the WSHdrer attribute.

**Note:**
A message body in the response is required when you perform an HTTP GET, POST, PUT, DELETE operation on a resource, otherwise the response results in the error-9106.

**Example responses in header and body**

PUBLIC FUNCTION help()

ATTRIBUTES (WSGet,
  WSPATH="/help")

RETURNS (INTEGER ATTRIBUTE(WSHeader, WSDescription="Reference number"), STRING)
The help function's RETURNS clause has two return values:

- An integer is returned in a header. It is specified with the WSHdr attribute.
- A string is returned in the body. It is specified without an attribute.

**Figure 127: Output of the HTTP response**

![HTTP response output](image)

In the output the header is given a default name, "rv0", at runtime. You can change default header naming via the WSName attribute, for example with:

```
RETURNS (INTEGER ATTRIBUTE(WSHeader, WSName="MyHeader"), STRING)
```

**Related concepts**

- Multipart requests or responses on page 3394

In GWS REST there is support for the standard multiple part message, in which more than one different sets of data are combined in a single body.

**Retrieve HTTP headers**

You can retrieve HTTP headers in your REST operation.

There are different ways for retrieving HTTP headers; such as using the WSHdr attribute as part of a function parameter, or retrieving headers via WSContext on page 3481.

The option you choose depends on your requirements:

- If you need to retrieve the header as part of the REST operation, you use WSHdr on page 3472 and WSName on page 3475 attributes in your function parameter. You can retrieve any HTTP header in this way. In case the header is not present, you must also set the WSOptl attribute on page 3476 attribute. For example, the remote address can be passed in the header by coding:

  ```
  ip_address STRING ATTRIBUTES(WSHeader, WSOptl, WSName="X-FourJs-Environment-Variable-REMOTE_ADDR")
  ```

- If you do not want the header to be part of the REST operation, you can use the WSContext on page 3481 mechanism. For example, the remote address and server name can be retrieved by setting a context dictionary variable (for example `context`) at the modular level with the WSContext attribute. This allows you to retrieve all X-FourJs-Environment-xxx set by the GAS by referencing a dictionary key value for the environment variable:

  ```
  PRIVATE DEFINE context DICTIONARY ATTRIBUTE(WSContext) OF STRING
  ```
Web services

DISPLAY context["Variable-REMOTE_ADDR"] -- displays the remote ADDR if set by the GAS
DISPLAY context["Variable-SERVER_NAME"] -- displays the server name if set by the GAS

Related concepts
Set query, header, or cookie parameters (if needed) on page 3382
You define these parameters in your function if the resource needs data to be passed as query, cookie, or header.

Handling file attachments with REST
The Genero REST high-level framework provides two mechanisms for handling attachments.

• Send (or receive) the complete file as a simple attachment.
• Send (or receive) a file in a MIME multipart message body.

Which method to use

<table>
<thead>
<tr>
<th>Situation</th>
<th>Method to choose</th>
</tr>
</thead>
<tbody>
<tr>
<td>If your REST service needs one file, whether it is a zip file, image, or PDF.</td>
<td>Send the complete file as a simple attachment. See Attach files with WSAttachment and WSMedia on page 3386.</td>
</tr>
<tr>
<td>If the design of your REST Web services requires multipart to attach files.</td>
<td>Send the file as multipart. See Multipart requests or responses on page 3394.</td>
</tr>
<tr>
<td>If you have several attachments to send in a single HTTP request or response message.</td>
<td>Send the file as multipart. See Multipart requests or responses on page 3394.</td>
</tr>
<tr>
<td>If you have a large data object, whether it is a binary, text file, or a BLOB in a database.</td>
<td>Send the data in a BYTE or TEXT object in the message body. See Transfer data in large objects on page 3390</td>
</tr>
</tbody>
</table>

Related concepts
Generate service description on demand on page 3406
You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

Attach files with WSAttachment and WSMedia
In GWS REST attachments are handled via the WSAttachment and WSMedia attributes.

If a parameter has a WSAttachment on page 3477 attribute, the REST engine treats the parameter value as a path to a file to be attached, while the data format of the file can be specified in the WSMedia on page 3478 attribute.

Attaching files in request and response
In this function, an image file is sent to the server in the request and another image is returned to the client. The wildcard (image/*) in WSMedia allows for all image types:

```
IMPORT os
PUBLIC FUNCTION EchoFile( input STRING ATTRIBUTE (WSAttachment, WSMedia="image/*") )
    ATTRIBUTES(WSPost)
    RETURNS STRING ATTRIBUTE (WSAttachment, WSMedia="image/*")
    DEFINE ok INTEGER
    LET ok = os.path.rename(input, "MyFile.png")
    RETURN "/usr/local/MyOtherFile.jpg"
END FUNCTION
```
Related concepts

Multipart requests or responses on page 3394
In GWS REST there is support for the standard multiple part message, in which more than one different sets of data are combined in a single body.

Transfer data in large objects on page 3390
Use the BYTE and TEXT data types to transfer large objects (LOBs) with a Genero RESTful web service.

Generate service description on demand on page 3406
You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

Download a file as an attachment to a response
This example demonstrates how to return a file as an attachment using the WSAttachment attribute

In order to return a file as an attachment to a client, set the WSAttachment attribute on page 3477 attribute on an output parameter.

**Example 1: downloading file using WSAttachment**

```plaintext
IMPORT com
IMPORT os

PUBLIC DEFINE myerror RECORD ATTRIBUTE(WSError="My error")
  code INTEGER,
  reason STRING
END RECORD

PUBLIC FUNCTION downloadImageFile()
  ATTRIBUTES (WSGet,
    WSPath="/files3/images",
    WSDescription="download image file to the client with WSAttachment",
    WSThrows="400:myerror")
  RETURNS (STRING ATTRIBUTE(WSAttachment, WSMedia="image/*") )
  DEFINE ret, fname STRING
  DEFINE ok INTEGER

  LET fname="favicon.ico"
  LET ok = os.Path.exists(fname)
  IF ok THEN
    LET ret = fname
  ELSE
    LET myerror.reason = SFMT("File (%1) does not exist", fname)
    CALL com.WebServiceEngine.SetRestError(400,myerror)
  END IF
  RETURN ret
END FUNCTION
```

In this example:

- A STRING type is defined with a WSAttachment attribute.
- A WSMedia attribute is added to handle the data format for images.
In Figure 128: Output of HTTP response to download image file on page 3388 the Content-Disposition response header in the output indicates that the content is expected as an attachment. Therefore, when the function is called, the file is downloaded and saved to the client locally in its TMP directory.

Related concepts

Multipart requests or responses on page 3394
In GWS REST there is support for the standard multiple part message, in which more than one different sets of data are combined in a single body.

Download a large object in the response body on page 3390
This example demonstrates how to send a large object in the message response body.

Example: upload a file as attachment in request body
Shows a sample function uploading an image file as attachment in the message request body.

In order to send a file as an attachment to the Web service, set the WSAttachment on page 3477 attribute on an input parameter.
Example 1: upload file as attachment using WSAttachment

```plaintext
IMPORT os

PUBLIC FUNCTION UploadFile( fname STRING ATTRIBUTES(WSAttachment,
    WSMedia="image/*") )
    ATTRIBUTES (WSPost,
        WSPath="/files2/fetch")
    RETURNS STRING ATTRIBUTE(WSMedia="text/plain")
    DEFINE ret, new_fname STRING
    DEFINE ok INTEGER
    LET new_fname = os.Path.pwd()||os.Path.separator()||new_fname
    LET ok = os.Path.rename(fname,new_fname)
    LET ret = SFMT("Got image: %1",new_fname)
    RETURN ret
END FUNCTION
```

In this example:
- "fname" is defined as type STRING with a WSAttachment attribute.
- The WSMedia attribute handles the data format for images.

The GWS stores the file in a temporary directory, and returns the absolute path to the file in the input parameter (fname). When the call to the function ends, the file will be removed unless you save it to a location on disk. You can use the `os.Path.rename` instruction to move the file from the temporary directory to a directory of your choice.

![Image file upload as attachment](image.png)

**Figure 129: Output of HTTP request to upload file**

In **Figure 129: Output of HTTP request to upload file** on page 3389 the image is sent as an attachment in the message body.

**Related concepts**

Upload a large object in the request body on page 3391
This example demonstrates how to upload a large object in the message response body.

Example: upload a file in a multipart request on page 3397
Shows an example of a method you might use from a client to upload an image along with other data in a function using a form-data type HTTP multipart request.

Transfer data in large objects

Use the BYTE and TEXT data types to transfer large objects (LOBs) with a Genero RESTful web service.

Specify an input or return parameter of a Web service function as a TEXT on page 307 or BYTE on page 290 type in order to transfer a large object (LOB) to a web service server or client.

**Which object to use**

<table>
<thead>
<tr>
<th>Situation</th>
<th>Data type to use</th>
</tr>
</thead>
<tbody>
<tr>
<td>Your web service transfers binary file contents. For example: an image, PDF, zip file, etc.</td>
<td>BYTE</td>
</tr>
<tr>
<td>You have a binary large object (BLOB) stored in a table and your web service must write it out to a file. For example, an image.</td>
<td>BYTE</td>
</tr>
<tr>
<td>Your web service transfers ASCII content. For example: text, HTML, etc.</td>
<td>TEXT</td>
</tr>
</tbody>
</table>

This method transfers data in the request body.

**Important:** To send a LOB from a REST client function you must, LOCATE it in memory or file to load the data before calling the server function. On the server REST function, you do not need to locate the input parameters TEXT/BYTE types as they are implicitly located in memory when the server function is called. See code samples in [Upload a large object in the request body](#) on page 3391.

**Related concepts**

Attach files with WSAattachment and WSMedia on page 3386

In GWS REST attachments are handled via the WSAattachment and WSMedia attributes.

Multipart requests or responses on page 3394

In GWS REST there is support for the standard multiple part message, in which more than one different sets of data are combined in a single body.

Download a large object in the response body

This example demonstrates how to send a large object in the message response body.

To transfer a large object (LOB) to a client, specify a return parameter using a TEXT on page 307 or BYTE on page 290 data type. The large object is returned in the response body.

**Example: downloading a TEXT object**

```public function help3()
  attributes (wsget,
    wsdescription="download text to the client in a TEXT object",
    wspath="/help/file3")
  returns ( INTEGER ATTRIBUTE(WShereader), TEXT )
  define t TEXT
  locate t in memory
  call t.readFile("file3.txt")
  return 3, t
end function```

In this example:
- The TEXT variable (t) is created to hold the file content and is located in memory.
- The readFile() method reads the content of the text file (file3.txt) into the TEXT variable (t).
- The TEXT variable (t) is transferred in the message body.
- The INTEGER variable, defined as a return parameter with the WSHeader attribute, is transferred in the response header.

```
GET /Myservice/help/file3 HTTP/1.1
Host: localhost:8090
Content-Type: text/plain; charset=UTF-8
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
Accept-Language: en-US,en;q=0.5
Accept-Encoding: gzip, deflate
Connection: keep-alive
Upgrade-Insecure-Requests: 1
HTTP/1.1 200 Success
rv0: 3
```  

**Figure 130: Output of HTTP response**

The header is given a default name ("rv0") at runtime. Use the WSName on page 3475 attribute to rename the header.

```
RETURNS (INTEGER ATTRIBUTE(WSHeader, WSName="MyHeader"), TEXT)
```

**Related concepts**
- Download a file in a multipart response on page 3396
  This example demonstrates how to return a file in a form-data type HTTP multipart response while also transferring data of other types in the same message response.
- Download a file as an attachment to a response on page 3387
  This example demonstrates how to return a file as an attachment using the WSAttachment attribute

Upload a large object in the request body
This example demonstrates how to upload a large object in the message response body.

To upload a large object (LOB) to a web service server, specify an input parameter using a TEXT on page 307 or BYTE on page 290 data type. The large object is sent in the request body. Any binary file contents (image, PDF, zip, etc.) may be uploaded using this method.

**Example: Uploading a BYTE object and writing to a file**

```
IMPORT os

PUBLIC FUNCTION UploadByteToFile(b BYTE)
```
ATTRIBUTES (WSPost,  
WSDescription="Upload BYTE and write to file on server",  
WSPath="/help/pdf")  
RETURNS STRING 
CONSTANT filename = "help.pdf" 
DEFINE ret STRING  
TRY  
CALL b.writeFile(filename)  
LET ret = SFMT("Data received, saved to file: %1",filename)  
CATCH  
LET ret = SFMT(" Error getting data, not saved to file: %1",filename)  
END TRY  
RETURN ret  
END FUNCTION

In this example:

- The large object is transferred in the BYTE input parameter b in the message body.
- The writeFile() method writes the content of the variable b to a file (help.pdf) on the server side.

**Example: Client app calling the function**

The client needs to load a BYTE object before calling the function.

```
IMPORT util
IMPORT FGL clientGWSStub

MAIN
  DEFINE wsstatus INTEGER
  DEFINE retS STRING

  DEFINE b BYTE
  LOCATE b IN MEMORY
  CALL b.readFile("help.pdf")

  CALL clientGWSStub.UploadByteToFile(b) RETURNING wsstatus, retS
  CASE wsstatus
    WHEN clientGWSStub.C_SUCCESS
      DISPLAY SFMT("Got %1 ", retS)
    OTHERWISE
      DISPLAY "wsstatus is : ", wsstatus
      DISPLAY "Error in getting file uploaded"
  END CASE

END MAIN
```

In this example:

- A BYTE variable b is created to hold the large object and the LOCATE instruction specifies where it is stored (MEMORY or FILE).
- The readFile() method reads the contents of a PDF file (help.pdf) into the BYTE variable b.
- A call to the server function is made specifying b as the input parameter. The data is transferred in the request body.

**Related concepts**

- **Example: upload a file in a multipart request** on page 3397
  Shows an example of a method you might use from a client to upload an image along with other data in a function using a form-data type HTTP multipart request.

- **Example: upload a file as attachment in request body** on page 3388
Shows a sample function uploading an image file as attachment in the message request body.

**Set data format with WSMedia**

It is important to set the correct MIME type for a Web service request or response. You can specify the data format via the WSMedia attribute.

For records and arrays in the message response the default MIME type can be JSON (**application/json**) or XML (**application/xml**). **WSMedia** on page 3478 can contain a comma-separated list of MIME types. The payload format is chosen according to that specified in the Accept header received from the client using the Web service.

In the example the **WSMedia** attribute is set for XML to send the list of users to the client in XML format. The output is customized by **WSName** on page 3475 and **XMLName** on page 3548 attributes.

**Example WSMedia with record type**

```plaintext
IMPORT com

TYPE profileType RECORD ...

PUBLIC DEFINE myError RECORD ATTRIBUTE(WSError="My error")
  code INTEGER,
  reason STRING
END RECORD

PUBLIC FUNCTION getUsersList()
  ATTRIBUTES (WSGet,
    WSPath="/users",
    WSDescription="Get list of users",
    WSThrows="400:Invalid,404:NotAvailable"
  )
  RETURNS (DYNAMIC ARRAY ATTRIBUTE(WSName="All_users_list",WSMedia="application/xml") OF profileType
    ATTRIBUTE(XMLName="User")
  )
  DEFINE usersList DYNAMIC ARRAY OF profileType
  DEFINE i INTEGER
  WHENEVER ERROR CONTINUE
  DECLARE c1 CURSOR FOR SELECT * FROM users
  WHENEVER ERROR STOP
  CASE
    WHEN SQLCA.SQLCODE == 0
      INITIALIZE usersList TO NULL
      LET i=1
      FOREACH c1 INTO usersList[i].*
        LET i=i+1
      END FOREACH
      CALL usersList.deleteElement(i)
    WHEN SQLCA.SQLCODE == NOTFOUND
      LET myError.reason = "Nothing found"
      CALL com.WebServiceEngine.SetRestError(404,myError)
    OTHERWISE
      LET myError.reason = SFMT("SQL error:%1 [ %2],SQLCA.SQLCODE, SQLERRMESSAGE)
      CALL com.WebServiceEngine.SetRestError(400,myError)
  END CASE
  FREE c1
  RETURN usersList
END FUNCTION
```
Example WSMedia with image

For WSMedia examples using images or files, see Example: upload a file in a multipart request on page 3397.

Customize XML serialization with WSName and XMLName

Use the WSName and XMLName attributes to customize serialization at runtime and improve the readability of the XML output.

Formatting XML output with WSName and XMLName

```
IMPORT com

TYPE profileType RECORD ... END RECORD

PUBLIC DEFINE myError RECORD ATTRIBUTE(WSError="My error")
    code INTEGER,
    reason STRING
END RECORD

PUBLIC FUNCTION getUsersList()
    ATTRIBUTES (WSGet,
        WSPath="/users",
        WSDescription="Get list of users",
        WSThrows="400:Invalid,404:NotAvailable"
    )
    RETURNS (DYNAMIC ARRAY ATTRIBUTE(WSName="All_users_list",WSMedia="application/xml")
        OF profileType
    )
    DEFINE usersList DYNAMIC ARRAY OF profileType
    ... function code
    RETURN usersList
END FUNCTION
```

The function returns the output in XML format as a string. The output contains the tags specified by the attributes.

- The **WSName** attribute for the array gives `<All_users_list>` as the root tag for the output.
- The **XMLName** attribute (XMLName="User") maps the BDL record (profileType) and tags each element with `<User>` in the XML document.

For example, when viewed in an XML viewer, it would display as shown.

```
<All_users_list>
    <User>
        ... record content
    </User>
    <User>
        ... record content
    </User>
    ...
</All_users_list>
```

**Note:** If you do not use the attributes, the names in the XML output are default names derived from DVM names, for example,"rv0", which may not be user-friendly.

**Multipart requests or responses**

In GWS REST there is support for the standard multiple part message, in which more than one different sets of data are combined in a single body.

You can specify an HTTP multipart request or response for transferring data of several MIME types, such as JSON, XML, simple string, and to upload or download files.
**Multipart/form-data support**

In the multipart/form-data type, entire files can be included in the data transfer without encoding. This is ideally suited for uploading and downloading image or text files to a Web service.

Separate parts are identified by the GWS REST engine's naming convention sequence for headers and body parts that start with "rv0" and goes to the "rvn"th number of parts. You can change default header naming by adding a value in the WSNName on page 3475 attribute to your parameter.

The GWS REST engine also creates a "boundary" string in the "Content-Type: " header. This boundary, is placed between the various parts, and at the beginning and end of the body of the message.

**Define multipart request body**

You define a multipart request body when you have more than one input parameters that do not have WSHeader, WSQuery, WSCookie, or WSParam attributes. The GWS handles this request as a multipart of form-data type.

**Important:**

A message body is required when you perform an HTTP PUT, POST or PATCH request to a resource, otherwise the request results in the error-9106.

**Example multipart request**

The example is of a multipart request function. The input parameter values "addressfld1" and "date2" are sent in separate parts in the request body:

```java
IMPORT com
IMPORT util

PUBLIC DEFINE myError RECORD ATTRIBUTE(WSError="My error")
  code INTEGER,
  reason STRING
END RECORD

PUBLIC FUNCTION updateUsersAddress(
  id INTEGER ATTRIBUTES(WSParam),
  addressfld1 STRING,
  date2 STRING)
ATTRIBUTES(WSPut,
  WSPut="/users/{id}",
  WSPutQuery="Update user address and date updated field",
  WSThrows="400:@myerror")
RETURNS STRING

DEFINE ret STRING
DEFINE dt DATETIME YEAR TO SECOND
LET dt = util.Datetime.parse(date2, "%Y-%m-%d %H:%M:%S")
IF (dt IS NULL) THEN
  LET ret = "Invalid date"
ELSE
  WHENEVER ERROR CONTINUE
  UPDATE course2 SET users_address= addressfld1, date_updated=dt
  WHERE @users_id = id
  WHENEVER ERROR STOP
  CASE
  WHEN SQLCA.SQLCODE == 0
    LET ret = SFMT("Updated user with ID: %1",id)
  WHEN SQLCA.SQLCODE == NOTFOUND
    LET ret = SFMT("No resource found for ID: %1",id)
  OTHERWISE
    LET myError.reason = SFMT("SQL error:%1 [%2]",SQLCA.SQLCODE, SQLERRMESSAGE)
    CALL com.WebServiceEngine.SetRestError(400,myError)
  END CASE
```

```java
END CASE
```
Define multipart response body

You define a multipart response body if you have more than one return values without WSHeader attributes. The GWS handles this as a multipart response of type form-data.

Important:

A message body in the response is required when you perform an HTTP GET, POST, PUT, DELETE operation on a resource, otherwise the response results in the error-9106.

Example multipart response

The example is a multipart response sample REST function. There are two string values defined in the RETURNS clause of the function. These do not have WSHeader attributes, so values are sent in separate parts in the response body:

PUBLIC FUNCTION help()
  ATTRIBUTES (WSGet,
    WSPath="/help")
  RETURNS (INTEGER ATTRIBUTE(WSHeader), STRING, STRING)
  RETURN 3, "Hello world", "Have a nice day."
END FUNCTION

Related concepts

Generate service description on demand on page 3406
You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

Transfer data in large objects on page 3390
Use the BYTE and TEXT data types to transfer large objects (LOBs) with a Genero RESTful web service.

Attach files with WSAttachment and WSMedia on page 3386
In GWS REST attachments are handled via the WSAttachment and WSMedia attributes.

Download a file in a multipart response

This example demonstrates how to return a file in a form-data type HTTP multipart response while also transferring data of other types in the same message response.

Example multipart response

PUBLIC FUNCTION help2()
  ATTRIBUTES (WSGet,
    WSPath="/help2")
  RETURNS (INTEGER ATTRIBUTE(WSHeader),
    STRING,
    TEXT ATTRIBUTE(WSName="txt_file") )
  DEFINE t TEXT
  CALL t.readFile("mytext.txt")
  RETURN 3, "hello world", t
END FUNCTION

In this example the help2 function returns an integer in the header and a string and a text file as multipart in the body.
Figure 131: Output of multipart HTTP response

In the output the header is given the default name, "rv0", at runtime.

In the multipart response parts are combined into one or more sets of data in the body. Parts are separated by boundaries, the \--MIME_boundary in the output example.

The text file part is identified by the name ("txt_file") that is defined via the WSName on page 3475 attribute.

Related concepts
- Download a file as an attachment to a response on page 3387
  This example demonstrates how to return a file as an attachment using the WSAttachment attribute
- Download a large object in the response body on page 3390
  This example demonstrates how to send a large object in the message response body.

Example: upload a file in a multipart request
Shows an example of a method you might use from a client to upload an image along with other data in a function using a form-data type HTTP multipart request.

Example multipart request

```
IMPORT os
IMPORT com

PUBLIC DEFINE myerror RECORD ATTRIBUTE(WSError="My error")
  code INTEGER,
  reason STRING
END RECORD

PUBLIC FUNCTION FetchFiles(
  id INTEGER,
  image STRING ATTRIBUTE(WSAttachment,WSMedia="image/*"),
  submit STRING)
ATTRIBUTES (WSPost,
  WSPath="/files/fetch",
  WSDescription="upload image file to the server from browser",
  WSThrows="400:@myerror")
RETURNS STRING ATTRIBUTE(WSMedia="text/html")
```
DEFINE ret, new_fname STRING
DEFINE ok INTEGER
IF id == 0 THEN
    LET myerror.code=999
    LET myerror.reason="Missing id"
    LET ret = SFMT("<HTML><body><h1>Must have an ID %1</h1></body></HTML>",id)
    CALL com.WebServiceEngine.SetRestError(400,myerror)
ELSE
    TRY
        LET new_fname = os.Path.basename(image)
        LET new_fname = os.Path.pwd()||"/"||new_fname
        LET ok = os.Path.RENAME(image,new_fname)
        LET ret = SFMT("Got image with ID %1",id)
    CATCH
        LET myerror.reason="Error uploading file"
        LET ret = SFMT("Error uploading file %1",id)
        CALL com.WebServiceEngine.SetRestError(400,myerror)
    END TRY
END IF
RETURN ret
END FUNCTION

The image file format is specified via the WSMedia on page 3478 attribute. The attachment is handled through the STRING data type and the WSAttachment and WSMedia attributes.

The "FetchFiles" function needs to be called through an HTML form for the user to select the file to upload. The form needs to have two input fields and one submit button, according to the function's input parameters.

1. Create the form from the code sample. Remember to change the action tag value to the URL of your server.
2. Save as, for example, upload.html on the client side.
3. Open the file locally in a browser to upload a file. Ensure the service is running.

```html
<!DOCTYPE html>
<html>
  <FORM NAME="upload" method="post" action="http://localhost:8090/Myservice/files/fetch" enctype='multipart/form-data'>
    <div>
      <label for="name">ID:</label>
      <input type="text" name="id"/>
    </div>
    <div>
      <label>pictures:</label>
      <input type="file" name="image" accept="image/png, image/jpeg" />
    </div>
    <input type="submit" name="submit" value="Send"/>
  </FORM>
</html>
```

In the output you see that the image is sent in parts that are combined into one or more sets of data in the body. Parts are separated by boundaries, the

```
---------------------------70482736912266
```

string in the output example.

On successfully receiving the file, the server returns the message to display in the browser. Otherwise, an error is returned and displayed.
POST /MyService/files/fetch HTTP/1.1
WS-DEBUG (Receive)
Host: localhost:8090
User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64; rv:64.0) Gecko/20100101 Firefox/64.0

Upload a large object in the request body on page 3391
This example demonstrates how to upload a large object in the message response body.

Set data format with WSMedia on page 3393
It is important to set the correct MIME type for a Web service request or response. You can specify the data format via the WSMedia attribute.

Handling application level errors
There are many situations in which you need to notify an error to a client using your REST Web service.

Errors in calls to Web services may occur for various reasons; for example:

- the user input is incorrect
- the resource does not exist
- the server response failed
- the client does not have access to the resource
- the database connection failed
In these cases, you normally return an HTTP status code in the range 400 to 599 with its default message. The most common ones you encounter are as follows:

- **client (400-499)**
  - 400 Bad Request
  - 401 Unauthorized
  - 403 Forbidden
  - 404 Not Found
- **server (500-599)**
  - 500 Internal Server Error
  - 501 Not Implemented

For information on the full range of HTTP status codes see RFC 2616.

There are some situations where it is more useful to describe the error specifically, and in your REST function you can use the error handling attributes for this purpose.

**Handling errors with attributes**

In GWS REST you can perform error handling using two attributes:

- with the `WSThrows` attribute, set on the `ATTRIBUTES()` clause of the function, you list errors that may be encountered accessing a resource. From this the client stub generated from the OpenAPI specification, handles the error corresponding to those HTTP status codes.
- with the `WSError` attribute, set on a public variable defined at the modular level, you can provide a description of the status-code when an error is encountered at runtime to replace the standard HTTP status code description.

In your function, you code to trap an error at runtime with a call to the `SetRestError()` method, to return the HTTP status code and a description to the client.

**Publishing errors**

When you generate the service description, the errors you declared in the `WSThrows` attribute, the code reference and the error detail, are published in the "responses" section for that function in the OpenAPI specification file. The modular variables declared with `WSError` attribute are found in the "component" section at the end of the specification file.

**Related concepts**

- Generate service description on demand on page 3406

You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

**Example: handling expected application errors**

Error handling is supported with the `WSThrows` and `WSError` attributes.

In your REST function expected errors, such as application level errors, are listed in the `WSThrows` attribute defined in the `ATTRIBUTES` clause of the function.

**Example using WSError with WSThrows**

In this example the expected error is for when a resource is not found so the HTTP status code "400" is listed in the `WSThrows` attribute. It also references the "userError" variable (@userError) defined with the `WSError` on page 3483 attribute for the description of the error at runtime.

**Note:** In the example, the variable is a record but you can define this as any suitable Genero BDL simple type.

You code to trap the error at runtime when a customer record is not found by updating the `WSError` attributed variable with a specific description of the HTTP status code, and calling the `SetRestError()` method to return it.

```import com```
PUBLIC DEFINE userError RECORD ATTRIBUTE(WSError="User error")
  message STRING
END RECORD

PUBLIC FUNCTION GetCustomersNameById( id STRING ATTRIBUTE(WSQuery) )
  ATTRIBUTES(WSGet,
    WSPATH="/customers",
    WSThrows="400:@userError")
RETURNS STRING
  DEFINE s STRING
  WHENEVER ERROR CONTINUE
    SELECT lname INTO s FROM customers WHERE @id = id
  WHENEVER ERROR STOP
  IF SQLCA.SQLCODE == NOTFOUND THEN
    LET userError.message = SFMT("Could not find customer id :%1",id)
    CALL com.WebServiceEngine.SetRestError(400,userError)
  END IF
  RETURN s
END FUNCTION

Related concepts
Example: handling an unexpected error on page 3401
Example of a method you can use to code for unexpected errors.

Example: handling an unexpected error
Example of a method you can use to code for unexpected errors.

Warning: In general, the recommended option is to list all the possible errors in order to have them generated in the OpenAPI specification file and trapped on the client side.

Not all errors can be anticipated. In this case, an unexpected error can be handled in your REST function. Unexpected error are the ones not listed in the WSThrows attribute.

Example: managing unexpected errors
In this example, an expected error is listed in the WSThrows attribute. In the code, the OTHERWISE clause traps an error which is not listed in the WSThrows attribute.

The call to the SetRestError() method returns the HTTP status code to the client. The error description is set to NULL, which allows the HTTP standard error description to be returned, but you could also return a description in this case; optionally using the variable defined with the WSError on page 3483 attribute.

IMPORT com

TYPE accountType RECORD ... END RECORD

PUBLIC DEFINE myError RECORD ATTRIBUTE(WSError="user error")
  message STRING
END RECORD

PUBLIC FUNCTION queryAccountsById( id VARCHAR(10) ATTRIBUTE(WSParam) )
  ATTRIBUTES(WSGet,
    WSPATH="/accounts/{id}",
    WSThrows="400:@myError")
RETURNS accountType ATTRIBUTES(WSName="body")
  DEFINE thisAccount accountType
  WHENEVER ERROR CONTINUE
    SELECT * INTO thisAccount.* FROM accounts WHERE @id = id
  WHENEVER ERROR STOP
  CASE
    WHEN SQLCA.SQLCODE = 0
      EXIT CASE
    WHEN SQLCA.SQLCODE = NOTFOUND

LET myError.message = SFMT("Could not find account id :%1",id)
CALL com.WebServiceEngine.SetRestError(400,myError)
OTHERWISE
  CALL com.WebServiceEngine.SetRestError(505,NULL)
END CASE
RETURN thisAccount.*
END FUNCTION

Related concepts

Example: handling expected application errors on page 3400
Error handling is supported with the WSThrows and WSError attributes.

Handling security

You handle security in GWS high-level REST via scopes.

Security is configured based on the recommendations of the OpenAPI specification via scopes implemented by OAuth, and Bearer token authentication. OAuth allows the user to access the protected content from the resource server without sharing their credentials. Instead access is granted by access tokens forwarded to the GWS REST service.

To implement security the Genero Application Server delegate service must be running. For more information, see the How to implement delegation and Genero Identity Provider (GIP) pages in the Genero Application Server User Guide.

If there is no access token, or there is no delegate service providing the verification, the security function is not executed. Security is executed if, and only if, the request contains a scope definition, and its value matches what is in the WSScope attribute.

Note: Testing your services with WSScope:

- When testing your service in standalone mode without a GAS, the WSScope is not checked. However, when behind a GAS, the appropriate scope is required and you will need to deploy and secure the service with the Genero Identity Provider (GIP).
- Alternatively, if you need to integrate Genero REST services security into your own environment system, you can also write your own delegate service to validate any kind of token, extract the scope from it, and forward it to the REST service.

Handling security errors

Access token errors are automatically handled by the GWS engine. You do not need to do anything in your code. If the client request does not have the correct access token, the service will return HTTP 403.

Publishing scopes

When you generate the service description, the scope you declared in the WSScope attribute, the user or group member detail, is published in the "security" section for that function in the OpenAPI specification file. If you declare scopes with a modular variable with the WSInfo and WSScope attributes, the "security" tag at the end of the specification file contains the security details.

Related concepts

Generate service description on demand on page 3406
You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

OAuthAPI overview on page 3504
The OAuthAPI library supports the OAuth protocol that authenticates user access and issues access tokens.

Example: set security with WSScope
You can set security using the WSScope attribute either at the function level or at the service level.

**Example 1 setting security at function level**

```plaintext
IMPORT com

TYPE profileType RECORD ...

PUBLIC FUNCTION FetchMyUserProfile( p_user_id INTEGER ATTRIBUTE(WSQuery) )
ATRIBUTES(
    WSGet,
    WSPath="/users",
    WSDescription="Returns a user profile, requires authentication",
    WSThrows="404:user not found",
    **WSScope**="profile, profile.me")
RETURNS profileType ATTRIBUTES(WSName="data",
    WSMedia="application/json, application/xml")

DEFINE p profileType
WHENEVER ERROR CONTINUE
SELECT * INTO p.* FROM users
    WHERE user_id == p_user_id
WHENEVER ERROR STOP
IF SQLCA.SQLCODE NOTFOUND THEN
    INITIALIZE p TO NULL
    CALL com.WebServiceEngine.SetRestError(404,NULL)
END IF
RETURN p.*
END FUNCTION
```

In this example the **WSScope** on page 3486 required for the REST operation to be executed is "profile" or "profile.me".

**Example 2 setting security at service level via WSInfo**

```plaintext
PUBLIC DEFINE serviceInfo
RECORD ATTRIBUTE(WSInfo,
    **WSScope**="users.fourjs")

    title STRING,
    version STRING,
    contact STRING
END RECORD
```

In this example the scope is set in the service information record of the module. The attributes set are **WSInfo** and **WSScope**. The scope required for all REST functions in the module to be executed is "users.fourjs".

**Related concepts**

- **WSInfo** on page 3488
  - Specify information about the Web service such as title, version, contact details, scopes, etc.

- **Register service with Identity Provider** on page 3403

  Register service with Identity Provider

  If you deploy a Web service on the Genero Application Server (GAS) that requires user authentication, you must first register the service with an Identity Provider that allows access to it.

  You can use the Genero Identity Provider (GIP) or a third party IdP, such as Google or Microsoft, etc., to do this. For more information, see the How to implement Single sign-on (SSO) and Genero Identity Provider (GIP) pages in the Genero Application Server User Guide.

  **Related concepts**

  - **Access to secure Web service** on page 3414
To access a secure REST Web service, the client application must have a valid access token.

**Provide service information**

Provide information about the service, such as title, version, contact details, etc., that is generated in the OpenAPI specification file.

In your service module:

1. Define a PUBLIC record with a `WSInfo` attribute. This record allows you to provide metadata about your REST service, which can be generated according to the OpenAPI standard and used by clients. This example record follows that OpenAPI specification:

```
# service module
PUBLIC DEFINE serviceInfo RECORD ATTRIBUTE(WSInfo)
   title STRING,
   description STRING,
   termOfService STRING,
   contact RECORD
      name STRING,
      url STRING,
      email STRING
END RECORD,
version STRING
END RECORD = (  
title: "my service",
version: "1.0",
contact: ( email:"helpdesk@mysite.com") )
```

**Note:** If you do not set a service information record, the default value as the name of the service module is used for the service title.

2. Add record fields as required. The GWS does not check the record structure used with `WSInfo` attribute. You are therefore allowed to add the fields you want to be available in the OpenAPI specification.

3. Add values for the record fields.

The information provided is then generated in the `openapi.json` or `openapi.yaml` specification file.

**Related concepts**

*Generate service description on demand* on page 3406

You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

*Publish a REST service* on page 3404

In publishing the service you provide your service to users who can access it on the net.

**Publish a REST service**

In publishing the service you provide your service to users who can access it on the net.

Functions of your service you want to publish, must be defined as PUBLIC. When you publish a service, only the functions that are public are generated in the OpenAPI specification file. Functions that are private, are not available as operations of the service and are therefore not generated.

To publish a service, for example, in the service's main module, you:

1. Import the service module.
2. Call on the `com.WebServiceEngine.RegisterRestService()` method to register the service.

**Web service main module**

This is an example of a module that runs a Web service. The IMPORT FGL statement imports the service module "serviceModule", allowing its public-defined variables and functions to be referenced.
In the call to the `RegisterRestService()` method, the Web service module "serviceModule.4gl" is registered with the GWS server as a REST service. The name of the service is set to "MyService". This is the public name given to the REST service, used in the URI endpoints to access its resources.

The call to `ProcessServices()` is made to start the service process within a `WHILE` loop. Within the loop requests for services are processed and various Web service engine errors are handled. The Web service runs until interrupted.

```plaintext
IMPORT com
IMPORT FGL serviceModule

MAIN
    DEFINE ret INTEGER
    CALL com.WebServiceEngine.RegisterRestService("serviceModule", "MyService")
    DISPLAY "Server started"
    CALL com.WebServiceEngine.Start()
    WHILE TRUE
        LET ret = com.WebServiceEngine.ProcessServices(-1)
        CASE ret
            WHEN 0
                DISPLAY "Request processed."
            WHEN -1
                DISPLAY "Timeout reached."
            WHEN -2
                DISPLAY "Disconnected from application server."
                EXIT PROGRAM  # The Application server has closed the connection
            WHEN -3
                DISPLAY "Client Connection lost."
            WHEN -4
                DISPLAY "Server interrupted with Ctrl-C."
            WHEN -9
                DISPLAY "Unsupported operation."
            WHEN -10
                DISPLAY "Internal server error."
            WHEN -23
                DISPLAY "Deserialization error."
            WHEN -35
                DISPLAY "No such REST operation found."
            WHEN -36
                DISPLAY "Missing REST parameter."
            OTHERWISE
                DISPLAY "Unexpected server error " || ret || "."
            END CASE
        IF int_flag<>0 THEN
            LET int_flag=0
        END IF
    END WHILE
    DISPLAY "Server stopped"
END MAIN
```

**Related concepts**

Generate service description on demand on page 3406
You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

**Generate service description on demand**

You can access a description of your GWS REST Web service through a query string on the URL of the Web service. The Genero REST Web service allows for the functions defined in your Web service to be generated according to the OpenAPI specification. You can choose to access the description by choosing to output it in either the JSON or YAML format:

http://host:port/gas/ws/r/group/xcf/resource?openapi.json

Or

http://host:port/gas/ws/r/group/xcf/resource?openapi.yaml

**Note:** The GWS service must be running on the specified port in order to provide the Web service information. The GWS server must be behind a GAS in production to handle the load.

The OpenAPI file allows you to see your entire Web service, including:

- Available resources (paths) and functions, for example, /add, /sub/{f}, /mult/{coef}/hello, etc., and operations (GET, POST, etc.)
- Parameters, input and output for each function
Figure 133: Parameters represented in the OpenAPI specification file

- Responses, such as error handling specifications, error codes and messages
Figure 134: Response codes represented in the OpenAPI specification file
- Service information, such as title, version, contact, etc.

```json
{
    "openapi": "3.0.0",
    "info": {
        "title": "my service",
        "version": "1.0",
        "contact": "fg@4js.com"
    },
    "servers": {
        "url": "http://Localhost:8090/Myservice"
    }
}
```

Figure 135: Sample of service information in OpenAPI specification file

### Generating the stub file

You can use the `fgrestful` on page 2085 tool provided by the Genero Web Services package to generate a stub file from the `openapi.json` file. The stub file is a Genero BDL file with code that will manage calls made by your client application to the Web service. For details, see the Get the RESTful Web service information on page 3410 page.
Testing the GWS service in stand-alone mode

If you are on a local server, you can start the GWS server as shown in Getting started with REST high-level on page 3375

REST API versioning

Options for versioning the API can be used when changes to API functions impact existing client access.

Changes to the API may affect functionality clients already depend on. For example, a change to the format of the response data or type (changing an integer to a float), will impact existing users. The options for managing this change will require versioning the API so that clients are not disrupted.

A new version of an API can be implemented by versioning either the resource URI, or specifying the version in a custom header. There are advantages and disadvantage in using either method and the choice depends on your preference.

URI Versioning

Putting the version in the URI is the recommended approach.

For example, a resource at:

```
http://host:port/gas/ws/r/group/xcf/resource
```

Is now at:

```
http://host:port/gas/ws/r/group/xcf/version/resource/
```

Even though this in principle breaks the constraint that the URI should refer to a unique resource, it is the preferred way. In effect it means that you have two versions of the API and are able to generate a different openapi.json specification per version based on the path of your REST API.

Versioning using a custom header

Alternatively, the version can be included in a custom header.

```
api-version:v2.0
```

The version must be specified by the client. Clients need to know which headers to specify before requesting a resource.
The API function retrieves the value of the header. If the version matches one specified, then that is the method that will be invoked. Based on this, the API can decide if it is capable of fulfilling the request and respond to the client appropriately.

**Version syntax**

The version specified need not be numeric, nor specified using the “\(v[x]\)” syntax. Alternatives such as dates, project names, or other identifiers that you find meaningful and flexible enough to change as the versions change can be used.

*Example: set version with WSP\(\text{Path}\)*

You can set version using the WSP\(\text{Path}\) attribute.

**Example setting version in the path**

```plaintext
IMPORT com

TYPE profileType2 RECORD ... END RECORD

PUBLIC FUNCTION FetchMyUser2Profile(p_user_id INTEGER ATTRIBUTE(WSP\(\text{Param}\)) )
  ATTRIBUTES(
    WSGet,
    WSP\(\text{Path}\)="/users/v2/(p_user_id)",
    WSDescription="Returns a user profile for API v2 ",
    WSThrows="404:user not found"
  )
  RETURNS profileType2 ATTRIBUTES(WSName="data",
    WSMedia="application/json,application/xml")

DEFINE p profileType2
WHENEVER ERROR CONTINUE
SELECT * INTO p.* FROM users
  WHERE user_id == p_user_id
WHENEVER ERROR STOP
IF SQLCA.SQLCODE==NOTFOUND THEN
  INITIALIZE p TO NULL
  CALL com.WebServiceEngine.SetRestError(404,NULL)
END IF
RETURN p.*
END FUNCTION
```

In this example there are changes to the profile record type (profileType2) that are not compatible with the existing version of the API. The WSP\(\text{Path}\) on page 3469 for the new function contains a version number (v2) that provides the path to the resource. An example of the resource URL is:

```
http://host:port/gas/ws/r/group/xcf/Accounts/users/v2/1
```

**Related concepts**

- **WS\(\text{Info}\)** on page 3488
  Specify information about the Web service such as title, version, contact details, scopes, etc.

- **Steps to writing a REST client application**
  Create, configure and deploy a Genero Web Services client generated from the high level REST framework.

- **Get the RESTful Web service information**
  To access a remote Web service, you must get the information from the service provider.

  If the server supports the OpenAPI specification, you can use the fglrestful on page 2085 tool provided by the Genero Web Services package to obtain the necessary information (like the SOAP WSDL). For secure Web services you need to get an access token.

**Related concepts**

- **Calling a web service function** on page 3413
A GWS REST service is called through a client application.

Generate service description on demand on page 3406
You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

Get service information from Web service
Using the fglrestful tool, you can generate the client stub directly from a REST Web service URL or an OpenAPI specification file.

The following steps describe the options.

1. Use the fglrestful tool to generate the stub.
   For example, from the Web service URL
   ```
   fglrestful -o clientStub http://host:port/gas/ws/r/group/xcf/resource?
   openapi.json
   ```
   For example, from an OpenApi service specification file
   ```
   fglrestful -o clientStub service-spec-file
   ```
   Where:
   a. clientStub specifies the file name of the stub in the output (-o) option.
   b. The URL of the Web service is specified with the query string ?openapi.json to get the specification file.
   Note: The "MyService" GWS REST service must be running on the specified port in order to provide the service information.

   The stub file can also be generated from a file containing the specification as shown in the second example.

   The stub file can be generated as described in the second example in step 1 on page 3411.

   2. Alternatively, to view the specification in the browser, you can use the Web service URL with the ?
   openapi.json query string.
   ```
   https://host:port/gas/ws/r/group/xcf/resource?openapi.json
   ```
   The OpenAPI specification is displayed formatted in JSON. You can copy and paste the output and save to a file. The stub file can be generated as described in the second example in step 1 on page 3411.

   Note: If you can not access the service because it is protected, you must get the access token using the
   getToken tool as described in Get service information from secure Web service on page 3411. For further
   information, see the getToken page in the Genero Application Server User Guide.

Get service information from secure Web service
To access a secure Web service, including its specification, you need an access token issued on behalf of an authorized user.

You can get the token using the gettoken tool and provide it in the URL query string to get the OpenAPI specification. The gettoken tool is located in the FGLDIR/web_utilities/services/gip/bin/gettoken directory.
The following steps describe the process.

1. Use the gettoken tool to get the access token.
   Line breaks have been added to the command example to improve readability.

   ```bash
   fglrun GetToken.42r password -u user -p mypw
   --idp https://host:port/gas/ws/r/services/GeneroIdentityProvider
   --savetofile mytoken.json myWSScope
   ```

   Where:
   a. The `password` command is used to get an access token on behalf of an authenticated user.
   b. The `user` name and `password` provided (`-u user -p mypw`) is that of a registered user in the IdP.
   c. The URL of the Genero Identity Provider (GIP) is specified in the `--idp` option.
   d. `mytoken.json` is the file name where the access token is saved.
   e. `myWSScope` is the scope of the service required in the token.

   **Note:** The access token is valid for 10 minutes.

   For further information, see the GetToken page in the Genero Application Server User Guide.

2. Add the token in the Web service URL query string to get the specification.

   ```bash
   https://host:port/gas/ws/r/group/xcf/resource?
   openapi.json&access_token=token
   ```

   The OpenAPI specification is displayed in the browser formatted in JSON. You can copy and paste the output and save to a file. The stub file can be generated as described in Get service information from Web service on page 3411.

3. Or alternatively, you can use the token with the `fglrestful` on page 2085 tool to generate the stub.

   ```bash
   fglrestful -o clientStub http://host:port/gas/ws/r/group/xcf/resource?
   openapi.json -t token
   ```

   Where:
   a. `clientStub` specifies the file name of the stub in the output (`-o`) option.
   b. The URL of the Web service is specified with the query string `?openapi.json` to get the specification file.

   **Note:** The "MyService" REST service must be running on the specified port in order to provide the service information.
   c. The token is specified in the token (`-t`) option.

   The `clientStub.4gl` generated from the specification contains the complete code to manage calls made by client applications to the Web service resources. You need to compile and link the module into your Genero REST client application. For details, see Call the stub functions on page 3415.

**Related concepts**

- Access to secure Web service on page 3414
- Generate service description on demand on page 3406
- Troubleshooting stub file creation on page 3413
Learn how to troubleshoot stub file creation.

**Troubleshooting stub file creation**

Learn how to troubleshoot stub file creation.

The stub file generated from the specification file must be error free or otherwise the stub file does not get generated. A variety of issues may cause errors. The most common errors are those caused by incompatible types, missing variables, or other issues.

The `fglrestful` tool writes errors to the standard output. You can see these if errors are reported when you generate the stub file. Errors, such as the following, will stop the generation of the stub file.

```
Error in /paths/Property/UpdateProperties/{applicationID}/post/requestbody
Reason : ComplexType='UpdatePropertiesRequestBodyType' not supported on binary operation
```

The error message relates to incompatible types. Messages contain the path to where in the `openapi.json` file errors occurred, and what the reason was. You can refer to the specification file to try to isolate the problem and determine if it is an issue that you can resolve or one that needs the assistance of your local Four Js support center.

**Display warnings**

Warnings, unlike errors, will not stop the stub file creation but displaying them may help you debug. You can opt to display warnings by running the `fglrestful` command with the warning option set to `yes`:

```
fglrestful -W yes -o stub_filename http://localhost:8090/MyService?openapi.json
```

For example, this warning describes a function with a duplicate id.

```
Warning in /paths/Liability/GetReasonTypes/{subscriberId}
Reason : OperationId=GetReasonTypes has already been defined, append _1
```

**Related concepts**

`fglrestful` on page 2085

The `fglrestful` tool produces REST web services stub files for client programs using an OpenApi specification.

**Calling a web service function**

A GWS REST service is called through a client application.

*Write the MAIN program code block*

Import the client stub, and call its functions.

To call a REST service function, in your client's main module, you:

1. Import the client stub module
2. If you are accessing a secure service, code within the `MAIN` program block to get the access token before calling any functions. See Main program code for access to secure service on page 3414.
3. Call the functions within the `MAIN` program block

```
IMPORT FGL clientStub
MAIN
  DEFINE wsstatus INTEGER
  DEFINE rets STRING
  DEFINE opt1 INTEGER
  LET opt1=22

  CALL clientStub.getUsersName(opt1) RETURNING wsstatus, rets

  IF wsstatus = clientStub.C_SUCCESS THEN
    DISPLAY "User name is ":rets
  ELSE
    DISPLAY "Error in getting user details"
  END IF
```
This example is a very basic version of the code. See also Call the stub functions on page 3415.

Related tasks
Main program code for access to secure service on page 3414
Code to get the access token for a secure Web service.

Access to secure Web service
To access a secure REST Web service, the client application must have a valid access token.

The access token got from the Identity Provider must be registered with the GWS engine so that each HTTP request to the service can use it, otherwise an authorization error is returned. For more information on secured Web services, see Handling security on page 3402.

The stub file generated by fglrestful on page 2085 contains all the definitions and the functions that your GWS client application needs to retrieve the access token. There is a sample included in Main program code for access to secure service on page 3414 so you can see how to configure your application and code for a secure Web service.

Related concepts
Generate service description on demand on page 3406
You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

OAuthAPI library on page 3504
The OAuthAPI library.

Main program code for access to secure service
Code to get the access token for a secure Web service.

To access a secure Web service, the user needs to get an access token that is provided by the Identity Provider securing the Web service. The OAuthAPI.init on page 3510 function can be used for this purpose if needed.

1. Set your app to use delegation in its application configuration file.
   This step is mandatory.

   `<APPLICATION Parent="defaultwa" ...>
   <EXECUTION>
   ...
   <DELEGATE service="services/OpenIDConnectServiceProvider">
   <IDP>IdP_URL</IDP>
   <CLIENT_PUBLIC_ID>XXXXXXXX</CLIENT_PUBLIC_ID>
   <CLIENT_SECRET_ID>XXXXXX-XXXXXX</CLIENT_SECRET_ID>
   </DELEGATE>
   ...
   </EXECUTION>
   </APPLICATION>`

   Where:
   - The OpenIDConnectServiceProvider is the delegation REST Web service in the $FGLDIR.
   - The IdP_URL can have an entry of localhost when everything runs on the same Genero Application Server. Otherwise, you must provide the Genero Identity Provider (GIP) URL. For example: http://othermachine.com:6394/ws/r/services/GeneroIdentityProvider
   - The OAuth access tokens for CLIENT_PUBLIC_ID and CLIENT_SECRET_ID are those you get from the IdP.

   For further information, see the Configure delegation for application or service page in the Genero Application Server User Guide.

2. In the MAIN/END MAIN clause of your client app, call the OAuthAPI.init function to get the OAuth access tokens at runtime. This must be done before calling any other service functions.
For example:

```
IMPORT FGL OAuthAPI

DEFINE my_user_id INTEGER

MAIN
  # ...

  # Init OAuthAPI
  IF NOT OAuthAPI.init(5, "AF350CBC-8801-4DFB-9A78-A95B25BB32AF", "8JEq3HBfXrmj/8vMP66iaRQnGrWVyjqr") THEN
    DISPLAY "Error: unable to initialize OAuth"
    EXIT PROGRAM 1
  ELSE
    LET my_user_id = OAuthAPI.getIDSubject
  END IF

  # ...

END MAIN
```

You can get user information coming from the IdP from variables with the prefix `OIDC_`. For example,

```
LET userEmail = fgl_getenv("OIDC_EMAIL")
```

For an example of OAuthAPI calls, see the `consoleApp` source in `FGLDIR\web_utilities\services\gip\src\console`.

When using a third-party IdP, if it supports OpenID Connect, then the OAuthAPI can be used the same as for Genero Identity Provider. For further information, see the OpenID Connect SSO pages in the Genero Application Server User Guide.

**Related concepts**

- [OAuthAPI library](#) on page 3504
  - The OAuthAPI library.
- [Access to secure Web service](#) on page 3414
  - To access a secure REST Web service, the client application must have a valid access token.
- [Write the MAIN program code block](#) on page 3413
  - Import the client stub, and call its functions.

**Call the stub functions**

Functions in the stub file allows you to write code in your own `.4gl` module that calls these functions as part of your client application.

The service information obtained from the REST Web Service provides information about using the service.

**Using parameters and return values**

To call a function in your client application, you must define variables for its input parameters and return values. These, for example, may be simple types or user-defined records.

Details for these variables can be obtained from the OpenAPI specification file (see [Generate service description on demand](#) on page 3406) or from the generated function in the stub file.

**Record type defined in client stub**

```
PUBLIC TYPE addUserRequestBodyType RECORD
  users_name STRING,
  users_address STRING,
  users_country STRING
```
Calling a stub function in the client app

In this example the this variable is defined as a record type based on a user-defined record in the client stub, clientStub.addUserRequestBodyType.

Values are passed to the variable before calling the function.

Variables are defined for the return code (wsstatus) and for error details returned by the call (res). See Handle GWS REST server errors on page 3416.

```
IMPORT FGL clientStub
FUNCTION myWScall()
    DEFINE this clientStub.addUserRequestBodyType
    DEFINE wsstatus INTEGER
    DEFINE res STRING
    LET this.user_name= "Mike Pantock"
    # ...
    CALL clientStub.addUser(this.*)RETURNING wsstatus, res
    CASE wsstatus
        WHEN clientStub.C_SUCCESS
            DISPLAY "Success adding new user"
            # ... function code
        OTHERWISE
            DISPLAY "Unexpected error :", wsstatus, res
    END CASE
END FUNCTION
```

Handle GWS REST server errors

When a call to a Genero Web Services REST function returns a status, you can check for server errors.

The error codes described in the "responses" section of the OpenAPI specification file are generated as constants on the client stub. You can reference these to trap errors in your code.

Error codes generated for expected errors in client stub by fglrestful

If it is an expected error (other than success), a value above 1000 is returned. In this example constants are generated in the client stub from the OpenAPI specification.

```
# Error codes
PUBLIC CONSTANT C_SUCCESS = 0
PUBLIC CONSTANT C_INVALID = 1001
PUBLIC CONSTANT C_NOTAVAILABLE = 1002
PUBLIC CONSTANT C_MYERROR = 1003
PUBLIC CONSTANT C_INTERNAL_SERVER_ERROR = 1004
```

If a record type for error handling is generated in the client stub, it can be referenced in your client application.

```
# generated myErrorErrorType
PUBLIC TYPE myErrorErrorType RECORD
    code INTEGER,
    reason STRING
END RECORD
```

```
# My error
PUBLIC DEFINE myError myErrorErrorType
```
Trapping server errors on the client side

A variable (wsstatus in the example) is defined to trap the status code in the return.

Details of expected errors in the response from the server can be displayed in the reference to the variable defined in the client stub, clientStub.myError in the example.

It is recommended to always handle unexpected errors (CASE OTHERWISE in the code example), as these may arise due to different transport layers. For an unexpected HTTP error, the HTTP status code (200-599) is returned, otherwise -1 is returned.

```
IMPORT FGL clientStub

# ... function performs call to the client stub function
FUNCTION myWSRESTcall()
    DEFINE rets INTEGER
    DEFINE wsstatus INTEGER

    DEFINE p_body clientStub.updateUsersRequestBodyType
    LET p_body.users_id = "4"
    LET p_body.users_name = "new name to be decided"
    # ...

    CALL clientStub.updateUsers(p_body.*) RETURNING wsstatus, rets
    CASE wsstatus
        WHEN clientStub.C_SUCCESS
            DISPLAY "Updated the user:"
        WHEN clientStub.C_INVALID
            DISPLAY "error code   ":", clientStub.myError.code
            DISPLAY "error reason ":", clientStub.myError.reason
        WHEN clientStub.C_NOTAVAILABLE
            DISPLAY "error code   ":", clientStub.myError.code
            DISPLAY "error reason ":", clientStub.myError.reason
        OTHERWISE
            DISPLAY "error code   ":", clientStub.myError.code
            DISPLAY "error reason ":", clientStub.myError.reason
            DISPLAY "wsstatus is : ", wsstatus
            DISPLAY "Unexpected error", rets
    END CASE
END FUNCTION
```

Change REST client behavior at runtime

The global endpoint record allows you to change the client behavior at runtime.

The high-level REST Genero Web Services generates a global record called tGlobalEndpointType that allows you to change the client behavior at runtime without the need for modifying any generated client stub.

**Global Endpoint type definition**

Bindings defined for the REST Web service can be changed at runtime.

The global endpoint type is generated when the fglrestful tool generates the stub file.

At runtime you can use endpoint to change the client behavior, such as the Web server address the client is bound to, or to change other bindings exposed on the Web service.

**REST global Endpoint type**

```
TYPE tGlobalEndpointType RECORD # REST Endpoint
    Address RECORD
        Uri STRING
    END RECORD,
    Binding RECORD
        Version STRING, # HTTP Version (1.0 or 1.1)
        ConnectionTimeout INTEGER,
        ReadWriteTimeout INTEGER,
        CompressRequest STRING
```
Description of variables:

- **Address.Uri**: Represents the location of the server.
- **Binding.Version**: Represents the HTTP version to use for communication (only 1.0 or 1.1 allowed, default is 1.1).
- **Binding.ConnectionTimeout**: Represents the maximum time in seconds to wait for the establishment of the connection to the server.
- **Binding.ReadWriteTimeout**: Represents the maximum time in seconds to wait for a connection read or write operation before breaking the connection.
- **Binding.CompressRequest**: Represents the compression option specified in the header Content-Encoding, gzip or deflate.

**Public endpoint variable**

In the stub file, an `Endpoint` variable of type `tGlobalEndpointType` is defined as public. The address of the Web service is set when the stub is generated by the Genero Web Services engine.

```plaintext
PUBLIC DEFINE Endpoint
tGlobalEndpointType
  = (Address: (Uri: "http://localhost:8090/MyService"))
```

**Set server endpoint**

Set the REST Web service location from client app at runtime.

To change the server location at runtime, set the record `Uri` member with a valid URL of another service. If you leave the variable unset, the client will connect to the server URL defined in the stub file at code generation time.

**Set server address**

In the stub file, an `Endpoint` variable of type `tGlobalEndpointType` is defined as public. You can set the address of the Web service via the client application with for example:

```plaintext
```

**RESTful Web services with low-level APIs**

With Genero Business Development Language, you can write a RESTful Web Services client or server application.

**The Calculator tutorial**

There are several ways to implement REpresentational State Transfer (REST) Web services. This documentation uses a tutorial based on a calculator Web services application, using the low-level APIs with URIs and verbs.

This tutorial is provided from both the client and the server perspective. In **Writing a Web services client application** on page 3418, you learn how to create a client application that accesses the Add function in a calculator Genero Web services server application, with the option to perform the data exchange in either JSON or XML. In **Writing a Web Services server application** on page 3430, you learn how to implement the Web service on the server side.

**Writing a Web services client application**

Create, configure and deploy a RESTful Genero Web Services (GWS) client.

In this section, you will learn about the basic steps of creating a client application to access the "Add" function in the calculator RESTful GWS Web Service that is detailed in the **Calculator RESTFul Web services server application**. The topics explain:

1. What functions are available on the Server, and which query parameters/arguments to use with the URIS (resource). See **Step 1: Obtain information about Web service resources** on page 3419.
2. What GWS packages you need, see Step 2: Import extension packages (com, xml, util) on page 3419.
3. What Genero Business Development Language records you need to define, see Step 3: Define the records on page 3420.
4. How to request the Web service functions. Step 4: Build the HTTP request on page 3421
5. How to get the result and handle errors. Step 5: Process the HTTP response on page 3422.

In discussing the above five steps, the Calculator RESTFul Web services client application is used to provide code examples.

**Step 1: Obtain information about Web service resources**
To access a remote RESTful Web services server, you must first get information about the services offered by a server from the service provider.

In REST, the name of the resources or functions and what query parameters or arguments to use with them are generally all that you require, as this information contains everything the client needs to interact with the required resource.

**Add Function**
In the code example for the Calculator RESTFul Web services server application, we know that the calculator demo service performs various calculator functions. Our client application simply wants to access the function to add values.

```plaintext
# Calculator Web Service add function

FUNCTION add()
  LET add_out.r = add_in.a + add_in.b
  LET add_out.status.code = 0
  LET add_out.status.desc = "OK"
END FUNCTION
```

The HTTP request must therefore use an URI with a resource name and the required parameters that matches the calculator function defined in the calculator Web service server side. Therefore, Add becomes the resource name part of the URI we need to include in our code.

```plaintext
# Sample request to add two numbers

GET http://localhost:8090/add?a=1&b=2
```

In the next step we start to code the client application, Step 2: Import extension packages (com, xml, util) on page 3419

**Step 2: Import extension packages (com, xml, util)**
The functions you need to create a REST Web Service client application are contained in the classes that make up the com package of the Genero Web Services (GWS). Use the IMPORT statement to include the required packages.

Since this example application also uses util.JSON and XML class data types for the data exchange, you need to include the following lines at the top of your module as instructions to import the required packages:

```plaintext
IMPORT com
IMPORT xml
IMPORT util
```

Inside your module's "MAIN" code block:

- Declare variables of the com class to handle the HTTP request and response.
- Declare xml.DomDocument and xml.DomNode objects of the XML class to handle the XML option for data exchange.

```plaintext
MAIN
  DEFINE req com.HttpRequest
```
In the next step we define some records **Step 3: Define the records** on page 3420

**Related concepts**
The util package on page 2726
These topics cover the classes for the util package.

**Step 3: Define the records**
In this step you define the records you need for the HTTP Request and Response and the processing of the data.

Declare a record to use for HTTP Request/Response status. The calculator demo application creates a user-defined `TYPE(TYP_status)` to reference when defining variables.

```vcl
TYPE TYP_status RECORD
  code INTEGER,   # The HTTP status code
  desc STRING    # The HTTP status description
END RECORD
```

Declare a public record called `info` to hold the pieces of information that make up the HTTP request you send out and that comes back in the response from the Web service. You will use this when processing the data and outputting it for display.

```vcl
PUBLIC DEFINE info RECORD
  url STRING,       # URI of resource on the server
  verb STRING,      # HTTP method (POST, PUT, GET, or DELETE)
  reqtype STRING,   # Request type identifier (Content-Type)
  request STRING,   # Request data format (application/json, or application/xml)
  status STRING,    # For HTTP Response
  resptype STRING,  # Response type identifier (Accept)
  response STRING,  # Response data format (application/json, or application/xml)
  result RECORD     # Record for runtime execution errors
    code INT,
    desc STRING
END RECORD
```

Declare two records, one (`add_in`) to hold operands for the add calculation and another (`add_out`) to hold the result of the calculation and response status. Recall that the type `TYP_status` was defined at the top of the module.

```vcl
DEFINE add_in RECORD
  a INTEGER,
  b INTEGER
END RECORD,

DEFINE add_out RECORD
  status TYP_status,
  r INTEGER
END RECORD
```

At this stage we are ready to code the HTTP Request, **Step 4: Build the HTTP request** on page 3421
Step 4: Build the HTTP request

In this step you code the HTTP request and perform the request to the server to add two numbers.

Include code inside a TRY/CATCH block to trap runtime exceptions. Assign two values to fields in the add_in record as operands for the calculation. For details about the add_in record we use in this topic, see Step 3: Define the records on page 3420.

```
TRY
  LET add_in.a = 1
  LET add_in.b = 2
CATCH
  ...
  ...
END TRY
```

Recall we defined the variable req as an object of the com.HTTPRequest class earlier, see Step 2: Import extension packages (com, xml, util) on page 3419. We instantiate this now by invoking the com.HttpRequest.Create class method to create an URI for our HTTP request; adding to the URI string:

- The resource name or name of the server function, "add" in our case.
- A question mark ("?"), to indicate a query string.
- A query string that contains two key/value pairs in the format "field=value" separated by an ampersand ("&"), for example ("a=1&b=2"). They make up the query parameters or arguments required by the server's "add" function which will be extracted for processing by the Web service. We assign the values for the calculation from the "add_in" record.

```
LET req = com.HttpRequest.Create("http://localhost:8090/add?a=" || add_in.a || ";b=" || add_in.b)
```

**Note:** In our example, we anticipate the calculator Web server is on the localhost. For a production environment you need to take care of URI parsing: making sure that the URI matches what your service expects.

Set the HTTP method with the "GET" verb to request the service from the calculator Web resource. We do this by calling the com.HTTPRequest object's setMethod function referenced by the req variable.

```
CALL req.setMethod("GET")
```

Next we add the Accept and Content-Type headers to the com.HTTPRequest object referenced by the req variable by calling the setHeader function. These headers specify to the Web service how we intend to receive and deliver content in the message body's media type, JSON or XML. Our preference is for JSON.

```
CALL req.setHeader("Content-Type", "application/json")
CALL req.setHeader("Accept", "application/json")
```

Finally, we are ready to perform the HTTP request and call the com.HTTPRequest object's doRequest function.

```
CALL req.doRequest()
```

In the next step we handle the response from the Web service, Step 5: Process the HTTP response on page 3422.
**Step 5: Process the HTTP response**

In the final step you process the HTTP response; check for errors, and process the data.

At this stage a response to our request from the Web service has been received and is stored in the variable, `resp`. We defined the variable `resp` as an object of the `com.HttpResponse` class earlier, see Step 2: Import extension packages (com, xml, util) on page 3419. Now it is time to process the response.

```plaintext
LET resp = req.getResponse()
```

Start checking for errors. First get the HTTP status code returned in the response by calling the `com.HttpResponse` object's `getStatusCode` function referenced by the `resp` variable. Assign the status code to the "status" field of the `info` record (for details about this record see Step 3: Define the records on page 3420).

```plaintext
LET info.status = resp.getStatusCode()
```

The standard HTTP code of 200 indicates a successful operation, so we check for this before looking at the data.

```plaintext
IF info.status = 200 THEN
```

If the HTTP response was good, we save the value for Content-type response header to the "resptype" field of the `info` record. The Content-type header defines the type associated with the message body's byte sequence. REST APIs commonly use "application/json" or "application/xml" to reveal the format of the message body.

```plaintext
LET info.resptype = resp.getHeader("Content-Type")
```

**Process for XML**

```plaintext
IF info.resptype.getIndexOf("/xml",1) THEN
    LET doc = resp.getXmlResponse()
    LET node = doc.getDocumentElement()
    CALL xml.Serializer.DomToVariable(node, add_out)
    LET info.response = node.toString()
ELSE # JSON response processing
    [...] END IF
```

If the Content-type indicates XML format, we store the HTTP response as data in the `xml.DomDocument` object referenced by the `doc` variable using the `getXmlResponse` function. We then get a reference to the root node of the `doc` variable object by instantiating the `node` variable defined as an object of the `xml.DomNode` class using the `getDocumentElement` function.

Recall the `doc` and `node` variables were defined earlier, see Step 2: Import extension packages (com, xml, util) on page 3419.

To serialize the XML data into the `add_out` variable, we pass a reference to the `node` object variable in a call to the `xml.Serializer.DomToVariable` function. To convert the data referenced in the `node` object variable to string, we use the `xml.DomNode.toString` function to store it in the "response" field of the `info` record.

**Process for JSON**

If the Content-type does not indicate XML format, then we process the response for JSON, as we anticipate this as the only other option REST APIs use to format the message body.

We store the HTTP response as a string in the "response" field of the `info` record with a reference to the `resp` variable, object of the `com.HttpResponse` class, using the `getTextResponse` function. Then we pass a reference to the `info` record in a call to the `util.JSON.parse()` function to convert the HTTP response to JSON format into the `add_out` record.

```plaintext
IF info.resptype.getIndexOf("/xml",1) THEN
```
# XML response processing

ELSE # JSON response processing
    LET info.response = resp.getTextResponse()
    CALL util.JSON.parse(info.response, add_out)
END IF

## Outputting to the display

Finally, we output the HTTP response to the display depending on the status code.

IF add_out.status.code = 0 THEN
    DISPLAY add_in.a, "+", add_in.b, "+", add_out.r # Display the response, status and result
ELSE
    DISPLAY "]", add_out.status.code, "]", add_out.r
END IF

## Handling Errors

If the HTTP request failed, we handle the error by formatting the HTTP response status code and description into the "response" field of the info record. Other program errors are caught in the CATCH block and stored in "result" fields of the info record.

TRY
    [...] IF info.status = 200 THEN [...] ELSE
    LET info.response = SFMT("[%1] %2", resp.getStatusCode(), resp.getStatusDescription())
END IF
CATCH
    # Catch other runtime execution errors from the SQLCA diagnostic record
    LET info.result.code = status
    LET info.result.desc = sqlca.sqlerrm
END TRY

This completes the tutorial for the calculator demo client application. We have seen the basic steps that a RESTful client application must perform in order to carry out a simple request to a Web service. To review the complete source code, see The RESTful calculator demo source on page 3436.

Each Web services client application will be different in the type of processing that is done. For more examples of Web service applications, see the code samples provided with the package in demo/WebServices.

### Configure a WS client to access an HTTPS server

Configuration steps to access a server in HTTPS.

To configure access to an HTTPS server, you need a client certificate.

**Important:** On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain typically holds the server certificate authority list. Therefore, the FGLPROFILE file security settings are ignored with the exception of the following: security.global.ca, security.global.ca.lookuppath, and security.global.systemca.

Before you begin, there are options to consider depending on how you wish to use the client certificate:

- If you do not have the certificate information in your FGLPROFILE file, Genero Web Services creates a certificate for you. This is an implicit or temporary certificate that is valid for a session only. For more information see HTTPS configuration on page 3305.
  
  **Note:** For the implicit certificate, no configuration is required.
• Alternatively, for stronger security, you generate a client certificate of your own, configure your application to use the client certificate generated, and add the configuration details to the FGLPROFILE file. Follow the steps outlined in this section.

**Note:** In a production environment, some servers provide a client certificate and you use the certificate as provided, and add the configuration details to the FGLPROFILE file.

The **openssl command line tool** can be used to create your own certificates for the configuration of secured communication. The following steps outline the configuration process:

**Related concepts**

- **Configuring the Apache Web server for HTTPS** on page 3460
  Configuration steps to secure a Web service for Apache server in HTTPS.

- **Certificates in practice** on page 3313
  Procedures and tools for creating, importing, and viewing certificates and keys.

- **Encryption and authentication** on page 3299
  A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

- **Accessing secured services** on page 3303
  Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web service.

**Create the client certificate**

Generate a root certificate authority that signs a client certificate.

In this task you create your own root certificate authority and client certificate using the OpenSSL command line tool.

1. Create the root certificate authority.
   a) Create the root certificate authority serial file.
      ```
      $ echo 01 > MyCompanyCA.srl
      ```
      This command creates a serial file with an initial HEX value 01. OpenSSL uses this file to track the serial numbers of certificates it creates. The serial file is typically given the same name as the CA with the extension .srl.
   
   b) Create the Certificate Signing Request (CSR) and private key.
      ```
      $ openssl req -new -out MyCompanyCA.csr -keyout MyCompanyCA.pem
      ```
      Follow the instructions to create the CSR.
   
   c) Create the Root Certificate Authority for a period of validity of 2 years.
      ```
      $ openssl x509 -trustout -in MyCompanyCA.csr -out MyCompanyCA.crt -req -signkey MyCompanyCA.pem -days 730
      ```
      **Note:** The private key file (MyCompanyCA.pem) of a Root Certificate Authority must be handled with care. This file is responsible for the validity of all other certificates it has signed. As a result, it must not be accessible by other users.

2. Create the client's X.509 certificate and private key.
   a) Create the client's Certificate Signing Request and private key.
      ```
      $ openssl req -new -out MyClient.csr
      ```
      **Note:** By default, openssl outputs the private key in the privkey.pem file. If you want to specify a different file name, or if your openssl version does not output the private key by default, add the -keyout <myprivkey>.pem to the command.
   
   b) Remove the password from the RSA private key.
\$ openssl rsa -in privkey.pem -out MyClient.pem

**Note:** The unprotected private key is output in MyClient.pem.

c) Create the client's certificate (self-signed X.509 certificate valid for a period of 1 year) trusted by the Root Certificate Authority created in step 1.

(line breaks added for document readability)

\$ openssl x509 -in MyClient.csr -out MyClient.crt -req -signkey MyClient.pem -CA MyCompanyCA.crt -CAkey MyCompanyCA.pem -days 365

**Note:** Most servers do not check the identity of the clients. For these servers, the client's certificate does not necessarily need to be trusted; it is only used for data encryption purpose. If, however, the server performs client identification, you must trust a Certificate Authority in which it has total confidence concerning the validity of the client's certificates.

**Note:** The purpose of the client's certificate is to identify the client to any server; therefore the subject of the certificate must correspond to the client's identity as it is known by the servers.

**Note:** To import the certificate in a keystore you can create a pkcs12 certificate. See Import a certificate and its private key into the Windows key store on page 3315.

**What to do next**

Configure your FGLPROFILE file for the client certificate. See Configure for the client certificate on page 3307.

**Related concepts**

Encryption and authentication on page 3299

A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

The OpenSSL (openssl) tool on page 3313

The openssl command line tool creates certificates for the configuration of secured communications.

**Related tasks**

View a certificate on page 3316

This procedure allows you to view a certificate using the openssl command.

Configure for the client certificate

Configure your application to use the client certificate generated. For production systems, you add the configuration details to your FGLPROFILE file.

You have generated a client certificate as described in Create the client certificate on page 3306.

In this task you add the certificate information to your FGLPROFILE file.

Add the client's security configuration to your FGLPROFILE file.

The client security entry defines the certificate and the associated private key used by the Genero Web Services client during an HTTPS communication. The security entry must be defined with an unique identifier (**id1** in this example).

```plaintext
security.id1.certificate = "MyClient.crt"
security.id1.privatekey = "MyClient.pem"
```

**Note:** If the private key is protected with a password, you must remove it or create a script that returns the password on demand. See Create the client certificate.

Your applications are configured to use the client certificate.

**What to do next**
Create the client's certificate authority list and configure the global certificate authority list (security.global.ca) in your FGLPROFILE file. See Configure for the certificate authority list on page 3308.

**Related concepts**

**FGLPROFILE entries for Web Services** on page 3489

The FGLPROFILE entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

**FGLPROFILE: HTTP(S) Proxy Authentication** on page 3496

FGLPROFILE entries can be used to define a connection to an HTTPS server via a proxy, and with HTTP and Proxy Authentication.

**Encryption and authentication** on page 3299

A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

**Related tasks**

**View a certificate** on page 3316

This procedure allows you to view a certificate using the openssl command.

**Configure for the certificate authority list**

The client needs to check to see if the server certificate is trusted. This is done using a certificate authority list. In this task you create the client's certificate authority list using the OpenSSL command line tool, and set the global certificate authority list in your FGLPROFILE file.

**Important:** On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain typically holds the server certificate authority list. Therefore, the FGLPROFILE file security settings are ignored with the exception of the following: security.global.ca, security.global.ca.lookuppath, and security.global.systemca.

1. Create the client's certificate authority list.
   a) Save the certificates of the HTTPS server to disk.
      Type the server's URL in your browser. When prompted, save all the certificates from the Certificate Hierarchy. For more information see, Selecting the certificate to add on page 3317 and Missing certificates on page 3311.
   b) Create the client's Certificate Authority List by running the following command for each of the certificates that you saved to disk.

      ```bash
      $ openssl x509 -in ServerCertificate.crt -text >> ClientCAList.pem
      ```

      **Note:** All trusted certificate authorities are listed. These are checked following a chain of child to parent certificates until a certificate is reached which is trusted. All other certificates that were trusted by the Root Certificate Authority will also be considered as trusted by the client. For more information see Certificate authorities on page 3301.

2. Set the global certificate authority list in your FGLPROFILE file.

   The global certificate authority list entry defines the file containing the certificate authority list used by the Genero Web Services client to validate all certificates coming from the different servers it will connect to.

   ```
   security.global.ca = "ClientCAList.pem"
   ```

   **Note:** The file is located based on the current execution directory. If you use Genero Studio, for instance, fglrun may not be executed in the same directory as when you use the command line. The recommended practice therefore is to specify an absolute path for the .pem, for example:

   ```
   security.global.ca = "/opt/usr/certs/ClientCAList.pem"
   ```

   If security.global.ca is not defined, Genero Web Services will look to see whether the operating system has a keystore, otherwise security.global.ca.lookuppath will be used. For further information, see Certificate authorities in HTTPS configuration on page 3305.
The client application is configured to use the appropriate certificate authority list to validate a server's certificate.

**What to do next**

In your FGLPROFILE file ensure there are configuration entries (ws.*) for the HTTPS server URL and for the HTTP authentication when accessing the HTTPS server. See *Add configuration entries in your FGLPROFILE file* on page 3309.

**Related concepts**

[Error: Peer certificate is issued by a company not in our CA list](#) on page 3310

When a client connects to a server using HTTPS, the client needs to trust the server it is in communication with. So the client needs to add the server's CAs (certificate authorities lists) to its trusted CAs.

[Enable OCSP](#) on page 3310

To enable OCSP (Online Certificate Status Protocol), set the `security.global.ocsp.enable` and `security.global.ocsp.url` entries in FGLPROFILE.

[FGLPROFILE entries for Web Services](#) on page 3489

The FGLPROFILE entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

[FGLPROFILE: HTTP(S) Proxy Authentication](#) on page 3496

FGLPROFILE entries can be used to define a connection to an HTTPS server via a proxy, and with HTTP and Proxy Authentication.

[Accessing secured services](#) on page 3303

Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web service.

**Add configuration entries in your FGLPROFILE file**

Add a set of configuration entries that specify the security configuration for GWS clients accessing an HTTPS server.

In this task you add configuration entries (ws.*) in your FGLPROFILE file for the HTTPS server URL and for HTTP authentication when accessing the HTTPS server. For an example, see *FGLPROFILE: HTTP(S) Proxy Authentication* on page 3496.

**Important:** On GMI mobile devices the iOS SSL/TLS layer is used for HTTPS, and the device Keychain typically holds the server certificate authority list. Therefore, the FGLPROFILE file security settings are ignored with the exception of the following: `security.global.ca`, `security.global.ca.lookuppath`, and `security.global.systemca`.

Add configuration entries for the server.

The following entries must be defined with an unique identifier (such as "myserver"):

   
   (Line breaks added for document readability)

b) `ws.myserver.security = "id1"

   Where the value (id1 in this example) must match the unique identifier defined by the client security entry created in *Configure for the client certificate* on page 3307.

**Tip:** The unique identifier "myserver" can be used in the BDL client code in place of the actual URL.

**Related concepts**

[FGLPROFILE entries for Web Services](#) on page 3489

The FGLPROFILE entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

[Accessing secured services](#) on page 3303

Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web service.

[Troubleshoot certificate issues](#) on page 3310
You may encounter known (and common) issues when completing the Genero Web Services tutorials or when adding Web services of your own. These issues and their solutions are presented in the following topics.

**Configure a WS client to connect via an HTTP Proxy**

Configuration steps to connect via a HTTP proxy.

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.

1. Add the location of the proxy to your FGLPROFILE file with the `proxy.http.location` entry.
   
   Add the entry `proxy.http.location` to your fglprofile. For the value, provide the IP address of the HTTP proxy and the port number where the HTTP proxy is listening, separated by a colon. For example, to have a client connect via a HTTP proxy located at the IP address "10.0.0.170" and listening on port number "8080", add this entry to your fglprofile:
   
   ```
   proxy.http.location = "10.0.0.170:8080"
   ```
   
   **Note:** To configure the client to connect via an HTTPS proxy, replace `http` with `https`.

2. Define the list of host names the client will not have to connect to via a proxy with the `proxy.http.list` entry.
   
   Add the entry `proxy.http.list` to your FGLPROFILE file. For the value, provide a semi-colon separated list of clients. For example, to exclude all hosts beginning with "www.mycompany.com" or "www.google." from connecting via a HTTP proxy, add this entry to your fglprofile:
   
   ```
   proxy.http.list = "www.mycompany.com;www.google."
   ```

**Related reference**

[Proxy configuration](#) on page 3492

**Configure a WS client to use IPv6**

Configuration steps to customize IPv6 for a WS client.

A Web Services client program can access a WS server using IPv6.

URLs that map to IPv6 addresses will be automatically handled by the Web Services library. It is also possible to specify an IPv6 address directly as URL in your BDL code by enclosing the address in [] square brackets, for example:

```
LET myURL = "http://[fe80::20c:29ff:fe05:9ca3]:80/index.html"
```

By default, the WS library will automatically use IPv6 addresses if available, and fallback to IPv4 if not. To overcome the default behavior, you can explicitly specify the IP version.

The platform where WS client programs execute must support IPv6.

1. If needed, force the IP version with the `ip.global.version` entry in your fglprofile file, by specifying "4" for IPv4 or "6" for IPv6.
   
   For example, to force IPv4 (when IPv6 is available):
   
   ```
   ip.global.version = "4"
   ```

2. When using IPv6 for link-local addresses, if several network interfaces exist on the machine, you can explicitly specify which interface must be used with the `ip.global.v6.interface.name` or `ip.global.v6.interface.id` entry in fglprofile.

   In order to specify the IPv6 network interface by name, use:
   
   ```
   ip.global.v6.interface.name = "eth0"
   ```

   **Important:** The `ip.global.v6.interface.name` entry is not supported on Microsoft™ Windows® platforms.

   In order to specify the IPv6 network interface by id, use:
Authenticate the WS client to a server (HTTP basic authentication)

Configuration steps to authenticate the client to a server.

See Basic or digest HTTP authentication on page 3491. For an example, see FGLPROFILE: HTTP(S) Proxy Authentication on page 3496.

Important: On GMI mobile devices, FGLPROFILE settings are ignored: Use the com.HTTPRequest.setAuthentication on page 2883 API instead.

1. Add HTTP authenticate entries to your FGLPROFILE file.

   To connect to a server with HTTP Authentication, define the client login and password with the same values as registered on the server side. These entries must be defined with an unique identifier (httpauth in this example) to define a HTTP Authentication with "mylogin" as login and "mypassword" as password:

   ```
   authenticate.httpauth.login = "mylogin"
   authenticate.httpauth.password = "mypassword"
   ```

   See [RFC2617] for more details.

2. Encrypt the password.

   Due to security leaks, it is recommended that you NOT have a password in clear text. The Genero Web Services package provides the tool fglpass, which encrypts a password with a certificate that is readable only with the associated private key. To encrypt the HTTP authentication password:

   a) Encrypt the clear text password with fglpass using the client certificate.

   ```
   $ fglpass -e -c MyClient.crt
   Enter password :mypassword
   ```

   Note: fglpass outputs the encrypted password on the console but can be redirected to a file.

   b) Modify the HTTP authentication password entry by specifying the security configuration to use to decrypt it ("id1" in our example)

   ```
   authenticate.httpauth.password.id1="HWTFu8QE2t3e5D4joy7js8mB95oOGTzLmcAor9j5DS+C
   loi1iGCwzV9eWpfmIWSON9IwoiJheYxfnu20uaGGmmiUGiHxT6341ePXNSsicu32Nt1Vp9t6RcSO
   wN/p9a6D4XtiD9iHW7iQvXhqC9uamd3gI9Q3GhWxOMM1Y/c8Y="
   ```

   Note: Hard returns have been added to the code sample above, for the purpose of printing and viewing within this document. The value for authenticate.httpauth.password.id1 is a single string with no spaces.

   Note: The size of the encrypted password depends on the size of the public key, and can change based on the certificate used to encrypt it.

3. Configure the client to authenticate to a server.

   As a client is able to connect to different servers that do not know the client with the same login and password, it is necessary to specify the login and password that corresponds to each server. To authenticate the client known as "myclient" with the password passphrase by the server myserver, add the following entry:

   ```
   ws.myserver.authenticate = "httpauth"
   ```

Related tasks

Configure a WS client to access an HTTPS server on page 3305
Configuration steps to access a server in HTTPS.

**Authenticate the WS client to a proxy**
Configuration steps to authenticate the client to a proxy (proxy authentication).

For an example, see FGLPROFILE: HTTP(S) Proxy Authentication on page 3496.

**Important:** On GMI mobile devices, FGLPROFILE settings are ignored: The device configuration for proxy will always be used.

1. Add an HTTP authenticate entry to your FGLPROFILE file.
   To connect via a proxy with HTTP Proxy Authentication, it is necessary to define the client login and password as registered on the HTTP proxy.
   
   The following two entries must be defined with an unique identifier (proxyauth for our example) to define a HTTP Proxy Authentication with `myapplication` as login and `mypassword` as password:
   ```plaintext
   authenticate.proxyauth.login = "myapplication"
   authenticate.proxyauth.password = "mypassword"
   ```
   
   See [RFC2617](https://www.ietf.org/rfc/rfc2617.txt) for more details.

2. For proxy authentication, an entry must be made to the HTTP proxy configuration in order to authenticate a client.
   
   To authenticate a client known as `myapplication` with `mypassword` as password by the HTTP Proxy, add the following entry to the HTTP proxy configuration:
   ```plaintext
   proxy.http.authenticate = "proxyauth"
   ```
   
   **Note:** To authenticate the client to a HTTPS proxy, replace `http` with `https`.

**Related reference**
Proxy configuration on page 3492

**Writing a Web Services server application**
To create a RESTful Genero Web services server application, there are a minimum of five steps that the server application must handle.

In discussing the five steps, the Calculator RESTful Web services server application is used to provide code examples.

**Step 1: Import extension packages**
Extension packages include classes and functions necessary for your Web services server application. Use the `IMPORT` statement to include these packages.

Include the following lines at the top of your module as instructions to import the required libraries:

```plaintext
IMPORT com
IMPORT util
```

Methods to create a REST Web Service server application are contained in the classes that make up the com library of the Genero Web Services (GWS).

The calculator demo application also uses methods from the util.JSON class for data exchange.

In the next step we start the server and listen for incoming requests, Step 2: Listen for requests on page 3430

**Step 2: Listen for requests**
Listen for an incoming request.

Define an object variable using the com.HTTPServiceRequest class identifier. This variable will reference the incoming HTTP service request. In addition, define an INTEGER variable to hold an error status, if needed.

```plaintext
DEFINE ret INTEGER
DEFINE req com.HTTPServiceRequest
```
Start the server engine with the method `com.WebServiceEngine.Start()`.

```plaintext
DEFER INTERRUPT

# Start the server
DISPLAY "Starting server..."

# Starts the server on the port number specified by the FGLAPPSERVER environment variable
# (EX: FGLAPPSERVER=8090)
CALL com.WebServiceEngine.Start()
DISPLAY "The server is listening."
```

Listen for an incoming request using `com.WebServiceEngine.getHTTPServiceRequest`. When a request is received, the variable `req` references the HTTP service request object. You can use the same object to send a response.

Include a `CATCH` block to trap runtime exceptions. For a RESTful Web service, include a check for error -15565, which is returned when an incoming request cannot be returned.

```plaintext
... # create the server
WHILE TRUE
    TRY
        LET req = com.WebServiceEngine.getHTTPServiceRequest(-1)
        ... parse and process the request ...
    CATCH
        LET ret = STATUS
        CASE ret
            WHEN -15565
                DISPLAY "Disconnected from application server."
                EXIT WHILE
            OTHERWISE
                DISPLAY "[ERROR] " || ret
                EXIT WHILE
        END CASE
    END TRY
END WHILE
```

For more information see `com.WebServiceEngine methods` on page 2829.

In the next step we extract the details of the incoming request. **Step 3: Parse the request** on page 3431

**Step 3: Parse the request**

Using methods of the `com.HTTPServiceRequest` class (among others), parse the details of the request.

An HTTP service request has been received and stored in an instance of a `com.HTTPServiceRequest` object.

To use the details of the request, the next step is to define a record to hold the pieces of information that come in with a request and to parse the request into the record. The demo creates a user-defined type `reqInfoTyp` to reference when defining the record.

**Note:** This topic details how the calculator demo server application parses the instance of the `HTTPServiceRequest` object. While your specific HTTP service requests may differ in the details, the parsing needs will be similar.

```plaintext
TYPE reqInfoTyp RECORD
    method STRING,
    ctype STRING,  # check the Content-Type
    informat STRING,  # short word for Content Type
    caccept STRING,  # check which format the client accepts
```
Define a variable based on the type.

```
DEFINE m_reqInfo reqInfoTyp
```

Call a function that takes the variable referencing the instance of the com.HTTPServiceRequest object as input. The purpose of the function will be to parse the HTTP service request into its components.

```
CALL getReqInfo(req)
```

**The getReqInfo function**

This function uses both the HTTPServiceRequest and StringTokenizer classes and methods to parse the request into the reqInfoTyp record.

```
FUNCTION getReqInfo(req)
```

Define the variables needed. The variable `req` references the instance of the HTTP service request object. The variables `str`, `val`, `token`, and `i` are used when parsing out details with the StringTokenizer classes and methods.

```
DEFINE req com.HTTPServiceRequest
DEFINE str, val base.StringTokenizer
DEFINE token STRING
DEFINE i INT
```

For the remainder of this topic, you are retrieving data from the instance of the HTTP service request object (referenced by the variable `req`) and populating the record variable designed to hold this data (`m_reqInfo`).

Initialize `m_reqInfo` to NULL. This ensures that there are no pre-existing values in the record variable.

**Note:** The variable `m_reqInfo` record was defined at the top of the module, and therefore can be used in this function.

```
INITIALIZE m_reqInfo TO NULL
```

Retrieve the value of the Content-Type request header. The Content-Type request header defines the format of the incoming message body. REST APIs commonly use "application/json" or "application/xml" to reveal the format of the message body. The server application anticipates the Content-Type to be either JSON or XML. The custom `getHeaderByName` function retrieves the value of the Content-Type header, and based on the return value, populates the input format variable (`m_reqInfo.informat`) with either "XML" or "JSON".

```
LET m_reqInfo.ctype = getHeaderByName(req,"Content-Type")
IF m_reqInfo.ctype.getIndexOf("/xml",1) THEN
  LET m_reqInfo.informat = "XML"
ELSE
  LET m_reqInfo.informat = "JSON"
END IF
```

Retrieve the value for Accept request header. The Accept request header is where the client application conveys its response preference. The server application expects the Accept request header to be either JSON or XML. The
custom `getHeaderByName` function retrieves the value of the Accept header, and based on the returned value, populates the output format variable `m_reqInfo.outformat` with either "XML" or "JSON".

```plaintext
LET m_reqInfo.caccept = getHeaderByName(req,"Accept")
IF m_reqInfo.caccept.indexOf("/xml",1) THEN
  LET m_reqInfo.outformat = "XML"
ELSE
  LET m_reqInfo.outformat = "JSON"
END IF
```

Parse out the HTTP method (verb) of the HTTP service request with the function `com.HTTPServiceRequest.getMethod()`, and populate the method variable `m_reqInfo.method` with the result.

```plaintext
LET m_reqInfo.method = req.getMethod()
```

While possible values could include GET, POST, PUT, HEAD, and DELETE, our demo server application expects GET, and the processing part of the server application code does not test or code for any verbs aside from GET.

Parse out the path and the query. Retrieve the URL resource using the function `com.HTTPServiceRequest.getUrl()`. To parse out the path and the query from the URL, call the custom `parseUrl` function. The path is placed in the path variable `m_reqInfo.path` and the query string is placed in the query variable `m_reqInfo.query`.

```plaintext
CALL parseUrl(req.getUrl()) RETURNING m_reqInfo.path, m_reqInfo.query
```

Take the query variable `m_reqInfo.query` and parse out the value pairs using the `StringTokenizer` class and methods. The value pairs of variable name and value are stored in the `m_reqInfo.items` dynamic array.

```plaintext
LET str = base.StringTokenizer.create(m_reqInfo.query,"&")
LET i=1
CALL m_reqInfo.items.clear()
WHILE str.hasMoreTokens()
  LET token = str.nextToken()
  LET val = base.StringTokenizer.create(token,"=")
  IF val.hasMoreTokens() THEN LET m_reqInfo.items[i].name = val.nextToken() END IF
  IF val.hasMoreTokens() THEN LET m_reqInfo.items[i].value = val.nextToken() END IF
  LET i=i+1
END WHILE
```

By the end of the custom `getReqInfo()` function, the HTTP service request object is parsed into the variables that comprise a `reqInfoType` record. The application can now access the values it needs to process the request.

**getHeaderByName function**

The purpose of this function is to take as input two things:

- The HTTP service request object in a `com.HTTPServiceRequest` variable.
- The name of the header type whose value you want to return.

In the demo application, this function is used to parse out the value for the Content-Type header request and the Accept header request.

To do this, the function uses the API methods `getRequestHeaderCount`, `getRequestHeaderName`, and `getRequestHeaderValue` against the `com.HTTPServiceRequest` object. The function first counts the number of header requests, and then cycles through them until it finds the specific header request that is being asked for. When the match happens, the value for that header is returned; if no match is found, then NULL is returned.

```plaintext
FUNCTION getHeaderByName(areq,hname)
```
DEFINE areq com.HTTPServiceRequest
DEFINE hname STRING

DEFINE aname STRING
DEFINE iname STRING
DEFINE i INT
DEFINE n INT

LET aname = hname.toLowerCase()
LET n = areq.getRequestHeaderCount()
FOR i=1 TO n
    LET iname = areq.getRequestHeaderName(i)
    IF aname.equals(iname.toLowerCase()) THEN
        RETURN areq.getRequestHeaderValue(i)
    END IF
END FOR

RETURN NULL
END FUNCTION

parseUrl function

For this function, the URL is passed in. This function divides the URL into two parts, the path (up to and including
the question mark) and the query. The path and the query are then returned to the calling function.

FUNCTION parseUrl(url)
    DEFINE url STRING
    DEFINE i INT

    LET i = url.getIndexOf("?",1)
    IF i = 0 THEN
        RETURN url, NULL
    ELSE
        RETURN url.substring(1,i), url.substring(i+1,url.getLength())
    END IF
END FUNCTION

For example, the URL being passed in by the demo client application is "http://localhost:8090/add?a=1&b=2". The
function then returns the path ("http://localhost:8090/add?") and the query ("a=1&b=2").

For more information see com.WebServiceEngine methods on page 2829

In the next step we process the incoming request, Step 4: Process the request on page 3434

Step 4: Process the request

Having parsed the HTTPServiceRequest object into its parts, you can now process the request.

In the previous step, the m_reqInfo record was populated with the values of the HTTPServiceRequest object.
The application now needs to work with these values.

Each Web services server application will be different in the type of processing that is done. For completeness,
this topic will highlight some of the processing that is happening in the calculator demo server application.

Despite having variables in the m_reqInfo record, four additional STRING variables are defined to hold the
method, the URL, the query, and the output format. In addition, an INTEGER variable is defined to hold an index
value, used by some of the custom processing functions.

DEFINE method STRING
DEFINE url STRING
DEFINE qry STRING
DEFINE acc STRING
DEFINE idx INT
With the record populated, the server application then populates the additional variables.

```plaintext
# Get the type of method
LET method = m_reqInfo.method
# Get the request path
LET url = m_reqInfo.path
# Get the query string
LET qry = m_reqInfo.query
# Get the output format
LET acc = m_reqInfo.outformat
```

In the demo server application, the `CASE` statement only tests for the GET method.

```plaintext
CASE method
  WHEN "GET"
    ... processing instructions
  OTHERWISE
    CALL setError("Unknown request:
      || url || \
      "
      || method)
    LET err.code = -3
    LET err.desc = ERR_METHOD
    CALL req.sendTextResponse(200,"OK",util.JSON.stringify(err))
END CASE
```

For the remainder of the processing code, the demo server application:

- Determines whether the request is for addition, subtraction, multiplication, or division
- Retrieves the values for the variables a and b
- Handles errors appropriately

For example, the source code that would process an addition request:

```plaintext
IF url.indexOf("/add?",1) > 0 THEN
  LET idx = getParameterIndex("a")
  IF idx = 0 THEN
    LET add_out.status.code = -1
    LET add_out.status.desc = ERR_PARAM_A
    CALL req.setResponseHeader("Content-Type","application/json")
    CALL req.sendTextResponse(200, "OK", util.JSON.stringify(add_out))
    EXIT CASE
  ELSE
    LET add_in.a = getParameterValue(idx)
  END IF
  LET idx = getParameterIndex("b")
  IF idx = 0 THEN
    LET add_out.status.code = -1
    LET add_out.status.desc = ERR_PARAM_B
    CALL req.setResponseHeader("Content-Type","application/json")
    CALL req.sendTextResponse(200, "OK", util.JSON.stringify(add_out))
    EXIT CASE
  ELSE
    LET add_in.b = getParameterValue(idx)
  END IF
  CALL add()
  ... send response
END IF
```

In the next step the server sends the response back to the client, **Step 5: Send response** on page 3435.

**Step 5: Send response**

Having completed the processing, the server sends the response back to the client.

The server application has the value or values that must be returned to the client. It now needs to format and send the response.
In the demo server application, the `setResponseHeader()` method sets the Content-Type to JSON.

```java
CALL req.setResponseHeader("Content-Type","application/json")
```

The `sendTextResponse()` sends three things: a code, a description, and the response data. In this case, the data is formatted as JSON using the `util.JSON.stringify()` method, which transforms a record variable into a flat JSON formatted string.

```java
CALL req.sendTextResponse(200, "OK", util.JSON.stringify(add_out))
```

**Related concepts**

**Step 6: Provide information about your service**

You must provide information about the services offered by your application to the developers of the Web services client applications that will interact with your server.

**Step 6: Provide information about your service**

You must provide information about the services offered by your application to the developers of the Web services client applications that will interact with your server.

Information that the client application developer will need to know:

- The names of the resources or functions, and the query parameters and arguments to use with them.
- What media type the server expects for receiving, and then delivering, the message body (such as "JSON" or "XML").
- The HTTP method the server is expecting (such as "GET")

See also [Step 1: Obtain information about Web service resources](#) on page 3419.

**The RESTful calculator demo source**

This calculator demo provides a sample RESTful Web services, demonstrating how to create a server and client application using low-level APIs.

These topics provide the full code of the calculator demo application, and compares how the server and client functionality relates.

**Calculator server source**

The source code for the server-side application included in the RESTful Web services calculator demo.

How Do I ... ?

These topics provide you with the information needed to perform specific tasks related to Genero Web Services (SOAP or RESTful).

Tip: See here for SOAP-specific "How Do I … ?” topics.

Call Java APIs from Genero in a SOA environment

How to call a Java library from Genero in a SOA environment, using Genero and Java Web services.

This can easily be done using the Java JAX-WS framework on a server, and a Genero application for the client part.

Note: There is no strong linkage between Genero and a java JVM. You can, for instance, upgrade the Java service without changing anything in your Genero code.

These topics are presented as a tutorial that uses a Java barcode creation library to build a picture from a code.

Related concepts

Call .NET APIs from Genero in a SOA environment on page 3450

How to call a .NET library from Genero in a SOA environment, using Genero and Web services, and IIS and Visual Studio .NET.

Recommendation

The usage of Genero Web Services to call a Java service is recommended in a SOA environment. It enables several Genero applications to connect to a centralized Java service without the need to start a new JVM for each running Genero application.

It also provides more flexibility because there is no strong linkage between Genero and the Java virtual machine. You can, for instance, upgrade the Java service without changing anything in your Genero code.

However, due to the XML serialization process and the HTTP transport protocol in Web Services, there can be some performance issues. So if your main concern is performance, it is recommended to use the Genero Java bridge.

Prerequisites

• A JRE 1.5 or above
• The Java barcode library (available here)
  • You must add these JARs to the Java CLASSPATH: barcode.jar and BarcodeReader.jar
  • The trial version has some functions partially implemented.
• Download the JAX-WS framework from the Sun® metro project here; add this JAR to the java CLASSPATH: webservices-tools.jar

Using the barcode library

The barcode library is composed of two libraries:

• A library for building a barcode image from a numeric code
• A library for reading a barcode image to return the numeric code

This section is based on the library you want to use in Genero.

In our tutorial, we create two functions called buildImage and readImage.

This is the Java implementation:

```java
buildImage( type : String, code : String) : byte[ ]
```

```java
try {
    Barcode builder=new Barcode();
    builder.setType(GetBarcodeBuilderType(type));
    builder.setData(data);
```
Web services

```java
builder.setAddCheckSum(true);
ByteArrayOutputStream out=new ByteArrayOutputStream();
if (builder.createBarcodeImage(out)) {
    byte[] ret = out.toByteArray();
    return ret;
} else {
    return null;
}
} catch (Exception e) {
    return null;
}
```

```java
readImage( type : String, img : byte[] ) : String
try {
    File f=new File("tmp.jpg");
    FileOutputStream stream=new FileOutputStream(f);
    stream.write(img);
    stream.close();
    String[] datas =
        BarcodeReader.read(f, GetBarcodeReaderType(type));
    if (datas==null) {
        return null;
    } else {
        String ret = datas[0];
        return ret;
    }
} catch (Exception e) {
    return null;
}
```

The following two functions convert the barcode type to the type expected by the library:

```java
private int GetBarcodeBuilderType(String str) {
    if (str.equals("CODABAR")) {
        return Barcode.CODABAR;
    } else if (str.equals("CODE11")) {
        return Barcode.CODE11;
    } else if (str.equals("CODE128")) {
        return Barcode.CODE128;
    } else if (str.equals("CODE128A")) {
        return Barcode.CODE128A;
    } else if (str.equals("CODE128B")) {
        return Barcode.CODE128B;
    } else if (str.equals("CODE128C")) {
        return Barcode.CODE128C;
    } else if (str.equals("CODE2OF5")) {
        return Barcode.CODE2OF5;
    } else if (str.equals("CODE39")) {
        return Barcode.CODE39;
    } else if (str.equals("CODE39EX")) {
        return Barcode.CODE39EX;
    } else if (str.equals("CODE93")) {
        return Barcode.CODE93;
    } else if (str.equals("CODE93EX")) {
        return Barcode.CODE93EX;
    } else if (str.equals("EAN13")) {
        return Barcode.EAN13;
    } else if (str.equals("EAN13_2")) {
        return Barcode.EAN13_2;
    } else if (str.equals("EAN13_5")) {
        return Barcode.EAN13_5;
    } else if (str.equals("EAN8")) {
        return Barcode.EAN8;
    }
```
} else if (str.equals("EAN8_2")) {
    return Barcode.EAN8_2;
} else if (str.equals("EAN8_5")) {
    return Barcode.EAN8_5;
} else if (str.equals("INTERLEAVED25")) {

        return BarcodeReader.RSS14;
    } else if (str.equals("RSSLIMITED")) {
        return BarcodeReader.RSSLIMITED;
    } else if (str.equals("UPCA")) {
        return BarcodeReader.UPCA;
Calling Java from Genero

The integration of one or several Java libraries with multiple methods in a Genero application can be performed, as described in the following topics.

**Step 1: Write a new java class**

Instead of writing the functions in 4GL, you simply need to write them in a Java class with the methods you want to use in 4GL. In our example, the two functions are `buildImage` and `readImage`. And of course, don't forget to import the necessary Java import instructions.

```java
import com.barcodelib.barcodereader.BarcodeReader;
import com.barcodelib.barcode.Barcode;
import java.io.*;
import javax.jws.*;
import javax.jws.soap.SOAPBinding;
import javax.xml.ws.Endpoint;

public class BarcodeService {
    public byte[] buildImage(String type, String data) {
        /*BUILDIMAGE IMPLEMENTATION CODE DESCRIBED ABOVE*/
    }
    public String readImage(String type, byte[] img) {
        /*READIMAGE IMPLEMENTATION CODE DESCRIBED ABOVE*/
    }
}
```

If you want the service to run standalone, you must also add the following main method to tell the system the port number on which the service will run:

```java
public static void main(String[] args) {
    String endpointUri = "http://localhost:9090/";
    Endpoint.publish(endpointUri, new BarcodeService());
    System.out.println("BarcodeService started at " + endpointUri);
}
```

In the next step we transform the Java class in a Web Service, **Step 2: Transform the Java class in a Web service** on page 3448.

**Step 2: Transform the Java class in a Web service**

To transform the Java class created in **Step 1: Write a new java class** on page 3448 into a Web Service, simply add a `WebService` annotation.

```java
@WebService(targetNamespace = http://www.mycompany.com/barcode",
    name="Barcode",
    serviceName="BarcodeService")
public class BarcodeService{
    ...
}
```
This defines all public and non static methods of the class as operations of the **BarcodeService** Web Service.

In the next step we start the Web Service, **Step 3: Start the service** on page 3449.

**Step 3: Start the service**

Compile the Java class created in **Step 2: Transform the Java class in a Web service** on page 3448, and run it.

Commands to compile and execute the service in standalone mode:

```
$ javac BarcodeService.java
$ java BarcodeService
```

Once the service is started, it is ready to accept requests and you can also retrieve its WSDL at the following URL:

http://localhost/9090/BarcodeService?WSDL

**Note:** If you want the service to be started on a Web server, you must deploy it first using Eclipse or the Web Server deployment tools.

In the next step we generate the client stub to access the BarcodeService, **Step 4: Generate BDL stub to access the Java library** on page 3449.

**Related concepts**
**Deploy a Web Service** on page 3459
Genero Web services need to be deployed on a Genero Application Server that plugs into a Web server, such as Apache. Understand what you need to implement for configuration and security.

**Step 4: Generate BDL stub to access the Java library**

Use the `fglwsdl` tool to generate the client stub to access the BarcodeService:

```
$ fglwsdl http://localhost:9090/BarcodeService?WSDL
```

This will create two `.4gl` files that must be compiled and linked into your BDL application in order to call the Java barcode library functions. These files contain the BDL interface to access the Java library where you will find the two functions, `readImage` and `buildImage`, defined in BDL.

In the final step we modify the existing application, **Step 5: Modify your BDL application** on page 3449.

**Related concepts**
**WS client stubs and handlers** on page 3328
To access a remote Web Service, you first must get the WSDL information from the service provider.

**Step 5: Modify your BDL application**

The last step is to modify the existing application where you want to use the Java library, by calling the BDL functions generated in the stub. Then compile your application and the previously generated stubs, and link everything together.

Your application is now ready to use the different features of your Java library.

**Related concepts**

**Example program**

This program calls the `buildImage` function of the Barcode Java library.

```
GLOBALS "BarcodeService_BarcodePort.inc"

MAIN
```
DEFINE wsstatus INTEGER

IF num_args() != 3 THEN
    CALL ExitHelp()
END IF

LET ns1buildImage.arg0 = arg_val(1)
LET ns1buildImage.arg1 = arg_val(2)
LOCATE ns1buildImageResponse.return IN MEMORY

LET wsstatus = buildImage_g()
IF wsstatus <> 0 THEN
    DISPLAY "Error ("||wsError.code||") : ",wsError.description
ELSE IF
    IF ns1buildImageResponse.return IS NULL THEN
        DISPLAY "Encoding failed"
    ELSE
        CALL ns1buildImageResponse.return.writeFile(arg_val(3))
    END IF
END IF
FREE ns1buildImageResponse.return
END MAIN

FUNCTION ExitHelp()
    DISPLAY arg_val(0)||" <type> <data> <filename>"
    DISPLAY "type : barcode type such as EAN8 or CODE128"
    DISPLAY "data : data to be encoded with a barcode [0-9A-D]"
    DISPLAY "filename : resulting image filename"
    DISPLAY "example : createImage EAN8 12358723A mybarcode.jpg"
EXIT PROGRAM (-1)
END FUNCTION

Conclusion
In a SOA environment, you can call any Java library from Genero using Web Services, and without a strong
dependency to a JVM. This follows SOA principles - it allows you to reuse the Java library in another BDL
application without any new development, you can update the Java part without recompiling any .4gl source, and
integrate any function available from a SOA platform.

Call .NET APIs from Genero in a SOA environment
How to call a .NET library from Genero in a SOA environment, using Genero and Web services, and IIS and Visual
Studio .NET.
There is no strong linkage between Genero and .NET. You can call a .NET library from a non-Windows® Genero
platform.
These topics are presented as a tutorial that uses a .NET barcode creation library to build a picture from a numeric
code, and C# as the development language. This works with any .NET language.

Related concepts
Call Java APIs from Genero in a SOA environment on page 3445
How to call a Java library from Genero in a SOA environment, using Genero and Java Web services.

Prerequisites
• IIS (Internet Information Services) Web server
• Visual Studio Professional Edition C#
  • Visual Studio is only needed for development. Once the service is built, you can deploy on any IIS Web
    Server.
- The .NET barcode library (available here)
  - The trial version has some functions partially implemented.
  - The .NET library is called BarcodeLib.Barcode.dll, and must be added to the Visual Studio Project.

**Using the barcode library**

This section is based on using the library in Genero. In our tutorial, we create one function called `buildImage`. This is the C# implementation:

```csharp
buildImage( type : String, code : String ) : byte[]
```

```csharp
Linear barcode = new Linear();
barcode.Data = code;
barcode.Type = GetBarcodeBuilderType(type);
barcode.AddChecksum = true;
// save barcode image into your system
barcode.ShowText = true;
byte[] ret = barcode.drawBarcodeAsBytes();
if (ret != null) return ret;
else return null;
```

You will also need to convert the barcode type to the type expected by the library. Therefore, you will need this function.

```csharp
private BarcodeType GetBarcodeBuilderType(String str)
{
    if (str.Equals("CODABAR")) {
        return BarcodeType.CODABAR;
    } else if (str.Equals("CODE11")) {
        return BarcodeType.CODE11;
    } else if (str.Equals("CODE128")) {
        return BarcodeType.CODE128;
    } else if (str.Equals("CODE128A")) {
        return BarcodeType.CODE128A;
    } else if (str.Equals("CODE128B")) {
        return BarcodeType.CODE128B;
    } else if (str.Equals("CODE128C")) {
        return BarcodeType.CODE128C;
    } else if (str.Equals("CODE2OF5")) {
        return BarcodeType.CODE2OF5;
    } else if (str.Equals("CODE39")) {
        return BarcodeType.CODE39;
    } else if (str.Equals("CODE39EX")) {
        return BarcodeType.CODE39EX;
    } else if (str.Equals("CODE93")) {
        return BarcodeType.CODE93;
    } else if (str.Equals("EAN13")) {
        return BarcodeType.EAN13;
    } else if (str.Equals("EAN13_2")) {
        return BarcodeType.EAN13_2;
    } else if (str.Equals("EAN13_5")) {
        return BarcodeType.EAN13_5;
    } else if (str.Equals("EAN8")) {
        return BarcodeType.EAN8;
    } else if (str.Equals("EAN8_2")) {
        return BarcodeType.EAN8_2;
    } else if (str.Equals("EAN8_5")) {
        return BarcodeType.EAN8_5;
    } else if (str.Equals("INTERLEAVED25")) {
        return BarcodeType.INTERLEAVED25;
    } else if (str.Equals("ITF14")) {
        return BarcodeType.ITF14;
    }
    return BarcodeType.OTHER;
}
```
Calling .NET from Genero

Step 1: Create an ASP.NET Web Service Application

Start Visual Studio, and create a new web project with the name "BarCodeService".

Figure 136: Visual Studio New Project; ASP.NET Web Service Application selected

In the next step we rename the generated files, Step 2: Rename the generated files on page 3452.

Step 2: Rename the generated files

Rename the generated class called Service1 with an appropriate name such as "BarCode", and rename the file Service1.asmx to BarCodeService.asmx, for instance.

The .asmx file is the file that is accessible from the IIS web server once the application is deployed. The .asmx file also contains a reference to the default generated class, Service1, which must also be renamed to the new name (BarCode in our tutorial), in case Visual Studio didn't make the change automatically.

The class view after renaming the class:
In the next step we add the barcode library as a reference, Step 3: Add the barcode library as a reference on page 3453.

**Step 3: Add the barcode library as a reference**

Right-click on the Solution Explorer, select Add Reference and use the Browse panel to enter the location of the barcode library called BarcodeLib.Barcode.dll:
Add the buildImage method

Step 4: Add the buildImage method

Remove the default generated HelloWorld method, and create the buildImage method.

Add the three using instructions to import the barcode library, and the instruction to declare buildImage as a WebMethod. Use the GetBarcodeBuilderType() method to convert a string to a code as expected by the barcode library.

```csharp
using BarcodeLib;
using BarcodeLib.Barcode;
using BarcodeLib.Barcode.Linear;

namespace BarCodeService
{
    /// <summary>
    /// Summary description for Service1
    /// </summary>
    [WebService(Namespace = "http://tempuri.org")]
    [WebServiceBinding(ConformsTo = WsiProfiles.BasicProfile1_1)]
    [ToolboxItem(false)]
    {
        [WebMethod]
        public byte[] buildImage(String type, String code)
        {
            try
            {
                Linear barcode = new Linear();
                barcode.Data = code;
                barcode.Type = GetBarcodeBuilderType(type);
                barcode.AddCheckSum = true;
                // save barcode image into your system
                barcode.ShowText = true;
            }
            catch (ParseException e)
            {
```

Note: By default, the barcode library will be copied to the right place when deploying on the IIS web server.
byte[] ret = barcode.drawBarcodeAsBytes();
    if (ret != null) return ret;
    else return null;
}
catch (Exception e)
{
    return null;
}
}

namespace BarCodeService
{
    // Summary description for Service
    // WebService(NameSpace = "http://tempuri.org/")
    // WebServiceBinding(ConformsTo = UniProfiles.BasicProfile1_1)
    // ToolboxItem(Icaise)
    // To allow this Web Service to be called from script, using ASP.NET
    {
        [WebMethod]
        public byte[] buildImage(String type, String code)
        {
            try
            {
                Linear barcode = new Linear();
                barcode.Data = code;
                barcode.Type = GetBarcodeBuilderType(type);
                barcode.AddCheckSum = true;

                // save barcode image into your system
                barcode.ShowText = true;
                byte[] ret = barcode.drawBarcodeAsBytes();
                if (ret != null) return ret;
                else return null;
            }
            catch (Exception e)
            {
                return null;
            }
        }
    }
}

Figure 139: BarCodeService.BarCode

In the next step we publish the service to your IIS Web server, Step 5: Publish the service on page 3456.
Step 5: Publish the service

Build the entire application, right-click on the solution, and select the publish operation. This will copy all necessary files to your IIS web server and make your application available at an URL, depending on where you deploy it on your IIS web server.

In our tutorial, the service will be located at the root of the server. In other words, it will be available at http://localhost/BarCodeService.asmx and the WSDL at URL http://localhost/BarCodeService.asmx?WSDL

Figure 140: Publish Web dialog

In the next step we generate the stub file, Step 6: Generate .4gl stub to access the .NET library on page 3456.

Step 6: Generate .4gl stub to access the .NET library

Use the fglwsdl tool to generate the client stub to access the BarcodeService, as follows:

$ fglwsdl http://localhost/BarCodeService.asmx?WSDL

This will create two .4gl files, which must be compiled and linked into your BDL application in order to call the .NET barcode library functions. These files contain the BDL interface to access the .NET library where you will find the function buildImage, defined in BDL.

In the final step we modify the existing application, Step 7: Modify your BDL application on page 3456.

Related concepts

WS client stubs and handlers on page 3328
To access a remote Web Service, you first must get the WSDL information from the service provider.

Step 7: Modify your BDL application

Modify your existing application, where you want to use the .NET library, by calling the BDL functions generated in the stub. Then compile your application and the previously generated stubs, and link everything together.

Your application is now ready to use the different features of your .NET library.

**Example BDL program**

This program calls the `buildImage` function of the Barcode.NET library.

```bdl
GLOBALS "BarCode_BarCodeSoap.inc"
MAIN
  DEFINE wsstatus INTEGER
  IF num_args() != 3 THEN
    CALL ExitHelp()
  END IF

  LET buildImage.type = arg_val(1)
  LET buildImage.code = arg_val(2)
  LOCATE buildImageResponse.buildImageResult IN MEMORY

  LET wsstatus = buildImage_g()
  IF wsstatus <> 0 THEN
    DISPLAY "Error ("||wsError.code||") : ",wsError.description
  ELSE
    IF buildImageResponse.buildImageResult IS NULL THEN
      DISPLAY "Encoding failed"
    ELSE
      CALL buildImageResponse.buildImageResult.writeFile(arg_val(3))
    END IF
  END IF

  FREE buildImageResponse.buildImageResult
END MAIN

FUNCTION ExitHelp()
  DISPLAY arg_val(0)||" <type> <data> <filename>"
  DISPLAY "type : barcode type such as EAN8 or CODE128"
  DISPLAY "data : data to be encoded with a barcode [0-9A-D]"
  DISPLAY "filename : resulting image filename"
  DISPLAY "example : createImage EAN8 12358723A mybarcode.jpg"
  EXIT PROGRAM (-1)
END FUNCTION
```

**Conclusion**

It is quite easy to interact with a .NET library from Genero using .NET Visual Studio and the web services. Of course you also need an IIS Web server installed on your Windows® system. This means that you can, in the same Genero application, interact with .NET and Java libraries without any strong linkage between Genero and the third party libraries you want to use. This meets the SOA principles that provide more flexibility to your entire BDL application.

You can integrate any new library from another vendor, without the risk of conflicts between different libraries that can happen if you had to link everything together in C or Java.

You can upgrade a third party library without recompiling the BDL application, which will still work.

You can use all these third party libraries in other BDL or other applications.

**Compute a hash value from a BDL string**

How to compute a hash value of a BDL string using the `security.Digest` API.

**Program Example**

This retrieves the hash value from the signature and returns it. The computed hash value is encoded in Base64, so you may have additional conversion to do.
Program example ComputeHash.4gl:

IMPORT SECURITY

MAIN

DEFINE result STRING

IF num_args() != 2 THEN
    DISPLAY "Usage: ComputeHash <string> <hashcode">
    DISPLAY " string: the string to digest"
    DISPLAY " hashcode: SHA1, SHA512, SHA384, SHA256, SHA224, MD5"
ELSE
    LET result = ComputeHash(arg_val(1), arg_val(2))
    IF result IS NOT NULL THEN
        DISPLAY "Hash value is: ", result
    ELSE
        DISPLAY "Error"
    END IF
END IF

END MAIN

FUNCTION ComputeHash(toDigest, algo)

DEFINE toDigest, algo, result STRING
DEFINE dgst security.Digest

TRY
    LET dgst = security.Digest.CreateDigest(algo)
    CALL dgst.AddStringData(toDigest)
    LET result = dgst.DoBase64Digest()
CATCH
    DISPLAY "ERROR : ", STATUS, " - ", SQLCA.SQLERRM
    EXIT PROGRAM(-1)
END TRY

RETURN result

END FUNCTION

Example execution:

$ fglrun ComputeHash "Hello World" SHA1
Hash value is: Ck1VqNd45QIvq3AZd8XYQLvEhtA=

The Genero Web Services security package provides classes and methods to support basic cryptographic features.

**Deploy a Web Service**

Genero Web services need to be deployed on a Genero Application Server that plugs into a Web server, such as Apache. Understand what you need to implement for configuration and security.

**Web services server program deployment**

The Genero Application Server (GAS) manages Web services. You must consider GAS configuration when deploying your Web service in a production environment.

**Introduction**

In a production environment, Genero Web Services becomes a part of a global application architecture handled by the Genero Application Server (GAS). The GWS DVMs are managed by the GAS.

This architecture takes care of:

- Security issues
- Scalability
- Load management
- Balancing of the Web service requests amongst the available virtual machines
- Runtime monitoring

**GAS configuration**

For deployment, the GWS Server application must be added to the GAS configuration. See *Configure applications for Web service* in the *Genero Application Server User Guide*.

The web services application can be added to the GAS in different ways:

- **GWS Server application implementing a single Web service.**
  
  This application can be deployed on various physical machines. A Genero Web Services VMProxy (GWSProxy) is started on each machine where the GWS Server application is executed, to manage the requests for a service and manage the DVMs that handle the requests. A single VMProxy can communicate with multiple GWS DVMs, and manage the load balancing.

- **GWS Server application implementing multiple Web Services.**
  
  The GWSProxy would manage the client requests, dispatching the request to the appropriate DVM and the appropriate web service.

**Note:** A Web Service Server must be stateless; several instances of the same Service can be created to support load balancing.

The basic deployment strategy can be implemented in varying permutations, depending on your business needs and the volume of requests.
### Figure 141: Deployment strategy

- Using the World Wide Web, a Web Service client requests WSDL information for a particular Web Service from the Web Server.
- The Web Service client uses this information to make a Web Service request from the Web Server.
- The Web server passes the request to the GAS dispatcher.
- The GAS dispatcher starts a GWSProxy, which will be in charge of the pool of DVMs that will serve the web service application.
- The GWSProxy will start the number of DVMs specified by the START element defined for the web service application.

For a more detailed explanation of the Services Pool for web services, refer to the GAS Architecture topic in the Genero Application Server User Guide.

### Access the web services server from a client application

To reach the web service from the internet, client applications must use the following URL form:

```
http://host_name/ws/r/app_id
```

1. `host_name` defines the web server host name where the GAS is running.
2. `app_id` is the XCF file of the GAS web services application.

### Related concepts

Introducing the GAS and JGAS on page 2183

The Genero Application Server (GAS) is an engine that plugs in to a Web server for the purpose of delivering Genero Web applications and services. A general knowledge of how they operate can be helpful in testing and deploying Web applications.

### Configuring the Apache Web server for HTTPS

Configuration steps to secure a Web service for Apache server in HTTPS.

The first three steps are for the creation of all X.509 certificates. Certificates are created using the OpenSSL command line tool. The next three steps are for server configuration.

### Related concepts

Encryption and authentication on page 3299

A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

The OpenSSL (openssl) tool on page 3313

The openssl command line tool creates certificates for the configuration of secured communications.

### Related tasks

View a certificate on page 3316
This procedure allows you to view a certificate using the `openssl` command.

**Step 1: Create the root certificate authority**
Generate a root certificate authority that signs a client certificate.

- Create the root certificate authority serial file:
  
  ```
  $ echo 01 > MyCompanyCA.srl
  ```

- Create the Root Authority's Certificate Signing Request and private key:
  
  ```
  $ openssl req -new -out MyCompanyCA.csr -keyout MyCompanyCA.pem
  ```

- Create the Root Certificate Authority for a period of validity of 2 years:
  
  ```
  $ openssl x509 -trustout -in MyCompanyCA.csr -out MyCompanyCA.crt
  -req -signkey MyCompanyCA.pem -days 730
  ```

**Important:** The private key file (`MyCompanyCA.pem`) of a Root Certificate Authority must be handled with care. This file is responsible for the validity of all other certificates it has signed. As a result, it must not be accessible by other users.

In the next step we create the server's certificate and private key, **Step 2: Create the server's certificate and private key** on page 3461.

**Step 2: Create the server's certificate and private key**
The server's certificate identifies the server as trusted by any client that connects to it.

- Create the server's serial file:
  
  ```
  $ echo 01 > MyServer.srl
  ```

- Create the server's Certificate Signing Request and private key:
  
  ```
  $ openssl req -new -out MyServer.csr
  ```

  **Note:** By default, `openssl` outputs the private key in the `privkey.pem` file.

- Remove the password from the private key:
  
  ```
  $ openssl rsa -in privkey.pem -out MyServer.pem
  ```

  **Note:** The key is also renamed in `MyServer.pem`.

- Create the server's Certificate trusted by the Root Certificate Authority:
  
  ```
  $ openssl x509 -in MyServer.csr -out MyServer.crt
  -req -signkey MyServer.pem -CA MyCompanyCA.crt -CAkey MyCompanyCA.pem
  ```

  **Note:** The purpose of the server's Certificate is to identify the server to any client that connects to it. Therefore, **the subject of that server's certificate must match the host name of the server as it is known on the network**; otherwise the client will not trust the server's identity and the communication is stopped. For instance, if the URL of the server is `https://www.MyServer.com/fastcgi/ws/r/MyWebService`, the subject must be `www.MyServer.com`.

In the next step we create the server's certificate authority list, **Step 3: Create the server's certificate authority list** on page 3462.
Step 3: Create the server’s certificate authority list
Create the certificate authority list and add the root certificate authority cert.

- Create the server’s Certificate Authority List:
  
  ```
  $ openssl x509 -in MyCompanyCA.crt -text >> ServerCAList.pem
  ```

  **Note:** As the server trusts only the Root Certificate Authority, the list contains only that one certificate authority; all other certificates that were trusted by the Root Certificate Authority will also be considered as trusted by the server.

In the next step we register the server's certificate authority list, Step 4: Register the server as a Web service in the GAS on page 3462.

Step 4: Register the server as a Web service in the GAS
Web services registered on the GAS are started automatically when the GAS starts.

As the Web server is in charge of the complete HTTPS protocol with all the clients, there is no additional GAS configuration needed to add security. Simply register the BDL server to the list of Web Services of the GAS. For more information, refer to the Genero Application Server User Guide.

For more details, see Web services server program deployment on page 3459.

In the next step we configure Apache for HTTPS, Step 5: Configure Apache for HTTPS on page 3462.

Step 5: Configure Apache for HTTPS
Add the locations of your certs to the Apache configuration file.

You must configure Apache to support HTTPS by adding the required modules. Refer to the Apache Web server documentation for more information.

- For the Apache 1.3 manual, go to http://httpd.apache.org/docs/1.3.
- For the Apache 2.0 manual, go to http://httpd.apache.org/docs/2.0/.

Once the Apache Web server supports HTTPS, you must change or add the following directives to the Apache configuration file:

- Set the Apache Web server Certificate Authority List directive created in Step 3:
  ```
  SSLCACertificateFile D:/Apache-Server/conf/ssl/ServerCAList.pem
  ```

- Set the Apache Web server Certificate and associated private key directives created in Step 2:
  ```
  SSLCertificateFile D:/Apache-Server/conf/ssl/MyServer.crt
  SSLCertificateKeyFile D:/Apache-Server/conf/ssl/MyServer.pem
  ```

- Require the Apache Web server to verify the validity of all client certificates:
  ```
  SSLSVerifyClient require
  ```

  **Note:** The Apache Web server must be started on a machine where the host is the same as the one defined in the subject of the server's certificate (www.MyServer.com in our example).

In the next step we configure Apache for HTTP basic authentication, Step 6: Configure Apache for HTTP basic authentication on page 3462.

Step 6: Configure Apache for HTTP basic authentication
Create login details for an authenticated user for the Apache web server, and add the location of your authentication file to the Apache configuration file.

You must configure Apache to support HTTP basic authentication by adding the required modules. Refer to the Apache Web server documentation for more information.

- For the Apache 1.3 manual, go to http://httpd.apache.org/docs/1.3.
- For the Apache 2.0 manual, go to http://httpd.apache.org/docs/2.0/.
Once the Apache Web server supports HTTP basic authentication, you must:

1. Add an user to the Apache Web server basic authentication file with the same login and password as defined for the client.

   Apache provides the tool htpasswd that you can use to create the file and add the user. To add the user `mylogin` with the password `mypassword` to a new file called `myusers`:

   ```
   $ htpasswd -c myusers mylogin mypassword
   ```

   **Note:** To add additional users, remove the option `-c`.

2. Add an Apache Web server location directive that enables you to group several directives for one URL. (In the example, the URL is `/fastcgi/ws/r/MyWebService`).

   The following example (based on Apache 2.0) defines the HTTP authentication type (Basic), with a user file (`user-basic`) containing the login and password of those who are allowed to access the service.

   ```
   <Location /fastcgi/ws/r/MyWebService>
   AllowOverride None
   Order allow,deny
   Allow from all
   #
   # Basic HTTP authenticate configuration
   #
   AuthName "Top secret"
   AuthType Basic
   AuthUserFile "D:/Apache-Server/conf/authenticate/myusers"
   Require valid-user # Means any user in the password file
   </Location>
   ```

   For more information about Apache Web server directives, refer to the Apache Web Server manual.

<tr>
<td>WSScope = &quot;{</td>
<td>scope ↓ ❱,❙,❍,❱&quot;</td>
</tr>
</tbody>
</table>

Resource operation attributes
Attributes that map an HTTP operation in a function to a REST resource.

Important: One HTTP verb action such as WSGet, WSPost, WSPut, or WSDelete is a mandatory attribute in a REST Web service function.

Related concepts
Define your resource operations on page 3377
Operations are the HTTP methods used to manipulate the resources of your Web service.

HTTP verbs and attributes
HTTP verbs are defined by the high-level RESTful attributes. Some verbs have requirements for request or response body and others do not.

Table 729: HTTP verbs and attributes on page 3466 provides a list of HTTP verbs and their corresponding attributes. In the Request body and Response body columns, you find information about each verb's requirements for message body. In summary:

- POST, and PUT requests are the only verbs that require an input message body. Failing to specify a message body in a request will cause the error-9106.
When you compile your Web service application, the fglcomp tool checks that attributes comply with these requirements.

**Table 729: HTTP verbs and attributes**

<table>
<thead>
<tr>
<th>Verbs</th>
<th>Attributes</th>
<th>Request body</th>
<th>Response body</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>WSGet</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>POST</td>
<td>WSPost</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>PUT</td>
<td>WSPut</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>DELETE</td>
<td>WSDelete</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

**Related concepts**

Set a request body on page 3383

Functions that create or update a resource need to set a request body for the incoming payload. You specify the request body in an input parameter.

Set a response body and header on page 3384

Functions that create, update, delete, or get a resource need to set a response body. You specify this in a return parameter without an attribute. Other return values can be sent in headers, using the WSHeader attribute.

**WSDelete**

In order to remove an existing resource, you set the WSDelete attribute.

**Syntax**

```
WSDelete
```

**Usage**

You use this attribute to specify the action of the HTTP verb DELETE to delete a resource. You set the WSDelete attribute in the ATTRIBUTES() clause of the function.

**Example using WSDelete to delete a resource**

```public function DeleteUserProfile(
    id STRING ATTRIBUTE(WSParam) )
attributes (WSDelete,
    WSPath="/users/{id}",
    WSDescription='Deletes a user profile',
    WSThrows='404:user not found')
returns STRING
    define ret STRING
    # ... function code ...
    let ret = sfmt("Deleted user with ID: %1",id)
    return ret
end function```

In this example the resource specified in the URL is deleted.

```
http://host:port/gas/ws/r/xcf/users/xxx
```

`xxx` is the user id replaced in the Genero BDL function.
**WSGet**
In order to retrieve a resource, you set the WSGet attribute.

**Syntax**

```
WSGet
```

**Usage**
You use this attribute to specify the action of the HTTP verb GET to return data from a resource. You set the `WSGet` attribute in the `ATTRIBUTES()` clause of the function.

**Example using WSGet to return a user record**

```
TYPE profileType RECORD ... END RECORD

PUBLIC FUNCTION GetUserProfile(
    id STRING ATTRIBUTE(WSParam)
) ATTRIBUTES (WSGet,
    WSPath="/users/{id}",
    WSDescription="Returns a user profile",
    WSThrows="404:user not found"
) RETURNS (profileType ATTRIBUTE(WSName="User_data", WSMedia="application/json")
)
    DEFINE data profileType
    # ... function code ...
    RETURN data.*
END FUNCTION
```

In this example the REST function gets the specified user record. The resource URL is:

```
http://host:port/gas/ws/r/xcf/users/xxx
```

`xxx` is the user id replaced in the Genero BDL function.

**Related concepts**

- Example: Get operation with WSGet on page 3377
- Example of methods you can use to get data from a resource with the WSGet attribute.

**WSPost**
In order to create a new resource, you set the WSPost attribute.

**Syntax**

```
WSPost
```

**Usage**
You use this attribute to specify the action of the HTTP verb POST to create a new resource. You set the `WSPost` attribute in the `ATTRIBUTES()` clause of your function.

**Example WSPost to create a new user record**

```
TYPE profileType RECORD ... END RECORD

PUBLIC FUNCTION CreateUserProfile( newUser profileType )
    ATTRIBUTES (WSPost,
        WSPath="/users",
        WSThrows="404:user not found")
```

**Example: Get operation with WSGet on page 3377**

Example of methods you can use to get data from a resource with the WSGet attribute.
returns string
define ret string
# ... function code ...
let ret = sfmt("Created user with ID: %1",id)
return ret
end function

In this example a new resource is created. newUser is data passed in the message body in either JSON or XML format. An example of the resource URL is:

http://host:port/gas/ws/r/xcf/users

WSPut
Update an existing resource with the WSPut attribute.

Syntax

WSPut

Usage
You use this attribute to specify the action of the HTTP verb PUT to update an existing resource. You set the WSPut attribute in the ATTRIBUTES() clause of the function.

Example WSPut to update a user record

TYPE profileType RECORD ...
END RECORD

PUBLIC FUNCTION UpdateUserProfile(
    id STRING ATTRIBUTE(WSParam),
    thisUser profileType )
ATTRIBUTES( WSPut,
    WSPath="/users/{id}",
    WSDescription="Update user with the given id",
    WSThrows='404:user not found')
returns string
define ret string
# ... function code ...
let ret = sfmt("Updated user with ID: %1",id)
return ret
end function

In this example, a resource is updated. thisUser is data passed in the message body in either JSON or XML format. An example of the resource URL shows xxx as the user id replaced in the Genero BDL function.

http://host:port/gas/ws/r/xcf/users/xxx

Path templating attributes
Attributes that define the format of the URL of the REST functions.

Related concepts
Set resource path with WSParam and WSPath on page 3380
Path parameters allow you to specify variables in the resource URL.

**WSPParam**
Specifies a value for a template path to a REST Web service resource.

**Syntax**

```
WSPParam
```

**Usage**

You use this attribute for path templating to specify values that are provided at runtime in function parameters. You set the WSP Param attribute in the ATTRIBUTES() clause of the function.

For each Genero BDL function parameter with a WSPParam attribute, there must be a matching template path in the WSPPath on page 3469. fglcomp checks to ensure that there is one template value per parameter, otherwise compilation error-9111 is thrown.

WSPParam is an optional attribute.

**Example path templating with WSPParam**

```plaintext
TYPE accountType RECORD ... END RECORD

PUBLIC FUNCTION getAccountById(id INTEGER ATTRIBUTE(WSPParam))

    ATTRIBUTES(WSGet,
        WSPPath="/accounts/{id}",
        WSDescription="Returns an account record",
        WSThrows="404:not found"
    )
    RETURNS accountType ATTRIBUTES(WSName="Account",WSMedia="application/xml")
    DEFINE p_accountRec accountType
    # ... function code ...
    RETURN p_accountRec.*
END FUNCTION
```

The client application needs to provide an appropriate parameter value when making a call to the function. For example, the variable part of the path (id) is replaced by the integer value /4 in the URL:

```
http://host:port/gas/ws/r/MyService/accounts/4
```

**Related concepts**

- Set resource path with WSPParam and WSPPath on page 3380
  Path parameters allow you to specify variables in the resource URL.
- Set query, header, or cookie parameters (if needed) on page 3382
  You define these parameters in your function if the resource needs data to be passed as query, cookie, or header.

**WSPPath**

Specifies a path to a REST Web service resource that identifies its function and allows parameters to be passed in the URL.

**Syntax**

```
WSPPath = "// path-element value-template /..."
```
where *path-element* is an identifier:

```
identifier
```

and where *value-template* is an identifier enclosed in curly brackets:

```
{identifier}
```

1. *path-element* is a slash-separated list of path elements
2. *value-template* elements are place holders for a slash-separated list of variable values.

**Usage**

You use this attribute to set the URL to a resource. A URL to, for example, the "users" resource is specified as follows:

```
WSPath="/users"
```

**Note:** The **WSPath** string begins with a slash (/), and there is a slash between each path element and/or template value.

If you need to specify a resource within a collection, such as a specific user identified by ID, and when a pattern could match many similar resources, it is specified with a path template.

```
WSPath=/users/{id}
```

The path template is an identifier enclosed in curly brackets { }. Zero, one, or several path templates can be specified. Values are substituted when a GWS client makes a call to the resource.

Path template values are provided at runtime in function parameters which have **WSParam** on page 3469 attributes. As many template values as path templates must be specified. In other words there must be a function parameter with a **WSParam** attribute to match each template path. **fglcomp** checks to ensure that there is one template value per parameter, otherwise compilation error-9111 is thrown.

You set the **WSPath** attribute in the **ATTRIBUTES()** clause of the function. **WSPath** is an optional attribute. If there is no **WSPath** specified, the function name (case sensitive) is the path to the resource in the URL.

**Example path templating with **WSParam**

```
TYPE accountType RECORD ... END RECORD

PUBLIC FUNCTION getAccountById(id INTEGER ATTRIBUTE(WSParam))

   ATTRIBUTES(WGet,
      WPath="/accounts/{id}",
      WDescription="Returns an account record",
      WThrows="404: not found"
   )
   RETURNS accountType ATTRIBUTES(WSName="Account",WMedia="application/xml")
   DEFINE p_accountRec accountType
   # ... function code ...
   RETURN p_accountRec.*
END FUNCTION
```

The client application needs to provide an appropriate parameter value when making a call to the function. For example, the variable part of the path *(id)* is replaced by the integer value /4 in the URL:

```
http://host:port/gas/ws/r/MyService/accounts/4
```
Related concepts

Set resource path with WParam and WPath on page 3380

Path parameters allow you to specify variables in the resource URL.

Set query, header, or cookie parameters (if needed) on page 3382

You define these parameters in your function if the resource needs data to be passed as query, cookie, or header.

Query, cookie, header attributes

Standard REST attributes defining parameters handling queries, cookies, and headers in REST functions.

WSQuery

Specifies parameters to be passed at the end of the request URL after a question mark (‘?’).

Syntax

```
WSQuery
```

This attribute supports a query in the URL. Zero, one, or several parameters can be specified.

WSQuery is an optional attribute.

Usage

You set the WSQuery attribute in an ATTRIBUTE() clause of an input parameter (only) of the function. Its use is suited to filtering on resource collections. The client application needs to provide appropriate parameter values in the URL when making a call to the function, such as /users?fname=john.

Example WSQuery

```
TYPE accountType RECORD
   id VARCHAR(10),
   fname VARCHAR(25),
   lname VARCHAR(25)
# ...
END RECORD

PUBLIC FUNCTION getAccountRecords(
   resourceId VARCHAR(10) ATTRIBUTES(WSQuery, WOptional, WSName = "id"),
   firstName VARCHAR(25) ATTRIBUTES(WSQuery, WOptional, WSName = "fname"),
   lastName VARCHAR(25) ATTRIBUTES(WSQuery, WOptional, WSName = "lname"))
   ATTRIBUTES (WGet,
      WPath = "/accounts",
      WDescription = "Fetches the accounts resource with the optional filter value(s) applied.",
      WScope = "officestore.user",
      WThrows = "404:Not Found,500:Internal Server Error"
   )
   RETURNS (DYNAMIC ARRAY ATTRIBUTE(WSName = "accounts") OF
      accountType ATTRIBUTES(XMLName = "account", WMedia = "application/json, application/xml"))
   
   DEFINE recList DYNAMIC ARRAY OF accountType
   # ... function code ...
   RETURN recList

END FUNCTION
```

This function has WSQuery parameters which are optional. This allows the function to be used to query any of the parameter values if provided in the query string of the URL, for example:

```
http://host:port/gas/ws/r/MyService/accounts?fname=value&lname=value
```
WSHeader

Defines custom headers in the request and response of Web service functions.

Syntax

```plaintext
WSHeader
```

Where:

WSHeader is defined in an `ATTRIBUTE()` clause in an input parameter or return value of the function.

Usage

You use the `WSHeader` attribute to define a custom header. It is valid to set this in input parameters and in return values. A typical use of `WSHeader` is to pass data related to the service in the form of HTTP header.

Example WSHeader in input parameter

```plaintext
IMPORT com

PUBLIC DEFINE myerror RECORD ATTRIBUTE(WSError="My error")
    code INTEGER,
    reason STRING
END RECORD

PUBLIC FUNCTION getRemoteAddress (ip_addr STRING
    ATTRIBUTE(WSHeader, WSOptional, WSName="X-FourJs-Environment-Variable-REMOTE_ADDR")
) 
    ATTRIBUTES (WSGet,
        WSPath="/users/ip",
        WSDescription="Get remote address of the client",
        WSThrows="400:Invalid,404:NotAvailable"
    )
    RETURNS ( INTEGER ATTRIBUTE(WSHeader), STRING)
    DEFINE ip STRING
    TRY
        LET ip=ip_addr
        IF ip IS NULL THEN
            LET ip="Got no remote address."
        ELSE
            LET ip = SFMT("Hello there, you're at %1",ip )
        END if
    CATCH
        LET ip="Error getting remote address."
        LET myerror.reason = SFMT("Error during execution: %1 [%2]", SQLCA.SQLCODE, SQLERRMESSAGE )
        CALL com.WebServiceEngine.SetRestError(400,myerror)
    END TRY
    RETURN 3, ip
END FUNCTION
```

In the call to the function, a header named "X-FourJs-Environment-Variable-REMOTE_ADDR" provides the IP address of the remote client. The input is optional as defined by the attribute `WSOptional`.

Tip: The `WSContext` on page 3481 attribute, if set, can provide your service with access to environment variables set by the GAS.
Example WSHeader in return value

PUBLIC FUNCTION help()
    ATTRIBUTES (WSGet)
    RETURNS (INTEGER ATTRIBUTE(WSHeader), STRING)
    # ... function code ... 
    RETURN 3, "hello world"
END FUNCTION

In the response, you define a custom header in the RETURNS clause of your function.

In the HTTP output the integer ("3") is returned in the header and the string ("hello world") is returned in the response body.

Unnamed parameters and return values are given default names, "rv0", "rv1", etc., at runtime. You can change default header naming via the WSName on page 3475 attribute, for example with: ATTRIBUTE(WSHeader, WSName="MyHeader")

WSCookie
Allows cookies to be passed to Web service REST function.

Syntax

WSCookie

Usage

You set this attribute to indicate that a parameter value will transport a cookie. The client application needs to provide the appropriate header and value when making a call to the function.

WSCookie is defined in an ATTRIBUTE() clause of an input parameter of the function.

WSCookie is an optional attribute.

Example WSCookie

IMPORT  com

TYPE profileType RECORD
    id INT,
    name VARCHAR(50),
    email VARCHAR(100),
    ccode VARCHAR(10)
    # ...
END RECORD

DEFINE myError RECORD ATTRIBUTE(WSError="My error")
    code INTEGER,
    reason STRING
END RECORD

PUBLIC FUNCTION getUsersByMyCountry(
    p_country STRING ATTRIBUTE(WSCookie, WSOptional, WSName = "Preferred_country") )
    ATTRIBUTES (WSGet,
        WSPath="/users",
        WSDescription="Get users with cookie (for country) if sent from client.",
        WSThrows="400:Invalid,404:NotAvailable"
    )
    RETURNS (
        DYNAMIC ARRAY ATTRIBUTE(WSName="Users",WSMedia="application/xml,application/json") OF profileType
In the call to the function, a header named "Preferred_country" provides the cookie value.

**Name, description, optional attributes**
Standard REST attributes define names for, and descriptions of parameters. Optional parameters are set using the optional attribute in REST functions.

**WSDescription**
Describes REST function parameters.

**Syntax**

```plaintext
WSDescription
```

**Usage**
You use this attribute to provide useful description for parameters in the function. You can set `WSDescription` on:

- Any input and output parameter of a REST operation.
- The attribute clause of the function.

Information you specify with this attribute, is generated for the function in the OpenAPI specification file. You can control generation of descriptions in the stub file with the `--comment` option of the `fglrestful` on page 2085 tool.

**Example using WSDescription**

```plaintext
TYPE orderType RECORD ... END RECORD

PUBLIC FUNCTION getOrders(  
category STRING ATTRIBUTE(WSQuery, WSOptional,  
WSName="cat",WSDescription="Product category"),  
sortfield STRING ATTRIBUTE(WSHeader, WSOptional,  
WSName="sortfld",WSDescription="Sort field"),  
popbrand STRING ATTRIBUTE(WSCookie, WSOptional, WSNamem =  
"popbrand",WSDescription="Most popular brand"))  
ATTRIBUTES (WSGet,
```
WSPath = "/orders",
    WSDescription = "Fetches orders from the resource with the optional filter value(s) applied."
    WSScope = "officestore.user",
    WSThrows = "404:Not Found,500:Internal Server Error"
) 
RETURNS (DYNAMIC ARRAY ATTRIBUTE(WSName = "Orders") OF orderType 
    ATTRIBUTES(XMLName = "order", 
        WSMedia = "application/xml") ) 

    DEFINE orderList DYNAMIC ARRAY OF orderType 

        # ... function code to get orders ...
        RETURN orderList 
    END FUNCTION

Related concepts

Set a request body on page 3383
Functions that create or update a resource need to set a request body for the incoming payload. You specify the request body in an input parameter.

Set a response body and header on page 3384
Functions that create, update, delete, or get a resource need to set a response body. You specify this in a return parameter without an attribute. Other return values can be sent in headers, using the WSHeader attribute.

WSName
Specify alternative names for parameters in a REST function.

Syntax

WSName

Usage

Use this attribute to specify names for parameters in a REST function. In general, you do not need to use WSName. Consider using it to improve the readability of input parameters or to formats the data returned in the response.

WSName is an optional attribute.

Example 1: Providing an alternative name

You need to use WSName to provide the required name, if the input parameter name cannot be used as a variable name in your REST function.

For example, if you need to pass parameters for the Genero Application Server environment, you will need to use WSName. These variables (for example, X-FourJs-XXX) have hyphens, which are not allowed in Genero BDL variables. WSName allows you to use a parameter name that is BDL friendly but provide the required name of the variable in the header.

PUBLIC FUNCTION getRemoteAddress (remote_ip_addr STRING 
    ATTRIBUTE(WSHeader, WSOptional, WSName="X-FourJs-Environment-Variable-REMOTE_ADDR") )

In the HTTP request, there will be a header named "X-FourJs-Environment-Variable-REMOTE_ADDR", not "remote_ip_addr". In your function, you reference the variable using the "remote_ip_addr" variable name.

Example 2: Providing a user-friendly parameter name

You would consider setting the WSName attribute clause of a parameter, if the parameter name is not obvious or user-friendly.
For example, if the parameter references a field name in a database table that is abbreviated, or could be ambiguous in your function, WSName provides you with an option to provide a clearer name.

```plaintext
PUBLIC FUNCTION getUsers(reg STRING ATTRIBUTE(WSQuery, WSOptional, 
                          WSName="region"), 
                          ccode STRING ATTRIBUTE(WSHeader, WSName="country") ) 
```

In the HTTP request:

- There will be a header named "country", not "ccode".
- In the URL to call the REST function, you must use the value specified by WSName (not the parameter name) for the query:

  ```plaintext
  http://host:port/gas/ws/r/MyService/users?region=alsace
  ```

**Example 3: Formatting output data**

You can use WSName to format the output data. It allows you to override the default naming convention ("rv0", "rv1", etc., ) that is otherwise output at runtime. By specifying a more recognizable name for the data, you improve the readability of the output.

In the example, the attribute names the array "Users". This name will appear as the root path for the output in JSON, or the root tag for the output in XML.

```plaintext
TYPE userType RECORD ... END RECORD 

PUBLIC FUNCTION getUsers()
  ATTRIBUTES (WSGet, 
              WSPath="/users", 
              WSDescription="Get users resource ", 
              WSThrows="400:Invalid,404:NotAvailable" ) 
  RETURNS (DYNAMIC ARRAY ATTRIBUTE(WSName = "Users") OF 
            userType ATTRIBUTES(WSMedia = "application/json, application/xml"))

  DEFINE regionList DYNAMIC ARRAY OF userType 
  # ... function code ... 
  RETURN regionList 
END FUNCTION
```

**Related concepts**

- Customize XML serialization with WSName and XMLName on page 3394
- Use the WSName and XMLName attributes to customize serialization at runtime and improve the readability of the XML output.

**WSOptional**

Qualifies a parameter as optional in a REST function.

**Syntax**

```plaintext
WSOptional
```

**Usage**

You use this attribute to specify a parameter in a REST function as optional. You set the WSOptional attribute in the ATTRIBUTE() clause of the parameter.
WSOptional can be set only with the following attributes:

- **WSQuery** on page 3471
- **WSHeader** on page 3472 (input, output)
- **WSCookie** on page 3473

**Example optional cookie**

```plaintext
IMPORT  com

TYPE profileType RECORD
   id INT,
   name VARCHAR(50),
   email VARCHAR(100),
   ccode VARCHAR(10)
   # ...
END RECORD

DEFINE myError RECORD ATTRIBUTE(WSError="My error")
   code    INTEGER,
   reason  STRING
END RECORD

PUBLIC FUNCTION getUsersByCountry(
   p_country STRING ATTRIBUTE(WSCookie, WSOptional, WSName = "Preferred_country")
) ATTRIBUTES (WSGet,
   WSPath="/users",
   WSDescription="Get users by country if the cookie is sent by client.",
   WSThrows="400:Invalid,404:NotAvailable"
) RETURNS (DYNAMIC ARRAY ATTRIBUTE(WSName="Users",WSMedia="application/xml,application/json") OF profileType)

   DEFINE countryList DYNAMIC ARRAY OF profileType
   IF p_country IS NULL THEN
      SELECT * FROM users
   ELSE
      SELECT * FROM users WHERE @ccode=p_country
   END IF
   #... function code ...
RETURN countryList
END FUNCTION
```

**File handling attributes**
Attributes that define file attachment handling in REST services and functions.

**WSAttachment**
Defines file attachments in the REST message.

**Syntax**

```plaintext
WSAttachment
```

**Usage**
You use this attribute to define attachment files. Files may be attached in the message response or request.
In order to send a file as an attachment, you can have only one input parameter in the request. You specify the absolute path to the file in this parameter.

The file attachment MIME type can be set by the WSMedia attribute. If WSMedia is not specified, the engine accepts it as the OpenAPI specification for all file types, "/*".

For instance, if a text file is to be returned as an attachment, you handle this by adding the attribute WSAattachment to a STRING parameter and by setting the WSMedia attribute to MIME type "text/plain". You must also provide the absolute path to the file.

**Example WSAattachment with WSMedia**

```plaintext
PUBLIC FUNCTION Get()
    ATTRIBUTES(WSGet)
    RETURNS (STRING ATTRIBUTE(WSAttachment, WSMedia="text/plain") )
        # ... function code ...
        RETURN "/usr/tmp/myfile.txt"
END FUNCTION
```

The REST engine copies the file to the temporary directory defined by the TMP environment variable.

**Note:** The file is removed from the temporary directory at the end of the REST operation to avoid a build-up of files on your disk.

If you are attaching an image, it is defined in WSMedia with a wildcard to allow for all image types:

```plaintext
input STRING ATTRIBUTE (WSAttachment, WSMedia="image/*")
```

If the file can be any type, WSMedia is not specified.

```plaintext
input STRING ATTRIBUTE (WSAttachment)
```

The payload format is chosen according to that specified in the Content-Type header received from the client using the Web service. You code in your function to replace the image/* placeholder in the Content-Type header with the actual value. This can be done, for instance, using the WSCContext attribute, to set the header.

**Related concepts**

- **Handling file attachments with REST** on page 3386
  The Genero REST high-level framework provides two mechanisms for handling attachments.

- **Multipart requests or responses** on page 3394
  In GWS REST there is support for the standard multiple part message, in which more than one different sets of data are combined in a single body.

**WSMedia**

Defines the data format of the REST message.

**Syntax**

```
WSMedia = " MIME-type [, ...]"
```

Where WSMedia is a comma-separated list of MIME types:

1. **MIME-type** is a supported data format type.

**Usage**

You use this attribute to define the supported data format of the message. You set the WSMedia attribute in the ATTRIBUTE() clause of variables and/or on input and output function parameters.
Example WSMedia with record variable

In this example a record is defined with a list of MIME types with WSMedia to allow the function handle different formats. The payload format is chosen according to that specified in the Accept header received from the client using the Web service.

```plaintext
PUBLIC DEFINE myRecord RECORD
  ATTRIBUTE (WSMedia=
    "application/json, application/xml, application/x-www-form-urlencoded")
    a INTEGER,
    b FLOAT,
    c STRING
END RECORD
```

Table 730: Supported MIME types on page 3479 outlines the data formats supported via the WSMedia attribute with corresponding default data types where applicable:

<table>
<thead>
<tr>
<th>MIME type</th>
<th>Default data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>application/json</td>
<td>Record and array</td>
</tr>
<tr>
<td>application/xml</td>
<td>Record and array</td>
</tr>
<tr>
<td>application/x-www-urlencoded</td>
<td>Record (only)</td>
</tr>
<tr>
<td>text/plain</td>
<td>Simpletype</td>
</tr>
<tr>
<td>application/octet-stream</td>
<td>BYTE</td>
</tr>
<tr>
<td>image/*</td>
<td>No default type</td>
</tr>
</tbody>
</table>

The actual format is chosen according to that specified in the Accept or Content-Type headers of HTTP requests and responses. See the example in WSContext on page 3481.

There is an order of precedence that defaults to the first MIME type listed in WSMedia when the Accept or Content-Type header is not present in the request. The format chosen can also depend on the data type used, for defaults, see Table 730: Supported MIME types on page 3479.

WSMedia and file attachments

If a file is to be attached, you can handle this through a parameter with a WSAAttachment on page 3477 and a WSMedia attribute. The REST engine is designed to accept the parameter value then as a path to a file to be attached. For instance, if the file is an image, it is defined with a wildcard to allow for all image types:

```plaintext
input STRING ATTRIBUTE (WSAttachment, WSMedia="image/*")
```

WSMedia is an optional attribute.

Related concepts

Handling file attachments with REST on page 3386
The Genero REST high-level framework provides two mechanisms for handling attachments.

Multipart requests or responses on page 3394
In GWS REST there is support for the standard multiple part message, in which more than one different sets of data are combined in a single body.

HTTP code attributes
Attributes that define HTTP code in the response from a REST functions.
WSRetCode
Defines the HTTP status sent in the REST response.

Syntax

```
WSRetCode = "↓ code ↓ code:description ↓ "
```

Where WSRetCode is a string enclosed in quotations and where:

1. `code` is an HTTP code representing successful status in the range 200 to 399.
2. `description` provides a description.

**Important:** If you use the `code` option without a description, the default fault description defined in RFC 2616 is returned to the client. If you use the `code` option with a description, there is no space before or after the colon (`:`).

**Usage**

You use WSRetCode in the ATTRIBUTES() clause of the REST function to specify the HTTP protocol status in the response. The HTTP code and HTTP description you provide is sent in the HTTP protocol response.

**Example using WSRetCode in REST function**

```
PUBLIC FUNCTION Add(
   a INTEGER ATTRIBUTE(WSQuery),
   b INTEGER ATTRIBUTE(WSQuery) )
ATTRIBUTES(WSGet,
   WSRetCode = "215:correct"
) 
RETURNS INTEGER
RETURN a + b
END FUNCTION
```

In this trivial example, instead of "200 OK", the HTTP response is changed to "215 correct".

**Figure 142: HTTP response using WSRetCode**

**Context handling attributes**
Attributes that defines the context for REST services and functions.
**WSContext**
Defines an injection variable to retrieve REST operation context values at the service level.

**Syntax**

```plaintext
WSContext
```

**Usage**
You can use it to retrieve REST operation context such as BaseURL, Media, and Scope, or you can set a default context for the Content-Type header if the WSMedia on page 3478 attribute value contains a wildcard.

You need to define a DICTIONARY variable in your REST module that specifies WSContext in an ATTRIBUTE() clause.

**Example definition for WSContext dictionary**

**Important:** The context variable needs to be a modular variable.

```plaintext
PRIVATE DEFINE Context DICTIONARY ATTRIBUTE(WSContext)OF STRING
```

The GWS engine sets the dictionary key/values before the function is executed. For examples of use in your REST function, see Table 731: Context dictionary on page 3482.
## Table 731: Context dictionary

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Media</strong></td>
<td>Provides one of the media values set in the <code>WSMedia</code> attribute of the input parameter. Or it provides the defaults if there is no attribute, or what the REST engine has chosen when several are possible.</td>
</tr>
<tr>
<td><strong>BaseURL</strong></td>
<td>Provides the base URL of the service when executed. For example, the URL is not the same in standalone as behind a GAS.</td>
</tr>
<tr>
<td><strong>Scope</strong></td>
<td>Provides the valid scope (if there is one) that grants access to the REST function.</td>
</tr>
<tr>
<td><strong>Content-Type</strong></td>
<td>Provides the real MIME-type the REST function returns if the <code>WSMedia</code> attribute value contains &quot;image/*&quot;.</td>
</tr>
</tbody>
</table>

**Example usage**

### Media

**DISPLAY**

```
context["Media"]
```

This may display, for instance, application/xml. If, for instance, `WSMedia` is set with a list of mime types, ("application/json,application/xml"), you can know the exact media type requested in the current execution of the function.

### BaseURL

**DISPLAY**

```
context["BaseURL"]
```

This displays the service's BaseURL, such as: HTTPS:// host:port/gas/ws/r/xcf/Account if the service has been registered as "Account".

This may be useful if your REST function has to query another function, for instance, and when the exact URL is needed.

### Scope

**DISPLAY**

```
context["Scope"]
```

This may display "profile.read".

If, for instance, `WSScope` on page 3486 has been set in the function with a list of scopes (for example, "profile.read, profile.write, profile.mgr"), it may be useful to know which one really applies in the current function execution.

**Important:** This is the only context dictionary value you can set at runtime.

**LET**

```
LET context["Content-Type"]="image/jpeg"
```

For example, this statement will set the returned `Content-Type` header to "image/jpeg" based on the media type requested at runtime.

*WSContext* is an optional attribute.
**WSContext with Content-Type set at runtime**

If the `WSMedia` return parameter attribute has a list of values or a wildcard value, "image/*", you code in a function to set the `Content-Type` header for the actual value returned at runtime in the response. Table 732: HTTP Header on page 3483 outlines options for defining the `Content-Type` header for the image.

**Table 732: HTTP Header**

<table>
<thead>
<tr>
<th>Header Name</th>
<th>Description</th>
<th>Required</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>The format of the image to upload.</td>
<td>Optional</td>
<td><code>image/jpeg</code>, or <code>image/png</code>, or <code>image/gif</code>, and so on.</td>
</tr>
</tbody>
</table>

**Example WSContext with Content-Type set at runtime**

```plaintext
PRIVATE DEFINE Context DICTIONARY ATTRIBUTE(WSContext) OF STRING
PUBLIC FUNCTION getImage( id INTEGER ATTRIBUTE(WSParam) )
  ATTRIBUTES (WGET,
    WSPartPath="/photos/{id}" )
  RETURNS STRING ATTRIBUTE (WSAttachment, WSMedia="image/*")
  DEFINE image BYTE
  DEFINE mime STRING
  # function code
  CASE mime
    WHEN "png"
      LET Context["Content-Type"]="image/png"
    WHEN "jpg"
      LET Context["Content-Type"]="image/jpg"
  END CASE
  RETURN image
END FUNCTION
```

**Error handling attributes**

Attributes that define error handling in REST services and functions.

**WSError**

Specifies a description of the status-code that is returned in the HTTP response.

**Syntax**

```plaintext
WSError = "description"
```

1. *description* defines a short description as the "Reason-Phrase" for the status-code that is returned in the HTTP response message.

**Usage**

You use this attribute in the management of application level errors in conjunction with `WSThrows` on page 3484. When you use `WSThrows` with the "code:@variable" option to return a description of the status-code instead of the standard HTTP status code description, you must reference a variable that has the `WSError` attribute.

You must set the attribute on a public variable defined at the modular level. You can define it as any Genero BDL simple or complex type depending on your requirements for the detail about the error. For example, if defined as a `RECORD` or `ARRAY`, by default, it will be serialized in `JSON/XML` on the client side. If you define it as a simple type, it will be serialized in `TEXT/PLAIN`.

You code in your REST function to set the variable at runtime with a specific reason for the HTTP status code. The response is sent in a call to the `com.WebServiceEngine.SetRestError` on page 2837 method referencing the variable.
When the client stub is generated from the OpenAPI specification of your Web service, the correct Genero BDL variable corresponding to the HTTP status code is deserialized on the client side.

**Example WSError in record variable**

```gen
PUBLIC DEFINE userError RECORD ATTRIBUTE(WSError="User error")
    message STRING
END RECORD
```

**Example WSError in integer variable**

```gen
PUBLIC DEFINE fatalError INTEGER ATTRIBUTE(WSError="fatal error")
```

WSError is an optional attribute.

**Related concepts**

- **Handling application level errors** on page 3399
- There are many situations in which you need to notify an error to a client using your REST Web service.

**WSThrows**

Defines a list of errors that may be encountered accessing a REST resource.

**Syntax**

```gen
WSThrows = "\{ code \| code: description \| code:@variable \} [...]
```

WSThrows is a comma-separated list of status codes and/or error descriptions where:

1. `code` is an HTTP status code in the range 400 to 599
2. `description` is text describing the error
3. `@variable` is a reference to a variable defined to handle error descriptions. The variable must be defined with a `WSError` attribute. It is returned in the response message body.

**Important:**

- There is no space before or after the colon (\:).
- If you use the `code` option on its own without a description, the default fault description defined in RFC 2616 is returned to the client.

**Usage**

You use this attribute to manage application level errors, such as a database record not found. If your function can potentially return one or more errors, you use `WSThrows` to declare those so that they can be generated in the OpenAPI specification for that resource.

For instance, HTTP status code 404 means resource not found, but using the `WSThrows` attribute you can respond to the client with `404: user id not found` in your function. To return a description of the status code like this, you must use `WSThrows` with the "code:@variable" option of the attribute, and reference a variable with the `WSError` attribute.

If you simply need to return an error code without a description, use `WSThrows` with `code`, or with a description use `code: description`.

For example, these are valid uses of `WSThrows`:

**Important:** You must use valid HTTP status codes. Use of HTTP status codes between 400 to 599 are valid, but use of codes between 200 to 399 representing successful HTTP status, results in `error-9117`.

```gen
WSThrows = "404, 402"
```

In this example, there are no descriptions of the error, just standard HTTP error messages (see RFC 2616) are returned and displayed on the client side.
WSThrows= "404:not found error, 402:hello world"

In this example, the content after the colon (:) is the description of the error displayed on the client side.

WSThrows= "404:@error1, 402:@error2"

Here error descriptions are provided in the WSErrcompanyror attributed variables referenced in @error1 and @error2.

If you need to ensure an error description other than the standard protocol message is returned to the client, you must use WSThrows with the "code:@variable" option. Otherwise the web server may replace your description with the standard HTTP error message.

WSThrows is an optional attribute.

Example function using WSThrows

In the example, the WSThrows attribute is set on the ATTRIBUTES() clause of the function. It has options to respond to a list of errors.

At runtime when errors are trapped, descriptions of the errors are generated. These are set in the myError and fatalError variables, which are defined with the WSErrcompanyror attribute. These will be returned in the message body.

A call is made to the SetRestError() method to return the HTTP status code, referencing the appropriate WSThrows option.

```plaintext
IMPORT com

TYPE profileType RECORD
  id INT,
  name VARCHAR(50),
  email VARCHAR(100)
END RECORD

PUBLIC DEFINE fatalError INTEGER ATTRIBUTE(WSErrcompanyror="fatal error")

PUBLIC DEFINE myError RECORD ATTRIBUTE(WSErrcompanyror="My error")
  code INTEGER,
  reason STRING
END RECORD

PUBLIC FUNCTION updateUser( thisUser profileType )
  ATTRIBUTES (WSPost,
    WSPa<e>sath.AddListener("/users",
    WSDescription ="Update user details",
    WSThrows ="400:@myError,
        412:@fatalError,406:should not happen" )
  RETURNS STRING
  DEFINE ret STRING
  TRY
    UPDATE users SET
      name = thisUser.name,
      email = thisUser.email
    WHERE @id = thisUser.id
    IF SQLCA.SQLCODE = 0 THEN
      LET ret = thisUser.id
    END if
  CATCH
    CASE
      WHEN SQLCA.SQLCODE = NOTFOUND
        LET myError.code = NOTFOUND
        LET myError.reason = SFMT("User with ID: %1 not found",thisUser.id)
  ```
CALL com.WebServiceEngine.SetRestError(400,myError) WHEN SQLCA.SQLCODE < 0
    LET fatalError = SQLCA.SQLCODE
    CALL com.WebServiceEngine.SetRestError(412,fatalError)
  OTHERWISE
    CALL com.WebServiceEngine.SetRestError(406,NULL)
END CASE
END TRY
RETURN ret
END FUNCTION

Related concepts
Handling application level errors on page 3399
There are many situations in which you need to notify an error to a client using your REST Web service.

Security handling attributes
Attributes that define security and information about the REST services and functions.

WSScope
Specify security in the REST service via scopes.

Syntax

   WSScope = " \{ scope \} , ..."  

Where WSScope is a comma-separated list of scopes and where:

1. scope defines access permission for the resource.

Usage
You use this attribute to specify security via scopes forwarded from the Genero Application Server to the GWS REST service.

WSScope is an optional attribute.

Note: Testing your services with WSScope:

- When testing your service in standalone mode without a GAS, the WSScope is not checked. However, when behind a GAS, the appropriate scope is required and you will need to deploy and secure the service with the Genero Identity Provider (GIP).
- Alternatively, if you need to integrate Genero REST services security into your own environment system, you can also write your own delegate service to validate any kind of token, extract the scope from it, and forward it to the REST service.

You can set the WSScope attribute in the service information record of the module at the service level or in the ATTRIBUTES() clause of the REST function.

Example using WSScope in the information record at the service level
When the scope is set in the service information record, all REST functions in the Web service are executed if, and only if, the request contains a scope definition that matches the value in the WSScope attribute.

PUBLIC DEFINE serviceInfo RECORD
   ATTRIBUTE(WSInfo, WSScope="users.myservice")
      title STRING,
      description STRING,
      termOfService STRING,
      contact RECORD
         name STRING,
         url STRING,
         email STRING
END RECORD,
  version STRING
END RECORD = (  
    title: "my service",
    version: "1.0",
    contact: ( email:"helpdesk@mysite.com") )

Note: The main purpose of the service information record (defined with the WSInfo attribute) is to document the REST service. If you are not setting the scope at the modular level here, the record is still needed to provide service information.

Example setting the WSScope in a REST function

If the call to a specific REST function requires user authentication, add the WSScope attribute in its ATTRIBUTES() clause.

For example, this function is only executed if the scope (WSScope) contains "dev.read". The GAS also needs to be started.

IMPORT com

TYPE profileType RECORD
  id INT,
  name VARCHAR(50),
  email VARCHAR(100)
END RECORD

PUBLIC
DEFINE myError RECORD ATTRIBUTE(WSError="My error")
  code INTEGER,
  reason STRING
END RECORD

PUBLIC FUNCTION getUsersList()
  ATTRIBUTES (WSGet,
    WSPath = "/users",
    WSDescription = "Get a list of all users, requires authentication",
    WSThrows = "400:Invalid,404:NotAvailable",
    WSScope = "dev.read")
  RETURNS (  
    DYNAMIC ARRAY ATTRIBUTE(WSName="Users",WSMedia="application/xml") OF profileType
    ATTRIBUTE(XMLName="User") )

DEFINE userList DYNAMIC ARRAY OF profileType
WHENEVER ERROR continue
DECLARE c2 CURSOR FOR SELECT * FROM users
WHENEVER ERROR STOP
CASE
WHEN SQLCA.SQLCODE = 0
  # ... function code ...
OTHERWISE
  INITIALIZE userList TO NULL
  LET myError.reason = SFMT("SQL error:%1 [\%2]",SQLCA.SQLCODE,
  SQLERRMESSAGE)
  CALL com.WebServiceEngine.SetRestError(400,myError)
END CASE
FREE c2
RETURN userList
END FUNCTION
How to determine the scope names

When determining the names for the scopes, it is important to understand the role of scopes. You create a scope in the Identity Provider (IdP) system and assign it to a group or a user, so that the user or group member will get an access token containing the scope name, and be allowed to access an operation that specifies the same scope name using the WSScope attribute.

The names you choose can be a simple name (such as "readonly"), or it can use dot notation (such as "readonly.dev" and "readonly.user") to provide a logical hierarchy. The hierarchy approach is optional; it is purely provided to allow you to organize your scopes in a logical manner that makes sense to you. Your end user would still need to belong to groups that have either "readonly.dev" or "readonly.user" scope assigned to them, the "dev" and "user" extensions do not in themselves have any meaning to the IdP.

For example, you could create a service access list with the server name of "ReadOnly", with two scopes defined: "ReadOnly.dev" and "ReadOnly.user". You would then set the ReadOnly.dev scope to the resources to be accessible to developers, and the ReadOnly.user scope to the resources to be accessible to users only.

When determining scope names, it may also be helpful to think of the overall solution, which can be a complex system with many services all working together. You can evaluate the access needs of the various services and operations, and then identify the list of scopes that would allow you to provide (or restrict) access to your various groups of users.

In summary, there is no restriction on the names you choose for scopes. You can set them as you wish, depending on what you want to achieve.

Related concepts
Handling security on page 3402
You handle security in GWS high-level REST via scopes.
Generate service description on demand on page 3406
You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

WSInfo
Specify information about the Web service such as title, version, contact details, scopes, etc.

Syntax

```plaintext
WSInfo
```

Usage

You use this attribute to specify information that describes the service such as the service title, version, and contact details.

The WSInfo attribute must be set in an ATTRIBUTE() clause on the information record at the module level. This allows you to provide service information that is useful to clients.

WSInfo is an optional attribute.

Example using WSInfo in the service information record

The example service information record follows the OpenAPI standard.

Note: The GWS does not check the record structure used with WSInfo attribute. You are therefore allowed to add the fields you want to be available in the OpenAPI specification.
url STRING,
email STRING,
END RECORD,
version STRING
END RECORD
END RECORD = (title: "Officestore RESTful Services.", version: "3.0",
contact: (email: "helpdesk@mysite.com") )

You can access a description of your GWS REST Web service through a query string on the URL of the Web service.

Web Services FGLPROFILE configuration

The configuration for the Genero Web Services is defined from entries in the FGLPROFILE file.

When using BDL Web Services on server side, it is the Web server that is in charge of the BDL Web Services server security, not the BDL server application itself. You must refer to your Web server manual to secure the server part of the Web Services.

**Note:** This is useful for deployment purposes, as no additional code modification is necessary, even if the location of the different servers change, or if different cryptography keys or X509 certificates are necessary for the same application but intended for several customers with their own needs.

The Genero Web Services secured communication and the support of XML-Security is based on the OpenSSL engine. It allows a BDL Web Services client, or a BDL application using the com or xml API, to communicate with any secured server over HTTP or HTTPS, and to handle encrypted and/or signed XML document in BDL coming from any other application.

FGLPROFILE entries for Web Services

The FGLPROFILE entries relating to Genero Web Services are divided between five categories: security, basic or digest HTTP authentication, proxy configuration, server configuration, and XML cryptography.

**HTTPS and password encryption**

The following table lists the FGLPROFILE file entries specifying the security certificates and algorithms the Web Services client uses for HTTPS and password encryption. These entries specify how an application using the low-level com or xml APIs performs secured communications.

**Important:** On iOS platform the security entries are not available because iOS SSL/TLS layer is used. However, you can configure the following security Web Services FGLPROFILE entries for GMI mobile devices: security.global.ca, security.global.ca.lookuppath, and security.global.systemca.

**Note:** Any entry defining a file on disk, for example security.global.ca, xml.keystore.calist, etc., can be set with a relative or an absolute path. If set as relative, the file is located based on the current execution directory. The recommended practice is to specify an absolute path in case fglrun is not always executed from the same directory.

**Table 733: Security Configuration FGLPROFILE entries**

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>security.global.script</td>
<td>File name of a script executed each time a password of a private key is required by the client. The security script accepts one argument corresponding to the file name of the private key for which the password is required, and must return the correct password or the client stops. For script examples, see <a href="#">Windows® Password Script Example</a> or <a href="#">UNIX™ Password Script Example</a>. This entry cannot be used if security.global.agent is set.</td>
</tr>
</tbody>
</table>
### Entry | Description
--- | ---
security.global.agent | Port number where the fglpass agent is waiting for requests. It returns the password that grants access to a private key when needed by a BDL application. The DVM and the fglpass agent perform authentication and exchange encrypted data over the local host network only. Refer to Using the password agent for details. This entry cannot be used if security.global.script is set.

security.global.agent.gid | Set this entry as true to specify agent authentication based on OS user group. This entry is only for UNIX® platforms. For more details, see Use the password agent on page 3292.

security.global.protocol | The SSL/TLS protocol to use for secured communications. Possible values are:
- TLSv1.2
- TLSv1.1
- TLSv1 (version 1.0)
- SSLv3
- SSLv23 (The default, enabling all supported protocols)

security.global.ca | File name of the Certificate Authority list, with the concatenated PEM-encoded third party X.509 certificates considered as trusted, and in order of preference.

security.global.ca.lookuppath | A list of directories containing certificate authorities. Genero Web Services will load the CA from the directories in this list. The entry is a list of directories separated by a semicolon.

security.global.windowsca | If set to true, build the Certificate Authority list from the Certificate Authorities stored in the Windows® key store. This entry is only valid on Windows® systems where security.global.ca is not set.

security.global.cipher | The list of encryption, digest, and key exchange algorithms the client is allowed to use during a secured communication. If this entry is omitted, all algorithms are supported. For more details about cipher, refer to www.openssl.org.

security.global.certificate | File name of the PEM-encoded client X.509 certificate to be used for any secured connection if not redefined in a specific server configuration.

security.global.privatekey | File name of the PEM-encoded private key associated to the above X.509 certificate and to be used for any secured connection if not redefined in a specific server configuration.

security.global.keysubject | The subject string of a X.509 certificate and its associated private key registered in the Windows® key store to be used for any secured connection if not redefined in a specific server configuration. This entry is valid only on Windows® systems.

security.global.systemca | When set to true, the Certificate Authority is loaded from the key store on Mac® OSX or Windows® systems, and from a predefined directory on Unix/Linux®. If set to false, the Certificate Authority is not loaded from the system-default location. Default is true. This entry is only valid where security.global.ca is not set.
### Entry Description

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>security.global.ocsp.enable</td>
<td>If set to <code>true</code>, once the server has been validated against local certificate authority, an additional request is performed to the certificate issuer's URL to ensure that no certificate has been revoked at time of connection. Default value is <code>false</code> (no additional request is done)</td>
</tr>
<tr>
<td>security.global.ocsp.url</td>
<td>Instead of checking revocation to the URL inside the issuer's certificate, you can specify a fixed URL where all OCSP requests will be sent. For example: security.global.ocsp.url = &quot;http://any_url&quot; By default, this entry is not set and the URL inside the certificate is used.</td>
</tr>
<tr>
<td>security.idsec.certificate</td>
<td>File name of the PEM-encoded client X.509 certificate.</td>
</tr>
<tr>
<td>security.idsec.privatekey</td>
<td>File name of the PEM-encoded private key associated to the above X.509 certificate. If the PEM file is password protected, you need to use the security.idsec.script or security.idsec.agent entries to supply the passphrase to decrypt the private key.</td>
</tr>
<tr>
<td>security.idsec.keysubject</td>
<td>The subject string of a X.509 certificate and its associated private key registered in the Windows® key store. This entry is valid only on Windows® systems.</td>
</tr>
</tbody>
</table>

**Note:**

1. The `idsec` keyword must be replaced with your own identifier, and all necessary entries must be set. See FGLPROFILE setting.
2. If an entry is defined more than once, only the last occurrence is taken into account.

**Related tasks**

Configuration steps to access a server in HTTPS.

**Basic or digest HTTP authentication**

The following table lists the FGLPROFILE entries that specify the login and password to use in the case of HTTP authentication to a server or a proxy. The entries also specify the login and password to use in an application using the low-level com or xml API.
### Table 734: HTTP basic or digest Authentication FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authenticate.idauth.login</td>
<td>The login identifying the client to a server during HTTP Authentication.</td>
</tr>
<tr>
<td>authenticate.idauth.password</td>
<td>The password validating the login of a client to a server during HTTP Authentication. As passwords are never recommended to be in clear text, you must encrypt them with the fglpass tool. For more information, see FGLPROFILE password encryption.</td>
</tr>
<tr>
<td>authenticate.idauth.realm</td>
<td>The string identifying the server to the client during HTTP Authentication. If the string does not match the server's string, authentication fails. This parameter is optional, but it is recommended that you check the server identity, especially if the server's location is suspicious.</td>
</tr>
<tr>
<td>authenticate.idauth.scheme</td>
<td>One of the following strings representing the different HTTP Authentication mechanisms.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Anonymous</strong> (default value) - The client does not know anything about the server, and performs a first request to retrieve the server authentication mechanism. It then uses the login and password to authenticate to the server using the Basic or Digest mechanism, depending on the server's returned value.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Basic</strong> - The client authenticates itself to the server at first request, by sending the login and the password using the Basic authentication mechanism.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Digest</strong> - The client performs a first request without any login and password, to retrieve the server information before authenticating itself to the server in a second request using the Digest mechanism.</td>
</tr>
</tbody>
</table>

**Note:**

1. The `idauth` keyword must be replaced with your own identifier, and all necessary entries must be set. See FGLPROFILE setting.
2. If an entry is defined more than once, only the last occurrence is taken into account.

**Related concepts**

- **Accessing secured services** on page 3303
  Security and authentication are important. Genero Web Services provides various communications options for a client to connect to a Web service.

- **Encryption and authentication** on page 3299
  A scenario involving a person (Georges) and his bank guides you through the concepts of secured communication, certificates, and certificate authorities.

**Proxy configuration**

The following table lists the FGLPROFILE entries that specify how the Web Services client communicates with a proxy. The entries specify the way an application using the low-level `com` or `xml` API communicates with a proxy.
Table 735: Proxy Configuration FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proxy.http.location</td>
<td>Location of the HTTP proxy defined as host:port or ip:port. If the port is omitted, the port 80 is used.</td>
</tr>
<tr>
<td>proxy.http.list</td>
<td>The list of beginning host names, separated with semicolons, for which the Web Services client does not go via the HTTP proxy.</td>
</tr>
<tr>
<td>proxy.http.authenticate</td>
<td>The authenticate.idauth the Web Services client uses to authenticate itself to the HTTP proxy.</td>
</tr>
<tr>
<td>proxy.https.location</td>
<td>Location of the HTTPS proxy defined as host:port or ip:port. If the port is omitted, the port 443 is used.</td>
</tr>
<tr>
<td>proxy.https.list</td>
<td>The list of host names, separated with semicolons, for which the Web Services client does not go via this HTTPS proxy.</td>
</tr>
<tr>
<td>proxy.https.authenticate</td>
<td>The authenticate.idauth the Web Services client uses to authenticate itself to the HTTPS proxy.</td>
</tr>
</tbody>
</table>

**Note:** If an entry is defined more than once, only the last occurrence is taken into account.

**IPv6 configuration**

The following table lists the FGLPROFILE entries that specify how the Web Services client uses the IPv6 network protocol.

Table 736: IPv4 and IPv6 FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip.global.version</td>
<td>Defines the IP version to be used. Possible values are &quot;4&quot; (IPv4) or &quot;6&quot; (IPv6). By default, when this entry is not defined, the WS library will try to use IPv6 and fallback to IPv4, depending on the operating system.</td>
</tr>
<tr>
<td>ip.global.v6.interface.name</td>
<td>Defines the name of the network interface to be used for IPv6 link-local addresses. For example, this entry can get values such as &quot;eth0&quot;, &quot;en0&quot;, &quot;ethernet_5&quot;.</td>
</tr>
<tr>
<td><strong>Important:</strong> This entry is not supported on Microsoft™ Windows® platforms.</td>
<td></td>
</tr>
<tr>
<td>ip.global.v6.interface.id</td>
<td>Defines the id of the network interface to be used for IPv6 link-local addresses. For example, this entry can get values such as &quot;1&quot;, &quot;2&quot;, &quot;11&quot;.</td>
</tr>
</tbody>
</table>

**Note:** If an entry is defined more than once, only the last occurrence is taken into account.

**Server configuration**

The following table lists the FGLPROFILE file entries that specify the correct way a Web Services client connects to an end point (usually a server).

**Note:** The entries specify also the way an application using the low-level com or xml API connects to an end point.
### Table 737: Server Configuration FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ws.idws.url</td>
<td>The end point URL of the server. The entry overwrites the global definition.</td>
</tr>
<tr>
<td></td>
<td>See Using * wildcards in server URLs on page 3498.</td>
</tr>
<tr>
<td>ws.idws.regex.url</td>
<td>A regular expression to define all possible URLs that can be used in this server configuration.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If the <code>ws.idws.url</code> is defined, the <code>regex.url</code> entry is ignored.</td>
</tr>
<tr>
<td></td>
<td>This regex entry follows W3C rules as described in <a href="https://www.w3.org/TR/xmlschema-2/#regexs">https://www.w3.org/TR/xmlschema-2/#regexs</a>.</td>
</tr>
<tr>
<td></td>
<td>See Using regular expressions in server URLs on page 3498.</td>
</tr>
<tr>
<td>ws.idws.cipher</td>
<td>The list of encryption, digest and key exchange algorithms the client is allowed to use during a secured communication to that server. The entry overwrites the global definition.</td>
</tr>
<tr>
<td>ws.idws.verifyserver</td>
<td>If set to <code>true</code>, the client performs a strict server identity validation. If not fulfilled, it stops the communication; otherwise no server identity verification is performed. The default value is <code>true</code>.</td>
</tr>
<tr>
<td>ws.idws.security</td>
<td>The security identifier (<code>security.idsec</code>) the client uses to perform HTTPS communication with the server. See also Add configuration entries in your FGLPROFILE file on page 3309.</td>
</tr>
<tr>
<td>ws.idws.authenticate</td>
<td>The <code>authenticate.idauth</code> the client uses to authenticate itself to the server.</td>
</tr>
</tbody>
</table>

### Note:

1. The `idws` keyword must be replaced with your own identifier. All necessary entries, depending on the remote server's configuration, must be set. See FGLPROFILE setting.
2. You can use the unique identifier in the `.4gl` code instead of the server URL, with the `alias://` prefix. For example, `alias://idws`.
3. If an entry is defined more than once, only the last occurrence is taken into account.

### XML configuration

The following table lists the FGLPROFILE entries that control XML to Genero values conversion, and XML cryptography key or certificate mapping.
Table 738: XML configuration FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xml.keystore.caclist</code></td>
<td>The list of PEM-encoded third party X.509 certificates, separated with semicolons, of the Certificate Authority considered as trusted, in order of preference.</td>
</tr>
<tr>
<td><code>xml.keystore.x509list</code></td>
<td>The list of PEM-encoded third party X.509 certificates, separated with semicolons, to be used to find out the correct X.509 certificate when getting an incomplete one in a XML signature or an encrypted XML document.</td>
</tr>
<tr>
<td><code>xml.idxml.key</code></td>
<td>The file name of a cryptography key. For instance <code>RSA.pem</code>, <code>DSA.der</code> or <code>HMAC.bin</code>.</td>
</tr>
<tr>
<td><code>xml.idxml.x509</code></td>
<td>The file name of a cryptography x509 certificate. For instance <code>Cert.crt</code>.</td>
</tr>
<tr>
<td><code>xml.serializer.supportEmptyStrings</code></td>
<td>Controls empty string XML nodes conversion to Genero STRING values. The default is false, empty XML tags are converted to NULL. If set to true, an empty XML tag is converted to an empty STRING value. As result, in Genero, the LENGTH() function will return zero and the IS NULL comparison operator will evaluate to FALSE. Note that this entry only works for the STRING data type, and if the tag is not present, the STRING is set to NULL.</td>
</tr>
<tr>
<td>`xml.signature.prefix = { &quot;prefix&quot;</td>
<td>&lt;none&gt; }`</td>
</tr>
<tr>
<td>`xml.encryption.prefix = { &quot;prefix&quot;</td>
<td>&lt;none&gt; }`</td>
</tr>
</tbody>
</table>

**Note:**

1. The `idxml` keyword must be replaced with your own identifier. See FGLPROFILE: XML cryptography on page 3497.
2. You can use the unique identifier in the `.4gl` code instead of the file name.
3. If an entry is defined more that once, only the last occurrence is taken into account.

**HTTP configuration**

The following table lists the FGLPROFILE entries control options for the HTTP protocol.
### Table 739: HTTP Configuration FGLPROFILE entries

<table>
<thead>
<tr>
<th>Entry</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>http.global.request.date</td>
<td>This entry applies to all <code>HTTPRequest</code> objects created in a program. The HTTP RFC 2616 specifies that a Date header should not be sent, if the HTTP request does not contain a body.</td>
</tr>
<tr>
<td></td>
<td>With the <code>http.global.request.date</code> FGLPROFILE entry, you can control this as follows:</td>
</tr>
<tr>
<td></td>
<td>• By default (no entry), or if <code>http.global.request.date = false</code>, no HTTP Date header is sent for GET, HEAD and DELETE requests.</td>
</tr>
<tr>
<td></td>
<td>• When <code>http.global.request.date = true</code>, an HTTP Date header is sent for any GET, HEAD, DELETE requests.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> For PUT and POST requests, the HTTP Date header is always sent.</td>
</tr>
</tbody>
</table>

**Note:** If an entry is defined more than once, only the last occurrence is taken into account.

### Examples

**SSL/TLS configuration examples.**

**Windows® BAT script for private key password**

Windows® BAT script sample returning a password, depending on the `.pem` file passed as parameter.

```batch
@echo off
REM -- Windows password script
IF "%1" == "Cert/MyPrivateKeyA.pem" GOTO KeyA
IF "%1" == "Cert/MyPrivateKeyB.pem" GOTO KeyB
GOTO end
:KeyA
ECHO PasswordA
GOTO end
:KeyB
ECHO PasswordB
GOTO end
:end
GOTO :EOF
```

**UNIX™ shell script for private key password**

UNIX® shell script sample returning a password, depending on the `.pem` file passed as parameter.

```bash
# UNIX password script
if [ "$1" == "Cert/MyPrivateKeyA.pem" ]
then
  echo PasswordA
fi
if [ "$1" == "Cert/MyPrivateKeyB.pem" ]
then
  echo PasswordB
fi
```

**FGLPROFILE: HTTP(S) Proxy Authentication**

FGLPROFILE entries can be used to define a connection to an HTTPS server via a proxy, and with HTTP and Proxy Authentication.

```ini
# Security configuration
security.global.script   = "Cert/password.sh"
security.global.ca       = "Cert/CAList.pem"
```
security.global.cipher = "HIGH" # Use only HIGH encryption ciphers
security.mykey.certificate = "Cert/MyCertificateA.crt"
security.mykey.privatekey = "Cert/MyPrivateKeyA.pem"

# Proxy HTTP Authentication
authenticate.proxyauth.login = "myapplication"
authenticate.proxyauth.password = "mypswd"
authenticate.proxyauth.scheme = "Basic"

# HTTPS Proxy configuration
proxy.https.location = "10.0.0.170"
proxy.https.list = "www.mycompany.com;www.mycompany.com"
proxy.https.authenticate = "proxyauth"

# Server HTTP Authentication
authenticate.serverauth.login = "mylogin"
authenticate.serverauth.password = "password"

# Server configuration
ws.myserver.authenticate = "serverauth"
ws.myserver.security = "mykey"

---

**FGLPROFILE: XML cryptography**
Use FGLPROFILE file entries to define XML cryptography and use the fglpass agent to get the private key passwords.

---

# Security configuration
security.global.agent = 4444

# Crypto configuration
xml.keystore.calist = "RSARootCertificate.crt;DSARootCertificate.crt"
xml.keystore.x509list = "RSA1024Certificate.crt;DSA1024Certificate.crt"
xml.id1.x509 = "RSA1024Certificate.crt"
xml.id2.x509 = "DSA1024Certificate.crt"
xml.id3.key = "RSA1024Key.pem"
xml.id4.key = "DSA1024Key.der"
xml.id5.key = "HMAC.bin"

---

**Related concepts**

**Encryption, BASE64 and password agent with fglpass tool** on page 3290
Genero Web Services supports password encryption with fglpass as password agent.

**Related reference**

**XML configuration** on page 3494
**FGLPROFILE: Server URL patterns**

FGLPROFILE entries can be used to define multiple server URLs, by using URL patterns.

**Understanding URL patterns**

By using URL patterns, you can create a URL base that applies to multiple server applications.

URLs matching the pattern can share server configuration (such as authentication and HTTPS).

FGLPROFILE entries using URL patterns apply to the following APIs:

- `com.HTTPRequest.Create()`
- `xml.DomDocument.load()`
- `xml.DomDocument.save()`
- `xml.StaxReader` methods
- `xml.StaxWriter` methods
- `com.TCPRequest.create()`

**Using * wildcards in server URLs**

To create a URL base, add a wildcard (`/*`) to the end of a URL in the FGLPROFILE file entry. A server application that starts with this URL (and that is not explicitly defined elsewhere) shares the configuration with other applications that also start with the same base URL. If an application has its own server configuration explicitly defined, it uses its specific entries instead of those defined by the wildcard configuration.

Consider this excerpt from a hypothetical FGLPROFILE file:

```plaintext
authenticate.auth.login    = "xxx"
authenticate.auth.password = "yyy"
authenticate.auth.scheme   = "Basic"
security.sec.certificate = "client.crt"
security.sec.privatekey   = "client.pem"

ws.myapp.url             = "http://mycompany.com/sample/*"
ws.myapp.authenticate    = "auth"
ws.myapp.security        = "sec"

ws.thirdapp.url          = "http://mycompany.com/sample/application3"
ws.thirdapp.authenticate = "auth3"
authenticate.auth3.login = "aaa"
authenticate.auth3.password = "bbb"
authenticate.auth3.scheme = "Basic"
```

Based on this example:

- Requests to "http://mycompany.com/sample/application1" and "http://mycompany.com/sample/demos/shoppingcart" use the same authentication and HTTPS configuration.
- A request to "http://mycompany.com/sample/application3" uses its specific authentication "auth3". No security configuration is defined for this URL, nor does it fall back on the shared security configuration defined for the base URL.

**Using regular expressions in server URLs**

To create a URL regex pattern, use the `ws.idws.regex.url` FGLPROFILE file entry, and define a regular expression that matches all server URLs to be associated with the "idws" server configuration.

**Note:** If the `ws.idws.url` is defined, the `regex.url` entry is ignored.

```plaintext
authenticate.auth.login    = "xxx"
```

Server configuration on page 3493

XML to BDL serialization options

By default, Genero Web Services XML to BDL serialization will raise errors, if the XML content does not match the BDL variable receiving the data.

To relax the serialization, you can specify the options `xml_ignoreunknownattributes` and `xml_ignoreunknownelements` to the `xml.Serializer` class.

For example, if the BDL variable is defined as follows:

```plaintext
DEFINE data RECORD ATTRIBUTES(XMLName="Demo"),
    val1 INTEGER ATTRIBUTES(XMLName="Value1"),
    val2 STRING ATTRIBUTES(XMLName="Value2"),
    attr INTEGER ATTRIBUTES(XMLAttribute,XMLName="MyAttr")
END RECORD
```

The following XML document will by default raise conversion errors because the "badAttr" attribute and the "Unexpected" node are not defined in the corresponding BDL variable:

```xml
<Demo MyAttr="hello" badAttr= "BAD">
    <Value1>128</Value1>
    <Unexpected>Will be ignored</Unexpected>
    <Value2>Hello</Value2>
</Demo>
```

To avoid the conversion error, set the following options:

```plaintext
CALL xml.Serializer.setOption( "xml_ignoreunknownattributes", TRUE )
CALL xml.Serializer.setOption( "xml_ignoreunknownelements", TRUE )
... 
CALL xml.Serializer.DomToVariable( doc, data )
```

Note: The options to relax the serialization cannot apply in complex cases, and the conversion error may still occur.

For more details, see `xml.Serializer.SetOption` on page 3043.

WSHelper library

The WSHelper library.

The WSHelper file

It is recommended that the `WSHelper.42m` library file is linked into every Genero Web Services Server or Client program. It is located in `$FGLDIR/lib`.

```plaintext
authenticate.auth.password = "yyy"
authenticate.auth.scheme = "Basic"

ws.myident.regex.url = "http://.*\strasbourg\4js\com:[0-9]{4}/.*"
ws.myident.authenticate = "auth"
```
**WSHelper variables and records**
The WSHelper library provides public variables and records.

**WSQueryType**
The WSHelper library defines `WSHelper.WSQueryType` as a dynamic array:

```plaintext
PUBLIC TYPE WSQueryType DYNAMIC ARRAY OF RECORD
    name STRING,
    value STRING
END RECORD
```

The fields of the record are:
1. `name` is the name of the query argument.
2. `value` is the value of the query argument.

**WSServerCookiesType**
The WSHelper library defines `WSHelper.WSServerCookiesType` as a dynamic array:

```plaintext
PUBLIC TYPE WSServerCookiesType DYNAMIC ARRAY OF RECORD
    name STRING, # Cookie name
    value STRING, # Cookie value
    path STRING, # Cookie path (or null)
    domain STRING, # Cookie domain (or null)
    expires DATETIME YEAR TO SECOND, # Cookie expiration date (or null)
    httpOnly BOOLEAN,
    secure BOOLEAN
END RECORD
```

The fields of the record are:
1. `name` is the name of the cookie to be set. This field is mandatory. It will be URL-encoded on the wire.
2. `value` is the value of the cookie to be set. This field is mandatory. It will be URL-encoded on the wire.
3. `path` is the main path the cookie has to be set for. Any path containing that main path will then return the cookie. If no name is set, the cookie will be set by the path the client has provided.
4. `domain`: the domain (hostname) or sub-domain (ex: .strasbourg.4js.com) the cookie will be set on client side. If not set, the domain will be the hostname provided by the client.
5. `expires`: a `DATETIME YEAR TO SECOND` (on local time) from when that cookie will expire, and thus not be sent by the client anymore. If `NULL`, the cookie is called session cookie and will be sent as long as the client keeps the session open.
6. `http_only` is set to `TRUE` if the cookie is only for the HTTP layer, `FALSE` if cookie can be accessible in JavaScript.
7. `secure`: true if cookie must only be sent in HTTPS, false for HTTP and HTTPS.
**WSHelper APIs**
The WSHelper library provides Genero BDL HTTP helper functions.

### Table 740: WSHelper functions

<table>
<thead>
<tr>
<th>Function Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SplitUrl(url STRING)</code></td>
<td>Splits a complete URL string into pieces.</td>
</tr>
<tr>
<td></td>
<td>RETURNS (scheme STRING, host STRING, port STRING, path STRING, query STRING)</td>
</tr>
<tr>
<td><code>FindQueryStringValue(query STRING, name STRING)</code></td>
<td>Get a query string value by name.</td>
</tr>
<tr>
<td></td>
<td>RETURNS STRING</td>
</tr>
<tr>
<td><code>SplitQueryString(query STRING)</code></td>
<td>Splits the query string of an URL into an array or key-value pairs.</td>
</tr>
<tr>
<td></td>
<td>RETURNS WSHelper.WSQueryType</td>
</tr>
</tbody>
</table>

**WSHelper.FindQueryStringValue**
Get a query string value by name.

**Syntax**

```gdsl
FindQueryStringValue(query STRING, name STRING)
RETURNS STRING
```

1. `query` is the query string where to look for a value.
2. `name` is the name of the value wanted.

**Usage**
Get a query string value by name.

In case of error, a NULL value will be returned.

**WSHelper functions example**

```gdsl
IMPORT FGL WSHelper

MAIN

DEFINE val, scheme, host, port, path, query STRING
DEFINE ind INTEGER
DEFINE ret WSHelper.WSQueryType

CALL WSHelper.SplitQueryString("name1=val1&name2=val2&name3=val3")
    RETURNING ret

FOR ind = 1 TO ret.getLength()
```

DISPLAY "Query",ind
DISPLAY " name is",ret[ind].name
DISPLAY " value is ",ret[ind].value
END FOR
LET val = WSHelper.FindQueryStringValue("name1=val1&name2=val2","name1")
CALL WSHelper.SplitUrl("https://cube.strasbourg.4js.com:3128/GWS-492/TestSplitURL/test1")
  RETURNING scheme, host, port, path, query
END MAIN

Output:

<table>
<thead>
<tr>
<th>Query</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>name is</td>
<td>name1</td>
</tr>
<tr>
<td>value is</td>
<td>val1</td>
</tr>
<tr>
<td>Query</td>
<td>2</td>
</tr>
<tr>
<td>name is</td>
<td>name2</td>
</tr>
<tr>
<td>value is</td>
<td>val2</td>
</tr>
<tr>
<td>Query</td>
<td>3</td>
</tr>
<tr>
<td>name is</td>
<td>name3</td>
</tr>
<tr>
<td>value is</td>
<td>val3</td>
</tr>
</tbody>
</table>

**WSHelper.SplitQueryString**
Splits the query string of an URL into an array or key-value pairs.

**Syntax**

```
SplitQueryString(
  query STRING )
RETURNS WSHelper.WSQueryType
```

1. *query* is the query string to be split into a dynamic array.

**Usage**

Split a given query string into a dynamic array of key-value pairs, defined as WSHelper.WSQueryType.

The pieces are returned in dynamic array of key-value pairs defined as a WSHelper.WSQueryType. See **WSHelper variables and records** on page 3500 for more information regarding **WSQueryType**.

NULL may be returned if a value is not found.

In case of error, a NULL value will be returned.

**WSHelper functions example**

```
IMPORT FGL WSHelper
MAIN
DEFINE val, scheme, host, port, path, query STRING
DEFINE ind INTEGER
DEFINE ret WSHelper.WSQueryType
CALL WSHelper.SplitQueryString("name1=val1&name2=val2&name3=val3")
  RETURNING ret
FOR ind = 1 TO ret.getLength()
  DISPLAY "Query",ind
```
DISPLAY " name is",ret[ind].name  
DISPLAY " value is ",ret[ind].value  
END FOR

LET val = WSHelper.FindQueryStringValue("name1=val1&name2=val2","name1")

CALL WSHelper.SplitUrl("https://cube.strasbourg.4js.com:3128/GWS-492/TestSplitURL/test1")
  RETURNING scheme, host, port, path, query  
END MAIN

Output:

Query          1  
  name is name1  
  value is val1  
Query          2  
  name is name2  
  value is val2  
Query          3  
  name is name3  
  value is val3  

**WSHelper.SplitUrl**

Splits a complete URL string into pieces.

**Syntax**

```plaintext
SplitUrl(
  url STRING )
RETURNS ( scheme STRING,
  host STRING,
  port STRING,
  path STRING,
  query STRING )
```

1. `url` is a STRING with the URL to be split in pieces.
2. `scheme` is the URL scheme (http, https, file, ...). It includes all parts before //
3. `host` is the hostname.
4. `port`: the port number, or NULL if there is none.
   
   **Note**: If NULL is returned, there is always a default port depending on the scheme: 443 for HTTPS, and 80 for HTTP.
5. `path` is the path of the URL.
6. `query` is the query string of the URL, or NULL if there is none.

**Usage**

Splits a complete URL string into pieces.

In case of error, a NULL value will be returned.

**WSHelper functions example**

```plaintext
IMPORT FGL WSHelper  

MAIN  
  DEFINE val, scheme, host, port, path, query STRING  
  DEFINE ind INTEGER  
```
DEFINE ret WSHelper.WSQueryType

CALL WSHelper.SplitQueryString("name1=val1&name2=val2&name3=val3")
RETURNING ret

FOR ind = 1 TO ret.getLength()
    DISPLAY "Query", ind
    DISPLAY " name is ", ret[ind].name
    DISPLAY " value is ", ret[ind].value
END FOR

LET val = WSHelper.FindQueryStringValue("name1=val1&name2=val2", "name1")

CALL WSHelper.SplitUrl("https://cube.strasbourg.4js.com:3128/GWS-492/TestSplitURL/test1")
    RETURNING scheme, host, port, path, query

END MAIN

Output:

Query 1
    name is name1
    value is val1
Query 2
    name is name2
    value is val2
Query 3
    name is name3
    value is val3

OAuthAPI library
The OAuthAPI library.

The OAuthAPI file
The OAuthAPI library is delivered in the FGLGWS package. It is recommended that the OAuthAPI.42m library file is linked into every Genero Web Services client program that requires access to a Web service secured by OpenID Connect. It is located in $FGLDIR/lib.

OAuthAPI overview
The OAuthAPI library supports the OAuth protocol that authenticates user access and issues access tokens.

The OAuth protocol is widely-used as a means of securing access to Web services. It allows client access by verifying the identity of the end user. Third party Identity Providers (IdP) usually provide this service, or you can secure your RESTful services using the Genero Identity Provider service that is delivered in $FGLDIR/web_utilities/services/gip. For more information, see the Genero Identity Provider (GIP) section in the Genero Application Server User Guide.

The OAuthAPI library provides functions that enables you to get metadata provided by the IdP, such as endpoints, access tokens, scopes, user profile, etc. It has functions that can support Web services that are started:

• Behind a Genero Application Server (GAS).
• Or for Web services that are not behind GAS, for example, in the case of a mobile app.
• Or for a service (server side) to connect (as a service client) to another service.

An application started behind a GAS has a slightly different means of implementing authentication than a mobile app, or a service to service. You will notice, however, that OAuth implementation follows basically the same pattern.
This involves the client calling an initialization function to register the token to access the secure RESTful Web service. Once OAuth is initialized, functions that create HTTP requests with the access token, and manage metadata can be used. See Post-initialization functions on page 3511.

## Authenticate with GAS

To authenticate an application that is behind Genero Application Server, OAuth is implemented through delegation.

A Genero delegate service for OpenID Connect is delivered in $FGLDIR/web_utilities/services. This must be running to manage all delegated requests for applications or services run on the GAS. For more information, see the pages on How to implement delegation in the Genero Application Server User Guide.

You call the `init()` method in your client app. This initializes OAuth by:

- Reading the GAS environment variable OIDC_ACCESS_TOKEN that contains the initial access token the app got from the Genero Identity Provider (GIP), or the third party Identity Provider.
- Initiating a global variable with that access token.

Then any REST request used in your application will automatically set the access token in a HTTP request header and get access to the service. See the Main program code for access to secure service on page 3414 topic.

## Authenticate without GAS

To authenticate an application that is not behind GAS, for example a mobile app, you need to implement OAuth in a specific way.

In your application code, these functions need to be called in the following order:

1. **FetchOpenIDMetadata()** to retrieve the metadata from the Identity Provider from the required URL.
2. **RetrievePasswordToken()** to return the access token.
3. **initService()** to register the access token.

See the code sample in OAuth access without GAS on page 3521.

## Authenticate a service to a service

To successfully authenticate a service (server side) to connect (as a service client) to another service protected by an access token, you will need to implement OAuth this way.

The access token got from the IdP to check access to the service, is also required to access the client service.

1. Call the InitService() function to initiate OAuth and to register the access token.
2. Then you can call any of the OAuthAPI methods, such as CreateHTTPAuthorizationRequest, to perform requests to the other service.

See the code sample in InitService().

## OAuthAPI variables and records

The OAuthAPI library provides public variables and records.

### RegisterRequestType

The OAuthAPI library defines the OAuthAPI.RegisterRequestType as a record:

```plaintext
PUBLIC
TYPE RegisterRequestType RECORD
   redirect_uris DYNAMIC ARRAY OF STRING, # REQUIRED
   response_types DYNAMIC ARRAY OF STRING, # OPTIONAL
   grant_types DYNAMIC ARRAY OF STRING, # OPTIONAL
   client_name STRING,
   client_description STRING,
   scope STRING # OPTIONAL
END RECORD
```

For more information on these parameters, see the Authorization Request section of the OAuth specification.
RegisterResponseType

The OAuthAPI library defines the OAuthAPI.RegisterResponseType as a record:

```plaintext
PUBLIC TYPE RegisterResponseType RECORD
    client_id STRING, # REQUIRED
    client_secret STRING, # OPTIONAL
    grant_types DYNAMIC ARRAY OF STRING, # OPTIONAL
    redirect_uris DYNAMIC ARRAY OF STRING, # OPTIONAL
    client_name STRING,
    client_description STRING,
    scope STRING # OPTIONAL
END RECORD
```

For more information on these parameters, see the Authorization Response section of the OAuth specification.

OpenIDMetadataType

The OAuthApp library defines the OAuthApp.OpenIDMetadataType as a public record:

```plaintext
PUBLIC TYPE OpenIDMetadataType RECORD
    issuer STRING, # REQUIRED
    authorization_endpoint STRING, # REQUIRED
    token_endpoint STRING, # REQUIRED
    userinfo_endpoint STRING, # RECOMMENDED
    jwks_uri STRING, # REQUIRED
    registration_endpoint STRING, # RECOMMENDED
    scopes_supported DYNAMIC ARRAY OF STRING, # REQUIRED
    response_types_supported DYNAMIC ARRAY OF STRING, # REQUIRED
    response_modes_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    grant_types_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    acr_values_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    subject_types_supported DYNAMIC ARRAY OF STRING, # REQUIRED
    id_token_signing_alg_values_supported DYNAMIC ARRAY OF STRING, # REQUIRED
    id_token_encryption_alg_values_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    id_token_encryption_enc_values_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    userinfo_signing_alg_values_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    userinfo_encryption_alg_values_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    userinfo_encryption_enc_values_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    request_object_signing_alg_values_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    request_object_encryption_alg_values_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    request_object_encryption_enc_values_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    token_endpoint_auth_methods_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    token_endpoint_auth_signing_alg_values_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    display_values_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    claim_types_supported DYNAMIC ARRAY OF STRING, # OPTIONAL
    service_documentation STRING, # OPTIONAL
    claims_supported DYNAMIC ARRAY OF STRING, # RECOMMENDED
    claims_locales_supported STRING, # OPTIONAL
    ui_locales_supported STRING, # OPTIONAL
    claims_parameter_supported STRING, # OPTIONAL
```
request_parameter_supported STRING, # OPTIONAL
request_uri_parameter_supported STRING, # OPTIONAL
require_request_uri_registration STRING, # OPTIONAL
op_policy_uri STRING, # OPTIONAL
op_tos_uri STRING, # OPTIONAL
end_session_endpoint STRING # OPTIONAL
END RECORD

For further details, refer to the OpenID Connect Core specification.
**OAuthAPI APIs**

</tbody>
</table>
Initialization functions
Functions that initialize OAuth by getting the access token.

OAuthAPI.init
To be called in a Genero app accessing a secure RESTful Web service started behind a Genero Application Server.

Syntax

```
Init(
    cnx_timeout INTEGER,
    client_id STRING,
    client_secret STRING )
RETURNS BOOLEAN
```

1. `cnx_timeout` is a connection timeout to the REST service with value in seconds.
2. `client_id` is the application ID assigned to the app when registered.
3. `client_secret` is the application secret created for the app.

Returns FALSE if the mandatory access token is null.

Usage
Use this function to initiate information provided by the Identity Provider to access the secure RESTful Web service. It calls environment variables containing the OAuth information got from the Genero Identity Provider (GIP) or a third party Identity Provider (IdP). It registers the access token and access information (such as subject, scopes, endpoints, etc.) with the GWS engine.

In case of error, a NULL value will be returned.

```
IMPORT FGL OAuthAPI
DEFINE my_user_id INTEGER
MAIN
    # ...
    # Init OAuthAPI
    IF NOT OAuthAPI.init(5, "AF350CBC-8801-4DFB-9A78-A95B25BB32AF", "8JEq3HBfXrmj/8vMP66iaRQnGrWVyjqr") THEN
        DISPLAY "Error: unable to initialize OAuth"
        EXIT PROGRAM 1
    ELSE
        LET my_user_id = OAuthAPI.getIDSubject
    END IF
    # ...
END MAIN
```

OAuthAPI.InitService
To be called in a Genero Web service started via OpenID Connect accessing another secure RESTful Web service as a client.

Syntax

```
InitService(
    cnx_timeout INTEGER,
    access_token STRING )
RETURNS BOOLEAN
```
1. `cnx_timeout` is a connection timeout from the REST service with value in seconds. The connection timeout is needed to avoid apps getting blocked by requests.

2. `access_token` is the valid access token for accessing the RESTful Web service.

   Returns FALSE if the mandatory access token is null.

**Usage**

Use this function to register the access token to be used when a service (server side) has to connect (as a service client) to another service protected by an access token. It checks if the OAuth service is initiated.

The role of the function is to register the access token, so that you can then call any of the OAuthAPI methods, such as `CreateHTTPAuthorizationRequest`, to perform requests to the other service.

In case of error, a NULL value will be returned.

In the code sample, the `WSContext` on page 3481 dictionary is defined to get some information coming from the service configuration file (.xcf).

The access token set during token validation to check access to the service is required to access the client service. Therefore, you need to call `InitService()` with it.

Typically, only the access token is required. If you need to get metadata, a call to `FetchOpenIDMetadata()` saves the metadata in an `OpenIDMetadataType` on page 3506 record.

**OAuthAPI.InitService function**

```falg
IMPORT FGL OAuthAPI
PRIVATE DEFINE ctx DICTIONARY ATTRIBUTE(WSContext) OF STRING
MAIN
  DEFINE metadata OAuthAPI.OpenIDMetadataType
  DEFINE access_token STRING
  DEFINE idp STRING

  # retrieve access_token
  LET access_token = ctx["OIDC_ACCESS_TOKEN"]

  # retrieve IDP URL
  LET idp = ctx["Parameter-IDP"]

  # retrieve metadata
  CALL OAuthAPI.FetchOpenIDMetadata(5, idp) RETURNING metadata.*

  # Init OAuth service
  IF NOT OAuthAPI.InitService(5, access_token) THEN
    DISPLAY "Cannot initiate OAuth service"
  END IF

  CALL MyOtherService(access_token)
  # ...
END MAIN
```

**Post-initialization functions**

Functions that manage metadata, tokens, and scopes.
**OAuthAPI.GetOpenIDMetadata**
Get metadata from the Identity Provider for a service running on a Genero Application Server (GAS).

**Syntax**

```
GetOpenIDMetadata ()
RETURNS OAuthAPI.OpenIDMetadataType
```

NULL may be returned if metadata is not found.

**Usage**

Use this function to retrieve metadata (such as registration endpoint, supported scopes, user information endpoints, etc.) provided by the Genero Identity Provider for access to a secure RESTful Web service. A request is made to return the metadata and the information is stored in the `OpenIDMetadataType` record.

**Note:**

If the service is not started behind the GAS, call the `FetchOpenIDMetadata()` function instead.

In case of error, a NULL value will be returned.

**OAuthAPI.GetOpenIDMetadata function**

```
IMPORT FGL OAuthAPI

DEFINE metadata OAuthAPI.OpenIDMetadataType
DEFINE ind INTEGER

MAIN
  # ...
  CALL OAuthAPI.GetOpenIDMetadata() RETURNING metadata.*
  IF metadata.issuer IS NULL THEN
    ERROR "IdP not available"
  ELSE
    DISPLAY "Registration endpoint is: ", metadata.registration_endpoint
    FOR ind = 1 TO metadata.scopes_supported.getLength()
      DISPLAY "Scope is: ", metadata.scopes_supported[ind]
  END FOR
  END IF
  # ...
END MAIN
```

**Related concepts**

**OAuthAPI.FetchOpenIDMetadata** on page 3518
Fetch metadata from the Identity Provider at the URL provided.

**ID token functions**

Functions that get access token metadata.

**OAuthAPI.GetIDPIssuer**
Get endpoint of the Identity Provider.

**Syntax**

```
GetIDPIssuer ()
RETURNS STRING
```

NULL may be returned if the metadata is not found.
Usage

Use this function to get the endpoint of the Identity Provider securing the RESTful Web service. IdP issuer information can be retrieved from the GWS engine once it has been initialized by `OAuthAPI.init` on page 3510.

In case of error, a NULL value will be returned.

**OAuthAPI.GetIDPIssuer function**

```fgo
IMPORT FGL OAuthAPI
DEFINE issuer STRING

MAIN
  IF NOT OAuthAPI.init(5, "AF350C80C-80A9-4DFA-9A78-A95B25BB32AF", "8JEq3HBfxrmj/8vMP66iaRQnGrWVyjqr" ) THEN
    MESSAGE "Error: unable to initialize OAuth"
    EXIT PROGRAM 1
  ELSE
    LET issuer = OAuthAPI.GetIDPIssuer()
  END IF

END MAIN
```

**OAuthAPI.GetIDSubject function**

Get OAuth subject identifier of ID Token.

**Syntax**

```fgo
GetIDSubject()
RETURNS INTEGER
```

NULL may be returned if the metadata is not found.

Usage

Use this function to get the subject identifier of the Identity Provider securing the RESTful Web service. IdP subject information can be retrieved from the GWS engine once it has been initialized by `OAuthAPI.init` on page 3510.

In case of error, a NULL value will be returned.

**OAuthAPI.GetIDSubject function**

```fgo
IMPORT FGL OAuthAPI
DEFINE sub INTEGER

MAIN
  IF NOT OAuthAPI.init(5, "AF350C80C-80A9-4DFA-9A78-A95B25BB32AF", "8JEq3HBfxrmj/8vMP66iaRQnGrWVyjqr" ) THEN
    MESSAGE "Error: unable to initialize OAuth"
    EXIT PROGRAM 1
  ELSE
    LET sub = OAuthAPI.GetIDSubject()
  END IF

END MAIN
```

**OAuthAPI.GetIDScopes**
Get OAuth ID Token authorization scopes.

**Syntax**

```
GetIDScopes()
RETURNS DYNAMIC ARRAY OF STRING
```

**Usage**

Use this function to get the list of authorization OAuth 2.0 scopes that the Identity Provider securing the RESTful Web service supports. IdP scope information can be retrieved from the GWS engine once it has been initialized by OAuthAPI.init on page 3510.

In case of error, a NULL value will be returned.

**OAuthAPI.GetIDScopes function**

```fgl
IMPORT FGL OAuthAPI
MAIN
DEFINE ind INTEGER
DEFINE scopes DYNAMIC ARRAY OF STRING

# ...
IF NOT OAuthAPI.init(5, "AF350CBC-8801-4DFB-9A78-A95B25BB32AF", "8Jeq3HBfxrmj/8vMP66iaRQnGrWVyjqr" ) THEN
  MESSAGE "Error: unable to initialize OAuth"
  EXIT PROGRAM 1
ELSE
  LET scopes = OAuthAPI.GetIDScopes()
  FOR ind = 1 TO scopes.getLength()
    DISPLAY "Scope supported is: ", scopes[ind]
  END FOR
END IF
# ...
END MAIN
```

**Access token functions**

Functions that manage OAuth access tokens.

**OAuthAPI.GetMyAccessToken**

Get a valid access token.

**Syntax**

```
GetMyAccessToken()
RETURNS STRING
```

NULL may be returned if the access token is not found or can not be renewed.

**Usage**

Use this function to retrieve the access token provided by the Identity Provider for access to a secure RESTful Web service. IdP token information is retrieved from the GWS engine once it has been initialized by OAuthAPI.init on page 3510. If the access token has expired, a new token is requested (if a refresh token is available) and returned.

In case of error, a NULL value will be returned.
OAuthAPI.GetMyAccessToken function

```plaintext
IMPORT FGL OAuthAPI
DEFINE access_token STRING
MAIN
IF NOT OAuthAPI.init(5, "AF350CBC-8801-4DFB-9A78-A95B25BB32AF", "8JEq3HBfxrmj/8vMP66iaRQnGrWVyjqr") THEN
    MESSAGE "Error: unable to initialize OAuth"
    EXIT PROGRAM 1
ELSE
    LET access_token = OAuthAPI.GetMyAccessToken()
END IF
# ...
END MAIN
```

Authorization request functions
Functions that manage HTTPRequest with OAuth access token.

OAuthAPI.CreateHTTPAuthorizationRequest
Create an HTTPRequest with OAuth access token.

Syntax

```plaintext
CreateHTTPAuthorizationRequest (url STRING )
RETURNS com.HTTPRequest
```

1. `url` is a STRING with the URL to connect to.

Returns a com.HTTPRequest object. NULL may be returned if the access token can not be renewed.

Usage
Use this function to create an HTTPRequest object with OAuth access token for access to a secure RESTful Web service.

In case of error, a NULL value will be returned.

OAuthAPI.CreateHTTPAuthorizationRequest function

```plaintext
IMPORT com
IMPORT FGL OAuthAPI
MAIN
DEFINE req com.HTTPRequest
DEFINE resp com.HTTPResponse
DEFINE url STRING
TRY
    # call the init function first
    # get request path
    LET url = fgl_getenv("OIDC_USERINFO_ENDPOINT")
    # Create oauth request
    LET req = OAuthAPI.CreateHTTPAuthorizationRequest(url)
    # Perform request
END TRY
```
CALL req.setMethod("GET")
CALL req.setHeader("Accept", "application/json")
CALL req.DoRequest()

# Retrieve response
LET resp = req.getResponse()

# Process response
CASE resp.getStatusCode()
  WHEN 200 # Success
    # ...
  OTHERWISE
    DISPLAY " Error code is: ", resp.getStatusCode()
    EXIT PROGRAM 1
END CASE

CATCH
  DISPLAY "ERROR : ", status, SQLCA.SQLERRM
  EXIT PROGRAM 1
END TRY
END MAIN

OAuthAPI.RetryHTTPRequest
Retry an HTTPRequest with OAuth access token to check if the access token has expired.

Syntax

RetryHTTPRequest ( 
  resp com.HTTPResponse  )
RETURNS BOOLEAN

1. resp is a com.HTTPResponse object.
   Returns TRUE if the access token has expired and the request must be sent again, FALSE otherwise.

Usage
Use this function to check whether the access token to a secure RESTful Web service has expired. If expired, it will perform the refresh and then do the request.
In case of error, a NULL value will be returned.

OAuthAPI.RetryHTTPRequest function

IMPORT com
IMPORT FGL OAuthAPI

MAIN

DEFINE req com.HTTPRequest
DEFINE resp com.HTTPResponse
DEFINE url STRING

TRY
  # Get path
  LET url = fgl_getenv("OIDC_USERINFO_ENDPOINT")

  WHILE TRUE
    # Create oauth request
    LET req = OAuthAPI.CreateHTTPAuthorizationRequest(url)

    # Perform request
CALL req.setMethod("GET")
CALL req.setHeader("Accept", "application/json")
CALL req.DoRequest()

# Retrieve response
LET resp = req.getResponse()
# Retry if access token has expired
IF NOT OAuthAPI.RetryHTTPRequest(resp) THEN
   EXIT WHILE
END IF
END WHILE

# Process response
CASE resp.getStatusCode()
   WHEN 200 #Success
   # ...
   OTHERWISE
      DISPLAY " Error code is: ", resp.getStatusCode()
   EXIT PROGRAM 1
END CASE
CATCH
   DISPLAY "ERROR : ", status, SQLCA.SQLERRM
   EXIT PROGRAM 1
END TRY
END MAIN

Related concepts
OAuth access without GAS on page 3521
Example getting OAuth access when the application is not behind GAS, for example a mobile app.

Helper functions
Functions that manage OpenID Connect metadata for Web services not behind a Genero Application Server.
OAuthAPI.RetrievePasswordToken
Return the OAuth service access token via username and password.

Syntax

RetrievePasswordToken(
   timeout INTEGER,
   TokenServiceURL STRING,
   usr STRING,
   pass STRING,
   scope STRING )
RETURNS ( STRING, INTEGER )

1. timeout. Defines the number of seconds.
2. TokenServiceURL. This is the token endpoint of the Identity Provider (IdP) securing the service.
3. usr. This is the user's login details.
4. pass. This is the user password.
5. scope. This is a space-separated list of scopes defining user access.

Returns a valid access token and when it expires in seconds. NULL may be returned if the access token is not available.

Usage
Use this function to retrieve a valid access token for a client app accessing a RESTful Web service using the username and password.
In case of error, a NULL value will be returned.

**OAuthAPI.RetrievePasswordToken function**

```plaintext
IMPORT FGL OAuthAPI

MAIN

DEFINE metadata OAuthAPI.OpenIDMetadataType
DEFINE token STRING
DEFINE expire INTEGER
DEFINE usr, pass, STRING
DEFINE scope STRING
DEFINE idp_url STRING

TRY
    # ...
    CALL OAuthAPI.FetchOpenIDMetadata(20, idp_url)
        RETURNING metadata.*
    IF metadata.issuer IS NULL THEN
        ERROR "IdP not available"
        EXIT PROGRAM 1
    ELSE
        CALL OAuthAPI.RetrievePasswordToken(5, metadata.token_endpoint, usr, pass, scope )
            RETURNING token, expire
        IF token IS NULL THEN
            DISPLAY "Unable to retrieve token"
            EXIT PROGRAM 1
        ELSE
            DISPLAY "Access token value :",token
            DISPLAY SFMT("Token expires in %1 seconds",expire)
        END IF
    END IF
END IF
CATCH
    DISPLAY "ERROR : ",status,SQLCA.SQLERRM
    EXIT PROGRAM 1
END TRY
END MAIN
```

**Related concepts**

**OAuthAPI.RetrieveServiceToken** on page 3520
Return the OAuth service access token via client app credentials.

**OAuth access without GAS** on page 3521
Example getting OAuth access when the application is not behind GAS, for example a mobile app.

**OAuthAPI.FetchOpenIDMetadata**
Fetch metadata from the Identity Provider at the URL provided.

**Syntax**

```plaintext
FetchOpenIDMetadata(
    timeout INTEGER,
    idp STRING )
RETURNS OAuthAPI.OpenIDMetadataType
```

1. `timeout` defines the number of seconds.
2. `idp` is the URL of the Identity Provider (IdP).

NULL may be returned if metadata is not found.
Usage
Use this function to retrieve the metadata (such as registration endpoint, supported scopes, user information endpoints, etc.) provided by the Identity Provider for access to a secure RESTful Web service. The information is retrieved in a requested to the IdP via the URL provided and stored in the OpenIDMetadataType record.

Note:
If the service is started behind the GAS, call the GetOpenIDMetadata() function instead.
In case of error, a NULL value will be returned.

OAuthAPI.FetchOpenIDMetadata function

```
IMPORT FGL OAuthAPI
PRIVATE DEFINE metadata OAuthAPI.OpenIDMetadataType
DEFINE idp_url STRING
MAIN
  # ...
  CALL OAuthAPI.FetchOpenIDMetadata(20, idp_url)
  RETURNING metadata.*
  IF metadata.issuer IS NULL THEN
    ERROR "IdP not available"
  ELSE
    DISPLAY "Registration endpoint is: ", metadata.registration_endpoint
  END IF
  # ...
END MAIN
```

Related concepts
OAuth access without GAS on page 3521
Example getting OAuth access when the application is not behind GAS, for example a mobile app.

OAuthAPI.ExtractTokenFromHTTPRequest
Return the OAuth access token.

Syntax

```
ExtractTokenFromHTTPRequest (req com.HTTPServiceRequest) RETURNS STRING
```

1. req is a com.HTTPServiceRequest object.

Returns the access token. NULL may be returned if the access token is not found.

Usage
Use this function to extract the access token from an com.HTTPServiceRequest object accessing a RESTful Web service.
In case of error, a NULL value will be returned.

OAuthAPI.ExtractTokenFromHTTPRequest function

```
DEFINE req com.HttpServiceRequest
DEFINE access_token STRING

TRY
  # Start server for all registered Web Services
  CALL com.WebServiceEngine.Start()

  WHILE TRUE
    LET req = com.WebServiceEngine.GetHttpServiceRequest(-1)
    IF req IS NULL THEN
      DISPLAY "HTTP request timeout...: ", CURRENT YEAR TO FRACTION
      EXIT PROGRAM 1
    ELSE
      # Retrieve access token
      LET access_token = OAuthAPI.ExtractTokenFromHTTPRequest(req)
      IF access_token IS NOT NULL THEN
        DISPLAY "token is: ", access_token
      END IF
    END IF
  END WHILE
CATCH
  DISPLAY "ERROR : ",status,SQLCA.SQLERRM
  EXIT PROGRAM 1
END TRY
END MAIN

Related concepts
OAuth access without GAS on page 3521
Example getting OAuth access when the application is not behind GAS, for example a mobile app.

OAuthAPI.RetrieveServiceToken
Return the OAuth service access token via client app credentials.

Syntax

RetrieveServiceToken(
  timeout INTEGER,
  TokenServiceURL STRING,
  client_id STRING,
  secret_id STRING,
  scope STRING )
RETURNS STRING, INTEGER

1. timeout. Defines the number of seconds.
2. TokenServiceURL. This is the token endpoint of the Identity Provider (IdP) securing the service.
3. client_id. This is the application ID assigned to the app when registered.
4. client_secret. This is the application secret created for the app.
5. scope. This is a space-separated list of scopes defining user access.

Returns a valid access token and when it expires in seconds. NULL may be returned if the access token is not available.

Usage

Use this function to retrieve a valid access token for a client app accessing a RESTful Web service using the client app's own client id and client secret credentials.

In case of error, a NULL value will be returned.
OAuthAPI.RetrieveServiceToken function

```plaintext
IMPORT FGL OAuthAPI

MAIN

DEFINE metadata OAuthAPI.OpenIDMetadataType
DEFINE token STRING
DEFINE expire INTEGER
DEFINE client_id STRING
DEFINE secret_id STRING
DEFINE scope STRING
DEFINE idp_url STRING

TRY
    # ...
    CALL OAuthAPI.FetchOpenIDMetadata(20, idp_url)
    RETURNING metadata.*
    IF metadata.issuer IS NULL THEN
        ERROR "IdP not available"
        EXIT PROGRAM 1
    ELSE
        CALL OAuthAPI.RetrieveServiceToken(5, metadata.token_endpoint,
            client_id, secret_id, scope )
        RETURNING token, expire
        IF token IS NULL THEN
            DISPLAY "Unable to retrieve token"
            EXIT PROGRAM 1
        ELSE
            DISPLAY "Access token value :",token
            DISPLAY SFMT("Token expires in %1 seconds",expire)
        END IF
    END IF
CATCH
    DISPLAY "ERROR : ",status,SQLCA.SQLERRM
    EXIT PROGRAM 1
END TRY

END MAIN
```

**Examples**

OAuthAPI Helper function examples.

OAuth access without GAS

Example getting OAuth access when the application is not behind GAS, for example a mobile app.

**OAuthAPI helper functions**

```plaintext
IMPORT com
IMPORT FGL OAuthAPI
IMPORT util

PUBLIC TYPE QueryUserInfoResponseBodyType DYNAMIC ARRAY OF RECORD
    user_id INTEGER,
    given_name STRING,
    family_name STRING,
    email STRING
END RECORD

# Error codes
PUBLIC CONSTANT C_SUCCESS = 0

PUBLIC FUNCTION QueryUserInfo(idp_url STRING, user_login STRING,
    user_password STRING) RETURNS(INTEGER, QueryUserInfoResponseBodyType)
```
DEFINE fullpath base.StringBuffer
DEFINE contentType STRING
DEFINE req com.HTTPRequest
DEFINE resp com.HTTPResponse
DEFINE resp_body QueryUserInfoResponseBodyType
DEFINE json_body STRING
DEFINE expire INTEGER
DEFINE meta OAuthAPI.OpenIDMetadataType

CALL OAuthAPI.FetchOpenIDMetadata(5, ipd_url) RETURNING meta.*
CALL OAuthAPI.RetrievePasswordToken(5, meta.token_endpoint, user_login, user_password, "profile") RETURNING access_token, expire
CALL OAuthAPI.initService(5, access_token)

TRY

# Prepare request path
LET fullpath = base.StringBuffer.Create()
CALL fullpath.append("/userinfo/v1/query")

WHILE TRUE

# Create oauth request and configure it
LET req =
OAuthAPI.CreateHTTPAuthorizationRequest(meta.userinfo_endpoint
SFMT("%1%2", Endpoint.Address.Uri, fullpath.toString()))

# Perform request
CALL req.setMethod("GET")
CALL req.setHeader("Accept", "application/json")
CALL req.DoRequest()

# Retrieve response
LET resp = req.getResponse()

# Retry if access token has expired
IF NOT OAuthAPI.RetryHTTPRequest(resp) THEN
END IF
EXIT WHILE
END IF

# Process response
INITIALIZE resp_body TO NULL
LET contentType = resp.getHeader("Content-Type")
CASE resp.getStatusCode()

# Parse JSON response
LET json_body = resp.getTextResponse()
CALL util.JSON.parse(json_body, resp_body)
RETURN C_SUCCESS, resp_body
END IF
RETURN -1, resp_body
OTHERWISE
RETURN resp.getStatusCode(), resp_body
END CASE
CATCH
RETURN -1, resp_body
END TRY
END FUNCTION
Attributes to customize XML serialization

See The Serializer class on page 3033 for information on setting serialization options when mapping BDL and XML data.

BDL to/from XML type mappings

Starting with Genero 2.0, you can add optional attributes to the definition of program variables to be used for XML serialization. These attributes can be used to map a BDL data type used in the input or output message of a Genero Web Service application to a specific XML data type, rather than using the default.

For example, if an XML Schema boolean data type is required for an application, and the corresponding BDL type is a SMALLINT, you can use an attribute to map the BDL SMALLINT variable to the XML boolean.

The following example uses the XSDBoolean attribute to map a BDL SMALLINT variable to an XML Schema boolean type, and assigns an uppercase name as the XMLName attribute:

```plaintext
GLOBALS
DEFINE invoice_out RECORD
  ok SMALLINT ATTRIBUTES(XSDBoolean,XMLName="OK")
END RECORD
END GLOBALS
```

If you assign your own XMLName attributes, be sure to respect the conventions when using the RPC Service Style.

See the Tutorial: Writing a GWS Server application for additional information about input and output messages.

Default BDL/XML mapping

By default, Genero Web Services maps BDL variables in the input or output messages of a WS application to their corresponding XML data types, enabling values to be passed between applications and Web Services. The XML data types conform to the standard XML Schema Definition (XSD):

Table 742: Default XML Mapping

<table>
<thead>
<tr>
<th>Data type of BDL variable</th>
<th>Default XML data type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>xsd:base64binary</td>

</tbody>
</table>

**XSDAnySimpleType**

Map BDL STRING or VARCHAR to XML Schema anySimpleType.

**XSDAnyType**

Map BDL STRING or VARCHAR to XML Schema anyType.

**XSDAnyURI**

Map BDL STRING or VARCHAR to XML Schema anyURI.

**XSDBase64binary**

Map BDL BYTE to XML Schema base64binary.

**Example**

```sql
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 BYTE ATTRIBUTES(XSDBase64binary,XMLName="Val")
END RECORD

<Role>
    <Val>F0FFC8D27FF001547FC219E1FFF009F0FFC8D27FF001547D</Val>
</Role>
```

**XSDBase64binary**

Map BDL BOOLEAN, SMALLINT or INTEGER to XML Schema boolean.

**Example**

```sql
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val INTEGER ATTRIBUTES(XSDBase64binary,XMLName="Val")
END RECORD

<Role>
    <Val>true</Val>
</Role>
```
### XSDByte
Map BDL TINYINT, SMALLINT or BIGINT to XML Schema `byte`.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 SMALLINT ATTRIBUTES(XSDByte,XMLName="Val")
END RECORD

<Root>
    <Val>-126</Val>
</Root>
```

### XSDDate
Map BDL DATE or DATETIME to XML Schema `date`.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DATE ATTRIBUTES(XSDDate,XMLName="Val")
END RECORD

<Root>
    <Val>2006-06-29+01:00</Val>
</Root>
```

### XSDDateTime
Map BDL DATETIME to XML Schema `dateTime`.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DATETIME ATTRIBUTES(XSDDateTime,XMLName="Val")
END RECORD

<Root>
    <Val>2006-06-29T09:35:26.13584+01:00</Val>
</Root>
```

### XSDDecimal
Map BDL DECIMAL to XML Schema `decimal`.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DECIMAL(5,3) ATTRIBUTES(XSDDecimal,XMLName="Val")
END RECORD

<Root>
    <Val>12.345</Val>
</Root>
```

### XSDDouble
Map BDL FLOAT to XML Schema `double`.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DECIMAL(5,3) ATTRIBUTES(XSDDecimal,XMLName="Val")
END RECORD

<Root>
    <Val>12.345</Val>
</Root>
```
Example

```sql
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 FLOAT ATTRIBUTES(XSDDouble,XMLName="Val")
END RECORD

<Root>
  <Val>12.78e-2</Val>
</Root>
```

**XSDDuration**

Map BDL INTERVAL to XML Schema `duration`.

Example

```sql
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTERVAL DAY TO SECOND ATTRIBUTES(XSDDuration,XMLName="Val")
END RECORD

<Root>
  <Val>P3DT10H30M45S</Val>
</Root>
```

**XSDEntities**

Map BDL STRING or VARCHAR to XML Schema `ENTITIES`.

**XSDEntity**

Map BDL STRING or VARCHAR to XML Schema `ENTITY`.

**XSDFloat**

Map BDL SMALLFLOAT to XML Schema `float`.

Example

```sql
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 SMALLFLOAT ATTRIBUTES(XSDFloat,XMLName="Val")
END RECORD

<Root>
  <Val>126.435</Val>
</Root>
```

**XSDGDay**

Map BDL DATETIME to XML Schema `gDay`.

Example

```sql
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME DAY TO DAY ATTRIBUTES(XSDGDay,XMLName="Val")
END RECORD

<Root>
  <Val>---25</Val>
</Root>
```
**XSDGMonth**

Map BDL DATETIME to XML Schema `gMonth`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME MONTH TO MONTH ATTRIBUTES(XSDGMonth,XMLName="Val")
END RECORD

<Root>
  <Val>--12</Val>
</Root>
```

**XSDGMonthDay**

Map BDL DATETIME to XML Schema `gMonthDay`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME MONTH TO DAY ATTRIBUTES(XSDGMonthDay,XMLName="Val")
END RECORD

<Root>
  <Val>--12-31</Val>
</Root>
```

**XSDGYear**

Map BDL DATETIME to XML Schema `gYear`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME YEAR TO YEAR ATTRIBUTES(XSDGYear,XMLName="Val")
END RECORD

<Root>
  <Val>2006</Val>
</Root>
```

**XSDGYearMonth**

Map BDL DATETIME to XML Schema `gYearMonth`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DATETIME YEAR TO MONTH ATTRIBUTES(XSDGYearMonth,XMLName="Val")
END RECORD

<Root>
  <Val>2006-06</Val>
</Root>
```

**XSDHexBinary**

Map BDL BYTE to XML Schema `hexBinary`.
**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 BYTE ATTRIBUTES(XSDHexBinary,XMLName="Val")
END RECORD

<Root>
  <Val>0FB6</Val>
</Root>
```

**XSDID**

Map BDL STRING or VARCHAR to XML Schema **ID**.

**XSDIDREF**

Map BDL STRING or VARCHAR to XML Schema **IDREF**.

**XSDIDREFS**

Map BDL STRING or VARCHAR to XML Schema **IDREFS**.

**XSDInt**

Map BDL INTEGER or BIGINT to XML Schema **int**.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XSDInt,XMLName="Val")
END RECORD

<Root>
  <Val>-1258</Val>
</Root>
```

**XSDInteger**

Map BDL DECIMAL to XML Schema **integer**.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(32,0) ATTRIBUTES(XSDInteger,XMLName="Val")
END RECORD

<Root>
  <Val>12678</Val>
</Root>
```

**XSDLanguage**

Map BDL STRING or VARCHAR to XML Schema **language**.

**XSDLong**

Map BDL BIGINT or DECIMAL to XML Schema **long**.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 DECIMAL(19,0) ATTRIBUTES(XSDLong,XMLName="Val")
END RECORD
```
Web services

END RECORD

```
<Root>
    <Val>1267488</Val>
</Root>
```

**XSDNCName**
Map BDL STRING or VARCHAR to XML Schema **NCName**.

**XSDName**
Map BDL STRING or VARCHAR to XML Schema **Name**.

**XSDNegativeInteger**
Map BDL DECIMAL to XML Schema **negativeInteger**.

**Example**

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DECIMAL(32,0) ATTRIBUTES(XSDNegativeInteger,XMLName="Val")
END RECORD
```

```
<Root>
    <Val>-4828</Val>
</Root>
```

**XSDNMTOKEN**
Map BDL STRING or VARCHAR to XML Schema **NMToken**.

**XSDNMTOKENS**
Map BDL STRING or VARCHAR to XML Schema **NMTokens**.

**XSDNonNegativeInteger**
Map BDL DECIMAL to XML Schema **nonNegativeInteger**.

**Example**

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DECIMAL(32,0) ATTRIBUTES(XSDNonNegativeInteger,XMLName="Val")
END RECORD
```

```
<Root>
    <Val>1589</Val>
</Root>
```

**XSDNonPositiveInteger**
Map BDL DECIMAL to XML Schema **nonPositiveInteger**.

**Example**

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DECIMAL(32,0) ATTRIBUTES(XSDNonPositiveInteger,XMLName="Val")
END RECORD
```

```
<Root>
    <Val>-8574</Val>
</Root>
**XSDNormalizedString**
Map BDL STRING or VARCHAR to XML Schema `normalizedString`.

**XSDnotation**
Not supported.

**XSDPositiveInteger**
Map BDL DECIMAL to XML Schema `positiveInteger`.

**Example**

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
   val1 DECIMAL(32,0) ATTRIBUTES(XSDPositiveInteger,XMLName="Val")
END RECORD

<Root>
  <Val>+41893</Val>
</Root>
```

**XSDQName**
Map BDL STRING or VARCHAR to XML Schema `QName`.

**XSDShort**
Map BDL SMALLINT or BIGINT to XML Schema `short`.

**Example**

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
   val1 SMALLINT ATTRIBUTES(XSDShort,XMLName="Val")
END RECORD

<Root>
  <Val>12678</Val>
</Root>
```

**XSDString**
Map BDL STRING, CHAR, TEXT or VARCHAR to XML Schema `string`.

**Example**

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
   val1 STRING ATTRIBUTES(XSDString,XMLName="Val")
END RECORD

<Root>
  <Val>Hello world, how are you ?</Val>
</Root>
```

**XSDTime**
Map BDL DATETIME to XML Schema `time`.

**Example**

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
   val1 DATETIME ATTRIBUTES(XSDTime,XMLName="Val")
END RECORD

<Root>
  <Val>Hello world, how are you ?</Val>
</Root>
```
**XSDToken**
Map BDL STRING or VARCHAR to XML Schema `token`.

**XSDUnsignedByte**
Map BDL SMALLINT or BIGINT to XML Schema `unsignedByte`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 SMALLINT ATTRIBUTES(XSDUnsignedByte,XMLName="Val")
END RECORD
```

```xml
<Root>
    <Val>254</Val>
</Root>
```

**XSDUnsignedInt**
Map BDL BIGINT or DECIMAL to XML Schema `unsignedInt`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DECIMAL(32,0) ATTRIBUTES(XSDUnsignedInt,XMLName="Val")
END RECORD
```

```xml
<Root>
    <Val>1267896754</Val>
</Root>
```

**XSDUnsignedLong**
Map BDL DECIMAL to XML Schema `unsignedLong`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 DECIMAL(32,0) ATTRIBUTES(XSDUnsignedLong,XMLName="Val")
END RECORD
```

```xml
<Root>
    <Val>12678967543233</Val>
</Root>
```

**XSDUnsignedShort**
Map BDL INTEGER or BIGINT to XML Schema `unsignedShort`.

**Example**

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
    val1 INTEGER ATTRIBUTES(XSDUnsignedShort,XMLName="Val")
END RECORD
```

```xml
<Root>
    <Val>12678967543233</Val>
</Root>
XML facet constraint attributes

The following attributes are facet constraints depending on the XSD data type used on a simple BDL variable to restrict the allowed value-space.

(Notice that some attributes are allowed only on some XSD data types).

Several facet constraints can be set on the same data type, and a mandatory values is expected (for example, XSDMinLength="8").

Table 744: Facet constraints between simple BDL and XML data types

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XSDLength</td>
<td>Define the exact number of XML character or bytes.</td>
</tr>
<tr>
<td>XSDMinLength</td>
<td>Define the minimum number of XML character or bytes.</td>
</tr>
<tr>
<td>XSDMaxLength</td>
<td>Define the maximum number of XML character or bytes.</td>
</tr>
<tr>
<td>XSDEnumeration</td>
<td>Define a list of allowed values separated by the character</td>
</tr>
<tr>
<td>XSDWhiteSpace</td>
<td>Perform a XML string manipulation before serialization or deserialization.</td>
</tr>
<tr>
<td>XSDPattern</td>
<td>Define the regular expression the value has to match.</td>
</tr>
<tr>
<td>XSDMinInclusive</td>
<td>Define the inclusive minimum value based on the data type where it is set.</td>
</tr>
<tr>
<td>XSDMaxInclusive</td>
<td>Define the inclusive maximum value based on the data type where it is set.</td>
</tr>
<tr>
<td>XSDMinExclusive</td>
<td>Define the exclusive minimum value based on the data type where it is set.</td>
</tr>
<tr>
<td>XSDMaxExclusive</td>
<td>Define the exclusive maximum value based on the data type where it is set.</td>
</tr>
<tr>
<td>XSDTotalDigits</td>
<td>Define the total number of digits.</td>
</tr>
<tr>
<td>XSFractionDigits</td>
<td>Define the number of digits of the fraction part.</td>
</tr>
</tbody>
</table>

XSDLength

Restrict the length of the data to the exact number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

Note:

1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater then XSDMinLength
2. XSDMaxLength cannot be used with XSDLength

Example

```
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDLength="12",
```
XSDMinLength
Restrict the length of the data to the minimum number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

Note:
1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater than XSDMinLength
2. XSDMaxLength cannot be used with XSDLLength

Example

```bdl
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDMinLength="12", XMLName="MyString")
DEFINE myByte BYTE ATTRIBUTES(XSDBase64Binary, XSDMinLength="8000", XMLName="MyPicture")
```

XSDMaxLength
Restrict the length of the data to the maximum number of XML characters allowed when set on a BDL STRING, VARCHAR, CHAR or TEXT, or the number of bytes allowed when set on a BDL BYTE.

Note:
1. XSDMinLength and XSDMaxLength can be used together, but XSDMaxLength value must be greater than XSDMinLength
2. XSDMaxLength cannot be used with XSDLLength

Example

```bdl
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDMaxLength="12", XMLName="MyString")
DEFINE myByte BYTE ATTRIBUTES(XSDBase64Binary, XSDMaxLength="8000", XMLName="MyPicture")
```

XSDEnumeration
Restrict the allowed value-space to a list of values separated by the characters |.

Note:
1. To escape the separator character, simply double it like the following ||
2. This attribute can be set on any simple BDL variable excepted on XSDBoolean.

Example

```bdl
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDEnumeration="one|two|three|four", XMLName="MyString")
```

```bdl
DEFINE myDec DECIMAL(3,1) ATTRIBUTES(XSDDecimal, XSDEnumeration="12.1|11.8|-24.7", XMLName="MyDecimal")
```
**XSDWhiteSpace**

Perform a XML string manipulation before serialization or deserialization depending on the following possible values:

- **preserve**: the XML string is not modified.
- **replace**: the XML string is modified by replacing each `\n`, `\t`, `\r` by a single space.
- **collapse**: the XML string is modified by replacing each `\n`, `\t`, `\r` by a single space, then each sequence of several spaces are replaced by one single space. Leading and trailing spaces are removed too.

**Note:**

1. The whiteSpace facet is always performed before any other facet constraints, or serialization or deserialization process.
2. For any BDL variable excepted STRING, CHAR and VARCHAR, only collapse is allowed.

**Example**

```nbdkind
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDWhiteSpace="replace", XMLName="MyString")

DEFINE myDec DECIMAL(3,1) ATTRIBUTES(XSDDecimal, XSDWhiteSpace="collapse", XMLName="MyDecimal")
```

**XSDPattern**

Define a regular expression the value has to match to be serialized or deserialized without any error.

**Note:**

1. The regular expression is defined in the XML Schema Part 2 specification available [here](#).
2. Backslash characters `\` in a regular expression must be escaped by duplicating it.

**Example**

```nbdkind
DEFINE myStr STRING ATTRIBUTES(XSDString, XSDPattern="A.*Z", XMLName="MyString")

DEFINE myZipCode INTEGER ATTRIBUTES(XSDInt, XSDPattern="[0-9]{5}", XMLName="MyZipCode")

DEFINE myOtherZipCode INTEGER ATTRIBUTES(XSDInt, XSDPattern="\\d{5}", XMLName="myOtherZipCode") # regex is \d{5} see note
```

**XSDMinInclusive**

Define the minimum inclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

**Note:** The minimum value cannot exceed the implicit minimum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the minimum value is -32768.

**Example**

```nbdkind
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDMinInclusive="-1000", XMLName="MyCode")

DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDMinInclusive="100.01", XMLName="MyRate")
```
XSDMaxInclusive
Define the maximum inclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

Note: The maximum value cannot exceed the implicit maximum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the maximum value is 32767.

Example

```plaintext
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDMaxInclusive="1000", XMLName="MyCode")
```

```plaintext
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDMaxInclusive="299.99", XMLName="MyRate")
```

XSDMinExclusive
Define the minimum exclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

Note: The minimum value cannot exceed or be equal to the implicit minimum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the minimum value is -32768.

Example

```plaintext
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDMinExclusive="-1000", XMLName="MyCode")
```

```plaintext
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDMinExclusive="100.01", XMLName="MyRate")
```

XSDMaxExclusive
Define the maximum exclusive value allowed and depending on the data type where it is set, namely all numeric, date and time data types.

Note: The maximum value cannot exceed or be equal to the implicit maximum value supported by the data type itself or the compiler will complain. For instance, with XSDShort the maximum value is 32767.

Example

```plaintext
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDMaxExclusive="1000", XMLName="MyCode")
```

```plaintext
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDMaxExclusive="299.99", XMLName="MyRate")
```

XSDTotalDigits
Define the maximum number of digits allowed on a numeric data type, fraction part inclusive if there is one.

Note:
1. The total digits value cannot be equal or lower then 0.
2. On a BDL decimal, the total digits value cannot be lower than the precision of the BDL decimal itself.
3. Notice that a decimal without any precision and scale value is a decimal(16), therefore the total digits value must be equal or greater than 16.

Example

```plaintext
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDTotalDigits="4", XMLName="MyCode")
```
**XSDMaxExclusive**

Define the maximum number of digits allowed on the fraction part of a numeric data type.

**Note:**

1. The fraction digits value set on a BDL data type without XSDDecimal set, can only be 0.
2. On a BDL DECIMAL, the fraction digits value cannot be lower than the scale of the BDL DECIMAL itself, and must be lower than the XSDTotalDigits value if set.

**Example**

```plaintext
DEFINE myCode SMALLINT ATTRIBUTES(XSDShort, XSDFractionDigits="0", XSDMaxExclusive="1000", XMLName="MyCode")
DEFINE myRate DECIMAL(4,2) ATTRIBUTES(XSDDecimal, XSDTotalDigits="5", XSDMaxExclusive="299.99", XMLName="MyRate")
```

**Customizing XML serialization**

The following attributes are used to change the default serialization of BDL into XML, and vice versa. Some attributes cannot have values, some may have values, and some attributes have mandatory values.

The following attributes cannot have values:

**Table 745: XML Serialization customizing - Attributes that cannot have values**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLOptional</td>
<td>Define whether the variable can be missing.</td>
</tr>
<tr>
<td>XMLNillable on page 3540</td>
<td>Define an XML element to be explicitly null and serialized with the xsi:nil=&quot;true&quot; value.</td>
</tr>
<tr>
<td>XMLElement</td>
<td>Map a BDL simple data type to an XML Element.</td>
</tr>
<tr>
<td>XMLElementNillable on page 3542</td>
<td>Define the default for all element members in a RECORD (defined by TYPE or DEFINE) to be serialized as xsi:nil=&quot;true&quot; if NULL.</td>
</tr>
<tr>
<td>XMLAttribute</td>
<td>Map a BDL simple data type to an XML Attribute.</td>
</tr>
<tr>
<td>XMLBase</td>
<td>Set the base type of an XML Schema simpleContent.</td>
</tr>
<tr>
<td>XMLAll</td>
<td>Map a BDL Record to an XML Schema all structure.</td>
</tr>
<tr>
<td>XMLChoice</td>
<td>Map a BDL Record to an XML Schema choice structure.</td>
</tr>
<tr>
<td>XMLSequence</td>
<td>Map a BDL Record to an XML Schema sequence structure.</td>
</tr>
<tr>
<td>XMLSimpleContent</td>
<td>Map a BDL Record to an XML Schema simpleContent structure.</td>
</tr>
<tr>
<td>XSComplexType</td>
<td>Map a BDL Record type definition to an XML Schema complexType.</td>
</tr>
<tr>
<td>XMLList</td>
<td>Map a one-dimensional array to an XML Schema list.</td>
</tr>
<tr>
<td>XMLSelector</td>
<td>Define which member of an XMLChoice record is selected.</td>
</tr>
<tr>
<td>XMLAny</td>
<td>Map a xml.DomDocument object to a wildcard XML element node.</td>
</tr>
<tr>
<td>XMLAnyAttribute</td>
<td>Map a BDL one-dimensional dynamic array of a record with 3 strings to XML wildcard attributes.</td>
</tr>
</tbody>
</table>
Values are mandatory for the following attributes: (for example, XMLName="myname")

Table 746: XML Serialization customizing - Attributes that must have values

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLName</td>
<td>Define the XML Name of a variable in an XML document.</td>
</tr>
<tr>
<td>XMLNamespace</td>
<td>Define the XML Namespace of a variable in an XML document.</td>
</tr>
<tr>
<td>XMLType</td>
<td>Force the XML type name of a variable.</td>
</tr>
<tr>
<td>XMLTypenamespace</td>
<td>Force the XML type namespace of a variable.</td>
</tr>
<tr>
<td>XSTypename</td>
<td>Define the XML Type Name of a BDL type definition.</td>
</tr>
<tr>
<td>XSTypenamespace</td>
<td>Define the XML Type Namespace of a BDL type definition.</td>
</tr>
<tr>
<td>XMLElementNamespace</td>
<td>Define the default XML namespace of all children defined as XMLElement in a</td>
</tr>
<tr>
<td></td>
<td>Record.</td>
</tr>
<tr>
<td>XMLAttributeNameSpace</td>
<td>Define the default XML namespace of all children defined as XMLAttribute in a</td>
</tr>
<tr>
<td></td>
<td>Record.</td>
</tr>
</tbody>
</table>

Values may be required for the following attributes: (for example, XMLOptimizedContent="image/*")

Table 747: XML Serialization customizing - Attributes that may have values

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLOptimizedContent</td>
<td>Set on STRING or BYTE data type so that such string content represents a file on disk to be transmitted as base64 binary in SOAP via HTTP attachment.</td>
</tr>
</tbody>
</table>

XMLOptional

Define whether a variable can be omitted or not. It specifies how a NULL value is interpreted in XML if it is optional. For an option to set an XML node nillable when the BDL variable is NULL but not optional, see the XMLNillable on page 3540 attribute.

Note:
1. The attribute cannot be set on a type definition.
2. The attribute cannot be set if the main variable is not a RECORD.

Example

The variable "ValTwo" is optional when null.

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
   val1 INTEGER ATTRIBUTES(XSDint,XMLName="ValOne"),
   val2 FLOAT ATTRIBUTES(XSDdouble,XMLName="ValTwo",XMLOptional)
END RECORD
```

In the resulting XML document, "ValTwo" is defined when not NULL

```
<Root>
   <ValOne>458</ValOne>
   <ValTwo>58.48</ValTwo>
</Root>
```

In the resulting XML document, "ValTwo" is not defined when NULL.

```
<Root>
   <ValOne>458</ValOne>
</Root>
```
XMLNillable

Define an XML element to be explicitly null and serialized with the `xsi:nil="true"` value. It specifies how a NULL value is set on an XML node when the BDL variable is NULL but not optional.

**Note:** The XMLNillable attribute cannot be set on a TYPE definition. If you need to set nillable in a record defined from a database schema with LIKE clause, the XMLElementNillable on page 3542 attribute supports an implementation that sets all elements in the record to XMLNillable.

The XMLNillable attribute is used on its own, or in combination with the XMLOptional on page 3539 attribute to specify conditions for the XML node depending on how you want the BDL variable value to be serialized:

- XML node optional (when null)
- XML node nillable (when null)
- Option of either XML node optional or nillable, with preference for nillable.

Examples are shown for each use.

**Example optional**

The variable "val2" is optional when null

```bdd
DEFINE var RECORD
  val1 STRING,
  val2 INTEGER ATTRIBUTES(XMLOptional),
  val3 FLOAT
END RECORD
```

The resulting XML document is:

```xml
<var>
  <val1>Hello</val1>
  <val3>3.1415</val3>
</var>
```

**Example nillable**

The variable "val2" is nillable when BDL variable is NULL but not optional.

```bdd
DEFINE var RECORD
  val1 STRING,
  val2 INTEGER ATTRIBUTES(XMLNillable),
  val3 FLOAT
END RECORD
```

In the resulting XML document "val2" is serialized with the `xsi:nil="true"`

```xml
<var>
  <val1>Hello</val1>
  <val2 xsi:nil="true"/>
  <val3>3.1415</val3>
</var>
```

**Example optional or nillable**

The variable "val2" is either optional or nillable if BDL variable is NULL.

```bdd
DEFINE var RECORD
  val1 STRING,
  val2 INTEGER ATTRIBUTES(XMLNillable,XMLOptional),
  val3 FLOAT
END RECORD
```
In the resulting XML document "val2" is missing as it is defined by XMLOptional (the default).

```xml
<var>
  <val1>Hello</val1>
  <val3>3.1415</val3>
</var>
```

Or the resulting XML document can show "val2" nillable:

```xml
<var>
  <val1>Hello</val1>
  <val2 xsi:nil="true"/>
  <val3>3.1415</val3>
</var>
```

**Note:** If both XMLOptional and XMLNillable are set and the BDL variable is NULL, the serialization process from BDL to XML uses XMLOptional by default. If you prefer to serialize as xsi:nil="true", you must specify the "preferred" value as a parameter of XMLNillable.

```bdl
DEFINE var RECORD
  val1 STRING,
  val2 INTEGER ATTRIBUTES(XMLNillable="preferred", XMLOptional),
  val3 FLOAT
END RECORD
```

### XML transformation into BDL

When getting an XML transformation into BDL, the Web Service engine will not raise an error and the variable is set correctly whether the variable tag is missing or has xsi:nil="true" set. In either case, the BDL variable is set as NULL.

**XMLElement (Optional)**

Map a BDL simple data type to an XML Element.

**Note:** The attribute cannot be set on a type definition.

**Example**

```bdl
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XMLElement, XSDunsignedShort, XMLName="Val1"),
  rec RECORD ATTRIBUTES(XMLName="Rec")
    val2 FLOAT ATTRIBUTES(XMLElement, XMLName="Val2"),
    val3 STRING ATTRIBUTES(XMLElement, XMLName="Val3")
END RECORD
END RECORD
```

```xml
<Root>
  <Val1>148</Val1>
  <Rec1>
    <Val2>25.8</Val2>
    <Val3>Hello world</Val3>
  </Rec1>
</Root>
```
XMLElementNillable

The XMLElementNillable attribute specifies that all members of a RECORD have to be serialized as xsi:nil="true" when NULL. This has the same effect as defining each individual element with the XMLNillable attribute.

**Note:** The XMLElementNillable attribute can only be set on records defined by TYPE or DEFINE.

The XMLElementNillable attribute supports the record defined with LIKE clause to use the table definition from a database schema:

```define var RECORD ATTRIBUTE(XMLElementNillable) LIKE customer.*```

If columns in the database table are allowed to be null, you must add the XMLElementNillable attribute to the record definition.

The XMLElementNillable attribute is not inherited by sub records.

**Basic example**

```define var RECORD ATTRIBUTE(XMLElementNillable)
   val1 STRING,
   val2 STRING
END RECORD```

```let var.val1 = "Hello"
let var.val2 = NULL```

In the resulting XML document, "val2" is serialized with the xsi:nil="true":

```<var>
   <val1>Hello</val1>
   <val2 xsi:nil="true"/>
</var>```

**Example using a sub record**

Since XMLElementNillable attribute is not inherited by sub records, you must set it on each sub-record if needed:

```define var RECORD ATTRIBUTE(XMLElementNillable)
   val1 STRING,
   val2 STRING,
   subrec RECORD
   val3 STRING
END RECORD
END RECORD```

In the resulting XML document, for instance, only "val1" and "val2" are serialized as xsi:nil="true" when NULL, but "val3" is not.

To have "val3" serialized as xsi:nil="true" when NULL, define:

```define var RECORD ATTRIBUTE(XMLElementNillable)
   val1 STRING,
   val2 STRING,
   subrec RECORD ATTRIBUTE(XMLElementNillable)
   val3 STRING
END RECORD
END RECORD```

**Examples with XMLNillable and XMLOptional**

The XMLElementNillable attribute does not allow values, so you cannot write XMLElementNillable="preferred" as you do for XMLNillable.
If `XMLOptional` on page 3539 is set on a record member, `XMLElementNillable` is not taken into account.

If you need `XMLNillable` to take precedence over `XMLOptional`, you must then specify `XMLNillable="preferred"` on the record member.

In the following sample, if "val2" is `NULL`, it will serialize to the tag not being present because `XMLOptional` hides `XMLElementNillable`. On the other hand, if "val3" is `NULL`, it will be serialized as `xsi:nil="true"`, because the record member is defined with `XMLOptional` and `XMLNillable` (preferred):

```
DEFINE var RECORD ATTRIBUTE(XMLElementNillable)
   val1 STRING,
   val2 STRING ATTRIBUTE(XMLOptional),
   val3 STRING ATTRIBUTE(XMLOptional,XMLNillable="preferred")
END RECORD
LET var.val1 = "Hello"
LET var.val2 = NULL
LET var.val3 = NULL
```

Will be serialized as:

```
<var>
   <val1>Hello</val1>
   <val3 xsi:nil="true"/>
</var>
```

**XMLAttribute**

Map a BDL simple data type to an XML Attribute.

**Note:**

1. The attribute cannot be set on a type definition.
2. The attribute can only be set on a RECORD's member.

**Example**

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
   val1 INTEGER ATTRIBUTES(XMLAttribute,XSDunsignedShort,XMLName="Val1"),
   rec RECORD ATTRIBUTES(XMLName="Rec1")
      val2 FLOAT ATTRIBUTES(XMLAttribute,XMLName="Val2"),
      val3 STRING ATTRIBUTES(XMLElement,XMLName="Val3")
END RECORD
END RECORD
```

```
<Root Val1="148">
   <Rec1 Val2="25.8">
      <Val3>Hello world</Val3>
   </Rec1>
</Root>
```

**XMLBase**

Define the simple BDL variable used as the base type of an XML Schema `simpleContent` structure.

The attribute can be set on one and only one member of a RECORD defined with the `XMLSimpleContent` attribute

**XMLALL**

Map a BDL Record to an XML Schema `all` structure.

The order in which the record members appear in the XML document is not significant.
Example

```xml
DEFINE myall RECORD ATTRIBUTES(XMLAll,XMLName="Root")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT   ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  val3  STRING  ATTRIBUTES(XMLName="Val3")
END RECORD

<Root Val2="25.8">
  <Val3>Hello world</Val3>
  <Val1>148</Val1>
</Root>

<Root Val2="25.8">
  <Val1>148</Val1>
  <Val3>Hello world</Val3>
</Root>
```

XMLChoice

Map a BDL Record to an XML Schema choice structure. The choice of the record's member is performed at runtime, and changes dynamically depending on a mandatory member. This specific member must be of type SMALLINT or INTEGER, and have an XMLSelector attribute set. The XMLChoice attribute also supports a "nested" value that removes the surrounding XML tag.

Note:

1. Valid selector values are indexes referring to members considered as XML element nodes. All other values will raise XML runtime errors.
2. Nested choice records cannot be defined as main variables; there must always be a surrounding variable.

Example

```xml
DEFINE mychoice RECORD ATTRIBUTES(XMLChoice,XMLName="Root")
  val1  INTEGER   ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT     ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  sel   SMALLINT  ATTRIBUTES(XMLSelector),
  val3  STRING    ATTRIBUTES(XMLName="Val3")
END RECORD

Case where "sel" value is 4

<Root Val2="25.8">
  <Val3>Hello world</Val3>
</Root>

Case where "sel" value is 1

<Root Val2="25.8">
  <Val1>148</Val1>
</Root>

Nested example:

```xml
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1  INTEGER   ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT     ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  choice RECORD   ATTRIBUTES(XMLChoice="nested")
    choice1  INTEGER ATTRIBUTES(XMLName="ChoiceOne"),
    choice2  FLOAT   ATTRIBUTES(XMLName="ChoiceTwo"),
  nestedSel SMALLINT ATTRIBUTES(XMLSelector)
END RECORD
```
Case where "nestedSel" value is 1

```xml
<Root Val2="25.8">
  <Val1>148</Val1>
  <ChoiceOne>6584</ChoiceOne>
  <Val3>Hello world</Val3>
</Root>
```

Case where "nestedSel" value is 2

```xml
<Root Val2="25.8">
  <Val1>148</Val1>
  <ChoiceTwo>85.8</ChoiceTwo>
  <Val3>Hello world</Val3>
</Root>
```

**XMLSequence (Optional)**

Map a BDL RECORD to an XML Schema sequence structure. The order in which the record members appear in the XML document must match the order of the BDL RECORD. The XMLSequence attribute also supports a "nested" value that removes the surrounding XML tag.

**Note:** Nested sequence records cannot be defined as main variables; there must always be a surrounding variable.

**Example**

```verbatim
DEFINE mysequence RECORD ATTRIBUTES(XMLSequence,XMLName="Root")
  val1 INTEGER ATTRIBUTES(XMLName="Val1"),
  val2 FLOAT ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  val3 STRING ATTRIBUTES(XMLName="Val3")
END RECORD

<Root Val2="25.8">
  <Val1>-859</Val1>
  <Val3>Hello world</Val3>
</Root>
```

Nested example:

```verbatim
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1 INTEGER ATTRIBUTES(XMLName="Val1"),
  val2 FLOAT ATTRIBUTES(XMLAttribute,XMLName="Val2"),
  sequence RECORD ATTRIBUTES(XMLSequence="nested")
    seq1 INTEGER ATTRIBUTES(XMLName="SeqOne"),
    seq2 FLOAT ATTRIBUTES(XMLName="SeqTwo")
END RECORD,
  val3 STRING ATTRIBUTES(XMLName="Val3")
END RECORD

<Root Val2="25.8">
  <Val1>148</Val1>
  <SeqOne>6584</SeqOne>
  <SeqTwo>85.597</SeqTwo>
  <Val3>Hello world</Val3>
</Root>
```
**XMLSimpleContent**

Map a BDL RECORD to an XML Schema `simpleContent` structure.

**Note:** One member must have the XMLBase attribute; all other members must have an XMLAttribute attribute. If not, the compiler complains.

**Example**

```xml
define mysimpletype record attributes(xmlsimplecontent, xmlname="root")
    base string attributes(xmlbase),
    val1 integer attributes(xmlattribute, xmlname="val1"),
    val2 float attributes(xmlattribute, xmlname="val2")
end record

<root val1="148" val2="25.8"> hello </root>
```

**XSComplexType**

Map a BDL RECORD type definition to an XML Schema `complexType`.

**Note:** You can have one member as a nested sequence or choice, or as an XMLList array with a nested sequence or choice as the array's elements; all other members must have an XMLAttribute attribute. If not, the compiler raises an error.

**Example**

```xml
type mycomplextype record attributes(xscomplextype,
    xstypename="mycomplextype", xstypenamespace="http://tempuri.org")
    name dynamic array attributes(xmllist) of record
        attributes(xmlsequence="nested")
        firstname string attributes(xmlname="firstname"),
        lastname string attributes(xmlname="lastname")
end record,
    date date attributes(xmlattribute, xmlname="date")
end record

<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    targetNamespace="http://tempuri.org" elementFormDefault="qualified">
    <xsd:complexType name="mycomplextype">
        <xsd:sequence maxOccurs="unbounded">
            <xsd:element name="firstName" type="xsd:string" />
            <xsd:element name="lastName" type="xsd:string" />
        </xsd:sequence>
        <xsd:attribute name="Date" type="xsd:date" use="required"/>
    </xsd:complexType>
</xsd:schema>
```

**XMLList**

Map a one dimensional array to an XML Schema element that has more than one occurrence.

**Example**

```xml
define myvar record attributes(xmlname="root")
    val1 integer attributes(xmlname="val1"),
    list dynamic array attributes(xmllist) of string
        attributes(xmlname="element"),
    val2 float attributes(xmlname="val2")
```

END RECORD

<Root>
    <Val1>148</Val1>
    <Element>hello</Element>
    <Element>how</Element>
    <Element>are</Element>
    <Element>you</Element>
    <Val2>0.58</Val2>
</Root>

**Note:** It is not possible to define an XMLList attribute on a main array.

**Related concepts**

- **Serialize XML from a dynamic array** on page 3553
  The XMLList and XMLName attributes can be used to serialize dynamic arrays to XML and vice versa.

**XMLSelector**

Define the index of the candidate among all members of an XMLChoice record that will be serialized or deserialized at runtime.

The index starts at 1.

The selector data type must be a SMALLINT or a INTEGER.

**XMLAny**

Map a Xml.DomDocument object to a wildcard XML element:

```plaintext
DEFINE myVar RECORD ATTRIBUTES/XMLName="Root",XMLNamespace="http://tempuri.org"
  val1 INTEGER ATTRIBUTES/XMLName="Val1"),
  any Xml.DomDocument ATTRIBUTES/XMLAny,XMLNamespace="##other"),
  val2 FLOAT ATTRIBUTES/XMLName="Val2"
END RECORD
```

```xml
<pre:Root xmlns:pre="http://tempuri.org" >
    <pre:Val1>149</pre:Val1>
    <pre2:Doc xmlns:pre2="http://www.mycompany.com">
        <pre2:Element>how</pre2:Element>
        <pre2:Element>are</pre2:Element>
        <pre2:Element>you</pre2:Element>
    </pre2:Doc>
    <pre:Val2>0.58</pre:Val2>
</pre:Root>
```

**Note:** Associated with XMLAny, the XMLNamespace attribute requires either:

- A list of space-separated URIs to accept each attribute belonging to one of this namespace URI as a wildcard attribute.
- The value `##any` to accept any attribute as a wildcard attribute.
- The value `##other` to accept any attribute not in the main schema namespace as a wildcard attribute.

For example:

- If XMLNamespace="http://tmpuri.org http://www.mycompany.com", then only the XML documents belonging to one of those namespaces will be accepted and serialized (or deserialized) into the Xml.DomDocument object.
- If XMLNamespace="##any", then any XML document will be accepted and serialized (or deserialized) into the Xml.DomDocument object.
• If XMLNamespace="##other", then any XML document not belonging to the targetNamespace of the XML Schema where the any definition is used will be accepted and serialized (or deserialized) into the Xml.DomDocument object.

**XMLAnyAttribute**

Map a one-dimensional dynamic array to wildcard XML attributes.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root", XMLNamespace="http://tempuri.org")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT ATTRIBUTES(XMLName="Val2"),
  attr  STRING ATTRIBUTES(XMLName="Attr", XMLAttribute),
  any   DYNAMIC ARRAY ATTRIBUTES(XMLAnyAttribute, XMLNamespace="##other")OF
    RECORD
      ns  STRING,
      name  STRING,
      value  STRING
    END RECORD
END RECORD
```

```xml
<pre:Root xmlns:pre="http://tempuri.org" pre:Attr="10"
  xmlns:pre2="http://www.mycompany.com" pre2:AnyAttr1="10" pre2:AnyAttr2="">
  <pre:Val1>148</pre:Val1>
  <pre:Val2>0.58</pre:Val2>
</pre:Root>
```

**Note:**

1. The attribute **XMLAnyAttribute** is only allowed on a one-dimensional dynamic array of a record with three members of type STRING. The **first** member is for the namespace of the wildcard attribute, the **second** member is for the name of the wildcard attribute, and the **third** member is for the value of the wildcard attribute. **The name cannot be null.**

2. Associated with the XMLAnyAttribute, the XMLNamespace attribute requires either:
   - A list of space-separated URIs to accept each attribute belonging to one of the namespace URIs as a wildcard attribute.
   - The value **##any** to accept any attribute as a wildcard attribute.
   - The value **##other** to accept any attribute not in the main schema namespace as a wildcard attribute.

   For example:
   - If XMLNamespace="http://tmpuri.org http://www.mycompany.com", then only the attributes belonging to one of those namespaces will be accepted and serialized (or deserialized) into the array.
   - If XMLNamespace="##any", then any attribute will be accepted and serialized (or deserialized) into the array.
   - If XMLNamespace="##other", then any attributes not belonging to the targetNamespace of the XML Schema where the anyAttribute definition is used will be accepted and serialized (or deserialized) into the array.

**XMLName**

Define the name of a variable in an XML document.

**Note:** The attribute cannot be set on a type definition.

**Example**

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  val2  FLOAT,
  val3  INTEGER ATTRIBUTES(XMLName="Val3")
```
XMLNamespace

Define the namespace of a variable in an XML document.

Note:
1. If the attribute is set on a Record, by default all members defined as XMLElement of that record are in the same namespace.
2. If the attribute is set on an Array, by default all elements defined as XMLElement of that array are in the same namespace.
3. The attribute cannot be set on a type definition.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root", XMLNamespace="http://tempuri.org")
  attr1 INTEGER ATTRIBUTES(XMLAttribute,XMLName="Attr1"),
  val1 FLOAT ATTRIBUTES(XMLName="Val1", XMLNamespace="http://www.mycompany.com"),
  val2 INTEGER ATTRIBUTES(XMLName="Val2"),
  attr2 STRING ATTRIBUTES(XMLAttribute, XMLName="Attr2",
    XMLNamespace="http://anyuri.org")
END RECORD
```

```
<Root xmlns:fs1="http://tempuri.org" Attr1="158"
  xmlns:fs2="http://www.mycompany.com">0.5</fs1:Val2>
</fs1:Root>
```

XMLElement

The XMLList and XMLName attributes can be used to serialize dynamic arrays to XML and vice versa.

XMLType

Force the XML type name of a variable by adding xsi:type at serialization or by checking xsi:type at deserialization.

Note: The attribute must be used with the XMLTypenamespace attribute; otherwise, the compiler complains.

Example

```
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
  XMLNamespace="http://tempuri.org")
  val1 FLOAT ATTRIBUTES(XMLName="Val1"),
  val2 INTEGER ATTRIBUTES(XMLName="Val2",
    XMLType="MyRecord",
    XMLTypenamespace="http://mynamespace.org")
END RECORD
```

```
<fs1:Root xmlns:fs1="http://tempuri.org">
  <fs1:Val1>0.5</fs1:Val1>
</fs1:Root>
```
XMLTypenamespace

Force the XML type namespace of a variable by adding `xsi:type` at serialization or by checking `xsi:type` at de-serialization.

**Note:** The attribute must be used with the XMLType attribute; otherwise the compiler complains.

**Example**

```bdl
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root", 
XMLNamespace="http://tempuri.org")

  val1 FLOAT ATTRIBUTES(XMLName="Val1"),
  val2 INTEGER ATTRIBUTES(XMLName="Val2", 
                          XMLType="MyRecord", 
                          XMLTypenamespace="http://mynamespace.org")

END RECORD
```

```xml
<fjs1:Root xmlns:fjs1="http://tempuri.org">
    <fjs1:Val1>0.5</fjs1:Val1>
    <fjs1:Val2 xmlns:fjs2="http://mynamespace.org" xsi:type="fjs2:MyRecord">-18547</fjs1:Val2>
</fjs1:Root>
```

XSTypename

Define the XML Schema name of a BDL type definition.

**Note:**

1. The attribute must be used with the XSTypenamespace attribute; otherwise the compiler complains.
2. The attribute is only allowed on a type definition.

**Example**

```bdl
TYPE myType RECORD ATTRIBUTES(XMLSequence, 
XSTypeName="MyFirstType", 
XSTypeNamespace="http://tempuri.org")

  val1 FLOAT ATTRIBUTES(XMLElement,XMLName="Val1"),
  val2 INTEGER ATTRIBUTES(XMLElement,XMLName="Val2",XMLOptional),
  attr STRING ATTRIBUTES(XMLAttribute,XMLName="Attr")

END RECORD
```

```xml
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema" targetNamespace="http://tempuri.org" elementFormDefault="qualified">
  <xsd:complexType name="MyFirstType">
    <xsd:sequence>
      <xsd:element name="Val1" type="xsd:double" />
      <xsd:element name="Val2" type="xsd:int" minOccurs="0" />
    </xsd:sequence>
    <xsd:attribute name="Attr" type="xsd:string" use="required" />
  </xsd:complexType>
</xsd:schema>
```

XSTypenamespace

Define the XML Schema namespace of a BDL type definition.

**Note:**

1. The attribute must be used with the XSType attribute; otherwise the compiler complains.
2. The attribute is only allowed on a type definition.

Example

```plaintext
TYPE myType RECORD ATTRIBUTES(XMLChoice,
    XSTypeName="MyFirstChoice",
    XSTypeNamespace="http://tempuri.org" )
val1  FLOAT  ATTRIBUTES(XMLElement,XMLName="Val1"),
val2  INTEGER ATTRIBUTES(XMLElement,XMLName="Val2",XMLOptional),
attr  STRING  ATTRIBUTES(XMLAttribute,XMLName="Attr",XMLOptional),
set   INTEGER ATTRIBUTES(XMLSelector)
END RECORD
```

```xml
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    targetNamespace="http://tempuri.org"  elementFormDefault="qualified" >
    <xsd:complexType name="MyFirstChoice">
        <xsd:choice>
            <xsd:element name="Val1" type="xsd:double" />
            <xsd:element name="Val2" type="xsd:int" minOccurs="0" />
        </xsd:choice>
        <xsd:attribute name="Attr" type="xsd:string" />
    </xsd:complexType>
</xsd:schema>
```

XMLElementNamespace

Define the default namespace of all members of a record also defined as XML elements.

Example

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
    XMLNamespace="http://tempuri.org",
    XMLElementNamespace="http://www.mycompany.com")
val1  FLOAT  ATTRIBUTES(XMLElement,XMLName="Val1"),
val2  INTEGER ATTRIBUTES(XMLElement,XMLName="Val2"),
attr  STRING  ATTRIBUTES(XMLAttribute,XMLName="Attr"),
END RECORD
```

```xml
<fjs1:Root xmlns:fjs1="http://tempuri.org"
    xmlns:fjs2="http://www.mycompany.com">
    <fjs2:Val1>0.5</fjs2:Val1>
    <fjs2:Val2>-18547</fjs2:Val2>
</fjs1:Root>
```

XMLAttributeNamespace

Define the default namespace of all members of a record also defined as XML attributes.

Example

```plaintext
DEFINE myVar RECORD ATTRIBUTES(XMLName="Root",
    XMLNamespace="http://tempuri.org",
    XMLAttributeNamespace="http://www.mycompany.com")
val1  FLOAT  ATTRIBUTES(XMLElement,XMLName="Val1"),
val2  INTEGER ATTRIBUTES(XMLElement,XMLName="Val2"),
attr  STRING  ATTRIBUTES(XMLAttribute,XMLName="Attr"),
attr2  DATE   ATTRIBUTES(XMLAttribute,XMLName="Attr2",XMLNamespace="http://anyuri.org"),
END RECORD
```

```xml
<fjs1:Root xmlns:fjs1="http://tempuri.org"
    xmlns:fjs2="http://www.mycompany.com"
    xmlns:fjs3="http://anyuri.org">
    <fjs2:Attr1>Hello</fjs2:Attr1>
    <fjs2:Val1>0.5</fjs2:Val1>
    <fjs2:Val2>-18547</fjs2:Val2>
</fjs1:Root>
```
XMLOptimizedContent

Set on STRING or BYTE data type so that such string content represents a file on disk to be transmitted as base64 binary in SOAP via HTTP attachment.

The XMLOptimizedContent attribute is allowed on BYTE or STRING data type.

The XMLOptimizedContent attribute adds value when used in one of these scenarios:

1. When MTOM is enabled and the XMLOptimizedContent attribute is set on a BYTE, it sets the variable that must be transmitted transparently as an HTTP part on the wire. See Message Transmission Optimization Mechanism (MTOM) on page 3297 for more information.
2. When MTOM is enabled and the XMLOptimizedContent attribute is set on a STRING, it contains the name of the file to be transmitted as a Base64 binary, with an optional mime-type hint, in order to avoid loading a file in a BYTE. See Message Transmission Optimization Mechanism (MTOM) on page 3297 for more information.
3. If the XMLOptimizedContent attribute is set to "swaRef" (XMLOptimizedContent="swaRef") and set on a STRING, the contents of the file are transmitted according to the SoapWithAttachmentRef specification. See swaRef (SOAP with attachments using wsi:swaRef) on page 3298 for more information.

If the XMLOptimizedContent attribute is set on a BDL STRING data type, it is expected to contain the name of the file that the Genero Web Service will load based on the current directory during transport of the MTOM request.

If the XMLOptimizedContent attribute is set on a BDL STRING data type, it will contain the absolute path of the file GWS has received during the transport of a MTOM response. The absolute path is based on the Genero temp directory settings and contains a UUID generated name. The programmer is in charge of moving the file or removing the file from disk.

The optional value is a hint to specify the mime-type of the data. The hint may be used by Java or .NET to generate different kinds of objects, depending on the information provided by the hint. For instance, on Java a mime type of "image" will generate a java.awt.Image object instead of a byte[] object.

Example

The Genero code:

```genero
define rec record
data1 byte attributes(xmloptimizedcontent,xmlname="mydata"),
date2 string attributes(xmloptimizedcontent="image/*",xmlname="myimage"),
data3 byte
end record
```

The XSD representation:

```xml
c<xsd:complexType name="rec">
  c<xsd:sequence>
    c<xsd:element type="xsd:base64Binary" name="MyData"/>
    c<xsd:element xmime:expectedContentTypes="image/*"
      type="xsd:base64Binary" name="MyImage"/>
    c<xsd:element type="xsd:base64Binary" name="data3"/>
  c</xsd:sequence>
 c</xsd:complexType>
```

Things to observe:

1. With the BYTE data type, regardless of whether the XMLOptimizedContent attribute is set, the same type (xsd:base64Binary) appears in the XSD.
2. The STRING holds the path to the document to transfer and is viewed as a BYTE in the XML exchange.
3. With the STRING data type, a mime type is specified.
Serialize XML from a dynamic array

The XMLList and XMLName attributes can be used to serialize dynamic arrays to XML and vice versa.

These attributes have distinct uses depending on the output you want.

The XMLList on page 3546 attribute is used especially to produce a list of the same elements from an array, without a surrounding tag. This output on its own is not valid XML because there is no parent node. For valid XML output, the attribute must be used inside another variable, such as a record. Compare Example 1: List of the same elements on page 3553 and Example 3: List inside a record on page 3554.

It is useful to use XMLList specifically to map a one dimensional array to an XML schema element that has more than one occurrence, inside another XML element.

An array (without XMLList), on the other hand, always produces a surrounding tag and thus a valid XML document. See Example 2: Array of the same elements on page 3553 and Example 4: Array inside a record on page 3554.

The XMLName on page 3548 attribute's function is to provide a name for XML elements. If you do not use the XMLName attribute, the tags used in the XML output are the names of the 4GL variables. Or if there are no variables, they are named "<element>".

Tip: The variables with these attributes you use to output to XML, may also be used to load an XML document into DYNAMIC ARRAY.

**Example 1: List of the same elements**

This example shows how an array defined with XMLList outputs a list of the same elements. Typically, this array is defined inside another variable (see Example 3: List inside a record on page 3554), because the resulting XML is not valid otherwise. The XMLName attribute is set to name the element.

```
DEFINE list DYNAMIC ARRAY(XMLList) OF STRING ATTRIBUTE(XMLName="MyElt")
```

This would produce an XML output like this:

```
<MyElt>One</MyElt><MyElt>Two</MyElt>
```

When viewed in an XML viewer, it would display as shown.

```
<MyElt>One</MyElt>
<MyElt>Two</MyElt>
```

**Example 2: Array of the same elements**

In this example an array is defined without XMLList. This produces output that is a valid XML document with an array of the same elements, and a surrounding tag. The XMLName attribute tags both the array and the elements.

```
DEFINE arr DYNAMIC ARRAY ATTRIBUTE(XMLName="SurroundingTag") OF STRING ATTRIBUTE(XMLName="MyElt")
```

The XML output may look like this:

```
<SurroundingTag><MyElt>One</MyElt><MyElt>Two</MyElt></SurroundingTag>
```

When viewed in an XML viewer, it would display as shown.

```
<SurroundingTag>
  <MyElt>One</MyElt>
  <MyElt>Two</MyElt>
</SurroundingTag>
```
Example 3: List inside a record

The XMLList must be defined inside another variable, such as a record, in order to produce output that is a valid XML document. Several lists may be included in the record.

```pascal
DEFINE myVar1 RECORD ATTRIBUTES(XMLName="Root")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  list  DYNAMIC ARRAY ATTRIBUTE(XMLList) OF STRING
    ATTRIBUTES(XMLName="MyElt"),
  val2  FLOAT   ATTRIBUTES(XMLName="Val2")
END RECORD
```

This would produce XML output like this:

```xml
<Root>
  <Val1>148</Val1>
  <MyElt>hello</MyElt>
  <MyElt>there</MyElt>
  <Val2>0.58</Val2>
</Root>
```

When viewed in an XML viewer, it would display as shown.

```
<Root>
  <Val1>148</Val1>
  <MyElt>hello</MyElt>
  <MyElt>there</MyElt>
  <Val2>0.58</Val2>
</Root>
```

Example 4: Array inside a record

This example shows that the array is output inside a surrounding tag inside the record.

```pascal
DEFINE myVar2 RECORD ATTRIBUTES(XMLName="Root")
  val1  INTEGER ATTRIBUTES(XMLName="Val1"),
  arr  DYNAMIC ARRAY ATTRIBUTES(XMLName="Sample") OF STRING
     ATTRIBUTES(XMLName="MyElt"),
  val2  FLOAT   ATTRIBUTES(XMLName="Val2")
END RECORD
```

This would produce XML output like this:

```xml
<Root>
  <Val1>148</Val1>
  <Sample>
    <MyElt>hello</MyElt>
    <MyElt>there</MyElt>
  </Sample>
  <Val2>0.58</Val2>
</Root>
```

When viewed in an XML viewer, it would display as shown.

```
<Root>
  <Val1>148</Val1>
  <Sample>
    <MyElt>hello</MyElt>
    <MyElt>there</MyElt>
  </Sample>
  <Val2>0.58</Val2>
</Root>
```

Error handling in GWS calls (STATUS)

When errors are encountered, the methods of GWS classes can throw exceptions and set the STATUS variable with the appropriate error number.

By default, the program will stop if an exception is thrown. You can trap the GWS errors with a WHENEVER ERROR handler or with a TRY/CATCH block. In the example, the readTextRequest() API is surrounded by a TRY/CATCH block:

```pascal
DEFINE req com.HTTPServiceRequest,
```
data STRING

LET req = com.WebServiceEngine.getHTTPServiceRequest(5)

TRY
  CALL req.readTextRequest() RETURNING data
CATCH
  CALL show_err(SFMT("Unexpected HTTP request read exception: %1", STATUS))
END TRY

For some errors, a human-readable description of the error code is available in the SQLCA.SQLERRM register.

**Related concepts**

Exceptions on page 502
Describes exception (error) handling in the programs.

**Related reference**

Genero BDL errors on page 3154
System error messages sorted by error number.

** Interruption handling in GWS calls (INT_FLAG)**

Genero Web Services (GWS) tests INT_FLAG to check if an application has been interrupted.

If INT_FLAG is set to TRUE, the DVM interrupts the GWS function processing and an exception is raised with error code -15553.

**Important:** Set the INT_FLAG register to FALSE before calling a GWS function. For example, after a dialog was stopped with a cancel action, the INT_FLAG is set to TRUE. If you do not reset INT_FLAG to FALSE, the next GWS function may be canceled.

As a general rule, surround GWS calls with a TRY/CATCH block (or WHENEVER ERROR handler), to detect both communication errors and interruptions.

```BDL
TRY
  LET INT_FLAG=FALSE
  ... req.sendXMLRequest(doc)
  ... CATCH
    CASE STATUS
    WHEN -15553 -- TCP socket error
      IF INT_FLAG THEN
        MESSAGE "An interruption occurred."
      ELSE
        ERROR "TCP socket error: ", SQLCA.SQLERRM
      END IF
    ELSE
    ... END CASE
END TRY
```

**Server API functions - version 1.3 only**

Server API functions can create a Web Services server in Genero BDL.

**Note:** These functions are valid for backward compatibility, but they are not the preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.
Table 748: APIs to create a Web Services server in Genero BDL (version 1.3 only)

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fgl_ws_server_setNamespace</strong> (namespace VARCHAR)</td>
<td>Defines the namespace of the service on the Web and must be called first, before all other functions of the API.</td>
</tr>
<tr>
<td><strong>fgl_ws_server_start</strong> (tcpPort VARCHAR)</td>
<td>Creates and starts the Web services server.</td>
</tr>
<tr>
<td><strong>fgl_ws_server_publishFunction</strong> (operationName VARCHAR, inputNamespace VARCHAR, inputRecordName VARCHAR, outputNamespace VARCHAR, outputRecord VARCHAR, functionName VARCHAR)</td>
<td>Publishes the given BDL function as a Web-Function on the Web.</td>
</tr>
<tr>
<td><strong>fgl_ws_server_generateWSDL</strong> (serviceName VARCHAR, serviceLocation VARCHAR, fileName VARCHAR)</td>
<td>Generates the WSDL file based on the BDL-server program.</td>
</tr>
<tr>
<td><strong>fgl_ws_server_process</strong> (timeout INTEGER)</td>
<td>Waits for an incoming SOAP request for a given time (in seconds) and then processes the request, or returns, if there has been no request during the given time.</td>
</tr>
<tr>
<td><strong>fgl_ws_server_setFault</strong> (faultMessage VARCHAR)</td>
<td>Return a SOAP fault string to the client at the end of the function's execution.</td>
</tr>
<tr>
<td><strong>fgl_ws_server_getFault</strong> ()</td>
<td>Retrieves the last fault string the user has set in a Web-Function, or an empty string if there is none.</td>
</tr>
</tbody>
</table>

**fgl_ws_server_setNamespace() (version 1.3)**
Defines the namespace of the service on the Web and must be called first, before all other functions of the API.

**Note:** This function is valid for backward compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

**Syntax**

```
fgl_ws_server_setNamespace ( namespace VARCHAR )
```

1. `namespace` is the name of the namespace.

**Example**

```
CALL fgl_ws_server_setNamespace("http://tempuri.org/")
```
fgl_ws_server_start() (version 1.3)
Creates and starts the Web services server.

Note: This function is valid for backward compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

```c
fgl_ws_server_start(
  tcpPort VARCHAR
)
```

1. `tcpPort` is a string representing either:
   - the **socket port number** (for a single Web Service server)
   - the **host** and **port** value separated by a colon (for a Web Service server connecting to an application server).
     The value of **port** is an offset beginning at 6400.

Note: If the FGLAPPSERVER environment variable is set, the tcpPort value is ignored, and replaced by the value of FGLAPPSERVER.

Usage

For development or testing purposes, you may start a Web Service server as a single server where only one request at a time will be able to be processed. For deployment, you may start a Web Service server with an application server able to handle several connections at one time using a load-balancing algorithm. The value of the parameter passed to the function determines which method is used.

Examples:

To start a standalone Web Service server:

```c
CALL fgl_ws_server_start("8080") # A single Server is listening
# on port number: 8080
```

To start a Web Service server attempting to connect to an application server:

```c
CALL fgl_ws_server_start("zeus:5") # The server attempt to connect
# to an application server located
# on host zeus and listening
# on the port number 6405
```

Possible runtime errors

- -15504: PORT_ALREADY_USED
- -15514: PORT_NOT_NUMERIC
- -15515: NO_AS_FOUND
- -15516: LICENSE_ERROR

fgl_ws_server_publishFunction() (version 1.3)
Publishes the given BDL function as a Web-Function on the Web.

Note: This function is valid for backward compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

```c
fgl_ws_server_publishFunction(
  operationName VARCHAR,
  inputNamespace VARCHAR,
  inputRecordName VARCHAR,
  outputNamespace VARCHAR,
  outputRecordName VARCHAR,
  description VARCHAR
)
```
1. operationName is the name by which the operation will be defined on the Web. The name is case sensitive.
2. inputNamespace is the namespace of the incoming operation message.
3. inputRecordName is the name of the BDL record representing the Web Function input message or "" if there is none.
4. outputNamespace is the namespace of the outgoing operation message.
5. outputRecord is the name of the BDL record representing the Web Function output message or "" if there is none.
6. functionName is the name of the BDL function that is executed when the Web Service engine receives a request with the operation name defined above.

Example

CALL fgl_ws_server_publishFunction(
    "MyWebOperation",
    "http://www.tempuri.org/webservices/", "myfunction_input",
    "http://www.tempuri.org/webservices/", "myfunction_output",
    "my_bdl_function")

Possible runtime errors

• -15503: FUNCTION_ALREADY_EXISTS
• -15501: FUNCTION_ERROR
• -15502: FUNCTION_DECLARATION_ERROR
• -15512: INPUT_VARIABLE_ERROR
• -15513: OUTPUT_VARIABLE_ERROR
• -15503: BDL_XML_ERROR
• -15518: INPUT_NAMESPACE_MISSING
• -15519: OUTPUT_NAMESPACE_MISSING

fgl_ws_server_generateWSDL() (version 1.3)
Generates the WSDL file based on the BDL-server program.

Note: This function is valid for backward compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

```javascript
fgl_ws_server_generateWSDL(
    serviceName VARCHAR,
    serviceLocation VARCHAR,
    fileName VARCHAR )
RETURNS INTEGER
```

1. serviceName is the name of the web service.
2. serviceLocation is the URL of the server.
3. fileName is the name of the file that will be generated.

Usage

The function returns:

• 0 if the file has been correctly generated.
• Any other values if the operation has failed.
Example

```plaintext
DEFINE mystatus INTEGER

LET mystatus=fgl_ws_server_generateWSDL(
"CustomerService",
"http://localhost:8080",
"C:/mydirectory/myfile.wsdl")

IF mystatus=0 THEN
  DISPLAY "Generation of WSDL done..."
ELSE
  DISPLAY "Generation of WSDL failed!"
END IF
```

fgl_ws_server_process() (version 1.3)

Waits for an incoming SOAP request for a given time (in seconds) and then processes the request, or returns, if there has been no request during the given time.

If a DEFER INTERRUPT or DEFER QUIT instruction has been defined, the function returns even if it is an infinite wait.

Note: This function is valid for backward compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

```plaintext
fgl_ws_server_process (timeout INTEGER)
RETURNS INTEGER
```

1. `timeout` is the maximum waiting time for an incoming request (or -1 for an infinite wait)

Usage

The function can return one of the following values:

- 0 Request has been processed
- -1 Timeout has been reached
- -2 The application server asks the runner to shutdown
- -3 A client connection has been unexpectedly broken
- -4 An interruption has been raised
- -5 The HTTP header of the request was incorrect
- -6 The SOAP envelope was malformed
- -7 The XML document was malformed

Example

```plaintext
MAIN

DEFINE mystatus INTEGER

DEFER INTERRUPT

LET mystatus=fgl_ws_server_process(5)# wait for 5 seconds

IF mystatus=0 THEN
  DISPLAY "Request processed."
END IF
IF mystatus=-1 THEN
```
DISPLAY "No request."
END IF
IF mystatus=-2 THEN  # terminate the application properly
  EXIT PROGRAM  # if connected to application server
END IF
IF mystatus=-3 THEN
  DISPLAY "Client connection unexpectedly broken."
END IF
IF mystatus=-4 THEN
  DISPLAY "Server process has been interrupted."
END IF
IF mystatus=-5 THEN
  DISPLAY "Malformed or bad HTTP request received."
END IF
IF int_flag<>0 THEN
  LET int_flag=0
  EXIT PROGRAM
END IF

END MAIN

**fgl_ws_server_setFault() (version 1.3)**
Return a SOAP fault string to the client at the end of the function's execution.

This function can be called in a published Web-Function.

**Note:** This function is valid for backward compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

**Syntax**

```plaintext
fgl_ws_server_setFault(
  faultMessage VARCHAR )
```

1. *faultMessage* is a string containing the SOAP Fault string that will be returned to the client.

**Example**

```plaintext
CALL fgl_ws_server_setFault(
  "The server is not able to manage this request."
)
```

**fgl_ws_server_getFault() (version 1.3)**
Retrieves the last fault string the user has set in a Web-Function, or an empty string if there is none.

**Note:** This function is valid for backward compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

**Syntax**

```plaintext
fgl_ws_server_getFault ()
RETURNS STRING
```

**Usage**
The function returns a string containing the SOAP fault string.

This function is only for testing the Web Services functions before they are published on the Web.

**Example**

```plaintext
DEFINE div_input RECORD
```
a INTEGER,
b INTEGER
END RECORD

Configuration API functions - version 1.3 only

Configuration API functions can modify the behavior of the Web Services engine for the client and/or server.

Note: These functions are valid for backward compatibility, but they are not the preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Table 749: Configuration API functions for Web Services engine behavior modification

<table>

</tr>
</tbody>
</table>

fgl_ws_setOption()
Sets an option flag with a given value, changing the global behavior of the Web Services engine.

Note: This function is valid for backward compatibility, but is not a preferred way to handle Genero Web Services. See the com package for the preferred classes and methods for handling Web services.

Syntax

```plaintext
fgl_ws_setOption(
   optionName VARCHAR,
   optionValue INTEGER)
```
1. *optionName* is one of the global **option flags**.
2. *optionValue* is the value of the flag.

**Example**

```
CALL fgl_ws_setOption("http_invoketimeout",5)
```

**Possible runtime errors**

- -15511: INVALID_OPTION_NAME

**fgl_ws_getOption()**

Returns the value of an option flag.

**Note:** This function is valid for backward compatibility, but is not a preferred way to handle Genero Web Services. See the **com package** for the preferred classes and methods for handling Web services.

**Syntax**

```
fgl_ws_getOption (  
    optionName VARCHAR)  
RETURNS INTEGER
```

1. *optionName* is one of the global **option flags**.

**Example**

```
DEFINE value INTEGER
LET value=fgl_ws_getOption("http_invoketimeout")
```

**Possible runtime errors**

- -15511: INVALID_OPTION_NAME

**Option flags**

**Table 750: Option flags**

<table>
<thead>
<tr>
<th>Flag</th>
<th>Client or Server</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>http_invoketimeout</td>
<td>Client</td>
<td>Defines the maximum time in seconds a client has to wait before the client connection raises an error because the server is not responding.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>A value of -1 means that it has to wait until the server responds.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default value is -1.</td>
</tr>
<tr>
<td>tcp_connectiontimeout</td>
<td>Client</td>
<td>Defines the maximum time in seconds a client has to wait for the establishment of a TCP connection with a server.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>A value of -1 means infinite wait.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default value is 30 seconds except for Windows®, where it is 5 seconds.</td>
</tr>
<tr>
<td>Flag</td>
<td>Client or Server</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>soap_ignoretimezone</td>
<td>Both</td>
<td>Defines if, during the marshalling and unmarshalling process of a BDL DATETIME data type, the SOAP engine should ignore the time zone information. A value of zero means false. The default value is false.</td>
</tr>
<tr>
<td>soap_usetypedefinition</td>
<td>Both</td>
<td>Defines if the Web Services engine must specify the type of data in all SOAP requests. This will add an &quot;xsi:type&quot; attribute to each parameter of the request. A value of zero means false. The default value is false.</td>
</tr>
<tr>
<td>wsdl_decimalsize</td>
<td>Server</td>
<td>Defines if, during the WSDL generation, the precision and scale of a DECIMAL variable will be taken into account. See WSDL generation option notes on page 3563. A value of zero means false. The default value is true.</td>
</tr>
<tr>
<td>wsdl_arraysize</td>
<td>Server</td>
<td>Defines if, during the WSDL generation, the size of a BDL array will be taken into account. See WSDL generation option notes on page 3563. A value of zero means false. The default value is true.</td>
</tr>
<tr>
<td>wsdl_stringsize</td>
<td>Server</td>
<td>Defines if, during the WSDL generation, the size of a CHAR or VARCHAR variable will be taken into account. See WSDL generation option notes on page 3563. A value of zero means false. The default value is true.</td>
</tr>
</tbody>
</table>

**WSDL generation option notes**

1. For a BDL type DECIMAL (5, 2), when `wsdl_decimalsize` is TRUE, the generated WSDL file contains the total size and the size of the fractional part of the decimal:

   ```xml
   <types>
   <simpleType name="echoDecimal5_2_a_dec5_2_out_FGLDecimal">
   <restriction base="decimal">
   <totalDigits value="5" />
   ```
When `wsdl_decimalsize` is FALSE, the total size and the size of the fractional part are not mentioned:

```
<message name="echoDecimal5_2">
  <part name="dec5_2" type="xsd:decimal" />
</message>
```

2. If the WSDL file does not contain the size, the client application has no way of knowing the size. In this scenario, a default value for the size is generated. For example, the exported server type `DECIMAL(5,2)` becomes a `DECIMAL(32)` on the client side.

3. It is better to keep the options `wsdl_arraysize`, `wsdl_stringsize` and `wsdl_decimalsize` set to TRUE (default) so that the BDL client application can do an exact type mapping.

### Using fglwsdl to generate code from WSDL or XSD schemas

The `fglwsdl` tool generates Genero (.4gl) code from WSDL / XSD schemas.

See `fglwsdl` on page 2081 for a complete description of the tool and its options.

#### Generate TYPE definitions from global XML elements or attributes

If a WSDL or a XSD has global XML elements or attributes defined with an inlined type, the `-fInlineTypes` option of `fglwsdl` generates a TYPE definition representing that inline type, using the original WSDL/XSD name of the element or attribute, concatenated with the string `'GlobalAttributeType'` or `'GlobalElementType'`.

For example, when using `fglwsdl -fInlineTypes`, the following schema:

```
<xs:element name="getAlertListRequestFlow">
  <xs:complexType>
    <xs:sequence>
      <xs:element name="getAlertListRequest" type="amp:getAlertListRequest" />
    </xs:sequence>
  </xs:complexType>
</xs:element>
```

will produce:

```
TYPE tgetAlertListRequestFlowGlobalElementType RECORD
  ATTRIBUTES (XMLSequence)
    getAlertListRequest tgetAlertListRequest
      ATTRIBUTES (XMLName="getAlertListRequest")
  END RECORD
DEFINE getAlertListRequestFlow tgetAlertListRequestFlowGlobalElementType
  ATTRIBUTES (XMLName="getAlertListRequestFlow")
```

Instead of:

```
DEFINE getAlertListRequestFlow RECORD
  ATTRIBUTES (XMLName="getAlertListRequestFlow",XMLSequence)
    getAlertListRequest tgetAlertListRequest
      ATTRIBUTES (XMLName="getAlertListRequest")
  END RECORD
```
These topics cover programming subjects about mobile applications

**Types of Genero Mobile apps**

Genero supports different types of mobile app architectures: development mode, standalone apps, partially-connected apps, and client-server apps.

When you are developing your app, and you execute the app on your development machine for display on a device or emulator, you are running the app in **development mode**.

When you follow the procedure to deploy your application to the device for testing or to distribute your app to your end users, you have a **deployed app**. A deployed app might be an app that executes irrespective of network availability, it might be an app that accesses device peripherals, it might be an app that requires network access.

**Note:** The DVM refers to the dynamic virtual machine, which is the process that executes the app code.

**Development mode**

In **development mode**, the app process is running on a server, and the forms are displayed on a mobile front-end.

This architecture is typically used when developing your application, as you can easily modify, recompile and execute your sources on the development machine, without the need to deploy the app on the device.

![Development mode diagram](image)

**Figure 143: Development mode**

**Standalone apps**

A **standalone app** has the DVM and display client entirely on the mobile device. This app executes irrespective of network availability and can access device peripherals such as the camera, contacts, email, calendar, GPS, and storage via exposed APIs (front calls). For database needs, this app can only connect to a local SQLite database.
Figure 144: Standalone app

Partially-connected apps

A partially-connected app has the DVM and display client entirely on the mobile device, yet this app includes items that require a network connection. This app must be able to run when no network connection is available. This app uses a network API to talk to any back-end.

Examples include:

- Web Services performed with JSON over HTTP; use RESTful methods to write data synchronization routines. With this example, business logic executes within the device’s Virtual Machine and the user is able to store captured data to a local SQLite database. When the network becomes available, the user synchronizes the stored data with the remote server’s database.
  
  **Note:** As of Genero Mobile 1.1, you can also write a Web Service using SOAP.

- A web component that runs Google Maps.

This app first operates without a network connection, and must be able to run without a network connection. Once network connectivity is restored, the app can perform network-dependent tasks such as synchronizing with a remote database, make a web service call, or use a web component.

If you are using GMI, and the device goes into standby mode, the application does not run in the background and activities with the network are suspended.
Client-server apps

With a client-server app or connected app, the bulk of the app runs on a remote server and the display client sits on the mobile device.

As with any deployed app, this app first starts on the mobile device; the DVM for the deployed app runs on the mobile device. The role of the deployed app, however, is to connect to a remote corporate server as an online terminal. It is the deployed app that launches the remote application using the runOnServer frontcall. The remote application's DVM and business logic reside on the remote server, somewhere in the network. The remote application is not limited to a SQLite database.

In the event that the network is interrupted, the Genero Mobile client app is suspended until service resumes.
Licensing considerations

Note: For specific mobile app license details, see your Software License Agreement, or contact your nearest Four Js sales office.

When deploying a Genero Mobile app, the type of mobile app architecture you need may have additional requirements for Genero licenses as follows:

- Development mode needs a development license.
- Partially-connected app consumes a Genero runtime license when the app connects to the Web service to synchronize with the network database.
- Client-server app consumes a Genero runtime license on the Genero Application Server.

Mobile development mode

Set up a development environment to display app forms on a mobile front-end.

In a command-line development environment, the runtime system (DVM) executes the application code on the development machine, displaying app forms through a mobile front-end installed on a device or emulator.

Once the app development is complete, you can build the real mobile app to be deployed on devices, as described in Deploying mobile apps on page 3588.

Important: When the Genero Mobile Development Client is running on a device, a Genero BDL program can connect and execute front calls. To avoid any security issues, stop the Genero Mobile Development Client app when you have completed your work, and consider uninstalling the app before giving the mobile device to another person or department.

Genero mobile development client for Android™

Set up a development environment to display app forms on an Android™ device.

Using the GMA front-end on Android™ devices

To display Genero application forms on an Android™ device in development mode (with programs executing on a computer), the GMA front-end app must be installed on the device (or emulator).

Note: With the GMA front-end installed on the mobile device, you can perform a classic GUI connection based on FGLSERVER.

Installing the GMA front-end application

Before installing the GMA front-end, fulfill the prerequisites to build an Android™ app, as described in Building Android apps with Genero on page 3591.

Perform the following steps, to install the GMA front-end from the archive:

1. Get the GMA package (for example, fjs-gma-1.30.00-build201703031626-allos.zip), contact your support channel for download details.
2. Unzip the archive, containing an APK ready to install.
3. Plug your device via USB cable to the computer.
4. Install the GMA front-end APK with the gmabuildtool command with the test option.

For example:

```
$ . ~/genero/devel/fgl/mobile/java-1.8.env
$ . ~/genero/devel/fgl/mobile/android-sdk.env
$ mkdir /tmp/gma
$ cd /tmp/gma
$ unzip ~/Download/fjs-gma-1.30.00-build201703031626-allos.zip
```

Archive: ~/Download/fjs-gma-1.30.00-build201703031626-allos.zip
Configure FGLSERVER and run the app

Once the GMA front-end is installed on the device, make sure that WIFI is enabled (or check that the TCP port is forwarded when using an emulator), you can start the GMA app.

The main GMA screen shows the IP address of the device and the TCP port it is listening to (0=6400).

On the development machine, define the FGLSERVER environment variable with the IP address of the device (or.

Now you are ready to run your app on the server and display on the Android™ device.

TCP port forwarding for GMA on Android emulator

When using an Android™ emulator, you can forward the TCP port with the adb forward command:

```
adb forward tcp:local_port tcp:gma_device_port
```

For example:

```
adb forward tcp:6401 tcp:6400
```

You can then connect to GMA with:

```
FGLSERVER=127.0.0.1:1
```

Enabling Universal Rendering

Universal Rendering can be enabled by using the gui.rendering FGLPROFILE entry.

This section contains information to create a mobile application to be deployed on Android™ devices.

Genero mobile development client for iOS

Set up a development environment to display app forms on an iOS device.

Installing the GMI front-end on iOS devices

To display Genero application forms on a device, the GMI front-end must be installed on the iOS device (or emulator).

Genero supports two types of GMI front-end apps for iOS:

- The ready-to-use "Genero Mobile Development Client" for iOS, available through the App Store.
  
  **Important:** Due to Apple® limitations, the Genero Mobile Development Client app is not allowed to listen to a TCP port to provide a GUI service. In order to establish the GUI front-end connection, the front-end must connect to the runtime system running on the development machine.

- A self-made GMI front-end, using the gmibuildtool to build a GMI front-end app with your own Apple® developer account.

  **Note:** With this configuration, you can perform a classic GUI connection based on FGLSERVER.
Using the Genero Mobile Development Client for iOS

Go to the App Store. Search for "Genero Mobile". Select and install the "Genero Mobile Development Client".

Once the GMI development client is installed on the device, make sure that WIFI is enabled and start the GMI app.

Note: Because of iOS app limitations defined by Apple, an app shipped on the App Store cannot listen to a TCP port to provide a GUI service. In order to display Genero form on the GMI development client, you will have to establish the GUI connection from the device to the server, after starting the fglrun process with the --gui-listen option.

The main GMI screen shows a URL field to let you enter the IP address / hostname and the TCP port the runtime system will listen to.

Note: Make sure that the firewall on the development machine allows incoming connections for the TCP port number specified with the --gui-listen fglrun option.

Start the application on the development server, by using the fglrun --gui-listen=portnum command:

```
fglrn --gui-listen=6500 main.42m
```

On the iOS device, enter the following in the URL field:

```
fgl://dev-server-hostname:6500
```

Then tap the [Connect] button to establish the GUI connection.

Build your own GMI front-end

In order to use the classic GUI connection mode with fglrun connecting to the mobile front-end via FGLSERVER, it is possible to create your own GMI front-end, with your own Apple® certificate and provisioning profile.

Note: As with other iOS apps, a self-made GMI front-end can only be created on a macOS® computer.

The generated GMI can then be deployed on your device or simulator. The GMI front-end will listen on the port 6400, to display applications running on a server through the FGLSERVER setting.

Before creating your own GMI front-end, fulfill the prerequisites to build an iOS app as described in Building iOS apps with Genero on page 3606.

In order to build your own GMI front-end:

1. Make sure that the installed the fjs-fglgmi*.zip archive into FGLDIR.
2. Go to the $FGLDIR/demo/MobileDemo/gmiclient directory.
3. Delete the complete build directory if it exists (can be done with a make clean command).
4. Compile the GMI front-end program files (main.42m, main.42f, etc): See Makefile for details.
5. Build the GMI front-end:
   - To build and install the GMI front-end on the simulator, first make sure that the simulator is started (open -a Simulator command), then execute the make command with the gmi.install rule:
     ```
     $ open -a Simulator
     $ make gmi.install
     ```
   - To build and install the GMI front-end on the device plugged to your Mac, get a development certificate and provisioning profile, then execute the make command with the gmi.install rule, by specifying the TARGET, the IDENTITY and the PROVISIONING_PROFILE variables:
     ```
     $ make TARGET=phone IDENTITY=WKRRJZ999 \
     PROVISIONING_PROFILE="/Library/MobileDevice/Provisioning Profiles/myapp.mobileprovision" \
     gmi.install
     ```
Once the GMI front-end is installed on the device, make sure that WIFI is enabled and start the GMI app. The main GMI screen shows the IP address of the device and the TCP port it is listening to (0=6400). On the development machine, define the FGLSERVER environment variable with the IP address of the device. Now you are ready to run your app on the server and display on the iOS device.

**Enabling Universal Rendering**

Universal Rendering can be enabled by using the `gui.rendering FGLPROFILE entry`.

**Related concepts**

Deploying mobile apps on iOS devices on page 3604

This section contains information to create a mobile application to be deployed on iOS devices.

### Language limitations

Genero language features not supported on mobile devices.

**Important:** This topic is provided as a quick glance at Genero Business Development Language limitations in mobile applications. Details can be found in the BDL reference topics.

**Platform specifics**

**Features with limited support**

The following language options have limited support:

- The `RUN` instruction has limited support on mobile platforms.
  - The `RUN` instruction is not supported on mobile devices, because of operating system limitations.
  - `RUN command WITHOUT WAITING` is not supported when programs run on an application server and display on a mobile device, because the Genero GUI protocol is not able to handle multiple connections at the same time.

**Unsupported features**

The following language features are not supported:

- The `INPUT ARRAY` instruction is not supported.
- The `base.Channel.openPipe` method is not supported.
- The Java interface cannot be used in apps running on iOS devices: There is no standard free JVM available.

### Environment variables

You may need to set environment variables for your app.

**Automatic environment variables**

When executing on a mobile device:

- `DBDATE` defaults to the regional settings defined on the device.
- `FGLAPPPDIR` is automatically defined to the application directory (`appdir`).

**Set environment variables**

Setting environment variables for your app must be done in an `fglprofile` file. This `fglprofile` file must be located in the `appdir` directory, beside the main program module.
To add an environment variable for your mobile app, use the following syntax:

```
mobile.environment.DBFORMAT="$:,::
```

Any existing environment variable setting is overwritten by the value set (using `mobile.environment.envvarname`) in the `fglprofile` file.

For more details, see Setting environment variables in FGLPROFILE (mobile) on page 263.

**Note:** Environment variables set in an FGLPROFILE file are only read when the deployed application runs on the mobile device. They are not read during development mode (that is when the VM runs on the development machine and the mobile client displays on the device). The FGLPROFILE environment variable settings are only for the VM component and are ignored by the GMA/GMI front-end component.

---

**App localization**

Mobile apps can be designed to display localized texts based on the language selected on the device.

**Application locale definition**

Make sure that your application locale is defined properly for development and deployment environments.

**Note:** With Genero mobile applications, the application locale must be UTF-8.

For more details, see Quickstart guide for locale settings on page 515.

**Using localized strings**

Localized string files (.42s) must be deployed in directories matching the language identifiers (`en` for English, `zh_TW` for simplified Chinese, etc), beside the program module.

Default string files can be provided in `APPDIR/defaults` as fallback directory, if the current mobile language does not match one of the language-specific directories provided by the application.

The list of .42s files required by the application must be defined in the unique `fglprofile` configuration file located beside the program module of your application.

For more details, see Localized string files on mobile devices on page 546 and Deploying mobile apps on page 3588.

**Querying user's preferred language**

The application can get the user's preferred language and regional settings as configured on the mobile device, by using the `standard.feInfo` front call with the `userPreferredLang` argument.

For more details, see User's preferred language on page 533 and `feInfo` on page 2651.

---

**App execution**

Mobile apps are started and stopped, and can switch between foreground and background states when running.

**Mobile app execution modes**

Mobile apps can be fully embeeded as a standalone or can execute on a server and display forms on the mobile device.

On iOS and on Android™, standalone Genero apps are installed and started on the device as other apps. In this configuration, the application program files, the runtime system and the database are present on the mobile device.
When a permanent network connection is available (WIFI), it is also possible to have a lightweight app installed on the device, that executes the real application code on a server, displaying forms on the device. With this architecture, your mobile app benefits from the processing power of the server, and can access a large database.

For more details, see Starting programs on a mobile device on page 489.

**Background/foreground modes**

Describes how to handle background or foreground modes in mobile apps.

**Mobile apps foreground and background modes**

Mobile apps can change their state from background mode to foreground mode and vice-verse. For example, when the user switches to another app, or when going back to the home screen, the current app goes to background mode. An app goes to foreground mode, when it is re-selected from the active apps list.

**Detecting foreground/background mode changes**

Genero BDL provides two predefined actions, to detect when the state of a mobile app changes:

1. The action *enterbackground* is fired, when the app goes to background mode.
2. The action *enterforeground* is fired, when the app goes to foreground mode.

**Note:** The *enterforeground* action is not fired when the app starts. This action is only fired when returning to foreground mode, after it was in background mode.

To execute code when the app goes to background or foreground mode, use on **ON ACTION** handler:

```plaintext
ON ACTION enterbackground  
  LET skip_timers = TRUE  
ON ACTION enterforeground  
  IF NOT ask_password() THEN  
    EXIT PROGRAM  
  ENF IF
```

For example, when the app enters background mode, it is recommended that the program suspend any activity, and skip code that would be executed in **ON TIMER** triggers.

On the other hand, when the app enters foreground mode, the program can for example ask the user's login/password again, for security reasons, to make sure that the mobile device did not end up in other hands while the app was in background mode.

To control action view rendering defaults and current field validation behavior when the *enterforeground/enterbackground* actions are used, consider setting action default attributes for these action in your .4ad file as follows:

```plaintext
<ActionDefaultList>  
  ...  
  <ActionDefault name="enterbackground" validate="no" defaultView="no" contextMenu="no"/>  
  <ActionDefault name="enterforeground" validate="no" defaultView="no" contextMenu="no"/>  
  ...  
</ActionDefaultList>
```

Another option is to define these action defaults attributes in the **ON ACTION** handlers:

```plaintext
ON ACTION enterbackground (VALIDATE=NO, DEFAULTVIEW=NO)  
  ...  
ON ACTION enterforeground (VALIDATE=NO, DEFAULTVIEW=NO)  
  ...
```
Checking if the app is currently in foreground mode

To know the current state of a mobile app, use the `mobile.isForeground` front call:

```groovy
define fg boolean
    call ui.interface.frontcall("mobile", "isForeground", [], [fg])
    if fg then
        ...
    end if
```

What does the app when in background mode?

On iOS, when the app is in background mode, the program cannot do anything meaningful outside push notifications or audio play.

On Android™, when the app is in background mode, the program can continue its execution.

Avoid Android™ to terminate app when in background (GMA)

On Android™ devices, an app can switch between foreground to background states.

The Android™ system can decide to stop an app in background state, for example when resources are required for other apps.

Genero programs running on servers are typically not prepared to be stopped at any time; except in case of major failure, it’s the program that decides when it terminates. On mobile devices, Android™ can decide to stop the app when it is in background state.

By default, when the app goes to background state, a notification is shown by GMA, to keep the app in foreground state, and avoid Android™ stopping the app. The notification disappears, when the app returns to foreground state.

Use the `androidKeepForeground` style attribute to control the way the GMA forces Android™ to keep your app alive. Set this attribute to "no" if your app can be stopped by Android™, when it is in background state. When this style attribute is set to "no", GMA will not display a notification, when the app switches to background mode.

**Important:** When using `androidKeepForeground=no`, Android™ may stop the app at any time. Make sure that the code is ready for this case.

For more details, see User Interface style attributes on page 1219.

App user interface

This section includes topics about user interface programming for mobile.

In general, the user interface of a mobile app written in Genero displays and reacts as a desktop or web application, while simultaneously respecting the device operating system look-and-feel. There are parts of the interface, however, that display and react in a specific way.

Take a look at each of the user interface items in this chapter, to understand how they are portrayed in a mobile app. A user interface feature not listed means there is nothing mobile-specific to its display or behavior.

**Note:** The topics of this section relate to the native rendering mode. When using the Universal Rendering mode, GBC web browser rendering rules apply.
Images and icons

For this topic, an image can refer to the IMAGE item type or the icons used in the app.

Image format support

Mobile apps written in Genero supports all image formats supported by the device OS. However, each platform has its own restrictions on which image formats it supports:

- Android image format support
- iOS image format support

Mobile devices have a much higher pixel density (a higher resolution) than classic desktop monitors. An image which looks nice on a desktop can appear small or as an upscaled image on a mobile device.

Providing the image resource

Genero supports different solutions to provide the image data in a mobile app, depending on the need (button icon, application picture, etc). To understand how to get image resource on mobile apps with Genero, see Providing the image resource on page 1149.

Image sizing on mobile devices

The IMAGE item type defines an area for the display of an image on a form.

Image layout and sizing can be controlled with form item attributes to adapt to the type of mobile device.

For more details, see Controlling the image layout on page 1148.

Default action icons

In general, you want the icons used for your mobile app to be the standard icons used by all apps for the mobile platform. Genero is set up to use such icons by default. For more details, see Action views on mobile devices on page 1777.

Genero also supports icon centralization based on TTF icons, to get a global consistent look and feel for all your mobile apps. For more details, see Providing the image resource on page 1149.

Action rendering

Actions are rendered with default action views following mobile platforms standards.

The top and/or bottom parts of the mobile app screen is dedicated to displaying default action views to the user.

A default action view is an implicit graphical item that can be tapped to fire the corresponding action.

The default action views are rendered on the mobile device using platform-specific standards, which are covered in Action views on mobile devices on page 1777.

  Action views are rendered following mobile specific standards.

**Toolbar rendering**

Toolbars allow control over where actions display (and in what order).

For desktop applications, the toolbar is a series of buttons typically contained in a toolbar object, located at the top of the form.

On Genero mobile apps, toolbars are rendered to the mobile platform standards.
Table 752: Mobile platform differences for toolbars

<table>
<thead>
<tr>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genero toolbar items appear in the Android™ <strong>action bar</strong>.</td>
<td>Genero toolbar items appear in the iOS <strong>toolbar pane</strong>.</td>
</tr>
</tbody>
</table>

**Related concepts**

- **Toolbars on mobile devices** on page 1439
  Toolbars can be used to control action view rendering on mobile devices.

- **Action views on mobile devices** on page 1777
  Action views are rendered following mobile specific standards.

**Topmenu rendering**

Topmenus provide a hierarchical menu in the app.

A topmenu will be displayed on the device by using the platform GUI standard specifications:
Table 753: Genero Mobile and topmenus

<table>
<thead>
<tr>
<th>GMA</th>
<th>GMI</th>
</tr>
</thead>
<tbody>
<tr>
<td>Genero topmenus appear as Android™ menu icon.</td>
<td>Genero topmenus appear as iOS menu icon.</td>
</tr>
</tbody>
</table>

A navigation drawer is visible in the action bar if a topmenu is available to the displayed form. The navigation drawer is a panel to the left of the app icon (seen as three bars).

A menu icon is visible in the navigation bar if a topmenu is available to the displayed form.

Related concepts
Topmenus on mobile devices on page 1449
Topmenus can be used to implement a general options menu in mobile apps.
Action views on mobile devices on page 1777
Action views are rendered following mobile specific standards.

**Keyboard type**

Depending on the data being entered, a mobile device is expected to display the keyboard that is appropriate for the data.

There are a variety of keyboard types for mobile devices. A field dedicated to phone number input is expected to display a keyboard specifically for phone number input.

The `KEYBOARDHINT` form field attribute provides a hint regarding the kind of data the form field contains:

```
ATTRIBUTES
EDIT f01 = customer.cust_phone, KEYBOARDHINT = PHONE;
...
```

Although Genero mostly respects the provided hint, the variable data type that is bound to the form field is also examined, to determine what keyboard to display:

- If the field is defined as a `DATE` or `DATETIME` field, the date picker displays regardless of the `KEYBOARDHINT` setting.
- If the field is a character string data, a text keyboard displays if `KEYBOARDHINT=NUMBER` for example.

For more details, see `KEYBOARDHINT attribute` on page 1378.

**List views**

Form tables in a mobile app render as list views.

List views are commonly used in mobile apps to present an indexed list of items or selectable list of options. They are also used to let users navigate through hierarchically structured data.

List views are displayed as either full list views or embedded list views.

The list view only displays the first two columns’ content and any associated row image, regardless of the number of columns defined.

No column header/title is displayed in mobile list views. Thus the mobile user cannot manipulate columns (hide, reorder, resize, or sort).

With full list views, the built-in reduce filter allows the user to filter the rows displayed.

The `JUSTIFY` attribute of the second column can influence how the rows are displayed.

Various options affect the rendering and behavior, by defining `TABLE` container attributes, `DISPLAY ARRAY` dialog attributes and `ON ACTION` handler attributes.

For complete details on implementing table views in a mobile app, see `Using tables on mobile devices` on page 1867.

**Split views**

Split views refer to the ability to access two forms side by side on a mobile device.

**Side by side views on mobile apps**

Many mobile apps offer a specific form layout, splitting the screen in two in order to show a list of the left side and a detail form on the right side. Such kind of layout can be implemented in Genero with the `Split views` on page 1900.

**Differences in how split views are handled by the clients**

There are differences between the Genero Mobile for iOS (GMI) and Genero Mobile for Android (GMA) implementations of split views and parallel dialogs, to include:

- When the application displays in a single pane or in two panes.
• How a user switches between the two panes.

There are also differences in how the split view renders between GMA and GMI.

**Figure 151: The stores2 demo rendered on an Android device**

With Genero Mobile for Android:

• The navigator pane renders as a menu in the left-hand side of the title bar.
• All buttons are merged.
• The title is not displayed when there is a navigator pane. If there is no navigator pane, the title of the current window is displayed.

With Genero Mobile for iOS:
• The navigator pane renders along the bottom of the app.
• Each window has its own title and its own buttons.

Figure 152: The stores2 demo rendered on an iOS device

Front call support
Genero Mobile provides front calls to interface with the device capabilities.

Use front calls to access mobile devices capabilities. For example, with the mobile/takePhoto front call, you can open the camera app of the device to take a picture.

Note: In a classical Genero client/server configuration, a front call is a remote procedure call that involves a round-trip between the front-end and the server where the application executes. For a standalone mobile app, this does not cause any latency. For a server-side app (using the runOnServer front call), however, latency can result.

The details for each front call can be found in Built-in front calls summary on page 2636.

Color and theming
Mobile applications must follow the platform colors and theming.

User interface design on mobile devices
Genero BDL provides several ways to define colors and styles for a mobile app. This section introduces features that can be used to customize your mobile app and adapt to the target platform user interface design. As a general rule, avoid using non-standard ergonomics and decorations, use defaults to let Genero render your forms depending on the platform standards. For example, the GMA front-end will use Google material design on Android™ devices.

Defining TTF icon colors
By default, TTF icons get the color of the platform theme. A default color can be defined for all TTF icons of a window with the defaultTTFColor style attribute. In order to define a color for a specific icon, add an #RGB color specification in your image to font glyph mapping file.

For more details, see Using a simple image name (centralized icons) on page 1150

App color theme on Android
Android™ apps can be created with a specific color theme following the Google material design.

When building the APK with the gmabuildtool, you can specify the general app colors with the --build-app-colors option.

For more details, see Define app's color theme on page 3597.

iOS specific UI elements
On iOS devices, some UI elements are specific to the platform and are not represented in the Abstract User Interface tree. In order to define the decoration of these elements, specific style attributes have been defined. For more details, see Decorate iOS UI elements on page 3582.

Screen orientation
Detecting screen orientation changes with the mobile device.

Detecting screen orientation changes
Mobile apps can adapt to the device orientation, when switching between portrait and landscape mode.

Screen orientation changes can be detected with the windowresized predefined action:

```
ON ACTION windowresized
```
Controlling screen orientation on GMA / Android

Use the allowedOrientations Window style attribute, to control screen orientation options on Android devices:

```xml
<Style name="Window.main">
  <StyleAttribute name="allowedOrientations" value="portrait_reverse" />
</Style>
```

For the complete list of possible values, see allowedOrientations style attribute.

Controlling screen orientation on GMI / iOS

On iOS devices using GMI, the screen orientation possibilities must be defined in the Info.plist resource file. Keys such as UISupportedInterfaceOrientations must be defined in the file, for example:

```xml
<?xml version="1.0" encoding= "UTF-8"?>
<!DOCTYPE plist PUBLIC  
"-//Apple//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd" >
<plist version= "1.0">
<dict>
  <key>UISupportedInterfaceOrientations</key>
  <array>
    <string>UIInterfaceOrientationPortrait</string>
    <string>UIInterfaceOrientationPortraitUpsideDown</string>
  </array>
  <key>UISupportedInterfaceOrientations~ipad</key>
  <array>
    <string>UIInterfaceOrientationPortrait</string>
    <string>UIInterfaceOrientationPortraitUpsideDown</string>
  </array>
</dict>
</plist>
```

For more details about Info.plist usage, see the section about defining iOS app properties in Info.plist.

Decorate iOS UI elements

This section describes the presentation style attributes that are supported for iOS devices.

Foreground colors

In order to define the foreground color for items used in the iOS navigation bar, toolbar, and some items in the forms (Buttons, SpinEdit, Radiogroups, and row checkmark and disclosure indicators in list views), the iosTintColor style attribute can be used at Window level:

```xml
<StyleList>
  <Style name="Window">
    <StyleAttribute name="iosTintColor" value="white" />
  </Style>
</StyleList>
```

Background colors

Background color of iOS specific elements can be defined with the following style attributes at the Window level:

- iosTabBarTintColor
• iosToolBarTintColor
• iosNavigationBarTintColor

For example:

```xml
<StyleList>
  <Style name="Window">
    <StyleAttribute name="iosTintColor" value="white" />
    <StyleAttribute name="iosNavigationBarTintColor" value="blue" />
    <StyleAttribute name="iosToolBarTintColor" value="blue" />
  </Style>
</StyleList>
```

**iosTintColor inheritance**

The **iosTintColor** style attribute can be used at Window level to defined the text color for Tabbar and Toolbar elements.

However, when defining the text color at Window level, it has an impact on the form elements such as Folder, Button, SpinEdit and RadioGroup too. For example, if you set **iosTintColor** to white at the window level, Folder, Button, SpinEdit and RadioGroup element will appear as if they were hidden.

To avoid this, set another text color at the Form element level, as shown in the next .4st style file:

```xml
<StyleList>
  <Style name="Window">
    <StyleAttribute name="iosTintColor" value="white" />
    <StyleAttribute name="iosNavigationBarTintColor" value="blue" />
    <StyleAttribute name="iosToolBarTintColor" value="blue" />
  </Style>
  <Style name="Form">
    <StyleAttribute name="iosTintColor" value="blue" />
  </Style>
</StyleList>
```

**Important:** Note that in the above example, the **iosToolBarTintColor** and **iosNavigationBarTintColor** define respectively the background color for the iOS navigation bar and the iOS toolbar.

For a complete description of these attributes, see [Style attributes reference](#) on page 1182.

**Database support on mobile devices**

On the device, a Genero app can use SQL for data management.

**Databases supported on mobile devices**

Only SQLite can be used on mobile devices. SQLite has a small footprint, is free and readily available.

The database driver (dbmsqt) and the SQLite library are built into the runtime system for mobile Genero apps. No database driver specification is required when running on mobile.

To read more about SQLite programming, see [Using SQLite database in mobile apps](#) on page 3584.

**Synchronizing data with a central database**

When local mobile app data needs to be synchronized with a central database, you must write your own synchronization routines using Web Services. You must implement a back-end service to collect mobile database updates and to send central database changes back to the mobile app.
Important: If you are using GMI, and the device goes into standby mode, the application does not run in the background and activities with the network are suspended. If you are synchronizing data with the server, and the device goes into standby, the synchronization is suspended until the device resumes from standby. If you have a long synchronization, you need to either disable the sleep to allow the synchronization to complete, or accept that the synchronization will suspend when the device goes into standby mode.

Related concepts
SQLite on page 1004

Using SQLite database in mobile apps
On the device, Genero Mobile uses the SQLite database only.

Running an app in development mode
When running an app in development mode (where the app runs on a computer), you can use any database server that Genero supports for the operating system of the server-side app.

Running an app on a mobile device
When running the application on the device, only SQLite can be used. The database must be created at the first application execution, or it must be delivered as the default database in the .ipa or .apk package.

Locale character set and length semantics
SQLite stores data in UTF-8 codeset, mobile apps will by default run in UTF-8 and with character length semantics (FGL_LENGTH_SEMANTICS=CHAR).

Creating the database
Mobile applications usually create their database at first execution. The SQLite database file must be created in the application sandbox, in a writable directory. If the database file does not exist in the current working directory (os.Path.pwd()), create an empty file and then perform a CONNECT TO instruction.
For more details, see Creating a database from programs on page 608.

Providing a default database
SQLite database file format is cross-platform. Instead of creating the database the first time the application starts, you might want to prepare a default database file in your development environment, and include it in the .ipa/.apk package.

Data types with SQLite
SQLite does not have strict data type checking as traditional databases. If you define a table column as a DECIMAL, you can still store character values in that column. Pay attention to this SQLite specific feature, to avoid invalid storage and type conversion errors in your application.
Consider using the following data types for maximum portability, especially when data needs to be synchronized with a central database server, where the data types must match to the types used in the mobile application: CHAR, VARCHAR, DATE, DATETIME YEAR TO MINUTE, DATETIME YEAR TO FRACTION(3), DECIMAL, SMALLINT, INTEGER, BIGINT, BYTE, TEXT.

Optimizing data changes
SQLite can be slow at doing commits, due to the data integrity technique used for transactions. Since each INSERT / UPDATE / DELETE statements acts as an individual transaction (i.e., auto-commit), there will be as many transactions/commits as data manipulation statements. For example, it takes about 10 seconds to insert 1000 rows on an Intel core i7 2.60GHz CPU / 5400.0 RPM HDD computer.
When executing code that modifies a lot of rows (for example, when inserting default data at first application execution, or when doing synchronization with a central database), enclose the SQL statements within a `BEGIN WORK / COMMIT WORK` transaction block to speed up the process:

```sql
BEGIN WORK
    FOR i=1 TO mylog.getLength()
        -- INSERT / UPDATE / DELETE statements
    END FOR
COMMIT WORK
```

### Enforcing foreign key constraints

SQLite 3.6.19 and + support foreign key constraints, with `ON DELETE CASCADE` and `ON UPDATE CASCADE` options. By default, however, foreign key constraints are not enforced. Each application must explicitly turn on the feature with a `PRAGMA` command. Immediately after the database connection, you can perform the `PRAGMA` command in an `EXECUTE IMMEDIATE` statement:

```sql
CONNECT TO connstr AS "c1"
EXECUTE IMMEDIATE "PRAGMA foreign_keys = ON"
```

### Truncating the SQLite database file

By default, when deleting rows, SQLite keeps the unused database file pages for future storage. As result, when deleting a large amount of data, the database file might be larger than necessary. Consider truncating the database file with the `VACUUM` SQL command (in an `EXECUTE IMMEDIATE` statement), if disk space is limited and when a lot of database rows were deleted.

Depending on the application, the `VACUUM` command can be executed:

- when starting the application, just after connecting to the database,
- after doing a large database operation (such as a synchronization with a central database),
- as a manual option that the user can trigger.

For example, after connecting to the database:

```sql
CONNECT TO connstr AS "c1"
EXECUTE IMMEDIATE "VACUUM"
```

### Sharing database files between Android apps

Two different Android™ apps (each packaged as a separate `.apk`) execute in their own sandbox, but have access to the storage area (SD-CARD) and therefore can share a common database file.

SQLite handles concurrent access to the same database file by setting a lock on the entire db file when modifying data (`INSERT/UPDATE/DELETE`). By default, if a writer process locks the file, other processes must wait until the lock owner process completes its transaction and releases the lock.

Because of Informix® compatibility, Genero BDL uses a default lock timeout or zero (i.e., not waiting for locks to be released). As result, when writing to a database file that is locked by another process, if the isolation level is `SERIALIZATION` (the default with SQLite), an application will get the SQL error -244.

To avoid this problem, you must change the default lock timeout with the `SET LOCK MODE` instruction, after starting the database session:

```sql
CONNECT TO connstr AS "c1"
SET LOCK MODE TO 5 -- seconds
```

The second process will then wait until the first process releases the lock. If transactions are short (milliseconds), having processes waiting for each other is transparent to the user.

Accessing device functions

Mobile apps can access device functions by using front calls.

Accessing device functions using frontcalls

Mobile applications typically want to access device functions such as geolocation, multi-media content (photos, videos), messaging (contacts database, email, sms).

This can be easily achieved by using front calls dedicated to mobile features. Note that some functions are platform specific, for example to launch an Android activity, or access to iOS device settings.

As a general rule, execute your front call in a TRY / CATCH block to catch errors:

```study
DEFINE status STRING,
    latitude, longitude FLOAT
TRY
    CALL ui.Interface.frontCall("mobile", "getGeolocation",
        [], [status, latitude, longitude] )
CATCH
    ERROR "Could not get coordinates..."
END TRY
```

For more details, see Genero Mobile common front calls on page 2697, Genero Mobile Android front calls on page 2713, Genero Mobile iOS front calls on page 2718.

Accessing Android™ device functions using the Java Interface

**Note:** On Android™ devices, some system functions can only be accessed in the context of a JVM. Use the Java Interface with the `com.fourjs.gma.vm.FglRun` class to access such system specifics.

Web Services on mobile devices

Web Services can be used within mobile applications.

Web Services and Genero Mobile for Android

Points to consider when using Web Services on Android™ platforms:

- V3 SSL Certificates are required.

For complete details about Web Services on GMA, see Web Services on GMA (Android) on page 3277

Web Services and Genero Mobile for iOS

Points to consider when using Web Services on iOS platforms:

- GWS configuration FGLPROFILE entries related to SSL/TLS keys (security.*) are not supported (uses iOS native SSL/TLS).
- When executing a long-running HTTP request, the app may go into background mode, and raise the runtime error -15553 when switching back to foreground mode.

For complete details about Web Services on GMI, see Web Services on GMI (iOS) on page 3276.
Debugging a mobile app

Different solutions are available to debug a mobile app.

**Debugging a mobile app in development mode**

When executing a mobile app program on a server, displaying the user interface on a mobile front-end defined by `FGLSERVER`, it is possible to debug the BDL code with the `fglrun -d` option:

```
$ export FGLSERVER=device-ip-address
$ fglrun -d main.42m
```

For more details, see Starting `fglrun` in debug mode on page 2143.

**AUI protocol debugging**

With app running on a server or on the device, it is possible to show AUI protocol exchanges in the console running the program on the server, by setting the `FGLGUIDEBUG` environment variable to 1. When this variable is set, you can watch user interface events that occur during program execution and how they are treated by the runtime system.

To set the `FGLGUIDEBUG` environment variable for an app running on the device, use an `FGLPROFILE fglrun.environment` entry. The output can be inspected with the program logs as described later in this section.

For more details, see `FGLGUIDEBUG` on page 275.

**AUI protocol logging in development mode**

With an app running on a server, it can be useful to log AUI protocol exchanges between the runtime system and the mobile front-end, to inspect the content, or replay a scenario. This is possible with the `--start-guilog` and `--run-guilog` options of `fglrun`:

```
$ fglrun --start-guilog=case1.log
```

The AUI protocol log file produced by the `--start-guilog` option can then be shared for analysis.

For more details, see Front-end protocol logging on page 1120.

**Debugging a mobile app running on the device**

When executing the mobile app on a device, and if the app has been created with debug mode, it is possible to establish a connection to the runtime system executing on the mobile device, by using the `fgldb` command line tool.

**Important:** On iOS devices, after installing the app, you need to enable the debug port in the app settings, otherwise the app will not listen to the debug port.

For example:

```
$ fgldb -m 192.168.1.23:6400
108 DISPLAY ARRAY contlist TO sr.*
(fgldb)
```

This way you can debug an app running on a device, by using the source code located on the server where the `fgldb` command is executed.

For more details, see Debugging on a mobile device on page 2145.

**Building mobile apps in debug mode**

In order to enable debug features of an app running on a mobile device, you need to build the app in debug mode:

- For Android:
The `gmabuildtool` provides the `--mode debug` option, to create a debug version of the APK.

For more details, see Building Android apps with Genero on page 3591.

• For iOS:

  The `gmibuildtool` provides the `--mode debug` option, to create a debug version of the IPA. The certificate defined in the provisioning profile must be a development certificate.

  **Note:** After installing the debug version of the app on your iOS device, you need to enable the debug port in the app settings.

  For more details, see Building iOS apps with Genero on page 3606.

### Browse the AUI tree created on the mobile front-end side

The content of the Abstract User Interface tree created on the mobile front-end side can be inspected from a web browser, when the app has been created with debug mode, or in development mode by executing the app on a server and displaying on the device.

To inspect AUI tree, open a web browser and enter the following URL:

```
http://device-ip-address:6480 (or 6400)
```

For more details, see Inspecting the AUI tree of a front-end on page 1108.

### Viewing embedded app program logs

The program logs of an app running on a device can be viewed in a browser, if the app was created in debug mode. VM messages (runtime errors, standard output and standard error) are available. This feature is not available if the app is built in release mode.

To inspect program logs, open a web browser and enter the following URL:

```
http://device-ip-address:6480 (or 6400)
```

A menu will then appear in the web page, where you can choose the VM output to be inspected.

### Debugging a WEBCOMPONENT HTML/JavaScript

The HTML content and JavaScript code can be debugged on GMA and GMI mobile devices.

For more details, see Debugging a web component on page 1928.

**Related concepts**

- Integrated debugger on page 2142
  Describes the command-line debugger you can use to find bugs in your programs.
- Program profiler on page 2165
  Find out what function is causing the bottleneck in your program.

### Deploying mobile apps

This section describes how to build and deploy mobile apps with Genero.

**Related concepts**

- App execution on page 3572
  Mobile apps are started and stopped, and can switch between foreground and background states when running.
- App localization on page 3572
  Mobile apps can be designed to display localized texts based on the language selected on the device.
- Environment variables on page 3571
You may need to set environment variables for your app.

Database support on mobile devices on page 3583
On the device, a Genero app can use SQL for data management.

**Deploying mobile apps on Android™ devices**
This section contains information to create a mobile application to be deployed on Android™ devices.

**Directory structure for GMA apps**
Platform-specific rules need to be considered when deploying on Android™ devices (GMA).

**The application sandbox**
On Android™ devices, applications are deployed in an application sandbox. The application can access and store data outside of its space, but then the data is also accessible by the other applications.

**Directory structure for a GMA application**
Inside its application sandbox, an Android™ app uses the following directory structure:

```
appdir/
 |-- main.42m
 |-- *.42m
 |-- *.42f
 |-- fglprofile
     ...
 |-- defaults/*.42s
 |-- de/
     |-- *.42s
 |-- fr/
     |-- *.42s
 |-- zh/
     |-- *.42s
     ...
 |-- ... other resource files/dirs ...
  ...
 |-- webcomponents
     |-- component-type
         |-- component-type.html
         |-- other-web-comp-resource
         ...
  |-- appdata/
     |-- ... writable app files ...
 tmpdir/
 |-- ... temporary files ...
```

**Program files directory (appdir)**
Application program files (.42m, .42f, and so on) need to be deployed in the appdir application base directory.

The program files directory can be found in programs with the `base.Application.getProgramDir` on page 2408 method.

**Important:** On Android™, the program files directory returned by the `base.Application.getProgramDir()` method is the same directory as the default working directory, returned by `os.Path.pwd()`.

The FGLAPPDIR environment variable is automatically set to the appdir directory.
Program name (MAIN)

When deploying on mobile devices, the name of the program file must be main.42m or main.42r.

Note: When using the command-line app build scripts, the name of the program file must be main.42?. When using Genero Studio, the packaging script takes care of renaming this file, if you have not named it main.

As with other program files, the "MAIN" module must be located under the appdir application program directory.

Working directory

On Android™ devices, the default current working directory is the appdir directory, and can be used for writable files.

The current working directory can be found in programs with the os.Path.pwd on page 2806 method.

Files that need to be writable (such as SQLite database files) can be created directly under the appdir directory. However, to better organize application files, create sub-directories such as appdir/appdata, keeping original files directly under the appdir directory. For example, create the application database under os.Path.pwd() || "/database".

Temporary directory (tmpdir)

A temporary directory is available for the application.

In order to find the temporary directory for the app, use the standard.feInfo front call, with the "dataDirectory" parameter.

To create a temporary file name, use the os.Path.makeTempName() method.

Language directories for localized strings

When the app starts, the appropriate .42s string files will be loaded from the directory corresponding to the current language settings of the mobile device. String files to be loaded can be defined in the app's fglprofile, or you can use the main program name to avoid fglprofile settings.

For each language supported by your application, a directory must exist under appdir, with a name including the locale codes. Default string files (in English for example) can be provided under appdir/defaults, in case the regional settings of the device do not match one of the locale directories of the app, otherwise the application will stop with error -8006.

For example:

```
appdir/defaults/mystings.42s
appdir/fr/mystings.42s
appdir/de/mystings.42s
```

For more details, see Localized string files on mobile devices on page 546.

Deploying a custom fglprofile file

If you need to set fglprofile entries for your mobile application, create a file with the name fglprofile, and deploy it under the appdir directory, along with the other program files.

See Understanding FGLPROFILE on page 255 for more details about fglprofile settings.

Creating the initial database file

When a mobile application starts for the first time, it typically creates a new database, or copies an existing database template file from the file directory (base.Application.getProgramDir on page 2408) to the working directory (os.Path.pwd on page 2806).
Note: It is recommended that different database file names are used for the original and final application database, as folders pointed to by `base.Application.getProgramDir()` and `os.Path.pwd()` can be the same on Android™ devices.

For more details about database creation on mobile devices, see Creating a database from programs on page 608.

Building Android™ apps with Genero
Genero provides a command-line tool to create applications for Android™ devices.

Basics
Genero mobile apps for Android™ are distributed as APK packages like any other Android™ app. APK packages can be published on the Google Play Store.

Genero provides the `gmabuildtool` command line tool, to build the APK package for your mobile application.

Important: You need to comply with some Google conditions before you can publish your app on the Play Store. This topic describes how the `gmabuildtool` tool builds Google Play Store ready APK packages.

For testing purposes, the tool can deploy and automatically launch the app on a specific device or simulator.

The tool has also an option to update the Android™ SDK and an option to manage scaffold archives.

Note: This documentation section implies that you are familiar with Android™ app programming concepts and requirements. For example, you will need the Android™ SDK tools to be installed (and up to date) to build your Android™ apps. For more details, visit the Android SDK tools download page.

Prerequisites
Before starting the command line tool to build or deploy the app, fulfill the following prerequisites:

1. The Genero BDL development environment (FGLDIR) must be installed to compile your program files.
2. The Java JDK must be installed.
   
   Important: JDK version 8 is required to build Android™ apps. For the latest information regarding system requirements and Java support, please refer to the Supported platforms and databases document, available on the “Products” download page of the Four Js Web site.
3. The GMA software components must be installed.
   
   The GMA buildtool and GMA binary archive are provided in the GMA distribution archive (`fjs-gma-*.zip`).

To set up the GMA installation directory, perform the following steps:

a. Create a dedicated directory (`gma-install-dir`)

b. Extract the content of the `fjs-gma-*.zip`.

c. Add the `gma-install-dir` directory to your PATH environment variable, in order to find the `gmabuildtool` command.

The `gma-install-dir` will contain the `gmabuildtool` command, and the original GMA scaffold archive (`gma-install-dir/artifacts`).

4. The Android SDK must be installed (an internet connection is required to download the SDK packages). For more details, see Install Genero Mobile for Android on page 40.
5. Download/upgrade the required Android™ SDK packages, by using the `gmabuildtool updatesdk` command.

   Note: Execute the `gmabuildtool updatesdk` command every time a new version of the GMA buildtool and GMA binary archive is installed.

   For more details, see Update the Android SDK with the GMA buildtool on page 3592.
6. Android™-specific app resources such as icons (in all required sizes) are required, along with the application program files.
7. If you plan to publish your app on Google Play, register to Google Play as a developer and create a Google Play project.
Environment settings
Define the following environment variables before starting the command-line buildtool:

- Android™ SDK environment settings (ANDROID_SDK_ROOT, PATH)
- Java JDK environment settings (JAVA_HOME, PATH)

Update the Android™ SDK with the GMA buildtool
After a fresh installation of the GMA buildtool and GMA binary archive, upgrade the Android™ SDK, to download all required Android™ SDK packages, with the gmabuildtool updatesdk command.

The Android™ SDK installation directory is required for the SDK update, and is found in ANDROID_SDK_ROOT environment variable, or with the --android-sdk option:

```
gmabuildtool updatesdk
   --android-sdk /use/local/32bits/android-sdk/r22.6.2
```

Use the --accept-licenses option to silently accept all Android™ SDK licenses.

```
gmabuildtool updatesdk
   --accept-licenses
   ...
```

If you need to specify a proxy to download the Android™ SDK, use the --proxy-host and --proxy-port options:

```
gmabuildtool updatesdk
   --proxy-host amadeus --proxy-port 3232
   ...
```

Use the --no-install-extras option to skip the installation of extra SDK modules such as Google's driver for Windows® and the HAXM for Windows® and OS X:

```
gmabuildtool updatesdk
   --no-install-extras
   ...
```

Manage GMA scaffold archives
The GMA scaffold archives can be managed by the gmabuildtool scaffold command.

In order to get the list of plugins installed in the GMA development environment, use the --list-plugins option:

```
$ gmabuildtool scaffold --list-plugins
   ...
cordova-plugin-device-motion.aar
cordova-plugin-media.aar
   ...
```

To install additional plugins in the GMA installation directory, use the --install-plugins option, for example:

```
$ gmabuildtool scaffold --install-plugins path-to-plugin-sources
```

For more usage examples, see Cordova plugins on page 3644.
Building your APK with the GMA buildtool

The gmabuildtool build ... command creates the APK from a set of files, and following the options passed as parameter.

```
gmabuildtool build ...
        build options ...
```

The process will be explained in details in the next sections of this topic.

For a complete description of the build command options, see gmabuildtool on page 2096.

Gradle build cache

To build Android™ apps, the GMA buildtool uses the Gradle toolkit.

Gradle can speed up APK creation time, by reusing outputs saved in a cache produced from previous builds. The gmabuildtool command uses the Gradle build cache.

On Unix-like platforms, the gmabuildtool Gradle build cache is in the /tmp/gma directory. On Windows®, it is in C:\tmp\gma.

**Important:** The Gradle build cache directory used by gmabuildtool (/tmp/gma or C:\tmp\gma) can grow to a significant size and consequently fill the disk. Take care to monitor the size of this cache and manually clean out the cache files, to ensure that it does not become too large in size.

Cleaning intermediate build files

The build process is optimized to avoid a complete APK rebuild every time you invoke the GMA buildtool.

The GMA buildtool creates intermediate archive files, that can be reused in the next build, if no changes are detected in application program files. However, these files might be corrupted, in case of user interruption or gradle build failure.

In this situation, you can use the --clean option of the gmabuildtool build ... command, to clean up the scaffold build directory, and restart with a fresh build:

```
gmabuildtool build --clean ...
        build options ...
```

Force scaffold update during build

During the build process, if not yet done, the GMA buildtool will automatically unzip the original GMA scaffold archive (gma-install-dir/artifacts) into the --build-project directory. During next builds, the scaffold files present in the project build directory will be reused.

If needed (especially, when upgrading GMA), you can force an update of these scaffold files with the --build-force-scaffold-update option of the gmabuildtool build command:

```
gmabuildtool build --build-force-scaffold-update ...
        build options ...
```

**Note:** When using the --build-force-scaffold-update option, the GMA buildtool will ask for a confirmation to remove the scaffold files in your project directory. In order to build silently and answer yes to all questions asked during the build process, use the --build-quietly option:

```
gmabuildtool build --build-force-scaffold-update --build-quietly ...
        build options ...
```
Specifying the GBC for Universal Rendering

When your app uses Universal Rendering mode, use the --build-gbc-runtime option to specify which GBC has to be bundled in the APK:

```
gmabuildtool build --build-gbc-runtime gbc-archive ...
```

The gbc-archive parameter is the ZIP archive of the GBC front-end, to be created as described in the Create a runtime zip topic in the Genero Browser Client User Guide.

If the --build-gbc-runtime option is used, the embedded applications will implicitly be displayed with Universal Rendering. There is no need to set the gui.rendering option in the FGLPROFILE. However, if gui.rendering="native" is set, the native GUI mode will be used, even if the GBC option is specified during the build.

Using an options file

To simplify option specification, create a file with the list of options to be passed to the gmabuildtool with the --input-options argument. Each option must be specified in a dedicated line (note that the main command argument appears in the first line):

```
$ cat myoptions.txt
build
   --build-output-apk-name MyApp
   --build-app-name MyApp
   --build-app-package-name com.example.myapp
   ...
$ gmabuildtool --input-options ./myoptions.txt
```

Elements used in building the Android™ app

The gmabuildtool build command builds the Android™ APK package from the following:

- The GMA binary archive, containing the GMA front-end and the FGLGWS runtime system. The original scaffold is provided in gma-install-dir/artifacts and unzipped/copied for APK builds into a directory defined by the --build-project option.
- The GBC to be used for Universal Rendering (--build-gbc-runtime option),
- The compiled application program and resource files (.42m, .42f, etc) (--build-app-genero-program* options),
- The prefix for the APK file name to be generated (--build-output-apk-name option),
- The name of the app (--build-app-name option),
- The version code of the app (--build-app-version-code option),
- The version name of the app (--build-app-version-name option),
- Android™ app specific resources:
  - Android™ app icons (all sizes) (--build-app-icon* and --build-status-icon-* options).
  - Android™ app specifics (to sign the app, not required in development mode):
    - The keystore alias, used with the keytool to generate the keystore file (--build-jarsigner-alias option).
    - The keystore file, generated from keytool (for the --build-jarsigner-keystore option).

Generate the keystore file to sign your app

In order to build an APK that can be deployed on the market (Google Play), you need to sign your Android™ app.

First, you need to generate a keystore file with the keytool Android™ utility.
The keystore file and keystore alias will be used by the gmabuildtool to sign the APK with the jarsigner utility. These signing credentials are passed to the buildtool with the --build-jarsigner-keystore and --build-jarsigner-alias options.

**Important:** There is critical information regarding app signing in the Android documentation. For example, in order to install new versions as updates to your app, each APK must use the same certificate: The signing key must not change during the lifetime of your app. Make sure that you read all details about Android app signing.

### Generated APK file name

The file name of the APK package is formed from:

1. The APK file name prefix defined by the --build-output-apk-name option (by default, "app"),
2. When building a debug version, the -debug suffix,
3. The .apk file extension.

For example, if the APK file name prefix is MyApp and is a debug package, the resulting APK file name will be: MyApp-debug.apk.

### Default build directory structure

For convenience, the buildtool supports a default directory structure to find all files required to build the APK:

```plaintext
<table>
<thead>
<tr>
<th>top-dir</th>
</tr>
</thead>
<tbody>
<tr>
<td>-- main.42m and other program files, as described in Directory structure for GMA apps on page 3589</td>
</tr>
<tr>
<td>-- gma</td>
</tr>
<tr>
<td>-- project</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>-- ic_app_hdpi.png</td>
</tr>
<tr>
<td>-- ic_app_mdpi.png</td>
</tr>
<tr>
<td>-- ic_app_xhdpi.png</td>
</tr>
<tr>
<td>-- ic_app_xxhdpi.png</td>
</tr>
<tr>
<td>...</td>
</tr>
</tbody>
</table>
```

In the above directory structure:

1. `top-dir` is the top directory of the default structure. It typically holds your application program files. The program files directory can be specified with the --build-app-genero-program option.
2. `top-dir/gma` is the default directory containing the GMA binary archive and the app icons.
3. `top-dir/gma/project` contains the scaffold files copied automatically by gmabuildtool from gma-install-dir/artifacts. This directory can be specified with the --build-project option.

### Android™ permissions

To use a mobile device feature such as the camera, an Android™ app must be created with the corresponding Android™ permission.

Android™ distinguishes "Normal Permissions" and "Dangerous Permissions": Dangerous Permissions require a user validation at runtime, the first time the device feature is used.

**Note:** Before Android™ 6, Dangerous Permissions defined by the app were set at app installation. Starting with version 6, Dangerous Permissions must be requested by the app code on demand.

Android™ permissions can be specified with the --build-app-permissions option of the gmabuildtool. Define the list of permissions as a single argument, by using the comma as separator.

For example:

```plaintext
gmabuildtool build \
```
Assuming that the permission was specified when building the APK, a Dangerous Permission required for a core GMA feature (like internet access), or a built-in front call, will make the GMA automatically ask for user confirmation. For example, if the app code makes a `chooseContact` front call, the GMA will automatically request the user to access the contacts database.

Other permissions (not related to core GMA features or built-in front calls) need to be specified when building the app.

**Note:** Dangerous Permissions not related to core GMA features or built-in front calls, need to be enabled by the app code. To request the user for a specific permission, perform a `askForPermission` front call, before using the feature.

The permissions listed below show Android™ "Normal Permissions", required for core GMA app features and built-in mobile front calls.

**Note:** Normal Permissions listed below are set by default. They do not need to be specified when building the APK.

- `android.permissionINTERNET`
- `android.permissionACCESS_NETWORK_STATE`
- `android.permissionCHANGE_NETWORK_STATE`
- `android.permissionACCESS_WIFI_STATE`
- `android.permissionREORDER_TASKS`
- `android.permissionKILL_BACKGROUND_PROCESSES`
- `android.permissionMOUNT_FORMAT_FILESYSTEMS`
- `android.permissionREAD_LOGS`
- `android.permissionWAKE_LOCK`
- `com.google.android.c2dm.permission.RECEIVE`
- `packageName.permission.C2D_MESSAGE`

The following list shows the Android™ "Dangerous Permissions", required for core GMA app features and built-in mobile front calls.

**Important:** Dangerous Permissions listed below are not set by default: They must be specified explicitly with the `--build-app-permissions` option, when building the APK.

- `android.permissionACCESS_FINE_LOCATION`: For `getGeolocation` on page 2703 front call.
- `android.permissionACCESS_COARSE_LOCATION`: For `getGeolocation` on page 2703 front call.
- `android.permissionREAD_CONTACTS`: For `chooseContact` on page 2699 front call.
- `android.permissionGET_ACCOUNTS`: Only on Android™ 5.1 and lower (< API 23), for `chooseContact` on page 2699 front call.
- `android.permissionREAD_PHONE_STATE`: For `feInfo (deviceid, iccid, imei)` front calls. Starting with Android 10 (API level 29), to access deviceid, iccid and imei identifiers, the device must be configured manually by adding the `READ_PRIVILEGED_PHONE_STATE` privileged permission. To set this permission manually, you need an Android Enterprise Program with fully managed devices (devices are owned by your company). Third-party apps installed from the Google Play Store can’t declare such privileged permissions. For more details, see [Android documentation](https://developer.android.com/guide/topics/permissions/android-permissions).
- `android.permissionWRITE_EXTERNAL_STORAGE`: For `importContact` on page 2706, `takeVideo` on page 2712, `takePhoto` on page 2712 front calls.
- `android.permissionREAD_EXTERNAL_STORAGE`: For `chooseVideo` on page 2700, `takeVideo` on page 2712, `choosePhoto` on page 2699, `takePhoto` on page 2712 front calls.

For a complete list of Android™ permissions, see [Android's Manifest permissions](https://developer.android.com/guide/topics/manifest/). 

```java
--build-app-permissions android.permission.READ_CALENDAR,...
```
**Define app's color theme**

To customize your Android™ app, it can be created with a color theme defined by a list of colors. The colors are specified as a comma-separated list of RGB colors with the --build-app-colors option.

**Note:** This feature is only available with Android™ 5.0 / SDK 21 and higher. With older versions of Android™, the colors specified with the --build-app-colors option will not take effect.

The value provided to the --build-app-colors option must be a comma-separated list of four hexadecimal RGB colors.

The position of the RGB value in the color list defines its purpose:

1. colorPrimary: The main color used in the app.
2. primaryDark: The color used for the status bar and the navigation bar.
3. accent: The accent color used for widgets and table lines.
4. actionbarText: The foreground color for the texts in the action bar.
5. primaryText: The text color for items in the whole application.
6. windowBackground: The window background color.
7. navigationBarBackground: The background color of the bottom bar.

By default, the color theme is the Genero purple color.

For example, to define a red color theme, use the following combination:

```
gmabuildtool build \
  ... \
  --build-app-colors \
  "#F44336,#B71C1C,#EF9A9A,#FFFFFF,#FF0000,#00AA00,#DDAA00" \
  ...
```

For more details, see Android material theme and Android color palette.

**Debug and release versions**

Android™ apps can be generated in a debug or release version. Release versions meet the requirements for distribution on Google Play, while debug versions are used in development. In debug mode, the app installed on the device will listen on the debug TCP port to allow fgldb -m connections.

Debug or release mode can be controlled with the --build-mode option of the gmbuildtool command:

```
gmabuildtool build \
  --build-mode debug \
  ...
```

By default the app is built in release mode.

**Building an Android™ app with gmbuildtool**

Follow the next steps to setup a GMA app build directory in order to create an Android™ app, based on the default directory structure:

1. Create the root distribution directory (top-dir)
2. Copy compiled program files (.42m, .42f, fglprofile, application images, web component files, etc) under top-dir.
3. Copy the default English .42s compiled string resource file under top-dir.
4. Create non-English language directories (fr, ge, ...) under top-dir and copie the corresponding .42s files.
5. Copy default application data files (database file for ex) under top-dir.
6. Create the top-dir/gma directory.
7. Copy Android™ app resources (icons) under top-dir/gma.
Once the build directory is prepared, issue the following commands to build the APK:

```bash
$ cd top-dir
$ gmabuildtool build \
   --android-sdk /home/mike/android/sdk \
   --build-force-scaffold-update \
   --build-apk-outputs /home/mike/work/example/outputs \
   --build-output-apk-name MyApp \
   --build-app-name MyApp \
   --build-app-package-name com.example.myapp \
   --build-app-version-name "10.02" \
   --build-jarsigner-alias android_alias \
   --build-jarsigner-keystore /home/mike/work/example/sign/android.keystore \
   --build-mode release \
   --build-app-permissions android.permission.ACCESS_WIFI_STATE,android.permission.CALL_PHONE
```

**Building an app with GMA custom extensions**

The `gmabuildtool build` command supports APK creation for applications using GMA custom extensions written in Java.

Before building the APK package, create the custom GMA binary archive with your extensions, as described in [Packaging custom Java extensions for GMA](#) on page 2223.

When your custom GMA binary archive is complete, build the APK package with the `gmabuildtool build` command. Use the `--build-project` option to specify the path to the Android™ Studio project that was used to build your custom GMA binary archive:

```bash
$ gmabuildtool build \
   ... \
   --build-project /home/mike/android_project/mycustgma \
   ...
```

**Note:** Other options have to be specified as for a regular build using the original standard GMI binary archive.

**Deploy and launch the app**

After building the APK package, for testing purposes, you can deploy and launch your app from the command line with the `gmabuildtool test` command.

**Note:** The `test` command is provided for development only. To deploy your app in production for several devices, use the regular publication channel of Android™ apps.

In order to deploy and launch the app, you must provide:

1. the path to the APK file

There must be only one Android™ device connected or running Android™ emulator.

```bash
$ gmabuildtool test \
   --test-apk /home/mike/work/example/outputs/MyApp-arm-debug.apk
```

**Related concepts**

[Genero Mobile common front calls](#) on page 2697

This section describes common front calls provided by all mobile front-ends.

[Color and theming](#) on page 3581
Mobile applications must follow the platform colors and theming.

**gmabuildtool**
The gmabuildtool is a utility to create and test applications for an Android™ device.

**Syntax**

```
 gmabuildtool command [option [...]]
```

1. *command* can be one of the following:
   - *updatesdk*: updates the Android™ SDK, to download packages required by GMA.
   - *scaffold*: manages scaffold archives.
   - *build*: builds an APK package.
   - *test*: deploys and launches an app on the device or emulator.

2. *option* can be a general or command-specific option, as described in Options on page 3599.

**Options**

**Table 754: General gmabuildtool options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Short option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--android-sdk <em>path</em></td>
<td>-as</td>
<td>The path to the Android™ SDK installation directory.</td>

</tr>
<tr>
<td>--build-app-name app-name</td>
<td>-bn</td>
<td>Application name. If not specified, the application name defaults to the current working directory.</td>
</tr>
<tr>
<td>--build-app-package-name name</td>
<td>-bpn</td>
<td>APK package name. It is recommended to format the package name as &quot;com.organization-name.app-name&quot;. If not specified, the application package name defaults to com.example.current-working-directory Android™ application permissions. The list of permissions is provided as a comma separated list of android.permission.* identifiers. For more details, see Android permissions on page 3595.</td>
</tr>
<tr>
<td>--build-app-permissions permissions</td>
<td>-ba</td>
<td></td>
</tr>
</tbody>
</table>

| Description |

Relative path to the main module of the application (can be .42m or .42r).

Defaults to main.42m

Defines the path to the application program files (.42m, .42f, etc)

The contents of this directory will be zipped and bundled inside APKs. This option can handle an already zipped Genero program archive.

If not specified, defaults to the current working directory.

**Note**: The path defined by this option is used as base directory for other options such as --build-project and application icon resources options.

Defines the path to application icon in hdpi.

Default is top-dir/gma/ic_app_hdpi.png, where top-dir is defined by the --build-app-genero-program option.

Defines the path to application icon in mdpi.

Default is top-dir/gma/ic_app_mdpi.png, where top-dir is defined by the --build-app-genero-program option.

Defines the path to application icon in xhdpi.

Default is top-dir/gma/ic_app_xhdpi.png, where top-dir is defined by the --build-app-genero-program option.

Defines the path to application icon in xxhdpi.

Default is top-dir/gma/ic_app_xxhdpi.png, where top-dir is defined by the --build-app-genero-program option.

Application name. If not specified, the application name defaults to the current working directory.

APK package name. It is recommended to format the package name as "com.organization-name.app-name".

If not specified, the application package name defaults to com.example.current-working-directory Android™ application permissions.

The list of permissions is provided as a comma separated list of android.permission.* identifiers. For more details, see Android permissions on page 3595.
<table>
<thead>
<tr>
<th>Option</th>
<th>Short option</th>
<th>Description</th>

<td>`--build-mode release</td>
<td>debug`</td>
<td><code>-bm</code></td>
</tr>
<tr>
<td><code>--build-output-apk-name name</code></td>
<td><code>-ban</code></td>
<td>Defines the prefix for the APK packages names. By default, this prefix is &quot;app&quot;. The file name of the APK package is formed from: 1. The APK file name prefix defined by the <code>--build-output-apk-name</code> option (by default, &quot;app&quot;). 2. When building a debug version, the <code>-debug</code> suffix, 3. The <code>.apk</code> file extension. For example, if the APK file name prefix is <code>MyApp</code> and is a debug package, the resulting APK file name will be: <code>MyApp-debug.apk</code>.</td>
</tr>
<tr>
<td><code>--build-project path</code></td>
<td><code>-bp</code></td>
<td>Defines the path to the directory containing the original GMA binary archive files (i.e. scaffolding), or the directory containing the Android™ Studio project, when building a customized GMA. Default is <code>top-dir/gma/project</code>, where <code>top-dir</code> is defined by the <code>--build-app-genero-program</code> option. Forces a silent build, by answering yes to all questions asked during the build process. By default, the user must answer to the build questions by yes/no. Status icon path for hdpi (high dots per inch) size. The default path is <code>top-dir/gma/ic_status_hdpi.png</code>, where <code>top-dir</code> is defined by the <code>--build-app-genero-program</code> option. If this option is not specified, yet you provide default files under the gma directory named like those defined for the default path, your package will use these files. If you don't provide any status icon files, the default files are used.</td>
</tr>
</tbody>
</table>
## Mobile applications

**Option** | **Short option** | **Description**
--- | --- | ---
`--build-status-icon-mdpi path` | `-bsm` | Status icon path for mdpi (medium dots per inch) size.
The default path is `top-dir/gma/ic_status_mdpi.png`, where `top-dir` is defined by the `--build-app-genero-program` option. If this option is not specified, yet you provide default files under the gma directory named like those defined for the default path, your package will use these files. If you don't provide any status icon files, the default files are used.

`--build-status-icon-xhdpi path` | `-bsxh` | Status icon path for xhdpi (extra-high dots per inch) size.
The default path is `top-dir/gma/ic_status_xhdpi.png`, where `top-dir` is defined by the `--build-app-genero-program` option. If this option is not specified, yet you provide default files under the gma directory named like those defined for the default path, your package will use these files. If you don't provide any status icon files, the default files are used.

- [Building Android apps with Genero](#) on page 3591

Generero provides a command-line tool to create applications for Android™ devices.

## Deploying mobile apps on iOS devices

This section contains information to create a mobile application to be deployed on iOS devices.

### Directory structure for GMI apps

Platform-specific rules need to be considered when deploying on iOS devices (GMI).

### The application sandbox

On iOS devices, program interactions with the file system are limited to the directories inside the app's sandbox.

### Directory structure for a GMI application

Inside its application sandbox, an iOS app uses the following directory structure:

```
appdir/
 |-- main.42m
 |-- *.42m
 |-- *.42f
 |-- fglprofile
 |   ...
 |-- defaults/*.42s
 |-- de/
 |   |-- *.42s
```

Program files
Program files directory (*appdir*)

Application program files (.42m, .42f, as well as other program resources) need to be deployed in the *appdir* directory.

**Important:** On iOS, the application program directory is read-only. Only the "Documents" directory is writable.

The program files directory can be found in programs with the `base.Application.getProgramDir` on page 2408 method.

The `FGLAPPDIR` environment variable is automatically set to the *appdir* directory.

Program name (**MAIN**)

When deploying on mobile devices, the name of the program file must be `main.42m` or `main.42r`.

**Note:** When using the command-line app build scripts, the name of the program file must be `main.42?`. When using Genero Studio, the packaging script takes care of renaming this file, if you have not named it `main`.

As with other program files, the "MAIN" module must be located under the *appdir* application program directory.

Working directory

The current working directory for an iOS application is typically a writable "Documents" directory, in the private folder of the app. For example, the path to the working directory can be "'/private/var/mobile/.../Documents".

The current working directory can be found in program with the `os.Path.pwd` on page 2806 method.

**Note:** Any file access without an absolute path will be relative to the current working directory.

Files that need to be writable (such as SQLite database files) must be created or copied from the program files directory into the working directory. Copy must be done by the app at first execution, by using `base.Application.getProgramDir` on page 2408, to find the program files directory, and `os.Path.pwd()`, to find the working directory.

Temporary directory (**tmpdir**) 

A temporary directory is available for the application.

In order to find the temporary directory for the app, use the `standard.fInfo` front call, with the "dataDirectory" parameter.

To create a temporary file name, use the `os.Path.makeTempName()` method.
Language directories for localized strings

When the app starts, the appropriate .42s string files will be loaded from the directory corresponding to the current language settings of the mobile device. String files to be loaded can be defined in the app's fglprofile, or you can use the main program name to avoid fglprofile settings.

For each language supported by your application, a directory must exist under appdir, with a name including the locale codes. Default string files (in English for example) can be provided under appdir/defaults, in case the regional settings of the device do not match one of the locale directories of the app, otherwise the application will stop with error -8006.

For example:

```
appdir/defaults/mystrings.42s
appdir/fr/mystrings.42s
appdir/de/mystrings.42s
```

For more details, see Localized string files on mobile devices on page 546.

Deploying a custom fglprofile file

If you need to set fglprofile entries for your mobile application, create a file with the name fglprofile, and deploy it under the appdir directory, along with the other program files.

See Understanding FGLPROFILE on page 255 for more details about fglprofile settings.

Creating the initial database file

When a mobile application starts for the first time, it typically creates a new database, or copies a existing database template file from the appdir program file directory (base.Application.getProgramDir on page 2408) to the working directory (os.Path.pwd on page 2806).

For more details about database creation on mobile devices, see Creating a database from programs on page 608.

Building iOS apps with Genero

Genero provides a command-line tool to build applications for iOS devices.

Basics

Genero mobile apps for iOS are distributed as IPA packages, like any other iOS app. Genero provides a command line tool to build the .ipa package for your mobile application, or the .app directory for simulators.

Note: This documentation section implies that you are familiar with iOS app programming concepts and requirements. In order to build your apps, you must have an Apple® developer account, as well as certificates and provisioning profiles to deploy your apps. For more details, visit the Apple developer site.

Prerequisites

Before starting the command line tool to build or deploy the app, fulfill the following prerequisites:

1. The Genero BDL development environment (FGLDIR) must be installed on the Mac computer to compile your program files.
2. The GMI archive (and gmibuildtool) must be installed and available.
   
   The GMI archive is provided as a ZIP archive (fjs-fglgmi-*.*.zip). Extract the archive into FGLDIR.
   
   Warning: If the GMI archive is not extracted into FGLDIR, the Xcode® project of the $FGLDIR/demo/MobileDemo/userfrontcall demo does not work.

For test purposes, the GMI zip archive can be installed elsewhere in a location of your choice. You may choose to do this to resolve problems resulting from several GMI versions. If you install elsewhere, define an environment variable GMIDIR on page 284 with the install location and add $GMIDIR/bin to the path.
**Note:** The GMI buildtool does not need GMIDIR; However, all the supplied GMI demos need GMIDIR in the Makefiles.

Check that the gmibuildtool command is available (add GMI-install-dir/bin to PATH for convenience).

**Important:** When re-installing a new GMI archive, remove all "build" directories created by the gmibuildtool.

3. Get an Apple® developer account, device identifiers (UDID) and corresponding identifiers to sign your iOS app (certificate, bundle id, provisioning profile).

**Important:** The UDID is the identifier of your physical device, it can be found with the `instruments -s` command when the device is plugged to the Mac. When deploying on a physical device, make sure that the UDID of the device is listed in the Apple® Developer account that is used to generate the provisioning profiles.

4. Xcode® must be installed on your Mac® OS X computer (utilities from Xcode® toolchain are required).

**Note:** Make sure that the installed Xcode® version supports the iOS versions of your mobile devices. As a general rule, update the Xcode® and iOS to the latest versions.

5. iOS app resources such as icons and launch images (in all required sizes).

### Finding the UDID of the plugged device

In order to find the UDID of the device plugged to your Mac, execute the `instruments -s` command, and identify the line describing your physical device:

```bash
$ instruments -s
Known Devices:
  fraise [55D6D6C1-DE87-52F0-865E-3C6DC79F13D7]
  Fourjs2 iPod touch (9.1) [78b7452fa9462c98c3bc7047da344314fd032004]
  iPad 2 (9.0) [19CDA827-CA55-46F1-9376-BF61E2ECEFDDBB]
  iPad Air (9.0) [F55E1207-C42B-472E-BD76-5B5AE46DE77A]
  iPad Air 2 (9.0) [A0E8C4C4-67CD-42CB-84DF-9C75AC773293]
...
Known Templates:
  "Activity Monitor"
  "Allocations"
  ...
```

In the above output, the UDID of the iPod® is 78b7452fa9462c98c3bc7047da344314fd032004.

### Environment settings

Before starting the command-line buildtool, make sure that Xcode® tools are available. Try `xcodebuild -version` from the command line:

```bash
$ xcodebuild -version
Xcode 11.3.1
Build version 11C504
```

### The gmibuildtool

The gmibuildtool command line tool can build IPA packages of iOS apps written in Genero.

In order to identify the exact product version number of each GMI component, use the `--version` option of the gmibuildtool:

```bash
$ gmibuildtool --version
GMI version:1.40.04
VM version:3.20.05
GWS version:3.20.05
```
Cordova ver:gm_1.30.14

**Manage GMI plugins**

In order to get the list of plugins installed in the GMI environment, use the `--list-plugins` option:

```
$ gmibuildtool --list-plugins
...
cordova-plugin-device-motion
cordova-plugin-media
...
```

To install additional plugins in the GMI installation directory, use the `--install-plugins` option, for example:

```
gmibuildtool --install-plugins path-to-plugin-sources
```

For more usage examples, see Cordova plugins on page 3644.

**Creating the GMI front-end for development purpose**

A self-made GMI front-end can be created with the `gmibuildtool` command. For more details, see Mobile development mode on page 3568.

**Specifying the target to build and deploy the iOS app**

The `gmibuildtool` command can build and install iOS apps for the simulator or for physical devices.

The build and/or install action is controlled by the `--device` option:

- By default, when not specifying the `--device` option, a GMI.app directory is created for the simulator.
- When specifying the `--device booted` option, the GMI.app directory is created and the app is installed on the booted simulator.
- When specifying the `--device phone` option, the GMI.app directory and .ipa file are created.
- When specifying the `--device physical-device-name` option (with a real physical device name plugged on your Mac), the GMI.app directory and .ipa file are created and the app is installed on the device.

By default, the generated GMI.app directory and .ipa archive can be found in $PWD/build sub-directories; however, you can specify the destination IPA file with the `--output` option.

**Specifying the GBC for Universal Rendering**

When your app uses Universal Rendering mode, use the `--gbc` option to specify which GBC has to be bundled in the iOS app package:

```
gmibuildtool ... --gbc gbc-archive ...
```

The `gbc-archive` parameter is the ZIP archive of the GBC front-end, to be created as described in the Create a runtime zip topic in the Genero Browser Client User Guide.

If this option is used, the embedded applications will implicitly be displayed with Universal Rendering. There is no need to set the `gui.rendering` option in the FGLPROFILE; however, if `gui.rendering="native"` is set, the native GUI mode will be used, even if the GBC option is specified during the build.

**Elements used to build the iOS app**

The `gmibuildtool` command builds the iOS app package from the following:

- The GMI binary archive, containing the GMI front-end and the FGLGWS runtime system library,

  **Note:** These files are provided in the `fjs-fglgmi-*`.zip archive.
Important: When re-installing a new GMI archive, remove all "build" directories created by the gmibuildtool.

- The GBC to be used for Universal Rendering (--gbc option),
- The compiled application program and resource files (.42m, .42f, etc),

Note: The application program files must include a main.42m or main.42r module.

- The display name of the app (--app-name option),
- The version of the app (--app-version option),
- The debug or release mode (--mode option),
- The certificate (to sign the app) (--certificate option),
- The bundle Identifier (--bundle-id option),
- The app provisioning profile (.mobileprovision file) (--provisioning option),
- iOS app specific resources:
  - App icons (--icons option),
  - Launch images (--launch-images option) or launch storyboard file (--storyboard option).

For a complete description of command options, see gmibuildtool on page 2102.

Default build directory structure

For convenience, the buildtool supports a default directory structure to find all files required to build the app:

```
top-dir
|-- main.42m and other program files, as described in Directory structure for GMI apps on page 3604
|-- gmi
    |-- Info.plist
    |  |-- LaunchScreen.storyboard or (default launch images)
    |  |    |-- Default@2x.png
    |    |-- Default-568h@2x.png
    |    |-- Default-Landscape.png
    |    |-- Default-Landscape-667h@2x.png
    |    |-- Default-Landscape-736h@3x.png
    |    |-- Default-Landscape@2x.png
    |    |-- Default-Portrait.png
    |    |-- Default-Portrait-736h@3x.png
    |    |-- Default-Portrait-667h@2x.png
    |    |-- Default-Portrait@2x.png
    |    |    ...
    |    |-- icon_29x29.png
    |    |-- icon_40x40.png
    |    |-- icon_57x57.png
    |    |-- icon_58x58.png
    |    |-- icon_72x72.png
    |    |-- icon_76x76.png
    |    |-- icon_80x80.png
    |    |-- icon_120x120.png
    |    |-- icon_152x152.png
    |    |    ...
```

In the above directory structure:

1. `top-dir` is the top directory of the default structure. It will typically hold your application program files. A different program files directory can be specified with the `--program-files` option.
2. `top-dir/gmi` is the default directory containing the app resource files such as icons:
a. **Info.plist** is the Information Property List File that will be used to build the app. Some properties will be overwritten by **gmibuildtool** options like --app-name and --app-version.

b. Provide either a launch screen storyboard or default launch images:

- **LaunchScreen.storyboard** is the default storyboard file for the app launch screen. This file can be specified with the **gmibuildtool --storyboard** option.
- **Default-*.*.png** are the app launch image files. The directory to find launch images can be specified with the **gmibuildtool --launch-images** option.

c. **icon_*.png** are the app icon files. The directory to find icons can be specified with the **gmibuildtool --icons** option.

**Debug and release versions**

iOS apps can be generated in a debug or release version. Release version are prepared for distribution on the App Store, while debug versions are used in development.

In debug mode, the app installed on the device can listen on the debug TCP port to allow **fgldb -m** connections, after enabling the debug port in the app settings.

Debug or release mode must be specified in the command line with the **--mode debug** or **--mode release** option. Additionally, if you want to deploy on a physical device, you need to use a provisioning profile corresponding to the debug or release mode:

- In debug mode, the certificate must be a development certificate.
- In release mode, the certificate must be a distribution certificate.

**Defining the app version and build number**

Apple distinguishes the app version number of a bundle (visible to the end user), from the build version number of a bundle (called a release version number in Apple docs).

You specify the app version number with the **--app-version** option of the **gmibuildtool** command. This option sets the **CFBundleVersion** property of the **Info.plist** file, and must match the version specified in iTunes® Connect.

In order to distinguish multiple builds (Apple's term is "releases") of the same app version number, define the build version number of your app with the **--build-number** option. This option sets the **CFBundleShortVersionString** property of the **Info.plist** file. For a given app version, you need to increase this build number, to be able to upload a new binary on iTunes® Connect.

**Note:** If you do not specify the **--build-number** option, the build version number defaults to the app version specified with the **--app-version** option.

**Defining app properties in the ./gmi/Info.plist file**

iOS app are created with a set of properties that are essential configuration information for a bundled executable. These properties are defined in the "Information Property List File", an XML formatted file named **Info.plist** by convention.

Most important **Info.plist** properties are defined with **gmibuildtool** options such as --app-name and --app-version. However, you may need to define other properties that are out of the scope of the buildtool. For example: background modes, device capabilities, screen orientations, permanent wifi, and so on.

In order to define specific app properties, create an **Info.plist** file in the **top-dir/gmi** directory before executing the **gmibuildtool**. Properties covered by the buildtool will be overwritten, while any other property defined in the **top-dir/gmi/Info.plist** file will be left untouched.

For more details about the **Info.plist** file structure, see Apple developer site page about Information Property List File.
Building an iOS app with gmibuildtool

Follow the next steps to setup a GMI app build directory in order to create an iOS app, based on the default directory structure:

1. Create the root distribution directory (`top-dir`)
2. Copy compiled program files (.42m, .42f, fgprofilie, application images, web component files, etc) under `top-dir`.
3. Copy the default English .42s compiled string resource file under `top-dir`.
4. Create non-English language directories (fr, ge, ...) under `top-dir` and copy the corresponding .42s files.
5. Copy default application data files (database file for ex) under `top-dir`.
6. Create the `top-dir/gmi` directory.
7. Copy iOS app resources (icons, launch screen, storyboard) under `top-dir/gmi`.
8. If needed, create an `top-dir/gmi/Info.plist` file, to define specific iOS app properties.

Once the build directory is prepared, issue the following commands:

```bash
$ cd top-dir
$ gmibuildtool \
   --output myapp.ipa \
   --app-name "My App" \
   --app-version "v3.1.6" \
   --bundle-id "com.example.mycompany.myapp" \
   --mode release \
   --certificate "iPhone Developer" \
   --provisioning "~/Downloads/myapp.mobileprovision" \
   --device phone
```

Building a GMI app with C extensions or custom front calls

In order to create an iOS app using C extensions written in Objective-C as in Implementing C-Extensions for GMI on page 2247, proceed as follows (the same technique can be used to build apps that include custom front calls):

1. Build a static library from your Objective-C sources, by using the `staticlib` target of the `$GMIDIR/lib/Makefile-gmi` generic makefile (specify the library file name with the `USER_LIBNAME` variable). The `staticlib` makefile target will produce a `.a` library file, by using all .m and .c files found in the current directory. For example:

   ```bash
   $ make -f $GMIDIR/lib/Makefile-gmi USER_LIBNAME=mylib.a staticlib
   ```

2. When building the app, specify the additional libraries with the `--extension-libs` option. For example:

   ```bash
   $ gmibuildtool ... --extension-libs "-lz libBPush.a mylib.a" ...
   ```

Regardless of whether the `--extension-libs` option is used, the gmibuildtool looks to see if `./gmi/*.a` exists. If they exist, it adds these static libs to the link list.

If a file called `./gmi/link_flags.sh` exists, this file is read by gmibuildtool to set additional link flags. For example:

```bash
#set LINK_FLAGS to add additional system libs or frameworks
LINK_FLAGS="-bz2 -framework MapKit"
```

In most cases the *.a files will be sufficient, for system frameworks like MapKit, as long as the following hint is specified in your .m source file:

```c
/* this avoids using -framework MapKit and instructs the linker to link with MapKit*/
@ import MapKit;
```
Only pure C libs such as `libbz2.a` actually need the `link_flags.sh` file, if no `--extension-libs` option is used and one of the static extension libs needs a system C library.

For complete examples, see `$GMIDIR/demo/MobileDemo/userextension` and `$GMIDIR/demo/MobileDemo/userfrontcall`

**Related concepts**

*Mobile development mode* on page 3568
Set up a development environment to display app forms on a mobile front-end.

**gmbuildtool**
The `gmbuildtool` is a utility to create and test applications for an iOS devices.

**Syntax**

```
gmbuildtool [options]
```

1. *options* are described in *Options* on page 3612.

**Options**

**Table 759: gmbuildtool options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--app-name application-name</code></td>
<td>Display name of the mobile app. This option can be specified to define the display name of the app, it sets the <code>CFBundleDisplayName</code> property in the <code>Info.plist</code> file. If not specified, the name defaults to &quot;Noname&quot;.</td>
</tr>
<tr>
<td><code>--app-version application-version</code></td>
<td>Defines app version visible to the users on the App Store. This option is mandatory and sets <code>CFBundleVersion</code> properties in the <code>Info.plist</code> file. <strong>Note:</strong> If the <code>--build-number</code> option is not used, <code>--app-version</code> will also set the both the <code>CFBundleShortVersionString</code> property. In iTunes® Connect, you define the version of your app, that must match the <code>CFBundleVersion</code> property in the <code>Info.plist</code> file of the app. If these versions do not match, the app cannot be published. Once the app is visible on App Store, the version specified in iTunes® Connect shows up in the &quot;Version&quot; section of the application page. The recommendation for the app version number is that it is a string comprised of three period-separated integers. For example: &quot;1.4.2&quot;</td>
</tr>
<tr>
<td><code>--bundle-id bundle-identifier</code></td>
<td>Defines the Bundle Identifier (a.k.a. App Id) for the app. This option is mandatory and sets the <code>CFBundleIdentifier</code> property in the <code>Info.plist</code> file. A bundle identifier is the unique identifier of your app, to let iOS recognize new app versions. When developing for the simulator, you can choose your own identifier. When creating an application for the App Store, the bundle identifier must be registered with Apple. If not specified, the name defaults to &quot;noname&quot; (for prototyping).</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>--build-cordova cordova-plugin-names</code></td>
<td>Defines Cordova plugins to be embedded in the app package. When specifying multiple cordova plugins, use the comma (,) as separator. The name of the plugin must match the Git repository name. It is case-sensitive. <strong>Note:</strong> To get the list of available Cordova plugins, use the <code>gmibuildtool --list-plugins</code> command.</td>
</tr>
<tr>
<td><code>--build-number build-number</code></td>
<td>Defines the build number used to upload a new binary of the same app version. This option must be used to distinguish different builds for the same app version. It sets the <code>CFBundleShortVersionString</code> property in the <code>Info.plist</code> file. The build number needs to be incremented in order to upload a new binary version of the same app version in iTunes Connect. If this option is not used, the build number defaults to the version specified with the <code>--app-version</code> option. The build number is a string comprised of three period-separated integers. For example: &quot;1.4.2&quot;</td>
</tr>
<tr>
<td><code>--certificate identity</code></td>
<td>Name of a certificate to sign the app. This option is mandatory to build apps for a physical device or for the app store. The certificate can be found in the Keychain® access program, in the &quot;Common Name&quot; field of the certificate panel. The command <code>security find-identity -v</code> can be used to list all available certificates.</td>
</tr>
<tr>
<td>`--crypto {yes</td>
<td>no}`</td>
</tr>
</tbody>
</table>
| `--device device-name` | Defines the name of a device or simulator.  
- By default, when not specifying the `--device` option, a `GMI.app` directory is created for the simulator.
- When specifying the `--device booted` option, the `GMI.app` directory is created and the app is installed on the booted simulator.
- When specifying the `--device phone` option, the `GMI.app` directory and `.ipa` file are created.
- When specifying the `--device physical-device-name` option (with a real physical device name plugged on your Mac), the `GMI.app` directory and `.ipa` file are created and the app is installed on the device. **Note:** Use the `instruments -s Xcode®` command to find the list of available devices (simulators or connected devices). |

**Related concepts**

Building iOS apps with Genero on page 3606
Genero provides a command-line tool to build applications for iOS devices.

**Running mobile apps on an application server**

From the mobile device, programs can be started remotely on an application server, and displayed on the device.

**Purpose of remote application execution for mobile devices**

Remote applications displayed on a mobile device allow the use of the processor, memory, storage and software resources available on a server, for mobile users.

**Note:** Executing remote/server applications for display on a mobile device requires a reliable and constant network connection. If the network connection fails, the application will stop, as with other client/server Genero front-ends.

Server applications can only be started through the Genero Application Server (GAS), by using the UA protocol available since version 3.00. You must set up and configure the GAS for the programs you want to start remotely. See the GAS documentation for more details.

**Note:** Applications executed on the GAS server must use the UTF-8 encoding. Mobile front-ends will reject any attempt to display forms of an application using an encoding other than UTF-8.

**Implementing the embedded mobile app**

Create a small application to be deployed on the mobile device, which then starts the application(s) on an GAS server.

The server application is started from the embedded application through the `runOnServer` front call. The embedded mobile application can be a very simple `MAIN / END MAIN` program, only performing the "runOnServer" front call.

For example, this is the very minimal embedded application, starting a program on the GAS:

```plaintext
MAIN
   CALL ui.interface.frontcall("mobile","runOnServer",
      ["http://myappserver:6394/ua/r/myapp"],[])
END MAIN
```

When the remote application starts, the graphical user interface displays on the mobile device.

The `runOnServer` front call returns when the called application ends, control goes back to the initial application executing on the mobile device.

**Note:** In development context, it is possible to execute the parent starter app on a server, display on a mobile device with `FLGSERVER` on page 280 set properly, and use the `runOnServer` front call. Because starting remote GAS applications is done with a front call, this configuration mimics an embedded starter app running on the device.

**Using the runOnServer front call**

The application executed on the server-side is identified by the first parameter of the `runOnServer` front call. This application must be delivered by the Genero Application Server. The parameter must contain an "ua/r" URL syntax (the UA protocol introduced with the GAS 3.00).

For example: `http://myappserver:6394/ua/r/myapp`

The URL may contain a query string, with parameters for the application to be executed by the GAS.

If needed, you can add a second argument to define a timeout as a number of seconds. The embedded application will wait for the remote application to start, until the timeout expired. If no timeout parameter is specified, or when zero is passed, the timeout is infinite.

In case of failure (application not found, timeout expired), the front call raises the runtime error -6333 and the HTTP status code of the request can be found in the error message details. Use a `TRY/CATCH` block to check if the execution the server application was successful:

```plaintext
MAIN
```
TRY
   CALL ui.interface.frontcall("mobile","runOnServer",
   ["http://myappserver:6394/ua/r/myapp"],[[]])
CATCH
   ERROR err_get(STATUS)
END TRY
END MAIN

Subsequent server-side application runs are allowed; the last active application will display on the device. However, it is not possible to navigate between started applications. Therefore, an application started with the runOnServer front call must only use the RUN instruction to start sub-programs. RUN WITHOUT WAITING is not supported.

**Passing parameters to the server application**

If needed, the embedded app can pass arguments to the server application by using parameter specification in the URL string, with the ?Arg=value1&Arg=value1&... notation:

```
DEFINE params, base, complete_url STRING
LET params = "Arg=verbose&Arg=5677"
LET url = "http://myappserver:6394/ua/r/myapp"
LET complete_url = base || "?" || params
```

The remote program can retrieve the parameters with the arg_val() built-in function.

**Note:** It is not needed to URL-encode the string passed to the runOnServer front call.

See the GAS documentation (AllowUrlParameters attribute) about passing parameters in the application URL.

This is an example of an embedded application to be deployed on the mobile device, which passes parameters to a server-side application:

```
IMPORT util
MAIN
   DEFINE arr DYNAMIC ARRAY OF STRING, x INT
   MENU "test"
   COMMAND "runOnServer"
      CALL arr.clear()
      LET arr[1] = "first argument"
      LET arr[2] = "second argument"
      LET x = do_run("http://10.0.40.29:6394/ua/r/test1", 10, arr)
   COMMAND "exit"
   EXIT MENU
END MENU
END MAIN

FUNCTION do_run(url,timeout,params)
   DEFINE url STRING,
      timeout SMALLINT,
      params DYNAMIC ARRAY OF STRING
   DEFINE i, r INTEGER, tmp STRING
   LET r = 0
   LET tmp = url
   FOR i=1 TO params.getLength()
      LET tmp = tmp || IIF(i==1,"?","&") || "Arg=" || params[i]
   END FOR
   TRY
      CALL ui.interface.frontcall("mobile","runOnServer",[tmp,timeout],[[]])
   CATCH
      ERROR err_get(STATUS)
      LET r = -1
   END TRY
   RETURN r
```
A sample server-side application:

```plaintext
MAIN
  MENU "Prog1"
    COMMAND "arg1" MESSAGE "Arg 1 = ", arg_val(1)
    COMMAND "arg2" MESSAGE "Arg 2 = ", arg_val(2)
    COMMAND "arg3" MESSAGE "Arg 3 = ", arg_val(3)
    COMMAND "Quit" EXIT MENU
  END MENU
END MAIN
```

Sharing files between embedded and server app

If files need to be shared between the embedded application and the server application, the application running on the GAS can only access the `data-directory` directory, in the sandbox of the embedded application that executes the "runOnServer" front call.

This matters when using file handling APIs such as `fgl_putfile()` and `fgl_getfile()` or front calls like `takePhoto` and `launchURL`.

The `data-directory` on the mobile device can be found with the `feInfo/dataDirectory` front call. In both the embedded app and the app running on the server, this front call will return the same directory.

The following workflow can be used:

1. Before starting the server application with a `runOnServer` front call, the embedded app must copy files to the `data-directory`.
2. While executing, the server application can retrieve files from the `data-directory` with `fgl_getfile()`, and send its own files to the `data-directory`, with `fgl_putfile()`.
3. When the server application terminates, the embedded app can read files the server application left in the `data-directory`.

**Note:** If several remote applications are started successively on the server with a `RUN` instruction, make sure to not overwrite files written by other server programs.

In order to write code for the embedded app, that can be executed in development mode (running on a server) and on the mobile device, you can adapt to the execution context: Make a simple file copy when executing on the mobile device, or do an `fgl_putfile()` call, when running on the development server. Check the execution context with the `base.Application.isMobile()` method.

This example, in the embedded app on the mobile device, copies a file from the device private directory to the `data-directory`:

```plaintext
IMPORT os
...
  CALL mobile_copy_to_data_dir("myfile.txt")
...
FUNCTION mobile_copy_to_data_dir(fn)
  DEFINE fn, dd, dst STRING, r INT
  CALL ui.interface.frontcall("standard","feInfo",["dataDirectory"],[dd])
    -- Always use / as path sep for Android/iOS dirs.
  LET dst = dd || "/" || os.Path.basename(fn)
  IF base.Application.isMobile() THEN
    -- Executing on device: make a simple copy to data-dir
    LET r = os.Path.copy(fn, dst)
    MESSAGE SFMT("COPY status = %1", r)
  ELSE
    -- Executing on dev server: make a file transfer to data-dir
    CALL fgl_putfile(fn, dst)
  END IF
```
Note: We do not use the `os.Path.join()` method here because it would add the path separator for the operating system where the application is executed. This would not be a problem when executing on the mobile device or Unix-like platforms. However, when running on a Windows® platform, the `os.Path.join()` method would join the directory and the file name with a backslash, and the resulting path would not fit Android™ or iOS directory path specification for the `data-directory`.

In the server application, use the `fgl_getfile()` function, to transfer a file from the mobile device `data-directory` to the local server disk:

```python
IMPORT os
...
    CALL server_get_from_data_dir("myfile.txt", "/tmp/server_file.txt")
...
FUNCTION server_get_from_data_dir(fn, dst)
    DEFINE fn, dst, dd, src STRING
    CALL ui.interface.frontcall("standard","feInfo",['dataDirectory'],[dd])
    -- Use / as path sep for Android/iOS dirs!
    LET src = dd || "/" || fn
    CALL fgl_getfile(src, dst)
END FUNCTION

```

Similarly, in the server application, use the `fgl_putfile()` function, to copy a file from the server application to the `data-directory` of the embedded app:

```python
IMPORT os
...
    CALL server_put_to_data_dir("/tmp/server_file.txt", "myfile.txt")
...
FUNCTION server_put_to_data_dir(src, fn)
    DEFINE src, fn, dd, dst STRING
    CALL ui.interface.frontcall("standard","feInfo",['dataDirectory'],[dd])
    -- Use / as path sep for Android/iOS dirs!
    LET dst = dd || "/" || fn
    CALL fgl_putfile(src, dst)
END FUNCTION

```

**Push notifications**

This section describes how to implement push notification with Genero.

A push notification is a short message sent by a central server entity to an app installed on a mobile device. In order to be notified, the app+device must register itself to a push service (a global service such as Firebase Cloud Messaging), and register also to a push provider (part of the custom application). To indicate that fresh information is available, notifications are sent by push providers to the push service, which broadcasts notifications to registered devices. The apps can then get details about the notification and display a little hint to the end user. Enterprise mobile applications can use push notifications to produce urgent and important updates for users.
Figure 153: This figure describes the workflow for a push notification (items in yellow are the components that can be implemented with Genero BDL)

Workflow:
1. The app registers to the push service.
2. The push service generates a unique token to identify the device+app and returns this token to the app.
3. The app transmits the token to the token maintainer.
4. The token maintainer stores the new token in a database.
5. Some event occurs in the global application workflow that requires a push notification to warn all registered devices/apps.
6. The push provider reads the database for registered tokens.
7. The push provider sends push notification requests to the push service.
8. The push service broadcasts the notification messages to all registered devices.

There are several push notification mechanisms available. This chapter covers the Firebase Cloud Messaging (FCM) and Apple Push Notification services (APNs).

Common components can be implemented on the same code base for both FCM and APNs push notification mechanisms: The mobile app and the token maintainer.

The complete source code is available of the FourJSGenero GitHub: https://github.com/FourjsGenero/ex_push_notification
Firebase Cloud Messaging (FCM)

Follow this procedure to implement push notification with FCM.

Introduction to FCM push notification

The push notification solution described in this section is based on the Firebase Cloud Messaging service. Familiarize yourself with FCM by visiting the Firebase Cloud Messaging web site.

Firebase Cloud Messaging services allow push servers to send notification message data to registered Android™ or iOS devices.

The system involves the following actors:

- The Firebase Cloud Messaging service (FCM):
  
  FCM provides push server and client identification. It also handles all aspects of queuing of messages and delivery to the target application running on registered devices.

- The registration tokens maintainer:
  
  A Web services server program maintaining the database of registration tokens with application user information. This program must listen to new device registration events and store them in a database. The push server program can then query this database to build the list of registration tokens to identify the devices to be notified.

- The push server program:
  
  Implemented by a third-party service or as a Genero BDL program using the Web services API. This push server program will send notification messages to FCM with two connection servers (HTTP and XMPP).

- Devices running the Genero app registered to the push notification server:
  
  Registered devices use the push notification client API to register, get notifications data and unregister from the service.

Note: The database used to store registration tokens must be a multi-user database (do not use SQLite for example), since two distinct programs will use the database.

Creating a FCM project

To initiate a push notification service dedicated to your applications, you must first create a Firebase Cloud Messaging project in the FCM console. Creating an FCM project will provide you:

- The google-services.json configuration file, to be bundled with your app.
- The "Server Key" is the authentication key to access Google services.

Steps to setup your FCM project:

1. Go to the FCM console and login with your Google developer account.
2. Add a new FCM project.
3. Add an (Android) app to your FCM project: Specify the same package name specified when building your app with the --build-app-package-name option of gmabuildtool.
4. Download the google-services.json configuration file. This file needs to be added to the appdir, beside other program files.
5. Skip other FCM project creation steps.
6. In the project overview page, go to the settings of the new created project.
7. Select the "Cloud Messaging" panel.
8. Copy the "Server Key" and save it to a file. This is the key to be send with the "Authorization:key=server-key" HTTP header when posting a message to the FCM server endpoint fcm.googleapis.com/fcm/send.

For more details about FCM project creation, visit the Firebase Cloud Messaging web site.
**Implementing the registration tokens maintainer**

To handle device registrations on the server side of your application, the same code base can be used for FCM and other token-based frameworks.

For more details, see Implementing a token maintainer on page 3631.

**Implementing the push server**

The push server will produce application notification messages that will be transmitted to the FCM service. The FCM service will then spread them to all mobile devices registered to the service with the Sender ID.

**Important:** The size of an FCM notification content cannot exceed 4 Kilobytes. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The push server will use RESTful HTTP POST requests to send notifications through the FCM service to the following URL:

"https://fcm.googleapis.com/fcm/send".

The HTTP POST header must contain the following attributes:

```
Content-Type: application/json
Authorization: key=server-key
```

where *server-key* is the Server Key obtained from the FCM project settings.

The push server program can be implemented with the Web Services API to make RESTful requests as follows:

```java
IMPORT com
IMPORT util

FUNCTION fcm_send_notif_http(server_key, notif_obj)
  DEFINE server_key STRING,
   notif_obj util.JSONObject
  DEFINE req com.HTTPRequest,
   resp com.HTTPResponse,
   req_msg, res STRING
  TRY
    LET req = com.HTTPRequest.Create("https://fcm.googleapis.com/fcm/send")
    CALL req.setHeader("Content-Type", "application/json")
    CALL req.setHeader("Authorization", SFMT("key=%1", server_key))
    CALL req.setMethod("POST")
    LET req_msg = notif_obj.toString()
    IF req_msg.getLength() > 4096 THEN
      LET res = "ERROR : GCM message cannot exceed 4 kilobytes"
      RETURN res
    END IF
    CALL req.doTextRequest(req_msg)
    LET resp = req.getResponse()
    IF resp.getStatusCode() != 200 THEN
      LET res = SFMT("HTTP Error (%1) %2",
                     resp.getStatusCode(),
                     resp.getStatusDescription())
      ELSE
        LET res = "Push notification sent!"
      END IF
    CATCH
      LET res = SFMT("ERROR : %1 (%2)", STATUS, SQLCA.SQLERRM)
    END CATCH
    RETURN res
  END TRY
END FUNCTION
```
The body of the HTTP POST request must be a JSON formatted record using a structure similar to the following example:

```json
{
  "collapse_key": "stock_update",
  "time_to_live": 108,
  "delay_while_idle": true,
  "data": {
    "stock_change": {
      "stock_id": "STK-034",
      "timestamp": "2015-02-24 15:10:34.18345",
      "item_count": 15023
    },
    "registration_ids": [ "APA91b...", "Hun4MxP...", "5ego..." ]
  }
}
```

**Note:** This notification message uses the "registration_ids" attribute to provide a list of devices to be notified. If you want to notify a single device, use the "to" attribute instead of "registration_ids", and pass a single registration token instead of a JSON array.

For more details about the JSON request structure in a FCM HTTP POST, visit the Firebase Cloud Messaging web site.

By convention, if the "data" member of the JSON request defines a "genero_notification" member, the front-end will show graphical notification (pop-up hint) with the "title", "content" and the "icon" values.

**Note:** The recommendation for GMA is that the icon is packaged in the APK and is accessible by name (as the gma_ic_genero.png in the drawable folders).

For example:

```json
...
  "data": {
    "genero_notification": {
      "title": "Stock has changed",
      "content": "New stock information will be retrieved from the backend server...",
      "icon": "stock_update"
    },
    ...
  },
  "registration_ids": [ "APA91b...", "Hun4MxP...", "5ego..." ]
}
```

The next code example implements a function that creates the JSON object, which can be passed to the `fcm_send_notif_http()` function described above. The only purpose of this notification message is to test the "genero_notification" pop-up hint. The function takes an array of registration tokens as a parameter, which will be used to set the "registration_ids" attribute:

```java
FUNCTION fcm_simple_popup_notif(reg_ids, notif_obj, popup_msg, user_data) 
DEFINE reg_ids DYNAMIC ARRAY OF STRING,
    notif_obj util.JSONObject, 
    popup_msg, user_data STRING
DEFINE data_obj, popup_obj util.JSONObject
CALL notif_obj.put("registration_ids", reg_ids)
```
The `fcm_simple_popup_notif()` and `fcm_send_notif_http()` functions can then be used as follows:

```java
import com
import util

main
constant server_key = "xyz..."
define reg_ids dynamic array of string,
    notif_obj util.JSONObject

let reg_ids[1] = "APA91bHun..."
let reg_ids[2] = "B4AA2q7xa..."

let notif_obj = util.JSONObject.create()
call fcm_simple_popup_notif(reg_ids, notif_obj, "This is my message!")
call fcm_send_notif_http(server_key, notif_obj)
end main

In order to use the tokens database maintained by a token maintainer program, your FCM push server can collect registration tokens as shown in the following example:

```java
function fcm_collect_tokens(reg_ids)
define reg_ids dynamic array of string
define rec record
    id integer,
    notification_type varchar(10),
    registration_token varchar(250),
    badge_number integer,
    app_user varchar(50),
    reg_date datetime year to fraction(3)
end record
declare c1 cursor for
    select * from tokens
    where notification_type = "FCM"
call reg_ids.clear()
foreach c1 into rec.*
    call reg_ids.appendElement()
    let reg_ids[reg_ids.getLength()] = rec.registration_token
end foreach
end function

The above function can then be used by another function to send the push message to all registered devices:

```java
function fcm_send_text(server_key, msg_title, user_data)
define server_key, msg_title, user_data string
define reg_ids dynamic array of string,
    notif_obj util.JSONObject,
info_msg STRING
CALL fcm_collect_tokens(reg_ids)
IF reg_ids.getLength() == 0 THEN
    RETURN "No registered devices..."
END IF
LET notif_obj = util.JSONObject.create()
CALL fcm_simple_popup_notif(reg_ids, notif_obj, msg_title, user_data)
LET info_msg = fcm_send_notif_http(server_key, notif_obj)
RETURN info_msg
END FUNCTION

Handle push notifications in mobile apps

To handle push notifications in mobile apps, the same code base can be used for FCM and other token-based frameworks.

For more details see Handling notifications in the mobile app on page 3637.

Follow this procedure to implement push notification with APNs.

Apple Push Notification Service (APNs)

Follow this procedure to implement push notification with APNs.

Introduction to APNs push notification

The push notification solution described in this section is based on the Apple Push Notification Service. Familiarize yourself with APNs by visiting the Apple Push Notification Service web site.

Apple Push Notification service allows push servers to send notification message data to registered iOS (and OS X) devices.

The APNs service transports and routes a remote notification from a given provider to a given device. A notification is a short message built from two pieces of data: the device token and the payload.

Note: Each device needs to be identified by its device token, and the provider must send individual notification messages for each registered device.

The system involves the following actors:

- The Apple Push Notification Service (APNs):
  
  APNs provides push server and client identification. It also handles all aspects of message queuing and delivery to the target applications running on registered devices. The APNs system includes a feedback service that can be queried to check for devices that have unregistered and no longer need to be notified.

- The device tokens maintainer:

  A Web Services server program maintaining the database of device tokens, with application user information. This program must listen to new device registration events, store them in a database, and from time to time query the APNs feedback service to check for unregistrations.

- The push provider:

  This program will send notification messages to the APNs server by using the com.APNS class and TCP request API. The push provider program will query the device token database to know which devices need to be notified.

- Devices running the Genero app registered to the push notification server:

  Registered devices use the push notification client API to register, get notifications data and unregister from the service.

Note: The database used to store device tokens must be a multi-user database (do not use SQLite for example), since two distinct programs will use the database.
**APNs push notification security**

iOS apps must be created with an Apple certificate for development or distribution, linked to an App ID (or Bundle ID) with push notification enabled. The provisioning profile used when building the IPA must be linked to the App ID with push enabled. Certificate, provisioning and bundle id must be specified to the GMI buildtool.

To create the push provider linked to your app, usually you need to create two Apple Push Notification certificates linked to your App ID (you select the App ID when you create a push certificate in the Apple member center): One certification for development and another for distribution. For more details about the push provider certificates, see [APNs SSL/TLS certificate](#) on page 2923.

Check also Apple Push Notification documentation for more details about certificate requirements for push notifications.

**Identifying target devices**

Each APNs client device is identified by a *device token*. A device token is an opaque identifier of a device that APNs gives to the device when an app registers itself for push notification. It enables APNs to locate in a unique manner the device on which the client app is installed. The device shares the device token with the push provider. The push provider must produce notification messages for each device by including the device token in the message structure.

**Important**: The mobile app obtains its device token by registering to the APNs service with the `registerForRemoteNotifications` on page 2708 front call. It is then in charge of sending its device token to the push provider; typically through a RESTful request. The push provider must collect and store the device tokens, as they need to be specified in a push notification message send by the push provider.

**Notification content (payload)**

In a notification message, the *payload* is a JSON-defined property list that specifies how the user of an app on a device is to be alerted.

**Important**: The size of an APNs notification payload cannot exceed 2 Kilobytes. Make sure that the resulting BYTE variable does not exceed this size limitation. If more information needs to be passed, after receiving the push message, apps must contact the server part to query for more information. However, this is only possible when network is available.

The payload must contain a list of "aps" records. Each "aps" record represents a notification message to be displayed as a hint on the device (for example, by adding a badge number to the app icon). The "aps" records can also contain custom data in a separate set of JSON attributes.

In the Genero mobile app, the notification messages are obtained by using the `getRemoteNotifications` on page 2703 front call, after a `notificationpushed` action was detected with an ON ACTION handler.

**Important**: When an iOS app is in background, silent push notifications can occur, but notification message data (i.e. the payload) may not be available. In such case, GMI is able to detect that a notification arrived (i.e. when the app badge number is greater than zero) and raise the `notificationpushed` action, but the `getRemoteNotifications` front call will return no message data (*data* return param is NULL). If such case, implement a fallback mechanism (based on RESTful web services for example), to contact the push notification provider and retrieve the message information.

Example of notification record list (JSON array) returned by the `getRemoteNotifications` front call:

```json
[
  {
    "aps" : {
      "alert" : "My first push",
      "badge" : 1,
      "sound" : "default",
      "content-available" : 1
    }
  },
]```
Badge number handling

With APNs, badge number handling is in charge of the application code: The push provider sends a badge number in the payload records, the app can check the message content, and must communicate with a server component, to indicate that the notification message has been consumed. The server program can then maintain a badge number for each registered device, decrementing the badge number.

In order to set or query the badge number for your app, use the following front calls:

- setBadgeNumber (iOS) on page 2719
- getBadgeNumber (iOS) on page 2719

In this tutorial, badge numbers are stored on the server database. The token maintainer handlers requests from apps to sync the badge number for a given device token, and the push provider program reads the database to set the badge number in the notification payload. When the app consumes messages, it queries and resets the app badge number with the getBadgeNumber/setBadgeNumber front calls, and informs the token maintainer to sync the badge number in the central database.

Communication channels

A provider communicates with Apple Push Notification service over a binary network interface, using a streaming TCP socket design in conjunction with binary content:

- The binary interface of the APNs development environment is available through the URL gateway.sandbox.push.apple.com on port 2195.
- The binary interface of the APNs production environment is available through the URL gateway.push.apple.com on port 2195.
- The binary interface of the APNs feedback service is available through the URL feedback.push.apple.com on port 2196.

For each interface, use TLS (or SSL) to establish a secured communication channel. The SSL/TLS certificate required for these connections is obtained from Apple's Member Center.

To establish a TLS session with APNs, an Entrust Secure CA root certificate must be installed on the provider's server. If the server is running OS X, this root certificate is already in the keychain. On other systems the certificate might not be available.

Creating an APNs certificate for the app

The Apple Push Notification Certificate identifies the push notification service for a given mobile app. This certificate will be created from an App ID (a.k.a. Bundle ID) and is used by the APNs system to dispatch the notification message to the registered devices.

For more details, see APNs SSL/TLS certificate on page 2923.
Implementing the device tokens maintainer

To handle device registrations on the server side of your application, the same code base can be used for APNs and other token-based frameworks.

For more details, see Implementing a token maintainer on page 3631.

Implementing the push provider

The push provider will produce application notification messages that will be transmitted to the APNs service. The APNs service will then spread them to all registered mobile devices, identified by their device token.

To send notification messages, the push provider must build binary messages by using the com.APNS API, provided by the Web Services library, and send TCP message requests over SSL/TLS to the following URLs:

- "tcps://gateway.sandbox.apple.com:2195" (for development)
- "tcps://gateway.push.apple.com:2195" (for production)

**Note:** In order to establish a secure connection to the APNs framework an SSL/TLS certificate needs to be defined in FGLPROFILE, as described in APNs SSL/TLS certificate on page 2923.

To send a notification message, the push provider must know the device tokens of the registered devices/applications.

**Note:** A distinct notification message must be sent for each registered device.

The following example demonstrates how to implement a function to send an APNs notification message. The function takes a device token and a JSON object as parameters. First, build the binary data with the com.APNS.EncodeMessage() method, then POST the data with a com.TCPRequest.doDataRequest() method. In case of success, the TCP request timeout will occur (APNs service only responds immediately in case of error), then use the com.TCPResponse.getDataResponse() method, to get status information. See com.APNS.EncodeMessage() for more details about notification message creation.

```java
IMPORT com
IMPORT security
IMPORT util

FUNCTION apns_send_notif_http(deviceTokenHexa, notif_obj)
    DEFINE deviceTokenHexa STRING,
        notif_obj util.JSONObject
    DEFINE req com.TCPRequest,
        resp com.TCPResponse,
        uuid STRING,
        ecode INTEGER,
        dt DATETIME YEAR TO SECOND,
        exp INTEGER,
        data, err BYTE,
        res STRING
    LOCATE data IN MEMORY
    LOCATE err IN MEMORY
    LET dt = CURRENT + INTERVAL(10) MINUTE TO MINUTE
    LET exp = util.Datetime.toSecondsSinceEpoch(dt)
    TRY
        --LET req = com.TCPRequest.create( "tcps://
gateway.push.apple.com:2195" )
        LET exp = util.Datetime.toSecondsSinceEpoch(dt)
        CALL req.setKeepConnection(true)
        CALL req.setTimeout(2) # Wait 2 seconds for APNs to return error code
        LET uuid = security.RandomGenerator.createRandomString(4)
```
DISPLAY "PUSH MESSAGE: ", deviceTokenHexa, "/", notif_obj.toString()
CALL com.APNS.EncodeMessage(
    data,
    security.HexBinary.ToBase64(deviceTokenHexa),
    notif_obj.toString(),
    uuid,
    exp,
    10
)
IF LENGTH(data) > 2000 THEN
    LET res = "ERROR : APNS payload cannot exceed 2 kilobytes"
    RETURN res
END IF
CALL req.doDataRequest(data)
TRY
    LET resp = req.getResponse()
    CALL resp.getDataResponse(err)
    CALL com.APNS.DecodeError(err) RETURNING uuid, ecode
    LET res = SFMT("APNS result: UUID: %1, Error code: %2", uuid, ecode)
    CATCH
        CASE STATUS
            WHEN -15553 LET res = "Timeout Push sent without error"
            WHEN -15566 LET res = "Operation failed ": SQLCA.SQLERRM
            WHEN -15564 LET res = "Server has shutdown"
            OTHERWISE LET res = "ERROR : ": STATUS
        END CASE
    CATCH
        LET res = SFMT("ERROR : %1 (%2)", STATUS, SQLCA.SQLERRM)
    END TRY
END TRY
RETURN res
END FUNCTION

The next code example implements a function that creates the JSON object defining notification content (payload). That object can be passed to the apns_send_notif_http() function described above:

FUNCTION apns_simple_popup_notif(notif_obj, msg_title, user_data, badge_number)
    DEFINE notif_obj util.JSONObject,
    msg_title, user_data STRING,
    badge_number INTEGER
    DEFINE aps_obj, data_obj util.JSONObject
    LET aps_obj = util.JSONObject.create()
    CALL aps_obj.put("alert", msg_title)
    CALL aps_obj.put("sound", "default")
    CALL aps_obj.put("badge", badge_number)
    CALL aps_obj.put("content-available", 1)
    CALL notif_obj.put("aps", aps_obj)
    LET data_obj = util.JSONObject.create()
    CALL data_obj.put("other_info", user_data)
    CALL notif_obj.put("custom_data", data_obj)
END FUNCTION

The apns_simple_popup_notif() and apns_send_notif_http() functions can then be used as follows:

IMPORT com
IMPORT util

MAIN

DEFINE reg_ids DYNAMIC ARRAY OF STRING,
    notif_obj util.JSONObject,
    i INTEGER

LET notif_obj = util.JSONObject.create()
CALL gcm_simple_popup_notif(notif_obj, "This is my message!", 1)

LET reg_ids[1] = "APA91bHun..."
LET reg_ids[2] = "B4AA2q7xa..."
...
FOR i=1 TO reg_ids.getLength()
    DISPLAY gcm_send_notif_http(reg_ids[i], notif_obj)
END FOR

END MAIN

In order to use the tokens database maintained by a token maintainer program, your APNs push provider can collect device tokens as shown in the example below. Note that the dynamic array contains token ids and badge numbers:

FUNCTION apns_collect_tokens(reg_ids)

DEFINE reg_ids DYNAMIC ARRAY OF RECORD
    token STRING,
    badge INTEGER
END RECORD

DEFINE rec RECORD
    id INTEGER,
    notification_type VARCHAR(10),
    registration_token VARCHAR(250),
    badge_number INTEGER,
    app_user VARCHAR(50),
    reg_date DATETIME YEAR TO FRACTION(3)
END RECORD,

x INTEGER
DECLARE c1 CURSOR FOR
    SELECT * FROM tokens
WHERE notification_type = "APNS"
CALL reg_ids.clear() 
FOREACH c1 INTO rec.*
    LET x = reg_ids.getLength() + 1
    LET reg_ids[x].token = rec.registration_token
    LET reg_ids[x].badge = rec.badge_number
END FOREACH
END FUNCTION

In order to handle badge numbers for each registered device, implement a function to update badge numbers in database:

FUNCTION save_badge_number(token, badge)

DEFINE token STRING,
    badge INT
UPDATE tokens SET
    badge_number = badge
WHERE registration_token = token
END FUNCTION

The above functions can then be used to send a push message to all registered devices:

FUNCTION apns_send_message(msg_title, user_data)

DEFINE msg_title, user_data STRING
DEFINE reg_ids DYNAMIC ARRAY OF RECORD
    token STRING,
    badge INTEGER
  END RECORD,
  notif_obj util.JSONObject,
  info_msg STRING,
  new_badge, i INTEGER
CALL apns_collect_tokens(reg_ids)
IF reg_ids.getLength() == 0 THEN
  RETURN "No registered devices..."
END IF
LET info_msg = "Send:
FOR i=1 TO reg_ids.getLength()
  LET new_badge = reg_ids[i].badge + 1
  CALL save_badge_number(reg_ids[i].token, new_badge)
  LET notif_obj = util.JSONObject.create()
  CALL apns_simple_popup_notif(notif_obj, msg_title, user_data, new_badge)
  LET info_msg = info_msg, "\n",
    apns_send_notif_http(reg_ids[i].token, notif_obj)
END FOR
RETURN info_msg
END FUNCTION

Handle push notifications in mobile apps
To handle push notifications in mobile apps, the same code base can be used for APNs and other token-based frameworks.

For more details see Handling notifications in the mobile app on page 3637.

Related concepts
Firebase Cloud Messaging (FCM) on page 3621
Follow this procedure to implement push notification with FCM.

Implementing a token maintainer
The token maintainer is a BDL Web Services server program that handles push token registration from mobile apps.

Basics
In order to implement a push notification mechanism, you need to set up a server part (token maintainer and push notification server), based on a push notification framework such as Firebase Cloud Messaging (FCM) or Apple Push Notification service (APNs). In addition, you need to handle notification events in your mobile app. This section describes how to implement the token maintainer, the server program that maintains the list of registered devices (i.e. registration tokens for FCM or device tokens for APNs).

Note: The max length of a push client token can vary depending on the push framework provider. If you need to store registration tokens in a database, check the max size for a token and consider using a large column type such as VARCHAR(250).

The same code base can be used for Android™ (using FCM) and iOS (using APNs) applications: The token maintainer will basically handle RESTful HTTP requests coming from the internet for token registration and token unregistration. For each of these requests, the program will insert a new record or delete an existing record in a dedicated database table.

Note: The database used to store tokens must be created before starting the token maintainer program. By default, the push demo program uses SQLite (dbmsqt) and the name of the database is "tokendb". To create this SQLite database, simply create an empty file with this name.

The push provider/server program can then query the tokens table to build the list of target devices for push notifications.
In the context of APNs, the token maintainer must also handle badge numbers for each registered device: When consuming notification messages, the iOS app must inform the token maintainer that the badge number has changed. This function is implemented with the "badge_number" command.

The token maintainer is a Web Services server program which must be deployed behind a GAS to handle load balancing. You can, however, write code to test your program in development without a GAS.

The act of registering/unregistering push tokens is application specific: When registering tokens, you typically want to add application user information. Genero BDL allows you to implement a token maintainer in a simple way.

**Note:** When executing this token maintainer program with APNs, you must pass the "APNS" command line argument to execute APNs feedback queries.

**MAIN block and database creation**

Start with the MAIN block, and the connection to a database. In this tutorial, we use SQLite as the database. The program will automatically create the database file and the tokens table if it does not yet exist.

```plaintext
IMPORT util
IMPORT com
IMPORT os

CONSTANT DEFAULT_PORT = 9999

MAIN
   CALL open_create_db()
   CALL handle_registrations()
END MAIN

FUNCTION open_create_db()
   DEFINE dbsrc VARCHAR(100), x INTEGER
   IF NOT os.Path.exists("tokendb") THEN
      CALL create_empty_file("tokendb")
   END IF
   LET dbsrc = "tokendb+driver='dbmsqt'"
   CONNECT TO dbsrc WHENEVER ERROR CONTINUE
   SELECT COUNT(*) INTO x FROM tokens WHENEVER ERROR STOP
   IF SQLCA.SQLCODE<0 THEN
      CREATE TABLE tokens ( id INTEGER NOT NULL PRIMARY KEY,
                          notification_type VARCHAR(10) NOT NULL,
                          registration_token VARCHAR(250) NOT NULL UNIQUE,
                          badge_number INTEGER NOT NULL,
                          app_user VARCHAR(50) NOT NULL, -- UNIQUE
                          reg_date DATETIME YEAR TO FRACTION(3) NOT NULL )
   END IF
END FUNCTION

FUNCTION create_empty_file(fn)
   DEFINE fn STRING, c base.Channel
   LET c = base.Channel.create()
   CALL c.openFile(fn, "w")
   CALL c.close()
END FUNCTION
```
Handling registration and unregistration requests

The next function is typical Web Service server code using the Web Services API to handle RESTful requests. Note that the TCP port is defined as a constant that is used to set FGLAPPSERVER automatically when not running behind the GAS:

```sql
IMPORT util
IMPORT com

CONSTANT DEFAULT_PORT = 9999

MAIN
...
CALL handle_registrations()
END MAIN

FUNCTION handle_registrations()
DEFINE req com.HTTPServiceRequest,
   url, method, version, content_type STRING,
   reg_data, reg_result STRING
IF LENGTH(fgl_getenv("FGLAPPSERVER"))==0 THEN
   -- Normally, FGLAPPSERVER is set by the GAS
   DISPLAY SFMT("Setting FGLAPPSERVER to %1", DEFAULT_PORT)
   CALL fgl_setenv("FGLAPPSERVER", DEFAULT_PORT)
END IF
CALL com.WebServiceEngine.Start()
WHILE TRUE
   TRY
      LET req = com.WebServiceEngine.getHTTPServiceRequest(20)
      CATCH
         IF STATUS==-15565 THEN
            DISPLAY "TCP socket probably closed by GAS, stopping
process..."
            EXIT PROGRAM 0
         ELSE
            DISPLAY "Unexpected getHTTPServiceRequest() exception: ",
            STATUS
            DISPLAY "Reason: ", SQLCA.SQLERRM
            EXIT PROGRAM 1
         END IF
      END TRY
      IF req IS NULL THEN -- timeout
         DISPLAY SFMT("HTTP request timeout...: %1", CURRENT YEAR TO
         FRACTION)
         CALL check_apns_feedback()
         CALL show_tokens()
         CONTINUE WHILE
      END IF
      LET url = req.getURL()
      LET method = req.getMethod()
      IF method IS NULL OR method != "POST" THEN
         IF method == "GET" THEN
            CALL req.sendTextResponse(200,NULL,"Hello from token
            maintainer...")
         ELSE
            DISPLAY SFMT("Unexpected HTTP request: %1", method)
            CALL req.sendTextResponse(400,NULL,"Only POST requests
            supported")
         END IF
         CONTINUE WHILE
      END IF
      LET version = req.getRequestVersion()
      IF version IS NULL OR version != "1.1" THEN
```
PROCESSING REGISTRATION AND UNREGISTRATION COMMANDS

The next function is called when a RESTful request is to be processed. The URL will define the type of command to be executed by the server:

- If the URL contains "/token_maintainer/register", a new token must be inserted in the database.
- If the URL contains "/token_maintainer/unregister", an existing token must be deleted from the database.

FUNCTION process_command(url, data)
DEFINE url, data STRING
DEFINE data_rec RECORD
    notification_type VARCHAR(10),
    registration_token VARCHAR(250),
    badge_number INTEGER,
    app_user VARCHAR(50)
END RECORD,
DEFINE p_id INTEGER,
DEFINE p_ts DATETIME YEAR TO FRACTION(3),
DEFINE result_rec RECORD
    status INTEGER,
    message STRING
END RECORD,
DEFINE result STRING
LET result_rec.status = 0
TRY
    CASE
    WHEN url MATCHES "*/token_maintainer/register"
        CALL util.JSON.parse( data, data_rec )
        SELECT id INTO p_id FROM tokens
            WHERE registration_token = data_rec.registration_token
        IF p_id > 0 THEN
            LET result_rec.status = 1
            LET result_rec.message = SFMT("Token already registered:
                [%1]",
                data_rec.registration_token)
        END IF
        GOTO pc_end
    END CASE
END TRY

IF p_id IS NULL THEN LET p_id=1 END IF
LET p_ts = util.Datetime.toUTC(CURRENT YEAR TO FRACTION(3))
WHENEVER ERROR CONTINUE
INSERT INTO tokens
VALUES( p_id, data_rec.notification_type,
data_rec.registration_token, 0, data_rec.app_user,
p_ts )
WHENEVER ERROR STOP
IF SQLCA.SQLCODE==0 THEN
LET result_rec.message = SFMT("Token is now registered:
[ %1 ]", data_rec.registration_token)
ELSE
LET result_rec.status = -2
LET result_rec.message = SFMT("Could not insert token in
database: [ %1 ]", data_rec.registration_token)
END IF
WHEN url MATCHES "token_maintainer/unregister"
CALL util.JSON.parse( data, data_rec )
DELETE FROM tokens
WHERE registration_token = data_rec.registration_token
IF SQLCA.SQLERRD[3]==1 THEN
LET result_rec.message = SFMT("Token unregistered:
[ %1 ]", data_rec.registration_token)
ELSE
LET result_rec.status = -3
LET result_rec.message = SFMT("Could not find token in
database: [ %1 ]", data_rec.registration_token)
END IF
WHEN url MATCHES "token_maintainer/badge_number"
CALL util.JSON.parse( data, data_rec )
WHENEVER ERROR CONTINUE
UPDATE tokens
SET badge_number = data_rec.badge_number
WHERE registration_token = data_rec.registration_token
WHENEVER ERROR STOP
IF SQLCA.SQLCODE==0 THEN
LET result_rec.message = SFMT("Badge number updated for Token:
[ %1 ]\n New value:
[ %2 ]\n", data_rec.registration_token, data_rec.badge_number)
ELSE
LET result_rec.status = -4
LET result_rec.message = SFMT("Badge update failed for token:
[ %1 ]", data_rec.registration_token)
END IF
END CASE
CATCH
LET result_rec.status = -1
LET result_rec.message = SFMT("Failed to register token:
[ %1 ]", data_rec.registration_token)
END TRY
LABEL pc_end:
DISPLAY result_rec.message
LET result = util.JSON.stringify(result_rec)
RETURN result
END FUNCTION
Showing the current registered tokens

The following function is called after a WebServiceEngine timeout, when no request is to be processed. Its purpose is just to show the current list of registered tokens in a server log (stdout):

```favorite
FUNCTION show_tokens()
    DEFINE rec RECORD -- Use CHAR to format
        id INTEGER,
        notification_type CHAR(10),
        registration_token CHAR(250),
        badge_number INTEGER,
        app_user CHAR(50),
        reg_date DATETIME YEAR TO FRACTION(3)
    END RECORD
    DECLARE c1 CURSOR FOR SELECT * FROM tokens ORDER BY id
    FOREACH c1 INTO rec.*
        DISPLAY "   ", rec.id, ": ",
        rec.notification_type, ": ",
        rec.app_user[1,10], "/ ",
        "(" , rec.badge_number USING "<<<<&", " ") ",
        rec.registration_token[1,20],想起来..."
    END FOREACH
    IF rec.id == 0 THEN
        DISPLAY "No tokens registered yet..."
    END IF
END FUNCTION
```

APNs feedback checking

When using Apple Push Notification service, the device token maintainer can also handle device unregistration by querying the APNs feedback service. The APNs feedback service will provide the list of device tokens that are no longer valid because the app on the devices has unregistered.

The token maintainer can use this service to clean up the token database.

**Note:** When using the APNs feedback service, an SSL/TLS certificate needs to be defined in FGLPROFILE as described in APNs SSL/TLS certificate on page 2923.

To get the list of unregistered devices, send an HTTP POST to the following URL:
tcps://feedback.push.apple.com:2196

The next function is called after a timeout when no request needs to be processed by the token maintainer:

```favorite
FUNCTION check_apns_feedback()
    DEFINE req com.TCPRequest,
         resp com.TCPResponse,
         feedback DYNAMIC ARRAY OF RECORD
            timestamp INTEGER,
            deviceToken STRING
    END RECORD,
    IF arg_val(1) != "APNS" THEN RETURN END IF
    DISPLAY "Checking APNs feedback service..."
    LOCATE data IN MEMORY
    TRY
        LET req = com.TCPRequest.create( "tcps://
            feedback.push.apple.com:2196"
```
CALL req.setKeepConnection(true)
CALL req.setTimeout(2)
CALL req.doRequest()
LET resp = req.getResponse()
CALL resp.getDataResponse(data)
CALL com.APNS.DecodeFeedback(data,feedback)
FOR i=1 TO feedback.getLength()
  LET timestamp =
    util.Datetime.fromSecondsSinceEpoch(feedback[i].timestamp)
  LET timestamp = util.Datetime.toUTC(timestamp)
  LET token = feedback[i].deviceToken
  DELETE FROM tokens
  WHERE registration_token = token
    AND reg_date < timestamp
END FOR
CATCH
  CASE STATUS
    WHEN -15553 DISPLAY "APNS feedback: Timeout: No feedback message"

**Handling notifications in the mobile app**

This topic describes how to handle push notification in the app running on mobile devices.

**Basics**

In order to implement a push notification mechanism, you need to set up a server part (token maintainer and push notification server), based on a push notification framework such as Firebase Cloud Messaging (FCM) or Apple® Push Notification service (APNs). In Addition, you need to handle notification events in your mobile app. This section describes how to implement push notification in the app with the push notification API available in Genero BDL.

The same code base can be used to handle push notifications for Android™ (using FCM) and iOS (using APNs) devices. Only the content of the notification message will have to be processed with specific code, as the structure of the message differs depending on standards defined by the push notification framework.

**Genero API for push notifications**

Genero BDL provides an API to handle push notification on mobile apps. Dedicated front calls are available to register to a push server, fetch push notification data, and unregister:

- registerForRemoteNotifications on page 2708
- getRemoteNotifications on page 2703
- unregisterFromRemoteNotifications on page 2713
To detect when a notification message arrives from the push server, a specific action called `notificationpushed` must be used by app code on a `ON ACTION` handler. This special action is referenced as a predefined action.

**Android™ app permissions for FCM push notifications**

Android apps using push notification services need specific permissions (Android manifest), such as:

- `android.permission.INTERNET`
- `android.permission.GET_ACCOUNTS`
- `android.permission.WAVE_LOCK`
- `com.google.android.c2dm.permission.RECEIVE`
- `application-package-name.permission.C2D_MESSAGE` where `application-package-name` is the Android™ package name of your app (for example, `com.mycompany.pushclient`)

Permissions are automatically set for Android™ APK packages by the GMA buildtool. As some permissions need to be prefixed with the package name, they are applied with the `--build-app-package-name` option.

See the FCM documentation for more details about required permissions for push notifications.

**iOS app certificates for APNs push notifications**

iOS apps must be created with an Apple® certificate for development or distribution, linked to an App ID (or Bundle ID) with push notification enabled. The provisioning profile used when building the IPA must be linked to the App ID with push enabled. Certificate, provisioning and bundle id must be specified to the GMI buildtool.

**Handling push notification in the app**

To handle push notifications in your mobile app, perform the following steps:

1. Register to the push service and get the registration token
2. Send the push notification token to your token maintainer
3. Handle notification events with the `notificationpushed` action
4. Eventually un-register from the push servers

**1 - Registering to the push service and to the push provider**

Register the app to the push notification service with the `registerForRemoteNotifications` front call.

- When using FCM, you must provide Sender ID to identify the FCM project.
- When using APNs, you can set the Sender ID to NULL.

**Note:** The app does not need to register for notification each time it is restarted. Even if the app is closed, the registration is still active until the `unregisterFromRemoteNotifications` front call is performed. At first execution, an app will typically ask if the user wants to get push notifications and register to the push service if needed. To disable push notification, apps usually implement an option that can be disabled (to unregister) and re-enabled (to register again) by the user. On Android™, the app must register for notification each time it is upgraded.

**Important:**

When an app restarts, if notifications are pending and the app has already registered for push notification in a previous execution, the `notificationpushed` action will be raised as soon as a dialog with the corresponding `ON ACTION` handler activates. The app then performs a `getRemoteNotifications` on page 2703 front call as in the usual way, to get the pending notifications pushed to the device while the app was off.

However, special consideration needs to be given to iOS devices. When push notification arrives for an iOS app that has not started, there is no mechanism to wake up the app and get the push data. Therefore, when the user starts the app from the springboard, there will never be any push data available. Depending on the context, implement the following programming patterns to solve this problem:
1. If the push notification contains a badge number, the app can verify if the badge is greater than 0 (with the `getBadgeNumber` front call) in order to perform a `getRemoteNotifications` front call. Even if there is no data available with the front call, it is recommended that the app sends a request directly to the server push provider to get last push data.

2. If the push notification does not contain badge numbers, it is still recommended that the app performs a `getRemoteNotification` front call when it starts. If there is no push data available from the front call, the recommendation is that the app sends a request to the server push provider to see if there is push data available. This is by the way also recommended when receiving a `notificationpushed` action during application life time.

3. If the user starts the app from the Notification Center, the app is launched with push data transmitted from the system, and the `notificationpushed` action is sent. It is recommended that the app perform a `getRemoteNotifications` front call and get the push data.

The `registerForRemoveNotifications` front call will return a registration token for the app which will be used by the push server (a.k.a push provider).

- When using FCM, the returned identifier is the FCM "registration token".
- When using APNs, the returned identifier is the APNs "device token".

```plaintext
DEFINE rec RECORD
   tm_host STRING,
   tm_port INTEGER,
   notification_type STRING,
   user_name STRING,
   registration_token STRING
END RECORD
...
LET rec.tm_host = "https://pushreg.example.orion"
LET rec.tm_port = 4930
LET rec.app_user = "mike"
LET rec.notification_type = "FCM"
...
DIALOG ATTRIBUTES(UNBUFFERED)
   INPUT BY NAME rec.tm_host,
      rec.tm_port,
      rec.notification_type,
      rec.user_name,
      rec.registration_token
   ATTRIBUTES(WITHOUT DEFAULTS)
END INPUT
...
ON ACTION register
   LET rec.registration_token = register(rec.notification_type,
      rec.user_name)
...
FUNCTION register(notification_type, app_user)
   DEFINE notification_type STRING,
      app_user STRING
   DEFINE registration_token STRING
   TRY
      CALL ui.Interface.frontCall(  
         "mobile", "registerForRemoteNotifications",
         [], [ registration_token ] )
      IF tm_command( "register", notification_type,
         registration_token, app_user, 0 ) < 0 THEN
          RETURN NULL
      END IF
   END TRY
```
2 - Sending a push notification token to your token maintainer

Once registered to the FCM or APNs service, the app must also register to the push server or push provider by sending the token obtained in step 1.

This is typically done by using a RESTful HTTP POST, sending the token (along with additional application user information) to a dedicated server program that maintains the list of registered devices/tokens.

The device token maintainer can be implemented in BDL as a Web Service program, as described in Implementing a token maintainer on page 3631.

In this tutorial, the `tm_command()` function implements token registration (as well as badge number handling for APNs):

```bdb
IMPORT com
IMPORT util
...
LET rec_tm_host = "https://pushreg.example.orion"
LET rec_tm_port = 4930
...
FUNCTION tm_command( command, notification_type, registration_token,
                      app_user, badge_number )
DEFINE command STRING,
    notification_type STRING,
    registration_token STRING,
    app_user STRING,
    badge_number INTEGER
DEFINE url STRING,
    json_obj util.JSONObject,
    req com.HTTPRequest,
    resp com.HTTPResponse,
    json_result STRING,
    result_rec RECORD
    status INTEGER,
    message STRING
END RECORD
TRY
    LET url = SFMT( "http://%1:%2/token_maintainer/%3",
                    rec_tm_host, rec_tm_port, command )
    LET req = com.HTTPRequest.create(url)
    CALL req.setHeader("Content-Type", "application/json")
    CALL req.setMethod("POST")
    CALL req.setConnectionTimeOut(5)
    CALL req.setTimeOut(5)
    LET json_obj = util.JSONObject.create()
    CALL json_obj.put("notification_type", notification_type)
    CALL json_obj.put("registration_token", registration_token)
    CALL json_obj.put("app_user", app_user)
    CALL json_obj.put("badge_number", badge_number)
    CALL req.doTextRequest(json_obj.toString())
    LET resp = req.getResponse()
    IF resp.getStatusCode() != 200 THEN
        MESSAGE SFMT("HTTP Error (%1) %2",
                      resp.getStatusCode(), resp.getStatusMessage())
    ELSE
        CALL json_result = resp.getData()
        IF json_result.isSuccess() THEN
            LET result_rec = json_result.getData()
            IF result_rec.status = 0 THEN
                MESSAGE SFMT("Registration succeeded (token=%1)",
                              registration_token)
                RETURN registration_token
            ELSE
                MESSAGE SFMT("Registration failed.")
                RETURN NULL
            END IF
        ELSE
            MESSAGE SFMT("Registration failed.")
            RETURN NULL
        END IF
    END IF
END TRY
MESSAGE SFMT("Registration succeeded (token=%1)", registration_token)
RETURN registration_token
END FUNCTION
```
When the app is declared as push notification client to the push server, continue with the normal program flow.

3 - Handling push notification events

To get and handle notification events, the current active dialog must implement the notificationpushed special action.

To control action view rendering defaults and current field validation behavior when the notificationpushed action is used, consider setting action default attributes for this action in your .4ad file as follows:

```
<ActionDefaultList>
  ...
  <ActionDefault name="notificationpushed" validate="no" defaultView="no"
    contextMenu="no"/>
  ...
</ActionDefaultList>
```

Another option is to define these action defaults attributes in the ON ACTION handler:

```
ON ACTION notificationpushed (VALIDATE=NO, DEFAULTVIEW=NO)
  ...
```

In the ON ACTION block for this action, query for notification messages by using the "getRemoteNotifications" front call, (passing the Sender ID as parameter when using FCM, for APNs the Sender ID must be NULL). This front call returns a JSON string containing a list of notification messages to be processed:

```
DEFINE notifs DYNAMIC ARRAY OF RECORD
  info STRING,
  ts DATETIME YEAR TO FRACTION(3)
END RECORD

... DEFINE x INTEGER

DIALOG ...
  DISPLAY ARRAY notifs TO sr.*
  END DISPLAY
  ...
  ON ACTION notificationpushed
    LET x=handle_notification()
```
CALL DIALOG.setCurrentRow("sr",x)

... END DIALOG ...

FUNCTION handle_notification()

DEFINE notif_list STRING,
    notif_array util.JSONArray,
    notif_item util.JSONObject,
    notif_data util.JSONObject,
    aps_record util.JSONObject,
    gcm_data_s STRING,
    gcm_genero_notification_s STRING,
    gcm_genero_notification util.JSONObject,
    info, other_info STRING,
    i, x INTEGER

CALL ui.Interface.frontCall(
    "mobile", "getRemoteNotifications",
    [ ], [ notif_list ] )

TRY

LET notif_array = util.JSONArray.parse(notif_list)
IF notif_array.getLength() > 0 THEN
    CALL setup_badge_number(notif_array.getLength())
END IF
FOR i=1 TO notif_array.getLength()
    LET info = NULL
    LET other_info = NULL
    LET notif_item = notif_array.get(i)
    -- Try APNs msg format
    LET aps_record = notif_item.get("aps")
    IF aps_record IS NOT NULL THEN
        LET info = aps_record.get("alert")
        LET notif_data = notif_item.get("custom_data")
        IF notif_data IS NOT NULL THEN
            LET other_info = notif_data.get("other_info")
        END IF
    END IF
ELSE
    -- Try GCM msg format
    LET gcm_data_s = notif_item.get("data")
    IF gcm_data_s IS NOT NULL THEN
        LET notif_data = util.JSONObject.parse(gcm_data_s)
        IF notif_data IS NOT NULL THEN
            LET gcm_genero_notification_s = notif_data.get("genero_notification")
            LET gcm_genero_notification = util.JSONObject.parse(gcm_genero_notification_s)
            IF gcm_genero_notification IS NOT NULL THEN
                LET info = gcm_genero_notification.get("content")
            END IF
            LET other_info = notif_data.get("other_info")
        END IF
    END IF
END IF
IF info IS NULL THEN
    LET info = "Unexpected message format"
END IF
MESSAGE SFMT("Notification message:
%1
%2", info, other_info)
CALL notifs.appendElement()
LET x = notifs.getLength()
LET notifs[x].info = SFMT("%1 (%2)", info, other_info)
LET notifs[x].ts = CURRENT
END FOR
CATCH
When using APNs, the app must handle the badge numbers attached to the device token. The app must:

1. Query the current badge number with the `getBadgeNumber` front call.
2. Compute the new badge number based on the number of notifications consumed.
3. Reset the badge number with the `setBadgeNumber` front call.
4. Inform the token maintainer to sync the badge number in the central database.

The following function handles badge numbers for the app:

```plaintext
FUNCTION setup_badge_number(consumed)
DEFINE consumed INTEGER
DEFINE badge_number INTEGER
TRY -- If the front call fails, we are not on iOS...
   CALL ui.Interface.frontCall("ios", "getBadgeNumber", [],
   [badge_number])
CATCH
   RETURN
END TRY
IF badge_number>0 THEN
   LET badge_number = badge_number - consumed
END IF
CALL ui.Interface.frontCall("ios", "setBadgeNumber", [badge_number], [])
IF tm_command( "badge_number", "APNS", rec.registration_token, 
   rec.user_name, badge_number) < 0 THEN
   ERROR "Could not send new badge number to token maintainer."
RETURN
END IF
END FUNCTION
```

4 - Unregistering the app from push notification

If the app no longer wants to get push notifications, unregister from the push provider (using a RESTful POST, in the `regunreg_token()` function), and unregister from the push service by using the "unregisterFromRemoteNotifications" front call.

- When using FCM, you must pass the FCM Sender ID as parameter.
- When using APNs, the parameter must be NULL.

```plaintext
... 
LET rec.tm_host = "https://pushreg.example.orion"
LET rec.tm_port = 4930
CALL unregister(rec.registration_token, rec.app_user)
...
```

```plaintext
FUNCTION unregister(notification_type, registration_token, app_user)
DEFINE notification_type STRING,
registration_token STRING,
app_user STRING
IF tm_command( "unregister", notification_type, 
   registration_token, app_user, 0 ) < 0 THEN
   RETURN
END IF
TRY
```
CALL ui.Interface.frontCall(
    "mobile", "unregisterFromRemoteNotifications",
    [ ], [ ]
)
CATCH
    MESSAGE "Un-registration failed (broadcast service)."
RETURN
END TRY
MESSAGE "Un-registration succeeded"
END FUNCTION

Cordova plugins
This section describes how to use Cordova plugins.

Understanding Cordova plugins
Cordova plugins allow you to access specific mobile device functionalities.

What are Cordova plugins in Genero?
Cordova plugins are based on the Apache Cordova cross-platform mobile development framework, to access mobile device functionality such as the accelerometer, the camera, the compass, the microphone, and more.

GMI and GMA act as a plugin container and provide a plugin API widely compatible with the original Cordova API. The implementation is Genero-specific and makes the native plugin interfaces available in Genero BDL through Cordova plugin front calls.

Cordova plugins with device simulator or in client/server GUI mode
Depending on the configuration used when executing your app, some Cordova plugins or plugin APIs may not be available and may cause a malfunction.

• When using a device simulator, some Cordova plugin will not work because the feature is not available on the simulator.
• When executing the app on a server in development mode or in "runOnServer" mode, the front calls are slowed down by the network roundtrips.

Installing Cordova plugins into the development environment
In order to be used, Cordova plugins have to be downloaded from the FOURJS Cordova GitHub or from the Apache Cordova GitHub, and must be installed by using the --install-plugin option of GMA or GMI build tools.

A Cordova plugin installation into GMA/GMI installation directories must be done by using a local clone of the GitHub repository.

For more details, see Installing Cordova plugins on page 3645.

Building apps with Cordova plugins
Installed Cordova plugins need to be specified in the build process when creating your app.

The Cordova plugins to be bundled with the app are specified with the --cordova-plugin option of GMA and GMI build tools:
• Embed Cordova plugins in a GMA app on page 3649
• Embed Cordova plugins in a GMI app on page 3649

Using Cordova plugin APIs (wrapper functions)
Access to the native code can be achieved using native Cordova APIs through Cordova plugin front calls.
To ease the usage of a Cordova plugin, a library of BDL functions can encapsulate the Cordova front calls. Most Cordova plugins provided by FOURJS are shipped with a BDL wrapper library, available from the FOURJS Cordova GitHub.

Installing Cordova plugins
Before usage, Cordova plugins need to be installed in the GMA or GMI development environment.

Requirements for Cordova plugins installation
The following tools and utilities are required to install Cordova plugins:

1. Cordova plugins are available on a GitHub repository. Therefore, the git command line tool is required to install Cordova plugins.
2. The gmabuildtool uses the make utility to compile FGL wrappers and install Cordova plugins. Therefore, the make utility must be installed in the computer.

Cordova plugin installation basics
GitHub contains a large number of Cordova plugins that can be used in your app, like those from the Apache GitHub for example, or the FOURJS Cordova GitHub.
Before installing the Cordova plugins in the GMA / GMI installation directories, you must first clone the GitHub repository to your local disk.

Upgrading GMA, GMI or FGL with GMI with installed Cordova plugins
Cordova plugins need to be re-installed in the following cases:

• With iOS/GMI: after upgrading the GMI package or the FGL package (the GMI package can be installed into the FGLDIR installation directory, or in a separate GMIDIR installation directory)
• With Android/GMA: after upgrading the GMA package (the GMA package is always to be installed in a dedicated GMADIR installation directory)

Important: In all cases, after upgrading an FGL, GMI or GMA environment where plugins have been installed, you need to re-execute the plugin installation with a gmabuildtool scaffold --install-plugin or gmibuildtool --install-plugin command.

Installing a Cordova plugin from a local clone of the GitHub repository
First clone the GitHub repository into a local directory:

```
$ cd /usr/dev/myplugins
$ git clone https://github.com/apache/cordova-plugin-network-information.git
```

Then install the plugin:

• For GMI / iOS:

```
$ gmibuildtool --install-plugins=/usr/dev/myplugins/cordova-plugin-network-information
```
- For GMA / Android™ (note that you need to use the "scaffold" command):

```
$ gmabuildtool scaffold \
  --install-plugins /usr/dev/myplugins/cordova-plugin-network-information
```

**Note:** The gmabuildtool compiles cordova plugins FGL wrappers at installation with the make command. Compiled .42m modules will be bundled inside the scaffold archive. Before building an apk, FGL wrapper binaries will be copied inside the application directory.

### Checking out a particular version from GitHub

If you want to test a particular version of a Cordova plugin, make a clone of the repository, and check out that version, then install the plugin:

```
$ cd cordova-plugin-network-information
$ git checkout specific-version
$ cd -
```

It is now possible to use the gmibuildtool or gmabuildtool to install this specific version.

**Note:** If a plugin with the same name is already installed, it is replaced by the new installation.

### Checking Cordova plugin installation

Use the --list-plugins option of the GMA or GMI build tool, to check that the plugin is properly installed:

- For GMI / iOS:

```
$ gmibuildtool --list-plugins
... cordova-plugin-network-information ...
```

- For GMA / Android™ (note that you need to use the "scaffold" command):

```
$ gmabuildtool scaffold --list-plugins
... cordova-plugin-network-information ...
```

The **cordova-plugin-network-information** name can now be used for bundling an application using that plugin.

### Finding Cordova plugin wrapper libs in development environment

After installing the Cordova plugin, if the plugin repository includes a BDL wrapper library, the fglrun runtime system needs to know where the .42m p-code modules can be found.

If there is a local clone of the GitHub repository, search for *.4gl files (typically prefixed with "fglcdv"), make sure they are compiled to .42m modules, and set the FGLLDPATH to the directory where the .42m files are located.

For example (on Unix/Linux), with the **cordova-plugin-media** repository clone:

```
$ cd cordova-plugin-media
$ find . -name "fglcdv*.4gl"
./fgl/fglcdvMedia.4gl
$ cd fgl
$ fglcomp fglcdvMedia.4gl (or make, if makefile is present)
$ export FGLLDPATH=$PWD (or export FGLLDPATH=$PWD:$FGLLDPATH)
Using a Cordova plugin API

Cordova plugin features can be used by invoking cordova front calls.

How to access Cordova plugin APIs

Cordova plugin APIs are available to the front-end and therefore need to be called through Cordova plugin front calls. Before calling a Cordova plugin function, you need to identify what native APIs are available. If provided, check the Cordova plugin API documentation for available functions.

It is a good practice to implement BDL wrapper functions that encapsulate the Cordova front calls specific to this plugin. BDL wrapper libraries are provided with the plugins on the FOURJS Cordova GitHub.

Identifying and verifying the version of available Cordova plugins at runtime

At runtime, the code of an app can query available Cordova plugins with the cordova.listPlugins and get details of the plugin with cordova.getPluginInfo front calls.

To verify the git version in the wrapper modules for usage in direct mode and GAS mode, implement an initialization function in the wrapper module, to check that the GIT_VERSION string defined in the git_version.txt file (found nearby the wrapper library sources) corresponds to the current available plugin version returned by the cordova.getPluginInfo front call:

```javascript
#include "git_version.txt"  -- defines GIT_VERSION
...
DEFINE initialized BOOLEAN
...
PUBLIC FUNCTION initialize()
  IF initialized THEN
    -- exclusive library usage
    DISPLAY "The library is already in use."
    EXIT PROGRAM 1
  END IF
  CALL checkGitVersion(GIT_VERSION)
  LET initialized = TRUE
END FUNCTION
...
PRIVATE FUNCTION checkGitVersion(version STRING)
  DEFINE rec RECORD
    git_version STRING
  END RECORD
  CALL ui.interface.frontcall("cordova","getPluginInfo",["Accelerometer"],
    [rec])
  IF NOT version.equals(rec.git_version) THEN
    DISPLAY sfmt("fglcdnMotion.4gl version mismatch, git version:%1,
      expecting:%2.",
      rec.git_version, version)
    EXIT PROGRAM 1
  END IF
END FUNCTION
```

Identifying Cordova plugin native APIs in JS sources

Cordova plugins are primarily targeted for JavaScript. Each plugin source directory has a www directory with JavaScript wrapper code calling into the native code.

For example, with the cordova-plugin-network-information plugin, the www/network.js file implements the following *getInfo* JavaScript function, that performs an exec() call of the "NetworkStatus.getConnectionInfo" native Cordova function:

```javascript
NetworkConnection.prototype.getInfo =
```
function(successCallback, errorCallback) {
    exec(successCallback, errorCallback,
        "NetworkStatus", "getConnectionInfo", []);
}

The BDL equivalent of the above exec() call is done with the generic Cordova front call "cordova.call":
CALL ui.Interface.frontCall( "cordova", "call",
    ["NetworkStatus","getConnectionInfo"], [result] )

Note: In the README.md files of the plugins, the available methods for the plugins are documented for the JavaScript wrappers and not the underlying native calls.

In order to find available native Cordova APIs, such as getConnectionInfo, search for the exec() calls in the js files of the www directory. The native Cordova function name is the fourth parameter of the exec() function.

Implementing an app that uses the Cordova plugin

After installing a plugin, you can create a Genero program using a function of this plugin, by using the generic front call for Cordova APIs.

For example:

IMPORT FGL fgldialog
MAIN
DEFINE result STRING
MENU "network"
    COMMAND "Info"
    CALL ui.Interface.frontCall( "cordova", "call",
        ["NetworkStatus","getConnectionInfo"], [result] )
    CALL fgl_winMessage("Result",result,"info")
    COMMAND "Exit"
    EXIT MENU
END MENU
END MAIN

Compile and build your app as usual (the installed Cordova plugins will be included).

Cordova plugin front calls overview

Cordova plugin front calls are generic functions that give access to the native Cordova APIs, in conjunction with the predefined cordovacallback action.

The cordova.call function issues a synchronous Cordova function call. In this case, the underlying native function is executed and the program waits until it returns. Results are provided in the front call output parameters.

The cordova.callWithoutWaiting function performs an asynchronous Cordova function call. The program continues while the Cordova function executes in parallel. The program can implement a trigger for the cordovacallback predefined action, to detect when results are available. To retrieve results of asynchronous calls, use the cordova.getCallbackDataCount, cordova.getCallbackData and cordova.getAllCallbackData front calls.

See these front calls in action in the demos provided on the FOURJS Cordova GitHub.

Implement BDL wrappers on top of Cordova front calls

For better code readability and maintenance, we strongly suggest you implement BDL functions that encapsulate Cordova front calls, as done with plugins available on the FOURJS Cordova GitHub.

Cordova plugin API internals

The IOS code is located in the src/ios directory of a plugin.
The Android™ code is located in the src/Android directory of a plugin.
The IOS code in src/ios/CDVConnection.m contains a method called

```
(void)getConnectionInfo:(CDInvokedUrlCommand*)command
```

This is the native objective-C method called by the front call.
The Android™ code in src/android/NetworkManager.java, contains an execute method for handling the getConnectionInfo string:

```
public boolean execute(String action, JSONArray args, CallbackContext callbackContext) {
if (action.equals("getConnectionInfo")) {
```

## Embed Cordova plugins in a GMA app
To be included in your app, Cordova plugins need to be specified in the build process.

### Including Cordova plugins in your Android APK package
Use the `gmabuildtool --build-cordova` command-line option, to specify which Cordova plugins to embed in your Android™ APK package:

```
gmabuildtool build
    --build-cordova cordova-plugin-contacts,cordova-plugin-device
```

### The plugin.xml file
A plugin can contain several assets (images, sounds, native forms) which are listed in the `plugin.xml` file that is bundled by gmabuildtool.

### Shipping the Cordova wrapper library with the app package
If the Cordova plugin front calls are called from BDL wrapper functions, the .42m p-code module of the wrapper library needs to be included in the APK package.

When building the APK package for an app using Cordova plugins, the `gmabuildtool` automatically includes the corresponding .42m wrapper module(s).

  This section contains information to create a mobile application to be deployed on Android™ devices.

## Embed Cordova plugins in a GMI app
To be included in your app, Cordova plugins need to be specified in the build process.

### Including Cordova plugins in your iOS IPA package
Use the `gmibuildtool --build-cordova` command-line option, to specify which Cordova plugins to embed in your iOS IPA package:

```
$ gmibuildtool --build-cordova=cordova-plugin-media,GeneroTestPlugin
```

### The plugin.xml file
A plugin can contain several assets (images, sounds, native forms) which are listed in the `plugin.xml` file that is bundled by gmibuildtool.
Shipping the Cordova wrapper library with the app package

If the Cordova plugin front calls are called from BDL wrapper functions, the .42m p-code module of the wrapper library needs to be included in the IPA package.

When building the API package for an app using Cordova plugins, the gmibuildtool automatically includes the corresponding .42m wrapper module(s).
